In the former part of this article we said, that a popliteal aneurism was one of those which occurred the most frequently. And its situation being such as to afford a full command of the vessel affected, this species of the disease has obtained a considerable degree of attention among surgeons, in hopes of their saving the limb as well as the life of the patient. After having made various trials, it is ascertained that the collateral branches of the femoral artery, of those of the profunda femoris, inosculating with the arteries of the leg, are generally sufficient to keep up the circulation in the lower extremity; and that the inosculating blood vessels of the arm, in like manner, will dilate and nourish the limb when the humeral artery has been tied; so that in most aneurisms of the extremities, we have a very considerable chance of preserving both the member and the life of the patient.

Paulus Ægineta, and after him the Arabian physicians, used to make two ligatures, one above and the other below the aneurism; after which they let out the coagulated blood found within the tumour, and healed up the wound according to the common principles of surgery. But *Guillemeau*, one of the disciples of *Ambrose Paré*, pointed out a more simple operation in the case of an aneurism at the bend of the arm: he laid bare the tumour, passed one ligature under the artery above the diseased part, then emptied the sac, and closed the wound. He directs the same plan to be adopted in other cases of aneurism: "Si en quelque autre partie extérieure, il se presente au chirurgien pareil aneurisme, il peut seurement decouvrir le corps de l'artere vers sa racine et partie supérieure, et la lier de même façon, sans autre cérémonie." (*Les Oper. de Chir. liv. x. c. vi.*)

In the year 1714, *M. Anel*, of Paris, published an improvement on *Guillemeau's* method; which consisted in making a longitudinal incision over the aneurism, without wounding it, then making a single ligature upon the vessel, close above the tumour, and leaving the rest to nature. It is almost needless to mention, that in all these operations the surgeon applied a tourniquet upon the affected limb, so as to obtain an entire command of the artery. By little and little *Anel* found the tumour disappear, until the whole was absorbed. This practice did not meet the approbation of surgeons in general, although it was often followed by *Heister* and some few later operators. Indeed that author thinks it doubtful "whether or no this method will succeed so as to save the limb in wounds of the large crural artery;" (*System of Surgery, part ii. sect. 1. chap. xiii. § 22.*) and it has therefore been reserved for our contemporaries, to determine the point by actual experiment. We do not wonder, however, at the doubt expressed by *Heister*, as he frankly confesses, that "he cannot conceive in what manner the blood is circulated through the lower parts of a limb, after this operation." How would he then have been surprised to learn, that it is even possible for a patient to recover of his limb,

limb, when the inguinal, or the subclavian artery, has been surrounded by a ligature!

During the month of June, 1785, M. Dessault, of Paris, performed the following operation for a popliteal aneurism (See Journ. de Médecine, tome lxx. p. 45—471. Encycl. Methodique, l'Article Aneurism, p. 137. and Sabatier de la Méd. Opératoire, tome iii. p. 7.): he made an incision about two inches above the aneurismal tumour in the patient's ham; and, when he had exposed the artery, he separated it from the adjacent nerve, and passed a ligature around it, leaving the aneurism uncutted. The wound was dressed in a simple manner, with a loose ligature cast around the former one, as an additional security against future bleeding. The symptoms for the first six days were mild, and promised a favourable event; but M. Dessault thought it prudent to tie the second ligature, &c., on the sixth day after the operation. The swelling diminished rapidly; the ligatures fell off on the eighteenth day, and there was a plentiful discharge of bloody matter on the day following, which caused nearly the entire disappearance of the aneurism. In short, the external opening was soon healed, and the cure seemed complete; when, unfortunately, the patient died of another complaint.

During the month of December, in the same year, an operation, somewhat similar to that of Dessault, was performed by Mr. John Hunter. (See Lond. Med. Journal, vol. vii. p. 391. and Transact. of a Society for the Improv. of Med. and Chir. Know. vol. i. p. 138.) Mr. Hunter's patient was a coachman, 45 years of age; he was admitted into St. George's hospital with a popliteal aneurism, which he had first perceived three years previously to his admission, and had observed it gradually increase during the whole of that period. It was so large as to distend the two ham-strings laterally, and make a very considerable rising between them; the pulsation was very distinct, and to be felt on every side of the tumour. The leg and foot of that side were so swelled as to be much thicker than the other, and were of a mottled brown colour; the swelling was not of the œdematous kind, but felt firm and brawny, probably from the extravasation of coagulable lymph; the leg retained its natural shape, excepting that it was larger. Previously to performing the operation, a tourniquet was applied upon the upper part of the thigh, but not tightened, that the parts might be left as much in their natural situation as possible.

The operation was begun by making an incision on the anterior and inner part of the thigh, rather below its middle, which incision was continued obliquely across the inner edge of the sartorius muscle, and made large, to give room for the better performing of whatever might be thought necessary in the course of the operation. The fascia which covers the artery was then laid bare about three inches in length, after which the artery itself was plainly felt. A slight incision, about an inch long, was then made through this fascia, along the side of the vessel, and the fascia dissected off; by this means the artery was exposed. Having disengaged the artery from its lateral connections by the knife, and from the other adhering parts by the help of a thin spatula, a double ligature was passed behind it, by means of an eyed probe. The doubling of the ligature brought through by the probe, was cut so as to form two separate ligatures. The artery was now tied by both these ligatures, but so slightly, as only to compress the sides together. A similar application of ligature was made a little lower. The reason for having four ligatures, was to compress such a length of artery as might make up for the want of tightness, it being wished to avoid great pressure on the vessel at any one part. The ends of the ligature were carried directly out

at the wound, the sides of which were now brought together, and supported by a sticking plaster and a linen roller, that they might unite by the first intention.

The limb was found, some hours after the operation, not only to retain its natural heat, but even to be warmer than the other leg. The second day after the operation, the brawny firmness of the leg was considerably diminished, and it was become soft, loose, and a good deal smaller, and the aneurismal tumour had lost more than one third of its size.

Nothing could shew more plainly the action of the absorbents, than the change the leg had undergone in so short a time; the diminution of the tumour probably arising from the fluid blood which it contained having passed into collateral branches, or into the tibial artery.

The fourth day, on the removal of the dressings, the edges of the wound were found united through its whole length, excepting where prevented by the ligatures; there was neither pain nor tumefaction in the part; but the aneurismal tumour was the same as on the second day.

On the ninth day after the operation there was a considerable discharge of blood from the part where the ligatures passed out; a tourniquet was therefore applied on the artery above, which stopped the bleeding; and, although the tourniquet was taken off a few hours after, no blood followed. The head of a roller was then placed upon the wound, in the direction of the artery, and over that the tourniquet, which was not, however, tightened more than was thought sufficient to take off the impetus of the blood in that portion of the artery.

On the tenth day appearances were much the same, only that between the compress and the knee there appeared a little fullness, like beginning inflammation. On the eleventh day this was gone off, and on the fifteenth some of the ligatures came away, followed by a small discharge of matter, the tumour in the ham being lessened. On the seventeenth day the parts surrounding the aneurismal tumour were more reduced and pliable, so that it was distinctly to be felt.

About the latter end of January, 1786, six weeks after the operation, the patient went out of the hospital, the tumour at that time being somewhat lessened, and rather firmer to the feel. He was ordered to come to the hospital once every week, and, in the mean time, to make some degree of pressure, by application of a compress and bandage, with a view to excite the absorbents to action, which in most cases has a good effect.

About the middle of February the tumour had decreased, and was become still firmer. March the 8th, the wound, which had cicatrized, broke out again, and the patient was taken into the hospital. About the 8th of April, some of the remaining thread of the ligature came away, and an inflammation appeared upon the upper part of the thigh. In the middle of May, a small abscess broke at some distance from the old cicatrix, at which opening some matter was discharged, but no pieces of ligature were observed. Several small threads were, at different times, discharged from the old sore, and the swelling subsided; but the thigh soon swelled again to a greater size than before, attended with considerable pain. In the beginning of July, a piece of ligature, about one inch in length, came away, after which the swelling went off entirely, and he left the hospital the 8th of July, at which time there remained no appearance of tumour in the ham, he being in every respect well.

After leaving the hospital, the man returned to his usual occupation of driving a hackney-coach; and being, from the nature of his employment, much exposed to cold, in March, 1787, he was seized with a fever of the remittent kind, which carried him off. He had not made any complaint

plaint of the limb on which the operation had been performed, from the time of his leaving the hospital.

He died on the 1st of April 1787, fifteen months after the operation; and leave was procured, with some trouble and considerable expence, to examine the limb, seven days after death, at which time it was entirely free from putrefaction.

The cicatrix on the anterior part of the thigh was scarcely discernible, but the parts under it felt hard. The ham had no appearance of tumour, and was to the eye exactly like that of the other limb; there was, however, a solid tumour perceptible to the touch, filling up the hollow between the two angles of the thigh bone.

The femoral artery and vein were taken out above the giving off the branch called profunda, and a little below the division into the arteriæ tibiales and interossee. The arteries and veins that were pervious being injected, the whole was carefully dissected.

The femoral artery was impervious from its giving off the arteria profunda as low as the part included in the ligature, and at that part there was an ossification for about an inch and an half along the course of the artery, of an oval form, the rim of which was solid, becoming thinner towards the centre, and not bony, but ligamentous. Below this part the femoral artery was pervious down to the aneurismal sac, and contained blood, but did not communicate with the sac itself, having become impervious just at the entrance.

What remained of the aneurismal sac was somewhat larger than an hen's egg, but more oblong, and a little flattened, extending along the artery below for some way; the blood pressing with greater force in that direction, and distending that part so as, in some measure, to give the appearance of a separate bag. The sac was perfectly circumscribed, not having the smallest remains of the lower orifice into the popliteal artery: whether this arose from the artery being pressed upon by the inferior portion of the sac, as appears to be the case in common, or was in consequence of the sac contracting after the operation, I will not pretend to determine; but it contained a solid coagulum of blood, which adhered to its internal surface. A section made of this coagulum, appeared to be composed of concentric lamellæ, uniform in colour and consistence.

The popliteal artery, a little way below the aneurismal sac, was joined by a small branch, very much contracted, which must have arisen either from the profunda, or the trunk of the femoral artery. About two inches below the sac, the popliteal gave off, or divided into, the tibiales.

The profunda was of the usual size, but a good deal ossified, for some length after leaving the femoral artery; the two tibials, where they go off from the popliteal, were in the same state.

The trunk of the femoral vein, where it passed along the side of the tumour, must have been obliterated; for at this part it appeared to send off three equal-sized branches, passing over different parts of the aneurismal sac: these must have been dilated branches, none of them having the course which the trunk of the vein should have pursued.

These appearances throw some light upon the changes which took place in the limb after the operation. The ligature upon the femoral artery impeded the passage of the blood into the sac so much, as to allow its contents to coagulate, and render the opening into it from the artery impervious. By this a stop was only put to the increase of the tumour, its reduction to the size met with in the dead body, must have been the effect of absorption.

The conclusion to be drawn from the above account, appears a very important one, viz. that simply taking off the

force of the circulation from the aneurismal artery, is sufficient to effect a cure of the disease, or at least to put a stop to its progress, and leave the parts in a situation from which the actions of the animal œconomy are capable of restoring them to a natural state.

We have given the history of this case at full length, because the method adopted by Mr. Hunter has been since followed, with some slight variations, in almost every part of Europe. There is no reason, we believe, for suspecting that Mr. Hunter took the hint of this operation from any of his predecessors: but, as Mr. Home has stated, this practice was the result of an opinion entertained by Mr. Hunter that the artery in aneurismal cases is generally diseased some way above the sac, and therefore that the common cause of failure arose from tying an unsound artery, not disposed to coalesce before the separation of the ligature.

The femoral and popliteal arteries are portions of the same trunk, presenting themselves on different sides of the thigh, and are readily come at in either situation; but where the artery is passing from the one side to the other, it is more buried in the surrounding parts, and cannot be exposed without some difficulty. In performing the operation for the popliteal aneurism, especially when the tumour is large, the ligature was commonly applied on the artery at that part where it emerges from the muscles. This mode of performing the operation will be found inadequate, if the disease of the artery extends above the sac; for if the artery should afterwards give way, there will not be a sufficient length of vessel remaining, to allow of its being again secured in the ham. To follow the artery up through the insertion of the triceps muscle, to get at a portion of it where it is found, becomes a very disagreeable part of the operation: and to make an incision upon the fore-part of the thigh, to get at and secure the femoral artery would be breaking new ground; a thing to be avoided, if possible, in all operations.

Mr. Hunter, from having made these observations, was led to propose, that in this operation the artery should be taken up in the anterior part of the thigh, at some distance from the diseased part, so as to diminish the risk of hæmorrhage, and to admit of the artery being more readily secured, should any such accident happen. The force of the circulation being thus taken off from the aneurismal sac, the progress of the disease would be stopped: and he thought it probable, that if the parts were left to themselves, the sac, with its contents, might be absorbed, and the whole of the tumour removed; which would render any opening into the sac unnecessary.

Numerous trials have lately been made in the different public hospitals which confirm the truth of Mr. Hunter's reasoning. He had several opportunities of performing this operation before he died, and generally with perfect success: but reiterated experience has shewn that it is best to secure the artery with only one strong ligature, without separating the vessel from its attachments. Some attempts have been made, both in London and Paris, to improve on this method, by giving a greater latitude for pressure on the artery, (either by the interposition of extraneous substances between the ligature and the vessel, or by employing a broad piece of tape;) but such attempts have been always attended with manifest disadvantages. The only considerable deviation from Mr. Hunter's mode, which we think deserves particular attention, is that of making two firm ligatures, about an inch distant from each other, and then dividing the artery between them; after the manner recommended by *Ætius*, thirteen centuries ago, for brachial aneurisms.

In comparing this procedure with that which has formerly been had recourse to in popliteal aneurisms, every

A N E U R I S M.

person must be struck with its decided superiority. The operation is in itself simple; it requires but a short time in the performance, and produces little, if any, affect on of the constitution; but its advantages are more clearly seen by contralling it with the common mode of operating for the popliteal aneurism. This is, by exposing the sac in the ham through its whole extent, laying it open, scooping out the blood, searching for the two offices leading into it, and taking up the artery with a ligature both above and below the sac. When this operation is over, there remains a large deep seated sore, composed of parts not perfectly in a natural state, and in a most disadvantageous situation; which sore is to suppurate, granulate, and heal; a process that is not soon performed, and which must leave a stiff knee for some time afterwards. Yet this is considering the operation in the most favourable view, since there is always a risk, from the artery being diseased so close to the sac, of the patient dying from a secondary bleeding; and when that does not happen, there is still some danger of not being able to support the constitution during the healing of a large sore, under circumstances so very unfavourable.

It must not be dissimbled, however, that there are sometimes very embarrassing circumstances attending the new operation, and that patients are not always free from the danger of hæmorrhage, even so late as the third or fourth week after the ligature of the artery. 1st. We can never be certain, in cases of spontaneous aneurism, that the vessel is not diseased along its course, above the part on which the ligature was made. 2dly. We have no positive security against the occurrence of an ulceration just under the ligature, from which a fatal bleeding may at any time ensue. 3dly. We cannot always effect an adhesion of the sides of the artery, so as to produce a perfect obliteration of its cavity, by any means within our power. Besides which, the first surgeons may possibly fail in their endeavours to include the naked vessel within a ligature; and at length may be compelled to make a fresh incision, or to amputate the patient's limb, in order to save his life. But, with all these disadvantages, some of which indeed must apply to any kind of operation for aneurism, we are fully persuaded that Mr. Hunter's plan is, on the whole, the most eligible and successful. It therefore cannot but strike us with surprize to find Mr. Benjamin Bell, in the last edition of his surgery (vol. iii. 1801.), declaring it to be doubtful "whether this operation, or that of amputating the limb *at the upper part of the thigh* will fall to be preferred." It only remains for us now to point out some of the principal rules to be observed, in cases where this operation is indicated.

No skill or precaution can avert the ill consequences which may ensue from a disposition in the trunk of an artery to form aneurisms: the objection, therefore, against tying the artery in this case, is not greater than it would be against amputating the limb "at its upper part." If an aneurism have formed spontaneously, the chance of recovery is not equal to that in which the disease arose from an accidental cause; but still, we conceive, the spontaneity of the complaint is not alone a sufficient objection against the method we are recommending. Suppose, then, we have determined on performing the operation; it is first necessary to reduce the quantum of blood in the vascular system, if the patient be plethoric and young. He should also be prepared, by giving him a few doses of laxative medicine, and by a previous course of abstemiousness, especially if there be any tendency to an inflammatory diathesis. All things being in readiness for the operation, let a tourniquet be placed on the limb; or let an assistant compress the artery in the best possible manner, where a tourniquet cannot be applied with ad-

vantage. Make your first incision through the skin and adipose substance; dissect steadily and cautiously down to the trunk of the vessel you are seeking for; clear away with the scalpel, or with your finger, all the cellular membrane which lies loosely in your way; open the fascial covering peculiar to the artery; then separate the vein and nerve accompanying it, without unnecessarily tearing the vessels from their surrounding attachments; and pass a moderate sized common ligature around the artery, with a sufficient degree of tightness to stop the circulation entirely.

These are the ordinary steps of this operation. But it is probably the safest way to make a second ligature, about an inch below the former, and then to cut between them, as was practised by the ancients, so that the divided extremities of the artery may retire into the adjacent muscular substance. This method has been approved by some of our best surgeons, and seemed to lessen the danger of a secondary hæmorrhage. In addition, however, to this security, a new mode of fastening the ligatures has been proposed and practised at Guy's hospital (see Med. & Phys. Journal for July, 1802.) "An eyed probe, armed with a double ligature, having a curved needle at each end, was conveyed under the femoral artery, and the probe cut away. The ligature nearest the groin was first tied; the other was separated an inch from the first, and tied also; then the needles were passed through the coats of the artery close to each ligature, and between them; the thread they carried was tied into the knot of the ligature which had been already secured around the vessel; and thus a barrier was formed in the artery, beyond which the ligature could not pass. The wound was united by the first intention, except where the ligature projected: one of the threads separated on the 14th, the other on the 15th day." This mode of securing the ligatures was found to be so effectual, that Mr. Astley Cooper was unable, in an experiment made on a dead subject, to remove the thread from its situation, even by injecting water into the artery with all his force. The suggestion was originally given to him by Mr. Cline, jun. and was put in practice in consequence of two cases having occurred, one to Mr. Cline (the father), and one to Mr. Cooper, in which the ligature slipped off the divided extremity of the blood vessel, after an operation for aneurism.

We have directed the artery to be tied alone; and not to be wantonly *detached* from the circumjacent cellular membrane, which gives support to the *vasa vasorum* nourishing the artery. For the same reason, we highly disapprove of all compresses, pads or instruments proposed to be laid in contact with the vessel; as these, we are of opinion, contribute to produce inflammation and ulceration of the artery, with all their dreadful consequences. The wound should be closed with adhesive plasters as accurately as possible, the ligatures hanging out, and a soft roller then passed over the limb for its further support. By this simple method, we have found the operation extremely successful; and there is but little comparative hazard of a secondary bleeding. Nay, it is even certain that ligatures may be made with complete success upon the great artery of the thigh, above Poupart's ligament; and of the arm above the axilla. (See the cases published by Mr. Keate, Mr. John Bell, and Mr. Abernethy.)

Other methods have been recommended by ingenious men in cases of aneurism; such as that of Mr. Lambert (Med. Obs. and Inq. vol. ii. p. 360.) who proposes to stitch the artery by means of the hare-lip suture, a plan which has been once imitated, without success, by Mr. John Bell; and likewise a contrivance of Mr. Deschamps (La Médecine éclairée, tome iii. p. 67.), for compressing the arterial tube,

tube, without surrounding it with a ligature. But, in our opinion, these methods promise to be less useful than they seem to be ingenious, and have not been generally approved by medical practitioners.

We have mentioned the *mixed* aneurism as a distinct species of this disease, because it is noticed as such by respectable authors. Dr. Monro, senior, we believe, was the first who described it (Edinb. Med. Essays and Observ. vol. ii. xvi.), and afterwards Dr. Wm. Hunter (Med. Obs. and Inquiries, vol. i. xxvi.); but the distinction is not well established, and is of very little practical importance. A much more valuable distinction has been introduced by Dr. Hunter, between common aneurisms and those which sometimes arise from bleeding: the latter has been denominated *VARICOSE aneurism*, or with more propriety the *aneurismal VARIX*; and it arises from an artery having been wounded through a vein, so that a communication or anastomosis is afterwards kept up between these two vessels, which closely unite by a lateral adhesion. This varicose tumour is not near so dangerous as the true or the spurious aneurism; for the veins alone become much dilated, and it can scarcely ever be necessary to have recourse to the ligature. Since Dr. Hunter published his account of this disorder, its true nature has been ascertained by the observations of various practitioners.

The aneurismal varix was first described by that anatomist with some degree of diffidence; but in a subsequent memoir, Dr. Hunter communicated to the world a further history of this curious disease, in the following terms:

"If ever this case happens, we are to suppose, that in the operation of bleeding the lancet is plunged into the artery through both sides of the vein, and that there will be three wounds made in these vessels, *viz.* two in the vein and one in the artery; and these will be nearly opposite to one another, and to the wound in the skin. This is what all surgeons know has often happened in bleeding; and the injury done the artery is commonly known by the jerking impetuosity of the stream whilst it flows from the vein, and by the difficulty of stopping it when a sufficient quantity of it is drawn.

"In the next place we must suppose, that the wound of the skin, and of the adjacent or upper side of the vein, heal up as usual; but that the wound of the artery, and of the adjacent or underside of the vein, remain open (as the wound of the artery does in a spurious aneurism), and by that means the blood is thrown from the trunk of the artery directly into the trunk of the vein. Extraordinary as this supposition may appear, in reality it differs from the common spurious aneurism in one circumstance only, *viz.* the wound remaining open in the side of the vein as well as in the side of the artery. But this one circumstance will occasion a great deal of difference in the symptoms, in the tendency of the complaint, and in the proper method of treating it; upon which account the knowledge of such a case will be of importance in surgery.

"It will differ in its symptoms from the common spurious aneurism principally thus. The vein will be dilated or become varicose, and it will have a pulsatile jarring motion, on account of the stream from the artery. It will make a hissing noise, which will be found to correspond with the pulse, for the same reason. The blood of the tumour will be altogether, or almost entirely fluid, because kept in constant motion. The artery, I apprehend, will become larger in the arm, and smaller at the wrist, than it was in the natural state; which will be found out by comparing the size and the pulse of the artery in both arms at these different places: the reason of which I shall speak of hereafter. And the effects of ligatures and of pressure upon the vessels, above the elbow and below it, will be what every person may rea-

dily conceive, who understands any thing of the nature of arteries and veins in the living body.

"The natural tendency of such a complaint will be very different from that of the spurious aneurism. The one is growing worse every hour, because of the resistance to the arterial blood; and if not remedied by surgery must at last burst. The other in a short time comes to a nearly permanent state, and, if not disturbed, produces no mischief, because there is no considerable resistance to the blood that is forced out of the artery.

"The proper treatment must therefore be very different in these two cases; the spurious aneurism requiring surgical assistance as much perhaps as any disease whatever; whereas, in the other case, I presume it will be best to do nothing.

"If such cases do happen, they will, no doubt, be found to differ among themselves in many little circumstances, and particularly in the shape, &c. of the tumefied parts. Thus the dilatation of the veins may be in one only, or in several, and may extend lower or higher in one case than in another, &c. according to the manner of branching, and to the state of the *valves* in different arms: and the dilatation of the veins may also vary on account of the size of the artery that is wounded, and of the size of the orifice in the artery, and in the vein.

"Another difference in such cases will arise from the different manner in which the orifice of the artery may be united or continued with the orifice of the vein. In one case, the trunk of the vein may keep close to the trunk of the artery, and the very thin *stratum* of cellular membrane between them, may, by means of a little inflammation, and coagulation of the blood among its filaments, as it were, solder the two orifices of these vessels together, so that there shall be nothing like a canal going from one to the other; and then the whole tumefaction will be more regular and more evidently a dilatation of the veins only. In other instances the blood that rushes from the wounded artery, meeting with some difficulty of admission and passage through the vein, may dilate the cellular membrane between the artery and vein, into a bag, as in a common spurious aneurism, and so make a sort of canal between these two vessels. The trunk of the vein will then be removed to some distance from the trunk of the artery, and the bag will be situated chiefly upon the underside of the vein. The bag may put on an irregular form, from the cellular membrane being more loose and yielding at one place than at another, and from being unequally bound down by the *fascia* of the *biceps* muscle. And if the bag be very large, especially if it be of an irregular figure, no doubt coagulations of blood may be formed, as in the common spurious aneurism."

As no surgical operation is required in this case, or but very rarely indeed, we need not dwell further on the subject of aneurismal *VARIX*. The disease has, in different instances, continued during the space of twenty or thirty years without getting worse, or demanding especial attention. See *VARIX* and *VARICOCELE*.

ANEWOLONDANE, in *Geography*, a small island of the Indian sea, near the coast of Ceylon.

ANFANT, a town of Persia, 30 miles north-west of Zareng.

ANFELDTHYDE, or *ANFALTHYLE*, in *Law*, a simple accusation; for the Saxons had two sorts of accusation, *viz.* *simplex* and *triplex*. That was called *single*, when the oath of the criminal, and of two more, were sufficient to discharge him: but his own oath, and the oaths of five more, were required to free him a *triplice accusatione*.

ANFOSSI, *Pasquale*, of Naples, in *Biography*. See *PASQUALE ANFOSSI*.

ANGADD, a barren desert of Africa, in the kingdom of Algiers, 28 leagues long, and 18 wide, formerly the west part of the province of Tlemcen, in the road to Fez: it contains a few villages inhabited by Arabs, the chief of which were Guagida, Tenzegzet, and Zecil.

ANGALA-DIAN, in *Natural History*, a name given by Buffon to a species of certhia, called lotenia by Gmelin. See CERTHIA LOTENIA.

ANGAMALA, a town of the East Indies, in Malabar, on the river Aicota.

ANGARA, a river of Russia, which rises in the lake Baikal, and runs into the Enussey, not far from Enusfeilk.

ANGARAEZ, a province of South America, in the empire of Peru, subject to the archbishop of Lima, 20 leagues north-west by west of the city of Guamanga. It abounds in all kinds of grain and fruits, besides vast droves of cattle both for labour and sustenance.

ANGARI, or ANGARI, in *Antiquity*, denote public couriers, appointed for the carrying of messages.

Αγγαρι is derived from a word, which, in the Persian language, signifies a service rendered by compulsion. Hence the Greeks borrowed their verb αγγαριων, *compellere*, or *co-gere*, and the Latins *angariare*.

The ancient Persians, Budæus observes, had their αγγαριωνδρομηται, which was a set of couriers on horseback, posted at certain stages or distances, always in readiness to receive the dispatches from one, and forward them to another with wonderful celerity, answering to what the moderns call posts, q. d. *postii*, as being posted at certain places or stages. This invention of couriers is ascribed to Cyrus. As the Persian empire, after its last conquests, was of a vast extent, and Cyrus required that all his governors of provinces, and the chief commanders of his troops should write to him, and give an exact account of every thing that passed in their several districts or armies: in order to render that correspondence the more sure and expeditious, and to put himself into a condition of receiving speedy intelligence of all occurrences and affairs, and of sending his orders with expedition, he caused post-houses to be built, and messengers to be appointed in every province. Having computed how far a good horse, with an active rider, could go in a day, without injury, he had stables built at equal distances from each other, and furnished them with horses, and grooms to take care of them. At each of these places he appointed likewise a post-master to receive the packets from the couriers as they arrived, and to give them to others, and to take the horses that performed their respective stages, and to find fresh ones. Thus the courier went continually night and day with extraordinary speed; nor did either rain or snow, heat or cold, or any inclemency of the season interrupt his progress. Herodotus (lib. viii. c. 18.) speaks of the same sort of couriers in the reign of Xerxes. The superintendency of the posts became a considerable employment; Darius, the last king of the ancient Persians, enjoyed it before he came to the crown. Xenophon takes notice, that this establishment subsisted in his time; and this perfectly agrees with what is related in the book of Esther concerning the edict published by Ahasuerus in favour of the Jews; which edict was carried through that vast empire with a rapidity that would have been impossible without these posts erected by Cyrus. See POST.

The *angari* were also called by the Persians *astande*; by the Greeks *παιροδρομοι*, on account of the long journies they made in one day, which, according to Suidas, amounted not to less than 1500 stadia.

ANGARI is also applied figuratively to porters, and others employed in laborious offices, as bearing burdens.

ANGARI, in *Geography*, a small river of Abyssinia, which gives name to a district in the province of Siri, not far from HAUZA. It rises in a plain near Montefegla, and joins the Bowiba.

ANGARIA is used, in a general sense, for any burden, or incumbrance, forcibly imposed on persons.

Some define *angaria* by personal services, which a party is compelled to discharge in his own person, or to serve at his own expence; or such services imposed on lands whereby a person is obliged to work for another, either with his horse, his ass, or the like.

ANGARIA, in the *Civil Law*, denotes a duty required of the subjects to furnish out horses and carriages for conveying of corn for the soldiers, and such things as belonged to the *fiscus*.

This duty goes by the name of *curfus publicus*, *angaria*, *parangaria*, *translatio*, and *avectio*. The horses used in this service are particularly called *paraveredi*, and *equi cursuales*.

Angariae are generally understood as exclusive of ships; though, on some occasions, these were pressed into the service for transporting provisions and the like.

Angariae differ from *parangariae*, in this, that the former are confined to public or main roads, the latter to oblique or cross roads.

In the Book of Feuds, the performance of *angariae* and *parangariae* are ranked in the number of royal services. Lib. ii. tit. 56.

The clergy were exempted from this service by two laws of Constantius; but he revoked this privilege in 360. The privilege was restored in 382, and confirmed by Honorius in 412; but was taken away again in 440. Bingham. Orig. Ecclesiae, lib. vi. c. 3. § 10.

ANGARIA, is also used, in *Ancient Military Writers*, for a guard of soldiers posted in any place for the security of it. Veget. lib. i. c. 3. lib. ii. c. 19. lib. iii. c. 8.

ANGARKA, in *Geography*, a river of Siberia, in the country of the Tschuktikes, which falls into the great river of Anuy.

ANGARO PORTO lies on the coast of Brasil, and is one of those good harbours and bays for which the coast between Point Negro, near Rio Grande, and Point Lucena, near Dou or Dulu, otherwise called Trieste-watering river, is famous.

ANGAXOS *Island*, or ANGOXAS, lies on the eastern coast of Africa, in S. lat. 16° 30', E. long. 38° 35'.

ANGAZYA, or ANGAZIZA, one of the Comorro islands, lying between the north end of Madagascar and the coast of Zanzibar. It is inhabited by Moors, who trade with various parts of the continent, and all the islands to the eastward, in cattle, fruits, and the other commodities of the island, exchanging them for calicoes, and other cotton cloths, for their own wear. Their bread is chiefly made of the kernel of the cocoa-nut, boiled or broiled, and spread over with honey; their drink is palm wine, or a juice extracted from the sugar-cane, and suffered to ferment, or the milk of the cocoa-nut. They never allow their women to be seen by strangers without permission from the sultan. Their houses are built of stone and lime, made of calcined oyster-shells, with which the walls and roofs are elegantly plastered, and the roofs and windows are covered with palm leaves, serving as a defence against the rain and the sun. The island is under the government of ten lords, the constitution being an aristocracy. S. lat. 17°. E. long. 58° 10'.

ANGE, ST. or ANGELO *Cape*, lies in the Morea, and has its south-east point projecting considerably into the sea. N. lat. 36° 27'. E. long. 33° 33'.

ANGE,

ANGE, DE ST. JOSEPH, his true name was La Brosse, in *Biography*, a Carmelite monk, born at Toulouse, was sent to Ispahan as a missionary. After residing several years in Persia, he returned to Europe, and was made provincial of his order in Languedoc. Having acquired a knowledge of the Persian language, he published, in 1681, *Pharmacopœia Persica, ea idiomatica Persica in Latinum translata*, 8vo. and, in 1684, *Gazophylacium Linguae Persarum, a Treasury of the Persian Language*, fol. at Amsterdam. This work is in great esteem, containing, besides an explanation of Persian words and terms, many entertaining historical anecdotes and observations.

ANGLIOGRAPHIA, compounded of *αγγειον*, *vessel*, and *γραφω*, *scribo*, *I describe*; the knowledge or description of all kinds of ancient instruments, vessels, and utensils, both domestic, military, and nautical.

Angiography also includes the consideration of the WEIGHTS, MEASURES, &c. used by the several nations.

ANGIOLOGY, in *Anatomy*, derived from *αγγειον*, *a vessel*, and *λογος*, *a discourse*, the history or description of the vessels of the body, which are those concerned in the circulation of the blood, and in absorption. See ARTERIES, VEINS, and ABSORBING VESSELS. The essential structure of vessels is the same in all. They are composed of thin skins or membranes, the inner part of which has a highly polished and secreting surface, allowing the contained fluids to glide along it without impediment, whilst the outer surface is rough and cellular, by which the vessel is connected to the surrounding parts. This essential part of the vessel is strong and unyielding, preventing it from rupture, and preserving it of an unvarying circular figure.

ANGIOTOMY, formed of *αγγειον*, *vessel*, and *τεμνω*, *feco*, *I cut*, in *Surgery*, is used by some to denote an artificial section of the vessels, as in bleeding.

In this sense angiotomy may be divided into PHLEBOTOMY and ARTERIOTOMY.

ANGEL, a spiritual intelligent substance, the first in rank and dignity among created beings.

The word *angel*, *αγγελος*, is not properly a denomination of nature but of office; denoting as much as *nuncius*, *messenger*, a person employed to carry one's orders, or declare his will. Thus it is St. Paul represents angels, Heb. i. 14. where he calls them *ministering spirits*; and yet custom has prevailed so much, that angel is now commonly taken for the denomination of a particular order of spiritual beings, of great understanding and power; superior to the souls or spirits of men. Some of these are spoken of in Scripture in such a manner, as plainly to signify that they are real beings, of a spiritual nature, of high power, perfection, dignity, and happiness. Others of them are distinguished as not having kept their first station (Jude vi.). These are represented as evil spirits, enemies of God, and intent on mischief. The devil as the head of them, and those as his angels, are represented as the rulers of the darkness of this world, or spiritual wickednesses or wicked spirits, *τα πνευματικα της πονηριας εν τοις επαιθετοις*, (Ephes. vi. 12. Locke's Paraphr.) which may not be unfitly rendered, the spiritual managers of opposition to the kingdom of God.

The existence of angels is supposed in all religions, though it is incapable of being proved *a priori*. Indeed, the ancient Sadducees are represented as denying all spirits; and yet the Samaritans and Caraites, who are reputed Sadducees, openly allow them: witness Abufaid, the author of an Arabic version of the Pentateuch; and Aaron, a Caraitic Jew, in his comment on the Pentateuch; both extant in manuscript in the king of France's library.

In the Alcoran we find frequent mention of angels. The

Mussulmen believe them of different orders or degrees, and to be destined for different employments both in heaven and on earth. They attribute exceedingly great power to the angel Gabriel, as to be able to descend in the space of an hour from heaven to earth; to overturn a mountain with a single feather of his wing, &c. The angel Arael, they suppose, is appointed to take the souls of such as die; and another angel, named Esraphil, they say, stands with a trumpet ready in his mouth to proclaim the day of judgment.

The heathen philosophers and poets were also agreed as to the existence of intelligent beings, superior to man; as is shewn by St. Cyprian in his treatise of the vanity of idols, from the testimonies of Plato, Socrates, Trismegistus, &c. They were acknowledged under different appellations; the Greeks calling them *dæmons*, and the Romans *genii*, or *lares*; and Epicurus seems to have been the only one among the old philosophers who absolutely rejected them.

Authors are not so unanimous about the nature as about the existence of angels. Clemens Alexandrinus believed they had bodies; which was also the opinion of Origen, Cæsarius, Tertullian, and several others. Athanasius, St. Basil, St. Gregory Nicene, St. Cyril, St. Chrysostom, &c. hold them to be mere spirits. It has been the more current opinion, especially in later times, that they are substances entirely spiritual, that can, at any time, assume bodies, and appear in human or other shapes.

Ecclesiastical writers make an HIERARCHY of nine orders of angels. Others have distributed angels into nine orders, according to the names by which they are called in Scripture, and reduced these orders into three hierarchies; to the first of which belong seraphim, cherubim, and thrones; to the second, dominions, virtues, and powers; and to the third, principalities, archangels, and angels. The Jews reckon four orders or companies of angels, each headed by an archangel; the first order being that of Michael, the second of Gabriel, the third of Uriel, and the fourth of Raphael. But though the Jews believe them to be but four, yet it seems, from some intimation in Scripture, that there were seven. Rev. iv. v. viii. 2.

By the ancient councils men are forbidden to frame or give particular names to angels; the only names owned by the church are Michael, Gabriel, and Raphael, to which is sometimes added Uriel. Du-Cange.

Before the Babylonish captivity, the Jews did not know the name of any angel; at least we find none mentioned in the books written before this event. Calmet. *Dist. Bib.* Authors are divided as to the time of the creation of angels; some will have it to have been before the creation of our world, or even before all ages, that is from eternity; this is Origen's opinion, who, according to Leontius, held that all spirits, angels, devils, and even human souls, were from eternity.

Others hold angels to have been created before the world, yet not from eternity; of which opinion are Nazianzen, and others. Others again maintain that they were created at the same time with our world, but on what day is disputed. Theodoret and Epiphanius fix their date from the first day.

Good angels are called *angels of light*, and *guardian angels*; and those on the contrary, who are the *devil's* ministers, *angels of darkness*, and *fallen angels*.

That angels are divine messengers employed on particular occasions for executing the divine will, has been a very prevalent opinion; but what is their sphere of action, and how far it extends, it is not easy to determine. Amongst the Jews it seems to have been a firm belief and tradition, that every man had a tutelary or guardian angel from his

birth; and our Saviour seems to refer to this opinion in Mat. h. xv. 10. The heathens were also of the same persuasion, and thought it a crime to neglect the admonitions of so divine a guide. Socrates publicly confessed himself to be under the direction of *Sufes*, an angel or demon, as did also Plotinus and others; on the tutelar genius of each person, they believed his happiness and good fortune depended. The ancient Persians so firmly believed the ministry of angels, and their superintendance over human affairs, that they gave their names to their months, and the day of their months, and assigned them distinct offices and provinces; and it is from them the Jews acknowledge that they have received the names of the months and angels, which they brought with them when they returned from the Babylonish captivity; after which we find they also assigned charges to the angels, and, in particular, the patronage of empires and nations; Michael being the prince of the Jews, as Raphael is supposed to have been of the Persians. Hyde *Reb. V. l. Part. c. 19 and 20.*

As to the fallen angels, it is not known at what time and for what offence they incurred the displeasure of the Almighty, and plunged themselves into an abyss of wickedness and misery. The time in which this event took place is generally imagined to have preceded the creation of the world; and some have accounted for it by the supposition, that the angels, being informed of God's purpose to create man after his own image, and to dignify his nature by Christ assuming it, and thinking their glory to be thus eclipsed, envied the happiness of man, and so revolted; and with this opinion that of the Mahometans has some affinity, who are taught that the devil, who was once one of those angels who are nearest to God's presence, and named Azazel, forfeited Paradise for refusing to worship or pay homage to Adam at the command of God. But whatever was the occasion, or the mode by which it was manifested, pride seems to have been the leading sin of the angels, and it ultimately terminated in rebellion and apostacy. Of these fallen angels there is supposed to have been a great number; and it is apprehended that there was some kind of gradation or subordination among them; one being considered as their prince, and called by several names, Belzebub, Satan, or Sannach, by the Jews; Ahariman by the Persians; and Eblis by the Mahometans.

The Scripture uses the term angel to denote other beings, or agents, besides those spirits that occupy a rank and dignity superior to man. Accordingly it has been a concurrent opinion of the Hebrew and Samaritan schools, that the word angel does not only mean a spirit, but sometimes also all sorts of powers or instruments which God is pleased to use, and by means of which he acts. So that the elements of the world, fire, air, winds, and storms, in particular vision, and in the language of Scripture, are called "angels of the Lord, which do his will." In this sense it is to be understood the expression of the Psalmist (Ps. civ. 4.), who maketh his angels spirits, his ministers a flame of fire," *i. e.* who maketh winds his angels, and lightnings his messengers. Moreover the Scriptures call a dream, a vision, a voice from heaven, a plague, a burning wind, "Angels of God;" and whatsoever God is pleased to do by them is said to be done by an "Angel of the Lord." For whatever declares God's will, or performs his pleasure, is "his angel." In the New Testament we find mention of an angel, by which God punished the blasphemous pride of Herod. Acts, xii. 23. We find another mention of an angel moving at certain seasons the pool of Bethesda. John, v. 4. In the Old Testament we have also mention of an angel destroying the numerous army of Sennacherib. 2 Kings, xix. 35. The punishment

inflicted on David for his sin in numbering the people, is described (1 Chron. xxi. 15.), by God's sending an angel to Jerusalem to destroy it, &c. Daniel also ascribes his deliverance in the lion's den to an angel. Dan. vi. 22. By the angel, in Acts, xii. 23. interpreters have understood the extraordinary distemper which proved fatal to him. In the case of David the persilience insisted upon Israel was the angel of God. See 2 Sam. xxiv. 15, 16. Thus the descent of the angel at the pool of Bethesda (John, v. 4.) may signify the extraordinary motion of the waters, which was the sign of the miraculous virtue that attended them; although some interpreters conceive that the angel, in this case, was an officer or messenger deputed from the temple to stir the pool, and that the warm entrails cast into it communicated the healing virtue to the waters. The angel of the Lord which went out and smote the camp of the Assyrians, seems to be explained by the promise of the prophet Isaiah. 2 Kings, xii. 6, 7. In the account of Daniel's preservation, "God sent his angel," seems immediately explained in this sense; "and hath shut the lions' mouths, that they have not hurt me." Dan. vi. 22. The effect was stopping the mouths of the lions; and in what way soever this was produced, under God's special direction and influence it may be said to be done by his angel, though a separate spirit had no concern at all in it. Thus also the Schechinah, or material symbol of glory, and the oracle from thence, may in this sense be called the angel of the Lord, and it is so called in Scripture; and though the true God himself was the only spirit, or intelligent agent, who acted and manifested himself on the occasion.

According to the opinion of those who maintain the fall of angels, they are represented as being cast out of heaven, abandoned to iniquity, and making it their business to seduce mankind, and taking pleasure in doing them all kinds of injury. Others, however, among whom we may reckon Dr. Pricketley, consider the fall of angels as very problematical; and though it cannot be said that the thing is absolutely impossible, yet they conceive that it seems, upon the face of it, to be very improbable. Besides, if such exalted beings as these are supposed to have sinned, and to have thereby become obnoxious to the divine displeasure, what end, they ask, could it answer to them to be so assiduous in seducing mankind? Indeed, upon the supposition that their existence and torments were to be everlasting, it may be conceived to give them a kind of gloomy satisfaction to have "brethren in iniquity," for their companions in their sufferings. Pricketley's Institutes, vol. ii. p. 433. Bekker, of Amsterdam, maintains, that the word translated "angels" in Jude, v. 6. and also 2 Pet. ii. 4. should be "messengers;" adding, that here is no reference to fallen angels, but to the history of the persons sent out by Moses to spy out, and make report of the land of Canaan; and to their false and wicked account, so as to discourage their countrymen from obeying the divine command.

ANGEL is more particularly applied to a person who sustained any particular character or commission. Accordingly there was an officer of the Synagogue, among the Jews, says Prideaux (Conn. vol. ii. 513.), who officiated in offering up the public prayers to God for the whole congregation, and who, as the mouth of the congregation, delegated as its representative, messenger, or angel, speaks to God in prayer for them, was therefore in the Hebrew language called "Sheliach Zibbor;" that is, "the angel of the church." He was also, according to Dr. Lightfoot, called קהן, or *episcopus*, because he overlooked the reader of the law.

In the Apocalypse, the denomination *angel* is also given to

to the pastors of several churches: who are called the *angel* of the church of Ephesus, the *angel* of the church of Smyrna, &c. This name, according to Prideaux (*ubi supra*), was borrowed from the Synagogue. For as the Shebachi Zibbor, in the Jewish Synagogue, was the prime minister to offer up the prayers of the people to God, he was also the bishop who presided over the church, the prime minister to offer up the prayers of the people to God in the church of Christ. Du-Cange adds, that the same name was anciently given to certain popes and bishops, by reason of their singular sanctity, &c.

ANGEL is also used, in *Commerce*, for an ancient gold coin struck in England; so called, from the figure of an angel impressed upon it. It weighed 4 pennyweights, and was $23\frac{1}{2}$ carats fine.

Its value in 3 Hen. VI. was 6s. 8d., in 1 Hen. VIII. 7s. 6d., in 34 Hen. VIII. 8s. in 6 Edw. VI. it was 10s., in 2 Eliz. it was 10s. and in 23 Eliz. the same. And the *half angel*, or, as it was sometimes called, the *angelot*, was the moiety of this; and the *quarter angelot* proportionable.

The angel now subsists no otherwise than as a money of account, denoting 10s.

The French have also had their *angels*, *demi-angels*, and *angelots*; but they are now disused.

ANGEL-fish, in *Ichthyology*, the English name of the Squallus Squatina of Linnæus; the French call it *ange*. See SQUATINA.

ANGEL, or ANGLÉS Road, in *Geography*, lies on the starboard side of Milford Haven, within the rocks, in the mid-channel of the haven to the east.

ANGELA, or ONGUELA, a town of Africa, in the kingdom of Barca, situate towards Egypt. Its territory, though mostly desert, hath good water, and produces dates.

ANGELIC, or ANGELICAL, something belonging to, or that partakes of the nature of, *angels*.

We have an *angelical* life, &c. St. Thomas is styled the *Angelical Doctor*. The *angelical* salutation is called by the Romanists *Ave Maria*; sometimes simply *angelus*.

ANGELIC garment, ANGELICA vestis, among our *Ancestors*, was a monkish garment which laymen put on a little before their death, that they might have the benefit of the prayers of the monks.

It was from them called *angelical*, because they were called *angeli*, who by these prayers *anime salutis succurrebant*. Hence, where we read the phrase *monachus ad succurrendum* in our old books, it must be understood of one who had put on the habit when he was at the point of death.

ANGELICA, in *Botany*, a genus of the *pentandria digynia* class and order, and of the natural order of *umbellata*, or *umbellifera*. Its characters are, that the *calyx* has an universal umbel, manifold, and roundish, and partial, when flowering, exactly globular; the universal involucre three or five-leaved, small; partial, eight-leaved, and small; proper, perianth five-toothed, scarcely observable; the *corolla* universal uniform, floscules all fertile; partial, petals five-equal, lanceolate, flattish, incurved, and caducous; the *stamina* have simple filaments, larger than the corolla, and simple anthers: the pistilium has a germ, inferior styles reflex, and stigmas obtuse, no *pericarpium*; fruit roundish, angular, solid, and bipartite; *seeds* two, ovate, flat on one side, and margined; convex on the other, scored with three lines. Martyn enumerates six, and Gmelin seven species. 1. *A. archangelica*, ang. sativa of Miller, garden angelica, with the odd leaflet of the leaves lobed. The root is thick, fleshy, and resinous; the stalk is erect, about the height of five feet, ramous,

hollow, round, smooth, and furrowed; the leaves are ternate and pinnated, leaflets are ovate-lanceolate, acute, gashed, and acutely serrated, smooth, subdecurent, with the odd one tripartite; the petiole at the base is membranaceous, nervous, very much dilated and ventricose; the umbels globose and multiradiate; the umbellules dense and hemispherical; the involucre consisting of a few linear deciduous leaflets; the involucrella suboctophyllous, linear-lanceolate and short; the calyx small, the petals ovate, inflex, and whitish-green; the fruit elliptic-roundish, compressed, and acutely ribbed. It is a native of the northern parts of Europe, and was cultivated here in 1568. With us it is found at Broadmoore, about seven miles north-west from Birmingham, is biennial, and flowers in September. In a cultivated state, says Withering, this is supposed to be the garden angelica, which is used in some distilled waters, and candied by the confectioners.

Mr. Miller makes a distinct species of the angelica, which grows naturally in Hungary, and some parts of Germany; about twice the size of the common sort, with much larger leaves, more deeply sawed on the edges, with the umbels much larger, and the flowers yellow. 2. *A. sylvestris*, water A. or wild A. with leaflets equal, ovate-lanceolate and serrate; the stem erect, about four feet high, round, smooth, and sosohe; the leaves bipinnate, and subglabrous, with leaflets ovate, distinct, acutely serrated, and serratures mucronate; the umbels hemispheric and multiradiate; the umbellules dense; the involucre subdiphyllous, and very narrow, and sometimes none; the involucre polyphyllous and setaceous; the calyx scarce visible; the petals ovate, inflex, and fleshy, and the fruit small: it is perennial, found in moist woods and hedges, and by the sides of rivers, and flowers in July. 3. *A. verticillaris*, with leaves very much divaricate, leaflets ovate and serrate, and stem verticilled, with peduncles; a native of Italy and Silesia, introduced in 1774 by M. Richard. 4. *A. atropurpurea*, purple A. with the outermost pair of leaves coadjoined, and the terminal leaf petioled; a native of North America, and cultivated by Mr. Miller in 1759. 5. *A. lucida*, shining A. with leaflets equal, ovate, and gash-serrate; a native of Canada, flowers in June, and the seeds ripen in August. 6. *A. Razulii*, panax alpina, &c. of Boec. with leaves bipinnate, leaflets lanceolate, serrate, and decurrent; a native of the Apennines and Piedmontese mountains, found on the former by M. Raoul, an apothecary at Perpignan, whence its trivial name. 7. *A. lobata*, with the inferior leaves biterminate; the leaflets petioled, ovate, and serrate; the superior ternate. 8. *A. integrifolia*, with the leaflets entire and petioled. Martyn's Miller. Gmelin. Willdenow. Smith. Flor. Brit.

Culture. All the sorts may be increased by seeds. The common angelica delights in a moist soil, in which the seeds should be sown soon after they are ripe; and when the plants are about six inches high, they should be transplanted at a large distance, about three feet asunder, on the sides of ditches or pools of water. In the second year they will flower, and their stems may be cut down in May, and heads will be put out from the sides of the roots, and thus they may be continued for three or four years; but if they had been permitted to seed, their roots would perish soon after. If they are permitted to seed, they last but two years.

Dietetic and medical uses. The stalks of garden angelica were formerly blanched, and eaten as celery. The young shoots are in great esteem among the Laplanders. In Norway bread is sometimes made of the roots. The gardeners near London, who have ditches of water in their gardens, propagate great quantities of this plant, which they sell to the confectioners, who make a sweet-meat with the tender

stalks cut in May. Bohemia and Spain are supposed to produce the best: the college of London formerly directed the roots brought from Spain only to be kept in the shops. Linnæus, however, assures us, that the plant proves most vigorous on its native northern mountains, and gives a decided preference to the root dug here either early in the Spring, or late in the Autumn. The roots of angelica are one of the principal aromatics of European growth, though not much regarded in the present practice. They have a fragrant agreeable smell, and a bitterish pungent taste; on being chewed they are first sweetish, afterwards acrid, and leave a glowing heat in the mouth and fauces, which continues for some time. The stalk, leaves, and seeds appear to possess the same qualities, though in an inferior degree. Dr. Lewis says, that on wounding the fresh root early in the Spring, it yields, from the inner part of the bark, an unctuous, yellowish, odorous juice, which, gently exsiccated, retains its fragrance, and proves an elegant, aromatic, gummy resin. Rectified spirit extracts the whole of the virtues of the root; water but very little; and, in distillation with the latter, a small portion of very pungent essential oil may be obtained. The Laplanders extol the utility of angelica, not only as food but as medicine. For coughs, hoarseness, and other disorders of the breast, they eat the stalks roasted in hot ashes; they also boil the tender flowers in dairy milk till it attains the consistency of an extract; and they use this to promote perspiration in catarrhal fevers, and to strengthen the stomach in diarrhœa, &c. According to the explanations of Sir John Pringle, the herb is antiseptic, but the efficacy of the leaves is soon lost by drying them. The seeds also, which come nearest to the roots, can scarce be kept till the Spring after they are gathered, without the loss of their vegetative power, as well as a diminution of their medicinal virtue. These are the only part of the plant which is ordered by the London College, and that only in compound spirit of aniseed. The aromatic quality of the root is more considerable than that of any other part; but as many other simples surpass angelica in aromatic and carminative powers, it is seldom employed in the present practice. All the parts of the wild angelica are similar in quality to those of the former species, but rather weaker, and the former may be more easily procured. Cows, goats, and swine eat it, but horses refuse it. Lewis. Murray. Woodville.

ANGELICA. See ÆGOPodium, CHÆROPHYLLUM, CICTUTA, LASERPITULUM, SELINUM, and SMYRNIUM.

ANGELICA *rue*. See ARABIA.

ANGELICA *water* is one of the compound waters of the shops; thus called from the *angelica* root, which is the chief ingredient in the composition, and the most active part of that plant. Neumann.

ANGELICA *grana*, a technical name given to Anderson's Scots pills.

ANGELICA was also a celebrated dance among the ancient Greeks, performed at their feasts.

It was thus called, from *αγγελος*, *nuncius*, *messenger*, because, as Pollux assures us, the dancers were dressed in the habit of messengers.

ANGELICI, an ancient order of knights, instituted in 1191, by Isaacus Angelus Flavius Comnenus, emperor of Constantinople.

They were divided into three classes, but all under the direction of one grand master. The first were called *torquati*, from a collar which they wore, and these were fifty in number. The second were called the *knights of justice*, and were ecclesiastics. And the third were called *knights fervitors*.

Justiniani will have this order to have been instituted in

the year 313, by Constantine; and supposes the occasion thereof to have been the appearance of an angel to that emperor, with the sign of a cross, and these words, *In hoc signo vinces*; but that there was such a thing as any military order in those days, is a mere fable.

ANGELICI, in *Ecclesiastical History*, were also a sect of ancient Christians. St. Augustin supposes them thus called from their yielding an extravagant worship to angels, and such as tended to IDOLATRY; though Epiphanius derives the name from their holding, that the world was created by angels.

ANGELINA *zanoni acosta*, in *Botany*. This is a tree of vast size, sometimes above sixteen feet thick, growing on rocky and sandy places in Malabar, in the East Indies. It bears ripe fruit in December, and continues bearing for a whole century.

The dried leaves heated, are said to alleviate pains and stiffness in the joints, and disperse an intumescence of the *testes* occasioned by a contusion, or any external violence; as also an *hydrocele*, or *pneumatocœle*. It is efficacious likewise in some venereal complaints, and hæmorrhoidal fluxes.

ANGELIO, PETER, in *Biography*, a modern Latin poet, was born in 1517, at Barga, a castle of Tuscany, and hence usually called Bargæus. Having made a great proficiency in Latin and Greek at the early age of ten years, he was prevented from pursuing his studies by the loss of his parent, and obliged to enter into the army. Afterwards, however, he renewed his application to literature, and studied law under Alciatus, at Bologna. But he was obliged to leave this place on account of some satirical verses which he wrote, and to go to Venice, where he was employed by William Pellicier, the French ambassador, in correcting the Greek MSS. which were copied for his sovereign Francis I. In 1542 he removed to Constantinople, where his life was brought into danger by his zeal for the honour of his own nation, which urged him to kill a Frenchman who spoke disrespectfully of it. From hence he escaped first to Genoa, and then to Milan; and from Milan he removed to Reggio, in Lombardy, and accepted an invitation to become public preceptor of Greek in that place. After a residence here of three years, he was invited by Cosmo I. duke of Florence, to a professorship, first of belles lettres, and afterwards of the ethics and politics of Aristotle, in the university of Pisa, where he continued 17 years. During his abode in this place, he defended it, with the aid of the scholars of the university, against an attack of Peter Strozzi, in the war of Sienna. In 1575 he was invited to Rome by the Cardinal Ferdinand de Medici, who entertained him liberally at his court, and recompensed him for the dedication of his poems, with a donation of 2000 gold florins. His latter days he spent at Pisa, living at ease on the munificence of his sovereign; and he died there in 1596. His works in Italian and Latin, both prose and verse, are numerous; but to his Latin performances he chiefly owes his reputation. In five books of miscellaneous Latin poems, he has happily imitated the style of Catullus. His "Cynegeticon," or Chase, in six books, first printed in 1568, and said to be the labour of 20 years, is reckoned one of the best specimens of modern Latinity, and highly commended by Lombin, De Thou, and Possevin. His "Syrias," an epic poem in 12 books, on the expedition of Godfrey of Bouillon to the Holy Land, was composed in his old age, and though it possesses elegance, it wants the majesty required for such a theme.

ANGELITÆ, *Angelites*, in *Ecclesiastical History*, certain Christians, thus denominated from *Angelium*, the name of a place in Alexandria, where their first assemblies were held.

The *Angelites* appear to have been the same with what are otherwise called *Severites*, sometimes *Theodosiani* and *Damianisti*, from the names of their leaders: sometimes also *Tabellionisæ*.

They made their first appearance in the time of the emperor Anathafius, and pope Symmachus, about the year of Christ 494.

The distinguishing tenets of the angelitæ were, that the several persons of the Trinity had no distinct essence, substance, or deity, but only a subsistence or deity in common, or indivisible among them.

ANGELL, in *Geography*, a river of North Wales, which runs into the DOVCY.

ANGELN. See ANGLEN.

ANGELLO, *Port of*, is an harbour on the South Sea coast, in the middle between St. Pedro and Capolita; a broad open bay with good anchorage, but bad landing; and the Spaniards reckon it as good a harbour as Guatulis.

ANGELO, *St.* a small but strong town of Italy, in the Capitanata. There are several other towns and castles of the same name in Italy, particularly the castle of St. Angelo at Rome. N. lat. 41° 43'. E. long. 15° 56'.

ANGELO *Monte*, *St.* a small port in N. lat. 41° 42', and E. long. 15° 13', within Cape Vettice on the west side of the gulf of Venice, is so called from a high mountain within the cape, and the first land made after entering the gulf.

ANGELO *Rio*, *St.* lies on the coast of Brasil, to the north-west from Cape St. Angustine, and is a large opening, without depth of water, blocked up with shoals, and rendered useless for navigation.

ANGELO BUONAROTI, MICHAEL, a celebrated painter, was born in the territory of Arezzo, in Tuscany, in 1474, and educated at Florence, where, pursuing the bent of his natural genius for sculpture and painting, in opposition to the remonstrance of his parents, he became, at the age of 14, the disciple of Dominico Ghirlandaio, who has gained great reputation by the artists which his school produced. Michael Angelo soon became superior to his instructor; and such was his uncommon merit, that Lorenzo de Medici took him into his service, and employed him in founding an academy at Florence for painting and sculpture; and also in executing several noble works, particularly in statuary, which gained him universal applause. By the death of his patron, and the disturbances which happened at Florence, he was obliged to quit the city; but he soon returned, and finished that incomparable figure of David with his sling, out of a large block of marble, which is deemed his master piece, and worthy of the hand of an antique artist. The distinguishing excellence of this great master was sculpture; and he was the first painter who communicated to the artists of Italy a taste for what is grand and elevated, and enabled them to abandon the dry, stiff manner of Perugino and others. Although he cannot be commended for his colouring, yet the grandeur, elevation, and sublimity of his ideas, the exquisite taste of his design, and the justness of some of his expressions, established his fame, notwithstanding many imperfections which have been imputed to him as a painter. He wanted elegance in the contours of his figures, and purity of outline; his attitudes are not always beautiful or pleasing; and he was, as Fresnoy observes, bold even to rashness, in which he often succeeded.

His acquaintance with anatomy qualified him for shewing every limb and joint of the human body, and the insertion, as well as the power of every muscle, with great precision; but in consequence of his anatomical skill, he was apt to give too great a strength and swell to the muscular parts. *How-*

ever, it is said, that Raphael himself derived improvement from observing the grand ideas of Buonaroti, though he far excelled him in elegant simplicity, grace, and nature.

The most capital performances of this extraordinary genius are "The Crucifixion," and "The Last Judgment," which is the ornament of the chapel of Sixtus V. in the Vatican. This picture employed him eight years; and as every muscle and limb are distinctly and curiously marked, the figures are entirely naked. This circumstance induced Biagio of Cesenna, the pope's master of ceremonies, to observe, that such an exhibition of naked figures was more suitable to a brothel than a chapel. But Michael Angelo revenged himself for this sarcasm, by painting the portrait of Biagio exceedingly like, representing him as a demon, with ass's ears, encircled with a large serpent, and placing him in hell. The pope frequently intreated Buonaroti to deliver his master of the ceremonies from this place of torment; but he made this excuse, that he might have been released if he had only been in purgatory, but as he was in hell there was no redemption for him.

A late judicious traveller, having viewed that famous composition with a most critical attention, and proportionable admiration, says, that while he stood before it his blood was chilled, and he felt as if all he saw was real; and the very sound of the painted trumpet seemed to pierce his ears. The composition, however, though grand, is not without perceptible faults. The faces express passions of the strongest kind, and communicate them to the beholders; but the bodies are of too gross an appearance. Indeed the face of our Saviour possesses a dignity, which language cannot describe; it has an astonishing mixture of divine sweetness and severity, which could only be happily expressed by the pencil of Angelo. M. Angelo discontinued painting in the 75th year of his age; and as he died at Rome in the 90th year of his age, A. D. 1563, he was splendidly interred in that city at the expence of Cosmo, duke of Tuscany; but by order of this prince, his remains were secretly conveyed to Florence, and deposited, with great funeral pomp, in a magnificent monument, enriched with three marble statues, representing Painting, Sculpture, and Architecture. Pilkington's Dict. Keyser's Travels, vol. ii. p. 150.

Sir Joshua Reynolds, in the spirited and masterly sketch which he has given of the character of M. Angelo in his "Discourse delivered to the Students of the Royal Academy," Dec. 10, 1795, describes him "as the exalted founder and father of modern art, of which he was not only the inventor, but which he, by the divine energy of his own mind, carried at once to its highest point of possible perfection." "M. Angelo (says this excellent artist and judge of merit,) possessed the poetical part of the art to a most eminent degree; and his mechanical excellence invigorated and emboldened his mind to carry painting into the regions of poetry, and to emulate that art in its most adventurous flights. M. Angelo equally possessed both the mechanical and poetical qualifications; yet of the former there were certainly great examples to be found in ancient sculpture, and particularly in the fragment known by the name of the Torso of Michael Angelo; but of that grandeur of character, air, and attitude, which he threw into all his figures, and which so well corresponds with the grandeur of his outline, there was no example; they could therefore proceed only from the most poetical and sublime imagination." "Were I now to begin the world again," says the ingenious president of the Royal Academy, "however unequal I feel myself to that attempt, I would tread in the steps of that great master: to kiss the hem of his garment, to catch the slightest of his perfections, would be glory and distinction enough

enough for an ambitious man. I feel a self-congratulation in knowing myself capable of such sensations as he intended to excite. I reflect, not without vanity, that these discourses bear testimony of my admiration of that truly divine man; and I should desire that the last words which I shou'd pronounce in this academy, and from this place, might be the name of Michael Angelo."

ANGELO AMERIGI DA CARAVAGGIO, MICHAEL, was born at the village of Caravaggio, in the Milanese, in 1599, and became the author of that style in which he painted, which was strong, and had a powerful effect, by the bold opposition of his lights and shadows. His style of painting was so new, and so surprising, that most of his contemporaries, such as Domenichino, Guido, and Guercino, studied to imitate it. His chief excellence consisted in colouring, but his attitudes are ill chosen, his figures inelegantly disposed, and his compositions manifest no fixed idea of grace or grandeur; nevertheless, some of his pictures are truly fine, and admirably finished with great mellowness of pencil. At first he painted fruit and flowers; but he afterwards devoted his whole attention to historical compositions and portraits. In the church of St. Martin, at Naples, there is a capital picture by Caravaggio, representing "Peter's denial of his Master," with figures at half length, and large as life. The master-piece of all his works, viz. "The Intombing of Christ," is now in the Louvre at Paris. He died in 1609, aged 40. Pilkington.

ANGELO, MICHAEL, called DE CAMPIDOGGIO, was born at Rome in 1610, and distinguished by the appellation Campidoglio, from an office which he held in the capitol at Rome. He was the disciple of Fioravanti, and peculiarly excelled in painting fruit and flowers. He died at the age of 60.

ANGELO CERQUOZZI, MICHAEL, called DI BATTAGLIA, was born in 1600, and denominated Di Battaglia from the excellence of his style in painting battles. He also painted fruit with such taste as rendered his performances, in this way, famous through Europe. He possessed so lively an imagination, and so ready a pencil, that he never sketched his designs, but merely marked them on the canvas as his fancy directed, and gradually retouched them, till he gave them their utmost perfection. He lived to the age of 60 years.

ANGELO COLONNA, MICHAEL, was born at Ravenna in 1600, and studied architectural painting under Girolamo Carti, called Dentone, in which branch of his profession he arrived at a considerable degree of eminence. In concurrence with Curti he enriched a great number of chapels and convents with various works. Philip IV. invited him to the court of Spain, where he was respected and encouraged; and he was also highly esteemed at the courts of Modena, Florence, Paris, and Parma. His principal works are grand compositions in the churches and convents of Italy, and in the palaces of the nobility. Pilkington.

ANGELOLATRIA, from *αγγελος*, *angel*, and *λατρευω*, *I worship*, the superstitious worship or adoration of angels.

ANGELOLOGIA, from *αγγελος* and *λογος*, *discourse*, the doctrine or science of angels, their nature, office, &c. Gerhard has published a sacred Angelologia, Musæus an apologetical Angelologia.

Some use the term Angelosophia in a sense much the same. A. Vareninus has given an Angelosophia.

ANGELOGRAPHIA, from *αγγελος* and *γραφω*, *I describe*, a description of angels, their orders, names, discipline, &c. This amounts to much the same with what others call angelologia. Casmannus and Manitius have published Angelographies.

ANGELONI, FRANCIS, in *Biography*, an historian and antiquary of the 17th century, illustrated the Roman history by medals, in a work published at Rome, in folio, in 1685, and entitled "Histoire Angulle par les Medailles depuis Julius Cesar jusq'a Constantin le Grand." He also wrote a "History of Terni," his native country, printed in 4to. at Rome, in 1646; where he died in 1652. Nouv. Dict. Hist.

ANGELOS, LOS, in *Geography*. See TLASCALA.

ANGELOS, PUEBLA DE LOS, or the *city of angels*, a town of Mexico, and new capital of the province of Los Angeles or Tlascala, supplies the place of the ancient city of Tlascala, which is now dwindled to a poor inconsiderable village, and situated not far from it. It lies in N. lat. 19° 30', and W. long. 99° 10', on the river Ziateua, in a fine valley, about 25 leagues to the eastward of Mexico. In the middle is a beautiful spacious square, from whence run the principal streets in a direct line, which are crossed by others at right angles. One side is almost entirely occupied by the magnificent front of the cathedral, and the other three consist of arcades, under which are the shops of tradesmen. The city is the see of a bishop, suffragan to the archbishop of Mexico. The number of inhabitants is computed at 60,000. In the town there are a mint, and glass-house, and a manufacture of excellent salt; and the adjacent valley produces vines and all sorts of European fruits. In the neighbourhood are several kinds of mineral waters.

ANGELOT, an ancient English gold coin, struck at Paris while under subjection to the English. It was thus called from the figure of an angel supporting the scutcheon of the arms of England and France. There was another coin of the same denomination struck under Philip de Valois.

ANGELOT is also used, in *Commerce*, to denote a small, fat, rich sort of cheese, brought from Normandy.

Skinner supposes it to have been thus called, from the name of the person who first made it up in that form, and perhaps stamped it with his own name. Menage takes it to have been denominated from the resemblance it bears to the English coin called *angelot*. It is made chiefly in the Pays de Bray, whence it is also denominated *angelot de Bray*. It is commonly made in vats, either square or shaped like a heart.

ANGELUS, in the *Church History* of France, denotes a prayer to the Holy Virgin, beginning with this word, instituted by John XXII. in the year 1326, and to be recited every day, morning, noon, and night. Lewis XI. established in France the practice of repeating it at noon; and he obtained from the pope an indulgence of 300 days for all the faithful who, at three o'clock, should rehearse three times on their knees an Ave Maria for the preservation of the king and kingdom. They began, toward the close of the year 1330, to use the angelus in an evening before they put out their fires; this prayer they entitled the pardon, on account of the indulgences attached to it.

ANGELY (L'), in *Geography*, a town of Germany, in the circle of Westphalia and bishopric of Liege, four miles south-west of Charleroy.

ANGEN, a small town of Lower Austria, belonging to the count of Peltzburg.

ANGER. Hutcheson defines anger, a propensity to occasion evil to another, arising upon an apprehension of an injury done by him; or, as archdeacon Paley defines it, anger is the pain we suffer upon the receipt of an injury or affront, with the usual effects of that pain upon ourselves.

Anger is either deliberative or instinctive; and the latter kind is rash and ungovernable, because it operates blindly without affording time for deliberation or fore-sight. Bishop Butler (sermon viii.) very justly observes, that anger is far

from being a selfish passion, since it is naturally excited by injuries offered to others, as well as to ourselves; and was designed by the Author of Nature not only to excite us to act vigorously in defending ourselves from evil, but to interest us in the defence or rescue of the injured and helpless, and to raise us above the fear of the proud and mighty oppressor. "Be ye angry, and sin not," is a scripture caution; and this supposes that all anger is not sinful, because some degree of it, and, upon some occasions, is inevitable. It becomes sinful, however, when it is conceived upon slight and inadequate provocations, and when it continues long. The cautions and precepts relating to anger evidently suppose, that this passion is within our power; and this power consists in so mollifying our minds by habits of just reflection, as to be less irritated by impressions of injury, and to be sooner pacified. Such reflections as the following, as they conduce to this purpose, may be considered as the sedatives of anger, *viz.* the possibility of mistaking the motives from which the conduct that offends us proceeded; how often *our* offences have been the effect of inadvertency, when they are construed into indications of malice; the inducement which prompted our adversary to act as he did, and how powerfully the same inducement has, at one time or other, operated upon ourselves; that he is suffering perhaps under a contrition, which he is ashamed, or wants opportunity, to confess; and how ungenerous it is to triumph by coldness or insult over a spirit already humbled in secret; that the returns of kindness are sweet, and that there is neither honour, nor virtue, nor use, in resisting them—for some persons think themselves bound to cherish and keep alive their indignation, when they find it dying away of itself. We may remember that others have their passions, their prejudices, their favourite aims, their fears, their cautions, their interests, their sudden impulses, their varieties of apprehension, as well as we: we may recollect what hath sometimes passed in our own minds, when we have got on the wrong side of a quarrel, and imagine the same to be passing in our adversary's mind now; when we became sensible of our misbehaviour, what palliations we perceived in it, and expected others to perceive; how we were affected by the kindness, and felt the superiority of a generous reception and ready forgiveness; how persecution revived our spirits with our enmity, and seemed to justify the conduct in ourselves, which we before blamed. Add to this, the indecency of extravagant anger; how it renders us, whilst it lasts, the scorn and sport of all about us, of which it leaves us, when it ceases, sensible and ashamed; the inconveniences and irretrievable misconduct into which our irascibility has sometimes betrayed us; the friendships it has lost us; the distresses and embarrassments in which we have been involved by it; and the sore repentance which on one account or other it always costs us.

But the reflection calculated above all others to allay that haughtiness of temper which is ever finding out provocations, and which renders anger so impetuous, is that which the Gospel proposes, namely, that we ourselves are, or shortly shall be, suppliants for mercy and pardon at the judgment-seat of God. Imagine our secret sins disclosed and brought to light; imagine us thus humbled and exposed; trembling under the hand of God; casting ourselves on his compassion; crying out for mercy—imagine such a creature to talk of satisfaction and revenge; refusing to be intreated, disdainful to forgive; extreme to mark and to resent what is done amiss; imagine this, and you can hardly bring to yourself an instance of more impious and unnatural arrogance. Paley's *Philos.* vol. ii. chap. vii. p. 261, &c.

Physicians and naturalists relate some very extraordinary

effects of this passion. Borrichius cured a woman of an inveterate tertian ague, by putting the patient into a violent fit of anger. The same passion has been excited with salutary influence in paralytic gout, and even dumb persons; and these last have, in some cases, recovered the use of speech. Etmuller, among other instances of singular cures wrought by anger, mentions a person, who, being afflicted with the gout, was provoked by his physician to a great degree, and thus cured. In some cases this passion, unduly excited, has proved mortal. Valentinian the First, Wenceslaus, Matthias Corvinus king of Hungary, and others, have fallen sacrifices to it. Instances might also be mentioned in which it has produced the epilepsy, jaundice, cholera morbus, diarrhoea, &c.

Anger, indeed, is of such a nature, that it quickly throws the whole nervous system into preternatural commotions by a violent stricture of the nervous and muscular parts: and surprisingly augments not only the *syctole* of the heart, and of its contiguous vessels, but also the tone of the fibrous parts in the whole body. It is also certain, that this passion, by the spasmodic stricture it produces in the parts, exerts its power principally on the stomach and intestines, which are highly nervous and membranous parts; whence the symptoms are more dangerous, in proportion to the greater consent of the stomach and intestines with the other nervous parts, and almost with the whole body.

The unhappy influence of anger likewise, on the biliary and hepatic ducts, is very surprising; since by an intense constriction of these, the liver is not only rendered scirrhus, but stones also are often generated in the gall-bladder, and biliary ducts; these accidents have scarcely any other origin than an obstruction of the free motion and efflux of the bile, by means of this violent stricture. From such a stricture of these ducts likewise proceeds the jaundice, which in process of time lays a foundation for calculus concretions in the gall-bladder. Lastly, by increasing the motion of the fluid, or the spasms of the fibrous parts by means of anger, a larger quantity of blood is propelled with an *impetus*, to certain parts; whence it happens, that they are too much distended, and the orifices of the veins distributed there, opened. It is evident from experience that anger has a great tendency to excite enormous hæmorrhages, either from the nose, the aperture of the pulmonary artery, the veins of the arms; or in women from the uterus; especially in those previously accustomed and disposed to such evacuations.

For the influence of this passion on the perspiration and urine of human bodies, see PERSPIRATION, &c.

ANGER, in *Geography*, a town of Germany, in the duchy of Stiria, 12 miles north-north-east of Graz.

ANGER is also a town of Germany, in the archduchy of Austria, eight miles south of St. Polten.

ANGERAP, a river of Prussia, which runs into the Pregel, near Georgenburg.

ANGERBACH, a river of Germany, which runs into the Havel, near Potsdam.

ANGERBURG, a modern, well-built, and flourishing town of Prussia, in a government of the same name. It is defended by a strong castle built in 1335 upon the bank of a lake, which is the source of the river Angerap. This lake, seven German miles long, and one and a half broad, is of great service to the town, and abounds with eels. In 1725 an arch-prefbytery was founded here, which has 12 churches under its jurisdiction. The best Prussian manna is produced in the environs of Angerburg.

ANGERMANLAND, or ANGERMANNIA, a province of Sweden, bounded on the north by Bothnia and Lapland,

on the east by the gulf of Bothnia, on the south by Medelpad, and on the west by Jämtland and Hälsjedalen. Its extent is about 14 Swedish miles in length, and 16 in breadth. It abounds with forests and mountains; amongst the latter of which the high mountain called Skoln is the most remarkable. The soil, however, is fruitful, and in four parts produces excellent corn. The district on the south side of Ångermanland river yields rye, pease, linseed, flax, and good barley; and the marlow lands afford good pasture for cattle. Here are also several fisheries, and lakes abounding with fish. This province maintains soldiers for the royal navy, and consists of a land-district jurisdiction, and two vogteys. It is the residence of the superintendent of this diocese, which is the chief magistracy, and divided into two provostships. The superintendency or bishoprick consists of the provinces of Ångermanland, Medelpad, Jämtland, Hälsjedalen, and the whole government of West Bothnia, Krimlapmark excepted, which belongs to the diocese of Abo. The province is divided into the north and south parts.

ÅNGERMANSKANAL, is one of the largest rivers in the whole kingdom of Sweden, being about a league in breadth at its mouth in the gulf of Bothnia, and navigable for small vessels several Swedish miles into the continent. The salmon-fishery in this river affords extraordinary profits to the country.

ÅNGERMUND, a town of the duchy of Courland, in the district of Piltina, 16 miles north-east of Piltina.

ÅNGERMUND is also a town and prefecture of Berg, in Westphalia, situate on the rivulet of Anger.

ÅNGERMUND, NEW, a town of Germany, in the circle of Upper Saxony, and neck-mark of Brandenburg; 36 miles north-east from Berlin. N. lat. 53° 1'. E. long. 14° 1'.

ÅNGERN, a small place, with a church and iron-works, in the prefecture of Tuckum, and duchy of Courland.

ÅNGERO, a town of Italy, in the kingdom of Naples, and Principato Citra; 11 miles west north-west from Salerno.

ÅNGERONA, in *Mythology*, a pagan deity of the Romans, similar to the Harpocrates of the Egyptians, and the Sigilon of the Greeks, supplicated by them for relief under the quinzey or argina. This deity is denominated by Praxiphanes the "Goddess of Silence and Calmness of Mind," because she banished all unreason and melancholy. She is represented with her mouth closed, and a finger applied to it, to denote patience, and the suppression of complaint. Her statue was set up in the temple of the goddess Voluptas, and thus furnished a moral allegory, intimating that patience under affliction led to subsequent and certain pleasure.

ÅNGERONALIA, in *Antiquity*, solemn feasts held by the Romans, the 21st of December, in honour of Angerona, or Angerona, the goddess of patience and silence.

Festus and Julius Modestus, quoted by Macrobius, Saturn. lib. 1. cap. 10. derive the name from *angina, squintancy*; and suppose the goddess to have been thus denominated, because she presided over that disease. Others suppose it formed from *anger, grief, pain*; to intimate that she gave relief to those afflicted therewith. Others deduce it from *angio, I press, I close*; as being reputed the goddess of silence, &c.

ÅNGEROT, in *Geography*, a small town of Westphalia, in the duchy of Berg, situated near the fall of the Anger into the Rhine, nine miles north from Duffeldorp.

ÅNGERS, anciently *Juliomagus* and *Andegarium*, a city of France, and capital of the department of the Mayne and Loire, situate on the Mayne, and divided by it into two parts, communicating with each other by two bridges. Before the revolution it was the capital of Anjou and the see

of a bishop, suffragan to the archbishop of Tours: its university was founded by St. Lewis in 1246, by whom also its castle, seated on a steep rock, was built; and its academy of the belles lettres in 1685. The first walls of this city were built by John, king of England, who was count of Anjou in 1214, but destroyed by Louis VIII. and rebuilt by his son, in their present form, in 1232; the city has 16 parishes, and several religious houses; the cathedral is venerable for its age, and beautiful with regard to its structure; the houses are covered with the black slate procured from the quarries of Angers, and hence Angers is called "The Black City." The manufacture of Angers before the revolution consisted of camblets, serges, and mixed stuffs, and it carried on a considerable trade in other commodities. Its population is estimated at 300,000 inhabitants. It is distant 23 leagues west from Tours, 18 north-east from Nantes, and 67 south-west from Paris. N. lat. 47° 28' 8". W. long. 0° 33' 5".

ANGERVILLE, a small town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Estampes, and four leagues distant from it.

ANGERVILLE is also a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Montivilliers, and two and a half leagues north-east from it.

ANGETENAR, in the *Arabian Astronomy*, denotes a fixed star, of the fourth magnitude, in the body of Cetus, or the whale.

ANGHIERA, in Latin *ANGLIERA*, in *Geography*, a town of Italy, in the duchy of Milan, and capital of a county of the same name, established by the emperor Wenceslaus in 1397, and situate at the foot of the Alps. It is well peopled, and has a good trade, and the adjacent country is fertile. It is directly opposite to Aroua, and separated from it by the lake called Lago Maggiore. N. lat. 45° 18'. E. long. 8° 19'.

ANGIGLOSSII, from *αγγιστος, confringo*, and *γλωσσα, lingua*, denote those who speak with difficulty, hesitation, or even stammering.

ANGILDUM, in our *Old Writers*, denotes a simple gold, that is, the simple value of the man, or other thing.

The word is compounded of the Saxon, *an, one*, and *gild, payment, price, or compensation*.

In this sense, *angildum* stands contradistinguished from *twigildum, a double compensation*; *trigildum, a triple compensation*.

ANGINA, in *Medicine*, an inflammation about the muscles of the *larynx* or *pharynx*, attended with an acute fever, difficulty of swallowing, and danger of suffocation.

The word is derived immediately from the Latin *ango, I vex*, formed of *αγγω, suffoco, strangulo*. See *CYNANCHE*.

ANGINA lini, in *Botany*, a name used by some of the later Greek writers, to express what the more ancient writers of this nation called *linozostis*, and the Latins *epilinum*; this was the *cuscuta* or *codder* growing on the flax, as that on the thyme was called *epithimum*. It was called *angina lini*, the quinzey of flax, from its choaking that plant.

ANGINA pectoris, in *Medicine*, a name given to a disease, dangerous and not extremely rare, first described by Dr. W. Heberden, and so called from the feat of the disorder, and the sense of strangling and anxiety with which it is attended. The doctor's account of it is in the second volume of the London Medic. Transf. p. 59. &c. See also Medic. and Phil. Comment. vol. ii. p. 95. The patient, while walking, especially if soon after eating, is affected with a painful sensation in his breast; at first, it is removed by his standing still, but afterwards it does not go off so suddenly: it comes

on in bed, obliges the patient to get up, and continues for an hour and more; sometimes, though rarely, it attacks the patient standing or sitting still. It is brought on by trivial accidents, coughing, &c. or any slight disturbance. In some it is worse in Winter, in others in Summer. The pulse, sometimes at least, is not disturbed. People affected with it often die suddenly, but some continue subject to it for upwards of 20 years. The patient commonly refers the seat of his complaint to the sternum, or to a line running across the middle of the sternum; and a pain in the middle of the left arm sometimes accompanies it.

The cause of this distressing malady was not understood till lately, it being often supposed a spasmodic affection, or a curies of the sternum; but it is now believed to be an ossification of the coronary arteries which supply the muscular substance of the heart with blood. This change of structure renders the heart unequal to the task of circulating the unusual quantity of blood thrown upon it by bodily exertions or passions of the mind; and hence it is that these are the exciting causes of the distress, in the early stages of the disease.

The prognosis must generally be unfavourable; but several means may be employed to diminish the sufferings of the patient, or to postpone the fatal issue of the disease. These are temperance in eating and drinking, and abstinence from violent exercise and passions. As angina pectoris commonly attacks persons disposed to obesity and plethora, these states should be avoided by a suitable regimen, and occasional bleeding and purging. The circulation should also be kept as equable as possible in every part of the system, by warm clothing, and avoiding the causes of local congestion. Wine, or other cordials, taken at bed-time, prevent or weaken night-fits, but opium is the most effectual relief; ten, fifteen, or twenty drops of the Thebaic tincture, taken at bed-time, may be safely continued as long as requisite.

This disease has been accurately described, and suitable preventives or remedies proposed, by Dr. Fothergill. Med. Obs. and Inq. vol. v. p. 233, 252.; and Dr. C. H. Parry, of Bath, has published an "Inquiry into the Symptoms and Causes of the Syncope Anginosa, commonly called Angina pectoris," 8vo. 1799. This work contains every thing then known on the subject.

ANGIOLELLO, JOHN MARIA, in *Biography*, an historian, of the 16th century, was a native of Vicenza, and followed the young sultan Mustapha, to whom he was a slave, in 1573, into Persia, in the dreadful war carried on by Mahomet II. at the head of nearly 200,000 men. As an eye-witness of the events of this war, he wrote "A History of Mahomet II." in the Italian and Turkish languages, dedicated to the sultan, freely written, and yet well received and liberally rewarded. A work, "Of the Life and Actions of the King of Persia," was printed at Venice, under the name of this writer in 1553; and he also wrote, in Italian, "A Relation of the Life and Actions of Uffun Cassan." Gen. Dict.

ANGIOPTERIS, in *Botany*. See ONOCLEA.

ANGIOSPERMIA, a term used by Linnæus, to express the second order of the *didynamia* plants, which have their seeds not lodged naked within the cup as in the *gymnospermia*, but inclosed in a capsule, and adhering to a receptacle in the middle of a pericarp. The class of *didynamia* contains the labiated and perfonated plants. The angiospermia are the perfonated, the others the labiated kind. In this order many of the corollas are perfonate, or labiate, with the lips closed; some, however, have bell-shaped, wheel-shaped, or triangular corollas.

To have seeds inclosed in a pericarp is common to all, and

hence the name of the order *angiospermia*. In most of the genera the calyxes are quinquefid; in some, however, they are bifid; one trifid, in many quadrifid, and in two multifid. This order, in Gmelin's edition of Linnæus, contains 87 genera. See DIDYNAMIA.

ANGITAS, in *Ancient Geography*, a river of Thrace, which runs from the north-east, and discharges itself into the Strymon, above Amphipolis.

ANGITIÆ LUCUS, or NEMUS, a forest of Italy, situate near the Lacus Fucinus. Pliny calls the inhabitants Lucenses. Angitia was the sister of Medea and Circe, and was regarded as a goddess, because she prescribed antidotes against poison and the bites of serpents. The name was probably derived from anguis, a serpent, a species of animals which abounded in this place. This forest is mentioned by Virgil (*Æn.* viii. v. 659.), and by Silius Italicus (*lib.* viii. v. 498.), and was situated in the country of the Marsi.

ANGITULA, a small river of Italy in Brutium, which discharged itself into the Thermaic gulf, near Nepita.

ANGLE, ANGULUS, in *Geometry*, the aperture or mutual inclination of two lines, meeting in a point.

Such is the angle BAC (*Plate II. Geometry, fig. 15.*) formed by the lines AB and AC, meeting in the point A.—The lines AB, and AC, are called the legs or the sides of the angle; and the point of intersection, the vertex or angular point.

Angles are sometimes denoted by a single letter affixed to the vertex, or angular point, as A; and sometimes, when several angles have the same vertex, by three letters, that of the vertex being in the middle, as BAC.

The measure of an angle, by which its quantity or magnitude is expressed, is an arc, DE, described from its vertex A, with any radius at pleasure between its legs, AC and AB; and the measure of the angle depends merely on the inclination of the lines by which it is formed, and not on the length of the radius, or the extent of the arc that bounds it.

Hence angles are distinguished by the ratio of the arcs which they thus subtend to the circumference of the whole circle.—And thus an angle is said to be of so many degrees, as are the degrees of the arc DE, by which it is measured.

Hence also, since similar arcs AB and DE, (*fig. 16.*) have the same ratio to their respective circumferences; and the circumferences contain each the same number of degrees; the arcs AB and DE, which are the measures of the two angles ACB, and DCE, are equal; and therefore the angles themselves must be likewise equal. Hence, again, as the quantity of an angle is estimated by the ratio of the arc subtended by it to the periphery, it is of no importance what radius that arc is described with; but the measures of equal angles are always either equal arcs, or similar ones; and contrarily.

It follows, therefore, that the quantity of the angles remains still the same, though the legs be either produced or diminished.—And thus in similar triangles, and in similar figures, the homologous or corresponding angles are also equal.

The taking or measuring of angles is an operation of great use and extent in surveying, navigation, geography, astronomy, &c. The instruments chiefly used for this purpose are quadrants, sextants, octants, theodolites, circumferentors, &c.

Mr. Hadley has invented a new and excellent instrument for taking angles, useful where the motion of the object, or any circumstance causing unsteadiness in the common instruments, renders the observations difficult or uncertain. Phil. Trans. N° 420, and N° 425. Mr. Dollond has likewise contrived

conve'd an instrument for measuring small angles. Phil. Trans. vol. xlviii. N. 73. See HADLEY'S QUADRANT and MICROMETER.

ANGLE, *to measure the quantity of an.*—1. On paper. Apply the centre of a protractor to the vertex of the angle C (*Plate I. Surveying, fig. 1.*), so that the radius CB may coincide with one of the legs: the degree shewn in the arc, by the other leg of the angle, will give the angle required. To do the same with a line of chords, see SECTOR. See GONIOMETRY.

2. On the ground.—Place a surveying instrument, *e. gr.* a semi-circle (*fig. 2.*), in such a manner as that a radius thereof CG may lie over one leg of the angle, and the centre C over the vertex. The first is obtained by looking through the sights F and G, towards a mark fixed at the end of the leg; and the latter, by letting fall a plummet from the centre of the instrument. Then, the movable index HI being turned this way and that, till through its sights you discover a mark placed at the extreme of the other leg of the angle; the degree it cuts in the limb of the instrument shews the quantity of the angle.

To take the angle with a QUADRANT, THEODOLITE, PLAIN TABLE, CIRCUMFERENTOR, COMPASS, &c. See the several articles.

To plot or lay down any given angle, *i. e.* the quantity of the angle being given, to describe it on paper. See FLOTTING and PROTRACTOR.

To bisect a given angle, as HIK (*Plate I. Geometry, fig. 17.*), from the centre I, with any radius at pleasure, describe an arc LM. From L and M, with an aperture greater than half LM, strike two arcs mutually intersecting each other in N. Then drawing the right line IN, we have HIN = NIK.

To trisect an angle, see TRISECTION.

Pappus, in his Mathematical Collections, lib. iv. treats of angular sections, and more particularly of trisections.

ANGLES are of various kinds and denominations.

With regard to the form of their legs, they are divided into *rectilinear, curvilinear, and mixed.*

ANGLE, *rectilinear, or right lined,* is that whose legs are both right lines: as BAC (*Plate I. Geometry, fig. 15.*).

ANGLE, *curvilinear,* is that whose legs are both of them curves.

ANGLE, *mixt, or mixtilinear,* is that, one of whose sides is a right line, and the other a curve.

With regard to their magnitude, *angles* are again divided into *right, acute, obtuse, and oblique.*

ANGLE, *right,* is that formed by a line falling perpendicularly on another; or that which subtends an arc of 90 degrees. Such is the angle KLM (*fig. 18.*)

The measure of a right angle, therefore, is a quadrant of a circle; and consequently all right angles are equal to each other.

ANGLE, *acute,* is that which is less than a right angle, or than 90°—as AEC (*fig. 19.*).

ANGLE, *obtuse,* is that greater than a right angle, or whose measure exceeds 90°—as AED.

ANGLE, *oblique,* is a common name both for acute and obtuse angles.

With regard to their situation in respect of each other, *angles* are divided into *contiguous, adjacent, vertical, alternate and opposite.*

ANGLES, *contiguous,* are such as have the same vertex, and one leg common to both.—Such are FGH and HGI (*fig. 20.*).

ANGLE, *adjacent,* is that made by producing one of the

legs of another angle. Such is the angle AEC (*fig. 19.*), made by producing a leg, ED, of the angle AED, to C. Two adjacent angles, *x* and *y*, or any other number of angles made at the same point E, over the same right line CD, are together equal to two right ones; and consequently to 180°. And hence one of two adjacent angles being given, the other is likewise given; as being the supplement of the former to 180°.

Hence also, to measure an inaccessible angle in a field, take an adjacent accessible angle, and subtract that from 180°, the remainder is the angle required.

Again, all the angles *x, y, o, E,* &c. made round a given point E, are equal to four right ones; and therefore all make 360°.

ANGLES, *vertical, or opposite,* are those whose legs are continuations of each other. Such are the angles *o* and *x*, (*fig. 19.*).

If a right line AB, cut another, CD, in E, the vertical angles, *x* and *o*, as also *y* and *E*, are equal. And hence, if it be required to measure, in a field, or any other place, an inaccessible angle, *x*; and the other vertical angle, *o*, be accessible; this latter may be taken in lieu of the former.

ANGLE, *alternate* See ALTERNATE.

ANGLES, *external,* are the angles of any right-lined figure made without it, by producing all the sides.

All the external angles of any figure, taken together, are equal to four right angles; and the external angle of a triangle is equal to both the internal and opposite ones.

ANGLES, *internal,* are the angles made by the sides of any right-lined figure within the said figure.

The sum of all the internal angles of any right-lined figure is equal to twice as many right angles as the figure hath sides, excepting four. This is easily demonstrated from Euclid, prop. 32. lib. i.

The external angle of a trapezium inscribed in a circle is equal to the internal opposite one; and the two internal opposite angles are equal to two right ones.

ANGLES, *homologous, or like,* are such angles in two figures, as retain the same order from the first, in both figures.

ANGLE *at the periphery,* is an angle whose vertex and legs do all terminate in the periphery of a circle. Such is the angle EFD (*Plate I. Geom. fig. 21.*)

ANGLE *in the segment,* is the same with that at the periphery.

It is demonstrated by Euclid, that all the angles in the same segment are equal to one another; that is, any angle EHD, is equal to any angle EFD in the same segment EFD.

The angle at the periphery, or in the segment, is comprehended between two chords EF and FD, and stands on the arc ED, and is measured by half that arc.

The measure of an angle without the periphery X (*fig. 22.*) is the difference between half the concave arc LM whereon it stands, and half the convex arc NO intercepted between its legs.

ANGLE *in a semicircle,* is an angle in a segment of a circle, whose base is the diameter of the circle.

It is demonstrated by Euclid, that the angle in a semicircle is a right one; in a segment greater than a semicircle, it is less than a right one; and in a segment less than a semicircle, it is greater than a right one.

Since an angle in a semicircle stands on a semicircle, its measure is a quadrant of a circle; and therefore is a right angle.

ANGLE *of a semicircle,* is the angle which the diameter of

of a circle makes with the circumference. The chief property of this angle is, that it is less than a right angle, and greater than any acute right-lined angle.

ANGLE *at the centre*, is an angle whose vertex is in the centre of a circle, and its legs terminated in the periphery thereof. Such is the angle CAB (*fig. 21.*).

The angle at the centre is comprehended between two radii, and its measure is the arc BC.

Euclid demonstrates, that the angle at the centre BAC is double of the angle BDC, standing on the same arc BC. And hence, half of the arc BC is the measure of the angle at the periphery.

Hence, also, two or more angles III, I, and HMI (*fig. 23.*) standing on the same, or equal arcs, are always equal. All angles at the centre are proportional to the arcs upon which they stand, and so are likewise all angles at the circumference.

ANGLE *without the centre*, HKI, is that whose vertex K is not in the centre, but its legs HK and IK are terminated in the periphery.

The measure of an angle without the centre is half the sum of the arcs HI and LM, whereon it and its vertical K stand when it is within the circle, or half the difference when it is without.

ANGLE *of contact*, is that made by the arc of a circle, or of any curve, and a tangent in the point of CONTACT.—Such is the angle IHK, (*fig. 24.*)

The angle of contact, in a circle, is proved by Euclid to be less than any right-lined angle; but from hence it does not follow, that the angle of contact is of no quantity, as Peletarius, Wallis, and some others, have imagined. V. Wall. Algeb. p. 71, &c. Clavius, on the other hand, rightly maintained, that it is not absolutely nothing, but that it is of no magnitude compared with a right-lined angle, being a quantity of a very different nature: such as a line with respect to a surface, or a surface with respect to a solid, &c. And since his time it has been proved by Sir Isaac Newton, and others, that angles of contact may be compared with each other, though not with right-lined angles, and that the proportions which they bear to each other may be assigned. Thus, the circular angles of contact IHK, IHL, are to each other in the reciprocal subduplicate ratio of the diameters HM, HN; and the circular angle of contact may be divided by describing intermediate circles into any number of parts, and in any proportion. And if, instead of circles, the curves be parabolas, and the point of contact H the common vertex of their axes, the angles of contact would in this case be reciprocally in the subduplicate ratio of their parameters. But elliptical and hyperbolic angles of contact would be reciprocally in the subduplicate of the ratio, compounded of the ratios of the parameters and the transverse axes. Moreover, if TOQ (*fig. 25.*) be a common parabola to the axis OP and tangent VOW, whose equation is $x=y^2$, x being the absciss OP, and y the ordinate PQ, and the parameter being 1; and if OK, OS, &c. be other parabolas to the same axis, tangent and parameter, their ordinate y being PR, or PS, &c. and their equations $x=y^3$, $x=y^4$, $x=y^5$, &c.; then the series of the angles of contact would be in succession infinitely greater than each other; that is, the angle of contact WOQ would be infinitely greater than WOR, and this again infinitely greater than WOS, and so on infinitely. Besides, between the angles of contact of any two of this kind, other angles of contact may be found *ad infinitum*, which shall infinitely exceed each other, and yet the greatest of them be infinitely less than the smallest right-lined angle. Thus also $x^2=y^3$, $x^3=y^4$, $x^4=y^5$, &c. denote a series of curves, of which every suc-

ceeding one makes an angle with its tangent infinitely greater than the preceding one; and the least of these, *viz.* that whose equation is $x^2=y^3$, or the semicubical parabola, is infinitely greater than any circular angle of contact.

ANGLE *of a segment* is that made by a chord with a tangent, in the point of contact. Such are IHK (*fig. 26.*) the angle of the lesser segment IMH, and IHL the angle of the greater segment INH. And the measure of each of these angles is half the alternate or supplemental segment, or it is equal to the angle in it; that is, the angle IHK=INH, and IHL=IMH.

ANGLES, *for the effects, properties, relations, &c. of, when combined into triangles, quadrangles and polygonous figures*, see TRIANGLE, QUADRANGLE, SQUARE, PARALLELOGRAM, POLYGON, FIGURE, &c.

ANGLES are again divided into *plane, spherical, and solid.*

ANGLES, *plane*, are those above-mentioned; which are defined by the inclination of two lines in a plane, meeting in a point.

ANGLE, *spherical*, is an angle formed on the surface of a sphere by the intersection of two great circles, or the inclination of the planes of two great circles of the sphere.

For the properties of spherical angles, see SPHERICAL Angle.

ANGLE, *solid*, is the mutual inclination of more than two planes, or plane angles, meeting in a point, and not contained in the same plane. For the measure, properties, &c. of solid angles, see SOLID Angle.

We also meet with other less usual sorts of angles among some geometricians; as

ANGLE, *horned, angulus cornutus*, that made by a right line, whether a tangent or secant, with the periphery of a circle.

ANGLE, *lunular, angulus lunularis*, is that formed by the intersection of two curve lines; the one concave, and the other convex.

ANGLE, *cissoïd, angulus cissoïdes*, is the inner angle made by two spherical convex lines intersecting each other. See Cissoïd.

ANGLE, *sistroïd, angulus sistroïdes*, is that which has the form of a SISTRUM.

ANGLE, *pelecoïd, angulus pelecoïdes*, is that in figure of a hatchet. See PELECOIDES.

ANGLE, in *Trigonometry*. See TRIANGLE, and TRIGONOMETRY.

For the sines, tangents, and secants of angles, see SINE, TANGENT, and SECANT.

ANGLE, in *Geography*, a town of France, in the department of Vendée, and chief place of a canton, in the district of Sables d'Olonne, ten miles west-south-west from Luçon.

ANGLE is also a town of France, in the department of Vienne, and chief place of a canton, in the district of Mont Morillon, on the Creuse, 25 miles east from Poitiers.

ANGLE, in *Mechanics*. *Angle of direction*, is that comprehended between the lines of direction of two conspiring forces. See DIRECTION.

ANGLE *of elevation*, is that comprehended between the line of direction of a projectile, and any plane upon which the projection is made, whether horizontal or oblique. Such is the angle RAB (*Plate I. Mechanics, fig. 3.*) which is comprehended between the line of direction of the projectile AR, and the horizontal line AB.

ANGLE *of incidence*, is that made by the line of direction of an impinging body, in the point of contact. Such is the angle DCA (*fig. 4.*)

ANGLE *of reflection*, is that made by the line of direction of

of the reflected body, at the point of contact from which it rebounds. See *is the angle C*

ANGLE, in *Optics*. *Visual*, or *optic angle*, is the angle included between the two rays directed from the two extreme points of an object to the centre of the pupil.—Such is the angle ABC (*Plate 1. Opticæ, fig. 1.*) comprehended between the rays AB and BC. The apparent magnitude of objects is greater or less, according to the angle under which they appear. See *APPARENT MAGNITUDE*.

Objects seen under the same, or an equal angle, always appear equal.

The least *rifle angle*, or the least angle under which a body can be seen, according to Dr. Hook, is one minute; though Dr. Jurin shews, that at the time of his debate with Hevelius on this subject, the latter could probably discover a single star made to fill all an angle as 20". But bodies are visible under smaller angles, as they are more bright or luminous. Dr. Jurin states the grounds of this controversy, and discusses the question at large in his Essay upon distinct and indistinct Vision, published in Smith's Optics, p. 148, &c.

ANGLE of the interval of two places, is the angle subtended by two lines directed from the eye to those places.

ANGLE of incidence, in *Catoptrics*, is the lesser angle, made by an incident ray of light, with the plane of a speculum; or, if the speculum be concave or convex, with a tangent in the point of incidence. Such is the angle ABD (*fig. 3.*) Or, as some define it, it is the angle which a ray of light makes with a perpendicular to that point of the surface of any medium on which it falls.

Every incident ray, AB, makes two angles, the one acute, ABD, the other obtuse, ABE; though sometimes both right. The lesser of such angles is the angle of incidence. See *INCIDENCE*.

ANGLE of incidence, in *Dioptrics*, is the angle ABI (*fig. 4.*), made by an incident ray, AB, with a lens, or other refracting surface, HI.

ANGLE of inclination, is the angle ABD, contained between an incident ray, AB, and the axis of incidence, DB. See *AXIS*, &c.

ANGLE of reflexion, } in *Catoptrics*. See *REFLECTION*.

ANGLE of refraction, } in *Dioptrics*. See *REFRACTION*.

ANGLE, in *Astronomy*. *Angle of commutation*. See *COMMUTATION*.

ANGLE of elongation, or *Angle at the earth*. See *ELONGATION*.

ANGLE, parallactic. See *PARALLACTIC angle* and *PARALLAX*.

ANGLE at the sun, is the angle under which the distance of a planet from the ecliptic is seen from the sun.

ANGLE of the East. See *NONAGESIMAL*.

ANGLE of obliquity, of the ecliptic, or the angle of inclination of the axis of the earth, to the axis of the ecliptic, is now nearly 23° 28'. By means of this inclination, such inhabitants of the earth as live beyond 45° of latitude, have more of the sun's heat, taking all the year round; and those who live within 45° have less of his heat, than if the earth always moved in the equinoctial. See *OBLIQUITY*, and *ECLIPTIC*.

ANGLE of longitude, is the angle which the circle of a star's longitude makes with the meridian, at the pole of the ecliptic.

ANGLE of right ascension, is the angle which the circle of

a star's right ascension makes with the meridian at the pole of the equator. See *RIGHT ASCENSION*.

ANGLE of Position. See *POSITION*.

ANGLE, in *Navigation*. *Angle of the rhumb*, or *loxodromic Angle*. See *RHUMB*, and *LOXODROMY*.

ANGLES, in *Fortification*, are understood of those formed by the several lines used in fortifying, or making a place defensible.

These are of two sorts; *real*, and *imaginary*. *Real angles* are those which actually subsist and appear in the works. Such are the *flanking angle*, the *angle of the epaule*, *angle of the flank*, and the *re-entering angle of the counterescarp*. *Imaginary*, or *ocult angles*, are those which are only subsistent to the construction, and which subsist no more after the fortification is drawn. Such are the *angle of the centre*, *angle of the polygon*, *flanking angle*, *salient angle of the counterescarp*, &c.

ANGLE of or at the centre, is the angle formed at the centre of the polygon, by two semi-diameters drawn from the centre to two adjacent angles, and subtended by a side of it. Such is the angle CKF (*Plate Fortificat. fig. 1.*) This is found by dividing 360 degrees by the number of sides in the regular polygon.

ANGLE of the circumference, is the mixt angle made by the arc drawn from one gorge to the other.

ANGLE of the counterescarp, is that made by the two sides of the counterescarp, meeting before the middle of the CURTIN.

ANGLE of the curtain, or *of the flank*, is that made by, or contained between, the curtain and the flank; such is the angle BAE.

ANGLE of the complement of the line of defence, is the angle arising from the intersection of the two complements one with another.

ANGLE, diminished, is the angle which is made by the meeting of the exterior side of the polygon with the face of the BASTION. Such is the angle BCF.

ANGLE of the polygon, is the angle GHM, intercepted either between the two internal sides GH, and HM, or the two exterior sides. This is the supplement of the angle at the centre, and is found by subtracting CKF from 180 degrees.

ANGLE of the epaule, or *shoulder*, is that formed by the flank and the face of the bastion. Such is the angle ABC.

ANGLE of the interior figure, is the angle GHM, made in H, the centre of the bastion, by the meeting in the innermost sides of the figure GH and HM.

ANGLE of the tenaille, or *flanking angle outward*, is that made by the twoasant lines of defence, *i. e.* the two faces of the bastion when prolonged.

ANGLE flanking inward, is the angle CIH, made by the flanking line with the curtain.

ANGLE, flanked, by some called the *angle of the bastion*, is the angle BCS, made by the two faces of the bastion, BC, CS; being the outermost part of the bastion, and that most exposed to the enemy's batteries, and therefore by some called the *point of the bastion*.

ANGLE of the flank, is that formed by the flank, and the curtain.

ANGLE forming the flank, is that consisting of one flank, and one *DEMI-gorge*.

ANGLE forming the face, is that composed of one flank, and one face.

ANGLE of the triangle, is half the angle of the polygon; or half the supplement of the angle at the centre.

ANGLE of the moat, is that made before the curtain, where it is intersected.

ANGLE,

ANGLE, *re-entering*, or *re-entrant*, is that whose vertex is turned inwards, towards the place.

ANGLE, *saliant*, or *fortant*, is that which advances its point toward the field.

ANGLE of the *tenaille*, or the *outward flanking angle*, called also the *angle of the moat*, or the *dead angle*, is made by the two lines *flanking* in the faces of the two bastions, extended till they meet in an angle towards the curtain. This always turns its point in towards the work.

ANGLE, *dead*, is a re-entering angle, which is not flanked or defended.

ANGLE of a *wall*, in *Architecture*, is the point or corner where the two sides or faces of a wall meet.

ANGLE *Bar*, in *Carpentry*, is that which is perpendicular to the horizon, in the angle formed by any two faces of a bow-window, whose plan is a polygon.

ANGLE *Bracket* of a cove or cornice, is that which stands in a perpendicular plane, passing through the diagonal of the plan, ranging in every right line horizontally, directed along the edges of the common ribs that are fixed on either side of it.

ANGLE *Rib* of a groin, is that which stands in the perpendicular plane passing through the diagonal of the plan, and ranging in right lines in every horizontal direction with the common ribs that are fixed on either side of it. These two last are the same in principle, their difference being only in the application; for their description, see a **GROIN**.

ANGLLEN, or **ANGELEN**, in *Geography*, a small district of the duchy of Sleswick, in Denmark, from 16 to 20 miles in length, and about as much in breadth, situate between Flensburg and Sleswick. see **ANGLES**.

ANGLER, a fisherman, or other person who practises **ANGLING**.

Anglers are to be distinguished from poachers. Some make the same difference between them, that is between the fair trader and smuggler. Accordingly the legislature has made the latter penal, but laid no restraint on the former. Angling can do no prejudice to the fish of a river. Anglers fish for their recreation, not for lucre; whereas poachers make it their livelihood.

ANGLER, in *Ichthyology*, the English name of the batrachos of Aristotle and Oppian, and the rana piscatrix of Pliny and Ovid: a species of **LOPHIUS**.

ANGLERIA, **PADRE CAMILLO DI CREMONA**, in *Biography*, author of a musical tract entitled, "Regole di Contrappunto," published at Milan 1622.

ANGLES of a *battalion*, in the *Military Art*, are those soldiers that are placed where the ranks and files terminate. See **BATTALION**.

The angles of a battalion are said to be *blunted*, when the soldiers at the four corners are removed, so that the square battalion becomes octagonal; this was an evolution very common among the ancients, though now disused.

ANGLES, in *Anatomy*, are understood of the *canthi*, or corners of the eye, where the upper eye-lid meets with the under.

That next the nose is called the *great* or *internal*, and that towards the temples, the *less* or *external angle*, or **CANTHUS**.

ANGLES, in *Astrology*, denote certain houses of a figure, or scheme of the heavens. Thus the horoscope of the first house is termed the *angle of the east*.

ANGLES, *Instruments for measuring horizontal*, in *Astronomy*. See **HORIZONTAL**.

ANGLES, in *Geography*, a town of France, in the department of the Haut, and chief place of a canton, in the district of St. Pons, three leagues west-north-west from St. Pons.

ANGLES, in *History*, are said to have been a tribe of the Suevi, who, in the time of Cæsar (Bell. Gall. lib. iv.), were the greatest and bravest of all the German nations. This tribe, after various adventures and migrations, settled in that part of the Cimbric Chersonesus, which now forms the duchy of Sleswick, where some vestiges of their name still remain in the district of Anglen. The most probable etymology of the name deduces it from the Saxon "Angel or Engel," signifying "a fish-hook;" and intimating that the Angles were much addicted to piracy, and were so called by the neighbouring nations, because, like fish-hooks, they caught all that was in the sea. From these people the English are said to have originated; for when they were solicited by the British ambassador to succour their countrymen against the Scots and Picts, they embarked, with greater spirit and in greater numbers than any of the other German nations; and having expelled the Picts, and made themselves masters of the country, they had the honour of giving their name to England and its inhabitants. The reason, it is said, why the name of Angles was preferred to that of Saxons seems to have been, because it was more distinctive and more honourable: there being at that time a large nation of Saxons on the continent, who were in disrepute on account of their manners, and the defeats which they had suffered from Charlemagne. It may be added, that the Angles constituted the greatest part of Egbert's subjects: all the northern, eastern, and midland counties, being inhabited by them. Egbert published an edict, dated at Winchester in the year 827, abolishing the distinctions of Saxons, Jutes, and English, commanding all his subjects for the future to be called by the latter name only. Rapin's Hist. vol. i. p. 89.

ANGLESEA, or **ANGLESEY**, the Mona of Tacitus, in *Geography*, the English name for Môn, an island on the northern extremity of Wales, from which it is separated only by a narrow channel, called the Menai. It is about 20 miles in length, by 17 miles in breadth; or as others say, 25 long, and 18 broad; and is one of the six counties of North Wales; which is divided into three hundreds: that is to say, Aber Fraw, with its townships of Llivon and Malltreath; Rhosyr, with its townships of Tindaethwy and Menaï; and Cemaes, with its townships of Twrcelyn and Talybolion. According to a late estimate Anglesea contains about 200,000 acres of land, and 20,000 inhabitants; and is divided into seven hundreds, 74 parishes, and four market towns; situate within the diocese of Bangor. The chief town is Beaumaris. The air is in general good, except when the thick fogs arise from the Irish seas; but in autumn it is cold and aguish. The soil, which, on the first aspect, appears rocky and mountainous, is nevertheless fertile, and produces a number of cattle, and great quantities of corn, sent annually to England. However much of the land lies undrained, and full of turf bogs, or pointed rocks; and yet there are some rich farms in the interior and along the coast, particularly that which is opposite to Caernarvonshire. The general face of the country is low, flat, and unpleasant.

This island, which is known to the Welsh only by the name of Môn, obtained the appellation of Anglesey, among the English, from the following circumstance: in the year 819, Egbert invaded North Wales; and after ravaging several districts, he passed over into Mona; defeated the Welsh, in a bloody battle near Beaumaris; and, in consequence of his victory, he got possession of the whole island. He was able to maintain himself there only for a short time; being driven out by Mervyn, king of North Wales; nevertheless, the English ever after continued to call the place Anglesey, or the island of the Angles.

According to a curious historical document, contained in

the British Triads, this isle once formed a part of the main land. The passage is to the following purport: "The three original islands adjoining to Britain were Orkney, Man, and Wight; and afterwards the sea broke the land, so that Môn became an island; and in like manner Orkney was broken; so that there were formed a multitude of islands; and other places on the coasts of Scotland and Wales were broken by the sea, and became islands."

The book entitled *Mona Antiqua Restaurata*, was written by Rowlands, to prove that Anglesea was the metropolitan seat of druidism. An hypothesis formed from the recital of the destruction of the druids there by Suetonius Paulinus; or probably suggested by a partiality for his native place, and certainly without duly weighing its title to that pre-eminence, for if he had done so, he must have discovered such a position to be destitute of any solid foundation.

Nothing more ought to be inferred from the account of the Druids having been found by the Romans in Anglesey, than that they were overtaken in their retreat; for they always avoided the seat of war, agreeably to their principles; but here they did not expect the appearance of the enemy so suddenly, and very likely they had not the means time enough of retreating farther.

In the next place, that island does not abound with any monuments or remains, in sufficient numbers to induce a belief of its having been the permanent centre of druidism; and in truth there is not perhaps a country in all Wales, and which abounds more with such vestiges than Anglesey.

It is also to be naturally supposed that the principal place of meetings would have been fixed upon in the most convenient situation for the different states of Britain and of Gaul to attend; and free from the obstructions of large rivers, and other obstacles; whereas the isle of Anglesey was peculiarly the reverse of all this; and we must, therefore, seek elsewhere for the alma mater of the Bards, Druids, and Ovates.

The open grounds of Wiltshire then necessarily draw our attention: there we find Avebury, the grand national circle of the Britons; and there too is it said to be by the bardic Triads; and compared with this, no similar work in the country bears any comparison in grandeur and extent of design.

The glory of Mona must, therefore, be confined to its proper sphere; for it never had a more extended orbit than it has now: in druidical times it had its small provincial circles, as in the present day it has its parish churches.

The greatest curiosity which Anglesea can boast, and the chief source of its wealth, is the Paris mountain, the name of which is most probably derived from the old Welsh word "Praos," signifying "brass," which might easily be corrupted into Paris. The copper-mines in this part of the island are supposed to have been known and worked by the Romans; a pool on the top of the mountain having been distinguished, long before the present works were formed, by the name of the Mine-pool. The mine of this mountain is considerably more than a mile in circumference, and on an average 1300 men are constantly employed in it. It has the singular advantage of being worked in the open air; a circumstance which expedites the labour, and secures the health of those that are employed.

Abundance of vitriolic water is found in these works, which is so strong as instantaneously to turn whatever steel or iron is dipped into it, to the colour and appearance of copper. This water is exposed to the sun in large open troughs, and the copper quality is extracted from it by a curious process. Great quantities of sulphur are also produced, and its sublimation is carried on in various spots upon the mountain, till at last the whole is collected into some large boiling-houses, and formed into rolls of brimstone.

The copper ore is then carried down to some smelting-house, constructed in the valley below near the sea-side, where every remaining operation is performed with wonderful art and assiduity. Lead-ore, rich in silver, is also found in the same mountain; and in the north-westerly part of the island is a quarry of green marble intermixed with asbestos.

Anglesea sends two members to the imperial parliament; one for the county, and one for Beaumaris.

ANGLÉSQUEVILLE, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Dieppe, 16 miles north from Rouen.

ANGLIA, EAST, in *History*, one of the kingdoms of the Heptarchy, founded by the Angles that landed on the eastern coasts of Britain, under 12 chiefs, the survivor of whom, Uffa, in 571, assumed the title of king of the East-Angles. This kingdom was bounded on the north by the Humber and the German Ocean, on the east by the same ocean, on the south by the kingdom of Essex, and on the west by Mercia. Its greatest length was 80, and its greatest breadth 55 miles. It contained the two counties of Norfolk and Suffolk, with part of Cambridgeshire. The chief towns were Norwich, Thetford, Ely, and Cambridge. Earpold, the fourth monarch of this kingdom, was converted to Christianity by the influence of Edwin, king of Northumberland; but his wife, who was an idolatress, soon brought him back to her religion. After his death, and the interregnum that followed, Sigebert, who had been educated in France, restored Christianity, and introduced learning among the East-Angles. Some pretend that he founded the University of Cambridge, or rather some schools in that place. Ethelbert, who was the last sovereign of this kingdom, and who received his crown from Etheldred in 790, was treacherously murdered by Offa, king of Mercia, in 792, who seized his kingdom; and from that time East-Anglia was united with Mercia.

ANGLICA, in *Entomology*, a species of *PIMELIA*, found in England very rarely. It is black, anterior part of the thorax roundish, wing-cases striated with dots, antennæ reddish at the apex. Gmelin. This is the description of Fabricius, which Gmelin adopts. It was described by Fabricius in the species *insectorum*, under the name *PIMELIA MORIO*; but in the last arrangement of insects by that author, it is placed in the genus *HELOPS*, under the specific name *Pimelia*. Gmelin makes a subdivision of the genus *pimelia*, under the name *Helops*, in which this species is included.—Also, a species of *CHRYSOMELA*, found in England. It is blue-black, wing-cases black, brassy and striated with dots; wings red. Forst. Nov. Inf.—Fabricius.

ANGLICANA, a species of *ALTIKA*, in the Fabrician arrangement, and found in England. It is in general black, except the wing-cases and shanks of the legs, which are pale. Fabricius.

ANGLICANÆ guttæ. See *GUTTÆ*.

ANGLICANUS sudor. See *SUDOR*.

ANGLICISM, a word, or phrase, in the English *IDIOM*; or a manner of speech peculiar to the English tongue.

ANGLICUS, in *Entomology*, a species of *CERAMBYX*, found in England and France. It has a spinous thorax, and two oblique yellow stripes on the wing-cases. Gmelin. This is the Fabrician description, and in that arrangement it belongs to the *RHAGIUM* genus. It is also the *leptura mordax* of Degeer, and *Stenocorus* of Geoffroy.

ANGLING is a branch of fishing; or the art of catching fish by means of a rod, to which is attached a line, a hook, and a bait. It is more generally practised for amusement than for profit, and is a sport of considerable antiquity, and followed with the greatest avidity by some persons in every rank in life. It has some eminent advan-

tages over many other rural sports; it is but little dangerous; incurs but little expence, and is productive of some profit. It is peculiarly fitted for the placid and thoughtful; nor need the gay and volatile despair of finding their attention engaged, while the more active mode of fly-fishing remains in use. Perhaps there are few pursuits that display more elegant attitudes than that of throwing the fly; nor are there but few in which the expectation is so much kept alive, with so little bodily or mental exertion, as in this delightful branch of the art. On the other hand, simple float angling has its advantages likewise; for in this the infirm and aged may partake, and the solitary or recluse may pursue the amusement, without fear of the interruptions of the busy or impertinent; here, likewise, the contemplative may combine relaxation with improvement, as few persons have a greater opportunity of studying nature in her varied garb than the angler.

The laws have ever been favourable to this pursuit, protecting the authorised fisher, and punishing the depredations of the poacher. As early as Edward I. we find, that imprisonment and triple damages, were awarded against any trespassers, if a-tainted at the suit of the party. 3 Ed. I. c. 20.

By Elizabeth it was enacted, that if any persons wrongfully take or kill fish, from any ponds, &c. kept for the purpose of angling, he or they shall be imprisoned, pay triple damages, and find security for his or their good behaviour for seven years. 5 Eliz. c. 21. The 22d and 23d Car. II. c. 29. recites, that the use of an angle, net, hair, noose, troll, or spear, or the taking of fish in any way, or the being aiding therein, without the consent of the owner, or lord of the manor, is forbidden; and that persons so offending shall, on discovery and conviction thereof, have triple damages awarded against them, to be levied by distress. And in the same statute it appears, that any justice of the peace is authorised to take and destroy every instrument used for these purposes. By the 4th and 5th W. III. c. 23. § 5, 6. no person was even to have or keep in his possession any net, angle, or other engine for the taking or destroying of fish, other than the makers and sellers thereof, and than the owners and occupiers of a river or fishery. And again, 5 Geo. III. c. 14. § 1, 2. not only persons who entered any park or other ground fenced in, wherein there was any water containing fish, and stole thereout; but those who receive and buy such fish, shall be subjected, equally with the offenders, to seven years transportation. By the same act, the taking fish unlawfully from any water, not situated in enclosed ground, is punishable by the forfeiture of 5*l.*; but by the black act, the breaking down of the head and mound of any fish-pond, was made felony without benefit of clergy.

There is no art, the practice of which appears more simple, at first view, than that of angling; yet there are few that require more nicety and precision, nor is there any for which it is more difficult to give precise rules. There is a species of acquired knowledge, amounting to a knack, that constitutes a successful angler, but which he can with difficulty impart to others.

The fish usually caught by angling are the salmon, salmon fry, salmon trout, bull trout or scurf, sewen or whiting, lattspring or shedder, mullet, smelt, barbel, flounder, eel; all which visit the salt water. Those which are likewise taken by this mode, and do not visit the salt water, are the trout, grayling, pike or jack, perch, tench, carp, chub, bream, rudd, roach, dace or darc, gudgeon, bleak or whiting, minnow, loach, &c. which several fish see under their proper heads.

These several fish require different tackle, baits of various

kinds, and some are taken in one season, while others are secured in another; of all which it is essentially necessary that the angler should be aware, as well as of the particular weather, favourable to the sport.

The tackle made use of must be carefully attended to, the principal of which is the rod. An angler intending to fish at a distance from home, should be furnished with two rods; if near home, he must still carry a spare top, or he may be much inconvenienced. When two rods are taken, it is prudent to let one be of the customary form; the other may be a strong cane, in the form of a walking-stick, which may prove useful in case of emergency. It should be so contrived as to fit the flock of the landing-net, and it will moreover be useful in fording rivers, &c. It is necessary to consider the size and nature of the fish in the choice of a rod. The larger kinds require one of considerable strength, with the addition of a reel and running line, passing through rings or eyes placed on the rod from one end to the other. A fishing-rod should be pliant, yet firm, with an easy play in the hand, and a regular bend, as though formed of one entire piece. Those which are jointed with ferrules are the best, and for large fish, as salmon, it is proper that within each ferrule there should be a male screw, to fit into a female screw, within the attached joint, by which means the rod is farther secured, and is certain of a regular play. In dry weather it is prudent to dip each joint in the water previously to introducing them to each other, and if any difficulty occurs in undoing them from the swelling of the wood, they should be held over a candle or before the fire. A rod should be kept neither too dry nor too moist; in the one case it becomes brittle, in the other it is rendered rotten. It should be hung up with a weight attached to the end, by which it is kept from warping, and it may be varnished to preserve it from worms. See *FISHING-rod*.

The angler should farther have a variety of lines of various strengths, and of colours adapted to the waters he sports in, which is a caution of the utmost moment, and not in general sufficiently attended to. Lines should be coiled or wound on a cylinder. When wound, as is usual, on a bit of split cane, or flat stick, forked at the two ends, or on long line machines, the sharp turns are apt to cut the gut or line. See *FISHING-lines*.

Hooks of various sizes are necessary, attached and unattached, with floats of cork, of quills and of porcupine spears. Spare caps, split shot, shoemaker's wax, bullets, plummets, are all likewise necessary; nor should the angler forget a clearing-ring, which is useful in disengaging the hook when entangled among weeds, or fastened to a stump. It is formed of a heavy brass or iron ring, of about two inches in diameter, with several yards of twine attached, and is made use of by passing it over the large end of the rod, and gently letting down the line to the obstruction; when by pulling the twine, the hook will be either disengaged, or it will be broken off without damage to the rest of the line, by straining it or the rod.

A disgorging is likewise among the requisites, as some fish by their eagerness swallow the hook with the bait; in which case, a piece of flat cane or wood, about six inches long, and half an inch wide, forked at the ends, and passed down the throat, removes the hook, by gently pulling the line. A landing-net will often be found necessary when a large fish is caught; those are the best whose hoops fold up, and the handle may be the walking-stick rod before mentioned. All these, with any other necessary articles, may be taken in a basket, first wrapped up in an oil skin case, when on the return, the fish in the basket will not injure them. For the articles necessary for fly fishing, see *FISHING-fly*.

It may in this place be remarked, that the prudent fisher will always be cloathed in grave colours, or at least in such as are not gaudy. For those who wade much, but which is not a prudent method, a short shooting-jacket is convenient. The experienced fisherman will always likewise provide himself with spirits, in case of falling into the water or other accidents. There are many other small articles also necessary, as twine, pliers, scissars, a penknife; and it will be found useful always to be furnished with some trimmers, to act, if the sport should not prove so good as expected.

The baits made use of must be particularly attended to by the angler, he should not only procure the best of every kind, but he must be careful to appropriate his bait to the fish he means to entrap, and likewise according to the various seasons. He must select such articles to allure most, that nature gives at that particular time in the greatest plenty. For the stomach of the fish is adapted to outward circumstances, preferring food at one time that at others it wholly rejects, and this is more particularly the case in fly fishing. An excellent mode of judging what bait is most likely to allure any particular kind of fish is, when one is caught to open it, and examine the stomach, and whatever is found there will surely be the proper bait for others. It is said, but with what truth we are not aware, that the eyes of other fish are a most excellent bait. Baits made use of in angling are of two kinds, the natural and artificial; the natural are whatever is eaten by the animal in a state of nature, as small fish, frogs, worms of most kinds, insects in great varieties, as beetles, butterflies, all the tribe of Summer flies, moths, wasps, hornets, grasshoppers, maggots of various kinds, and snails; vegetables are used with success, as wheat, barley, peas, beans, &c.: artificial baits are the forming of whatever imitates the natural food of the animal, as the making and painting small fish, and the imitating flies of various kinds, which latter forms a very considerable and intricate branch of the art. See *FLY-FISHING*. Artificial baits are likewise various compositions in the form of paste: pastes are made with dough, bread, all kinds of flour mixed with honey, suet, butter, oil, &c. and in mixing these, it is found useful to add a little cotton, tow, or lint, to make the paste more adhesive. The spawn of other fish is frequently used as a bait with success, and it is very commonly potted for this purpose.

Ground-bait is a previous method made use of by anglers to induce fish to frequent particular spots; some are in the habits of throwing this kind of bait into particular places every now and then, by which they are almost certain of finding sport among the fish who resort to this favoured place. Others only do it in the evening, or even an hour before they angle. Ground baits are of grains, barley, moistened bread, raspings, blood mixed with chopped liver, &c. In running streams a tin box is introduced, bored with holes, with a plummet to sink it, and a line to draw it back at pleasure, the worms, crawling through these holes gradually, are a great inducement to the fish to hover about the spot. All the recipes of fetid oils and other allurements are useless. See *FISHING-baits*.

The proper seasons for angling are from the Spring to the Autumn, but much depends on the kind of fish angled for; some may be caught at all times, others, as those of passage, are only to be met with at particular seasons, and others, though always confined to one piece of water, yet are nearly torpid during the Winter, and are found only in the deeps.

Weather influences fish much, and when the wind is in some points, few fish will bite. The most unfavourable is the eastern quarter; when the wind is easterly no sport is to be expected. A warm lowering day is the most favourable, with flying showers, and a slight ripple on the water. Water

slightly disturbed induces good sport; fish then do not easily distinguish the tackle, and are most voracious, having fasted while the stream was clear. Hence angling is always good when turbid water is clearing, or in the rise before it becomes too thick. Opening a mill-dam, raising a sluice, or the turning water from a meadow, induces the angler good sport, as it induces the fish to come to meet the food they expect. In waters affected by the tide, the flood is the best time for angling; but either ebbing or flowing is fit. Whirlpools, eddies, the mill-tails, sides of bridges, and under the arches, are places the anglers should not pass over.

All places not disturbed by wind or weather are proper; deep spots, covered with weeds, are much sought after by fish.

Sometimes when you are angling in any spot, and have had good sport, and the fish suddenly leave off biting; it is probable a pike or some fish of prey is at hand, in which case a minnow, placed on your hook alive, will probably take him; but the trimmers, before mentioned, are the best preventive. See *FISHING*.

ANGLING, Bladder, differs from trimmer angling, in this; instead of a cork, a bladder is made use of, by which means much diversion is occasioned; for as the bladder is drawn under the water by the force of the fish; it returns by its own want of specific gravity, which serves to strike him more forcibly and prevents his disgorging the hook.

ANGLING, Float, is made use of in contradistinction to ground angling, trimmer angling, and fly angling, &c. and consists in the use of a line longer than the rod by two or three feet, with shot not to sink the float, but to let it go under water on the slightest touch or bite of the fish. In the rivers a cork float is most proper, in standing water a quill is generally used. Perch, chud, carp, tench, barbel, and grayling, are caught in this manner.

ANGLING, Ground, is practised with a fine rod and line, without a float, and sometimes produces excellent sport. A bullet or plumb of lead is attached to the line, eight or nine inches from the baited hook, by boring a hole and passing the line through it; at the lower end placing a shot in the usual manner to prevent the plummet from slipping. This mode proves excellent for large deep-swimming wary fish; and in Winter when they confine themselves wholly to the deeps. A well-scoured worm is an excellent bait for this method, which is found very successful against the barbel. When one of these fish is observed to take the bait, as he bites strong, he should be instantly struck; the rod used for him likewise should be ringed, and furnished with a winch or reel, and twenty-five or thirty yards of line, which should have gimp to the bottom of it. But as a general rule for other fishes, the rod and line should be fine, and when the bait is observed to be taken, the angler should not strike immediately; but slacken his line, to give the fish an opportunity to swallow the hook. Trout are often taken in this manner, as well as chub; for the former, morning and evening prove the best, except in cloudy weather, or muddy water, when you may fish for him the whole day.

ANGLING, Night, is of two kinds; that wherein the angler attends in person to watch his sport; and that wherein he lays lines in different modes, as trimmers, bladders, &c. and returns in the morning to see his success. By the former method may be taken some of the finest and largest fish of most kinds; but among trout it has been found singularly successful; and it is observed, that the largest trout are caught by this means in the still clear deeps. The tackle used in this sport should be strong, and the bait striking; as the large garden-worm, snails, a minnow, &c.

Cast off at a distance, drawing your line gently against the stream, if any; not suffering it to sink, but keeping it near the surface. A float may be used or not at discretion. When the fish rises, the noise will alarm the angler, who is then to give both time and line enough to swallow the hook, when slightly striking secures him. When this method does not succeed, it will be prudent in the angler to apply a plummet, as in ground angling, and to sink his bait, for though there may be fish in that part, they may not probably be disposed to rise.

ANGLING, Sea. It is frequent for persons to go out in boats some way from shore, to angle for whiting, cod, &c. From pier heads, and the mouths of rivers likewise, it is often successfully practised: from the former are often taken haddock, cod, whiting, plaice, and small barbel, by means of a strong rod and line well leaded, with a cork float, and a large hook, baited with scoured red worms, shrimps, and gentles, a raw muscle, the inside of a small crab, whipt round the hook with a little white wool; or a bit of any other fish. If the water is very deep, the bait is permitted to pass to about mid water; if not, towards the bottom.

ANGLING, Snap, is a method made use of for those fish that easily part with the bait when taken; or for any fish, at those times when they are spawning, for being then sick, they will easily disgorge the bait before the hook has been struck, but by means of a double spring hook, which is struck with a forcible jerk the contrary way to that in which the fish runs, he is secured. The best hooks made use of for this purpose are purchased at fishing-tackle shops, being made with a double spring. The rod should be strong and the line strong likewise, and not so long as the rod, with a large cork float. The mode of baiting the snap hook is thus: make a hole with a sharp penknife in the side of the bait fish, then put the gimp that is fastened to your hook into it, and draw it out at the mouth, till the spring hook comes to the place where the incision was made; when this is done, put it into the belly of the fish, then have a piece of lead, about the size of a horse bean, though of an oval form, with a hole through it from end to end large enough for the gimp to go through, draw it down to the fish's mouth, then put it in it, and sew it up.

ANGLING, Trimmer, is an economical mode made use of either at night, or when you are fishing by other methods, by setting some trimmers at a distance, waiting the event, and continuing your angling in another part. It is particularly successful in meers, canals, large ponds, or any still water. It requires a round cork, six inches in diameter, with a groove on which to wind your line, except so much of it near the line hook, as will allow the bait to hang about mid-water; and so much of the other end as will reach to the bank or a stump; but if you have a boat, they need not be fastened at all. As soon as a fish takes the bait and runs away with it, the line unwinds itself off the trimmer without giving any check; but it will be prudent when you come to the line, to give a slight jerk to make your prey more secure.

ANGLO-CALVINISTS, a name given by some Ecclesiastical Historians to the members of the church of England, because their doctrinal articles are built on the system of Calvin; though some modern writers, without sufficient reason, pretend that the doctrinal system of the English church is Arminian.

The Anglo-Calvinists make one of the four branches or

divisions of Calvinism; and as such stand distinguished from the pure CALVINISTS, the PISCATORIANS, and the ARMINIANS.

ANGLOISE, in *Musie*, an English country-dance, is so called in France. tune and figure.

ANGLO-NORMANS, in *History.* See **NORMANS.**

ANGLO-SAXONS. See **SAXONS.**

ANGLO-SAXON language, that spoken by the ancient Angli, or Saxons, who settled in England.

It was thus called from the people, who were partly Angli, partly Saxon.

It is otherwise denominated simply, *Saxon.*

The Anglo-Saxon, or English-Saxon, is properly the original English; being the language which our Saxon ancestors first established in this island. It is now called Anglo-Saxon, to distinguish it from the modern or present English.

Many extravagant things have been advanced concerning the great antiquity and superior excellence of the Anglo-Saxon language, which was a dialect of the Gothic or Teutonic. According to some writers, it was the most ancient and most excellent language in the world; spoken by our first parents in Paradise, and from it they pretend to derive the names Adam, Eve, Cain, Abel, and those of all the antediluvian patriarchs. But it will be sufficient for us to say, that the Teutonic or Anglo-Saxon tongue is so ancient, that it is impossible to trace it to its origin; and that it was so excellent and copious, as to enable those who spoke it to express all their ideas with sufficient force and perspicuity. Some have said that this language consisted almost entirely of words of one syllable; but we do not find that the most ancient specimens of this language abound in any remarkable degree in monosyllables; but they contain a competent number of words, consisting of two, three, and four syllables. Some learned men have either discovered, or imagined, a very great affinity between the Greek and the Anglo-Saxon, both in their radical words, and in their general structure; and it must be acknowledged, that in some of the words which they have selected, the similarity is very observable, whilst in others it seems to be fanciful and far-fetched. With regard to their general formation and structure, a great analogy has been observed between these two languages, in the termination of the infinitive of their verbs, in the use of their articles and negatives, and in the manner of comparing their adjectives and compounding their words, and also in some other particulars. The affinity between these languages is supposed to have been occasioned by the vicinity, relationship, and commercial intercourse between the Goths and Greeks in very remote ages. The Anglo-Saxon language in this country underwent gradual changes, but from the specimens of different ages we may perceive the difference that subsisted between the Anglo-Saxon and modern English; and, at the same time, discover their great resemblance, and the gradual approaches of the former of these languages to the latter. The following is a specimen of the most ancient copy of the Lord's prayer in Saxon, with a very literal translation, said to have been written by Æadfrid, bishop of Lindisfarne, about A. D. 700.

Urin Fader thic arth in heofnas,
Our Father which art in heaven;

1. Sic gehalgad thin noma,
be hallowed thine name;

2. To eymeth thin ryc,
To come thine kingdom;

3. Sic thin willa sue is in neofnas and in eorthis,
Be thine will so is in heaven and in earth;

4. Urin

4. Urin hilef ofswiſſlie fel us to daig,
Our loaf ſuper-excellent give us to day ;
5. And forgeſe us ſeylda urna, ſue we forgeſan ſeyldgum
urum,
And forgive us debts ours, ſo we forgiven debts of
ours ;
6. And no inlead uſig in euſnung,
And not lead us into temptation ;
7. Ah gefrig uſich frum iſle,
But free us each from evil. Amen.

In this ſpecimen we ſee that there are not above three or four words altogether obſolete, and quite unintelligible to an Engliſh reader. The language ſpoken by our anceſſors above a thouſand years ago was copious, expreſſive, and muſical ; abounding very much in vowels, diphthongs, and polyſyllables, which are eſteemed the greateſt excellencies of language. The ſubſtance of it reſembles modern Engliſh, and moſt of the words are ſtill in uſe, though the ſpelling and meaning of many of them are changed. The Anglo-Saxon language was ſteadily retained by the Engliſh ; and it overcame all the efforts of the Conqueror and his ſucceſſors to ſubſtitute the Norman in its place. It forced its way at length into the courts of juſtice, from which it had been excluded almoſt 300 years ; and in 1362, an act of parliament was made, that all pleadings in all courts, both of the king and of inferior lords, ſhould be in the Engliſh tongue. The Anglo-Saxon that was ſpoken in England about 200 years after the conqueſt, was ſurpriſingly pure, and had very little mixture of Latin, French, or any other language. In the courſe of the 14th century, it gradually changed into what may be called Engliſh. This was owing to various cauſes. The animosity ſubſiſting between the poſterity of the Normans and Anglo-Saxons was extinguished, and they were conſolidated, in a great meaſure, by inter-marriages and other means, into one people. Many of the Normans, who were engaged in agriculture, trade, and manufactures, found it neceſſary to ſpeak the prevailing language of the multitude. Moreover, Chaucer, Gower, Wickliſſ, and others, compoſed voluminous works, both in proſe and verſe, in Engliſh ; and being men of learning, well acquainted with French and Latin, and ſome of them with Greek and Italian, they borrowed many words and idioms from thoſe languages, with which they adorned and enriched their own. Thus the Anglo-Saxon tongue was greatly changed, and the language of the beſt writers approached nearer to modern Engliſh than that of Robert of Glouceſter and others who flouriſhed in the 13th century. Nevertheleſs, the Engliſh of the 14th century was ſtill ſo different from that of the 18th and 19th, that a mere Engliſh reader cannot always underſtand it without a gloſſary. Beſides various dialects and different modes of pronouncing the Engliſh prevailed, at the time to which we now refer, in different diſtricts. Henry's Hiſt. vol. iv. p. 363—373, vol. viii. p. 391—395.

ANGLO-SAXON verſions of the New Teſtament are extant in manuſcript, and a copious account is given of ſeveral of them in Le Long's Bibliotheca Saera ; the beſt edition of which is that of Maſh, published at Halle, in ſix vols. 4to. 1778—1790. Some books of the Bible were tranſlated by Biſhop Eadfrid, and the goſpel of St. John by Bede ; but the tradition that King Alſred tranſlated the greateſt part of the New Teſtament is very uncertain. The whole verſion has never been printed, but the four goſpels have been published by Matthew Parker, William Liſle, and Thomas Maſh, in 1571, 1638, and 1665 ; and as they are evidently tranſlated from the old Latin, they may be of uſe in determining the readings of that verſion. Maſh's Michaelis, vol. i. p. 158.

ANGLURE, in *Geography*, a town of France, in the department of Marne, and chief place of a canton, in the diſtrict of Sezanne, three leagues ſouth-ſouth-eaſt from Sezanne.

ANGLUS, THOMAS, in *Biography*, an Engliſh Catholic prieſt, whole name was White ; was a profeſſed follower of the Ariſtotelian philoſophy in the ſeventeenth century. Being of a roving diſpoſition, he wandered through ſeveral parts of Europe. After reſiding for ſome time at Paris and at Rome, he was principal of a college at Liſbon, and ſub-principal at Douay. In England he adopted the opinions of Sir Kenelm Digby, with whom he lived, and reſiſted the efforts made by Deſ Cartes to profelyte him to his own ſyſtem. He was a man of a ſingular character, and combined ſome degree of acuteness with conſiderable obſcurity of underſtanding ; but his writings did not excite the notice and oppoſition which he expected. Some of them, however, were cenſured by the congregation of the Index Expurgatorius at Rome, in 1658 ; particularly a treatiſe entitled “*Inſtitutiones Peripateticæ ad mentem ſummi viri clariffimique Philoſophi Realmi Equites Anglæ,*” printed at Lyons in 1646. He wrote alſo “*Queſtio Theologica,*” with a view of reconciling, in the principles of Digby's peripateticism, free will with eſſential grace ; “*Inſtitutiones Theologicæ,*” and ſeveral other traſts. He is ſaid to have written, at the period of the commencement of the conteſts between Charles I. and his parliament, in favour of the doctrine of paſſive obedience ; and he ſurvived the reſtoration of Charles II. Gen. Diſt.

ANGOI, or ANGOV, in *Geography*, a province of Africa, ſituate upon the Loango coaſt, lying between Congo on the north, and Congo on the ſouth ; ſeparated from the former by the river Cabind, and from the latter by the Zaire. The inhabitants are extremely indolent, and the country little cultivated ; the coaſts abound with fiſh, and the foreſts with apes and other animals ; the chief town is Bomba-Cengoy. The chief port is Cabinda, at the mouth of a river of the ſame name, about five leagues north of Cape Palmerino, on the north ſide of the mouth of the Zaire. The bay lies commodiouſly for trade, wooding and watering on the ſea-ſhore.

ANGOKA, ANGOXA, or ANGADOXA, *iſlands* of, are iſlands of Africa in the Mozambique Gulf, and to the ſouth of Mozambique, ſituate in 16° 20' ſouth latitude. They are ſterile, but inhabited. The violent currents occaſioned by the river St. Eſprit, and which drive veſſels to the north-north-weſt againſt the ſhores of the continent, terminate near the northernmoſt of theſe iſlands.

ANGOL, or *Villa nueva de los Infantes*, a town of South America, in the province of Chili, ſituate on the arm of the river Biobia, and about 125 miles north north-eaſt of Baldivia. This is one of the moſt agreeable towns in Chili. S. lat. 37° 36'. W. long. 72° 59'.

ANGOLA, a country of Africa, anciently called Abonda, or Ambonda, and afterwards Dongo, and by the Portuguese Angola, may be divided into Angola proper, or that which was formerly a province of Congo, and the kingdom of Angola. In the firſt ſenſe, it is confined between two rivers of Danda, which parts it from that in the north, and that of Coanza on the ſouth. In the ſecond ſenſe, including its additional conqueſts, it extends along the Ethiopic coaſts from the mouth of the Danda, ſituate in S. lat. 8° 10', to that called St. Francis, in 13° 15', according to ſome ; but according to the moſt accurate geographers, quite to Cape Negro, in 16° 21'. According to this laſt extent, Angola forms a coaſt of 480 miles, but its greateſt depth eaſtwa d

eastward has not been ascertained. The whole of Angola proper abounds with mountains, interspersed with a few plains, on the sea side, and between the ridges of the mountains. The kingdom of Angola, in its most flourishing state, contained the following 17 provinces; *viz.* Chisama, under the 11th degree of south latitude, and near the mouth of the Coanza; which produces an excellent salt, and fine honey and wax; Sumbi, in the same climate with the former, admirably adapted for breeding cattle and sowing grain, if the inhabitants were not shamefully indolent; Benguela, retaining the title of a kingdom; Rimba, situate between Sumbi on the west, Lubolo on the north, Temba on the east, and Scetta on the south, and producing great quantities of grain and of fish; Scetta, south of the former, and north of Benguela, extremely mountainous, and having a rock that extends 30 miles, the top of which is cultivated and inhabited, and enjoys salubrious air and water, and in the lower parts feeding large herds of cattle: Bembea, extending on one side along the sea, and on the other dividing Angola from the other foreign states in the south, populous, and abounding with cattle; Teniba, a flat low province, full of rivers and small streams, and abounding with wild cattle and wholesome roots; Oacco, situate between the Coanza on the north-east, and Lubolo on the south-west, beautifully variegated with hills and plains, and furnished with springs and streams which render it fertile; Cabezzo, having Coanza on the north-east, and Rimba on the south-west, populous, and well stored with cattle and other provisions, and having also a mine of iron on a mountain called the Iron Mountain; the lord of Oacco was baptized in 1657, and the lord of this province in 1658, and they both induced many of their subjects to become Christians: Lubolo, situate along the southern banks of the Coanza, famed for its noble palm-trees, and yielding in great abundance oil, wine, and other produce: most of the inhabitants are Christians. The ten provinces above recounted lie on the south side of the Coanza; and within the Coanza is Loanda, an island on the coast of the kingdom of Bengo, chiefly remarkable for the capital of Angola, called San Paulo de Loanda, built upon it by the Portuguese in 1578, large and populous, and well defended: Bengo, commonly known by the name of Zenza, yielding maize and manioc root, of which the inhabitants, who are all Christians, make their bread; Danda, situate on a river of this name, dividing Angola from Congo; well watered, and fertile in grain and all kinds of fruits, but much infested with crocodiles and serpents; the inhabitants are Christians: Moseche, extending along the northern banks of the Coanza, very fertile in manioc, having mines of several metals, and possessing zimbis, or shell-money, of such exquisite beauty, that the Congoeze will give a slave for a collar of them, and so much valued as to be worn by persons of the highest rank, particularly the ladies, about their necks, arms, legs, and middle: Illamba, divided into the higher, between Bengo and Calacata; and the lower, between Danda to the north, and Bengo to the south, both fertile and tributary to the Portuguese, and the former having mines of excellent iron: Oarii, contiguous to Moseche, well watered, and distinguished by the libalto, or ancient royal residence of the kings of Angola; and Embacca, or Miembacca, situate on the north side of the river Lucala, wholly subject to the Portuguese.

The principal rivers of Angola are the Danda, Coanza, Rimba, Lutano or San Francisco, and Congo; the traffick of this country is slaves, of whom the number is very great, partly for sale and partly for domestic use. The traffick is said to have dwelled the people of their humanity, as parents

sell their children, and husbands their wives, at a very cheap rate. Polygamy is prevalent in this country; and so is also, amongst those people that are not converts to Christianity, the inhuman custom of butchering a great number of human victims at the funeral obsequies of their relations, and piling their carcases in heaps on their tombs.

Before the arrival of the Portuguese, this kingdom was subject to the kings of Congo, and governed by a deputy. One of these deputies, whose name is said to have been Ngola, or Angola, shook off the Congoeze yoke, and assumed the royal title. In this rebellion the ambition of Ngola was assisted by the Portuguese, who, discovered this coast in the year 1484. Ngola lived to a very advanced age, and was much respected; but having raised a favourite slave to the rank of lieutenant-general, he fell a sacrifice to the treachery and ambition of this viceroy, who, in order to effect his purpose and secure the succession, pretended great respect for Zunda Riangoia, one of the king's daughters. Upon his death, which happened suddenly, the princess was universally acknowledged and crowned queen of Angola. Such were the pride and jealousy of the queen, that she would not marry, because she would have no rival; and as she feared a competition on behalf of the two sons of her sister, she ordered them to court under a pretence of having them educated as her children and heirs to her crown; but upon the arrival of the eldest, she instantly caused him to be murdered. The incensed parent avenged herself by plunging a dagger in her breast; and for this act of retributive justice, the Angolans placed the crown on her head, but she immediately surrendered it to her surviving son. He was succeeded by one of his younger sons, Dambi Angola, who, upon ascending the throne, determined to put all his brethren to death. Two of them, however, escaped. Dambi was a monster of perfidy, cruelty, avarice, and lewdness; but happily for his subjects, his reign was not of long duration. Dambi was succeeded by Ngola Chilvagni, a warlike prince, who extended his conquests along the rivers Danda, Lucalla, Zanda, and Coanza, and literally tinged them with blood. Having carried his victories within eight leagues of Loanda San Paulo, he caused a tree to be planted, which he fixed as the limit of his ravages, near which the Portuguese afterwards erected a fortress, and they called the tree Isanda, or Isandaura. This ambitious and successful monarch could not forbear fancying himself to be one of the deities of the country, and exacting honours similar to those which were paid to them. It was not long, however, before he was observed to submit to the fate of other mortals. His successor, Ngingha Angola, was a cruel tyrant; but the country was soon delivered from his oppressions; and exchanged those of the father for the more severe and grievous ones of the son, Baudi Angola. The life of this oppressor was threatened by the rebellion of his aggrieved subjects; but the Portuguese defeated the rebels, and thus ensured the favour of the king, who took them into his service, and even into his council. The Portuguese general was the favourite at court, and more especially with the daughter of the sovereign. Her attachment was soon discovered by the father; and with a mind inflamed by resentment, and an apprehension that a connexion of this kind would be the means of depriving him of the crown, he formed a resolution to extirpate all the Portuguese, as a measure essential to his own security. They were, however, apprised of his designs by the young princess; and retreated into the kingdom of Congo, without interruption or molestation. The Portuguese general obtained permission of the king of Congo to sail for Lisbon, under a promise of returning with a powerful reinforcement, in order to avenge himself on the perfidious

dious sovereign of Angola. He soon obtained the desired ornament, and returned, at the head of his squadron, up the river Coanza: he landed his forces about two leagues from Massungano, a city on the banks of the Coanza, and erected a fortress for their security. The king of Angola prepared for his defence; but in an engagement between his forces and the Portuguese, he suffered a total defeat, and was merely able to escape with his life. His discontented subjects united with the victorious troops of the admiral, and after committing many dreadful ravages, executed their purpose of mauling their sovereign. Bandi Angola was succeeded by his son Ngola Bandi, who began his reign by wreaking his resentment upon all who had opposed his election. The next objects of his hatred and jealousy were the Portuguese; but they, though much inferior in number, obliged him to save his life by flying, first into the island of Chicenda, in the river Coanza, and from thence into one of the neighbouring deserts of Oaceo, where he was permitted to live among the wild beasts, without any other attendance than that which the deserts afforded him. Having been guilty of treachery in evading the fulfilment of a contract with the Portuguese governor, and dreading his resentment, he condescended to intreat his sister Zingha, whose son he had murdered, to undertake an embassy to the governor, and to procure peace with him upon any terms. In order to effect her purpose, he advised her even to embrace the Portuguese religion, if it should prove the means of facilitating her negotiations. Zingha accepted the office, and was received by the viceroy in a very respectful manner. During her stay at Loanda San Paulo, she consented to be instructed in the principles of Christianity; and professing her approbation of them, she was baptized with great solemnity in the year 1622, which was the 40th of her age. The articles, which were settled between Zingha and the governor, were ratified by her brother; and he requested a priest to be sent, in order to instruct him in the Christian religion. But he refused to be baptized, because the person who administered it was the son of one of his slaves. Ngoli Bandi delayed executing the stipulated articles, and determined to renew the war against the Portuguese. In executing this purpose, his troops were all cut off, and he was forced to swim into a little island in the Coanza, where he was pursued; and he escaped being murdered by terminating his life with a dose of poison administered to him by order of his sister Zingha. Zingha ascended the throne; and, in order to secure her power, she murdered her nephew with her own hand. The object to which her principal attention and anxiety were directed, was the deliverance of the realm from the Portuguese, who were now become numerous, wealthy, and powerful, and who were dreaded by all her subjects. With this view she commenced a war against them, and gained at first some temporary advantages. At length she was abandoned by her allies, and by her own forces, and obliged to abdicate her dominions, and to retire into some of the eastern deserts, where she remained unmolested. During her retirement, the Portuguese appointed Angola Oari, a descendant of the royal family, to be king; and before they crowned him obliged him to declare himself a Christian, and to be baptized under the name of John. His reign, however, was of short duration; death made way for his successor, Philio, the second Christian king, who prolonged his reign to the year 1660. Zingha, in the mean while, seeing herself stripped of eleven of her best provinces, and divested of her authority and tribute in the other five, renounced her religion, and devoted herself to all the idolatrous superstitious and inhuman rites of the Giagas; and she thus acquired such authority and influence, that they were ready, at the

first intimation of her will, to follow her through the most hazardous enterprises. By this influence she was able to harass the Portuguese, and to keep them in a state of perpetual terror. At length they sent two deputies to negotiate a peace with her; but their embassy was unsuccessful. Upon renewing the war before the fortress of Massungano, she lost a great number of her men, her two sisters were taken prisoners, and she herself escaped with great difficulty. Zingha had two councils, one for affairs of state and war, the other for religious concerns: the first consisted of four officers; the other of five singolos, or priests of the Giagas religion. Having convened these nine counsellors to deliberate, she proposed to them whether she should embrace the Christian faith, or continue in the religion of the Giagas. She had recourse to the usual mode of consulting the spirits of her ancestors, and the oracle's decree was such as she had foreseen. The demon declared against his own interest, and exhorted her to be reconciled to the faith from which she had apostatized. Whilst this scene was carried on, she had her troops collected, and in the speech, which she addressed to them, she confessed and bewailed her apostasy, and declared her purpose of conforming to the observance of the Christian precepts and rites. Her address was received with universal acclamation, and she considered this as a happy omen of their speedy conversion. The consequence was her reconciliation with the Portuguese, and singular zeal and activity in promoting the profession of Christianity among her subjects. She prohibited the practices of heathenism which then prevailed, under the severest penalties; and in order to encourage marriage, and thus to restrain the plurality of women, she took a husband, and published an edict against polygamy, which produced effect. She also reformed the tyranny of the lords in her dominions, who did not allow their vassals to marry without their licence, for which they paid a considerable sum. Nothing seemed to be now wanting to complete the progress of Christianity but a new supply of missionaries from Europe; in order to obtain these, she sent a letter to Rome in the year 1658, and received a favourable answer in 1662. The pope's letter was publicly announced in the new church which she had built, on the 15th of July, and she repaired to the place, with the letter suspended about her neck in a rich golden purse. After much solemn ceremony on this occasion, she gave a magnificent treat to the Portuguese resident, and to all her court, which was accompanied with the grant of largesses to her chief officers, and with a release of a number of her slaves; and terminated in her performing, at the head of her ladies of honour, who were dressed and armed in the Amazonian style, a kind of combat, in which this princess, though above 80 years of age, behaved with great vigour and activity. Whilst the queen was diligently employed in promoting the conversion of her subjects in her new capital, she was seized with a disorder which proved fatal. Father Antony attended her in her last moments, and received instructions concerning her interment; and she committed the whole conduct of her last obsequies to him; she likewise recommended, with her last breath, the propagation of Christianity, the protection and encouragement of the missionaries, and the enforcement of all the edicts against the impious rites of the Giagas. On the 17th of December, in the 82d year of her age, she closed her life and reign. The deceased queen was buried with great pomp; and, from respect to her memory, her sister Barbara, who succeeded her, was inaugurated a second and a third time, with joyful acclamations. She was a very zealous Christian, but her efforts to promote Christianity were restrained or discouraged by an ill-natured and cruel husband, whose name was

Mona Zingha, and who had been raised by the late queen from the condition of the son of a slave to the rank of her chief general. The queen's disorder and infirmities increased, and, after a short reign of about two years and a half, she closed her life A. D. 1666. Mona Zingha succeeded her, and exhibited sufficient evidence of his abhorrence of Christianity, and of his steady attachment to the abominable rites of the Giagan sect. To remove all doubt with regard to his sentiments, he caused five young ladies of the first rank to be buried alive in his wife's grave. By various methods to which he had recourse, he almost extirpated Christianity; but his career was soon stopped by Don John, the prince's Barbara's first husband, from whom she had been divorced on account of his having another wife. Upon his arrival, the usurper fled into an island in the Coanza; but he returned again, and having killed Don John, regained the throne without any further opposition. Don Francisco, however, the son of Don John, headed an army against the usurper, and Mona Zingha having been defeated and slain, Don Francisco became sole master of the empire. The following kings of Angola possessed only a shadow of royalty. The last of this description was Ngola Sedesio, who revolted, and was taken prisoner. His head was cut off, put in pickle, and sent from Loanda to Lisbon. After this it does not seem that the Portuguese government have thought it proper or perhaps safe to amuse their Angolic subjects with even a mock monarch of their own nation: but they have committed the sole command of the kingdom to the viceroy of Angola, and his council. This kingdom hath long since been erected into a bishopric, suffragan to that of St. Thomas. The manners, language, religion, dress, and ceremonies of the Angolese, are similar to those of the inhabitants of CONGO. Mod. Un. Hist. vol. xiii.

ANGOLENSIS, in *Ornithology*, a species of *FALCO*, found in Angola. It is white, cerc bluish, orbits flesh-coloured and naked, primary wing-coverts and base of the tail black. Gmelin. The size of this species is half as large again as the kite. The bill is whitish, long, and but little curved; irides straw colour; head and neck clothed with feathers, craw pendulous; head, neck, back, breast, belly, and lesser wing-coverts of a pure white; greater wing-coverts and primaries black; the last tipped with white; end of the tail white; legs dirty white and scaly. Latham, Gen. Syn. This species was first described by Mr. Pennant from specimens in the collection of R. P. Parry, Esq. He observes, that they were very restless and querulous, and more active than is usual with this sluggish race.

ANGOLENSIS, a species of *MEROPS*, of a shining golden-green colour, with a cinereous band through the eyes spotted with black; wings and wedge-shaped tail cinereous beneath; chin yellow, throat chestnut. Gmelin. This is *APIASTER ANGOLENSIS*, and *Le Guepier d'Angola* of Brisson, who figured and described it from a drawing sent to him by M. Le Poivre. It is *Le petit Guepier vert & bleu à queue étagée* of Buffon, and *Angola bee-eater* of Latham, Gen. Syn. This bird is five inches and a half in length. The bill is three quarters of an inch in length, and black; the irides red; upper part of the head, neck, body, and wings, are green glossed with gold; on each side of the head an ash-coloured stripe dotted with black, beginning at the base of the bill, and passing through the eyes; breast, belly, sides, and thighs, greenish blue, with a slight golden tinge; under-tail coverts greenish, intermixed with chestnut. The side feathers of the tail margined with cinereous; legs ash-coloured, claws black. Latham, &c.

ANGOLENSIS, a species of *LOXIA* that inhabits Angola. This is the black grosbeak of Edwards, and Angola gros-

beak of Latham. It is blue-black, belly ferruginous, and a white spot on the wing. Gmelin. Size of the common bulfinch, length five inches, bill dusky, eyes dark, ridge of the wing white, legs purplish flesh-coloured.

ANGOLENSIS, a species of *EMBERIZA*, about the size of a finch, that inhabits Angola. This is the gros-bec à poitrine couleur de feu of Salerne, whose description has been adopted by Latham and Gmelin. It is black, crown of the head and neck yellow, and tail long. It is the Angola bunting of the Gen. Syn. The bill is short like that of the bulfinch, and the breast is fire-coloured.

ANGOLENSIS, a species of *TRINGILLA*: above it is brownish ash colour, beneath orange, front of the head black, round the eyes, and on each side of the throat white, rump pale yellow, wings and tail brown. Gmelin. This kind inhabits Angola, where the male bears the name of uegral, or tobaque; the female benguelinha; or at least it is conjectured by Edwards and Latham, that these are the two sexes of the same species. It is the size of the common linnet. The supposed male has the bill brown, upper part of the head, neck, and body brownish ash-colour, each feather darkest on the middle; the greater wing-coverts and quills brown, edged with yellow; tail brown edged with grey; legs flesh-coloured. The female has the upper parts rufous brown, sides of the head pale rufous, near the base of the bill a brown mark, which passes towards the hind head; from the breast to the vent pale rufous, spotted with brown. This is the *Vengoline* of Buffon and the Hon. D. Barrington. Phil. Trans. *Linaria Angolensis* of Brisson, and *Angola finch* of Latham. The last author has given a new specific character to this bird in the Ind. Orn. It is ash-coloured brown, with brown spots; beneath chestnut; front of the head and chin black; cheeks and throat spotted with white; rump pale yellow.

ANGOLI, a name given by Buffon and others to the Madras gallinule, *FULICA MADERASPATANA* of Gmelin. See *MADERASPATANA*.

ANGON, in the *Ancient Writers on Mechanics*, denotes a military engine of the bow-kind. Others again speak of it as a kind of javelin used by the French, the iron head of which resembled a fleur de lys. It is the opinion of some writers, that the arms of France are not fleur de lys, but the iron points of the angon, or javelin of the ancient French.

ANGONÆUS, in *Anatomy*, a name given by Riolanus and others to a muscle called by the generality of other writers *anconeus*, and *cubitalis minor*.

ANGOR is used by some physicians to denote a shrinking inwards of the native heat of the body, or its retiring to the centre; upon which ensues a pain, and palpitation of the heart, attended with sadness and melancholy.

In this sense angor amounts to much the same with what the Greeks call *agonia*.

The angor is reputed a bad symptom, when it happens in the beginning of an acute fever.

ANGORA, ANGOURA, ANGOURI, and formerly ANCYRA, in *Geography*, a town of Natolia, in Asiatic Turkey. This is an agreeable city, in a lofty situation, and has many vestiges of its ancient magnificence and splendour. The castle has a triple inclosure, and the walls are formed of large pieces of white marble, and a stone resembling porphyry. The number of inhabitants is estimated at 80,000. The trade is chiefly in yarn, of which our shalloons are made, and in their own manufacture of Angora stuffs, made principally of the fine hair of a particular breed of goats, which, like that of the cats, occurs in no other country. The soil of the adjacent country is a fine red marl. The bashaw of Angora has about 30 purfes annually; and here are about 300 janizaries,

under the command of a sultan. The Armenians have seven churches, besides a monastery; and the Greeks two. N. lat. $39^{\circ} 30'$. E. long. $32^{\circ} 5'$.

Angora is famous for the battle between Tamerlane and Bajazet, A. D. 1402, which has immortalized the glory of the former, and the shame of the latter.

ANGOT, a province or kingdom of ABYSSINIA, formerly rich and fertile, but almost ruined by the Gallas, who are now in possession of it.

ANGOTE, a town of Africa, in the kingdom of Congo, and province of Pango.

ANGOULEME, a city of France, and capital of the department of Charente; before the revolution, the capital of Angoumois, and see of a bishop, suffragan of Bourdeaux. It is seated on a rock, at the foot of which runs the river Charente. The inhabitants are said to be about 8000, and their manufacture is paper. N. lat. $45^{\circ} 3' 3''$. E. long. $8^{\circ} 45'$.

ANGOUMOIS, a district of France, before the revolution a province, bounded on the north by Poitou, on the east by Limosin and Marche, on the south by Perigord, and on the west by Saintonge. It is between 15 and 18 French leagues in length, and about 16 in breadth. The principal rivers are the Charente and Touvre; there are many iron mines in this province, and the land produces wheat, rye, barley, oats, saffron, wine, and all kinds of fruits.

ANGOUSTRINA, a town of France, in the department of the Eastern Pyrenées, and chief place in the district of Prades, on the frontiers of Spain; four miles north-east of Puyarda, and eight west of Mont Louis.

ANGOY. See GOY and LOANGO.

ANGRA, a sea-port town of Terceira, one of the Azores, the capital of that island and of all the Azores, and the residence of the governor. It is situated in a bay between two mountains on the south side of the island, and it is equally secure against storms and the assault of an enemy. On these hills are two pillars, and a watchman who gives signals of ships approaching the island by means of flags. The town is said to have received its name from Angra, a creek, bay, or station for shipping; this bay being the only convenient harbour in all the Azores. It opens from the east to the south-west, is not above four cables length in breadth, and, according to Frezier, it has not above two cables of good bottom. In summer, ships may ride here with safety; but when the storms of winter come on, the approach of which is indicated by clouds hanging on the Pico, a high mountain in another of the Azores, and the fluttering and chirping of flocks of birds round the city, ships should put off with all expedition to sea. The town is well built and populous, and is an episcopal see, under the jurisdiction of the archbishop of Lisbon. It has five parishes, a cathedral, four monasteries, and as many nunneries, besides an inquisition and a bishop's court, which extends its jurisdiction over all the Azores, Flores, and Corvo. The town is surrounded by a wall and dry ditch, and defended by a strong castle, in which king Alphonso was imprisoned by his brother Peter, in 1668. The houses have a handsome external appearance, but they are indifferently furnished, for which the Portuguese allege, as a plea for their poverty, that warm furniture would be inconvenient in so hot a climate. N. lat. $38^{\circ} 39'$. W. long. $27^{\circ} 12' 15''$. At Angra are kept the royal magazines for anchors, cables, sails, and all sorts of stores, for the royal navy or for merchantmen in distress. All maritime affairs are under the inspection of an officer called "desfambargador," who hath subordinate officers and pilots for conducting ships into the harbour, and the proper watering places. The English, French, and Dutch, have each a consul here, though their commerce

with the Azores is not very considerable. Mod. Un. Hist. vol. xii. p. 55, &c.

ANGRA DE LOS REYES, a town of South America, in the captainship of Rio de Janeiro in Brazil, subject to the Portuguese, about 36 miles from Rio de Janeiro. It is situate upon the coast, in a small bay, whence it has its name: being, in English, King's Bay. It has two churches, a monastery, a small guard-house of about 20 soldiers. Its chief produce is fish. S. lat. $22^{\circ} 28'$. W. long. $17^{\circ} 41'$.

ANGRA Bay, or Great Bay, lies on the western coast of Africa, to the north of Cape Blanco, in N. lat. $20^{\circ} 55'$, and W. long. $17^{\circ} 10'$. This is the most westerly coast of Africa.

ANGRA River is also on the coast of Africa, in N. lat. 1° , and E. long. $9^{\circ} 35'$, having at its mouth the island of Korisco, about five leagues south of Cape St. John, which is its northerly extreme point, as Cape Etluras, seven leagues from Cape St. John, is the southerly point.

ANGRA River is also on the same coast, and on the south side of the equator, and of the river Gabon.

ANGRA *Island* lies in the Persian gulf, and has a spacious harbour at Burka; but it is uninhabited.

ANGRAB, a river of Abyssinia, formed by several streams in the provinces of Tcherkin and Sire, and which, by its confluence with the Gaangua, forms the Tacazze.

ANGRECUM, in *Botany*. See EPIDENDRUM.

ANGRIVARI, in *Ancient Geography*, a people of Germany, supposed by some to have been the same with the Angerii of the middle age; situate, according to Tacitus (Annal ii. c. 8.), between the Wefer and the Ems, and extending eastward beyond the Wefer as far as the Cheruffi, on which side they raised a rampart; with the Tubantes on the Ems to the south; to the west the Ems and the confines of the Brueteri, and to the north between the Chamave and Ansbarii. They are placed by Ptolemy between the Cauchi and Catti, or Suevi. Their territory is supposed now to contain a part of the country of Schaumburg, half of the bishopric or principality of Minden; and to the south, the greatest part of the bishopric of Osnaburg, the north part of the county of Techenburg, and a part of the county of Ravensberg. Some trace of the name is observable in a small town of Ravenberg, called Engern.

ANGROGNA, a parish of Piedmont, watered by a river of the same name, and producing excellent fruits, particularly chestnuts. This is a valley surrounded by high mountains, to which there is access only by two passes. At a village called La Tour, the valley preachers used to officiate, and qualify young men for the ministry, without disturbance, before the reformation.

ANGRUS, a river of Illyria, which, according to Herodotus, ran towards the north-east, passed along the plain of the Triballi, and discharged itself into the Brongus, which joined the Illyr.

ANGSANA, or ANGSANA, in *Botany*, names by which some authors have described the *draco arbor* or *dragon-tree*; one of the trees said to afford the sanguis draconis, or dragon's blood of the shops.

It is esteemed an astringent, and an excellent remedy in the apthæ.

ANGUADA Cape, in *Geography*, is the most westerly point of Porto Rico Island in the West Indies, and is distant from Cape Sumana, or the nearest land at the north-east of Hispaniola island, 22 leagues.

ANGUEAH, a considerable river of Abyssinia, not far from Kellah, in N. lat. $14^{\circ} 24' 34''$. Where Mr. Bruce crossed it, it was 50 feet broad and three deep, and the largest river which he had seen in Habesh. It was perfectly clear, and ran rapidly over a bed of pebbles. It was full of small fish,

fish, esteemed excellent. It has its name from a beautiful tree which covers both its banks, and which, by the colour of its bark and richness of its flowers, is a great ornament to it. Bruce's Trav. vol. iii. p. 113.

ANGUEG, in *Zoology*, a name given in Abyssinia to the water-lizard, or caudiverbera of the Italians.

ANGUILLA, in *Ichthyology*, a name by which some former naturalists distinguished the species of *ATHERINA HESPETUS* of LINNÆUS, a small fish that inhabits the shores of the Mediterranean sea. *Pisciculus anguilla Venetiis dictus; forte hespetus Rondeletii, vel atherina ejusdem.* Wil. Ich.

ANGUIENSIS, in *Ancient Geography*, a place of Africa, situate, according to Haradin, in Numidia.

ANGUIER, FRANCIS and MICHAEL, in *Biography*, sculptors, were born at Eu in Normandy. The elder, Francis, was born in 1604; and having been brought up under Guillin, a sculptor at Paris, was sent for to England, and there acquired a sufficiency to enable him to visit Italy for improvement. After having spent two years in Italy, he returned to France, and was made keeper of Antiques by Louis XIII., and had apartments in the Louvre. He was employed in several celebrated works, chiefly of the monumental kind, such as the tomb of James Souvre, at St. J. in de Lateran; and the mausoleum of the last duke de Montmorency, at Moulins. He died at Paris in 1669.

Michael was born in 1612, became an artist at 15, and employed his first savings under Guillin, at Paris, for visiting Italy, where he entered into the school of the famous Algardi at Rome. After 10 years he returned to France, and assisted his brother in executing the monument of Montmorency. His reputation was great, and he was employed, according to the taste of the times, in many works of decoration. He adorned the apartment of queen Anne of Austria, in the old Louvre, with many allegorical figures; he executed the altar-piece of the church of St. Denis de la Chartre, and the rich sculpture of the gate of St. Denis. His last work was a marble crucifix over the high altar of the church of Sorboane. He died in 1686. Gen. Biog.

ANGUILLARA, in *Geography*, a town of Italy, belonging to the Venetian States in the Paduan, 12 miles south of Padua.

ANGUILHAS, *Cape d'*, lies to the east of the Cape of Good Hope, on the African coast in the Indian Ocean, in S. lat. 34° 52', and E. long. 20° 6'.

ANGUILLA, or *Snake Island*, so called from its snake-like form, is the first of the smaller Antilles, and the most northerly of all the Carribee islands possessed by Britain in the West Indies. On the south side it has good anchorage and a gentle current, but on the east side it is inaccessible on account of flats, shoals, and small islands. It was discovered and settled by the English in 1650; but the first cultivators were molested by rapacious invaders, particularly French pirates; and, after the revolution, a party of wild Irish. New settlers from Barbadoes and other English Caribbees, knowing the value of the soil, removed to Anguilla, and carried on a lucrative trade, without any government, civil or ecclesiastical. In 1745, a small body of their militia resisted the attack of a considerable number of French, and obliged them to retire with great loss. The inhabitants subsist mostly by farming, planting India corn, and other kinds of husbandry. The climate is healthy, and the people strong and vigorous. The exports, in 1770, amounted, in sugar, rum, and cotton, to near 6000l. The island is 10 leagues in length, and three in breadth; and is situated 25 leagues north-west of Barbuda, and 15 from St. Christopher's. N. lat. 18° 15'. W. long. 62° 57'.

ANGUILLA is also a bank island, and east of the great Ba-

hama bank, and north of the island of Cuba. N. lat. 23° 22'. W. long. 78° 47'.

ANGUILLA, in *Ichthyology*, a species of *MURENA*. This is the common eel, having the lower jaw longest, and the body of one colour. Linn. & Gmel. The dorsal fin is said to contain 1000 rays, pectoral fin 19, and the anal fin 100. See EEL.

ANGUILLA INDICA, in *Natural History*, a name given by Willoughby to a species of *TRICHIURUS* in the Linnæan arrangement of fishes. See *TRICHIURUS INDICUS*.

ANGUILLÆ, a species of *TÆNIA* that inhabits the intestines of eels. The head is sessile, distinct, and thickest, joints oblong, with irregular protuberances, and two mouths on one side. The body consists of about 600 joints, and is sometimes four feet in length, front of the head truncated, the first eight joints longest. The upper joints of the body are nearly square, and twice as long as they are broad, the lower ones eight times as broad as they are long. Gmelin, Redi, &c. This is *tænia claviceps* of GOEZE.

ANGUILLARA, in *Geography*, a town of Italy, in the estates of the church and province of Patrimonio; situate on a small river near the lake of Bracciano, 12 miles north-west from Rome.

ANGUILLARA, GIOVANNANDRA DELL', in *Biography*, an eminent Italian poet, was born of a mean family at Sutri, in 1517. From Rome, where he was engaged with a printer, and whom he left on account of an intrigue with his wife, he went to Venice, and formed an intimate acquaintance with a bookseller, who bought his translation of Ovid's *Metamorphoses*, which contributed to his reputation. It was first published at Paris, and dedicated to Henry II.; and his fame, in consequence of this work, was probably the cause of the pomp with which his tragedy of *Cædipus* was acted at Vicenza, in 1565, where Palladio was employed in erecting a magnificent temporary theatre for the purpose. He undertook a translation of Virgil's *Æneid*, but never finished it. By various other poems, satirical and burlesque, he obtained a precarious subsistence. He died at Rome in indigent circumstances, and in consequence of his dissolute mode of living. Gen. Biog.

ANGUILLARA, LEWIS, an Italian botanist of the 16th century, travelled over the greater part of Greece, the islands of Cyprus and of Candia, over Switzerland, &c. Returning to Italy, he was made director of the botanical garden at Padua, in which post he continued to the time of his death, in 1550. He left behind him a work on the knowledge of simples, in Italian, which was published by Murinelli, at Venice, in 4to. in 1561. It was afterwards translated into Latin by C. Bauhine, and printed at Basle in 1593, in 8vo. Haller says (*Bib. Botan.*), Anguillara was the first Italian who had travelled to acquire a knowledge of plants, in which he attained so much perfection as to be able to correct the works of Dioscorides and of Matthioli. "Eximius auctor, si que recte viderat, paulo fusius docuisset." This deficiency is supplied by Bauhine, in his edition of his works.

ANGUILLARIA, in *Botany*. See *ARDISIA*. Anguillaria is made a distinct genus by Gmelin, though his *ang. bahamensis* and *ang. excelsa* are the same plant. Linn. *Transf.* vol. iii. p. 22.

ANGUILLARIS, in *Ichthyology*, a species of *SILURUS* that inhabits the Nile, and is described by Hasselq. and Russel. Aleppo. The dorsal fin is single, and consists of 70 rays, and it has eight beards. Gmelin. Body above the lateral line marbled with black and grey, beneath reddish grey. It has two beards on the upper lip, four on the lower lip, and one at each angle of the mouth. The rays of the gill membrane are nine, dorsal fins 70, and sometimes 72, pectoral fins eight, ventral fins seven, anal fin 50, and caudal fin 20.

ANGUILLARIS, a species of GONIUS, having a single dorsal fin and red tail. Gmelin. This kind inhabits China, is fat, and slippery like an eel. The teeth are exerted out of the mouth, the fins are all red, dorsal and anal fin unite with the tail, pectoral fins very small and roundish, and the skin somewhat transparent.

ANGUILLE, Bay and Cape, in Geography, lie on the west side of Newfoundland island in the gulf of St. Lawrence, about 10 leagues north from Cape Ray, the south-western extremity of the island. N. lat. $47^{\circ} 55'$. W. long. $59^{\circ} 11'$.

ANGUILLE is also a bay on the north-north-east side of the Island of St. John's, in the gulf of St. Lawrence, opposite to Magdalen isles, having St. Peter's harbour on the east, and Port Chimene on the north-west.

ANGUILLIFORM, ANGUILLIFORMIS, in Zoology, having the shape or appearance of an eel. The word is derived from *anguilla*, an eel, and *forma*, shape or appearance; and was formerly applied by naturalists to a number of different fishes that are soft, lubricous, and destitute of very apparent scales. Several of those, as the sea serpent, conger, &c. are now included with the eel (in the Linnaean arrangement), in the genus *muræna*, and the others are chiefly referred to that of *anmodytes*, *ophidium*, or *petromyzon*.

ANGUILLULA, in Natural History, a species of VIBRIO found in vegetable sediment, four parts, infusions of blighted wheat, and other grain, &c. and known generally by the name of paste-eel. It is of equal size throughout, and somewhat rigid. Gmelin. See EELS *microscopic*.

ANGUINA, in Botany. See CALLA and TRICOSANTHES.

ANGUINA, in Conchology, a species of SERPULA that inhabits the Indian Ocean. The shell is roundish and somewhat spiral, with a longitudinal articulated fissure. It varies considerably in form, being either round or angular, straight or waved, smooth or rough, and the articulations of the fissure often obsolete. The SERPULA MUZICATA of Born is a variety of this species. Gmelin.

ANGUINA, in Entomology, a species of phalæna, of the BOMBYX family, found in North America by Abbot, and described by Dr. Smith. The anterior wings are clouded, base and transverse streak pale; a whitish spot with a double black pupil near the apex.

ANGUINA, in Natural History, a species of SERTULARIA, called the snake coralline by Ellis. It is destitute of denticles, and the stem is simple, with clavated obtuse branches, each of which has a lateral aperture. Gmelin, Ellis, &c. This kind inhabits the Mediterranean Sea; it is white, soft, and flexible, and adheres to other marine substances.

ANGUINA, in Zoology, a species of LACERTA, having a verticillated tail which is stiff at the extremity, striated body, and subulated feet without toes. This is *vermis septentiformis ex Africa* of Seba, and *chalcides pinnata* of Laur. The head is rather depressed and small, ears transverse, body round and verticillated, the scales on each side longitudinally furrowed; tail twice as long as the body, sharply pointed at the end; legs six, anterior ones slender, body covered with subulate scales. Gmelin. The general description of this creature does not clearly correspond with those of the authors quoted by Linnæus and Gmelin. The figure in Seba is about 15 inches in length, of which the body is four inches: the whole is covered with ovate scales, is brown above, with dusky longitudinal stripes, yellowish beneath, and ash coloured on the sides. It is common in muddy places about the Cape of Good Hope.

ANGUINEAL *hyperbola*. See HYPERBOLA and CURVE.

ANGUINEI *versus*, in Poetry, those which may be read backwards.

These are otherwise called recurrent verses. Such, *e. g.* are,

“Optimum jus, lex amica, vox differta:
Differta vox, amica lex, jus optimum.”

ANGUINUM, ovum, among *Ancient Writers*, denotes an extraordinary sort of an egg, said to be produced by the joint *saliva* of a cluster of snakes interwoven and twined together; and when it was found, it was raised up in the air by the hissing of these serpents; and was to be caught in a clean white cloth before it fell to the ground. The person who caught it was obliged to mount a swift horse, and to ride away at full speed to escape from the serpents, who pursued him with great rage until they were stopped by some tree.

The opinions which the Druids, both of Gaul and Britain, entertained of their anguinum, or serpent's egg, both as a charm and a medicine, are in a very high degree romantic and extravagant. The method of ascertaining the genuineness of this was no less extraordinary. It was to be encased in gold, and thrown into a river; and if it was genuine, it would swim against the stream. “I have seen,” says Pliny (H. N. l. xxi. c. 3.), “that egg; it is about the bigness of a moderate apple; its shell is a cartilaginous incrustation, full of little cavities, such as are on the legs of the polypus; it is the insignia or badge of distinction of the Druids.” Among other wonderful virtues ascribed to this egg, it was represented as particularly efficacious for rendering those who carried it about with them, superior to their adversaries in all disputes, and for procuring on their behalf the favour and friendship of great men. We have the following account of this egg, in the part of a Druid, in Mason's “Caractacus:”

—————“But tell me yet,
From the grot of charms and spells,
Where our matron sister dwells,
Brennus, has thy holy hand
Safely brought the Druid wand;
And the potent adder-stone,
Gendered 'fore the autumnal moon,
When in undulating twine,
The foaming snakes prolific join;
When they hiss, and when they bear
Their wondrous egg aloof in air;
Thence, before to earth it fall,
The Druid in his hallow'd pall
Receives the prize,
And instant flies,
Follow'd by the envenom'd brood,
Till he crosses the crystal flood?”

Some have thought that the serpent's egg was a mere fraud contrived by the Druids to delude the vulgar, who purchased these marvellous eggs at a high price. Others have imagined that the story of the anguinum was an emblematical representation of the doctrine of the Druids concerning the creation of the world. The serpents, they say, represent the divine wisdom forming the universe, and the eggs the emblem of the world formed by that wisdom. It may be added, that the virtue ascribed to the anguinum of giving those who possessed it a superiority over others, and endearing them to great men, may perhaps be intended to represent the natural effects of learning and philosophy.

Our modern Druideesses, says Mr. Pennant, have an opinion of the virtues of the ovum anguinum, “glain neidr,” as the Welch call it, or the “adder-gum;” according to the modern philosophers, similar, though inferior, to that which the ancients entertained concerning it: they merely apply it to assist in cutting children's teeth, to cure chin-cough, or

to cure an ague. These eggs were, in reality, beads of glass, to which the Druids annexed a charm; and they were of a rich blue colour, either plain or streaked.

ANGUINUS, in *Entomology*, a species of CURCULIO that inhabits Germany. It is cylindrical, grey, and lined with brown. Gmelin. This insect somewhat resembles curculio paraplecticus, the legs and underside of the body are grey, dotted with black, the beak much bent, wing cases marked longitudinally with a double row of minute excavated points.

ANGUIS, in *Zoology*, the name of a genus of serpents in the Linnæan arrangement, which is distinguished from the rest by having the belly and under part of the tail covered with scales like those on the other parts of the body. Gmelin. The species, according to Gmelin, are, striatus, mceagris, colubrinus, miliaris, jaculus, maculatus, reticulatus, cerastes, natus, lumbricalis, laticauda, scytale, cryx, fragilis, ventralis, platurus, lineatus, clavicus, annulatus, scutatus, corallinus, rufus, hepaticus, and tessellatus; which see respectively.

ANGUIS BIPES, in *Natural History*, the Linnæan name of a creature in the class AMPHIBIA, inserted in the *twelfth edition* of the *Systema Natura*, but referred by Gmelin from the genus ANGUIS to that of LACERTA. The latter author also refers ANGUIS QUADRUPES of Linnæus to the same genus. See LACERTA SERPENS.

ANGUIS, in *Conchology*, a species of TURBO figured in Martyn's Univ. Conch. It is striated transversely, green striped with black; pearly within. Gmelin.

ANGUIS Æsculapii, see COLUBER.

ANGUIUM lapis, a name given to a supposed stone in Germany, which is of a cylindrical figure, and has a cavity capable of admitting a finger, and of a yellow colour, with a great many variegations. The vulgar call it *duchaneck*, and have an idle opinion of its having its origin in some manner from a serpent-ant. De Boot, who had seen many of them, declares them to be fictitious, and made of glass tinged with two or three colours. These were probably of the same kind, and used for the same purposes, with the ANGUINUM ovum.

ANGULAR, something that relates to, or hath angles. Angular objects at a distance appear round; the little inequalities disappearing at a much less distance than the bulk of the body.

ANGULAR Motion, in *Mechanics* and *Astronomy*. is the motion of a body which describes an angle, or which moves circularly round a point. Thus, a pendulum has an angular motion about its centre of motion; and the planets have an angular motion about the sun. Two moveable points M and O (*Plate I. Mechanics, fig. 3.*), one of which describes the arc MN, and the other, in the same time, the arc OP, have an equal, or the same, angular motion; although the real motion of the point O be much greater than that of the point M, viz. as the arc OP is greater than the arc MN. The angular motions of revolving bodies, as of the planets about the sun, are reciprocally proportional to their periodic times; and they are also as their real or absolute motions directly, and as their radii of motion inversely.

ANGULAR motion is also a kind of motion composed of a right-lined and circular motion, or in which the moveable body slides and revolves at the same time. Such is the motion of the wheel of a coach, or other vehicle. The phenomena. &c. of such motion, see accounted for under the article ROTA Aristotelica.

ANGULAR, acute, *scision*. See ACUTE.

ANGULAR, capital, see CAPITAL.

ANGULAR column, see COLUMN.

ANGULAR niche, see NICHE.

ANGULAR, *Angulatus*, in *Botany*, denotes a stem, &c. having edges or corners, opposed to cylindrical. A stem may have one, two, three, four, or more angles or corners. The white archangel hath four. The flower-de-luce, or flag, has an angular capsule.

ANGULARIS *Scapule*, in *Anatomy*, a name given by Winslow, and some others, to the muscle of the shoulder generally called the LEVATOR *scapule*.

ANGULATA, in *Zoology*, a small species of LACERTA, first discovered by Rolander in America. The body is brown above, and covered with carinated scales; those on the belly are smooth; under the throat are two large rounded scales; the head is naked, with various, unequal, elevated wrinkles, which appear truncated at the collar, or behind the head; tail very angular, and half as long again as the body: the specific character of this snake is, tail very long and hexagonal, with carinated and mucronated scales. Gmelin.

ANGULATA, in *Entomology*, a species of HESPA, that inhabits Cayenne. The antennæ are fusiform, body yellow; head, dorsal line on the thorax, and waved, margin of the wing-cases black. Fabricius and Gmelin.

ANGULATA, a species of PIMELIA, that inhabits Egypt. The wing-cases are spinous, the lateral line elevated and serrated. Fabricius. This is the tenebrio spinosus of Forsk. and tenebrio asperimus of Pall. This insect is black and without wings, and the wing-cases not divided; the thorax is rough, with three rows of spines, and intermediate rows of tuberculated ones, the lateral line deeply serrated.

ANGULATA, a species of CANTHARIS, found in the island of Amsterdam, South Seas. It is of a testaceous colour, thorax angulated and spinous, end of the wing-cases blue, antennæ and legs black. Fabricius.

ANGULATA, a species of PHALÆNA, of the *bombyx* tribe. The wings are incumbent, angulated, testaceous-brown colour, with numerous black dots, and two obsolete bars of ash colour. Fabricius. This must not be confounded with the BOMBYX ANGULATA of Gmelin, N^o 475, whose description is taken from *bombyx*, N^o 26, of the species insectorum of Fabricius, and should have been written *argulata*, instead of *angulata*.

ANGULATA is also a species of PHALÆNA, of the *geometra* tribe. The wings are angular and tailed; it is varied with large and small grey streaks, and a black dot near the tail. Fabricius and Gmelin. This is a small insect, and inhabits Africa. Gmelin has also another species of PHALÆNA, of the *geometra* tribe, under the name of angulata; the wings are angular and pale. It inhabits Europe. Gmel. 1298.

ANGULATA, a species of ARANEA. It is ovate, front and sides acutely angulated; centre of the thorax excavated. This is a European insect, lives in trees, and spins a perpendicular web.

ANGULATA, in *Conchology*, a species of TELLINA that inhabits the Indian ocean. This shell is somewhat ovate, and marked with transverse recurved ribs, anterior part angulated, and no lateral teeth. Gmelin. This is about an inch and a half in length, and two inches in breadth. It differs from tellina virgata, which it in some respects resembles, in being less oblong, entirely white, the anterior angle seated more outwardly, and the aperture behind oval. Gmel.

ANGULATA, a species of ANOMIA. The sides of the base compressed, anterior part plaited, three teeth in the middle. Gmelin. Found in a fossil state; this shell is smooth, and varies in the number of plaits on the anterior part.

ANGULATUS, in *Zoology*, a species of COLUBER, of a brownish colour, with dark or blackish, broad, lanceolate, transverse

transverse bands meeting alternately beneath. The Linnæan specific character is, scales of the belly one hundred and seventeen, and those of the tail seventy. The length of this snake is above two feet, head rather small, and covered with large scales; the scales of the body disposed in about nineteen longitudinal rows, and each scale rather strongly carinated: its specific name is taken from the angular appearance of the body. This kind is a native of Asia.

Dr. Shaw having observed, that the number of abdominal and subcaudal scales vary considerably in different specimens, has assigned this species a new specific character, *subfusus*, taking transversis lanceolatis nigricantibus, subtus alternatim concurrentibus. Gen. Zool.

ANGULATUS, in *Entomology*, a species of ATTELATUS, that inhabits Cayenne. It is ferruginous, wing-cases angulated, black in the disk. Fabricius. Antennæ black, ferruginous at the base; thorax ferruginous, with a black spot at the base.

ANGULATUS, a species of CARABUS, of the apterous kind. It is black and hairy, thorax guttered, wing-cases furrowed, with two interrupted yellow stripes. Inhabits Coromandel. Fabricius.

ANGULARUS, a species of GRILLUS, that inhabits Germany. It is yellowish, abdomen brown, segments of the joints obtuse and angular. Fabricius.

ANGULATUS, a species of CANCER, with two spines on each side of the thorax, fore-claws very long. Gmelin.

ANGULOSA, in *Conchology*, a species of TELLINA, that inhabits America. This shell is oval, rather flat, and transversely striated: one end inflected and angulated; first tooth of the hinge bifid, lateral ones remote. Gmelin and Chemnitz.

ANGULOSA is likewise a species of ARCA, that inhabits the shores of the African and American ocean. It is ventricose, longitudinally marked with striæ and fine lines, and has one side angulated; the beaks are contiguous, hinge arched. Gmelin. Its general colour is brown, with a few spots.

ANGULOSA is also the specific name of a PATELLA, figured by Lister and Martin. It is rather oval, white, thin, striated, and varied with spots and dots of red; margin octangular. Gmelin. An orange-coloured shell, with elevated white striæ and dots, bottom yellow, central orange ring and white margin; figured by Martini; is supposed to be a variety of this species. Its native country is not ascertained.

ANGULOSA, in *Natural History*, a species of MADREPORA, that inhabits the American seas. It is short, thick, cellular, smooth, and white: the specific character is, dichotomous, falcigiate, with terminal, turbinated, angular stars; the lamella or gills dentated. Pallas and Gmelin.

ANGULOSUS, in *Conchology*, a species of ECHINUS. It is hemispherical, with granulated spaces, and double series of warts, the larger ones divided by serrated sutures down the middle; three series of pores upon the avenues. The native country is unknown; it is of a cinereous grey tinged with violet. Seba, Klein, Gmelin, &c.

ANGULUS, in *Natural History*, a species of TRICHONA, described by Müller, Hist. Verm. It is angular, with a hairy tip. Gmelin. This kind is found in infusions of hay; it is long and convex, and is divided by an articulation into two parts, of equal breadth, but differing in length, the fore part shorter than the hind part, the apex furnished with short waving hair, indistinct molecules within, and no hair on the posterior part.

ANGURIA, in *Geography*. See ANGORA.

ANGURIA, in *Botany*, a genus of the *monocotyledon*

(*dianthis monogyria*, Gmelin), and natural order of *cucurbitaceæ*. Its characters are, that it has male and female flowers; the calyx of the male is monophyllous, quinquefid, swelling at the base, divisions lanceolate and short; the corolla is pentapetalous, spreading, growing to the border of the calyx; the stamina have two filaments, opposite, inserted into the calyx, anther creeping up and down; the calyx and corolla of the female as in the male; the filaments of the stamina as in the male, but 10 anthers; the pistillum has an inferior oblong germ, style semibifid, and stigmas bifid and acute; the pericarpium a pome, oblong, quadrangular, and bilocular; the seeds are very many, oval, compressed, and nestling.

There are three species: 1. *A. trilobata*, with three-lobed leaves; a native of Cathayana in South America, where it flowers in June. 2. *A. pedata*, with leaves pedate and serrate; a perennial plant, climbing trees, by means of long tendrils, to the height of 20 feet; a native of St. Domingo; flowering in September, and fruit ripening in December. 3. *A. trifoliata*, with leaves ternate and quite entire; a native of St. Domingo; differing from the former in having the leaves quite entire and narrower, and several fruits collected together.

ANGURIA. See CUCURBITA.

ANGUS, in *Geography*, a district of the county of Forfar in Scotland, formerly an earldom belonging to the Douglasses, now extinct.

ANGUSTA, in *Entomology*, a species of MANTIS, that inhabits the island of Antigua. It is greenish, tail bifurcated, antennæ as long as the body, and filiform. Gmelin.

ANGUSTA, a species of TENTHREDO, found in Europe. It is black, the body narrow, and covered with greyish down. Gmelin.

ANGUSTA, in *Conchology*, a species of PATELLA. The shell is depressed, white, with elevated streaks, of which every fourth is larger than the rest; aperture very narrow, with a chestnut coloured band on the outside, and a green belt within. Gmelin. This is about three quarters of an inch in length.

ANGUSTATA, in *Entomology*, a species of CASSIDA, found in India. It is yellowish, posterior part of the wing-cases narrow. Gmelin.

ANGUSTATA, a species of PIMELIA, that inhabits the southern parts of Russia and Egypt. It is glossy, posterior part of the thorax narrow, wing-cases pointed at the end. Gmelin. This creature lives in the dry dung of animals, under stones, &c. and is supposed to be the tenebrio longicornis of Pallas.

ANGUSTATA, in *Conchology*, a species of LEPAS, figured by Bonani. The shell is elongated, smooth, of six valves, the aperture narrow, and operculum small. Gmelin. It is grooved where the valves unite, and is sometimes striated with red and white.

ANGUSTATA, a species of CYPREA. It is narrow, and of a brown colour, with reddish spots. Gmelin and Gualteri.

ANGUSTATUS, in *Entomology*, a species of CURCULIO, sometimes, though rarely found in England. It is cylindrical and black, wing-cases obtuse and punctated. Fabricius.

ANGUSTATUS, a species of CRYPTOCEPHALUS in Gmelin's arrangement, and CISTELLA of Fabricius; the thorax and wing-cases are of an obscure reddish brown, and black in the middle. Fab. Inhabits England.

ANGUSTATUS, a species of CARABUS, that inhabits Germany. The thorax is cylindrical and blue, wing-cases testaceous, black at the tips. Fabricius.

ANGUSTATUS, a species of CIMEX, with oblong body, and

and filiform antennæ; it is black, with an elongated head and thorax. Gmelin and Thunb.

ANGUSTIA, in *Ancient Geography*, a town of Europe in Dacia, according to Ptolemy.

ANGUSTICLAVIA, or ANGUSTUS CLAVUS, in *Antiquity*, a *tunica*, embroidered with little purple studs, or flowers, worn by the Roman knights, inferior magistrates, and some officers of the army.

The word is compounded of *angustus*, *small*, and *clavus*, *stud*, because those ornaments were smaller in this garment than in the *laticlavus* which was worn by the senators.

ANGUSTIFOLIUS, in *Botany*, denotes narrow-leaved.

ANGUSTURA *Bark*, in the *Materia Medica*, a species of bark imported here in convex pieces, about an inch and an half or less in breadth, and about six inches long. It is hard and compact, of a yellowish brown colour, and covered with a whitish, uneven epidermis. In powder it has the yellow appearance of rhubarb; its taste is bitterish and aromatic; its odour, when recent, is said to be not ungrateful. An ounce of this bark yields, by means of alcohol, about two drams of a resinous, bitter extract; and from the same quantity, nearly three drams and a half of a gummy extract may be obtained by water. This drug, according to some, should be called *Augyline*, from St. Augustine, in East Florida; but it is more properly named *Angustura*, from a place of this name in South America, whence it was brought by the Spaniards to the island of Trinidad.

The tree which produces it is not ascertained. Some suppose it to be *MAGNOLIA glauca*; but it has been thought, with greater probability, to be the bark of the *BRUCEA antidyenterica*, or *BRUCEA ferruginea* of L'Heritier and Aiton; for the description of the bark of this tree given by Mr. Bruce agrees very well with the cortex angusturæ; and this opinion is confirmed by the bark of a living plant of this species growing in the royal garden at Kew.

This bark has been successfully used during the 12 years from 1789, in which it has been known as a medicine in this country, under the characters of a febrifuge, tonic, and astringent. In intermittents it has been found no less effectual than Peruvian bark, and generally more acceptable to the stomach; and in cases of diarrhœa, dyspepsia, schrophule, and great debility, it has been found to be an useful remedy. The doses in which Mr. Brandi has exhibited this remedy have been, of the powder as much as 20 grains every three hours, but generally less.

The infusion is made with half an ounce of the bruised bark to a pint of boiling water; the decoction of the same strength; the dose, one ounce to an ounce and an half. Of the tincture, prepared with one ounce of bark to 16 of proof spirit, the dose is about one drachm. Woodville's *Med. Bot.* vol. iv. p. 162. Murray's *Mat. Med.* vol. vi. p. 172--177. Brandi's *Exp. and Obs. on the Angustura bark*, 1791.

ANGUSTUS, in *Entomology*, a species of *CIMEX*, that inhabits China. It is greyish above, beneath yellowish; antennæ and legs testaceous brown. Fabricius.

ANGUSTUS, in *Conchology*, a species of *MUREX*. This shell is narrow, the first wreath of the spire plaited longitudinally, and ribbed transversely, the rest smooth and round, beak ribbed transversely. Gmelin.

ANHALDIN, *anhaldinum*, an epithet given to various medicines, formerly kept as secrets in the family of Anhalt. Three of the most celebrated medicines under this denomination are a corrosive, a water, and a spirit.

The corrosive, as described by Burggrave, is compounded of calcined antimony, sublimate mercury, sal ammoniac, and calcined tartar, distilled and rectified. The Anhaltin water,

or rather spirit, is a farrago of several aromatics, balsamics, and turpentine distilled with spirit of wine. It is nauseous to the palate; but has been applied externally in the palsy, syncope, vomiting, and gripes. Murray, *Mat. Med.* vol. i. p. 36.

ANHALT, in *Geography*, a principality of Germany, in the circle of Upper Saxony, terminating to the north-east on the marche of Brandenburg, to the east on the electorate of Saxony, to the south on the county of Mansfeld, to the north-west on the duchy of Brunswick, and to the north on the principality of Halberstadt and the duchy of Magdeburg, and extending about 90 miles from east to west, and in its greatest breadth about 35 miles. The soil produces corn and hops, and various kinds of fruits. The rivers, which are the Elbe, the Mulde, the Saale, the Wipper, the Seike, the Bude, the Futine, the Zita, the Nuke, and the Roslan, yield excellent fish. The mines afford lead, copper, silver, iron, coals, sulphur, vitriol, alum, saltpetre, and other minerals; and the principal article of trade is beer. The air is healthy, though cold. In this principality are 19 towns and two boroughs, and the number of inhabitants is about 100,000. Christianity was introduced into Anhalt in the ninth century; and the reformation took place in 1521. Until 1596, the whole country professed Lutheranism; but at that time Calvinism was introduced. This principality derives its name from the castle of Anhalt; and the princes of Anhalt are descended from the Ascanians. Some of the best genealogists derive their origin from Berentobaldus, who made war upon the Thuringians in the sixth century; and in the German history the princes of this family make a conspicuous figure. Joachim Ernest II. was the founder of all the present princes of Anhalt. He died in 1586; and five of his sons shared their father's territories. To the eldest of the family they all agreed to submit; and with him, to whom belonged *Anhalt-Diffau*, was vested the supreme government. The other four are *Anhalt-Bernburg*, *Anhalt-Schaumburg*, *Anhalt-Coblen*, and *Anhalt-Zerbst*. Each of the reigning lines has its regency, exchequer, and consistory. The annual produce of the whole principality of Anhalt is estimated at between 5 and 600,000 rix dollars.

ANGHELITUS, formed of the verb *anelo*, *I breathe with difficulty*, signifies a shortness and thickness of breath, as in an *ASTHMA*. See *RESPIRATION*.

ANHIMA, in *Ornithology*, a name given by Maregrave, Willughby, Ray, and other old writers, to the *PALAMEDEA CORNUTA* of Linnæus. See *CORNUTA PALAMEDEA*.

ANHINGA, a species of *PLOTUS*, having a smooth head, and white belly. Gmelin. This is the anhing of Maregrave, Brisson, Ray, and others; and *white bellied darter* of Latham.

This species is scarcely so big as a mallard in the body, but its length from the tip of the bill to the end of the tail is not less than two feet ten inches; the bill is three inches long, straight, pointed, and jagged at the edges; the colour greyish, yellowish at the base; head small, neck very long and slender, and covered with downy feathers of a rufous greyish colour; upper part of the back and scapulars dusky or blackish, the middle of each feather dashed with white; lower part of the back, rump, and upper tail coverts black; belly pure silvery white; tail of twelve large black feathers, legs and toes yellowish grey.

It inhabits Brasil, and feeds on fish, which it is said to catch with much cunning and dexterity, first drawing up its neck like a serpent, and then darting its bill upon its prey. Like the corvorant, this bird builds the nest upon trees, generally those which grow by the sides of rivers. When at rest

rest it frequently sits with the head drawn in between the shoulders, like the heron. It is for the most part very fat, but the flesh has an oily, rank, and disagreeable taste.

ANHLOTE, in *Law*, a single tribute or tax. The words *anhlot* and *anfot* are mentioned in the laws of William the Conqueror; and their sense is, that every one should pay, according to the custom of the country, his part and share, as *scot and lot*, &c. *Leg. W. I. cap. 64.*

ANHOLT, in *Geography*, a seignory of Westphalia, lies between the bishopric of Münster, the duchy of Cleve, and the county of Zutphen. When the ancient lords of Anholt became extinct, towards the close of the 12th or beginning of the 13th century, a female heir of this house transferred it to her consort John of Brankhorst. His two sons divided the maternal and paternal estates, and thus Count Theodorica obtained the sovereignty of Anholt. In 1641, he gave this seignory to his daughter, who was married to Leopold Philip Charles, prince of Salm, whose house, on account of this seignory, enjoys both seat and voice in the Westphalian college of the counts of the empire, and also at the diets of the circle of Westphalia. The province of Guelders, in the Low Country, now appropriates to itself the superiority over this seignory. The chief place in it is *Anholt*, a small town and citadel lying in the Old Yssel. N. lat. 51° 54'. E. long. 6° 7'.

ANHOLT, is an island of Denmark, in North Jutland, situate in the Cattegat, eight miles from the coast of Jutland on the west, ten from Zealand on the south, and seven from Smaland on the east. It is surrounded with sandbanks, and, therefore, dangerous to seamen, but a fire is constantly kept up in a light-house upon it. On each side of it is a channel, as ships may be sailing for Copenhagen on the east or on the west side of Zealand. Professor Bugge observes, that in all the best maps of the Cattegat, the position of Anholt is very erroneous. The light-house and the whole isle are from seven to nine minutes too much westerly; and the distance from the light-house to the Swedish coast, in a direction perpendicular to the meridian of the light-house, is, in all maps hitherto published, nearly four English miles, or one-eighth part of the whole, too great. Experience has taught the navigators that they come too soon down upon Anholt; or that, on cruising between Anholt and Sweden, they over-run their reckoning, which was ascribed to the currents; whereas, the true reason was the great error in the geographical and hydrographical position of Anholt in a narrow and dangerous passage. The light-house is in N. lat. 56° 44' 20". E. long. 11° 39' 51". *Phil. Transf. vol. lxxxiv. p. 46.*

ANHUIBA, in *Botany*, a name by which some authors call the *SASSAFRAS* tree, the wood of which is so much used in medicine.

ANHYDROS, a name given by the ancient Greeks, and from them copied by the Romans in the time of Pliny, to express one of those kinds of the *STRYCHNA*, or nightshades, which, when taken internally, caused madness.

ANI, in *Ornithology*, a species of *CROTOPHAGA*, in the Linnæan and Gmelinian arrangement, and very briefly described as *Cr. minor pedibus scanforis* (small feet-climbers). This character is, perhaps, insufficient to distinguish it from another species of the same genus described by Gmelin, as *Cr. major pedibus scanforis*, without attending to the characters admitted by other authors; both are of a blackish violet colour, and have the edges of the feathers glossed with green, but in the former the green has a coppery aspect: the bill of this is also shorter in proportion, and rises higher at the top, and its usual length is thirteen inches and an half, which is about four inches and an half less than that of *C. ma-*

major. Some authors have been disposed to consider them as the two sexes of the same species, or mere varieties; but both sexes of each seem to be well ascertained, and Dr. Latham says he is assured they are distinct species, and never mix together.

This is the Brazilian bird, called by Maregrave in his History of Brasil, *ANI*; and *Plittaco* congener *Ani*, by Ray and Willughby. It is not, however, peculiar to this part of South America, being also found in Guiana. It is *Mondula tota nigra major garrula*, *mandibula superiore arcuata* of Sloane, Jamaica; and is likewise described as a *Well Indian* bird by Brown. Catesby calls it the razor-billed blackbird; Buffon, *ani des Savaues*, and in the *Pl. enl. Petit Bout-de-Petun*. *Crotophagus*, by Brisson, and it is supposed the *Cacalotol* of Ray is the same bird.

"Contrary to all other birds, the *Crotophaga Ani*," says Dr. Latham, "have the singularity of many lying in the same nest, to make which they all unite in concert; and, after laying their eggs, sit on them close to each other, in order to hatch them, each unanimously striving to do the best for the general good; and when the young are hatched, the parents, without reserve, do the best to feed the whole flock. A still greater singularity occurs, which is, that as soon as each female lays her eggs, she covers them with leaves, doing the same thing whenever she is obliged to leave the nest for food: this might be necessary in a cold climate; but why it should be wanted in a hot one, seems not clear, especially as it has not been observed in other birds. It generally has two broods in a year, except accidents happen; in which case it has been known to make three nests. The eggs are about the size of those of a pigeon, of a sea-green colour, spotted at the ends."

"Their food is various; worms, insects, fruits, and grain, according to the season. They have the same manners as the greater ani, *C. major*, and are continually gregarious, from ten to thirty in a flock, whether it be in breeding time or not. They are not difficult to be shot, not being so wild as many other birds; but are known to chatter much on the sight of a man, though they do not fly to a great distance; hence they are not well relished by sportsmen, as, like jays in England, they are the occasion of hindering his sport in respect to other game, without making him amends in their own flesh, which is never sought after for food, being rank and unfavoury." *Vide Gen. Syn. tom. i. p. 362.*

ANI, a name adopted by Dr. Latham in his arrangement, *Gen. Syn.* for the Linnæan genus *CROTOPHAGA*; thus the species *C. ani* is called the *lesser ani*, *C. major*, *greater ani*, *C. ambulatoria*, *walking ani*; and, no doubt, the newly-discovered species described as *C. varia*, *rufo nigroque varia*, in *Ind. Orn.* of the same author, would have been called the *variegated ani*, had any English name been assigned to it.

ANI, a name given by some early writers on natural history to the *UPUPA MEXICANA* of Linnæus, and Mexican pomepops of Latham. *Avis ani Mexicana cauda longissima*. Seba, &c.

ANI, or **ANIKAGA**, in *Geography*, a town of Greater Armenia, in Asia, in the government of Kers, and under the beglierbeg of Erzerum. Its walls are watered by a river, which descends with rapidity from the mountains of Mingrelia. It was formerly known under the name of *Am*; and was so considerable and so strong, that the ancient kings of Armenia deposited their treasure in its castle.

ANIAN Straits, lie between the north-east extremity of Asia, and the north-west point of the continent of America. The west point of this strait is N. lat. 65° 52', and W. long. 169° 20', and the east point, called Cape Prince of Wales, in N. lat. 65° 46', and W. long. 168° 15'; and its breadth is about 14 leagues. See *BEERING'S Straits*.

ANIAN is also a barren, sandy desert, which is excessively hot, and inhospitable, on the east coast of Africa; frequented only by wandering Arabs, who live in camps. It lies upon or near the Eastern Ocean and the Red Sea. See ABEX.

ANIAN-FU, or ANIEN, a town of China, in the province of Chuquami.

ANIANA, in *Ancient Geography*, a town placed by Ptolemy in Mesopotamia.

ANIANE, in *Geography*, a town of France, in the department of the Herault, and chief place of a canton in the district of Lodeve, 13 miles west-north-west of Montpellier. N. lat. 43° 41'. E. long. 3° 29'.

ANJAR, a town of Asia in Syria, between Aleppo and Alexandretto.

ANIBA, in *Botany*. See CEDROTA.

ANICETUS, Pope, in *Biography*, a Syrian by birth, succeeded Pope Pius, according to Eusebius, in the year 157; but, according to other writers, at a somewhat earlier period. In his time, the Gnostic doctrines of Valentine and Marcion prevailed at Rome; but many of the persons who adopted them were reclaimed by Polycarp, who came from Smyrna to Rome, in order to settle the controversy about the celebration of Easter. Anicetus differed with him on this point; and after a conference, each retained his own opinion, whilst both of them manifested mutual forbearance and charity. In token of their amity they communicated together at the eucharist; and Anicetus testified his respect for Polycarp, by yielding to him the honour of performing the service on the occasion. Happy would it have been for the Christian church, if the successors of Anicetus had manifested a similar disposition. Several ordinances and decrees are ascribed to this pope by modern writers, but their authority is doubtful, and therefore they are not worthy of notice. After having governed the church 11 years, he died, as some have said, a martyr; but of this there is no sufficient evidence. The letters ascribed to him are spurious. Euseb. Eccl. Hist. lib. iv. c. 11. 14. 22. Dupin. Bower.

ANICH, PETER, a mathematician, mechanic, and astronomer, was born of obscure parentage at Oberperzuff, near Inspruck, in 1723; and discovered an early taste for the sciences of astronomy and geometry, which Father Hill, a Jesuit, and professor in the university of Inspruck, afforded him an opportunity of cultivating. In a short time he was distinguished by his knowledge both of astronomy and mechanics. He made a very curious pair of globes for the university of Inspruck, and constructed many mathematical instruments of his own invention. He also delineated maps with neatness and accuracy. He died much regretted in 1766; and the empress queen testified her respect for his memory, by settling upon his sister a pension of 50 florins. Nouv. Dict. Hist.

ANICULA, in *Conchology*, a name given by Rumphius to a species of conus, called by Linnæus and later authors, CONUS MONACHUS; which see.

ANICULUS, in *Entomology*, a species of CANCER, having an ovate thorax, ciliated at the sides, and rugged, hairy legs. Fabricius. This creature inhabits the southern ocean, and is the largest of the family *Parasitici*. The rostrum is bifid, teeth elongated and acute; the eyes cylindrical and porrected; thorax smooth, tail soft, claws and legs rugged, with hairy tufts.

ANJENGO, in *Geography*, a small town and factory, with a fort, on the coast of Malabar, belonging to the East India company. The chief trade of this settlement is pepper, and rupees are the current money. N. lat. 8° 39'. E. long. 76° 40'.

Vol. II.

ANIERES, a town of France, one league north-west from Paris.

ANIGRUS, in *Ancient Geography*, a river of Triphylia, in the territory of Elis, to the north of Lepreum. Its source was in Lepithas, a mountain of Arcadia; the inhabitants of which thought that it was the same with the Mingeus of the ancients, mentioned by Homer. Near this river was a cavern, called the cave of the nymphs *Anigrades*, or *Anigrades*, mentioned by Strabo and Pausanias; and it was pretended that any persons who had a complaint of the skin might be cured, if, after having sacrificed to the nymphs, they swam over the Anigrus.

ANIKAN, or INGHENIFRAN, a town of Africa, on the Gold Coast, where the English and Portuguese have both a factory and a fort.

ANILL, in *Botany*. See INDIGOFERA.

ANILIS, in *Entomology*, a species of MUSCA, in the Linnæan system, and BIBIO in that of Fabricius. It is villous, whitish grey, with transparent whitish wings, and is found in Europe. Gmelin.

ANILLE, in *Heraldry*, a mill-rind, or, as the French term it, a fer de moline.

ANIM, in *Ancient Geography*, a town of Palestine, situate in the mountains of the tribe of Juda, according to the book of Joshua.

ANIMA, a SOUL; whether rational, sensitive, or vegetative.

The word is pure Latin, formed of *animus*, breath.

ANIMA is sometimes used by physicians to denote the principle of life in the body.

In which sense Willis calls the blood *anima brutalis*.

ANIMA is also figuratively used by chemists for the volatile principles in bodies, whereby they are capable of being raised by the fire.

In which sense we meet with *anima jaspidis*, the soul of jasper, &c. Phil. Trans. N° 74. p. 2233.

ANIMA is more peculiarly applied to simple medicines, artfully exalted by solution and extraction, to a high degree of power.

In which sense we meet with *anima aloes*, *anima rhabarbari*, *anima veneris*, &c.

Sometimes also it denotes medicines which are peculiarly salutary to particular parts of the body. Thus we meet with

ANIMA articularum, which is a denomination sometimes given to HERMODACTYLS, on account of their efficacy in disorders of the joints.

ANIMA hepatis, soul of the liver, a term applied by the chemists to the *sal martis*, salt of iron or steel; on account of its utility in distempers of that part.

It is more usually prescribed under the name of *vitriolum martis*.

ANIMA pulmonum, used for *crocus*, or saffron, by reason of its supposed great use in diseases of the lungs.

ANIMA mundi, q. d. *soul of the world*, or of the universe, denotes a certain pure ethereal substance or spirit, diffused, according to many of the ancient philosophers, through the mass of the world, informing, actuating, and uniting the divers parts thereof into one great, perfect, organical, and vital body or animal. See PLASTIC Nature.

Plato treats at large of the *ψυχη τε κοσμου*, in his *Timæus*; and is even supposed to be the author of the *dogma*; yet interpreters are much at a loss about his meaning. Aristotle, however, taking it in the common and obvious sense, strenuously opposes it.

The modern Platonists explain their master's *anima mundi*

by a certain powerful ethereal spirit, which in the heavens exists perfectly pure, as retaining its proper nature; but on earth, pervading elementary bodies, and intimately mixing with all the minute atoms thereof, it assumes somewhat of their nature, and becomes of a peculiar kind. So the poet;

“ Spiritus iatus alit, totosque infusa per artus
Mens agitat molem, & magno se corpore miscet.”

They add, that this *anima mundi*, which more immediately resides in the celestial regions as its proper seat, moves and governs the heavens in such manner, as that the heavens themselves first received their existence from the fecundity of the same spirit: for that this *anima*, being the primary source of life, every where breathed a spirit like itself, by virtue whereof various kinds of things were framed conformable to the divine ideas.

The notion of an *anima mundi* is rejected by most of the modern philosophers; though M. du Hamel thinks without any great reason, since the generality of them admit something very much like it. Thus the Peripatetics have recourse to celestial influxes, in order to account for the origin of forms, and the secret powers of bodies.

The Cartesians have their subtle matter, which answers to most of the uses and intentions of Plato's *anima mundi*; being supposed to flow from the sun, and the other heavenly bodies, and to be diffused through all the parts of the world, to be the source or principle of all motion, &c.

Some later philosophers, in the place of these substitute fire; and others a subtle elastic spirit, or *medium*, diffused through all parts of space.

The principal thing objected to, on the Christian scheme, against Plato's doctrine of the *anima mundi*, is, that it mingles the Deity too much with the creatures; confounds, in some measure, the workman with his work, making this, as it were, a part of that, and the several portions of the universe so many parts of the godhead. Yet is the same principle asserted by Seneca, Epist. 92. *Totum hoc quo continemur, & unum est, & Deus. Et socii ejus sumus, & membra*—

ANIMA gemmarum, a term used by Becher and some others, to express that principle, to which the gems, and other beautiful stones owe their colours.

This *anima lapidum* is no more than the metalline sulphur to which these stones and gems, naturally colourless, owe their tinges; and, like other metalline sulphurs, it may be raised and evaporated by fire. Becher, Phys. Subt.

ANIMA saturni, the soul of lead, a preparation of lead, serving to many purposes in the enamel work. The method of making it is this: put litharge, powdered fine, into a glazed earthen vessel, and pour distilled vinegar upon it to the height of four fingers; let it stand till the vinegar is of a white or milky hue; pour off this coloured vinegar and put on fresh, and so do till the vinegar will no longer be coloured by the litharge; then set these liquors together in open glazed earthen vessels, that the white powder may subside, and the vinegar be poured off clear. This white substance is the *anima saturni*. Sometimes this white matter will not precipitate without the addition of water; and sometimes it is necessary to evaporate the liquors, but by that means it is always prepared. Neri's Art of Glass, p. 184.

ANIMACHA, or *ANIMACA*, in *Geography*, a river of India, in Malabar, which rises in Calicut, and discharges itself into the sea, in the vicinity of Cranganor.

ANIMADVERSION, formed of *animus*, the mind, and *adverto*, I turn to, sometimes signifies correction, and sometimes remarks or observations made on a book, &c. and

sometimes a serious consideration and reflection on any subject, by the rules of criticism.

ANIMAL, in *Natural History*, an organized and living body, endowed with the powers of sensation, and of spontaneous loco-motion. The word is derived from *anima*, soul, and literally denotes something that is endued with a soul. Boerhaave defines an animal to be an organical body, consisting of vessels and juices, and taking in nutrition by a part called the mouth; whence it is conveyed into another called the intestines, into which it has roots implanted, whereby it draws in its nourishment after the manner of plants. The imperfection of this definition is obvious, not merely as it excludes the sentient principle, but because it distinguishes the animal by the instruments or means of its nutrition, which it possesses in common with vegetables, and which, notwithstanding some variation in their form and structure, are not sufficient to constitute an essential distinction. Dr. Tyson fixes the criterion of an animal in the “*ductus alimentalis*,” i. e. a gula, stomach, and intestines, all which make one continued canal; but this definition is liable to the same objection with that of Boerhaave. Some, as Klein and others, have defined animals, from their loco-motion, as being capable of shifting from place to place, whereas plants adhere to the same subject. This property they assume as the great characteristic by which animals may be distinguished from the other orders of beings. On this principle, however, oysters, muscles, cockles, &c. would be almost excluded from the class of animals, inasmuch as they usually adhere, or grow to rocks, &c. and yet it is certain that these creatures are real animals. But loco-motion alone is not sufficient to constitute the generic difference of animals; nor indeed does it sufficiently distinguish an animal from a plant. Many instances are produced, in which plants manifest loco-motive power. This is the case with those denominated sensitive plants, many of which, upon the slightest touch, shrink back, and fold up their leaves; as the snail, on the slightest touch, retires into its shell. There are some, on which if a fly perches, instantly close and crush the insect to death. Plants also change their position and form in different circumstances and seasons; they take advantage of good weather, and guard themselves against bad weather; they open their leaves and flowers in the day, and close them at night; some close before sun-set, and some after; some open to receive rain, and some close to avoid it; some follow the sun, and some turn from it; the leaves of some plants are in constant motion during the day, and at night they sink to a kind of rest or sleep. It has also been observed that a plant has a power of directing its roots for procuring food; and that it has a faculty of recovering its natural position, after it has been forced from it. A hop-plant, for instance, in twisting round a pole, directs its course from south to west, as the sun does; if it be tied in the opposite direction, it dies; but if it be left loose in this direction, it will regain its natural course in a single night. A honey-suckle proceeds in a certain direction till it be too long to sustain itself; it then acquires strength by shooting into a spiral form; and if it meet with another plant of the same kind, both these coalesce for mutual support, one twisting to the right and the other to the left. Lord Kaimes mentions many other instances in which plants manifest a faculty of loco-motion; and, perhaps, in almost as eminent a degree as some animals. Muscles, e. g. are fixed to one place as much as plants; nor have they any power of motion, besides that of opening and shutting their shells; nor do they seem, in this respect, to have any superiority, with regard to the powers of motion, to the sensitive plant and others of a similar kind.

In order, therefore, to form a complete and satisfactory distinction between animals and vegetables, as well as minerals, it is necessary to combine with spontaneous locomotion, which they unquestionably possess in a more perfect degree than plants, the powers of sensation. These seem to be unexceptionably distinguishing and characteristic. However, M. Buffon (*Nat. Hist.* by Smellie, vol. ii. p. 6.), after allowing that, although progressive motion constitute a perceptible difference between an animal and a vegetable, this distinction is neither general nor essential; proceeds to state, that sensation more essentially distinguishes animals from vegetables. But he adds, that this distinction is neither sufficiently general nor decided. If sensation, he says, implied no more than motion consequent upon a stroke or impulse, the sensitive plant enjoys this power; whereas, if by sensation we mean the faculty of perceiving, and of comparing ideas, it is uncertain whether brute animals are endowed with this faculty. If it should be allowed to dogs, elephants, &c. whose actions seem to proceed from motives similar to those by which men are actuated, it must be denied to many species of animals, particularly to those that appear not to possess the faculty of progressive motion. If the sensation of an oyster, *e. g.* differ in degree only from that of a dog, why do we not ascribe the same sensation to vegetables, though in a degree still inferior? In examining the distinction which arises from the manner of feeding, he observes, that animals have organs of apprehension, by which they lay hold of their food: they search for pasture, and have a choice in their aliment. But it is alleged, that plants are under the necessity of receiving such nourishment as the soil affords them, without exerting any choice in the species of their food, or in the manner of acquiring it. However, if we attend to the organization and action of the roots and leaves, we shall soon be convinced, that these are the external organs by which vegetables are enabled to extract their food; that the roots turn aside from a vein of bad earth, or from any obstacle which they meet with, in search of a better soil; and that they split and separate their fibres in different directions, and even change their form, in order to procure nourishment to the plant. From this investigation he concludes, that there is no absolute and essential distinction between the animal and vegetable kingdoms; but that Nature proceeds by imperceptible degrees from the most perfect to the most imperfect animal, and from that to the vegetable; and that the fresh-water polypus may be regarded as the last of animals and the first of plants. After examining the distinctions, this author proceeds to state the resemblances which take place between animals and vegetables. The power of reproduction, he says, is common to the two kingdoms, and is an analogy both universal and essential. A second resemblance may be derived from the expansion of their parts, which is likewise a common property, for vegetables grow as well as animals; and though some difference in the manner of expansion may be remarked, it is neither general nor essential. A third resemblance results from the manner of their propagation. Some animals are propagated in the same manner, and by the same means, as vegetables. The multiplication of the sacceron, or vine-creeper, which is effected without copulation, is similar to that of plants by seed; and the multiplication of the polypus by cuttings, resembles that of plants by slips. Hence it is inferred, that animals and vegetables are beings of the same order, and that Nature passes from the one to the other by imperceptible degrees; since the properties in which they resemble one another are universal and essential, while those by which they are distinguished are limited and partial. Dr. Watson, bishop of Llandaff, has examined, with his usual judgment, the distin-

guishing marks between animals and vegetables. See *Ess.* iii. in the fifth volume of his *Chemical Essays*, 12mo. 1787. He rejects, as insufficient, both *figure* and *spontaneous motion*; and if *perception* be substituted in their stead, it will be found to be a criterion that is in many respects liable to exceptions. However, the ingenious and learned prelate produces many chemical, physical, and metaphysical reasons, which serve to render the supposition not altogether indefensible, that vegetables are endowed with the faculty of perception. Dr. Percival, likewise, in a paper read before the Literary and Philosophical Society of Manchester, produces several arguments to evince the perceptive power of vegetables. From the reasoning adduced by both these ingenious writers, of which a more particular account will be given in the sequel of this work (see *PLANTS and VEGETABLES*), those who duly advert to it, will, we conceive, incline to the opinion, that plants are not altogether destitute of perception. But on a question that has perplexed and divided the most ingenious and inquisitive naturalists, it is very difficult to decide. If we extend to the vegetable kingdom that kind of vitality with which sensation and enjoyment are connected, there will remain no discernible boundary between this and the animal kingdom; and that which has been considered as the distinctive characteristic of animals, and by which they are separated from vegetables, will be abolished. For a discussion of this question more in detail, see *BRUTE, INSTINCT, Physiology of PLANTS*, and particularly the article *SENSATION*. Before we close this article, we shall add, that the principle of self-preservation belongs to all animals; and it has been argued, that this principle is the true characteristic of animal life, and that it is unquestionably a consequence of sensation. There is no animal, when apprehensive of danger, that does not put itself into a posture of defence. A muscle, when it is touched, immediately shuts its shell; and as this action puts it into a state of defence, it is ascribed to a principle of self-preservation. Those who adopt this reasoning, allege, that vegetables do not manifest this principle. When the sensitive plant, for instance, contracts from a touch, it is no more in a state of defence than before; for whatever would have destroyed it in its expanded state, will also destroy it in its contracted state. They add, that the motion of the sensitive plant proceeds only from a certain property called *IRRITABILITY*; and which, though possessed by our bodies in an eminent degree, is a characteristic neither of animal nor vegetable life, but belongs to us in common with brute-matter. The sensitive plant, after it has contracted, will suffer itself to be cut in pieces, without making the least effort to escape. This is not the case with the meanest animal. An hedge-hog, when alarmed, draws its body together, and expands its prickles, thus putting itself in a posture of defence. When thrown into the water, the same principle of self-preservation prompts it to expand its body and swim. A snail, when touched, withdraws itself into its shell; but if a little quick-lime be sprinkled upon it, so that its shell is no longer a place of safety, it is thrown into agonies, and endeavours to avail itself of its loco-motive power, in order to escape the danger. Muscles and oysters also, though they have not the power of progressive motion, constantly use the means which Nature has given them for self-preservation.

We ourselves possess both the animal and vegetable life, and ought to know whether there be any connection between vegetation and sensation, or not. We are conscious that we exist, that we hear, see, &c. but of our vegetation we are absolutely unconscious. We feel a pleasure in gratifying the demands of hunger and thirst; but we are totally ignorant of the process by which our aliment is formed into

chyle—the chyle mixed with the blood, the circulation of that fluid, and the separation of all the humours from it. If we then, who are more perfect than other vegetables, are utterly insensible of our own vegetable life, why should we imagine that the less perfect vegetables are sensible of it? We have within ourselves a demonstration that vegetable life acts without knowing what it does; and if vegetables are ignorant of their most sagacious actions, why should we suppose that they have any sensation of their inferior ones; such as contracting from a touch, turning towards the sun, or advancing to a pole? As to that power of irritability which is observed in some plants, our solids have it when deprived both of animal and vegetable life; for a muscle cut out of a living body will continue to contract, if it be irritated by pricking, after it has neither sensation nor vegetation. The following moral reason has also been suggested against believing vegetables to be endued with sensation: if this were the case, they would suffer pain when they were cut or destroyed, and their state would be very unhappy if they had not the least power to avoid the injuries duly offered them. Accordingly it is maintained, that the goodness of the Deity is conspicuous in not giving to vegetables the same sensations as to animals; and as they have no means of defence, we may conclude from this circumstance, that they were granted as food to animals. *Encycl. Brit.* On the other hand, those who are of opinion that plants possess powers of perception, allege that their hypothesis recommends itself by its consonance to those higher analogies of nature, which lead us to conclude, that the greatest possible ocean of happiness exists in the universe. The bottom of the sun is overspread with plants of the most luxuriant magnitude; and immense regions of the earth are overspread with perennial forests. Nor are the Alps, or the Andes, destitute of herbage, though buried in depths of snow: and can it be imagined that such profusion of life subsists without the least sensation or enjoyment? Let us rather, with humble reverence, suppose, that vegetables participate, in some low degree, of the common allotment of vitality; and that one great Creator hath appointed good to all living things, “in number, weight, and measure.” Percival, *ubi supra*.

For an account of the various systems that have been adopted in the distribution of animals, see *ZOOLOGY*. See also *MAMMALIA*, *BIRDS*, *AMPHIBIA*, *FISHES*, *INSECTS*, and *WORMS*. For other particulars relating to their number, analogous structure, sagacity, instinct, &c. see *COMPARATIVE ANATOMY*, with the articles referred to under that head, *BRUTE*, *GENERATION*, *INSTINCT*, *MIGRATION*, *Oviparous*, *Viviparous*, &c. &c.

ANIMALS make the principal figures in *Heraldry*, both as bearings and as supporters, &c.

ANIMAL is also used adjectively to denote something that belongs to, or partakes of, the nature of an animal body. Thus we say *animal food*, *animal economy*, &c.

Moralists frequently oppose the *animal* part, which is the sensible, fleshy part of a man, to the rational part, which is the understanding.

ANIMAL actions are those peculiar to animals, or which belong to animals as such:

Such are *SENSATION* and *MUSCULAR MOTION*.

ANIMAL carib. See *EARTH*.

ANIMAL flower, a name indiscriminately applied to a variety of different creatures in the *VERMES* tribe, that bear some resemblance to a flower; and is synonymous with *sea anemone*, *urtica marina*, or *sea-nettle*, &c. These, for the most part, belong to the *mollusca* order in the Linnæan system, as the *actinæ*, and *holothuriæ*; yet the same is given

to the *tubulariæ* and *hydræ*, which belong to an entirely different order, the *zoophyta* of Linnæus. See *ACTINIA*, *ANEMONE*, (*sea*), *HOLOTHURIA*, *TUBULARIA*, and *HYDRA*.

ANIMAL functions, among *Physicians*. See *FUNCTION*.

ANIMAL gluc. See *GLUE*.

ANIMAL gods, *dii animales*, in *Mythology*, those into which human souls are converted by means of certain religious ceremonies.

Labeo has written expressly on the animal gods.

ANIMAL heat. See *HEAT*.

ANIMAL hunger. See *HUNGER*.

ANIMAL liquors. The common opinion is, that all the animal liquors, excepting chyle and milk, are of an alealescent nature; but M. Quesnay, in his book *Sur l’Oeconomie Animale*, affirms, that our gelatinous liquors contain a very accelescent salt, capable of resisting a heat of two hundred degrees. The proof of which, says he, offers itself daily to every one: who is it that has not remarked, that broth made with flesh, well freed from fat, when corrupted, becomes as sour as verjuice? The foundation on which M. Quesnay builds his doctrine concerning animal liquors, is the separation of milk into its oily, cheesy, and watery substances. *Med. Ess. Edinb.*

ANIMAL magnetism. See *MAGNETISM*.

ANIMAL manures, in *Agriculture*, are all such as are formed from the decomposition of animal substances of any kind, as flesh, blood, hair, wool, bones, fat, &c. Agricultural writers consider them, in general, as more powerful in their effects, in promoting vegetation, than such as are derived from vegetable matters. However, on account of their being seldom procured in large quantities, they are mostly made use of in the state of mixture or combination with other materials, either of the earthy or littersy kinds; in both which cases they may be highly beneficial. In the former by the action of the ammoniac, which is constantly formed in large quantities, during the decomposition and decay of animal matters on the mould, and rendering it more suitable for the support of plants; and, in the latter, by their well known property of promoting fermentation, and thus hastening the reduction of the materials into the state of manure. See *MANURE*.

ANIMAL matter, in *Chemistry*. The ancient division of all natural bodies into the three grand classes of *mineral*, *vegetable*, and *animal*, a division founded upon simple observation, and not upon pre-conceived theory, may still be retained as a classification of some practical utility to the chemist, though infinitely less so than to the physiologist.

A complete knowledge of the chemistry of animal matter would comprehend an intimate analysis of all the materials out of which it is formed, and of their mode of combination; whereby, from a few simple elements, the great variety of aliments used by the living animal are produced: it would also require a minute examination into the process of digestion and assimilation of food, step by step, in order to trace the curious and interesting conversion of inanimate matter into an integrant part of the living animal; and more than all, it would include an investigation into the most secret recesses of nature, in order to determine how far the known laws of chemical affinity are affected by animal organization, and by the vital principle. The very imperfect progress which has been made in this branch of chemical inquiry shews the great and almost insuperable difficulties which attend its pursuit; and, notwithstanding the real discoveries made by modern chemists, and the self-complacency with which they are so often brought forward, little else can be related on the chemistry of animal matter, than a collection

lection of detached facts and unconnected experiments, from which no plausible theory of the process of animalization has been deduced, and but little assistance has been afforded to the science of physiology, and perhaps still less to the cure of disease.

Before we enumerate the particular parts of animal matter which have afforded the greatest scope to chemical experiment, it may be proper to premise a few remarks on the materials out of which animal matter is formed; on the mode in which they are elaborated within the living body; and on the chemical properties which appear to be common to every part of the animal kingdom.

Two principal functions, possessed, apparently, by every living creature, prepare the materials out of which the animal body is constituted, and from which it draws perpetual supplies: these are, *digestion* and *respiration*.

The food taken in by the mouth is the most obvious and abundant source of supply to the body; and this cannot be said to have become an integrant part of the animal which receives it, till it has been prepared in the stomach by the process of digestion, and till the chyle, or nutritive part which it furnishes, has been further assimilated in the lymphatics, and, at last, added to the mass of circulating blood.

The vegetable kingdom furnishes, directly or indirectly, the whole of alimentary matter, except the common diluent, water. Hence, chemists have with great propriety directed much of their inquiries relating to this subject, to an examination of the characteristic differences which exist between vegetable and animal matter in general, and some important facts have appeared, which we shall presently relate. The *ultimate* analysis of vegetables, or that which reduces them to their simplest forms, furnishes us with very few materials. Of these, water is by far the most abundant ingredient; carbonaceous matter the next in quantity, and equally constant; and chemical analysis will also shew a certain portion of hydrogen and of oxygen unconnected with the composition of water, and a few saline and earthy parts, which, from their constant occurrence, have a claim to be considered as necessary constituents of vegetable matter. In tracing the decomposition of vegetable aliment, however, it should be remembered, that these materials are presented to the animal organs, not merely as so much hydrogen, carbon, and oxygen, but in the intermediate and already very compounded forms of farina, sugar, mucilage, and the like; forms in which their tendency to chemical change is much stronger than when they are reduced to their simplest mode of existence.

With regard to that very large proportion of aliment which is furnished from the animal kingdom itself, forming so much of the food of man, and the whole nutriment of many entire classes of living creatures, this, it is obvious, is still produced indirectly from vegetable matter, and the art of chemistry has not yet been able to detect any very sensible difference between the first, and the subsequent results of assimilation by animal organs. The most accurate chemical analysis could not determine with any certainty, whether a given portion of animal substance was a part of a carnivorous or a herbivorous animal; and this single circumstance shews, perhaps, as much as any other, the very imperfect state of our knowledge of the changes produced during digestion in the living organs.

A chemical change equally important with digestion, and still more uniform and constant in its operation, is the action of the external air on the animal fluids through the medium of respiration. The part which immediately receives the action of the air, is the blood whilst circulating in the extreme branches of the pulmonary arteries and veins in the cells of

the lungs. Under the articles *RESPIRATION*, and *BLOOD*, we shall relate more at large the facts that have been discovered by the successive labours of some of the most ingenious philosophers which the world has produced, which prove incontrovertibly the analogy between this process and that of combustion, and its connexion with the animal temperature. There can be no doubt that respiration is a chemical process, the operation of which, as it is exerted on the general mass of circulating fluid, is extended through every part of the living body; and perhaps its effects are more peculiarly and exclusively *chemical*, than most of the other animal functions. Respiration too may properly be considered as the last step in the process of the assimilation of food, since the chyle, when thoroughly elaborated, is thrown into the mass of blood returning to the heart, whence it directly passes to the lungs (entirely in some classes of animals, and partially in others), and is subjected to the chemical action of the external air, before it renews the round of circulation to supply the different purposes of the body.

As a defective respiration, in the case of original mal-conformation as well as of disease, produces a train of disorders which are very strongly and pointedly marked, we may infer that the chemical analysis of the several parts of the body, if we had the means of sufficient accuracy of examination, would readily indicate the deficiency in so powerful a chemical agent as the atmospherical air. Opportunities for such an examination have not, however, been sufficiently frequent, nor is it certain that, in the present state of chemical knowledge, they could be rendered very conclusive.

In considering the mode whereby alimentary matter is *assimilated*, or undistinguishably blended with the solids and fluids of the living animal in which this function is going on, a very interesting inquiry presents itself, namely, to determine how far this process is purely *chemical*, (that is, conducted by the same laws of simple and complex affinity which operate on inanimate matter), and how far it is affected by the circumstances of the *living principle*. In favour of the former opinion the following arguments may be urged:—first, that the food, whether derived from the vegetable, or the animal kingdom, or from a mixture of both, is a substance which strongly tends to spontaneous decomposition, in whatever situation it is placed; and that, *ceteris paribus*, it is more or less digestible in proportion to its greater or less disposition to chemical change. Likewise, as we have before mentioned, it is already a very compounded mixture, composed of simple elements indeed, but united by very complex affinities; and when in the form of animal flesh, of vegetable farina and the like, it is infinitely more liable to chemical change than if it were reduced to its elementary parts. Secondly, it may be urged, that a part at least of the preparation which the food undergoes in the organs of digestion is obviously a series of chemical processes. By the action of the teeth, of the gizzard, and similar apparatus, the mechanical process of *comminution* is performed: to this succeeds *maceration* in the saliva, in the gastric liquor, and in other animal secreted juices: the contractile power of the stomach affords constant *pressure* and *agitation* to the materials which it contains: a separation of the different parts of the heterogeneous mass under digestion, or a species of *filtration*, is performed by the lacteals and the mesenteric glands: during the course of circulation, a most intimate *mixture* takes place between the fresh supply of nutritive matter from the aliment, and the animal juices already contained in the vessels; and lastly the newly assimilated chyle undergoes a process similar to *combustion*, whilst in a state of intimate division within the ultimate ramifications of the pulmonary

pulmonary vessels. To this it may be added, that the temperature of the animal in which these several processes are carrying on, is found by experiments out of the body to be highly favourable to that gradual and complex chemical change which educes from animal or vegetable matter the greatest variety of important products.

Thirdly, it may be alleged, in answer to the forcible objection which will immediately arise to an explanation of digestion on purely chemical principles, from the impossibility of carrying on the same process *out* of the body, that the chemist cannot imitate animal digestion, because he has not all the materials at command, and especially because he cannot construct, by mechanical means, any apparatus resembling in the most distant degree the curious, beautiful, exquisitely elaborated and complicated organs which nature has furnished for this important process. This imitation has appeared so hopeless, that no such attempt has, to our knowledge, been made; for the valuable and interesting experiments of the late eminent physiologists, Spallanzani and Hunter, on what may be called, a partly *artificial* digestion, which will be mentioned in a future part of this work, do not come under this point of view.

It is far from our intention, however, to deny that in this, as well as in other functions of the body, the vital principle is to be esteemed as an agent *sui generis*, of the highest importance; and, from the disturbance which certain affections of the nervous system will directly produce on the whole process of digestion, we cannot, perhaps, at any period trust to merely chemical facts for an explanation of its phenomena. The difficulty of investigation into the subject, which at all times is great, is moreover constantly increasing in proportion as the process of assimilation advances, and at last becomes insurmountable, from the impossibility of gaining access to the interior parts of the animal structure, without producing a total derangement of the functions, and destroying life.

The chemist must, therefore, content himself with examining in detail the properties of animal matter, wherein very sensible differences may be detected, both between different parts and organs, and between the same parts and species, taken at the several periods of life, at different states of activity, and under the various circumstances of health and disease.

Chemists have long directed their attention to discover some characteristic properties common to every species of animal matter, whereby it might be distinguished from the products of the vegetable kingdom. Formerly the method of analysis was principally directed to the process of distillation in a retort, by a heat, at first gentle, and afterwards increased gradually, till every part of the animal matter was volatilized, and only a fixed residue of very difficult combustion, called *caput mortuum*, remained in the retort. The difference between animal and vegetable matter, when subjected to distillation, is highly important, and is well laid down by the celebrated Neuman, one of the most skilful and accurate chemists of his time. "Animal substances," he observes, "a few excepted, on being distilled in close vessels, by a strong fire, give over, not a manifest acid liquor as vegetables do, but an urinous or volatile alkaline one, and commonly more or less of a concrete volatile alkaline salt, together with an empyreumatic oil more fetid than the oils of vegetables, and of a different kind of factor. On calcining the remaining coal in open vessels, and elixating the ashes with water, we sometimes obtain a portion of a kind of fixed saline matter, but very rarely a perfect alkali, like that extracted from the ashes of vegetables." In the analysis by fire, therefore, the production of ammonia,

or volatile alkali, is the most striking circumstance which characterizes animal matter; and hence the preparation of sal ammoniac, salt of hartshorn, and a variety of the ammoniacal salts, from the distillation of horn, bones, urine, camel's dung, and other animal matter, which forms a very extensive branch of chemical manufactures.

Animal putrefaction, considered as a method of chemical analysis, gives results similar to those of distillation, particularly in the production of the volatile alkali; and hence it has long been remarked by the manufacturers of this alkali, that the product is much increased by suffering the materials to undergo a certain degree of putrefaction.

Chemists, however, were fully aware that the existence of ammonia, in its alkaline state, in fresh animal matter, could not with certainty be inferred from its appearance after distillation, but only the presence of the materials out of which the volatile alkali may be composed. So, the author last quoted expressly observes, that "the volatile alkalis obtained from animals are artificial productions, never found to exist naturally in any animal substance in its perfect state. They are generated by the action of fire, and by putrefaction, and not by any known power besides."

The method of analysis, by simple distillation, has another imperfection (besides that of the introduction of an alkali, formed by the process, and not previously contained in the substance examined), which is, that it confounds in a few common products of distillation, a variety of parts, which in their natural state possess very specific and distinguishing qualities. This is particularly the case with those active and acrid substances, which produce such powerful effects, either as medicines or poisons. It cannot but be a very imperfect analysis which exhibits no striking difference between the mildest and the most acrimonious substances; between the common articles of food, and those animal products of which the minutest portion introduced into the living body is capable of exciting the most violent commotions.

Modern chemistry has added to the analysis by fire, the use of a more refined and delicate mode of experimenting, the advantage of which we shall presently shew; though it must be confessed that it still throws little, if any, light on those inquiries into the animal body which are the most interesting to the naturalist and physician.

Another important difference between animal and vegetable matter when analysed by fire, is found in the fixed residuum which remains after distillation in close vessels. In vegetable matter this is composed principally of charcoal, in a very pure and easily combustible state, and of a small proportion of vegetable ashes, from which a fixed alkali is procurable. In animal matter, the coal which remains is very difficult of combustion, and leaves, for the most part, a large proportion of PHOSPHORIC salts, generally united with lime. Likewise, if the animal matter be mixed with a fixed alkali before calcination, the PRUSSIC acid, a substance peculiarly of animal origin, is found in the residue of combustion.

The great energy with which the nitrous acid acts upon almost every substance immersed in it, has long rendered it a most valuable instrument of analysis to the chemist; but as this acid is itself more or less decomposed in by far the greater number of operations in which it is employed, a previous knowledge of the intimate nature of this acid is requisite, in order to enable the chemist to explain the appearances which it produces when in chemical action. This having been obtained by the ingenious researches of several eminent chemists, among whom we may particularly mention the names of Cavendish and Priestley, the use of the nitrous acid has thrown considerable light on the nature of

animal matter. The experiments of M. Berthollet on this subject (Mem. Acad. des Sciences, 1780 and 1785), are so complete and original, as to leave little further to be done by subsequent experimenters, to explain the ultimate composition of the great mass of animal matter.

M. Berthollet began his operations by treating various animal substances with nitrous acid, in the same method which Bergman had pursued in order to obtain that acid from sugar, which has been termed the *saccharine* or *oxalic*. He chose silk for his first experiment, on account of the apparent uniformity of its composition. On distilling silk with seven or eight times its weight of nitrous acid, it was soon attacked by the acid, gave out copious red fumes, and presently dissolved into a clear bluish liquor. This, on cooling, yielded a considerable quantity of crystals of oxalic acid, exactly similar to that obtained from sugar by a similar treatment. Besides this acid, however, there was found swimming on the surface of the liquor, when cooled, a quantity of oily or greasy matter, which again dissolved by heat, and remained in intimate combination with the solution of the oxalic acid. To obtain this greasy matter, M. Berthollet observes, less of the nitrous acid should be used than is necessary to give the largest product of oxalic acid.

This excellent chemist then repeated the experiment with a variety of animal matters, in all of which he found similar results, though with a wide difference in the respective proportions of animal grease, and oxalic acid. Of all the substances used, wool was found to give the greatest quantity of oxalic acid. From six gros M. Berthollet obtained somewhat more than half the weight of the crystallized acid, whereas sugar itself only gives about one third of its weight. Skin and hair gave nearly the same results as wool. On the other hand, animal muscle or flesh, deprived as much as possible from any adhering fat, yielded, with nitrous acid, a very large portion of the abovementioned grease, and a very small quantity of oxalic acid, which could hardly be separated by crystallization from the grease which the liquor contained. Sixteen ounces of veal, reduced by drying to four ounces, yielded three gros (eight of which make an ounce) of oxalic acid, and a small portion of grease. Thirty-two ounces of whites of eggs, hardened by boiling, and reduced by drying to two ounces, gave two gros and a half of acid, and a moderate quantity of grease.

The author then proceeds to some remarks on the nature of this peculiar greasy matter, which deserve attention.

Vegetable substances, he observes, though certainly containing oil in their composition, when treated with nitrous acid, have their oil so entirely destroyed by its action, that no traces of it can be detected after this operation. Animal matter, on the contrary, always yields more or less of an oily or greasy substance after distillation with nitrous acid, which grease in part adheres strongly to the oxalic acid, and makes it difficult of crystallization, and in part combines with the distilled acid, giving it an unusual yellow colour, and the disagreeable odour of all animal oils. This latter portion may be separated chiefly, but not entirely, by saturating the acid with an alkali, when the animal oil concretes into a stiff grease.

The animal oil differs also from the vegetable, particularly in giving much volatile alkali by distillation, whereas the vegetable yields an empyreumatic acid. It is to be observed, that the oil, both animal and vegetable, which is here spoken of, is not that which in animals is separated in the form of fat, and is secreted in the cells of the adipose membranes; and in vegetables, is deposited in the oil cells of seeds and fruits, or united with mucilage and farina in the emulsive plants; but it is an oil which seems to be most intimately united with every animal and vegetable substance, and never

appears in the form of oil or grease, unless when separated by some powerful chemical agent, such as the nitrous acid.

We have mentioned it to be the most striking characteristic of animal matter, to yield a certain quantity of ammonia by distillation *per se*; and we shall now return to this subject, which indeed is directly connected with all that has preceded, and examine into the cause of this product. Under the article AMMONIA, we mentioned how much chemistry was indebted to the successful labours of M. Berthollet for a knowledge of the exact proportion of the constituent parts of this alkali, and particularly of the theory of its production during the decomposition of animal matter.

Ammonia is formed of about three parts of azot, or animal mephitis, as it is sometimes termed, and one of hydrogen. A simple and convincing proof that it is not originally contained in animal matter in the form of an alkali, is, that after animal substances have been dissolved in nitrous acid, no nitrated ammonia can be detected by the minutest examination. But the constituent parts of the volatile alkali must be contained in the animal matter, otherwise it could not yield it by simple distillation. Dr. Priestley has observed, that when animal flesh is immersed in nitrous acid, there is an immediate disengagement of gas which is chiefly phlogisticated (*azotic*) air, but sometimes mixed with nitrous gas, and with fixed air. With the same view, M. Berthollet added to an ounce of silk (Mem. Acad. des Sciences, 1785), six ounces of concentrated, pale, nitrous acid, at the temperature of 70°. Nearly 120 ounce measures of gas were disengaged without heat, of which a small part was absorbed by lime water, and was fixed air, and the remainder gave all the appearances of azotic air. The silk being entirely dissolved, a small portion of the greasy matter which we have mentioned above, concreted, and was separated from the solution. Lime-water being added, no precipitation took place, which was a proof that no oxalic acid had yet been formed by the action of the nitrous acid, for, adding afterwards a drop of oxalic acid, an immediate precipitate appeared. The solution being then gently warmed, a violent effervescence took place, nitrous gas was given out in abundance, with the production of much heat, and the solution *now* contained a considerable quantity of oxalic acid. From this experiment it appears, that there are two distinct periods of the operation of nitrous acid on animal matter; the first, its action without heat; the second, after heat has been applied. The first produces a large portion of nearly pure azotic gas, and it is interesting to determine whence is its origin, as azot is a constituent part of nitrous acid, as well as of animal matter; it is rendered highly probable, however, that the azotic gas produced in the first instance, owes its origin to the animal matter, and not to the nitrous acid, since the latter is capable of acting afterwards with equal energy, as if heat had been applied immediately, and of giving as much nitrous gas. Moreover, M. Fourcroy has observed, that the nitrous acid, after being digested *without heat* upon animal matter, is able to saturate as much alkali as before the process, which is as convincing a proof of its non-decomposition as we can well have. Therefore, we may consider it as well established, that when nitrous acid and animal matter are digested together, without using artificial heat, the azotic gas which is produced in such abundance arises solely from the animal substance; that at this period no oxalic acid is formed, but some of the peculiar greasy matter is produced. Afterwards, on heating the mixture, the nitrous acid is itself rapidly decomposed, forming the nitrous gas which escapes, and giving its oxygen to that part of the animal matter which furnishes the basis of the oxalic acid, besides probably occasioning other changes

ANIMAL MATTER.

changes in which, as the component parts of the nitrous acid are also found in animal matter, the exact operation of the materials furnished by each cannot be distinguished.

The proof of the existence of azot in animal matter being thus established, we can readily account for the formation of ammonia during distillation *per se*, or putrefaction, by an union of the animal azot with hydrogen, which may be furnished ally from the animal substance, perhaps from the decomposition of water, which is abundantly contained in every part of the animal kingdom.

Another proof of the connexion between the azot of animal matter, and the production of ammonia, has been furnished in the following ingenious manner by M. Berthollet. For this purpose he made comparative experiments between the inflammable air of marshes, the gas furnished by the distillation of sugar, of charcoal, and of oil, and the gas yielded by silk distilled *per se*. Of these four latter substances (for the former may be neglected for our present purpose), the sugar, charcoal, and oil, are vegetable, and give no ammonia by distillation; the latter is animal, and, like all animal matters, produces this alkali. The gas furnished by each was exposed to lime water, and detonated with oxygen, in order to absorb every thing but the azot. Now, as the silk, being of animal origin, contained much more azot than the other substances, it ought to have left a much greater residuum of azotic gas, unless the latter entered into some new combination during the distillation of the silk, by which its form of azotic gas would be lost. As the residuum was not sensibly greater than the rest, the azot must have assumed a new form during distillation, and this could have been no other than the volatile alkali which was directly dissolved in the water, through which the distilled gasses passed unto the recipient.

Experiments of a later date than those of M. Berthollet, just cited, have shewn a disengagement of azotic gas, or a production of ammonia from animal matter, by the action of some other of the more powerful acids, and even of the fixed alkalies; but the operation of these is not yet satisfactorily explained, nor does it illustrate in so striking a manner the composition of the animal kingdom.

The limits between animal and vegetable matter, laid down by the presence of azot and the production of ammonia, though for the most part sufficiently precise, are, in a few instances, surpassed.

These are, by those vegetable products, which have been termed *vegeto-animal*, because they resemble certain corresponding animal matters in the characteristic properties above mentioned.

The *gluten* of wheat, and some other parts of vegetables, bears a considerable affinity to animal gluten in various properties, and, like it, contains azot, and yields ammonia. The *albumen* found in the fresh juice of the succulent parts of the tetradynamous plants, is equally similar to the albumen of animals; and the vegetable fungi, when under putrefaction, exhibit to the chemist appearances strongly resembling those of decomposing animal matter.

In the analysis of animal matter, we have principally dwelt on the operation of the nitrous acid, as it has been the means of elucidating this subject in a peculiar manner, and as it furnishes a method of comparison by which the action of other chemical agents may be inferred with considerable accuracy. A few words should, however, be said on the operation of other re-agents in analysis.

The effect of heat on animal matter varies according to the degree which is applied. A gentle warmth simply dissipates the watery part, during which operation the sub-

stance generally loses a great part (sometimes by far the greatest) of its weight and bulk.

Animal matter, when thus dried, is long preserved from putrefaction, as moisture is essential to this process of decomposition. So, bodies of animals that have been overwhelmed in the dry hot sands of the African deserts, are first thoroughly desiccated, and then will remain in this medium for many years unaltered. A lower degree of warmth, however, if not sufficient to evaporate the moisture from animal substance, favours putrefaction, and increases all the tendencies to decomposition. On the other hand, animal matter, so perishable in itself, is preserved to all appearance absolutely unaltered, whilst exposed to a severe freezing cold. The blood (which when at rest in a moderate temperature, even within the blood-vessels, but especially when drawn out, very speedily coagulates), if suddenly frozen before coagulation, retains for a while its original properties; and when thawed in a gentle warmth, at *first* becomes liquid, and *afterwards* coagulates. In like manner, animal flesh employed for food may be preserved, when frozen, for any length of time; and, if thawed gradually, retains all its properties, even to the peculiar flavour which it possessed at first. A degree of heat from about 150° to that of boiling water, begins to produce upon animal matter certain chemical changes independent of the mere evaporation of water: the most important of these is the coagulation of the albumen, which is an abundant and almost constant ingredient in the animal juices. Under the article of albumen we have given the opinions of chemists concerning the cause of the singular property of coagulation by heat, which, however, is still not very clearly ascertained. Albumen, when once coagulated, is no longer soluble in boiling water, and hence it may be separated with ease from any watery solution in which it may be contained. A heat considerably greater than that of boiling water causes animal matter to swell considerably, to twist in every direction as if it still retained some degree of irritability; to soften or melt down, to exhale a copious dense vapour of a foetid smell; and, according as the heat is regulated, to yield an empyreumatic oil, an ammoniacal liquor, and often the prussic acid, with a considerable quantity of carbonic and hydrogen gasses, arising from the total decomposition of the substance employed.

Water is another re-agent in the analysis of animal matter, which may often be employed with considerable advantage. All the soft parts of animals, when kept immersed in cold water for a considerable time, appear to become thoroughly penetrated with this liquor, have their texture softened, and their bulk enlarged, and yield to its dissolving power all their saline, gelatinous, and albuminous contents. This solution is likewise considerably assisted by the commencement of putrefaction, which soon takes place in moist animal matter at a moderate warmth. The gluten or coagulum of the blood is, however, insoluble in water, when it has once separated by coagulation from the circulating liquor; and hence, by long and repeated effusion of cold water, the coagulum of blood may be freed from the red globules which give it its colour, and from every other extraneous matter, and at last remains in a state of great purity, in the form of a grey, tenacious, and elastic substance. Muscular flesh may be, in like manner, brought, by mere washing with cold water, into a similar state of purity. Animal oil or fat, which is naturally mixed with a kind of mucilage, may also be freed from it by melting, and repeated mixture with water, assisted by strong agitation. Heated water is a more active agent in softening the texture of animal matter, and extracting its soluble part; and the assistance of a boiling temperature renders completely soluble every kind of condensed

denf'd animal membrane, fuch as fkin, cartilage, tendon, and the like. At the fame time, however, heat coagulates the albumen, and renders it infoluble in water, fo that to obtain the full action of water on animal matter, it fhould be ufed firft cold, or only moderately warmed, and afterwards heated to ebullition. But there is no foft part of animal matter which can refift the united action of water and heat, when a temperature much above the boiling point is employed, by means of Papin's digefter. Gluten, albumen, gelly, and falts, are then all brought down to complete folution; the oil alone, for the moft part, remaining unmixed. Papin's digefter, therefore, when judiciously employed, may prove an inftrument of fome importance in animal analysis: but its ufe is attended with this inconvenience, that the fubftances difsolved in water by its powerful affiftance, cannot be feparated from each other by any means with which we are acquainted.

The cauftic alkalis are alfo employed in the analysis of animal matter, particularly as a folver for gluten and coagulated albumen, after the action of water has been exhaufted. The folution of animal matter in alkali, which is the moft familiar to us, is that of oil or fat, forming the well-known compound, SOAP. It would be of advantage to the experimental chemift if the operation of the alkalis were here confined to the oily ingredient, as this is fo little foluble in any other menftruum. But the inconvenience of ufig thefe powerful re-agents is fimilar to that of employing Papin's digefter, for they act with great energy on all the foft parts of animals indifcriminately, and confound the whole in one faponaceous mafs. This, indeed, may be confidered in general as the principal obftacle to any fatisfactory analysis of animal matter, that all the methods which the chemift can employ, are too general in their operation, and little calculated to mark thofe fhades of difference in the animal compofition, which, though perhaps flight when chemically confidered, certainly produce very important effects on the functions of the *living* body.

The chemistry of animal matter appears to us to be ftill too little known to admit of any fcientific arrangement which can give juft and comprehensive views of this extenfive, interefting, and complicated fubject. We fhall, therefore, refer the reader to the feveral articles under their refpective heads, which include, either generic diftinctions, fuch as gluten, albumen, gelly, and the like; or fpecific folids and fluids, fuch as bone, blood, milk, fkin, &c. The detail of a variety of important experimental inquiries which have been made by feveral eminent chemifts, affords an abundance of interefting matter, which promifes a copious harveft of difcovery to the follower of this branch of chemical purfuit.

ANIMAL motion is the fame with what we call *muscular motion*.

It is divided into two branches; natural or involuntary, and fpontaneous.

ANIMAL oil, fee OIL.

ANIMAL fecretion is the act whereby the divers juices of the body are fecreted or feparated from the common mafs of blood, by means of the glands. See SECRETION.

ANIMAL fpirits are a fine fubtle juice or humour in animal bodies; fuppofed by many to be the great inftrument of muscular motion, fenfation, &c.

The ancients diftinguifhed fpirits into three kinds, *viz.* animal, vital, and vegetative: but the moderns have reduced them to one fort, *viz.* animal; about the nature of which, and the matter whence they are formed, great difputes have

VOL. II.

arifen among anatomifts, though their exiftence has never been fairly proved.

In the *History of the Royal Academy of Sciences at Paris*, an. 1750, there is an ingenious memoir on this fubject by Mr. Beitin. He undertakes to prove, that the nervous fluids, or animal fpirits, circulate; that if they depart from the brain, they return to it by the nerves. In fhort, he propofes to form the courfe of this fluid into a fystem of circulation, lefs demonftrable, indeed, to the fenfes than that of the circulation of the blood, but, in other refpects, grounded on equally folid reafons.

As it is hard to define what could never yet be brought under the judgment of our fenfes, all that we fhall here offer concerning them, is, that they muft needs be extremely fubtle bodies, which efcape all manner of examination by the fenfes, though ever fo well affifted: and pervade the trafts of the nerves, which yet have no difcovery of cavity or perforation; nor could ever by any experiment be collected; yet are conftantly moving in vaft quantities, as they muft of neceffity be, to perform all thofe mighty operations which are afcribed to them. However, the antiquity of the opinion claims fome reverence.

By the help of thefe fpirits we are furnifhed with a vaft number of precarious folutions of great *phenomena*; and without them we muft leave a great chafm in the philofophical hiftory of animal bodies; but, after all, the *phenomena* that would, in this cafe, be unexplained, are, perhaps, to us inexplicable.

They are fuppofed to be feparated in the brain from the fubtleft parts of the blood; and thence carried by the nerves to all the parts of the body, for the performance of all animal and vital functions; and the difcovery of the GALVANIC *electricity* will probably throw confiderable light on this obfcure fubject. See NERVOUS FLUID.

ANIMAL fubftances, comprehend all the component parts of animals, of what ufe or intention foever they may be.

ANIMAL foffile fubftances, thofe found buried in the earth at various depths, and embodied among various *strata*.

These are principally of four kinds: 1. Sea fhells. 2. The teeth, bony palate, and bones of fifhes. 3. The bones of land animals. And, 4. complete fifh. See FOSSILE BONES, FOSSILE SHELLS, MARINE remains, and FOSSILE IVORY.

ANIMAL fubftances, fermentative quality of. See FERMENT, and FERMENTATION.

ANIMAL fystem, imports the whole clafs of beings endowed with animal life.

In which fenfe *animal fystem* amounts to the fame with what chemifts and others call the *animal kingdom*.

ANIMAL is alfo fometimes applied, in a figurative fenfe, to artificial or moral things.

Hobbes confiders government as a huge complex animal, under the denomination of *Leviathan*.

The reafon of the appellation is founded on the analogy between an animal and a political body. The fovereign, or legiflative power, answers to the foul; the magiftrates, to the limbs or members; rewards and punifhments are the nerves; riches, the ftrength; counfellors, the faculty of memory; equity, reafon; fedition, ficknefs; civil war, death.

ANIMALCULE, ANIMALCULUM, a diminutive of animal, and applied, in a general manner, to thofe creatures whofe true figure cannot be difcerned without the help of glaffes, and more efpecially of fuch as are invifible to the naked eye.

Animalcules are ufually divided into two, and, by fome, into three diftinct fections, *vifible*, *microfcopical*, and *invifible*: the firft, though vifible, cannot be accurately dif-

cles, are much longer than the tails of tadpoles are; and it is observed, that the animalcules in the semen of fishes have tails much longer, and more slender, than those in the semen of other animals, inasmuch that their extremities are not to be discerned without the bell glasses.

These animalcules appear to be very vigorous and tenacious of life; for they have been observed to move long after the animals, from which they were taken, were dead; and seem to be peculiar to the semen, as nothing that has the least appearance of life has been yet discovered in the blood, spittle, urine, gall, or chyle.

The production of animalcula infusoria is very surprising. In four hours time, an infusion of cantharides has produced animalcules less than even the tails of those in the semen of animals; and it is said, that hot mutton gravy, secured in a phial with a cork, and afterwards set among hot ashes, to destroy as effectually as possible every living creature that could be supposed to exist in it, has, nevertheless, been found swarming with animalcules, after standing a few days.

In the Philosophical Transactions, vol. lix., is the following curious account of the animalcules produced from an infusion of potatoes, and another of hemp-feed, by the late Mr. Ellis. "On the 25th of May, 1768, Fahrenheit's thermometer 70°, I boiled a potatoe in the New River water, till it was reduced to a mealy consistence. I put part of it, with an equal proportion of the boiling liquor, into a cylindrical glass vessel that held something less than half a wine pint, and covered it close immediately with a glass cover. At the same time I sliced an unboiled potatoe; and, as near as I could judge, put the same quantity into a glass vessel of the same kind, with the same proportion of New River water not boiled; and covered with a glass cover, and placed both vessels close to each other.

"On the 26th of May, twenty-four hours afterwards, I examined a small drop of each by the first magnifier of Wilson's microscope, whose focal distance is reckoned at $\frac{1}{100}$ part of an inch; and, to my amazement, they were both full of animalcula, of a linear shape, very distinguishable, moving to and fro with great celerity; so that there appeared to be more particles of animal than vegetable life in each drop.

"This experiment I have repeatedly tried, and always found it to succeed in proportion to the heat of the circumambient air; so that even in winter, if the liquors are kept properly warm, at least in two or three days the experiment will succeed.

"What I have observed are infinitely smaller than spermatic animals, and of a very different shape: the truth of which every accurate observer will soon be convinced of, whose curiosity may lead him to compare them; and, I am persuaded, he will find they are no way akin.

"At present, I shall pass over many curious observations which I have made on two years experiments, in order to proceed to the explaining a hint which I received last January from M. de Saussure, of Geneva, when he was here; which is, that he found one kind of these animalcula infusoria that increase by dividing across into nearly two equal parts.

"I had often seen this appearance in various species a year or two ago, as I found upon looking over the minutes I had taken, when I made any new observation; but always supposed the animals, when in this state, to be in coition.

"Not hearing, till after M. de Saussure left this kingdom, from what infusion he had made his observation; his friend, Dr. de la Roche, of Geneva, informed me, the latter end of February last, that it was from hemp-feed.

"I immediately procured hemp-feed from different seedsmen in different parts of the town. Some of it I put into

New River water, some into distilled water, and some into very hard pump water. The result was, that in proportion to the heat of the weather, or warmth in which they were kept, there was an appearance of millions of minute animalcula in all the infusions; and, some time after, oval ones made their appearance. These were much larger than the first, which still continued: these wriggled to and fro in an undulatory motion, turning themselves round very quick all the time they moved forwards. I was very attentive to see these animals divide themselves; and, at last, I perceived a few of the appearance of *fig. 3. a*, as it is represented by the first magnifier of Wilson's microscope: but I am so well convinced by experience that they would separate, that I did not wait to see the operation: however, as the following sketches, which I have drawn from five other species, will very fully explain this extraordinary phenomenon, there will be no difficulty in conceiving the manner of the first. See *fig. 4. 5, 6, 7, 8*.

"The proportion of the number of these animals, which I have observed to divide in this manner, to the rest, is scarce 1 to 50; so that it appears rather to arise from hurts received by some few animalcula among the many, than to be the natural manner in which these kinds of animals multiply; especially if we consider the infinite quantity of young ones which are visible to us through the transparent skins of their bodies, and even the young ones that are visible in the young ones while in the body of the old ones.

"But nothing more plainly shews them to be zoophytes than this circumstance, that when, by accident, the extremity of their bodies has been shrivelled for want of a supply of fresh water, the applying more fresh water has given motion to the part of the animal that was still alive; by which means this shapeless figure has continued to live, and swim to and fro all the time it has been supplied with fresh water."

The preceding remarks of Mr. Ellis are particularly satisfactory, as they point out the manner in which animalcula of various other kinds may be produced by infusions of vegetable matter; but it is probable he is mistaken respecting the species generated in the infusion of hemp-feed; and which is called *volvex ovalis*, or egg-shaped *volvex*. Perhaps this is *volvex globulator*, Linn., which is usually spherical, but of an oval form at intervals, and especially at the time the infant brood is separated from the parent: for it seems at that moment to divide, and become two distinct animalcules, as Mr. Ellis mentions. Vide *Plate III. of Vermes Infusoria, Microscopical Objects, &c. &c.*

As the different species will be more fully noticed in their respective places, we shall conclude our remarks with a few observations on the doctrine of equivocal generation, and the different opinions that have arisen respecting the origin and nature of animalcules in particular. Before the invention of microscopes, the doctrine of equivocal generation, both with regard to animals and plants of some kinds, was universally received; but this instrument soon convinced every intelligent person, that those plants which formerly were supposed to be produced by equivocal generation, arose from seeds; and the animals, in like manner, from male and female. But as the microscope threw light upon one part of nature, it left another involved in darkness: for the origin of animalcula infusoria, or the spermatic animals already mentioned, remains as yet as much unknown as that of many other kinds was, when the doctrine of equivocal generation reigned in full force.

The discovery of spermatic animalcules was thought to throw some light on the mysterious affair of generation itself; and the minute creatures were imagined to be each of them individuals of the same species with the parent. Here

the infinite number of these animalcules was an objection, and the difficulty remained as great as before; for, as every one of these animalcules must necessarily be produced from a male and female, to explain their origin by animalcular generation in the same manner, was only explaining generation by itself.

This hypothesis, therefore, having proved unsatisfactory, others have been invented. M. Buffon, particularly, hath invented one, by which he at once annihilates the whole animalcular world; and in this he has been followed by several ingenious philosophers. His hypothesis is diametrically opposite to that of Leeuwenhoeck, who described many distinct species of the spermatic animalcula as living bodies, and conceived it necessary that one or more of them should penetrate, or impregnate, the ovum, to effect the purpose of generation.

From a variety of experiments made on the human semen (mas.), M. Buffon concludes, that what have been called spermatic animals, are not creatures really endowed with life, but something proper to compose a living animal; and he distinguishes them by the name of *organic particles*. The same individual kinds of animals he declares he has found in the fluids separated from the ovaria of females; and for the truth of this appeals to the testimony of Mr. Needham, who was an eye witness of his experiments. He also brings an additional proof of his doctrine from Mr. Needham's observations on the milt of the calmar, a species of cuttlefish. Here the spermatic animals, at least what have only the appearance of life, are vastly larger than in any other creature, so as to be plainly visible to the naked eye. After considering the organization of these particles very fully, he concludes, that they are not animalcula, or endowed with life; and infers, that all the moving bodies that are to be found in the infusions of either animal or vegetable substances, are of a similar nature. To discover whether all the parts of animals, and all the seeds of plants contained moving organic particles, he made an infusion of flesh of different animals, and of the seeds of more than twenty different species of vegetables; and, after remaining some days in close glasses, had the pleasure of seeing organic moving particles in all of them. In some they appeared sooner, in others later; some preserved their motions for months, and others soon lost it. Some, at first, produced large moving globules, resembling animals, which changed their figure, split, and became gradually smaller. Others produced only small globules, whose motions were extremely rapid; and others produced filaments, which grew longer, seemed to vegetate, and then swelled, and poured forth torrents of moving globules. This observation gave rise to a new system; Baron Munchausen, perceiving that the last mentioned moving globules, after moving for some time, began to vegetate, concluded they were at first animals, and then plants: an hypothesis which Mr. Ellis endeavoured to overturn, by asserting, that they were no other than the seeds of that genus of fungi called *mucor*, or mouldiness; and that their motion is owing to numbers of minute animalcules attacking them for food.

M. Buffon is not, however, content with denying life only to those beings where the signs of it are most equivocal, but includes, in the same rank of organic particles, almost every animal too small to be discovered by the naked eye; and even some of those whose motions are evidently perceptible to the naked eye. He observes, that "almost all microscopic animals are of the same nature with the moving bodies in the seminal fluids, and infusions of animal and vegetable substances. The eels in paste and vinegar, &c. are all of the same nature, and derived from the same origin.

There are, perhaps, as many beings that either live or vegetate, produced by a fortuitous assemblage of organic particles, as by a constant and successive generation. Some of them, as those of the calmar, are only a kind of machines, which, though exceedingly simple, are very active. Others, as the spermatic animalcules, seem to imitate the movements of animals. Others resemble vegetables in their manner of growth and extension. There are others, as those of blighted wheat, which at pleasure can be made alternately to either live or die, and it is difficult to know to what they should be compared. There are still others, and in great numbers, which are at first a kind of animal, then become a species of vegetables, and again return alternately to their vegetable state. The eels in paste have no other origin than the union of the organic particles of the most essential part of the grain. The first eels that appear are certainly not produced by other eels; but though they are not propagated themselves, they fail not to engender other living eels. By cutting them with the point of a lancet, we discover smaller eels issuing in great numbers out of their bodies. The body of this animal seems to be only a sheath, containing a multitude of smaller animals, which perhaps are other sheaths of the same kind, in which the organic matter is assimilated into the form of eels."

The accurate experiments of Baker, Ellis, Muller, Corti, Rosfredi, and many others, sufficiently refute the inconclusive reasoning of Buffon; and we cannot do better than conclude, in the words of a late ingenious writer, Mr. Adams, who has treated at some length on the same subject in his *Essays on the Microscope*.

"Though we can by no means pretend to account for the appearance of most animalcula, yet we cannot help observing, that our ignorance of the cause of any phenomenon is no argument against its existence. Though we are not, for instance, able to account in a satisfactory manner for the origin of the native Americans, yet we suppose M. Buffon himself would reckon it absurd to maintain, that the Spaniards, on their arrival there, found only ORGANIC PARTICLES moving about in disorder. The case is the very same of the eels in paste, to whose animation he objects. They are exceedingly small in comparison with us; but, with the solar microscope, Mr. Baker has made them a more respectable appearance, so as to have a diameter of an inch and an half, and a proportionate length. They swam up and down very briskly; the motion of their intestines was very visible; when the water dried up, they died with apparent agonies, and their mouths opened very wide. Now, were we to find a creature of the size of this magnified eel gasping in a place where water had lately been, we should certainly never conclude it to be merely an ORGANIC PARTICLE, or fortuitous assemblage of them, but a fish. Why then should we conclude otherwise with regard to the eel in its natural state, than that it is a little fish? In reasoning on this subject, we ought ever to remember, that however essential the distinction of bodies into great and small may appear to us, they are not so to the Deity, with whom, as Mr. Baker well expresses himself, 'an atom is a world, and a world but as an atom.' Were the Deity to exert his power a little, and give a natural philosopher a view of a quantity of paste filled with eels, from each of whose bodies the light was reflected as in the solar microscope; our philosopher, instead of imagining them to be mere organic particles (as the paste would appear a little mountain), would probably look upon the whole as an assemblage of serpents, and be afraid to come near them. Whenever, therefore, we discover beings, to appearance endowed with a principle of self-preservation, or whatever we make the characteristic

characteristic of animals, neither the smallness of their size, nor the impossibility of our knowing how they came there, ought to cause us to doubt of their being animated."

ANIMALIZED Matter of Vegetables. See **VEGETO-Animal Matter.**

ANIMALLY, in *Geography*, a town of Hindostan, in the Coimbatore country, 35 miles west of Daraporum, and 18 south of Coimbatore. N. lat. $10^{\circ} 40'$. E. long. 77° .

ANIMATE, **ANIMATED**, something endued with life, or a living soul.

In mechanics, *animate power* is used to denote a man, or brute; in contradistinction to *inanimate power*, as springs, weights, &c.

Naturalists and philosophers differ extremely in assigning the characters, subjects, and species of animate bodies. Some include stocks and stones in this rank; others exclude brutes themselves.

Some of the ancient philosophers have held all nature to be *animated*; that the sun, the earth, the planets, rivers, trees, stones, &c. are so many animals; others, that the whole system is only one huge animal, informed with a soul, or *anima mundi*. Plato, in *Timæo*. Morhoff. Polyh. Phil. lib. ii. p. 1. cap. 11.

ANIMATED Horse-hairs. See **GORDIUS SETA.**

ANIMATED is also used to denote a thing impregnated with vermin or **ANIMALCULES.**

In this sense the whole earth may seem to be animated; since in every part of it we meet with an infinite number of animals, either visible or invisible; they are found in air, water, earth, plants, and even in the hardest stones; and there is, perhaps, no animal known which does not breed numbers of others in the different parts of its body.

ANIMATED mercury, among *Chemists*, signifies quicksilver, impregnated with some subtle and spirituous particles, so as to render it capable of growing hot when mingled with gold.

ANIMATED needle, a needle touched with the loadstone, or **MAGNET.**

ANIMATION, signifies the informing of an animal body with a soul.

Thus the *fetus* of the womb is said to come to its animation, when it begins to act as a true animal; or after the female that bears it is *quick*, as the common mode of expression is.

The learned are not agreed about the time when the female becomes quick; some compute it at forty days after conception; others fix it about the middle of the term of **GESTATION.**

T. Fienus Gardinius, Verde, Fort. Licetus, F. de Bonnonia, have written expressly on the animation of the **FŒTUS**; Fr. Zanellis, on the animation of the **SEED.**

ANIMATION is also used by some *Mechanical Philosophers* for the act of soliciting the descent of a body, so as to give it continually new degrees of **ACCELERATION.**

ANIMATOR is also used, by *Alchemists*, for the operation of fermenting a white foliated earth, with a kind of philosophical or celestial water or sulphur.

ANIMATION is also used, in a moral or figurative sense, for the act of giving life and force to a discourse, or the like.

ANIMATION is also used by *Hermetic Philosophers*, to denote a certain state of perfection to which a body is brought by some appropriate process, in virtue whereof it becomes capable of producing some extraordinary *phenomena.*

ANIMATION, *suspended*, for the method of treatment in cases of, see **DROWNING.**

ANIME, **ANIME** & *cancaum*, in *Pharmacy*, a kind of resin, whereof there are two kinds, the *western* and *eastern.*

The *western* flows from an incision of a tree in Brazil and New Spain, and in the island of Antigua, called *courbaril*, a species of **HYMENÆA**; and by Pifo, itaiba: the liquid juice, according to Pifo, running down from the tree, sinks into the ground, and is afterwards dug up; so that the larger masses are often full of earth.

The *eastern* gum anime, which is a finer sort, is distinguished into three kinds: the first is white; the second blackish, in smell like myrrh; the third pale, resinous, and dry.

The small tears are the purest; it has little taste, but an agreeable smell; it easily breaks between the teeth, but if chewed for some time, it softens, and becomes adhesive. Laid on red-hot iron, it melts immediately, catches flame, and burns quickly away, leaving a small quantity of white ashes. It gives but little or nothing to water, but dissolves entirely in rectified spirit; the solution being of a yellow colour, with the odour of the anime, and a warm, pungent, bitterish taste. A small portion of essential oil is obtained by distilling with water a large quantity of anime. This resin has often been confounded with gum copal.

The Brazilians are said to employ anime in fumigations for pains proceeding from cold and rheumatism; they also chew it for the relief of colics and flatulencies; it has been also recommended in catarrhal and paralytical affections; and applied for complaints of this kind, bruises, &c. in liniments and plasters. With us, however, it is rarely, if ever, made use of for any medicinal purpose. The Indians prepare from it an excellent varnish. Lewis and Murray. In our shops we have only the American sorts of this resin.

ANIMÉ, in *Heraldry*, a term used by the French heralds, when the eyes of any rapacious animal are borne of a different colour. The English blazon it *incensed.*

ANIMELLÆ, the glands under the ears, &c. called also *lacrimeæ.*

ANIMETTA, in *Ecclesiastical Writers*, denotes the pall or cloth wherewith the cup is covered in the eucharist.

ANIMI deliquium. See **LIPOTHYMYA** and **SWOONING.**

ANIMOTHA, in *Ancient Geography*, a town of Arabia, according to the *notitia imperii.*

ANINA, a town of India, on the other side of the Ganges, according to Ptolemy.

ANINACHA, was also, according to Ptolemy, a town of India beyond the Ganges.

ANINETUS, **ANINETUM**, or **ANITATUM**, in *Geography*, a town of Asia under the patriarchate of Constantinople.

ANINGA, in *Commerce*, a root growing in the Caribbee islands, of use in the refinement of sugar.

The decoction of this root is found a more certain, as well as more innocent means of clarifying sugar, than the sublimate and arsenic used for this purpose, before the discovery of the *aniga.*

ANIO, or **ANIEN**, of Statius (lib. i. v. 20.), in *Ancient Geography*, now **IL TEVERONE**, a river of Italy, rises in Mount Treba or Trevi, towards the frontier of Abruzzo, passes through the country of the Æqui, then separates the Latins from the Sabines, forms three large lakes in its course, and running through the Tiburtine territories, it precipitates itself from a great height, and forms a rapid cataract, whence Horace "Præcepit Anio." It falls into the Tiber, about three miles to the north of Rome, not far from Antemnæ. The epithet, formed from the name of this river, is **Anienus**; and this was said to be the name of the god of the river.

ANIOIA, in *Geography*, a town of Italy, in the kingdom of Naples, 13 miles south-east of Nicotera.

ANJOU, so called from the ancient *Andes*, or *Andegavi*, a province of France before the revolution, about seventy miles

miles long and sixty broad; it bounded to the east by Touraine, to the south by Poitou, to the west by Bretagne, and to the north by the river Maine. The capital is ANGERS; besides which, the chief towns are La Fleche, Chateau-Gontier, Saumur, Brissac, Beauge, Passavant, Beaufort la Vaule, Beaupreau, &c. It has many rivers, six of which are navigable; namely, the Loire, Vienne, Thoué, Loire, Mayenne and Sarthe. The climate is temperate, and the face of the country agreeably diversified with hills and vallies. The productions of the soil are wine, chiefly white, grain, peas and beans, flax, hemp, and various kinds of fruit-trees, particularly walnuts and apple-trees. The fine pastures of Anjou furnish rich breeds of cattle; it has also several coal and iron mines, and good quarries of slate, stone, and marble; there are also saltpetre works, and some glass-houses: its commerce principally consists of wine, brandy, grain, cattle, cloths, luffs, ironmongery, &c. It formerly consisted of two counties, which, towards the end of the ninth century, were united; and it was annexed to the crown by Philip Augustus, in the year 1202. The departments of Mayne and Loire, the Sarthe and the Mayenne, now contain a part of this province.

ANJOU Cabbage, in *Botany*. See CABBAGE.

ANJOUAN, or AMIYAM, in *Geography*, a very small island of Africa, in the Æthiopic ocean. It is situated in the Mozambique gulf, between Madagascar and the coast of Zanguebar. The soil is fertile, and it produces excellent fruits.

ANIRITTE, in *Ancient Geography*, a people of the northern part of Marmarica, according to Ptolemy.

ANISCALPTOR, in *Anatomy*, a muscle, otherwise called *LATISSIMUS dorsi*.

ANISE-SEED, *anisum*, *anisum herbarius*, *anisum vulgare*, in the *Materia Medica*, a medicinal seed, produced by an umbelliferous plant of the same name, which is a species of PIMPINELLA, an annual plant, growing naturally in Egypt, Syria, and other eastern countries; and cultivated for culinary and medicinal uses in France, Spain, Malta, Upper Saxony, and Thuringia. It was cultivated here in the time of Turner, in 1551; but our summers are seldom warm enough to bring the plant to perfection. The seeds are annually imported from Malta and Spain; and the seeds of Spain, which are smaller than those of France and Germany, are accounted the best.

Anise-seeds are roundish and striated, flattened on one side and pointed at one end, of a pale colour inclining to green. They have an aromatic smell, and a pleasant warm taste, accompanied with a degree of sweetness. They totally give out their virtue to rectified spirit; the tincture is of a bright lemon colour, and agreeable taste. The spirit distilled from the filtered tincture has a light taste of the seeds, but the greatest part of their virtue is left behind in the extract, which is a pleasant, sweetish, moderately warm, and not very pungent aromatic. Infused in water, they impart a little smell, but scarcely any taste; and in distillation they give out their whole flavour. With the water rises an essential oil, to the quantity of an ounce or more from three pounds; this oil is of a yellowish colour, and it congeals, when the air is not sensibly cold, into a butyraceous white conerete; its smell is extremely durable and diffusive, but in taste is milder and less pungent than that of any other distilled vegetable oil.

The seeds likewise yield by expression an oil of greenish colour, less grateful taste, and strongly impregnated with the flavour of the seeds; sixteen ounces, lightly moistened by being exposed to the steam of boiling water, are said to afford one ounce. This oil is composed of a gross, insipid, inodorous one, such as the common expressed oils, and a part

of the essential oil of the seed, on which the flavour depends. The essential oil is contained in the outer thin skin of the seeds, and the expressed oil in the kernel itself.

Anise-seeds, which are ranked among the four greater hot seeds, have been long employed as a carminative and aromatic; they have also been esteemed useful in pulmonic complaints, and to possess, like those of feniel, a power of promoting the secretion of milk, and on this account given to nurses; in proof of which it is alleged from Geoffroy, that the odour is perceived in the milk. But their chief use is in flatulent colics, in the gripes to which children are subject, in flatulent pains and obstructions of the breast, in weakness of the stomach and indigestion, in diarrhæas, and for strengthening the tone of the viscera and intestines in general; and hence they were called by Van Helmont, "Solamen intelligentium." The essential oil, which is the only official preparation of aniseeds now directed by the Pharmacopœias, is usually grateful to the stomach, and may be taken in the dose of twenty drops. In diseases of the breast, the oil is preferred; but in flatulencies and colics, the seeds, in substance, are said to be more effectual. It is asserted, that the oil is poisonous to pigeons. A spirituous water prepared from a mixture of equal parts of aniseed and angelica, by drawing off a gallon of proof spirit from half a pound of each of the seeds, is commonly kept in the shops, and proves an elegant carminative cordial. They are usefully combined with the purgatives that are administered in flatulencies and gripes. Lewis. Newman. Murray. Bergius.

ANISE-SEED, *florary*. *anisum stellatum*, is a seed thus called from the affinity it bears in smell to the common anise-seed, and the star like figure of its *capsule seminales*. It is the produce of a small tree growing in Tartary, China, and the Philippine islands, which is the *ILLICIVUM anisatum* of Linnaeus.

It was first brought into Europe from the Philippine islands by an English mariner, named Thomas Candy, Candish, or Cavendish, in his return from a voyage round the world in the year 1601. The natives call it *damor* and *zingi*; the Europeans sometimes *foeniculum Sinesse*, or Chinese fenel; botanists, *anisum Indicum*, *anisum peregrinum*, *anisum exoticum Philippinarum insularum*, *cardamomum Siberiense*, *badianum*, &c. In smell and taste this resembles the common anise-seed; but with the aromatic taste is combined a sweetness, and in both respects it is stronger. The capsules or husks affect the tongue more than the seed, but the flavour of the seeds is accompanied with a greater sweetness. The seeds afford in distillation with water, the largest quantity of essential oil; and the capsules yield with spirit, the most acrid, resinous extract. The oil is more limpid, and more fragrant, than that of the common anise-seeds; and the spirituous extract is much warmer and more pungent: for medical purposes, the capsules and seeds are bruised together.

Its virtues are of the same kind with those of the common anise seed, only that it is sweeter, more grateful, penetrating, and aromatic. It is reputed a general cordial and strengthener, and used for this purpose in the eastern countries, and in some parts of Europe; but it has not been received in practice among us, and is rarely found in the shops.

The Chinese use it in the preparation of their tea, and they chew it for sweetening their breath; and after their example, the Dutch also use it in this liquor, pretending it makes it more pleasant.

The wood is also imported into Europe, where it is employed in works of marquetry and mosaic: it is also called *anil*. Lewis. Murray. Newman. Cartheuser.

ANISIFOLIUM, in *Botany*. See LIMONIA.

ANISOCALIUM,

ANISOCALIUM, a name given by some naturalists to the *SERTULARIA MYRIOPHYLLUM* of Linnæus; *myriophyllum pelagicum* of Zanich. Ginani, &c.; *muscus maritimus*, *filicis folio* of C. Bauh. and pheasants' tail coralline of Ellis. See *MYRIOPHYLLUM*, *SERTULARIA*.

ANISOMARATHRUM, in *Botany*. See *SCANDIX*.

ANISUM Africanum. See *BUBON*.

ANISUS, or **ANASUS**, in *Ancient Geography*, a river of Norica, which falls into the Danube.

ANITHA, a town of Arabia Petraea, according to Ptolemy.

ANTIGORGIS, a town of Hispania Bœtica, mentioned by Livy (lib. xxv. c. 32.), when describing the campaign of Cornelius and Scipio, who advanced to this town, and encamped in the sight of the enemy, from whom they were separated by the river.

ANIUS, a river called *Æas* by Stephan. Byz.; and by Livy, *Aous*; which discharges itself into the Adriatic to the south of Apollonia.

ANIUS, *Lugo Sulatorio*, a place of Campania, near Puteoli.

ANIZA, in *Geography*, a town of Arabia, 200 miles north-west from Jamama.

ANIZY LE CHATEAU, a town of France, in the department of the Aisne, and chief place of a canton, in the district of Chauny, eight miles north-east of Soissons, and ten south-east of Chauny.

ANKER, *Анкор*, a liquid measure chiefly used at Amsterdam, &c.

The *anker* is the fourth part of the *awon*, and contains two *stekans*; each *stekan* consists of sixteen *mengles*, the *mengle* being equal to two Paris pints.

ANKER, in *Geography*, a river of England, which rises about one mile and a half south-west of Hinkley, in Leicestershire, and joins the Tame at Tamworth, in Warwickshire.

ANKEVEEN, a town of the United Netherlands, in the State of Utrecht, one mile and a half south-west from Naerden.

ANKLE, *Joint of the*, in *Anatomy*, is made by the apposition of the astragalus, or upper bone of the foot, to the lower part of the tibia and fibula, which are, for that purpose, tied together by a strong band of ligaments both before and behind.

The tibia and fibula send down two processes, called malleoli, which are applied to the sides of the astragalus, support it in its situation, and render the joint very secure. The form of the bones allows them to be moved chiefly forwards and backwards, so that the joint is accounted a ginglymus. When the back part of the astragalus is moved forwards, the toes are pointed to the ground, and the foot is said to be extended; in the contrary position, it is said to be bent upon the leg.

When the joint is bent, the form of the astragalus so exactly corresponds to the space in which it is received between the tibia and fibula, that no motion can take place; but when it is extended, the narrow back-part of the astragalus coming forwards between the malleoli, a space exists between the bones, and a motion of the astragalus from side to side (such as takes place in directing our steps) is permitted.

In this joint we have the usual apparatus of cartilages to cover the ends of the bone; a capsule to contain the synovia; portions of fat, denominated synovial glands; and restraining ligaments to bind the bones together (see *JOINT*, *Structure of*). The capsule of that joint appears in front a little loose, so that it can be pinched up with a pair of forceps,

and here also are seen those portions of fat which have been accounted synovial-glands: behind, the capsule is covered by bands of restraining ligaments which conceal it, and strengthen that part of the joint; but the principal strength and restraint to the improper motions of the joint is found, as is common in ginglymoid articulations, at the sides. The internal lateral ligament (*ligamentum deltoideus malleoli interni* of Weitbrecht), which is radiated, extends from the point of the malleolus internus to the astragalus and os calcis. The external lateral ligament (*ligamentum malleoli externi perpendicularare*, Weitbrecht), extends from the point of the malleolus externus to the os calcis. There are also two other bands of ligaments passing from the fibula to the astragalus, one in front, and the other behind the last-mentioned ligament. Weitbrecht mentions these under the names of *ligamentum malleoli externi, antierius & posterius*. These ligaments are in a state of great tension, and prohibit any motion when the joint is bent; but are relaxed, and allow of that motion which is useful in the direction of our steps when it is extended.

ANKLE, *luxation of*, in *Surgery*; see *LUXATION* and *DISLOCATION*.

ANKUN, in *Geography*, a town of Germany, in the circle of Upper Saxony and principality of Anhalt; is so near to Zerbit on the west, that it is denominated a suburb to that city, but has a corporation of its own.

ANLERY, a town of France, in the department of the Nycore, and chief place of a canton, in the district of Decane, 15 miles east from Nevers.

ANN, *Cape*, is the point of land, in the town of that name, or *GLOUCESTER*, which forms the north side of Massachusetts Bay, as Cape Cod does the south side. It was so named in honour of Ann, consort of king James I. N. lat. 42° 45'. W. long. 70° 17'.

ANN, *St.* is the chief town of the province of Parana, in the eastern division of Paraguay, in South America.

ANN, *St.* a lake in Upper Canada, to the north of Lake Superior, which sends its waters north-easterly into James's Bay, through Albany River. Its north-eastern point lies in N. lat. 50°. W. long. 88°.

ANN, *Fort*, in the state of New York, lies at the head of Battyaux navigation, on Wood Creek, which falls into South Bay, Lake Champlain, near Skenesborough.

ANN's, *St.* a port, on the east side of Cape Breton island, accommodating fishing-vessels, and lying on the north-west side of the entrance into Labrador Lake. N. lat. 47°. W. long. 60°.

ANN's, *St.* a small town on the river St. John's, in the province of New Brunswick, about 80 miles from St. John's, and almost opposite to Frederick-town. It is at present the seat of government.

ANN's, *St.* sometimes called *Egane*, lies at the bottom of a bay, on the north-east part of Borneo island, in the East Indies. N. lat. 5° 50'. E. long. 116° 20'. This bay, called *St. Anne's Bay*, is a very considerable bay of the Eastern Ocean, opposite to St. Michael's islands. It has a free and open entrance, a good depth of water, and safe anchorage.

ANN's, *St.* a bay of Campeachy, in the Gulf of Mexico, in N. lat. 18° 10'. and W. long. 92° 25', nearly south-west from Cape Concededo.

ANN's, *St.* is a harbour on the north coast of the island of Jamaica, in N. lat. 18° 54', and W. long. 77° 12'. It is a good anchoring-place, and the largest sugar ships may lie with their sides close to the wharf.

ANN's, *St. Point*, is to the larboard of the entrance into Milford Haven, on the coast of Wales.

ANN'S, *St. Point*, is also in the straits of Magellan, in that part which bends to the south, and on the west side of it, on the Patagonian shore, four leagues from Cape Froward, the most southerly point of the American continent. Here are good wooding, watering, and fishing.

ANN'S, *St. Port, Arglus, or Killough*, lies on the east coast of Ireland, between Carlingford and Strangford.

ANNA is one of the three principalities into which Arabia Deserta is divided.

ANNA is also one of the chief cities of the above principality, and was formerly a famous market town, though it is now not much frequented. It is situated in N. lat. $33^{\circ} 57'$, E. long. $42^{\circ} 10'$, on the river Euphrates, in a fruitful and pleasant soil, and has two streets which are divided by the river: that on the Mesopotamia side is about two miles long, and thinly peopled by traders; that on the opposite side is about six miles in length, and this part is inhabited by the principal people. Every house has some ground belonging to it, which produces a variety of excellent fruit-trees, as lemons, oranges, citrons, quinces, figs, dates, pomegranates, and olives: some of the flat ground is sown with corn and other grain, which it yields in great abundance. The city is the common rendezvous of all the robbers that infest the country; here they hold their council, and settle their plans of depredation; and from hence they disperse themselves into all parts of the desert. This is one of the great thoroughfares through which the caravans pass to and from Aleppo, Tripoli, Damascus and Bagdad, and some other parts of the Turkish empire; and it is with difficulty, such is the character of the inhabitants, that the Turkish aga and the janizaries, who are kept here, can levy the tribute imposed by the Turks on all the commodities carried through this city. Mod. Un. Hist. vol. xxxvi. p. 440.

ANNA, in *Ancient Geography*, is a town of Palestine, to the north of Jericho. Josephus calls it *Aina*; and Berkeley thinks it is the same with Kana.

ANNA, a town placed by the periplus of Scylax on the coasts of Lydia; supposed to be *Avvaz*, or *Anza*, which belongs to Ionia or Caria.

ANNABERG, in *Geography*, a mine town of Germany, in the circle of Erzgebirg and electorate of Saxony, five miles south-south-west from Wolkenstein. The occupation of its inhabitants consists partly in mining, but chiefly in the lace-trade. The silver-mines of Schreckenbergr are not far from the town.

ANNABI, the name of mountains in Independent Tartary, supposed by M. d'Anville to be those of Altai; but they are evidently those of Alak, called by some Musart, on the north of Little Bucharia.

ANNABON, or ANNOBON, or *Happy Year*, the name given to an island of Africa by the Portuguese, who discovered it on New Year's Day, in 1526. This island lies to the east of St. Matthew, in S. lat. $1^{\circ} 50'$, and E. long. $5^{\circ} 10'$, 25 leagues south from St. Thomas island, and 45 from Cape Lopez Gonfalvo. According to Pyrad, it is five or six French leagues in circuit; but Baudrand makes its compass ten leagues. It has two high mountains, which being almost always covered with clouds, occasion frequent rain. It has a number of fertile vallies, producing Turkey corn, rice, millet, potatoes, yams, bananas, pine-apples, citrons, oranges, lemons, figs, tamarinds, and other delicious fruits. This island also affords oxen, hogs, sheep, goats, and poultry, in great plenty, and abundance of fish; but the only mercantile production is cotton, which is said to be equal to any produced in India; the quantity, however, is small. The

governor is a Portuguese; but the majority of the inhabitants are natives, who pay him implicit obedience, and are bigoted in their attachment to the Roman Catholic faith. There are two rocks on the south-east end of the island, which are dangerous to shipping: they are inhabited by a number of birds, so tame, that the sailors frequently feed and catch them with their hands. Ships, sailing for Europe from the Cape of Good Hope, frequently make this island; and the right road for them is on the north-east side, where they may anchor in six or seven fathoms water, and good ground.

The climate is wholesome, and the air clear and serene. Every part of the island is watered by pleasant brooks and fresh-water springs, which, in all high tides, become brackish: the banks are covered with palms, from which the inhabitants obtain their wine by incision; and among other fruits, this island produces a species of black nut of a purgative quality. Most of the dwellings on this island are cane-huts: the inhabitants are meanly clothed; the women have the upper part of the body naked; they carry their children on their backs, and suckle them over the shoulder; the men wear a linen-girdle round the loins, with a small flap before. Mod. Un. Hist. vol. xi. p. 459.

ANNABURG, formerly called *Lochau*, a town of Germany, in the Electorate of Saxony, and in a prefecture of the same name. This town is situated on an island, and contains a citadel which Anne, consort to the elector Augustus, caused to be rebuilt in the year 1572; whence the name. N. lat. $51^{\circ} 42'$, E. long. $12^{\circ} 54'$.

ANNA COMNENA, in *Biography*, was the daughter of the emperor Alexius Comnenus I. by his wife Irene, and no less distinguished by her talents than her rank. She was born at Constantinople in 1083, and devoted herself to the study of literature and philosophy, by which she acquired the reputation of the most learned lady of her age. Upon the death of Constantine, the son of Michael Duas, her intended husband, she married Nicephorus Bryennius, a young nobleman of distinction; on whose behalf she joined with the empress Irene in soliciting her father, in his last illness, to disinherit his son. When this scheme failed, she excited a conspiracy for deposing her brother; and upon her husband's impeding its success, she lamented that nature had mistaken their sexes, as he ought to have been the woman. Her plot was defeated; and Anna was punished by the confiscation of her property, which, however, was restored to her by the emperor; but she lost her whole influence at court. Having lost her mother first, and afterwards her father in 1118 (see ALEXIUS I.), and her husband in 1137, she endeavoured to soothe her mind in retirement, by composing a history of her father's reign; a work that was finished in 1148, still extant, and preserved in the collection of Byzantine historians. "This history was written," says Mr. Gibbon (Hist. vol. ix. p. 83. Svo.), "with an elaborate affectation of rhetoric and science, that betrays in every page the vanity of a female author." Nevertheless, it forms an useful contrast to the degrading and partial statements of the Latin historians. Zonaras gives her an excellent character, and informs us, that she engaged vigorously in the pursuit of learning, and had a peculiar attic elegance in her style; and being endued with a genius suited to elevated contemplations, she improved her natural abilities by intense study, for she was perpetually reading, or conversing with men of learning. Gen. Dict.

ANNAGH, in *Geography*, an island on the west coast of Ireland, about five miles in circumference, between the isle of Achiland the main land of the county of Mayo. N. lat. $53^{\circ} 58'$, W. long. $9^{\circ} 39'$.

ANNAGH, a small island of Ireland, in Lough Conn, in the county of Mayo, eight miles from Killala.

ANNAGH island, a small peninsula on the west coast of Ireland, and west coast of the county of Mayo.

ANNAGH UAN, a small island on the south-west coast of the county of Galway, 22 miles west from Galway.

ANNA IVANOWNA, in *Biography*, the second daughter of the Czar Ivan Alexiowitch, elder brother of the Czar Peter the Great, was born in 1693, married in 1710 to Frederick-William, duke of Courland, left a widow in 1711, and advanced to the Russian empire on the decease of Peter II. in 1730. Her counsels were under the absolute direction and influence of Ernest John Biren, a favourite of mean descent. Notwithstanding attempts to prevent his coming to Russia, he appeared immediately upon her arrival at Moscow; and formed a party, by whose influence the crown was offered to Anna, with the despotic authority possessed by her predecessors. Biren governed with vigour and capacity; but with such rigour, that more than 20,000 persons are said to have been sent to Siberia during this reign, though the empress herself was of a gentle and merciful disposition. The influence of Biren was so great, that though he treated the empress with arrogance and disrespect, he was able to carry any measure by a mere threat of returning to Courland, of which she made him grand duke. He lived in a style of magnificence superior to her's; and she had no table of her own, but used to dine with his family. The election of a king of Poland, a treaty to be concluded with Persia, and a war with the Turks, were the transactions that occupied Anne in the first years of her reign. Augustus, elector of Saxony, supported by Russia and Austria, became king of Poland, under the name of Augustus III. In 1735, Russia made a formal surrender of all her Persian possessions, for which the Russian merchants obtained mercantile privileges, to a considerable extent, in the territories belonging to Persia. The empress also, on this occasion, concluded a defensive treaty with the Shah against the Turks. Although, during the reign of Anne, the Russians and Austrians combined their forces, and threatened to shake the Ottoman empire, yet the expectations that were formed from the united efforts of these two powers were utterly disappointed. The Austrians made overtures of peace to the Turks; and instead of having made new conquests, they were obliged to restore Belgrade, the rampart of Hungary against the Turks; and the articles agreed upon between the Porte and Austria, were signed at Belgrade, September the 11, 1739. Soon after this event, the vizier manifested a disposition to negotiate even with Russia, nor was the empress averse from the measure: accordingly, on the 18th of September, a peace was effected between the court of St. Petersburg and the Porte. The conditions of this peace were, that Azof should be evacuated, together with its territory, and lie waste as a boundary between the two empires. Russia, however, was allowed to build a fortress on the Don, and the Porte was at liberty to construct another in the Kuban. The Greater and the Less Kabardia were to remain unoccupied as a frontier. The Russians were prohibited from keeping a fleet either in the Palus Mæotis, or in the Euxine; and the Russian merchants had licence only to carry on commerce in Turkish bottoms, in the latter. The Moldau, and all the other conquests made by the Russians, were restored to the Turks. In this contest, so disadvantageously terminated, Russia had lost above 100,000 men, and expended prodigious sums of money. Soon after the conclusion of peace with the Turks, the Russians were threatened by Sweden; but before the storm could burst from these threatening appearances, the empress Anne died,

in 1740, aged 47; and left the crown to her grand-nephew, Ivan, under the regency of Biren. Anne, during her reign of 10 years, acquired some portion of fame, by completing many things that had been begun by her uncle Peter I. Although her war with the Turks did not redound to much benefit, yet it convinced the Porte of the superiority of the Russian arms. The canal along the Ladoga lake, commenced under Peter I. conducive to the easier conveyance of provisions to St. Petersburg, was completely finished under Anne, in 1738. Anne renewed the project for investigating whether any connexion subsisted between North America and Siberia, and for exploring those regions that were unknown. Anne likewise, by the advice and assistance of Count Munich, improved the discipline of the Russian army; and established a seminary for the military education of young men of good families. With a view to the extension of commerce, Anne was induced to relinquish the Persian provinces; she fought for expert and industrious artificers and manufacturers, and procured for the country a great number of manufacturers in woollen stuffs and silk. She executed a new treaty of commerce with Great Britain, and governed at home with gentleness and equanimity, except in cases where punishment was thought necessary, which she inflicted with severity. The manners of the court at Petersburg, during her reign, took a softer and politer turn; drunkenness was discouraged, and the more decent pleasures of music and dancing were promoted.

Under Anne, the number of subjects was augmented by the return of the Zaporogian Cossacks to their submission to the Russian sceptre; the territory of the empire was also enlarged by the submission of the Kirghises; and thus the commerce between Russia and China was secured against the interruption which had been occasioned by the hostilities of the neighbouring Russian tribes. The reign of Anne would have been more happy for Russia, and her memory had in greater honour, if her favourite Biren had not abused the confidence she reposed in him, and rendered a multitude of persons and families completely wretched. *Tooke's Hist. of Russia*, vol. ii. p. 207—239.

ANNALE, in some *Middle-Age Writers*, denotes a day held every year in commemoration of the dead. In which sense *annale* amounts to the same with what is otherwise called *anniversarium*.

ANNALE is more particularly applied to the masses celebrated, during the space of a year, for the dead.

ANNALES libri, in the *Civil Law*, denote books wherein the acts and proceeding of a whole year were contained.

In which sense *annales* stand opposed to *semestres libri*, wherein the acts and constitutions of six months were contained. See **ANNALS**.

ANNALES baculi, denote a kind of wooden almanacks used among our ancestors, called also *runstocks*, or *clogs*.

ANNALES, in *Middle Age Writers*, denote yearlings, or young cattle of a year old, or under two.

ANNALES also denote a kind of rent, or annual revenue.

ANNALIS Actio, in the *Civil Law*, denotes an action which may be put in practice any time within the year. In the like sense we meet with *annale decretum*, or *negatum*, *annalis rescissio*, &c.

ANNALIS clavus, in *Roman Antiquity*, the nail which the prætor, consul, or dictator, fixed every year in the wall of Jupiter's temple, on the ides of September, to shew the æra or number of years from the building of Rome. This custom was afterwards changed, and the years were reckoned by the **CONSULS**.

ANNALIS exceptio, a kind of privilege anciently granted the people of Italy, that whoever had made a contract could not be compelled to the performance or payment of what had

been agreed on within the year. Some extend this privilege so as to render it still more grievous, by computing the year exclusive of all holidays.

ANNALS *Lex*, a law fixing the age for enjoying the different offices at Rome, which was first made by L. Valerius or L. Julius, a tribune of the commons, A. U. 573; and hence his family had the surname of *Annales*. Liv. lib. xl. c. 47.

ANNALS, an historical account of the affairs of a state, digested in the order of years.

The difference between *annals* and *history* is variously assigned by various authors. Some say that history is properly a recital of things which the author has seen, or been a by-stander to. What they build upon is, the etymology of the word; history in the Greek, signifying the knowledge of things present; and, in effect, *historia* properly signifies *to see*. On the contrary, *annals*, say they, relate to the transactions of others, and such as the writer never saw.

Of this opinion the great annalist, Tacitus himself, seems to have been; because the first part of his work, which treats of former times, he calls *annals*; but when he comes down to his own times, he changes his title, and calls it *history*. According to Sempronius Asellio, *annals* are a bare relation of what passes each year; whereas *history* relates not only to the transactions themselves, but also to the causes, motives, and springs of them. The annalist merely states his facts, but the historian reasons and descants on them.

Of this last opinion Cicero appears to have been, because when speaking of annalists, he says, *Unam dicendi laudem putant esse breviter, non exornatores rerum, sed tantum narratores*. He adds that history, in its original, was the composition of annals. Cicero relates the origin of annals: to preserve the memory of transactions, the *pontifex maximus*, says he, wrote what passed each year; and exposed it on a table, in his own house, where every one was at liberty to read it. This they called *annales maximi*; and this custom was kept up till the year of Rome 620. *Annales maximi* consisted of eighty books. They were most of them destroyed in the burning of the city by the Gauls. After the time of Sylla the pontifices seem to have discontinued the custom of compiling annals; but several private persons composed historical accounts of the Roman affairs, which, from their resemblance to the pontifical accounts in the simplicity of their narration, they likewise styled *annales*; as Cato, Pictor, Piso, Hortensius, and Tacitus. The like annals were kept from the earliest ages by the Egyptians, Babylonians, Persians, Chaldeans, &c.

The *Annals of Grotius* is a book finely written, and contains excellent materials. Grotius is not so particular as Strada, but more profound, and comes much nearer to Tacitus.

ANNAMATIA, in *Ancient Geography*, a place of Lower Pannonia.

ANNAMETHUS, an island in the Indian ocean, according to Pliny, who makes it dependent on Arabia Felix.

ANNAMOOKA, in *Geography*. See АНАМОКА.

ANNAN, the capital of Annandale, in Scotland, is a small town, and royal borough, pleasantly situate on a river of the same name, which abounds with salmon, and is navigable, within half a mile of the town, for vessels of 250 tons burden. The river at the town is crossed by a bridge of five arches. It was formerly a place of trade, but lying contiguous to the English border, and in the track of their western incursions, it was often pillaged, destroyed, and burned: the last of these destructive inroads was in the reign of Edward VI. when Lord Wharton, president of the Marches, burned the town, and demolished the church. In this town, there

was formerly a castle which was built by the Bruces, after they became lords of Annandale. The export-trade of Annan at present consists of grain; and a building for carding and spinning of cotton has lately been erected, and there are some appearances of increase. N. lat. 54° 40'. W. long. 3°.

ANNAND, WILLIAM, in *Biography*, a Scots episcopalian divine, was the son of William Annand, minister of Ayr, and born in that town in 1633. His father was obliged to quit Scotland in 1638, on account of his loyalty to the king, and attachment to episcopalian government; and he was admitted, in 1651, a scholar in the university of Oxford. Having completed his education, and distinguished himself by his loyalty and zeal for episcopalianism, he removed to Scotland in 1662; and in 1676, he was nominated to the deanery of Edinburgh. He died in 1689, and was interred in the Greyfriars church at Edinburgh. The titles of his works, which he wrote in English, are as follows, *viz.* "Fides Catholica;" or, The Doctrine of the Catholic Church, in Eighteen Great Ordinances, &c. Lond. 1661-2, 4to. "Panem Quotidianum;" or, Daily Bread, in Defence of set Forms of Prayer. Lond. 1662, 4to. "Pater Noster;" or, Our Father, an explanation of the Lord's Prayer. Lond. 1670, 8vo. "Mysterium Pietatis;" or, The Mystery of Godliness, Lond. 1672, 8vo. "Doxologia." Lond. 1672, 8vo. "Dualitas;" including "Lex Loquens;" or, The Honour of Magistracy: and "Duum Unitas;" or, The Agrgement of Magistracy and Ministry, &c. Biog. Brit.

ANNANDALE, in *Geography*, a district or division of Dumfries-shire, in Scotland, the capital of which is ANNAN. Upon the death of David II. in 1371, the lordship of Annandale descended to Thomas Randolph, earl of Murray; and by his sister Agnes, was transferred to the Dunbars, earls of March: after their forfeiture, it passed to the Douglasses, who lost it in the same way; and from them it went to Alexander, duke of Albany, who lost it by his rebellion against his brother king James III. From his time, it continued in the hands of the king, and was the great key of the western border. This district is a fertile vale, about 24 miles long and 14 broad: it was formerly, on account of its vicinity to England, subject to depredation, so that it was left uncultivated; but of late, the culture it has undergone has given it a new aspect.

Annandale formerly constituted part of the Roman province of Valentia: and as the wall of Severus terminated here, it abounds with Roman stations and antiquities. Some of the Roman camps are preserved; and the traces of a military road are visible in different parts of the country. Annandale is a marquissate belonging to the Johnstones, and the chief of that name.

ANNANO, a strong fort of Italy in the duchy of Milan, situate on the river Tanaro; twice taken by the French, and restored to the Duke of Savoy in 1706. N. lat. 44° 40'. E. long. 8° 30'.

ANNANORE is a Portuguese factory, lying on the western coast of the peninsula of India, 21 leagues nearly S. E. from Goa.

ANNA PERENNA, in *Mythology*, the sister of Dido; of whom fable relates, that she fled with Æneas to Italy, where she fell a sacrifice to the jealousy of Lavinia, and was drowned by her in the river Numicus, whence she was denominated the Numician nymph. It is certain, that the Carthaginians and Romans paid her divine honours. It is said, that the surname *Perenna* was derived, "a perennitate cultus," from the perpetuity of her worship. The feast of this deity was celebrated by the Romans in the ides of March, on the banks of the Tiber; on which occasion the people

people devoted themselves to every kind of amusement and pleasure. Ovid refers to this goddess, in the third book of his *Faсти*. Some writers maintain, that Anna was the moon, because its revolutions formed "annum," the year.

ANNAPOLIS, in *Geography*, a river of Nova Scotia, rises in the east, and passes into the bay of Fundy, through the basin of its own name; on the south side of which, at the mouth of the river, stands *Annapolis Royal*. The tide flows up this river thirty miles; and it is navigable for ships of any burden 10 miles; for those of 100 tons, 15 miles; and for boats, within 20 miles of Horton.

ANNAPOLIS, a county on the above river, adjoining to King's county, having five townships, *viz.* Wilmot, Granville, Annapolis, the chief towns Clare and Morekton, and chiefly inhabited by Canadians, Irish, and New-Englanders.

ANNAPOLIS *Royal*, called by the French *Port Royal*, when a colony was settled here by M. de Ponts in 1605; is the chief town of a county of this name, and stands on the south side of the river and bay of Annapolis.

This is reckoned the finest harbour in the world: it is two leagues long, and one broad; and has a small island called Goat Island, almost in the middle of the basin, which is said to be large enough to contain several thousand ships; its depth of water is no where less than four or five fathoms; the bottom is good; and ships may be secured from all winds. The entrance, however, is difficult, so that only one ship can pass in or out at a time; and it must go stern foremost, on account of the strong current and tides: the fogs also are very great here. The gulf through which ships pass into the bay is about three quarters of a mile wide and about one and a half long; and on each side the land is rocky and mountainous. The town is not large, but has some very handsome buildings. It is fortified, and cannot be easily attacked except by bombardment. The fort in its present state is capable of containing about 100 men. Furs are here exchanged by the Indians for European goods. N. lat. 45° 10'. W. long. 64° 5'.

ANNAPOLIS is also the chief town of Ann-Arundel county, and the capital of the state of Maryland. It stands at the mouth of the Severn, 30 miles south of Baltimore, 32 east by north from the federal city, 72 south-west from Wilmington, and 132 south-west from Philadelphia. It was formerly called Severn; and in 1694, it was made a port and town. It is situated on a peninsula formed by the river and two small creeks; and affords a beautiful prospect of Chesapeake bay, and the eastern shore beyond it. This town is the wealthiest of its size in the United States. The houses, about 300 in number, are spacious and elegant, indicating great wealth: the state-house is a noble building, and stands in the centre of the city, whence the streets diverge in every direction. N. lat. 38° 56' 15". W. long. 75° 8'.

ANN-ARUNDEL, the name of a county in Maryland, which lies between Patuxent and Patuxent rivers, and has Chesapeake bay to the south-east. Its chief town is Annapolis. This county contains 22,598 inhabitants, of whom 10,131 are slaves.

ANNAT, or ANN, in *Scots Law*, denotes half a year's stipend, which the law allows to the executors of the ministers of the church of Scotland, over and above what was due to the minister himself, for his incumbency.

ANNAT, FRANCIS, in *Biography*, a French Jesuit, confessor to Louis XIV. was born at Rovergue, in 1590. Having taught philosophy six years, and theology seven years, in the University of Toulouse, he was invited to Rome to be censor-general of the books published by the society, and theologian-general. On his return to France, he was distinguished by successive offices of honour to which

he was appointed, and at length he was made confessor to the king, in which post he continued for 16 years; nor was he allowed to retire from court till within about four months of his death. It is said, though not with much authority, that when Madame de la Valiere was taken into the royal favour, he entreated permission to lay down his office. During his long connexion with the court, he never employed his interest in providing for his poor relations. He was chargeable, however, with the crime of persecuting those who professed new opinions, and particularly the Jansenists; and he has been reproachfully denominated "The Flail of Heretics." He died at Paris in 1670. His writings, chiefly on the controversy with the Jansenists, are numerous; and the principal of them were collected in three volumes, and printed at Paris in 1666. Gen. Dict.

ANNATES, ANNATA, in *Ecclesiastical Writers*, denote a year's income, due anciently to the pope upon the death of any bishop, abbot, or parish-priest; and to be paid by his successor.

ANNATES are also called from the Latin *annus*, YEAR; because their rate is after the value of one year's purchase; and they are the same with what of later days are called *primitie*, or *first-fruits*; with this only difference, that first-fruits with us are paid to the king.

The invention of annates is ascribed, by a late writer, to Anthonin, bishop of Ephesus, who exacted from all bishops consecrated by him, a sum proportionate to the annual revenues of their sees. The council of Ephesus, held in 400, condemned this exaction, but not till Anthonin was dead. It was long after that annates got footing in the western church. The time when they were first introduced is very obscure. Clement V. is said to have been the first pope who imposed annates on England for three years; to which Edward I. immediately consented; but the parliament boldly opposed it; the pope's bull was declared abusive, and the king revoked his consent. Polydore Virgil (*Inv. et Rer. lib. viii. c. 2.*) says, that the council of Vienne, which was held in 1311, under Clement V. made an effort to suppress the annates; a circumstance which shews they subsisted in his time. John XXII. the successor of Clement, published a bull, whereby he reserved the first year's fruits of all ecclesiastical benefices that continued vacant for three years, archbishoprics, bishoprics, and abbaties, being exempted; but by degrees the first fruits were exacted, without observing whether the benefices were vacant three years or not. Benedict XII. who succeeded John, followed his example; and it was also imitated by succeeding popes; but the authority of their bulls extended no farther than their own lives. In 1399, during the schism of the antipopes, Boniface IX. issued the first bull for establishing perpetual annates; not merely to be granted as a charitable supply on extraordinary occasions, but as a matter of right annexed to the dignity of the sovereign; so that he decreed what was local and particular, to be universal and perpetual. Before his time, the annates were not fixed, and the clergy often refused to pay them; but afterwards, the tax was not only imposed at pleasure, but frequently doubled, tripled, and quadrupled. However, it was always a grievance complained of and remonstrated against both by the people and the clergy. There were even popes who condemned annates; and the secular princes frequently objected to the payment of them, forbidding any money to be carried out of their dominions on this account. See Lefant's *Hist. of the Council of Constance*, vol. ii. p. 147, &c. Nic. de Clamangis, A. Massa, Gallelius, Campegius, and Fimandus Cordubensis, have written expressly concerning annates.

Matthew Paris, in his *History of England*, for the year

year 746, relates, that the archbishop of Canterbury, in virtue of a grant or concession of the pope, received annates of all the benefices that became vacant in England. Before this time, among the laws of king Iua, who began his reign in the year 712, there is an order for the payment of them. But, in after-times, the holy see thought fit to take these away from the bishops and archbishops, and appropriate them to themselves. And from the popes, the parliament under Henry VIII. took them, passing an act in 1532, against levying them, and gave them to the crown. 25 Hen. VIII. cap. 20. Finally, queen Anne restored them to the church by appropriating them to the augmentation of poor livings. See *FIRST FRUITS*.

ANNATTA, in *Geography*, the name of a river and bar in the island of Jamaica, nearly north from the town of Kingston, on the north side of the island. N. lat. 18° 32'. W. long. 76° 41'.

ANNATOM. See *ANATOM*.

ANNE, in *Biography and History*, queen of England, was the second daughter of king James II. by his first wife Anne Hyde, and was born in 1664. In 1683, she married prince George, brother to the king of Denmark, by whom she had several children, though none of them lived to maturity. Upon the progress of the prince of Orange, and the retreat of the king, prince George, who was under the influence of lord Churchill, afterwards duke of Marlborough, as well as some other persons of distinction, retired to the camp of the advancing prince. When this news reached London, the princess Anne, dreading the king's displeasure, withdrew herself, in company with the bishop of London and lady Churchill, and fled to Nottingham. The intelligence of her flight was the occasion of great distress to her father: because he foresaw, in this incident, the total expiration of his royal authority; and because he was abandoned by a child, whom he had always regarded with the most tender affection. "God help me," cried he, in the extremity of his agony, "my own children have forsaken me!" Upon her disappearance, so violent were the prejudices that prevailed, the unhappy father was thought to have put her to death; and if the truth had not been seasonably discovered, the populace, and even the king's guards themselves, might have been engaged, in revenge, to commence a massacre of the priests and Catholics. Upon the settlement of the crown, in 1689, on the prince and princess of Orange, it was enacted by the Convention-bill, that the princess of Denmark should succeed after the death of the prince and princess of Orange. Accordingly, she ascended the throne, on the death of king William III. in 1702. The splendour and importance of her reign were owing more to the circumstances of the times, and to the influence of her ministers and favourites, than to any display or exertion of talents on her own part: as she possessed no energy of mind, and her disposition was meek and timid, she surrendered herself to the direction of others, and distinguished herself merely, or principally, by a strong predilection for tory principles in church and state. "Mildness, timidity, and anxiety," says Dr. Somerville, "were constitutional ingredients in the temper of this princess; and to their influence chiefly we may ascribe most of the interesting occurrences in her government and private life." Under the guidance of the counsels of the duchess of Marlborough, to which she had been accustomed to surrender herself in the earlier period of her life and reign, she pursued the projects for reducing the power of Louis XIV. of France, which her predecessor had begun; and after a series of successes, more glorious to her arms than profitable to the nation, the war closed by the peace of Utrecht, in 1713. Much more important to the prosperity of the nation, than all the bril-

liant successes of Marlborough's campaign, was the union of England and Scotland, which took place on the 1st of May 1707. The contention of parties was very violent during almost the whole of the queen's reign; and more especially towards the close of it, when it was apprehended that the queen, and those in whom she confided, wished to secure the succession to her exiled family; and when she evidently favoured the tories in such measures, as justly alarmed the whigs and the friends of constitutional liberty. Of this kind was the *SCOTSM-BILL*, which, after violent debates during its progress through both houses, obtained the royal assent on the 25th of June 1714. But the death of the queen, August the 1st, in the same year, the very day in which this bill was to take effect, rendered it in a great measure ineffectual. The queen's death, in the 50th year of her age and 13th of her reign, was occasioned by a dropsy, contracted or aggravated by her habits of living. Although Queen Anne had no energy of mind, she was not deficient in understanding; and her private character was amiable. She has been charged, however, by some, with the crime of deserting her father in his distress. This charge has been obviated by the peculiar circumstances in which she was placed, and by the state of the nation, when her husband, by his example, countenanced this measure. "The habit (says Dr. Somerville) of a blind deference to the advice of lord and lady Churchill, and a conscientious anxiety for the Protestant religion, exposed to the extremity of danger, risted the emotions of filial tenderness, in a moment of singular perplexity and agitation, and precipitated her into an action which would have been inexcusable, if it had been the result of cool deliberation, and originated from motives of interest and ambition." In the management of her fortune this princess was economical, and yet she was not deficient in charity; and she even exceeded it in her bounty to her favourites. In the discharge of religious duties, she was regular and exemplary; and she manifested her zeal for the safety and prosperity of the church in various ways; some of which, indeed, were reckoned as impolitic and unjust; and particularly by augmenting, at her own expence, the livings of the poor clergy. See *AUGMENTATION*. "She possessed a considerable degree of taste for the fine arts, amused herself with music and painting, and delivered her public speeches with a melodious propriety, that charmed the ears of her audience. The deceitfulness of grandeur, as a criterion of happiness, was remarkably verified in the life and reign of queen Anne. We beheld a nation rising, under her auspices, to the summit of prosperity. Whilst signal successes crowned her military exertions abroad, agriculture, commerce, manufactures, science, and literature, advanced with rapid steps at home; every event, and every improvement, which contribute to the opulence, the power, and the renown of a nation, distinguish the reign of queen Anne as the most propitious and brilliant recorded in the annals of Britain. But when we follow this princess into retirement, and survey the incidents of her private life, how much are we struck with the distinction between external grandeur and personal felicity! She survived a numerous family of children; the Duke of Gloucester, destined by the act of settlement to succeed her, lived to the age of 12, and exhibited early blossoms of every accomplishment that could elevate the hopes of a nation, and delight the heart of a parent. The possession of a crown, held upon the condition of ratifying the degradation and exile of her own family, must have cost her many a pang, which she durst not impart to her most confidential friends. Whilst looked up to as the first potentate in Europe, and loaded with congratulations upon the success of her arms, she was a slave in her own house; and subjected to daily

daily affronts and mortifications, from the insolence and usurpations of her own servants. Emancipated, at length, from her chains, she only entered upon a new scene of vexation and trial; and all her remaining days were embittered by the jealousies of her people, the turbulence of faction, and the contentions and outrage of a distracted cabinet." By her subjects, whose prejudices coincided with her own, she was honoured with the title of the "Good Queen Anne." Without attaching much merit to the queen herself, as either a patron or promoter of literature, the period of her reign was distinguished as a kind of Augustan age of English learning, on account of the number of admirable and excellent writers who flourished at this time.

ANNE of Austria, queen of France, the daughter of Philip III. king of Spain, by Margaret of Austria, was born in 1604, and married to Louis XIII. in 1615. From this connexion, she did not derive much happiness; for Cardinal Richelieu contrived to persuade the king that she was concerned in conspiracies against his life. Suspicions were thus excited, which rendered it necessary for her to answer interrogatories; and on her confession, to ask pardon of the king, and promise to alter her conduct. When the king died, in 1643, she was declared sole regent during the minority of her son Louis XIV. Her whole confidence was reposed in Cardinal Mazarin; who ruled with such despotism, that discontents arose, which produced a civil war, and obliged her to fly with her son from Paris, and to solicit the assistance of the great Condé. In the conflicts and vicissitudes of this period, the queen manifested great firmness; at length, the young king assumed the reigns of government, in 1661; and the queen retired, to pass the remainder of her life in pious exercises. In 1666, she died of a cancer, after having endured the pains of it with exemplary patience. In early life, the court of France was much indebted to her for its characteristic politeness and amenity. *Nouv. Dict. Hist.*

ANNE BOLEYN, queen of Henry VIII. of England, was the daughter of sir Thomas Boleyn, employed by Henry in various embassies, by a daughter of the duke of Norfolk; and born in 1507. At an early age she was taken to Paris, and resided there for a considerable time. Here she acquired a vivacity of manners and conversation, which was further set off by her personal charms. Henry, whose attachments were very variable, was enamoured when he saw her; and as he could not obtain the favour he solicited on any other terms, he hastened to seek a divorce from Catharine of Arragon, and whilst the grant of it was delayed, he married Anne Boleyn in November 1532; and publicly declared her queen in the April following. In September she was delivered of a daughter, who was afterwards the famous queen Elizabeth. Anne Boleyn had imbibed the principles of the reformers during her residence with the duchess of Alençon; and her influence was for some time usefully employed in widening the breach between the king and the court of Rome; and in overthrowing the power of that haughty favourite cardinal Wolsey. But her enemies were assiduous in their endeavours to supplant her; and the king's new passion for lady Jane Seymour, tended to inflame those jealousies of her conjugal fidelity which the levity of her carriage had excited, and in some measure justified. Having been accused of adultery with several officers of the household, and with her own brother, lord Rochford, she was brought to her trial for high treason, found guilty on very insufficient evidence, and sentenced to be beheaded: the sentence was executed in May 1536. At her death, she confessed indiscretion, but persisted in denying any serious guilt. Her letter to the king, written after her condemnation, enhances her character and understanding

in our estimation. Many calumnies have been circulated against this queen, by the bigotry of the Catholics, on account of the service she rendered to the cause of the Reformation. It is not possible to ascertain her innocence with regard to the crime charged against her; but as an approved writer observes, "it seems much less certain that she was criminal, than that her husband was a capricious and bloody tyrant." *Burnet's Hist. Reformation*, vol. iii. p. 113. *Hume's Hist.* vol. iv. p. 79—159.

ANNE, ST. of *St. Swick Hollein*. This order was instituted in the year 1738, by Charles VI. emperor of Russia. The badge of the order is a cross, composed of four large rubies set in gold, the angles between the cross set with diamonds, and on the centre a medallion with the figure of St. Anne. It is worn pendant to a broad crimson velvet ribbon edged with yellow. The star of the order is of silver, with eight equal points or rays; on the centre a red cross on a gold ground, with the following motto written on a red ground, AMANTIBUS JUSTITIAM, PIETATEM, FIDEM.

ANNE'S, ST. Bay, in *Geography*. See ST ANN'S.

ANNE'S, ST. Bay, is a bay on the coast of Labrador, in North America, between Davis's inlet on the north, and Cape Charles, which is the north point of the entrance into the straits of Beileisle, on the south. It is about N. lat. 54°, and W. long. 57°.

ANNE'S, ST. Cape and Island, lie south by east from Sierra Leone river, on the west coast of Africa. The cape is the north-west point of the island, which is a narrow slip of land, near 80 miles in length from west by north to east by south. The inner passage within the channel is called Furno of St. Anne.

ANNE, ST. LARPANA, OR ROTA, is one of the Ladrões, or Marianne islands, at the distance of seven leagues from Guam, and is about 45 miles in circumference, situate in N. lat. 14°. This is a pleasant and fertile island, finely diversified with rising grounds, covered with lofty trees, and beautiful plains of a rich black soil, and very well watered. There are two excellent ports, one on the south, and the other on the north-west side of the island.

ANNE CHARÉS, Island and Road, lie on the east side of St. Thomas island, under the equator, and 40 leagues west from the mouth of the river Gabon, on the continent of Africa. This island is only a great rock, and the road is under its lee.

ANNE'S, ST. Gulf, is round Cape Blanco, the most westerly point of Africa, which forms a peninsula, as this gulf runs up northerly within the land, which bears away towards the east. It is a large bay, with good sandy ground.

ANNE, Cape Queen, lies on the coast of Greenland, in the Northern Ocean, in N. lat. 64° 15', and W. long. 50° 35'.

ANNE'S, QUEEN, Forland, lies on the northern main from Hudson's Straits, in N. lat. 64° 8', and W. long. 74° 41'.

ANNE'S, ST. Harbour, is in the island of Martinico, and has good anchorage and a safe port.

ANNE'S, ST. in *Ecclesiastical History*, is a festival of the Christian church, celebrated by the Latins on the 26th of July; but by the Greeks, on the 5th of December. It is kept in honour of Anne, or Anna, the mother of the Virgin Mary.

ANNEALING, or as it is popularly called, *Nealing*. See NEALING.

ANNEBAUT, in *Geography*, a town of France, in the province of Normandy, situate on the Rille, and enjoying the title of marquise.

ANNECY;

ANNECY is a city of Savoy, and capital of the Genevois, seated between Chambery and Geneva, on a lake to which it gives name, at the mouth of the river Sier, which passes through it. This lake is about 10 miles long and 3 wide. Annecy is the see of a bishop, whose diocese includes Faucigny, Chablais, the country of Gex, and part of Bugy. It has piazzas in several streets for sheltering the people from rain, several collegiate and parish churches, and convents for men and women. It is 10 miles south of Geneva, and 21 north-north-east of Chambery. N. lat. 45° 56'. W. long. 5° 57'.

ANNECY, OZ, is now a village half a league north-east of Annecy. It was formerly a considerable town.

ANNERY is the name of one of the tribes who inhabit the deserts round Palmyra, which is remarkable for the finest breed of horses in the world; the other is the Mowalli, who are much better soldiers, but fewer in number, and little inferior in the excellence of their horses. The Annery possess the country towards the south-west, at the back of Libanus, about Bozra, down the Hawran; and southward towards the borders of Arabia Petrea and mount Horeb. The Mowalli inhabit the plains east of Damascus to the Euphrates, and north to near Aleppo.

ANNESEI, in *Ancient Geography*, a place of Africa, situate, according to Antonine, in the track of the "Septis Magna," to Alexandria.

ANNESLEY, ARTHUR, in *Biography*, earl of Anglesey, and lord privy-seal in the reign of Charles II. was the son of Sir Francis Annesley, bart. Lord Mount-Morris, and Viscount Valentia in Ireland, and born at Dublin in 1614. At the age of 16 years, he was sent to the university of Oxford, where he pursued his studies with such assiduity, as to engage the esteem of several respectable persons, who considered him as an honour to Magdalen College, with which he was connected, and a young man of great hopes. At the commencement of the dispute between king Charles I. and his parliament, he inclined to the royal cause, and sat in the Oxford parliament in 1643. He afterwards abandoned the king's party, and was admitted into the confidence of the other; and was deputed in 1645, by the parliament, as one of the commissioners at Ullster, where he concluded the business with which he was entrusted, to universal satisfaction, and very much to the benefit of the Protestant cause in Ireland. In his negotiation with the Marquis of Ormond, lord lieutenant of that country, in 1647, he exercised prudence and temper, and brought the negotiation to a happy issue. On his return to England he steered a kind of middle course between the extremes of party violence; had no concern with the king's trial and death; and on account of his opposition to some of the illegal acts of Cromwell, he was put among the number of secluded members. After the death of Cromwell, when there were appearances of the revival of the old constitution, he joined with those who determined to recal the king, and entered into a correspondence with him. After the restoration, he was rewarded for his services on this occasion with a barony and an earldom; and he manifested his loyalty, by sitting as one of the judges on the trial of the regicides. Having been employed at home and in Ireland in several important offices, he was made privy-seal in 1673. At the time when it was the practice to contrive popish plots, he was charged by Dangerfield, at the bar of the house of commons, with an attempt to stifle evidence in this matter; and yet he was the only lord, who, in the house of peers, dissented from the vote of the commons, asserting the belief of an Irish popish plot. On this account, he was unjustly charged with being a secret papist. In 1682, when the succession produced a considerable degree of agita-

tion, he represented, in strong terms, and in a memorial to the king, the fatal consequences of the duke of Norfolk's attachment to popery; and freely enjoined on the king his obligation to govern according to law. This freedom and faithfulness were not well received; and he was dismissed from his office of privy-seal in 1682. From this time, he lived very much in retirement; but his ambition was not asleep; for it appears, that he conducted himself so as to secure the favour of the duke of York, when James II., to such a degree, that he designed him for the office of lord chancellor, if the design had not been prevented by his death, in April 1686, in the 73d year of his age. He left several children by his wife, who was one of the co-heiresses of sir James Altham.

The earl of Anglesey appears to have been possessed of distinguished talents, and extensive and various learning. He was a good writer, and the author of several publications in politics and religion, as well as history. He was a ready, but not a graceful speaker: he was indefatigable in business, and of a grave deportment, and sober manners. His versatility has been censured, and, perhaps, not unjustly; but we discover strong traces of integrity in his conduct. He succeeded, probably, in too great a degree in ingratiating himself with men of all parties; and it does not much add to his reputation, that he was designed for chancellor at a time when Jefferies was at the command of the king. *Biog. Brit.*

ANNESLEY, SAMUEL, a non-conformist minister, was born at Haxley, in Warwickshire, about the year 1620, and educated at Oxford. Whilst he was a student, he was distinguished by his temperance and industry. From Calamy, it appears that he was ordained after the Presbyterian mode; though Wood says, that he received episcopal ordination. He was chaplain to the earl of Warwick; and afterwards rector of Chiffe in Kent, a valuable living, with peculiar civil jurisdiction.

During the civil wars, he was zealously attached to the parliamentary interest; and, in 1648, preached a violent sermon before the parliament, in which he inveighed against the king, who was then a prisoner in the Isle of Wight.

Under the protectorate, he surrendered Cliffe, and was presented to the vicarage of St. Giles's, Cripplegate. He was ejected in 1662, but continued preaching till his death, which happened in 1696. Annesley had the reputation of being a pathetic preacher, as well as a pious, prudent, and very charitable divine, laying by the tenth part of his income for the use of the poor. Some of the sermons which he published are contained in the "Morning Exercise of Cripplegate;" printed in 1674. *Biog. Brit.*

ANNET, in *Geography*, one of the smaller Scilly islands, near the south-east coast of England, about half a league from St. Agnes island.

ANNESTUS, in *Ancient Geography*, or **ANNESTRUS**, in town of Arabia Felix.

ANNEXATION, in a *legal sense*, the act of joining or uniting some less considerable thing to a greater.

ANNEXED, something joined to, or dependent on another.—Thus, we say, such a farm, such an advowson, is annexed to such a fee, such a manor, &c. Charles VIII., in the year 1486, annexed Provence to the crown of France.

ANNIBALI, DOMENICO, in *Biography*. See **DOMENICO**.

ANNIENTED, or rather **ANNIENTED**, formed of the verb *aneantir*, to bring to nothing, or to annihilate, a term sometimes used in law-books, in the sense of frustrated, or annulled.

ANNIHILATION, compounded of *ad*, to, and *nihil*, nothing, the act of reducing a substance into nothing; or of totally

totally destroying and taking away its existence. Annihilations stands opposed to creation; the one supposes something made out of nothing, the other something reduced to nothing.

All annihilation must be metaphysical, or supernatural; bodies naturally admit of changes and alterations in their form, but not of annihilation.

The ancient philosophers in effect denied all annihilation as well as creation, resolving all the changes in the world into new modifications, without supposing the production of any thing new, or destruction of the old.

By daily experience they saw compounds dissolved, and in their dissolution nothing perished, but their union or connexion of parts: when in death the body and soul were separated, the man they held was gone, but the spirit remained in its original, the great soul of the world, and the body in its earth from whence it came; these were again wrought by nature into new compositions; and entered new states of being which had no relation to the former. According to some, nothing is so difficult as annihilation; it requires the infinite power of the Creator to effect it; some go farther, and seem to put it out of the power of God himself. According to others, nothing is so easy; existence is a state of violence; all things are continually endeavouring to return to their primitive nothing; it requires no power at all: nay, what is more, it requires an infinite power to prevent it.

The Talapoins hold it the supreme degree of happiness, to have the soul totally annihilated, and freed from the burden and slavery of transmigrations.

Some Christians maintain, that God will annihilate the souls of the damned, after a certain term of punishment; and this annihilation, they say, is the second death. Irenezus, according to M. du Pin, was of this opinion. See DEATH, HELL, and PUNISHMENT.

ANNIHILATION is also used, in *Political Arithmetic*: thus, when the capital stock of any public fund is reduced, so much as is reduced is said to be annihilated.

ANNI NUBILES, among *Law Writers*, the legal age at which a maid becomes fit for marriage; which is at twelve years.

ANNIS *Communibus*. See COMMUNIBUS.

ANNISEED. See ANISE-SEED.

ANNIVERSARY, is properly the yearly return of any remarkable day; anciently also called a *year-day*, or *mind-day*; that is, a memorial day.

The word is from *annus* and *verto*, on account of its returning every year.

ANNIVERSARY *days, dies anniversarii*, among our ancestors, more particularly denote those days on which the martyrdoms of the saints were yearly celebrated in the church; as also days whereon, at every year's end, men were wont to pray for the souls of their deceased friends. *Anniversaria dies ideo repetitur defunctis, quoniam nescimus qualiter eorum causa habeatur in alia vita*. This was the reason given by Alcuinus, in his Divine Offices. The first origin of anniversary days is referred by some writers to Pope Anacletus, and by others to Felix I.

ANNIVERSARY *winds*, are those which blow constantly at certain seasons of the year.

These are otherwise called *Etesian winds*; such are the *TRADE winds* and *MONSOONS*.

ANNIVERSARY is more particularly used for the *annale*, or *mass*, rehearsed daily for the space of a year after a person's death.

ANNIUS, of Viterbo, or JOHN NANNI, in *Biography*, a Dominican monk, was born, in 1427, and distinguished as an impudent impostor. Furnished with talents and learning,

he employed himself in writing books from his own invention, which he introduced to the world as genuine remains of several ancient authors, in "Seventeen books of Antiquities." This curious collection contained several tracts of Archilochus, Xenophon, Herodotus, Manetho, Megasthenes, Philo, Q. F. Picitor, M. Cato, Antoninus Pius, Sempromius, &c. &c. This work was first published at Rome in 1498; a second edition was published by Venetus at Venice; and in 1552, it was published in 8vo. at Antwerp. The editor pretended to have found the books at Mantua; and the imposition was for some time successful. Vossius and Bayle mention ten advocates for the genuineness of these writings. On the other hand, the most approved critics examined these pieces, and pronounced them spurious; and this judgment is now universally received. Annus died at Rome in the year 1502. Gen. Dict.

ANNOBON, in *Geography*. See ANNABON.

ANNO *Domini*, q. d. *in the year of our Lord*; the computation of time from the EPOCH of the incarnation of Jesus Christ. This is generally inserted in the dates of all public writings, with an addition of the year of the king's reign.

ANNOISANCE, in *Law*. See NUISANCE.

ANNOMINATION, *annominatio*, in *Rhetoric*, the same with what is otherwise called PARONOMASIA.

ANNONA, *Guanabanus* of Plum. in *Botany*, a genus of the *polyandrii polygynia* class and order, of the natural order of *coadunatae*, and the *anone* of Justieu: its characters are, that its *calyx* is a perianthium three-leaved and small, leaflets cordate, concave, and acuminate; the *corolla* has six petals, cordate, and sessile; the three alternate interior ones less; the stamina have scarcely any filaments, anthers very numerous, placed on the receptacle; the *pystilium* is a roundish germ, placed on a roundish receptacle; styles nine, stigmas obtuse, numerous, covering the whole germ; the *pericarpium* a berry, very large; roundish, clothed with a scaly bark, one-celled (or a compenna berry, as in *Vabus*); seeds very many, hard, ovate-oblong, placed in a ring, and netting. Martyn enumerates ten, Willdenow eighteen, and Gmelin nineteen species. 1. *A. muricata*, rough-fruited custard apple, or four lop, *guanabanus* of Plum. *Araticu-pouhe* of Mareg. Pif. and Ray, with leaves oval-lanceolate, smooth and acute, fruits muricate, petals ovate, the interior ones obtuse, shorter. This is a middle-sized tree, rarely above twelve or fourteen, or at most twenty feet high. It is a native of the West Indies, common in every savannah of Jamaica, and flowering in the spring. The smell and taste of the fruit, flowers, and whole plant, resemble very much those of black currants. There is a variety in Jamaica, with inodorous leaves, large flowers of a fulvous colour, and spherical mucronate fruits. It was cultivated here in 1656 by Mr. J. Tradescant, jun. 2. *A. tripetalu*, *A. charimolia* of Miller, broad-leaved custard apple, with leaves ovate, acute, pubescent beneath, flowers three-petalled, and petals lanceolate, coriaceous, and tomentose. This grows to a large tree, with numerous branches, in South America. The fruit is esteemed by the Peruvians as one of their most delicate sorts. It was cultivated, in 1739, by Mr. Müller. 3. *A. squamosa*, *A. tuberosa* of Rumph. *atamaram* of Rheed and Ray, undulated custard apple, or sweet lop, with leaves oblong, acute, and smooth, fruits obtusely scaled, outer petals lanceolate and inner ones minute. This is a small tree about eight feet high, and commonly a shrub; a native both of the East and West Indies; the fruit is sweet, and eaten in these countries; cultivated in 1739, by Miller. 4. *A. reticulata*, *guanabanus fructu aureo*, &c. of Plum. *Anonamaram* of Rheed and Ray, netted custard apple, with leaves oblong-lanceolate, acute and smooth, fruits ovate and reticulate-areolate, outer petals lanceolate, and inner minute.

This

This is a tree growing to the height of twenty-five feet and more, with spreading branches; a native both of the East and West Indies; and the fruit, according to Browne, is much esteemed by many people; but Swartz says, that it is seldom eaten; cultivated at Hampton court in 1690. 5. *A. hexafetala*, *A. fenfis* of Gmelin, long-leaved custard apple, with leaves elliptic-oblong, acute, and smooth, petals spatulate, equal and acute; a native of China, and cultivated in the East Indies; introduced in 1758, by Hugh, duke of Northumberland: suspected by Loureiro not to be different from the third sort. 6. *A. palustris*, guanabana palustris, &c. shining-leaved custard apple, with leaves oblong, rather obtuse and smooth, and fruits areolate. This is a small tree, about a fathom in height; growing wild in soft marshy places in Jamaica, and bears a fine sweet-scented fruit, of no disagreeable flavour; but it is said to be a strong narcotic, and on that account not eaten. It is called *alligator apple*: its wood is so soft, that it is used instead of corks to stop up their jugs and calabashes; and hence it is now universally denominated the *cork-wood* in Jamaica: introduced here in 1778, by Dr. T. Clarke. 7. *A. triloba*, trifid-fruited custard apple, with leaves elliptic, acute, and smooth; flowers pendulous and campanulate, calyxes ovate, and petals many and oval. This tree's trunk is about the size of a man's leg, and its height about ten or twelve feet. All parts of it have a rank, if not a fetid smell; and few, except negroes, relish the fruit; it usually grows in low shady swamps, and in a very fat soil. It is a native of the Bahama islands, Carolina, Maryland, and Virginia; and the seeds are frequently brought to England, under the name of *papaw-tree*; introduced in 1736, by P. Collinson, Esq. 8. *A. glabra*, smooth custard apple, with leaves lanceolate-ovate, and fruits conoid smooth: grows to the height of about sixteen feet, has an eatable fruit, sweet but somewhat insipid; it is the food of guanas, and many other wild creatures. A native of North America. 9. *A. asiatica*, Asiatic custard apple, with leaves lanceolate, smooth, shining, and marked with lines: a middle-sized tree, with spreading branches; a native of the East Indies; cultivated there and in China. 10. *A. africana*, African custard apple, with leaves lanceolate, pubescent: a native of America, though distinguished by the epithet *africana*.

These fruits are much esteemed by the natives of the countries where they naturally grow; are esteemed very cooling and wholesome, and are frequently given to sick persons. 11. *A. aegyptiaca*, with elliptic leaves and globose fruits. 12. *A. aperemou*, with leaves oblong, very entire, tomentose, and somewhat sessile, and smooth fruits. Aubl. pl. Guian. 13. *A. paludosa*, with leaves oblong, very entire, tormentose, under rutose, and tuberculated fruits. Aubl. pl. Gui. 14. *A. punctata*, with leaves oblong, smooth and very entire, and punctated fruits. Aubl. 15. *A. longifolia*, with leaves linear-oblong, very entire and smooth, and punctated reticulated fruits. Aubl. 16. *A. ambotai*, with leaves ovate, acute, very entire, beneath ferruginous-tomentose tube. 17. *A. rufescens*, with leaves ovate-cordate, petiolate, beneath tomentose, and tomentose fruits. Aubl. 18. *A. amara*, with leaves cordate, smooth, petiolate, under yellowish, and tomentose fruits. Aubl. 19. *A. mucosa*, with oblong leaves, areolated fruits, and external corolla monopetalous. Jacq. Obl. Bot. This is reckoned by Willdenow, a variety of the *A. reticulata*. To those species that have been above enumerated Willdenow adds—*A. pygmaea*, *A. pygmaea* of Bartram, with lanceolate acute leaves, and oblong acute petals, the interior the longer: a native of Florida: *A. obovata*, *A. grandiflora* of Bartram, with leaves obovate and somewhat obtuse, oblong smooth fruit, obovate

obtuse petals, the exterior the larger: a native of Florida. *A. grandiflora*, with leaves ovate-oblong and petiolate, of Vahl; with leaves ovate-lanceolate, smooth, and very large flower, of L. Marck; and with leaves ovate-oblong, fruit elliptic and somewhat rough, and petals pubescent and oblong, the interior the shorter, of Willdenow: *A. amplexicaulis*, with leaves cordate-oblong, acute, double-rowed, and embracing the stem, of L. Marck; or with leaves cordate-oblong and embracing, of Willdenow: a native of Madagascar and of the island of Mauritius.

Culture, &c. The seventh sort will thrive in the open air in England, if the situation be warm; but the plants must be trained up in pots, and sheltered in winter for two or three years; and in the spring they may be turned out of the pots, and planted in the open ground. The other sorts, which are natives of the hot parts of America, or the East Indies, are too tender to live in this country, unless they are preserved in warm stoves: the seeds that are brought over must be sown on a good hot-bed, or in pots of light earth, and plunged into a hot-bed of tanner's bark in February, which is the best time, that the plants may get strength before the colds of autumn. They should be kept in the bark-stove, and with careful management they will make great progress; but in warm weather, they should have plenty of fresh air. As they advance in their growth, they should be cautiously shifted into larger pots, constantly remain in the tan-bed; and they will thus be vigorous. They are preserved for the sake of the beauty of their leaves, as few of them flower, and none produce fruit in England. The stoves in which they are placed should, during the winter season, be kept to the ananas heat, as it is marked on the botanical thermometer. The earth should be light and rich, and the tan-bed frequently turned over and refreshed. In summer they should have frequent waterings; but in winter they should be seldom watered, not oftener than once a week in open weather; and in frost, it will be sufficient to water them once in two or three weeks. Martyn's Miller.

ANNOŒA, in *Ancient Writers*, denotes victuals, or provision, or corn for a year.

ANNOŒA civilis, the corn with which the granaries of cities were filled every year, for the subsistence of the citizens.

The tax, called the *annona*, or supply of corn for the use of the army and capital, was a grievous and arbitrary exaction, which, in the time of Justinian, exceeded, perhaps in a ten-fold proportion, the ability of the farmer, and his distress was aggravated by the partial injustice of weights and measures, and the expence and labour of distant carriage.

ANNOŒA militaris, the corn and other provision laid up in the magazines, for the subsistence of an army during the campaign.

In ancient writers we also meet with the phrases *singula annona*, *binæ annona*, *ternæ annona*: with regard to which Salmastius lays down this rule, that when *annona* occurs in the singular number, it includes not only corn, but flesh, wine, oil, and other necessaries; whereas, when it is used in the plural number, it imports bread alone. Aquinas is not contented with this rule, but instead of it advances another, *viz.* that *annona* in the singular number includes all kinds of provision; and, in the plural, imports so many rations or pittances of bread, flesh, and the like, distributed to so many men.

In this sense, soldiers are sometimes said to have risen to the benefit of five or more *annona*; that is, were entitled to so many rations. The Emperors Arcadius and Honorius took

great pains to reduce this profusion. Hence we read of *annonæ præfectus*, or *curator*, who superintended the sale of corn; *annonæ struitor*, who managed the military provisions; *annonarius*, an officer appointed to distribute provisions to the soldiers; and *annonarii*, denoting monopolists.

ANNONAGE, *annonagium*, a tax on corn.

ANNONAGE is much the same with *frumentage*.

ANNONAY, in *Geography*, a town of France, in the department of the Ardèche, and chief place of a canton in the district of Mezen, four leagues north-west of Tournon, and 11 north of Privas. N. lat. 45° 15'. E. long. 4° 52'.

ANNOT, or ANOT, a town of France, in the department of the lower Alps, and chief place of a canton, in the district of Castellane; two leagues west of Entrevaux, and three north-east of Castellane.

ANNOTATION, formed of *ad*, and *nota*, note, a succinct commentary, or remark on a book or writing; in order to clear up some passages, or to draw some induction or consequence from it.

ANNOTATION, in the *Civil Law*, denotes a kind of rescript or grant from the emperor, signed with his own hand. But this annotation differed from a mere rescript and a pragmatic sanction.

It took its name from the note or subscription at the bottom, which was in red letters.

ANNOTTO, in *Commerce*, a kind of red dye, brought from the West Indies. This is otherwise denominated *arnatto*, *anate*, *attole*, and *roucou*.

It is procured from the pulp of the seed-capsules of a shrub called *achiote* and *urucu*; the *Bixa orellana* of Linnæus, which grows seven or eight feet high, and produces oblong hairy pods, somewhat resembling those of a chestnut. Within each of these are thirty or forty irregularly figured seeds, which are enveloped in a pulp of a bright red colour, and unpleasent smell, somewhat resembling the paint called red lead when mixed up with oil; and it was used as paint by some of the Indians, in the same manner as woad was used by the ancient Britons. The seeds, together with the red tough matter that surrounds them, are softened in a wooden trough with water, until, by a kind of fermentation, which spreads a very nauseous smell, and by diligent stirring and pounding, the kernels are separated from the pulp. This mass is then strained through a sieve, and boiled; upon which a thick reddish scum, which is the pigment, separates. When skimmed off, it is carefully inspissated in another kettle; and after being completely cool, is moulded in roundish lumps, wrapt round with leaves of trees, and packed for sale. It seems to partake of the nature of vegetable albuminous matter. The method of extracting the pulp, and preparing it for market, is simply by boiling the seeds in clear water, till they are perfectly extricated; after which the seeds are taken out, and the water left undisturbed for the pulp to subside. It is then drained off, and the sediment distributed into shallow vessels, and dried generally in the shade. See *ROUcou*.

The annotto is now only prepared by the Spaniards. The English had formerly a manufacture at St. Angelo, now ruined. This drug is preferred by the dyers to indigo, and sold one-fourth dearer. The double Gloucester cheese is coloured with this dye, not with marygolds. Some of the Dutch farmers use it to give a rich colour to their butter, and great quantities are said to be applied to the same purpose in the English dairies. The poor people use it instead of saffron; and it is sometimes mixed as an ingredient in chocolate, during the grinding of the cocoa, in the quantity of about two drams to the pound, in order to give it a reddish

colour; but the opinion of its being an earth has brought it into disrepute, and this use of it has been discontinued. Some have recommended it as a good cordial, and a preventative against retention of urine. It is used by the Spaniards in America as a gentle laxative, as an antidote to the dysentery, and a stomachic. But it is never prescribed for medical purposes in Europe.

To water it gives only a pale brownish yellow colour, and is not soluble in that liquid, nor in spirit of wine; but, in order to be fit for dyeing, it requires an alkaline menstruum, to which it gives a bright orange colour; and hence it is useful as an ingredient in *VARNISHES* and *LACQUERS*, and in dyeing wax of a vermilion colour. Wool and silk, boiled in a solution of it by alkaline salts in water, acquire a deep, but not a durable orange dye; for though it is not changed by alum or acids, it is discharged by soaps, and destroyed by exposure to the air. It is said to be an antidote to the poisonous juice of *manibot*, or *castuda*. The liquid sold under the name of "Scott's nankeen dye," seems to be nothing but annotto dissolved in alkaline ley.

See more of this artificial preparation, and the manner of making it, in Dr. Lewis's *Commercium Phil. Techn.* p. 224, &c. or Neumann's Works, p. 433, &c. Murray, *Med.* vol. iii. p. 392. Gren's *Chem.* vol. i. p. 443.

ANNUAL, something which returns every year, or closes at the end of the year. Thus we say, an annual or yearly feast, office, commission, rent, revenue, income, &c.

The annual motion of the earth, see proved under *EARTH*.

ANNUAL is sometimes used for the yearly rent or income of a prebendary, &c.

In which sense *annuale* amounts to the same with what we otherwise call *annat*.

ANNUAL is also used, in *Ecclesiastical Writers*, to denote a yearly office, said for the soul of a person deceased on the day of his obit, or anniversary.

ANNUAL, in the *Scottish Law*, denotes any yearly revenue or due paid at certain times, either legal, as *Martinfests* and *Whitfuntide*; or conventional, as the parties agree.

In the acts of parliament made by Queen Mary, mention is made of *ground-annual*, *fee-annual*, and *top-annual*; the meaning whereof is somewhat uncertain. See *ANNUAL*.

ANNUAL argument of longitude. See *ARGUMENT*.

ANNUAL epacts. See *EFACT*.

ANNUAL equation of the mean motion of the sun and moon, and of the moon's apogee and nodes. See *EQUATION*.

ANNUAL leaves, are such leaves of plants as come up afresh in the spring, and perish in winter. These stand opposed to *ever-greens*.

ANNUAL plants, called also simply *annuals*, in *Gardening*, commonly signify such plants as are of one year's duration, or which continue for the summer season, or a few months only. In general, however, all such plants as rise from seed sown in the spring, arrive at maturity in the summer or autumn following, producing flowers and ripe seed; and which afterwards perish in their tops and roots, are considered as annuals. This last effect takes place in most sorts in the autumn and winter following; though some hardy kinds, when late sown, will stand over the winter until the ensuing spring, especially those of the esculent sorts; but very few of the flowering kinds remain longer than October or November, unless protected by a greenhouse, garden-frame, or some other covering of a similar nature.

The plants of this tribe are very numerous, as most of

those of the herbaceous kinds, consisting of uncultivated plants, weeds, &c.; and also a number of cultivated garden and field plants, both of the esculent and flowery ornamental kinds, are of this description. The last sort are often termed simply *annuals*. They are likewise very extensive, and both of the hardy and tender kinds, some of which, from the peculiarity of their nature, and others from their producing beautiful flowers, are cultivated as ornaments to the flower garden and pleasure ground, during the summer and autumnal seasons.

The flowering annual plants are distinguished by gardeners into the *hardy* and *tender* sorts; the former being such as are capable of being raised from seeds sown on beds, borders, or other places in the natural and open ground; while the latter constantly require to be sown, and to have in some degree the aid of hot-beds, in order to promote their healthy growth.

The first sort, or the hardy annuals, are also mostly sown in places where they are designed to remain and flower without being transplanted, as many of them do not succeed under such management; some, however, will answer in either method, and may be occasionally transplanted.

But the tender annuals, after being sown and brought to a proper state of growth in hot-beds, are generally to be transplanted about May or June, either into pots or borders in the open ground.

1. *Hardy Annuals*.—The following are some of the principal of the hardy sort of flowering annuals: *adonis*, or adonis flower; *alkekengi*, white flowered, blue, yellow berried, red berried; *amaranthus*, prince's feather, love lies bleeding, purple; *chrysan*, white, sweet scented; *amethystea*, blue; *bulm*, moldavian; *belvedere*, or summer cypress; *calendula*, or cape marigold; *candy tuft*, white flowered, purple, large white, crimson; *catch-fly*, lobels red flowered, white purple, caterpillar; *clary*, red topped, white topped; *convolvulus*, three coloured minor, minor blue and white, minor blue, major blue, great white, great striped blue, great purple, red; *cyanus*, or bluebottle, blue-flowered, purple, white, red, striped blue and white; *cucumber*, sporting; *devil in a bush*, blue flowered, white, nettle leaved; *fumatory*, yellow; *hawk-weed*, yellow, red; *hedge-hog trefoil*, snail-shaped, prickly, turbinate, globular, orbicular, long crooked twisted; *honeyswort*, greater, less; *holly-hock*, Chinese variegated, double flowered; *jacobsa*, or ragwort, purple flowered white; *Indian corn*, tall growing, dwarf; *kidney beans*, scarlet runner, dwarf scarlet, large white runner; *ketmia*, bladder; *larkspur*, upright blue, upright purple, upright white, upright rose-coloured, white rocket, rose rocket, dwarf rose rocket, dwarf white rocket, dwarf blue rocket, dwarf red rocket, branching, blue branching, white branching, double and single flowered of all the different sorts; *lavatera*, cretan red flowered, white, purple; *lupine*, dwarf yellow, large yellow, white, great hairy blue, great hairy rose coloured, narrow leaved blue; *lychnis*, dwarf; *marigold*, double orange coloured, double yellow, double lemon coloured, gold coloured, party coloured, yellow ranunculus flowered, childing or profliferous, cape marigold; *mallow*, curled leaved, oriental; *mignonette*, odoriferous or sweet scented; *nasturtium*, major or large growing, minor or dwarf; *nolana*, peruvian dwarf blue; *nigella*, or devil in a bush; *pansey*, or heart's ease, common small variegated, large Dutch variegated, large purple, yellow, purple and yellow, purple yellow and white; *peas*, sweet scented, purple, white, painted lady, scarlet, tangier; *pea*, winged; *pea*, crown, white blossomed crown, painted lady crown, rose coloured; *periscaria*, oriental, red flowered, white flowered; *poppy*, large double

purple, double red, white variegated, red and white spotted or carnation, dwarf red, dwarf purple, dwarf variegated, double and single of all the different sorts; *queen's balm*, *scabious*, purple sweet, red flowered, white, striped, hen and chicken flowered, Harry flowered; *snail trefoil*, *stock gillflower*, ten weeks, purple flowered, red, white, scarlet dwarf French, wall-flower leaved red, wall-flower leaved purple, wall-flower leaved white; *stock virgin*, purple white; *snap dragon*, annual with white flowers, purple flowers, major or greater with flowers, purple white, yellow, scarlet, red and white, purple and white, red and yellow, white and red, yellow and red, yellow and white, scarlet gold dotted; *strawberry spinach*, *sun-flower*, annual, tall growing dwarf, double flowered of each sort; *sweet sultan*, purple, red, white, yellow; *toad flux*, three-leaved yellow, three-leaved purple, three leaved blue, variegated, white, branching yellow, tobacco, hardy round leaved, Virginia long leaved, Virginia broad leaved; *Virginia* or *virgin's stock*, *Venus's looking glass*, purple, white; *Venus's navelwort*, blue flowered; *xeranthemum* or *eternal flower*, red, white, purple, double flowered.

The authors of the "Universal Gardener," in which the above list is contained, observe, that the general season for sowing all sorts of hardy annual plants is in the spring, from about the middle or latter end of February to the middle or latter end of April, for the principal *blow*; and also some in May and the beginning of June, for successive and late flowering, especially those of the quick flowering kinds of short duration, as *candy tuft* and *virgin stock*, &c.

The order or method of sowing all these is principally in little patches or clumps, to remain as mentioned above. These patches should be formed from about three or four, to five, six, or eight inches in diameter, at moderate distances, and in some sort of regularity, towards the front, middle, and back parts of the borders or beds; and also in a varied manner in respect to the plants; the smaller growing sorts being constantly sown more or less towards the fronts of the borders, according to their degrees of growth; and the larger kinds more backwards, in the same proportion. Some may likewise be occasionally sown in pots; and in all of which, each sort and respective varieties should be sown in separate patches, &c. from about a quarter of an inch to half an inch or an inch in depth, or but little more, according to the sizes of the different sorts of seeds; observing in this business to generally loosen and break the earth a little, so as to render it fine for each patch, especially if hard, stubborn, or cloddy; then drawing off a little depth of mould, according to circumstances, to one side, sow the seeds many or few together in the patches, proportionately to the sizes of the respective plants, covering them regularly with the earth drawn aside to the depth required; and thus proceed in general, always placing a small short stick, or some other mark, to each patch as the sowing goes on, in order to distinguish the places.

Some may also be occasionally sown in drills, either in beds separately, or on the borders; the low growing kinds towards the fronts, and the larger sorts towards the back parts; in which order of growing may be had *virgin stocks*, *candy tuft*, *larkspur*, *sweet peas* of the different sorts, *lupines*, *tenweek stocks*, &c.

After sowing, if it be dry warm weather, it will be beneficial to give occasional light waterings, both before and after the plants are come up, especially during their more early growth; and when they are come up about an inch or two in height, those in the patches will, in many sorts, require thinning, especially those of a large, tall growth, and bushy

bushy kind, such as *sun-flowers*, *persicaria*, *Indian corn*, *tobacco*, *belvedere*, *marigold*, &c.: some to one good plant in each patch; others to two or three plants, as *lavatera*, *curled and oriental mallow*, *strawberry*, *spinach*, *Chinese hollyhock*, *xeranthemum*, *amaranthus*, *scabious*, *sweet fultan*, and similar kinds; and some also left in small bunches, as *candy tuft*, *lupines*, *larkspurs*, *sweet peas*, *cyanus*, *nastrurtium*, *convolvulus*, *Venus's looking-glass*, and *navel wort*, *mignonette*, *virgin flock*, *moldavian balm*, and many others of similar growth. Or some tenweek stocks and mignonette may either remain thin in patches, or, where too thick, some of each sort be transplanted in that order, three, four, or five together, or as required; also in many of the other sorts, some may occasionally be thinned out for transplanting, when required to supply deficiencies, &c. always performing the business, as much as possible, in showery weather.

It is farther remarked by the same writers, that in the advancing growth of the plants, the principal culture is to keep them clean from weeds; and where any large sorts remain too close or crowded together, to thin them according to their growth in some regular order; and in the larger tall growing kinds, some will require the support of sticks, as also most of the climbing or trailing sorts, particularly the sweet peas, convolvulus major, and large nasturtium, &c.; and to the climbers, some upright small branching sticks, trimmed up a little regularly, should be placed; the convolvulus and scarlet bean being volubilate, or twining climbers, will ascend spirally upon any straight upright stick, pole, or stake.

If it should be required to have any desirable sorts of these hardy annuals of moderate growth to flower early, they may be forwarded by sowing the seeds in pots in February or March, and placing them in a hot-bed, or more successfully in a hot-house, &c.; such as *scarlet* and other *sweet peas*, *virgin flock*, *candy tuft*, *mignonette*, *tenweek stocks*, *dwarf lupines*, *dwarf larkspurs*, *queen's balm*, and several others, especially of similar moderate growth.

As all the plants of this tribe of annuals generally produce plenty of ripe seed in autumn, care should be taken to save proper supplies of the different best sorts, as it ripens in perfection, in order to have plenty for sowing the ensuing spring to raise a production of new plants for flowering the following summer. In some sorts the scattered, or self-sown seeds, disseminated from the plants on the borders, will often come up naturally early in the spring; such as *larkspur*, *prince's feather*, *persicaria*, &c.; and which, if permitted to stand, will flower sooner than the spring sown plants; but as many of these often rise irregularly, they should be transplanted while young into some regular order; and as they are only chance productions, they should not prevent the regular sowing.

2. *Tender Annuals*.—The principal sorts of which are contained in the following list: *African marigold*, orange coloured, lemon coloured, deep yellow fistulous or quilled, waved flowered, dwarf, sweet scented, double flowered of each sort; *amaranthus*, *greater or true, *bloody, trailing or love lies bleeding; **balsam*, red, scarlet, purple, striped, variegated, double; **basil*, common greater upright, sweet with broad leaves, fringed leaved, purple leaved, tricolor leaved, red flowered, purple flowered, long spiked, &c., least or bush basil with hoary leaves, dark purple leaved, variable leaved, &c.; *calendula*, or cape marigold; **capsicum*, long podded, short podded, heart podded, bell podded, angular podded, cherry podded, olive podded, red podded, scarlet podded, yellow podded; *China-aster*, blue flowered, purple, red, white, striped, variegated, bonnet flowered,

quilled flowered, double and single of each sort; *Chinese hollyhock*, variegated, double; *chrysanthemum*, yellow, white, cream coloured, sulphur coloured, fistular or quilled, double and single of each sort; *convolvulus*, major, with deep purple flowers, red, blue, white, deep blue; **cucumber*, snake shaped; **egg plant* or *melangena*, white, fruited, purple fruited; *French marigold*, deep yellow, golden yellow, crimson coloured velvety, crimson and yellow striped, variegated crimson and yellow, sweet scented dwarf, double and single of each sort; *gourd*, orange, pear shaped, striped pear shaped or squash, carbuncled, warted, long taper, long crooked, horn shaped, large barrel shaped, large globular, large oval, hemispherical yellow, stone coloured, flesh coloured, sandy coloured, party coloured, white, &c.; **globe amaranthus*, purple headed, white variegated, silver spiked; *Indian corn*, tall growing dwarf; *India pink*, bright red, purple white, red and white variegated, differently variegated, numerous, large imperial, double and single of each sort; **love apple*, red fruited yellow fruited, cherry shaped; **marvel of Peru*, red flowered, yellow, white, purple, striped, long tubed flowered; **melon*, snake shaped or serpent cucumber; *mignonette*, sweet scented; *nolana*, trailing blue; **palma christi*, major or tall growing, minor or lesser, most broad leaved, lesser leaved, &c.; *persicaria*, oriental, red flowered, white; *sultan flower* yellow; *stock gilliflower*, ten weeks, red, purple, white, scarlet, dwarf scarlet, dwarf white, wall flower leaved, white, wall flower leaved purple, double of each sort; *tobacco*, Virginia long leaved, Virginia broad leaved; **tree-amaranthus*, **zinnia*, red flowered, yellow.

In respect to the culture of the more tender annuals, it is remarked in the same work, that they should be mostly either sown in a moderate hot-bed in March or April, and the young plants forwarded a little in growth therein, till settled warm weather, in the middle or latter end of May; and then transplanted; or sown in a bed of natural earth or warm border in April, protected under a garden frame or glasses, or at least defended in cold nights by garden mats; and in either method to be transplanted, in May or beginning of June, into beds, borders, pots, &c. in the flower and pleasure garden, to remain for flowering in summer and autumn. But that, where the convenience of a hot-bed is attainable, it is always advisable to raise a principal supply by that means for earlier transplanting and flowering, as a portion of the different sorts may be sown and raised in one hot-bed, smaller or larger, according to the quantity required; such as a bed for one light, or for two or three light frames; or where considerable supplies are wanted, a larger extent of hot-bed will be necessary in proportion; making the bed or beds in March or the beginning of April, and defending them with a frame and lights, or hand-glasses; or in want of these, protecting them with an awning of mats in cold nights and bad weather, observing, in general, that only a moderate hot-bed, of about two feet thick in dung, will be sufficient; earthing it at top five or six inches deep, with fine rich mould; in which sow the seed in small drills crossways, drawn with the finger two or three inches asunder, from half an inch to an inch deep, according to the size of the different sorts of seeds, which should be sown regularly, each sort separately, and covered in evenly with the earth the same depth, giving them air occasionally, by raising one end of the glasses an inch or two; or if a covering of mats, by taking them off, or turning them up in front in the day time; and, according as the plants advance in growth, admitting a larger portion of fresh air to strengthen and harden them by degrees, giving also occasionally

sionally gentle waterings. Continue in this manner the care of the young plants until advanced two or three inches in growth, when it will be of advantage to prick out a quantity of the principal sorts into another moderate hot-bed, three, four, or five inches asunder; or others into natural beds of light earth under frames and glasses, or to be defended occasionally by mats; but in deficiency of hot-beds, frames, &c. they may, in general, be pricked out in the middle or latter end of May into natural beds in the open ground; all of which should be watered at the time, and afterwards occasionally; and shaded with mats from the sun, if convenient, till the plants have taken fresh root; observing also to give those in the hot-beds and under-glasses less or more air every mild day. When in three, four, or five weeks, in either of these beds, they have acquired a tolerable degree of strength and size, as four, five, or six inches growth, or more, according to the difference of the sorts, they should all be finally transplanted about the middle or latter end of May and beginning of June, into the open ground on the beds, borders, and other compartments, and into pots, to remain for flowering, taking the opportunity of moist weather, if possible, for the work; and, where convenient, to remove and replant some sorts with a little ball of earth adhering about the roots, as it will be of great advantage in their more early flowering; watering them as soon as planted out, and afterwards as occasion may require, till freshly rooted, and they discover signs of a renewal of growth.

It is added, that as where any of the above raised plants have remained some time in the seed bed not pricked out, they may probably have drawn one another up into a weekly growth, care should be taken to plant them out in May, as soon as the weather is settled and favourably temperate, especially the more tender species that have this mark * prefixed to them.

It is also observed, that tenweek stocks and mignonette may be sown in a hot-bed so early as February, or any time in March, in order to raise a few plants to prick out into pots, three or four in each, for the earliest flowering; or some may be sown in March in the natural earth, or a warm border, under glasses or other occasional shelter, for early transplanting in April or May, into pots and flower borders, &c.

In the gourd kinds, when designed to raise them in hot-beds, they should not be sown before April; for if sown earlier, they are apt to grow too large before the season becomes sufficiently warm to admit of planting them out in the open ground; or in the beginning or middle of May some may be sown in the natural ground, both for transplanting, and in patches to remain.

But where hot-beds, frames, glasses, and other similar conveniencies are deficient, many of the species and varieties of this class, as has been just observed, may be raised in the open ground, especially if not generally sown till the beginning, or towards the middle or latter end of April, according to the state of the season, sowing them in a warm border or other compartment, of light earth, or in pots placed in similar situations; and when the plants are advanced several inches in growth, pricking them out into beds, or finally planting them out in May and the beginning of June. In this way they will all flower in tolerable perfection, but not generally so soon by a few weeks, nor all in an equal degree of full growth and perfection, as those which are forwarded in hot-beds, or under the protection of frames, glasses, &c. to a proper size for earlier setting out.

The sorts that will occasionally the most readily succeed

without the assistance of hot-beds, &c. are the *African* and *French marigold*, *crisanthemum chinensis*, *polian flower*, *Indian pink*, *love lies bleeding*, *Chinje lily*, *persecaria*, *tobacco*, *tenweek stock*, *nolana*, *mignonette*, and *Indian corn*; also gourds, if not sown till May; and four times *palma christi* and the *love apple*, in a temperate warm season. All these may be sown in beds or borders of natural earth, in warm situations, as has been observed, but not in most of the sorts before the middle of April; the plants being pricked or planted out in May or June into beds, borders, and pots, to remain for flowering.

In sowing the above sorts in the natural ground for want of hot-beds, if the beds or borders in which they are sown be defended under frames or hand-glasses, or sheltered with mats, it will be of much advantage in raising the plants more successfully to a forwarder growth; and they will sooner attain proper strength for transplanting out and flowering.

There are some however of this kind, that cannot be raised in any tolerable perfection without hot-beds to bring them forward at first to a proper growth for transplanting. But when in want of hot-beds, sow some under glasses about the middle or latter end of April or beginning of May; and when the plants are advanced a few inches in growth, in the latter end of May or beginning of June, plant them out into borders, beds, and pots. The method by means of pots, beds, frames, and glasses, is, however, by much the best.

In finally pricking out the plants in May and June, where they are to remain for flowering, showery weather is also of great advantage; and where any particular sorts can be removed and replanted with little balls of earth about their roots, that method should not be omitted. The business may be performed in some with a garden trowel to make proper apertures, as for those with balls of earth or full roots; and others with a dibble, according to their growth. In most sorts, planting them singly, or one plant only in a place, and disposing them in the borders, &c. in a diversified manner, the smaller sorts more or less forward, and the larger kinds towards the middle and back parts, in some proportion to their different degrees of growth, as before directed. Some of the other principal sorts may also be placed in pots as required. But in the tenweek stocks, and other similar plants, it is always advisable to plant some in patches, three or four plants together, about three inches apart, both in the borders and in pots, in order that, as being of small growth, their flowers together may appear more conspicuous, and have a greater chance of producing some double flowered plants. Some mignonette and nolana, as being low plants, may also be planted in the same order. The love apple and gourd being of extensive rambling growth, may be planted against a south wall, paling, treillage, &c. especially the love apple, in order to have their extending branches trained thereto, that they may ripen their fruit more effectually in autumn. Gourds of the small fruited kinds may be planted in a similar manner, or against the railing of arbours, &c. in order to be trained up thereto in their advancing growth; others in capacious spaces, in large borders, &c. to have room to extend along the ground, or to be trained up to strong tall stakes. Moderate watering should be given directly in every case, especially in dry weather, and repeated occasionally till the plants have taken fresh root, and begun to grow.

The after-culture is chiefly to keep the plants clear from over-running weeds, and to give occasional support to those of large or tall growth; and sometimes where any branch

out very irregularly, or in a rambling manner, in their advanced growth, as often happens in the African and French marigolds and crysanthemum, &c. they should be trimmed to the regular order: and some sorts, as the love apple and the 'gourd' kinds, if planted any where in the borders, being of a very rampant growth, be trained up to strong stakes, as before observed, both to prevent their over-running the adjacent plants, and that their fruit may appear more conspicuous, and ripen in greater perfection, especially the love apple. And such plants as have been planted in pots, will now be ready for moving in their respective pots occasionally, when in flower, to adorn particular compartments of the garden or other places, as may be required; and as the earth in the pots dries very fast in hot weather, they will require watering every day or two during the season. All or most of these plants will be flowering in June or July, and continue, in general, till September or October; and the greater part of them are highly ornamental, though there are a few sorts that are of little or no value for their flowers, as the capficum, love apple, egg plant and gourd, being chiefly esteemed for the appearance of their fruit; and the palma chrilli for its majestic growth and large palmated leaves. All the sorts produce ripe seed in Autumn, and soon after wholly perish: particular attention should therefore be given to collect proper supplies of seed from the best flowering plants of the different sorts: when dry, to be preserved for use in the succeeding spring.

There is, in addition to the above, a still more tender kind of annual plants; and which, according to the writers already mentioned, are superiorly ornamental and curious; some in the beauty of their flowers, others in the singularity of their beautifully coloured leaves, as in the *amaranthus tricolor* and *bicolor*; some for the curiosity of their fruit, as in the *egg plant* and *snake melon*, &c.; and the *humble* and *sensitive plants*, from the singularly beautiful sensitive motion of their leaves; the *ice plant*, in its icy-like or crystalline appearance; and the *tree amaranthus*, both in its large tall growth branching widely around, and its vast pendulous flower-spikes often two or three feet long or more.

These are chiefly comprehended in the following list:

3. *Tendrest Annuals*.—*Amaranthus*, tricolor, bicolor, maximus or tree amaranthus, bloody, &c.; *balsamine* or *bal-sum*, double striped, double scarlet, double purple, double bizarre; *broualia*; *cock's comb*, tall purple headed, dwarf purple, crimson, buff coloured, yellow, branching; *convolvulus*, scarlet; *egg plant*; *globe amaranthus*; *humble plant*; *ice plant*, or diamond ficoides, oval leaved, pinnatifid leaved; *marvel of Peru*; *martynia*, purple flowered, red, white; *melon*, snake shaped; *stramonium*, double white, double purple, double striped; *sensitive plants*, double flowered annual, common shrubby, humble; *zimbia*.

These very tender annuals are all to be raised in hot-beds in the spring, under frames, &c. till May or June; and in order to obtain them in a tolerable degree of perfection, two different hot-beds, at three, four, or five weeks intervals, will be necessary for sowing or raising them in: one the latter end of February, or any time in March, but not later than the beginning of April; the young plants, when about one, two, or three inches in height, being pricked out, some into small pots singly, others in the earth of the bed, three or four inches asunder, the whole being in the same bed if there be room enough, if not, into another hot-bed; and when they have advanced in growth, so as to crowd one another, they should be removed into another hot-bed, under a deeper frame, or the frame raised at bottom

occasionally, as the plants rise in height. Some should be put in large pots, and others potted that were not so before, plunging the pots in the earth of the bed; or some may be put in the bed, six or eight inches asunder: water is then to be given in general, and the glasses put on. The whole from their first growth, must have an admission of fresh air every day, by raising the upper end of the glasses one, two or three inches, supplying them with moderate waterings. In this way they may be forwarded until the latter end of May, or some time in June, according to their growth or the temperature of the season, as before suggested; but in the mean time, in their advancing state, inure or harden them by degrees to the weather, particularly by gradually admitting a larger share of air, or by sometimes taking the glasses off entirely in warm days, &c.

The *humble* and *sensitive* plants should, in general, be continued constantly under glasses, in a green house, &c. or in a room window within, in the full sun; as, if fully exposed to the open air, it would deprive them of much of their lively sensitive motion, in which curious singularity their principal merit consists.

In order to raise some of the more curious sorts of this kind of annuals in the greatest perfection, such as the tall *cock's comb*, *tricolor*, *bicolor*, *double balsams*, *stramoniums*, *globe amaranthus*, *egg plants*, &c. it will be necessary to have two or three different successional hot-beds under frames and glasses, at a month's interval; that is, a small one in March, to sow the seeds, and raise the plants an inch or two high in; a second in April, of larger dimensions, in which to prick out the young plants from the seed bed, three, four, five, or six inches asunder; and sometimes a third in May, for a larger frame to receive them when transplanted in pots to remain till June, and they grow to full size; observing that while they are in the second and last hot-beds, the frames be occasionally raised or augmented in depth, according as the plants rise in height.

The first hot-bed for the seed should be made, as already directed, of suitable dimensions, and about two feet and a half deep in dung; the frame and glasses then put on, leaving one end of them open, to let out the rank steam of the dung; and in a few days, or when the first great steam and heat of the bed are gone off, the earth, which must be rich, light and dry, be put on four or five inches thick. The seeds of different sorts may now be sown, each kind separately, in small shallow drills, drawn with the finger, covering them with fine mould, from a quarter to half an inch deep, or with the very small seeds but very thinly. The glasses are then to be put on again, setting one end of them a little open, for the evaporation of the rising steam of the bed, covering them every night with garden mats. The plants mostly appear in a few days, when fresh air must be judiciously and with caution admitted, by propping up the ends of the glasses about an inch or two every mild day; and when the earth becomes dry, a very slight sprinkling of water be given in a sunny forenoon. The glasses should be mostly kept close in the nights; but if a strong steam and heat take place, they may be raised a little at one corner, for air to enter, and the steam to pass away, hanging the end of a mat over the tilted part, and continuing to cover the glasses with mats every night.

The care of the seedling plants is to be continued in the beds for about three weeks, or till they are advanced one, two, or three inches in growth, according to the different sorts; they are then to be pricked out into another new-made hot-bed.

When the plants in the seed hot-bed are advanced one, two,

two, or three inches, as above, another hot-bed should be put in readiness to receive them, making it for a two or three light frame according to the quantity of plants that are ready for the purpose. When the bed has imparted a proper degree of warmth to the earth, take up the plants with care, and in the same manner as directed above, prick them out into this, four or five inches distant, then give them a very light watering, and occasionally shade them in the middle of sunny days till they have struck fresh root; and admit air as before every fine day, by raising the upper ends of the glasses one or two inches; also occasional light waterings two or three times a week, in warm weather, and defend them in the nights with mats, and raise the frames, according as they extend in height, as before advised. After having had four or five weeks growth in this bed, if they have advanced considerably, so as to meet and crowd one another much, it will be adviseable, as already noticed, to remove them into a third and final hot-bed where it can be conveniently obtained; some being planted in the bed, others previously potted and placed in them, to be covered by glasses, as directed above.

The frames, glasses, or other conveniences for these uses should be sufficiently large, especially for the tall plants, and capable of being raised at pleasure, as they advance in growth. The other management being the same as directed above. (See HOT-BED.)

Before the plants are finally set out, they should always be occasionally exposed, and have the air freely admitted to them in the frames, at proper times, in order to harden them. And about the latter end of June, or beginning of July, when the weather is settled, they may be removed in their pots to the places where they are designed to remain for the summer.

This class of annual plants should always occupy the principal situations both in gardens and pleasure grounds, as in the most public and most frequented compartments in the front courts, &c.

The only culture that is necessary in any of the different sorts, when removed into the full air, is principally to supply them with suitable quantities of water, especially those in pots; and occasionally to such as are in borders, when first planted out, and till fast rooted; and to keep the whole clean from weeds, and supported with sticks, &c. where required.

They all flower from June or July till the end of autumn; and in August and September ripen seed, which should then be gathered from the best and most perfect plants, when the weather is quite dry.

The particular management of the different plants will be found under the *genera* to which they respectively belong.

ANNUAL meadow grass, called in some parts of England Suffolk grass, is a species of grass which makes the finest turfs, and seems well adapted to dairy-farms. See *POA ANNUA*.

ANNUALIA, yearly oblations anciently made by the relations of deceased persons on the day of their death.

This day they called *year-day*, &c. and on it mas was celebrated with great solemnity.

ANNUEL, *ground*, according to Skene, is when the property of any land, whether built or unbuilt, is let or sold for a yearly rent, to be paid either to the proprietor, or to some chaplain or priest.

ANNUEL, *free*, is either when the mail or due is disposed of as a yearly revenue; or, when the land or tenement is let in a fee-farm hereditary, for a certain yearly sum to be paid under the denomination of *feuda firma*.

ANNUEL, *top*, is a due given or assigned out of houses or buildings, where the property remains with the former owner, only with the condition of his paying the said *annuel*.

ANNUEL of Norway, of which mention is made in the acts of parliament of King James the Third, was an annuel payment of an hundred marks sterling, which the kings of Scotland were obliged to pay to the kings of Norway, in satisfaction for some pretensions which the latter had to the Scottish kingdom, by virtue of a conveyance made thereof by Malcolm Canmor, who usurped the crown after his brother's decease.

This *annuel* was first established in 1266; in consideration whereof the Norwegians renounced all title to the succession of the isles of Scotland. It was paid till the year 1468, when the *annuel*, with all its arrears, was renounced in the contract of marriage between King James the Third, and Margaret, daughter of Christian the First, king of Norway, Denmark and Sweden. See Skene de verb. Signif.

ANNUENTES Musculi, in *Anatomy*, a pair of transverse muscles, at the root of the *verteb æ* of the back, called also by Mr. Cowper *RECTI interni minores*, because they lie under the *RECTI majores*.

They are called *annuentes*, from *annuere*, to nod towards, because they help to nod the head, or draw it directly downwards and forwards.

ANNUITIES signify any interest of money, rents, or pensions, payable from time to time, at particular periods.

The most general division of annuities is into *annuities certain*; and annuities the payment of which depends on a *contingency*; such, in particular, as the continuance of a life.

Annuities have been also divided into annuities in *possession* and annuities in *reversion*; the former meaning such as either *have* commenced, or are to commence *immediately*; and the latter such as will not commence till some particular future event has happened, or till some given period of time has expired.

Annuities may be farther considered as *payable yearly*, *half-yearly*, or *quarterly*.

The present value of an annuity is that sum which, being improved at compound interest, will be sufficient to pay the annuity.

The present value of an *annuity certain*, payable yearly, and the first payment of which is to be made at the end of a year, is calculated in the following manner.

Let the annuity be supposed to be 100*l.* the present value of the first payment of it, or of an hundred pounds to be received a year hence, is that sum in hand, which being put out to interest, will increase to 100*l.* in a year. In like manner, the present value of the second payment, or of 100*l.* to be received two years hence, is that sum in hand, which being put out to interest, will increase to 100*l.* in two years. The like is true of the value of the 3d, 4th, 5th, &c. payments; and the sum of the values of all the payments is the value of the *annuity*.

Let the interest be supposed to be 4 *per cent.* The sum which improved at 4 *per cent.* interest for the year will produce 100*l.* at the end of the year, is the sum which bears the same proportion to 100*l.* that 100*l.* bears to 100*l.* with 4 added to it, that is, to 104*l.* Say then, as 104*l.* is to 100*l.* so is 100*l.* to a fourth proportional, which will be 96.15, or 96*l.* 3*s.* the value of the first payment.

Again, the sum which improved at 4 *per cent.* for two years,

ANNUITIES.

years, will produce 100*l.* at the end of 100 years, is the sum which being now put out to interest will produce in a year that sum which in one year more will produce 100*l.* that is, it is the sum that will produce in a year 96*l.* 3*s.*; for it has been just shewn, that 96*l.* 3*s.* will in a year produce 100*l.* Say then, as 104*l.* is to 100*l.* so is 96*l.* 3*s.* or 96.15, to a fourth proportional, which will be 92.45, or 92*l.* 9*s.* The value therefore of the second payment is 92*l.* 9*s.*

By proceeding in this method it will be found that the value of the 3d, 4th, 5th, &c. payments, are £88.89, £85.48, £82.19, &c. The sum of 10, 20, or 100 of these values, is £811, £1359, £2450, respectively, or the present value of an annuity of 100*l.* payable for 10, 20, or 100 years. The sum of an infinite number of these values is 2500*l.* or the value of a perpetual annuity of 100*l.* at 4 per cent.

In general: suppose r to denote 1*l.* increased by its interest for a year, or the amount of 1*l.* in a year. Then $\frac{1}{r}$ will be the present value of 1*l.* to be received a year

hence; for r is to 1 as 1 is to $\frac{1}{r}$. Also $\frac{1}{r^2}$ will be the value of 1*l.* to be received at the end of two years; for r is to 1 as $\frac{1}{r}$ is to $\frac{1}{r^2}$. In like manner, $\frac{1}{r^3}$,

$\frac{1}{r^4}$, $\frac{1}{r^5}$, &c. will be the values of 1*l.* to be received at

the end of 3, 4, 5, &c. years respectively; and $\frac{1}{r^n}$ will be the value of 1*l.* to be received at the end of n years. The value, therefore, of an annuity of 1*l.* for n years is

$\frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3} + \frac{1}{r^4}$ &c. continued to n terms. And the value of the perpetuity is the series continued in infinitum.

In order to find the sum of n terms of this series, put S equal to it, or $S = \frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3}$, &c. $+ \frac{1}{r^n}$.

Then,

$$S r = 1 + \frac{1}{r} + \frac{1}{r^2}, \text{ \&c. } + \frac{1}{r^{n-1}}. \text{ And}$$

$$S r - 1 = \frac{1}{r} + \frac{1}{r^2}, \text{ \&c. } + \frac{1}{r^{n-1}} = S - \frac{1}{r^n}. \text{ There-}$$

$$\text{fore } S r - 1 = S - \frac{1}{r^n}. \text{ And consequently}$$

$$S r - S = 1 - \frac{1}{r^n}, \text{ and } S = \frac{1}{r-1} - \frac{1}{r-1} \times \frac{1}{r^n}$$

This is the general theorem for finding the sum of any given number of the first terms of the series $\frac{1}{r} \times \frac{1}{r^2}$

$+ \frac{1}{r^3}$, &c. that is, for finding, from the rate of interest

given, the value of an annuity certain, payable yearly for any number of years. If the annuity is a perpetuity, it is plain

that $\frac{1}{r^n}$, or the last term vanishing, $\frac{1}{r-1} \times \frac{1}{r^n}$ also vanishes; and, consequently, that the expression becomes

$S = \frac{1}{r-1}$: from whence it results that the value of a perpetuity is always unity divided by the interest of 1*l.* for a year, or 100*l.* divided by the rate of interest.

Annuities certain differ in value as they are made payable, yearly, half-yearly, quarterly, or at shorter intervals. Let r , instead of denoting as before, 1*l.* increased by its interest for a year, denote the interest only of 1*l.* for a year, and let n denote the term or number of years during which the annuity is to be paid. By reasoning as in the former case, the

value of the annuity will be $\frac{1}{1+r} + \frac{1}{1+r}^2 + \frac{1}{1+r}^3 \dots$

$$\dots + \frac{1}{1+r}^{2n} \dots \text{ or } \frac{1}{1+r} + \frac{1}{1+r}^2 + \frac{1}{1+r}^3$$

$$\dots + \frac{1}{1+r}^{4n}, \text{ according as it is payable, either}$$

half-yearly or quarterly. The first of these series is $= \frac{1}{r}$

$$- \frac{1}{r} \times \frac{1}{1+r}^{2n} \dots \text{ and the second is } = \frac{1}{r} - \frac{1}{r} \times$$

$$\frac{1}{1+r}^{4n} \dots \text{ If the annuity is made payable at } m, \text{ any}$$

smaller fraction of a year, the sum of the series will be $= \frac{1}{r} - \frac{1}{r} \times \frac{1}{1+r}^{mn}$; so that when m becomes infinite, or

the annuity is made payable momentarily, the series will be $= \frac{1}{r} - \frac{1}{r} \times \frac{1}{1 + \frac{r}{1000, \text{ \&c. }}}$ n . By the Bino-

$$\text{mial Theorem } 1 + \frac{r}{1000, \text{ \&c. } } \Big|^{1000, \text{ \&c. } } n \text{ is } = 1 + r n +$$

$$\frac{r^2 n^2}{2} + \frac{r^3 n^3}{2 \times 3} + \frac{r^4 n^4}{2 \times 3 \times 4} \text{ \&c. which series is known to ex-}$$

press the number of which $r n$ is the hyperbolic logarithm. Let this number be called N , and the value of the annuity

in this case will be $= \frac{1}{r} - \frac{1}{r N} \dots$ If P be put for $\frac{1}{r}$

or the perpetuity, and $y, b, g,$ and $m,$ for the values of the annuity according as it is payable, yearly, half-yearly, quarterly, or momentarily, the general theorems will then be

$$y = P - P \times \frac{1}{1+r}^n$$

$$b = P - P \times \frac{1}{2 + \frac{r}{2}}^{2n}$$

$$g = P - P \times \frac{1}{1 + \frac{r}{4}}^{4n}$$

$$m = P - P \times \frac{1}{N}$$

ANNUITIES.

Example I.

Let the rate of interest be 4 per cent and the term five years; and consequently $r = .04$, $n = 5$, $P = 25$, then

$$y = 25 - 25 \times \frac{1}{1.04^5} = 4.4518$$

$$b = 25 - 25 \times \frac{1}{1.02^{10}} = 4.4913$$

$$q = 25 - 25 \times \frac{1}{1.01^{20}} = 4.5125$$

$$m = 25 - 25 \times \frac{1}{1.22198} = 4.5415$$

Example II.

Let the rate of interest be the same, and the term for which the annuity is payable 25 years.

Then,

$$y = 15.6220$$

$$b = 15.7118$$

$$q = 15.7694$$

$$m = 15.8010$$

Example III.

Interest being the same, let the term be 50 years.

Then,

$$y = 21.4822$$

$$b = 21.5491$$

$$q = 21.5820$$

$$m = 21.6160$$

Example IV.

Interest being the same, let the term be 100 years.

Then,

$$y = 24.595$$

$$b = 24.523$$

$$q = 24.532$$

$$m = 24.542$$

Sums may also be made payable at longer intervals than a year: such are fines required at stated times for the renewal of leases. Supposing those periods to be at the end of every n^{th} year, the series expressing their value will be

$$\frac{1}{1+r}n + \frac{1}{1+r}2n + \frac{1}{1+r}3n \dots \text{ad infinitum} = \frac{1}{1+r}n - 1,$$

that is, divide $1l.$ by the amount of $1l.$ in n years (see Tab. I.) lessened by unity, multiply the quotient by the fine, and the product will be the present value of all those fines for ever, if the first of them be payable at the end of n years. But if the fine be now due, unity must be added to the above-mentioned quotient, and the sum being multiplied by such fine, the product will be the value in this case.

Example. Supposing an estate of $10l.$ per annum held by lease, renewable every seven years at a certain fine of $20l.$: what is the value of such estate, computing at five per cent.?

Ans. The amount of $1l.$ in seven years, by Tab. I. is 1.628895 . Deducting unity from this number, and dividing $1l.$ by $.628895$, the remainder, we have 1.59 for the quotient, which, being multiplied into $20l.$ the given fine, produces $31.80l.$ for the present value of all such fines, supposing the first of them to be paid at the end of seven years. Now since the fee simple is worth 20 years purchase, or $200l.$ it follows that the difference between $200l.$ and $31.80l.$ or $168l. 4s.$ will be the value of this estate, subject to the payment of the fines every seven years. But if the fine be due, it will be worth $20l.$ less, or $148l. 4s.$

The value of the reversion of a perpetual annuity, to be entered upon after a particular term, is "the value of the annuity for the given term subtracted from the perpetuity."

For example; the value of an annuity, to be entered upon 10 years hence, is (reckoning interest at 4 per cent.) 8.11 (the value by Tab. III. of an annuity certain for 10 years,) subtracted from 25 (the perpetuity), or 16.89 ; that is, $16\frac{1}{2}\%$ years purchase nearly. If the annuity is to be entered upon at the end of 18 years, the value will be 12.66 subtracted from 25 , or 12.34 years purchase.

If the reversion be not a perpetuity, but an annuity, certain for a given term, to be entered upon after another given term, the value will be "the value of the annuity for the first term subtracted from its value for both terms, added together; that is, supposing the reversion an annuity for eight years, 10 to be entered upon after ten years, the value is (reckoning interest at 4 per cent.) the difference between 8.11 (the value of an annuity by Tab. III. for 10 years) and 12.659 (the value by the same Table of an annuity for 18 years) or 4.548 , which is little more than $4\frac{1}{2}\%$ years purchase.

The following Tables, together with the account of their construction and use, contain all that is most important on the subject of annuities certain.

TABLE I.

Shewing the amount of the principal in a given number of years, not exceeding 100, at any rate of compound interest, from three to six per cent.

ANNUITIES.

Table I. continued.

Construction of Table I.

The numbers in this Table are the powers of 1*l.* increased by its interest for a year: that is, they are the powers of the amount of 1*l.* in a year, at the several rates of interest: supposing *r* to be that amount, they are *r*, *r*², *r*³, *r*⁴, &c.

Use. To find the amount of any sum in any number of years, not exceeding 100. Ans. Opposite to the given number of years, and under the rate of interest, is the amount of 1*l.* in that time, which, multiplied by the given sum, produces the required amount.

Examples.

1. What will 10*l.* amount to in 100 years, at 4 per cent. per ann. compound interest? Ans. 50.504948, multiplied by 10, is 505*l.* 1*s.*
2. What will 250*l.* amount to in 50 years, at 5 per cent. per ann. compound interest? Ans. 11.4674 multiplied by 250, is 2866*l.* 17*s.*

TABLE II.

Shewing the principal that will amount to 1*l.* in any number of years not exceeding 100; or the present value of 1*l.* to be received at the end of any number of years not exceeding 100; discounting at any rate of compound interest from 3 to 6 per cent.

The numbers in this Table are the reciprocals of the corresponding numbers in the last, or the quotients of unity divided, by those numbers; that is, $\frac{1}{r}, \frac{1}{r^2}, \frac{1}{r^3}, \frac{1}{r^4}$,

&c. Supposing r to denote $1l.$ with its interest for a year. Use. To find what the present value is of any sum payable in any future time: and also what principal will amount to a given sum in any number of years. *Ans.* Opposite to the given number of years, and under the rate of interest, is the present value of $1l.$ to be received at the end of the given time, or the sum that will amount to $1l.$ in that time, which, multiplied by the given sum, produces the required value or principal.

1. What is the present value of 1000*l.* to be received 10 years hence, reckoning compound interest at 5 per cent.? *Ans.* .613913, multiplied by 1000, is 613*l.* 18*s.* 3*d.* nearly.

2. What principal will amount to 1000*l.* in 10 years, at 5 per cent. per ann. compound interest? *Ans.* .613913, multiplied by 1000*l.*, is 613*l.* 18*s.* 3*d.*

3. What sum put out for 25 years at 4½ per cent. compound interest will clear a debt of 4000*l.*? *Ans.* .332731, multiplied by 4000, is 1330*l.* 18*s.* 6*d.*

ANNUITIES.

TABLE III.

The present value of an annuity of 1*l.* for any number of years not exceeding 100, at any rate of compound interest from 3 to 6 per cent.

Years.	At 3 per Cent.	3½ per Cent.	4 per Cent.	4½ per Cent.	5 per Cent.	6 per Cent.

Construction of Table-III.

The 2d, 3d, 4th, &c. numbers in this Table, are the sums of the first 2, 3, 4, &c. numbers in the second; that is, the sums of $\frac{1}{r} + \frac{1}{r^2}$, of $\frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3}$, of $\frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3} + \frac{1}{r^4}$, &c.

Use. To find the present worth of an annuity for any given term. Multiply the present value opposite to the given number of years, and under the rate of interest, by the given annuity, and the product will be the answer.

Example.

What is the present value of an annuity of 40*l.* to continue 20 years, at 4 per cent? *Ans.* 13.590326, multiplied by 40, is 543*l.* 12*s.* nearly.

ANNUITIES.

TABLE IV.

The amount of an annuity of *1l.* in any number of years not exceeding 100, when improved at compound interest.

Years	At 3 per Cent.	$3\frac{1}{2}$ per Cent.	4 per Cent.	$4\frac{1}{2}$ per Cent.	5 per Cent.	6 per Cent.

Construction of Table IV.

The first number of each column in this Table is unity. The second is the first number in this Table added to the first number in the first Table. The third number is the second in this table added to the second in the first Table, and so on: that is, the numbers in this Table are 1, $1+r$, $1+r+r^2$, $1+r+r^2+r^3$, &c. which series, by proceeding in the same manner as in the case of $\frac{1}{r} + \frac{1}{r^2} + \frac{1}{r^3}$, &c. expressing the value of an annuity certain, may be found
$$= \frac{r-1}{r-1}$$

Use. To find the amount of an annuity forborne any number of years not exceeding 100. Multiply the amount in the Table opposite to the given number of years, and under the rate of interest, by the given annuity. The product is the answer.

Examples.

1. What will an annuity of 50*l.* amount to in 15 years, at $3\frac{1}{2}$ per cent. compound interest? *Ans.* 19.29581, multiplied by 50, is 964*l.* 15*s.* 8*d.*

2. What is the amount of an annuity of 20*l.* in 28 years, at 4 per cent? *Ans.* 49.9675, multiplied by 20, is 999*l.* 7*s.*

3. A person is possessed of 1000*l.* principal, bearing 4 per cent. interest, and in order to increase his income, resolves, in addition to the interest of 40*l.* to take out of his principal 20*l.* the first year, and afterwards as much more as will be necessary to make a constant income of 60*l.* per ann. in what time will he reduce his principal to nothing? *Ans.* In the same time that an annuity of 20*l.* would increase at 4 per cent. compound interest to 1000*l.* that is, in 28 years by the preceding question.

He that would gain farther information on this subject should consult Malcolm's Arithmetic, from page 595 to the end; Simpson's Algebra, sect. 16; Mr. Dodson's Mathematical Repository, p. 298, &c. Jones's Synopsis, ch. 10. Phil. Transf. vol. lxvii. p. 109, &c.

For an explanation of the doctrine of annuities on lives, see ASSURANCE, COMPLEMENT, EXPECTATION, LIFE ANNUITIES, MORTALITY, REVERSIONS, SURVIVORSHIPS.

ANNUITY, in Law, is a thing very distinct from a rent-charge, with which it is often confounded; because a rent-charge is a burden imposed upon, and issuing out of lands; whereas, an annuity is a yearly sum, chargeable only upon the person of the grantor. Therefore, if a man by deed grant to another the sum of 20*l.* per annum, without expressing out of what lands it shall issue, no land at all shall be charged with it; but it is a mere personal annuity; which is of so little account in the law, that if granted to an eleemosynary corporation, it is not within the statutes of mortmain: and yet a man may have a real estate in it, though his security is merely personal.

If the annuitant of an annuity payable half yearly, since the last term of payment, die before the half year is completed, nothing is due for the time he lives. There are now very few, if any grants of annuities, without a covenant for payment, expressed or implied; and therefore, where a distress cannot be made, or is not approved of, the grantee may bring an action of covenant, and recover the arrears in damages, with costs of suit. And that action is now usually brought, real actions, and writs of annuity, being much out of use.

The practice of purchasing annuities for lives, at a certain price or premium, instead of advancing the same

sum on an ordinary loan, arises usually from the inability of the borrower to give the lender a permanent security for the return of the money borrowed, at any one period of time. He therefore stipulates (in effect) to repay annually, during his life, some part of the money borrowed; together with legal interest for so much of the principal as annually remains unpaid, and an additional compensation for the extraordinary hazard run of losing that principal entirely by the contingency of the borrower's death; all which considerations, being calculated and blended together, will constitute the just proportion or quantum of the annuity which ought to be granted. If, by the terms of the contract, the lender's principal is *boni fide* (and not colourably) put in jeopardy, no inequality of price will make it an usurious bargain; though under some circumstances of imposition, it may be relieved against in equity. To throw, however, some check upon improvident transactions of this kind, which are usually carried on with great privacy, the statute 17 Geo. III. c. 26 usually called the "Annuity Act," has directed, that upon the sale of any life-annuity of more than the value of 10*l.* per annum (unless on a sufficient pledge of lands in fee-simple, or stock in the public funds), the true consideration, which shall be in money only, shall be set forth and described in the security itself; and a memorial of the date of the security, of the names of the parties, *cestuy que trusts*, *cestuy que vies*, and witnesses, and of the consideration money, shall, within 20 days after its execution, be enrolled in the court of Chancery, (the security shall be null and void; and in case of collusive practices respecting the consideration, the court in which any action is brought, or judgment obtained upon such collusive security, may order the same to be cancelled, and judgment (if any) to be vacated: if the security be set aside for want of complying with the formalities of the act, the consideration, if fair and legal, may be recovered back by the grantee, in action of "assumpsit" against the person *actually* receiving such consideration money, but not against a surety: and also all contracts for the purchase of annuities from infants, shall remain utterly void, and be incapable of confirmation after such infants arrive to the age of maturity. Blackst. Com. vol. ii. p. 40—461, &c.

ANNUITIES, *Publicæ*. See NATIONAL DEBT and FUND.

ANNULAR, ANNULARIS, something that relates to, or resembles a ring, by the Latins called *annulus*.

ANNULAR cartilage, or ANNULARIS, in Anatomy, is the second cartilage of the *larynx*, being round, in shape much resembling a ring, and invelling the whole *larynx*; called also *cricoides*. See LARYNX.

ANNULAR eclipse, in Astronomy. See ECLIPSE.

ANNULAR ligaments, *ligamenta annularia*, is a name given to those ligaments which confine the tendons of the CARPUS and TARSUS.

Add, that the sphincter muscle of the anus is also called *annularis*, or *annular* muscle, from its figure.

ANNULAR process, or protuberance, is a prominent part of the MEDULLA oblongata. See BRAIN.

ANNULAR is also an epithet given to the fourth finger; popularly called the ring finger.

ANNULARIA, in Entomology, a species of PHALÆNA, of the *geometra* section. The wings are cinereous, with a brown streak, a ring in the middle, and two brown bands behind: inhabits Germany. Fabricius, Gmelin, &c.

ANNULARIS, a species of CERAMBYX, in the section *callidium*, Gmelin's arrangement. The thorax is spotted with black, wing-cases bidentated and rather greenish, with three black bands, the first annular: inhabits Siam. Fabricius and Gmelin.

ANNULARIS,

ANNULARIS, is also a species of *TENTHREDO*, that inhabits Austria. It is shining black, tips of the antennæ white, shanks of the legs ferruginous. Fabricius.

ANNULARIS, in *Ichthyology*, a species of *CHÆTODON*. The body is striated, and has a small ring on the lateral line. Gmelin. The body is brown, with blue incurvated streaks, and covered with very small scales; the irides of the eyes are silvery; gill-covers of two pieces, the anterior one of which is toothed and spinous; lateral line parallel with the back, anus in the middle of the body; anal fin, round with a streak of blue; dorsal fin, black brown, the others white. This is ikan batoc jang aboe, and ikan pampus cambodia, of Valent. Ind. &c.

ANNULATA, in *Entomology*, a species of *CASSIDA*, found in India, and described by Fabricius. It is blue, with two rufous spots on the thorax, and rings of the same colour on the wing-cases. Fab. and Gmelin. *Obs.* This is a large species; the thorax is obscure, with a faint rufous spot on each side; wing-cases gibbous, dull blue, with six rufous annulations; beneath, black, with a rufous dot on both sides each segment of the abdomen.

ANNULATA, a species of *CHRYSOMELA*, in the section *altica*. It is brown bronzed; wing-cases striated and crenated; base of the antennæ rufous; shanks of the four anterior legs rufous, with a bronzy-brown annulation. Linnæus and Gmelin.

ANNULATA, a species of *NEPA*, that inhabits the coast of Coromandel. It is with a tail, subrotund, pale brown; shanks of the anterior legs pale, annulated with brown. Fabricius.

ANNULATA, a species of *SPHINX*, in the Linnæan arrangement; *ZYGAENA*, in that of Fabricius. It is black, with six yellow spots on the anterior wings; base of the posterior wings and spot yellow; abdomen annulated with yellow; inhabits New Holland.

ANNULATA, a species of *PHALÆNA*, found in Hamburg, and described by Fabricius. The wings are black, with snowy-white spots; shanks of the legs annulated with white.

ANNULATA, a species of *PHRYGANEÆ*, that inhabits Europe. It is brown, with long antennæ annulated with white; inner and posterior margins of the wings ciliated. Linnæus, Gmelin, &c.

ANNULATA, a name under which two different species of *TENTHREDO* are described by Gmelin in the *Systema Naturæ*; one is the Linnæan species of that name, but the other is adopted, with great impropriety, from the mantissa of Fabricius. To prevent in some measure the confusion which might evidently arise from the same name being assigned to two distinct insects, it is necessary to attend to the characters of the two sections to which they belong. *Tenthredo annulata*, Linn. is in the section "antennis filiformibus, articulis 7—9;" antennæ filiform, with from seven to nine articulations; and the other in that of "antennis ex-articulatis, extrorsum crassioribus;" antennæ without articulations, and thickest at the tip. The first species is yellow, with the antennæ somewhat clavated and black; tip of the shanks and ends of the feet annulated with black. The second is black, the abdomen yellow, feet of the posterior legs black, annulated with white. Fabricius Mantif. Both kinds inhabit Europe.

ANNULATA, a species of *APIS*, found in Europe. It is small, and smells like musk; the colour is black; front and rings on the legs white. Linnæus and Fabricius.

ANNULATA, a species of *TIPULA*. The wings are brown, variegated; thighs annulated with white; inhabits Europe. Linnæus, Fabricius, &c.

ANNULATA, a species of *CONOPS* that inhabits Europe. The thorax is black; abdomen cylindrical, varied with yellow and black; base of the wings and legs ferruginous, the latter annulated with brown. Linnæus and Gmelin.

ANNULATA, a species of *PODURA*. It is livid, with black rings; and inhabits Europe. Fabricius and Gmelin. This is a podura livida lutca, annulis transversis nigris of Geoffroy.

ANNULATA, in *Conchology*, a species of *OSTREA*, that inhabits the North Seas; and supposed by some to be a variety of *ostrea papyracea*. The shell is equivalve, orbicular, and white, with concentric semi-circles. Gmelin and Müll.

ANNULATA, a species of *VOLUTA*. It is white, smooth, with a carinated dorsal ring; its habitation is unknown, and there is a variety of it (β), undulated with pale red. Gmelin, Martini, &c.

ANNULATA, a species of *HELIX*. The shell is umbilicated, slightly depressed, and white; wreaths four, the first gibbous and bicarinated. Gmelin.

ANNULATORIUS, in *Entomology*, a species of *ICHNEUMON*, found in Great Britain, and described by Fabricius from a specimen in the cabinet of Sir Joseph Banks, Bart. The scutellum is yellowish; thorax spotted, and four first segments of the abdomen margined with yellow; wings transparent. Fabricius and Gmelin.

ANNULATUM, in *Conchology*, a species of *DENTALIUM*. It is round and striated obliquely: found in a fossil state. Gmelin, Guettard, &c.

ANNULATUS, in *Conchology*, a species of *TROCHUS*, found in the sands of the Indian sea. The wreaths are reversed, and ribbed on each side; aperture almost square. Gmelin, Chemn. &c. This is a small species, scarcely exceeding a quarter of an inch in length, and the number of wreaths are usually from twelve to fifteen.

ANNULATUS, is likewise the specific name of a shell of the *TURBO* genus; its native place is unknown: it is figured by Gualteri, and thus very concisely characterized by Gmelin; wreaths with a prominent and margined future: this shell is white, a quarter of an inch in length, aperture suboval.

ANNULATUS, in *Entomology*, a species of *CURCULIO*, that inhabits North America. It is pale, thorax and wing-cases streaked with black. Fabricius and Gmelin. The streaks are disposed transversely, one upon the thorax, and two on the wing-cases.

ANNULATUS, a species of *CERAMBYX*, in the section or family, *stenocorus*. The thorax is lineated, wing-cases unidentated, antennæ long, with three white rings. Fabricius and Gmelin. *Obs.* The thorax is grey, with four white lines; the wing-cases grey, brown at the tip, and edged with white; and the legs grey, with brown annulations. Cabinet of Sir Joseph Banks, Bart.

ANNULATUS, a species of *GRYLLUS*, in the section *locusta*, having a flattish thorax, gibbous front, wings bluish-black, and blue within: it inhabits America, and is of a reddish grey, and rough, with elevated dots; abdomen annulated, with a few greenish rings; antennæ yellow, with black rings.

ANNULATUS, a species of *CIMEX*, described by Fabricius and Gmelin as a native of Virginia. It is greyish, thighs annulated with white. This belongs to the family *spinofus*, in the Gmelinian arrangement of cimices, and must not be confounded with another of the same name in the family *oblongus*, which is an European insect. It is black, posterior part of the thorax and anterior of the wing-cases greyish; legs annulated with brown. Gmelin. There is also another

another species of cimex in the family *reduvius*, called **ANNULATUS**, which likewise inhabits Europe. The tips of the antennæ are capillary; body black, with sanguineous spots on the under side. Linnæus. This last is *cimex niger rutipes* of Degeer.

ANNULATUS, a species of *ICHNEUMON*, that inhabits Europe. It is black, with rufous legs; thighs and feet of the posterior pair annulated with white. Gmelin.

ANNULATUS, a species of *ASILUS*, that inhabits India. It is cinereous; abdomen black at the end; thighs testaceous, annulated with black. Fabricius and Gmelin.

ANNULATUS, a species of *CULEX*. It is brown; abdomen and legs annulated with white; wings spotted. Fabricius and Gmelin. In the size and shape, this resembles the common gnat (*culex pipiens*); the beak is half the length of the body. Inhabits Germany and Denmark.

ANNULATUS, in *Ornithology*, a species of *ORIOLEUS* that inhabits America, and is considered as a bird of prey. It is yellow; head and neck black; greater wing-coverts and quill-feathers blackish, edged with pale yellow; a blackish band across the tail. Gmelin, &c.

This is the ring-tailed oriole of Latham; *avis ocozinitzcan* of Seba; *arc-en-queue* of Buffon; *ïterus cauda annulata* of Brisson; and *cornix flava* of Klein. It is about the size of a pigeon; the bill yellow, and a little bent at the point; head and neck black; body yellow; tail yellow; each feather marked transversely with a broad blackish band; and which, when the tail is expanded, forms a crescent, with the concave part towards the body; legs grey.

ANNULATUS, in *Zoology*, a species of *COLUBER*; described by Linnæus and Gmelin, as having 190 abdominal scuta or plates on the belly, and 96 subcaudal scales; but it appears from synonymous authors, that the number of those plates and scales vary exceedingly in different specimens, and that its specific characters should rather be taken from the colour, form and disposition of the spots, which are less liable to variations: in one instance, for example, the abdominal scuta amounted to only 184, and the subcaudal scales to 60; in another to 186—84; and in a third to 196—95. Its general description is, back, cinereous grey, brownish, or brownish-white, with a band, or series of round, alternate, brown spots, that occasionally join or become confluent, especially at some distance down the neck, and are furrounded with pale margins; belly white. Dr. Shaw's specific character is, *C. griseus, maculis dorsalibus rotundis fuscis pallido marginatis*. Grey snake, with round, brown, dorsal spots, with pale margins. Vol. iii. p. 2. 490.

This creature inhabits America, is from a foot and an half to two or three feet in length; the head is rather large, as are also the scales that cover it; the tail gradually tapering.

ANNULATUS, a species of *ANGUIS*, of a white colour, with straight brown stripes that meet on the under side; tail tapering, and a double row of imbricated scales beneath. Laur. Gmelin.

ANNULET, from the Latin *annulus*, a ring, in *Heraldry*, granted in coat-armour to those who were in confidence, or entrusted with especial commissions by the king; the annulet, or ring, being the gage of the royal favour and protection. It is also borne as a mark of filiation for the fifth son. The colour of the *annulet* must always be expressed.

Annulets were anciently reputed a mark of nobility and jurisdiction; it being the custom of prelates to receive their investiture *per baculum & annulum*.

ANNULETS, in *Architecture*, are small square members, in

the Doric capital, placed under the quarter ground. They are also called *fillets*, *lyflets*, &c.

ANNULET is also used for a narrow flat moulding, common to other parts of a column; *viz.* the bases, &c. as well as the capital; so called, because it encompasses the column around. In which tense annulet is frequently used for *bagnette*, or *little astragal*.

ANNULLING, compounded of *ad* and *nullus*, none; *q. d.* *undoing*; the abolishing of an act, procedure, sentence, or the like.

ANNULOSUS, in *Entomology*, a species of *ICHNEUMON*, found in Europe. It is black; antennæ slightly annulated with black; legs rufous; sting short. Linnæus and Gmelin.

ANNULUS, in *Conchology*, a species of *CYPRITA*, very common about Amboyna, and also Alexandria. It is of an ochreous colour on the outside, and blue within. Its specific character is, shell furrounded on the back with a yellow ring. Linnæus and Gmelin. This is the *thoracicum quadratum* of Rumphius.

ANNULUS, in *Entomology*, a species of *CASSIDA*, that inhabits Cayenne. It is yellowish, brown in the disk, and annulated in the middle with yellow. Fabricius, *Spec. Inf.*

ANNULUS, a species of *APIS*, grey and downy, thorax black; and a black clouded band in the middle of the abdomen. Linnæus and Gmelin. Inhabits Europe.

ANNULUS, or *Ring*, in *Geometry*. The area of it may be had by finding the areas of the outer and inner circles, and their difference is the area required. Or, multiply the sum of the diameters by their difference, and the product by $\frac{7854}{10000}$.

ANNUNCIADE, or **ANNUNCIATION**. This order was instituted by Ame VI. earl of Savoy, under the title of the *Collar*, in 1362, in honour of the fifteen divine mysteries of the rosary. Favin, on a mistaken ground, calls it *The Order of the Manes of Love*, in regard its founder had received of his lady a bracelet made of the tresses of her hair, plaited in love-knots; and that the Founder should signify *frappes, entres, rompes tout*. It remained, however, as the collar, till Charles III. or Le-bon, duke of Savoy, who bestowed on it the title of the *Annunciation*, from the picture of the Annunciation which he annexed to the collar. The founder appointed the number of knights to be fifteen; among whom was Sir Richard Mufard, an English gentleman, in 1434; their number was increased in 1568, to twenty. Rienc castle, in Buger, was their principal seat. The ancient collar was of gold, three fingers broad; on which were engraved the letters F.E.R.T. and one Knot, called the *Savoy Knot*, at the end of each F.E.R.T. which, with three other Knots entwined one within the other, made up the circumference pendant at the collar, without any figure. The initials were supposed to be for the words *Fortitudo Ejus Rhodum Tenuit*, alluding to Amadeus le Grand, who so valiantly defended Rhodes against the Turks in 1310. This, however, was long after the house of Savoy took that device, as appears from the coins of Lewis de Savoy, baron de Vaud, who died in 1301; as also from the monument of Thomas de Savoy, who died in 1233, whereon was lying at the feet of his portraiture, a dog, bearing a collar about his neck, with the word *Fert*; also a silver coin of Peter de Savoy (who erected in England the building of that name in the Strand, temp. Hen. III.) whereon is the word *FERT*, in Gothic characters. Duke Charles III. surnamed the Good, in 1518, ordered that the badge or *mystery* of the Annunciation of the Blessed Virgin should be represented within a circle of gold, formed of true-

true-lover's knots, pendant to the collar, which was to be of gold, weighing two hundred gold crowns, and composed of the letters F. E. R. T. intermixed with true-lover's knots, separated by fifteen roses of gold, five of them enamelled *white*, five *red*, and five partly *white and red*, and edged with two thorns gold. The knights wear in common the badge pendant to three small chains of gold round the neck. The reigning king of Sardinia is sovereign of the order.

ANNUNCIATION, compounded of *ad* and *nuncio*, *I declare*, the tidings which the angel Gabriel brought to the Holy Virgin, of the incarnation of Christ.

The Greeks call it *ευαγγελισμοσ*, *good tidings*, and *χαριστισμοσ*, *salutation*.

ANNUNCIATION is also the name of a feast, celebrated annually on the 25th of March, popularly called *Lady-day*, in commemoration of that wonderful event.

Some authors are of opinion, that the feast was originally solemnized in honour of our Saviour; and that the holding it in the name and honour of the Virgin is of much later standing. This feast seems to be of great antiquity. Among the sermons of St. Augustin, who died in 430, we have two upon the Annunciation. Proculus, who died in 446, and Chrysostom in 407, have, in their works, discourses on this subject. But the Protestant writers reject these authorities, and the writings on which they are founded, as spurious. Bingham refers the commencement of this feast to the seventh century.

Several of the eastern churches celebrate the Annunciation at a different season from those of the west. The Syrians call it *Basfarach*, q. d. *search, inquiry*; and mark it in the calendar for the first day of December. The Armenians hold it on the fifth of January: thus anticipating the time, to prevent its falling in Lent; but the Greeks make no scruple of celebrating the festival even in Lent. In the west likewise, there has been some variation as to the time of keeping this feast. The tenth council of Toledo, in 636, ordained it to be celebrated eight days before Christmas.

The Jews also give the title Annunciation to part of the ceremony of their passover; *viz.* that, wherein they explain the origin and occasion of that solemnity. This explanation they call *הגדרה*, *Haggada*, q. d. the *Annunciation*.

ANNUNCIATOR, in the *Greek Church*, an officer whose business is to give notice of the feasts and holydays to be observed.

ANNUNTIATE, **ANNUNTIADA**, or **ANNUNTIATA**, a denomination common to several orders, both religious and military; instituted with a view to the Annunciation. The first religious order of this kind was instituted in 1232, by seven Florentine merchants. These are also called *servites*, q. d. *servants*.

The second was a nunnery at Bourges, founded in 1500, by Joan of Valois, queen of France, after her divorce from Lewis XII.

The third was also a nunnery, founded by a Genoese lady in 1604. The fourth was a friary, founded by Cardinal Torrecremata, at Rome, in 1460; which last became so very rich, that they gave fortunes of 60 Roman crowns to above four hundred girls, on the anniversary of the Annunciation.

ANNY, in *Geography*, a river of France, on the coast of the English channel, north of the river Soame, and south from Boulogne.

ANOA, in *Zoology*, *bos bubalus anoa*, a variety of the buffalo, mentioned by Pennant, *Hist. of Quadr.* vol. i.

p. 30. This animal is about the size of a middling sheep; it inhabits the mountains of Celebes; is very fierce, lives in small herds, sheltering itself in the caverns of the mountains; is caught with difficulty, and is very impatient of confinement.

ANOBIUM, in *Entomology*, a genus of **COLEOPTEROUS** insects, in the Fabrician system, having four clavate palpi, or feelers; jaws obtuse and dentated; lip entire; and antennæ filiform; with the three extreme joints elongated, and rather thicker than the others. Fabricius. This genus includes some insects of the **PTINUS** and **DERMESTES** genera, of the Linnæan system, and **BYRRHUS** of Geoffroy; besides some new species not described by either. In the *Species Infectorum*, the species of this genus are, *perlinax*, *molle*, *frumentarium*, *flavipes*, *nigrum*, *lineatum*, *cyaneum*, & *minutum*, in all eight species: the arrangement in the last system of that author, *Entomologia Systematica*, is somewhat different, being *tessellatum*, *striatum*, *rufipes*, *castaneum*, *perlinax*, *holcti*, *molle*, *paucicum*, *abictis*, *planum*, *capense*, *minutum*, *micans*, & *nitidum*.

Olivier adopts the genus **ANOBIUM** after Fabricius, describing the species *tessellatum*, *striatum*, *castaneum*, & *paniceum*, as insects of that genus; and Gmelin, in the *Systema Naturæ*, makes the first division of the **PTINUS** of Linnæus, "palpis clavatis," (clavate feelers), **ANOBIUM** of Fab. to distinguish them from the true *ptini* which have the feelers filiform. Professor Thunberg has also described several species of anobium in his *Nov. Inf.* as *rutipes*, *cœruleum*, &c. but which Gmelin consigns to the **DERMESTES** genus in the Linnæan system.

ANOCCHUS, an imaginary name of a *medicine*, concerning which many fruitless conjectures have been made. The word occurs only in Gaza's translation of the account which Theophrastus has left us of the **EUONYMUS** of those times. The author says, that the goats which eat the leaves and fruit of the euonymus were killed by it, and that they died of a stoppage of the bowels, which he has expressed by the word *ανοχος*, derived from the verb *ανεσχεν*, which signifies a retention of the stools.

It is to be observed by the way, that the euonymus of the Greeks could not be the same plant known at this time by that name, since the cattle eat our euonymus or *jusquiam* whenever they can get it, and that without any danger; but the descriptions of these plants in the ancient and modern authors shew also that they were very different.

ANOCTORON, in *Ecclesiastical History*, a name used by some writers for a church.

Anoctora properly import Roman halls, divers of which were converted into churches. In which sense *anoctora* amount to much the same with **BASILICÆ**.

ANOCYSTI, in *Natural History*, the name of one of the subdivisions of the **ECHINUS** genus, in the arrangement of Klein and other naturalists; consisting of such as have the vent at the top of the shell, and all the tentacula simple, (auro verticali, tentaculis undique simplicibus). This is the first of the three principal divisions of the echini in the Linnæan system, by Gmelin; the second is **BRISSEI** of Müller, in which the vent is situated at the bottom of the shell, and the mouth destitute of tentacula; the third is **SPATANGI** of Müller, having the vent on the side, and the mouth furnished with pencilled tentacula. Each of those divisions are again subdivided according to the shape of the shell. See **ECHINUS**.

ANODA, in *Botany*. See **SIDA**.

In Gmelin's edition of Linnæus, *anoda* is a genus of the *monadelphia polyandria* class and order; the characters of which

which are, that the *calyx* is simple, semiquinquefid, permanent, and very much dilated by the ripe fruit; and the *capsule* is many-celled, above hemispherical, beneath flattened, with single-seeded cells. There are three species. 1. *A. dilectiana*, with triangular leaves, the lower crenated, the upper obsoletely crenated and petiolated, with peduncles axillary, single-flowered, and very long. 2. *A. hastata*, lida eriolata, with cordate, angulate leaves; the upper elongated and bilobed, with very long, axillary, and single-flowered peduncles. 3. *A. triloba*, with the inferior leaves cordate, somewhat angulate and crenated; the upper trilobed, with axillary, solitary, very long, and single-flowered peduncles.

ANODYNE, derived from the privative α , and *oduvau*, *dolo*, to be in pain, in *Physic*, is understood of such remedies, as calm and alluage pain. It is now generally employed for those medicines which relieve pain by diminishing or destroying sensibility; and in this sense, the general term is allowable.

Anodynes are of two kinds; the first proper, called also *palegorics*. The second spurious, or improper, which rather stupefy than alleviate; acting only by inducing a stupor, drowsiness, or sleep. These are more properly called *narcotics*, *hypnotics*, or *opiates*.

The true *anodynes* are applied externally to the part affected. Such, among the class of simples, are the onion, lily, root of mallows, leaves of violets, elder, &c. Camphor is said to be the best anodyne in nervous cases, and at the decline of fevers.

Anodynes should not be given without great caution, nor on a full stomach, nor in dropries. Hemlock procures ease and sleep, without causing that head-ach next morning, usually complained of after taking opium. If the pulse be strong, a larger dose is safe; if weak, a less dose must be given.

We have also certain compound medicines in the shops, prepared with this intention, and called by this name. Such is the *anodyne liniment*, commonly called *anodyne balsam*, prepared in the following manner: take of opium one ounce, white Castile soap four ounces, camphor two ounces, essential oil of rosemary half an ounce, and rectified spirit of wine two pounds; digest the opium and soap in the spirit for three days; then to the strained liquor add the camphor and oil, diligently shaking the vessel. It is recommended not only for procuring ease in the most racking extremities of pain, but also for assisting in discharging the peccant matters that occasioned it. This balsam is much the same with the modern *opodeldoc*. A ready way of preparing an useful, safe, and efficacious *anodyne*, is as follows: take half an ounce of opium, dissolve it in a gentle heat in three ounces of water, strain the solution, and evaporate it to a dry substance; grind this to powder in a glass mortar with twice the quantity of loaf-sugar, and you have an excellent preparation of opium, to be given three or four grains for a dose. Shaw's Lect. p. 233.

By dissolving the opium thus in water, we get rid, not only of its gross and foul parts, but also of its resinous, which are found much more pernicious than the rest; and by dividing its parts afterwards with sugar, the medicine is rendered more uniform, resoluble, and miscible with animal fluids.

But however opium is prepared, it still must be acknowledged, that it retains qualities that make it little less than a poison in a very large dose; whence it were much to be wished something could be found that would be more innocent, and yet answer the same purpose. And this camphor and nitre will do on many, though not on all occasions,

An *anodyne* ointment may be prepared, by mixing ten dram. of olive oil, half an ounce of yellow wax, and one dram of crude opium. Opium, thus externally applied, will in some degree produce the same effect, as when it is used under the form of anodyne balsam, in which state it produces effects more immediately; but under this form, its effects are more permanent. The present ointment also furnishes an useful dressing for sores attended with severe pain. For Hoffman's anodyne, see LIQUOR *Mineralis Anodynus*.

ANOINTED. See CHRIST, and MESSIAH.

ANOINTERS, in *Ecclesiastical History*, a religious sect formerly subsisting in some parts of England, so called from the ceremony they used in anointing all persons before they admitted them into their church. They founded their opinion of anointing upon the fifth of James, verses 14 and 15. See Plot's Oxfordsh. 208.

ANOINTING, a term used by painters. It implies their method of restoring the effect of the colours, after the oil has been drained out of them, by the absorption of the ground of the picture, or the former coat or layer of colours, whilst they were drying, termed improperly the sinking of the colours. This anointing is performed by means of varnish, oil, or both together, rubbed in with an hard hogs hair tool. Besides restoring the appearance of the colours, it has another effect; that of disposing the picture to receive with advantage the future touches of the brush or pencil. When the anointing is newly laid on, it promotes softness and union; and when almost, but not perfectly dry, it disposes the picture to receive smart or crank touches. Some painters have been more liberal in the quantity of varnish, &c. in anointing than may be judicious; too much oil should not be applied to the more brilliant and lighter parts of pictures; nor should japanners' gold-size be introduced in anointing, unless with great caution.

Without an application of this nature, it would be almost impossible for the painter of delicate works to proceed with any degree of certainty. The best mixture for this purpose, is an equal quantity of strong drying oil and mastic varnish united. This will retain its clammy nature long enough for the purpose of the artist, while he covers with paint the anointed portion.

Those who proceed more slowly with the pencil than is usual, will do well to use a little fat linseed oil with the mixture we have mentioned, which will not so soon grow hard or dry. Gerard Lairesse, whose pictures retain their colours, has recommended this mixture with fat oil, upon retouching pictures; and this in a plentiful manner, in order that the picture may not require varnishing. On the contrary, Mr. Bardwell recommends the anointing as necessary, but that almost the whole should be wiped off with an old silk handkerchief, before the paint is applied to the picture. The glazing colours should in general be applied with a liberal use of the anointing mixture; and those colours which are used in the scumbling of pictures should be employed more sparingly. See GLAZING and SCUMBLING. Titian appears to have proceeded in this manner with his pictures, and to have thus produced his most admirable effects.

ANOLE, in *Zoology*, the name of a species of lizard common in the West Indies, about houses and plantations. It is of the size of the common lizard of Europe, but its head is longer; its skin is of a yellowish colour, and its back variegated with green, blue, and grey lines running from the neck to the tail. They creep into holes for the night, and there make a continual and very disagreeable noise; in the day time, they are always in motion.

ANOLYMPIADES, in *Antiquity*, a name given by the Eleans to those Olympic games which had been celebrated under

under the direction of the Pisæans and Arcadians. The Eleans claimed the sole right of managing the Olympic games, in which they sometimes met with competitors. The hundred and fourth Olympiad was celebrated by order of the Arcadians, by whom the Eleans were at that time reduced very low; this, as well as those managed by the inhabitants of Pisa, they called *ανολυμπιαδας*, unlawful Olympiads, and left them out of their annals, wherein the names of the victors, and other occurrences, were registered. Potter, Arch. Græc.

ANOMALA, in *Conchology*, a species of PATELLA, in the family "integerrimæ abique vertice mucronato." It is a coarse, brown, orbicular shell, with the vertex submarginal; and inhabits the deeps of the Norway seas. Müll. This shell is minute and rough, with fine elevated dots; sometimes of a cinereous colour, and blue beneath. The animal consists of two reddish, tough, twisted masses, which are fringed the whole length; the fringes are yellow, composed of rigid hairs, and connected with the rest of the body by a blue tendon; the ovaries are ramose, and orange; the eggs globose. It is uncertain whether this shell belongs to the patella genus or not. Müll. Gmelin.

ANOMALISTICAL Year, in *Astronomy*, called also *periodical year*, is the space of time in which the earth passes through her orbit.

The anomalistical, or common year, is somewhat longer than the tropical year; by reason of the PRECESSION of the equinox. The apses of all the planets have a similar progressive motion; whence they take a longer time in arriving at the aphelion, which has advanced a little, than in attaining to the same fixed star. E. G. The tropical revolution of the sun, with respect to the equinox, is $365^d 5^h 48' 45''$; but the sidereal revolution, or return to the same fixed star, is $365^d 6^h 9' 10\frac{1}{2}''$; and the anomalistic revolution is $365^d 6^h 15' 20''$, because the sun's apogee advances each year $65\frac{1}{2}''$ with respect to the equinoxes; and the sun cannot arrive at the apogee till he has passed over $65\frac{1}{2}''$ more than the revolution of the year answering to the equinoxes. To find the anomalistic revolution, use this proportion: As the whole secular motion of a planet, minus the motion of its aphelion, is to 100 years, or 3155760000 seconds, so is 360° to the duration of the anomalistic revolution.

ANOMALOUS, *irregular*, something that deviates from the ordinary rule and method of other things of the same kind.

The word is not compounded of the privative α and $\nu\omicron\mu\omicron\varsigma$, *λατν*, as is usually imagined; for whence, on such supposition, should the last syllable *al*, arise? But it comes from the Greek *ανωμαλις*, *uneven*, *rough*, *irregular*, formed of the privative α and *ομαλος*, *plain*, *even*.

ANOMALOUS verbs, in *Grammar*; are such as are irregular in their conjugations; deviating from the rules or formulas observed by others.

There are anomalous verbs, or irregular inflexions of verbs, in all languages. In the English, the chief irregularity of our anomalous verbs lies in the formation of the preter tense, and passive participle; though this only holds of the native Teutonic or Saxon words, and not of the foreign words, borrowed from the Latin, French, &c.

The principal irregularity arises from the quickness of our pronunciation, whereby we change the consonant *d* into *t*, cutting off the regular ending *ed*.

Thus for *mixed*, we write *mixt* or *mix'd*; for *dweltled*, *dwelt*, or *dwell'd*; for *snatched*, *snatcht*, &c. But this property is rather of the nature of a contraction than an irregularity; and is complained of by some of our politer writers

as an abuse, to the disadvantage of our language, tending to disfigure it, and turn a tenth part of our smoothest words into clusters of consonants; which is the more inexcusable, because our want of vowels has been the general complaint of the best writers.

Another irregularity relates to the preter tense, and passive participle. Thus *give*, if it were regular, or formed according to the rule, would make *gived*, in the preter tense, and the passive participle; whereas it makes *gave* in the preter tense, and *given* in the passive participle.

ANOMALY, in *Grammar*, denotes an irregularity in the accidents of a word, whereby it deviates from the common rules of paradigms, whereby other words of the like kind are governed.

ANOMALY, in *Astronomy*, is an irregularity in the motion of a planet, whereby it deviates from the *aphelion* or *apogee*, or the angular distance of a planet from the APHELION or APOGEE; that is, the angle formed by the line of the apses, and another line drawn through the planet.

Kepler distinguishes three kinds of *anomaly*; *mean*, *eccentric*, and *true*.

ANOMALY, *mean*, or *simple*, in the *Ancient Astronomy*, is the distance of a planet's mean place from the apogee, which Ptolemy calls the angle of mean motion.

In the modern astronomy, it is the time in which a planet, describing an ellipse APQ (*Plate I. Astronomy, fig. 9.*), round the sun in the focus, moves from its aphelion A, to the mean place or point of its orbit P; or, it is the angular distance of the planet at a given time from the aphelion, supposing that it had moved uniformly with its mean angular velocity.

Hence, as the elliptic area ASP, is proportional to the time in which the planet describes the arc AP; the area may represent the mean anomaly. Or thus, the area ASN, found by drawing a line IP through the planet's place, perpendicular to the line of the apses AQ, till it cuts the circle AVQ, and drawing the line SN, may represent the mean anomaly; for this area is every where proportional to the former area ASP, as is demonstrated by Dr. Gregory, Phil. Transf. N^o 447. Or, if ST be drawn perpendicular to the radius NC produced, then the mean anomaly will be proportional to ST + the circular arc AN, as Keil has demonstrated in his "Astronomical Lectures," Lect. II. Hence, if ND be taken equal to ST, the arc AD, or the angle ACD, will be the mean anomaly for practical purposes, expressed in the degrees of a circle; the number of those degrees being to 360° , as the elliptic trilineal area ASP, is to the whole area of the ellipse; and the degrees of mean anomaly are those contained in the arc AD, or angle ACD.

ANOMALY of the *eccentric*, or of the *centre*, in the *Modern Astronomy*, is an arc AK, of the eccentric circle (*fig. 9.*), included between the aphelion A, and a right line NI, drawn through the centre of the planet P, perpendicularly to the line of the apses AQ; or, it is the angle ACN at the centre of the circle. Hence the eccentric anomaly is to the mean anomaly, as AN to AN + ST; or, as AN to AD; or, as the angle ACN to the angle ACD.

In the *Ancient Astronomy*, it is an arc of the zodiac, terminated by the line of the apses, and the line of the mean motion of the centre. See the methods of finding the *anomaly of the eccentric*, in Phil. Transf. N^o 447.

ANOMALY, *true*, or *equated*, is the angle at the sun ASP, under which a planet's distance AP from the aphelion appears; or, it is the angle or area, taken proportional to the time in which the planet moves from the mean place P, to its aphelion A; or, in other words, it is the angle formed by

the radius vector, or line SP, drawn from the sun to the planet, with the line of the apsidæ.

Hence, in the sun's motion, it will be the distance of his true place from the apogee.

The true anomaly being given, the mean one is easily found. But it is much more difficult to find the true anomaly from the mean anomaly given, at least by any direct process. Kepler, who first proposed this problem, and from whom it is called "Kepler's Problem," could not find a direct method of resolving it, and therefore used an indirect one, by the rule of false position; as may be seen in Kepler's Epitomæ Astron. Copern. p. 695. See also Wolfius's Elem. Astron. apud Oper. § 692, &c. tom. iii. p. 47. For the angle ASP, which is the true anomaly, being given, the point P will be given, and consequently the proportion of the area ASP to the whole ellipse, or of the mean anomaly to 360°. For the further illustration of this subject, let a body move uniformly in the circle from A to D with the mean angular velocity of the body in the ellipse, whilst the body moves in the ellipse from A to P; then, from what has been above stated, the angle ACD is the mean, and the angle ASP the true anomaly; and the difference of these two angles is called the equation of the planet's centre, or PROSTHAPHERESIS. Let p = the periodic time in the ellipse or circle (the periodic times being supposed equal), and t = the time of describing AP or AD; then, as the bodies in the ellipse and circle describe equal areas in equal times, about S and C respectively, we have the area ADC : area of the circle :: $t : p$, and area of the ellipse : area ASP :: $p : t$; also the area of the circle : area of the ellipse :: area ASN : area ASP; consequently the area ADC : area ASP :: area ASN : area ASP, and hence ADC = ASN; from which, let the area DCN, which is common, be taken away, and the area DNC = SNC; but DCN = $\frac{1}{2}$ DN × CN, and SNC = $\frac{1}{2}$ ST × CN; therefore ST = DN. Now if t be given, the arc AD will be given; for as the body in the circle moves uniformly, we have $p : t :: 360^\circ : AD$. Thus we always find the mean anomaly at any given time, provided that the time be known when the body was in the aphelion; hence, by finding ST or ND, we shall know the angle NCA, called the eccentric anomaly, from whence, by one proportion, we shall be able to find the angle ASP the true anomaly. The problem is therefore reduced to this; to find a triangle CST, such, that the angle C + the degrees of an arc equal to ST may be equal to the given angle ACD. This may be expeditiously done by trial in the following manner, given by M. de la Caille in his Astronomy. Find what arc of the circumference of the circle ADQE is equal to CA, by saying, 355 : 113 :: 180° : 57° 17' 44", 8 the number of degrees of an arc equal in length to the radius CA : hence CA : CS :: 57° 17' 44", 8 : the degrees of an arc equal to CS. Assume, therefore, the angle SCT, multiply its sine into the degrees in CS, and add it to the angle SCT, and if it equal the given angle ACD, the supposition was right; if not, add or subtract the difference to or from the first supposition, according as the result is less or greater than ACD, and repeat the operation, and in a very few trials you will obtain the accurate value of the angle SCT. The degrees in ST may be most readily obtained by adding the logarithm of CS to the logarithm of the sine of the angle SCT, and subtracting 10 from the index, and the remainder will be the logarithm of the degrees of ST.

Having found the value of AN, or of the angle ACN, the eccentric anomaly, we may proceed to find the angle ASP, or the true anomaly.

Let v be the other focus, and put AC = 1; then by Eucl. b. ii. prop. 12. $SP^2 - Pv^2 = vS^2 + 2vS \times vI = \frac{vS + 2vI}{vS} \times vS = \frac{2Cv + 2vI}{2C} \times 2SC = 2CI \times 2SC$; hence $SP + Pv : 2CI :: 2SC : SP - Pv$; or $2 : 2CI :: 2SC : SP - 2 - SP$, or $1 : CI :: SC : SP - 1$; hence $SP = 1 + CS \times CI = 1 + CS \times \text{cof. ACN}$. By plain trigonometry, $\frac{1 - \text{cof. ASP}}{1 + \text{cof. ASP}} = \text{tang. } \frac{1}{2} \text{ASP}$. See Mauduit's Trig. or Crackelt's Transl. ch. i. Th. 6. But SP , or $1 + CS \times \text{cof. ACN} : \text{rad.} = 1 : SI$, or $CS + CI$, or $CS + \text{cof. ACN} : \text{cof. ASP} = \frac{CS + \text{cof. ACN}}{1 + CS \times \text{cof. ACN}}$. Hence $\text{tang. } \frac{1}{2} \text{ASP} = \left(\frac{1 - \text{cof. ASP}}{1 + \text{cof. ASP}} \right) = \frac{1 + CS \times \text{cof. ACN} - CS - \text{cof. ACN}}{1 + CS \times \text{cof. ACN} + CS + \text{cof. ACN}} = \frac{1 - CS + \text{cof. ACN} \times CS - 1}{1 + CS + \text{cof. ACN} \times CS + 1} = \frac{SQ - \text{cof. ACN} \times SQ}{SA + \text{cof. ACN} \times SA} = \frac{1 - \text{cof. ACN}}{1 + \text{cof. ACN}} \times \frac{SQ}{SA} = (\text{by the above theorem in Trigon.}) \text{tang. } \frac{1}{2} \text{ACN} \times \frac{SQ}{SA}$; therefore $\sqrt{SA} : \sqrt{SQ} :: \text{tang. } \frac{1}{2} \text{ACN} : \text{tang. } \frac{1}{2} \text{ASP}$; consequently, as ACN is known, we obtain ASP the true anomaly. E. G. Required the true place of Mercury on August 26, 1740, at noon, the equation of the centre, and its distance from the sun. By M. de la Caille's Astronomy, Mercury was in its aphelion on August the 9th at 6^h 37'. Hence, on August the 26th, it had passed its aphelion 16^d 17^h 23'; therefore, 87^d 23^h 15' 32" (the time of one revolution) : 16^d 17^h 23' :: 360° : 68° 26' 28", the arc AD, or mean anomaly. Now (according to this author), CA : CS :: 1011276 : 211165 :: 57° 17' 44", 8 : 11° 57' 50" = 43070", the value of CS reduced to the arc of a circle, the log. of which is 4.6341749. Also, 68° 26' 28" = 246388". Assume the angle SCT to be 60° = 216000", and the operation to find the angle ACN will stand thus:

	4.6341749		
	9.9375306	log. of	216000 = a
	4.5717055	-	37300

		253300	
		246388	

		6912 = b	
	4.6341749	-	209088 = a - b = 58° 4' 48" = c
	9.9287987	-	36557
	4.5629736	-	245645
		-----	246388
		-----	743 = d
	4.6341749	-	209831 = c + d = 58° 17' 11" = e
	9.9297694	-	36639
	4.5639443	-	246470
		-----	246388
		-----	82 = f

$$f_3 - \frac{e^3}{2} + \frac{f_1^3}{2 \cdot 3} + \frac{cy^4}{2 \cdot 3 \cdot 4} - \&c. \text{ Also rad.} = 1 : \sin.$$

$$AN \text{ or } \angle SCF :: SC = g : ST \text{ or } ND \text{ or } y = ge - \frac{g^2 f}{2} -$$

$$\frac{\frac{1}{2} g^3}{2} + \frac{\frac{1}{2} f^3}{3} + \frac{\frac{1}{2} cy^4}{2 \cdot 3 \cdot 4} - \&c. \text{ hence } ge = y + \frac{g^2 f}{2} + \frac{\frac{1}{2} g^3}{2} -$$

$$- \frac{\frac{1}{2} f^3}{2 \cdot 3} - \frac{\frac{1}{2} cy^4}{2 \cdot 3 \cdot 4} + \&c. \text{ Put } g^2 = e, 1 + gf = a, \frac{g^2 e}{2} = b,$$

$$\frac{gf}{2 \cdot 3} = c, \frac{g^3}{2 \cdot 3 \cdot 4} = d, \&c. \text{ hence } e = ay + by^2 - cy^3 -$$

$$dy^4 + \&c. \text{ and by the reversion of series, } y = \frac{z}{a} -$$

$$\frac{bz^2}{a^2} + \frac{2b^2 + ac}{a^3} \times z^3 - \frac{5abc - 3b^2 + a^2 d}{a^4} \times z^4 \&c. \text{ but}$$

$$b = \frac{g^2 e}{2} = \frac{e}{2}, d = \frac{e}{2 \cdot 3 \cdot 4}, \&c. \text{ therefore } y = \frac{z}{a} -$$

$$\frac{z^2}{2a} + \frac{ez^4}{a^3} - \frac{5ez^5}{2a^6} \&c. \text{ If the arc AN be greater than}$$

90° and less than 270°, *f* becomes negative, and therefore *gf* or *e* will be negative; hence $y = \frac{z}{a} - \frac{z^3}{2a^3} - \frac{ez^3}{a^4} + \frac{5ez^5}{2a^6} \&c.$ Now to reduce the value of *y* into degrees, we know that an arc equal to radius, or unity, is equal to 57.29578 degrees = *r*; hence $1 : r :: \frac{z}{a} - \frac{z^3}{2a^3} + \frac{ez^3}{a^4}$

- &c. : the degrees of the arc $y = \frac{rz}{a} - \frac{rz^3}{2a^3} + \frac{rcz^3}{a^4}$ - &c. For the orbit of the earth, the first term will be sufficient, not differing from the truth the ten thousandth part of a degree. In other cases it may be necessary to take more terms.

Ex. Let the eccentricity of the earth's orbit be 0.01691, the mean distance being = 1, and the mean anomaly 30°; to find the true anomaly.

Log. of <i>g</i>	-	-	-	8.2281436
Log. sin. of <i>e</i> = 30°	-	-	-	9.6989700
Log. of <i>r</i>	-	-	-	1.7581226
<hr/>				
Log. of <i>rgz</i> , or <i>rz</i>	-	-	-	9.6852362
Log. of <i>a</i>	-	-	-	0.0063137
<hr/>				

Log. of $\frac{rz}{a}$ - - - 9.6789225 - - the

natural number corresponding to which, being a decimal, is 0°, 47744 = 28' 38" = *y*, which is true to a second; therefore AN = 29° 31' 22"; hence

Log. tan. 14° 45' 41"	-	9.4207653
$\frac{1}{2}$ Log. SQ = 98309	-	2.4962966
<hr/>		

$\frac{1}{2}$ Log. SA = 101691	-	11.9170617
	-	2.5031412
<hr/>		

Log. tan. 14° 32' 25" - - 9.4139205

Hence the true anomaly is 29° 4' 50"; consequently the equation of the centre is 55' 10". See Keill's Astronomical Lectures, Lecture xxii. Vince's Astronomy, vol. i. p. 104-112.

ANOMIA, in *Conchology*, the name of an extensive genus of bivalves, of which some of the fossil species were first described by Columna, as conchæ rariores anomix. The name *anomia* was retained by Woodward in his arrangement of fossil shells; after which three of the recent species were

figured and described by Gualteri, in his new genus terebratula; but Linnæus adopted the name Columna had given to the fossil kinds in preference to terebratula; and it has been in general adhered to by later conchologists, in describing the recent as well as fossil kinds of this family of shells.

The genus anomia is concisely defined by some authors as a shell inequivalve, one valve gibbous towards the beak, the other flat, and perforated near the hinge. The character in the *Sytema Nature*, is the shell inequivalve, one valve being flattish, and the other gibbous at the base, and one of them usually perforated near the base; the hinge has a linear prominent cicatrix, and a lateral tooth within on the margin of the flat valve, and there are two bony rays for the base of the animal. The animal, which had been very imperfectly known, is described by Gmelin, from which it appears to be of a new genus; the body is thin and slender, emarginated, and ciliated or fringed; the hairs affixed to the upper valve; and it has two arms, which are linear and longer than the body. Some conchologists separate the fossil kinds from those which are found in a recent state. Linnæus, and after him, Gmelin, arrange them together in the following order: craniolaris, pectinata, ephippium, cepa, electrica, squamula, patelliformis, scobinata, aurita, retusa, gryphus, pecten, striatula, truncata, reticularis, plicatella, crispa, lacunosa, pubescens, faretta, caput serpentis, terebratula, angulata, hylterita, biloba, placenta, sella, spinosa, aculeata, muricata, squama, punctata, undulata, capensis, detrun-cata, sanguinolenta, vitrea, cranium, dorsata, psittacea, tridentata, spondyloces, ventricosa, gryphoides, flexuosa, rugosa, cylindrica, nucleus, avenacea, & sandalium, which see respectively.

ANOMOEANS, ΑΝΟΜΟΕΙ, in *Church History*, a sect of Christians who denied any similitude between the essence of the Father and that of the Son. See TRINITY.

The word is composed of the privative α, and ομοιος, similar, resembling; q. d. different, dissimilar.

Anomæans was the name whereby the pure Arians were distinguished in the fourth century, because they not only denied the consubstantiality of the Word, but even asserted, that he was of a nature different from that of the Father; in contradistinction to the Semi-Arians, who indeed denied the consubstantiality of the Word, but who owned, at the same time, that he was like the Father. The Semi-Arians condemned the Anomæans in the council of Seleucia; and the Anomæans condemned the Semi-Arians in the council of Constantinople and Antioch, erasing the word ομοιος, like, out of the formula of Rimini and that of Constantinople.

ANOMORHOMBOIDA, in *Natural History*, the name of a genus of spars.

The word is derived from ανωμαλος, irregular; and ρημοειδης, a rhomboidal figure.

The bodies of this genus are pellucid crystalline spars of no determinate regular external form, but always breaking into regularly rhomboidal masses; easily fissile, and composed of plates running both horizontally and perpendicularly through the masses, but cleaving more readily and evenly in an horizontal than in a perpendicular direction; the plates being ever composed of irregular arrangements or rhomboidal concretions.

Of this genus there are five known species, which have all, in some degree, the double refraction of the island crystal.

ANONA, in *Botany*. See ACHRAS, ANNONA, CHRISOPHYLLUM, CRATÆVA, and SLOANEA.

ANONIS, see GLYCINE, HEDISARUM, ONONIS, and SOPHORA.

ANONIUM, in *Ancient Geography*, a town of the northern part of Italy, belonging to the Euganians, to the west of Venetia.

ANONUS *Fons*, a fountain of Laconia, according to Pausanias, situate near mount Taygeta.

ANONYMA, in *Conchology*, a species of *OSTREA*. The shell is rather oblong, with narrow scaly rays; the interstices broad, with perpendicular lines; and the ears with perpendicular wrinkles. Lift. Gmelin. It is variegated with angular streaks and spots.

ANONYMOS. See CHELONE.

ANONYMOUS, formed of the privative α , and $\omega\nu\mu\alpha$, name, something that is nameless, or to which no name is affixed.

The term is chiefly applied to books which do not express their author's name, and to authors whose names are unknown. Decker, advocate of the imperial chamber of Spire, and Placcius of Hamburg, have given treatises of anonymous books. Burc. Gotth. Struvius treats of the learned men who have endeavoured to investigate the authors of anonymous books.

ANONYMOUS, in *Anatomy*, a name sometimes given to parts newly discovered, or first taken notice of.

ANONYMOUS is also an appellation anciently given to the second cartilage of the throat, by later writers, called *cricoides*, or *annuliformis*.

ANONYMOUS, in *Commerce*. Partnerships in trade in France are styled anonymous, when they are not carried on under any particular name, but wherein each of the partners trades visibly on his own account, and in his own name; after which all the partners give one another an account of their profit or loss in trade. These sorts of partnerships are concealed, and known only to the parties themselves.

ANONYMOUS *partnerships in trade*, are also in France such wherein persons of fortune and quality deposit sums of money, in order to share the profits and loss. To this end those who furnish the capital have no trouble in carrying on the trade, nor do their names appear to be any way interested therein.

ANONYMOUS, in *Law*. The sending *anonymous* letters, or letters with a fictitious name, demanding money, &c. or threatening, without any demand, to kill any of the king's subjects, or to fire their houses, out-houses, barns, or ricks, is felony by the *BLACK Act*, 9 Geo. I. cap. 22. Amended by statute 27 Geo. II. cap. 15. This offence was formerly high treason by the statute 8 Hen. 5. c. 6.

ANOPOEA, in *Ancient Geography*, a mountain of Greece, being part of the chain of mountains, called Oeta. A small pass in this mountain formed a communication between Thessaly and the country of the Epicnemidian Locrians.

ANOPOLIS, an appellation given to the town of Arcaea in the isle of Crete. Steph. Byz.

ANOPSHEER, in *Geography*, a town of Hindostan, in the province of Oude, 50 miles east-south-east of Delhi. N. lat. 28° 20'. E. long. 78° 38'.

ANOREXY, ANOREXIA, in *Medicine*, loss of appetite, or loathing of food.

The word is compounded of the privative α , and $\alpha\pi\epsilon\sigma\omega$, *appeto*, I desire.

Anorexia is seldom an idiopathic disease, but a frequent attendant on many.

Causes.—It is present, in some degree, in all febrile complaints, and then usually attended by a furr on the upper surface of the tongue, which commonly indicates its intensity; for, as the furr disappears, the appetite returns. It occurs in jaundice; and accompanies a weakness in the organs subservient to digestion and chylication. Persons addicted to the abuse of spirituous liquors are seldom free from it. The sight of any shocking accident, distressing news, depressing passions, or the being present at any surgical opera-

tion, will often abolish the appetite of a person, even when longing for his dinner.

A symptom depending, on so many causes, must require considerable diversity in the

Treatment.—When it is symptomatic of other diseases, the cure cannot be effected without that of the original complaint. When it arises from the habit of drinking spirits, taking opium, tobacco, or any other poison, the custom must be relinquished, and the digestive organs invigorated by stomachics. See *DYSPEPSIA*.

ANOSMIA, denotes a diminution or abolition of the sense of smell. It is either organic, owing to a disease in the membrane lining the internal parts of the nostrils, and varying according to the nature of the disease; or atonic, without any evident disease of the membrane of the nose. See *SMELLING*.

ANOSSI, CARCAUSSI, or ANDROBEIZAHA, in *Geography*, a province of Madagascar, situate in S. lat. 23° 18'; and extending from the province of Manatenga to the river Mandrerei in 26°. This province is watered by several rivers, that run into the Franchere, Ramevate, or Immour, which rises in the mountain Manghage, and discharges itself into the sea, in S. lat. 25° 18', two small leagues from Port Dauphin. At its mouth is formed a lake, called Amboue, half a league wide, and of sufficient depth for any ship. Crocodiles breed in this river, and in every other in the island. The cape, which is half a league distant from the mouth of the Franchere, is called by the French St. Romain, and by the negroes, Cape Ramevate, or Hehoale. The coast beyond this cape forms a bay, in the middle of which the land runs out in a peninsula, to the north of which lies Fort Dauphin, and over against it Port Dauphin: this bay is called by the French Dauphin Bay; and it is convenient for shipping and boats, which may ride here very safely. This province includes several islands and peninsulas along the coast. The country is beautiful, and fertile in pastures for cattle, abounds in fruit-trees, and, if carefully cultivated, would afford every necessary of life. It is surrounded by high mountains, and diversified by numerous hillocks and fruitful plains. The most remarkable towns are Franchere, Imanhal, Cocombes, Andravoule, Ambonnetanha, Maromamou, Imours, Marufoutouts, and Fananghaa, besides several villages and hamlets throughout the country. The mountains are covered with wood and shrubs; but about four leagues distant from Fort Dauphin, the adjacent hills are quite destitute of trees. The inhabitants of the province are whites and negroes. The whites form three estates, or different degrees; and are distinguished by the names of Rohandrians, Anacandrians, and Ondzathi; the negroes are also subdivided into four classes, *viz.* Voadziri, Lohavohits, Ontsoa, and Ondeves. These people have neither religion nor temple; they keep up a custom of immolating beasts on particular occasions, in sickness, on planting yams or rice, on the circumcision of children, declarations of war, first entry into new-built houses, and on the funerals of their parents. They offer the first born-beast to the devil and to God, naming the devil first in this manner, "Dianbilis Aminan-habare, or lord-devil and God." The country seems to have been originally inhabited by negroes; and the whites took possession of it about 200 years ago; but they were subdued by the French. In 1642, Capt. Rivault obtained leave from Cardinal Richelieu to establish a colony here; and the French, who, after some opposition, settled here, built Fort Dauphin, which is advantageously situated, as it is sheltered from dangerous winds, and its entrance is convenient for all sorts of shipping. The natives, however, after some years of tranquillity and social intercourse, became jealous of the French, and formed a conspiracy to cut off all the French in

one day, which they carried into effect. The Fort Dauphin, which was erected in 1644, was accidentally destroyed by fire in 1656, but it was soon after repaired; and its garrison is thus enabled to carry on frequent wars with the natives. *Mod. Un. Hist.* vol. xi. p. 397, &c. See MADAGASCAR.

ANOTTA, in *Botany*. See BIXA.

ANOTTA Bay, in *Geography*, a bay on the north coast of the island of Jamaica. N. lat. 18° 19'. W. long. 76° 33'.

ANOUEC, the name of a range of mountains in the Birman empire, between Ava and Arracan.

ANOUT. See ANHOLT.

ANPITS, in the *Military Art*, in some *Middle Age Writers*, denotes a breast-work, answering to what is otherwise called *barbacan*.

ANREDERA, in *Botany*, a genus of the *pentandria digynia* class and order: the characters of which are, that the *calyx* is bipartite, with the lacinie carinated at the back; and it has one *seed* covered by a membranaceous, compressed, and two winged *calyx*. There is one species, viz. *andredera spicata*.

ANSA, or AISA, in *Geography*, a river which passes by Aquilea, in the country of Friuli; and runs into the Adriatic, between Grado and Marano.

ANSÆ, ANSES, in *Astronomy*, those apparently prominent parts of the planet Saturn's ring, discovered in its opening, and appearing like handles to the body of that planet. The Latin word literally signifies *handles*, or *ears*, of divers utensils.

ANSANI, GIOVANI, in *Biography*. See GIOVANI.

ANSARS, or ANSARIANS, in *Geography*, a people of Syria, employed in cultivation; and called in that country by the plural name *Ansaria*; in Delisle's maps, *Ensyrrians*; and in those of D'Anville, *Nassaris*. The territory which these people occupy, is that chain of mountains which extends from Antakia to the rivulet called *Nahr-el-Kabir*, or the great river. The history of their origin, though little known, is instructive. The following account is given in the words of a writer (*Affemani*, *Biblioth. Orient.*), who has drawn his materials from the best authorities. "In the year of the Greeks, 1202 (A. D. 891), there lived, at the village of Nafar, in the environs of Koufa, an old man, who, from his fastings, his continual prayers, and his poverty, passed for a faint: several of the common people declaring themselves his partisans, he selected from among them twelve disciples to propagate his doctrine. But the magistrate of the place, alarmed at his proceedings, seized the old man, and confined him in prison. In this reverse of fortune, his situation excited the pity of a girl who was slave to the gaoler, and she determined to give him his liberty. An opportunity soon offered to effect her design. One day, when the gaoler was gone to bed intoxicated, and in a profound sleep, she gently took the keys from under his pillow, and, after opening the door to the old man, returned them to their place unperceived by her master: the next day, when the gaoler went to visit his prisoner, he was extremely astonished at finding he had made his escape; and the more so, since he could perceive no marks of violence. He therefore judiciously concluded he had been delivered by an angel, and eagerly spread the report, to avoid the reprehension he merited; the old man, on the other hand, asserted the same thing to his disciples, and preached his doctrines with more earnestness than ever. He even wrote a book, in which, among other things, he says: 'I, such a one, of the village of Nafar, have seen Christ, who is the word of God, who is Ahmad, son of Mohammad, son of Hanafa, of the race of Ali; who also is Gabriel; and he said to me: Thou art he who readeth with understanding; thou art the man who speaketh truth; thou art the camel which preserveth the faithful from wrath;

thou art the beast which carrieth the burden; thou art the Holy Spirit, and John the son of Zachary; go, and preach to men that they make four genuflexions in praying; two before the rising of the sun, and two before his setting, turning their faces towards Jerusalem; and let them say three times, God Almighty, God most high, God most great; let them observe only the second and third festival; let them fast but two days annually; let them not wash the prepuce, nor drink beer, but as much wine as they think proper; and, lastly, let them abstain from the flesh of carnivorous animals.' This old man, passing into Syria, propagated his opinions among the lower orders of the country people, numbers of whom believed in him. And, after a few years, he went away, and nobody ever knew what became of him."

Such was the origin of the Ansarians, who are, for the most part, inhabitants of the mountains before mentioned. They are divided into several tribes or sects; such as the *Shamsia*, or adorers of the sun; the *Keibia*, or worshippers of the dog; and the *Kadmoufia*, who pay a particular homage to that part in woman which corresponds to the priapus; and who hold nocturnal assemblies, in which, it is said, after certain discourses, they extinguish the light, and indulge promiscuous lust. Many of the Ansarians believe in the metempsychosis; others reject the immortality of the soul; and, in general, such are the anarchy and ignorance that prevail among them, they adopt any opinions which they think proper, following the sect they like best, and frequently attaching themselves to none.

Their country is divided into three principal districts, farmed by the chiefs called *Mokaddamin*. Their tribute is paid to the pacha of Tripoli, from whom they annually receive their title. Their mountains are, in general, not so steep as Lebanon, and, consequently, are better adapted to cultivation; but they are also more exposed to the Turks; and hence it happens, that, with greater plenty of corn, tobacco, wines, and olives, they are more thinly inhabited than those of their neighbours the Maronites and the Druzes. Volney's *Travels in Egypt and Syria*, vol. ii. § 1. p. 1—8.

ANSARIUM, in the *Civil Law*, a duty imposed on all provisions carried in vessels with *anse*. This was otherwise called *ansurium*, and the collectors of it *ansuri*.

ANSATUM *Telum*, according to some, denotes a dart or javelin, with an *amentum* fastened to it.

Others rather take the *anse* of a javelin to be those two eminaences about the middle of the *cuspis*, or point, which hinders the weapon from piercing through the whole body. The Tartars are obliged to put their names to their arrows, that the hand which shoots them may be known. When Philip of Macedon was wounded at the siege of a certain town, these words were found on the javelin, "After has given this mortal wound to Philip."

ANSATUS, in *Conchology*, a species of MUREX. It is brown, transversely striated; spire sharp-pointed; whorls convex, distant, and knotty at the base; beak long. Gmelin. The length of this shell is about five inches and an half, and the striae are large and small alternately.

ANSAUVILLERS, in *Geography*, a town of France, in the department of the Oise, and chief place of a canton, in the district of Breteuil, five miles south-south-east of Breteuil.

ANSCHARIUS, in *Biography*, bishop of Hamburg and Bremen, was born in Sor, in France, at Corbia, in the diocese of Amiens. He was recommended by the emperor Louis as apostolic missionary to Harold king of Denmark, who had been lately converted to the Christian faith; and by his preaching he made many profelytes among the Danes. Under the authority of Olave, king of Sweden, he undertook the instruction of his subjects in the Christian religion,

religion, but with less success. By the council held at Aix-la-Chapelle, in 832, an episcopal see was instituted at Hamburgh, and Ansharius was its first bishop. When his church was burnt by the Normans, in 845, the see of Breinen was added to that of Hamburgh; and Ansharius removed to Bremen, where he resided till his death, in 865. He wrote the life of Willihad, the first bishop of Bremen; and his own life written by Mabillon, is reprinted by Fabricius, in his "Memoires pour l'Histoire de Hamburgh."

ANSCOTE, in our *Ancient Law Books*, the same with *ansbote*. See SCOT.

ANSE, in *Geography*, a town of France in the department of the Rhone and Loire, and chief place of a canton in the district of Villefranche; four leagues north of Lyons.

ANSEL *Weight*, See ANCEL *weight*.

ANSELM, in *Biography*, archbishop of Canterbury, was born at Aoulla in Piedmont, A. D. 1034, of noble and pious parents, who were at great pains to give him a good education. Having lost his mother Ermengarda when he was about seventeen years of age, he abandoned his studies, and indulged his youthful passions to such a degree, that his father refused to see him, or admit him into his house, on which he left his native country, and travelled into France. After some time, attracted by the fame of Lanfranc, he settled at the abbey of Bec, and prosecuted his studies with such ardour under that great master, that he soon excelled all his fellow students in learning. In the year 1060, he became a monk of the Benedictine order, and in three years after he succeeded Lanfranc, both as prior and teacher of the sciences; in both which stations he acquitted himself so much to the satisfaction of the society, that he was unanimously elected abbot on the first vacancy, A. D. 1078. The abbey of Bec had several estates in England, which obliged Anselm sometimes to visit this kingdom; and in these visits he gained the friendship of several of the greatest men. He happened to be here in the year 1093, when William II., in a fit of sickness, was prevailed upon to fill the see of Canterbury, which had been kept four years vacant, and nominated him to that high office. After a long and obstinate opposition to his own advancement, in which his sincerity has been suspected, he was forced into the chamber of the sick monarch, who, in a very pathetic manner, asked "Why he endeavoured to ruin him in the next world, which would infallibly follow, in case he died before the archbishopric was filled?" The abbot still persisted in his refusal, kneeling, weeping, and entreating the prince to change his purpose. The pastoral staff was at length forced into his hand, and he suffered himself to be invested with his office; not, however, before he had obtained a promise of the restitution of all the lands which were in the see in the time of Lanfranc. The temporalities of the archbishop being secured, Anselm submitted to do homage to the king, and was consecrated on the fourth of December 1093. Soon after his consecration, the king intending to wrest the duchy of Normandy from his brother Robert, and endeavouring to raise what money he could for the purpose, Anselm offered him a voluntary gift of five hundred pounds, which the king thought too small, and refused to accept. "I entreat your highness," said Anselm, "to accept the present; it will be more honourable in you to receive a less sum with my consent than to extort a greater by force. If your highness allow me the freedom and privilege of my station, my person and fortune shall be at your service; but if I am treated like a slave, I shall be obliged to stand aloof, and keep my fortune to myself." The offer was, however, for the present, rejected; and when it was afterwards hinted to Anselm, that a repetition of it might conciliate the royal favour, he answered, "God forbid that I should suppose my

sovereign's favour may be purchased with a small sum of money, like a horse at a fair! Persuade the king not to set a price on his favour, but to treat me, on honourable terms, as his spiritual father, and I am ready to pay him the duty of a subject. As for the five hundred pounds, which he was pleased to refuse, they are given to the poor." The king, upon being informed of what had passed, was much displeas'd, and declared he would never acknowledge Anselm for his ghostly father; he wanted neither his prayers nor his benedictions, and he might go whither he pleased. At another time, when William required from the archbishop his quota of men for an expedition against Wales, he sent them out so wretchedly equipped, that he threatened him with a prosecution. Anselm, on his part, considered the demand as oppressive, treated the king's complaint with silent contempt, and demanded the restitution of all the revenues of his see, and made his appeal to Rome. In opposition to the king's express prohibition, but not without repairing to the court of Rome to attempt his justification, he left England, and the king instantly confiscated the temporalities of the archbishopric.

At Rome, Anselm was received with great respect, as a defender of the rights of the holy see, and a meritorious sufferer in the cause of religion. He accompanied the Pope to his country seat near Capua, and received from him numerous proofs of friendship: but upon their return to Rome the pope's friendship for Anselm was put to a severe trial. In consequence of a letter sent from Urban II. to William, soon after Anselm's arrival at Rome, demanding his reinstatement in all the emoluments and privileges of his see, an ambassador arrived from England to vindicate the conduct of the king. The ambassador was at first received with haughtiness, and was commanded by the pope to return and inform his master, that unless he would hazard the highest censure of the church, he must instantly reinstate Anselm in the archiepiscopal rights. Notwithstanding this, after some struggle between duty and interest, the pope accepted a large present, and abandoned the cause of his friend. Finding himself deserted by the court of Rome, Anselm left the city in disgust, and went to Lyons, where he remained till the death of William Rufus.

Henry I. who, on his accession to the throne, employed every expedient to support the authority which he had usurped; and being well acquainted with the interest which Anselm's piety and zeal had obtained in the affections of the people, immediately after his coronation recalled their favourite from exile, who landed at Dover, Sept. 23, 1100. A few days after, he was received at Salisbury by the king with every possible mark of respect and affection. But this cordiality was not of long continuance. As soon as Anselm was commanded to do homage to the king for the temporalities of his see, he returned a flat refusal, and produced the canon of the late council of Rome in vindication of his conduct; declaring, that if the king insisted upon his pretensions to the homage of the clergy, he could keep no communion with him, but must instantly leave the kingdom. The king, unwilling to resign the right of bestowing ecclesiastical benefices, and of receiving the homage of his prelates, but at the same time, dreading the departure of the primate, proposed, or rather solicited a truce, till both the parties could send ambassadors to the pope, to know his final determination: to this Anselm, at the earnest entreaty of the nobility, at last agreed.

During this interval, Anselm performed many services for the king. In a synod which was summoned at Lambeth, he obtained a decision in favour of the king's intended marriage with Matilda, although she had already worn the veil, without taking the vows. When the kingdom was invaded

by Robert duke of Normandy, in July 1101, Anselm contributed more than any man, by his example, his exhortations, and his authority, to keep the nobility steady in their attachment to King Henry, and thereby preserved him on the throne. In return, the king professed great reverence for the wisdom and sanctity of Anselm, and promised to pay a strict regard to the rights and privileges of the church. But when the dinner was over, and the messenger from pope Paschal II. returned with a peremptory negative upon lay-investiture, the contest between the king and the archbishop was renewed. Henry resolved not to relinquish the important prerogative of granting church preferment within his own dominions, yet desirous to avoid a rupture with the pope and Anselm, sent three bishops to Rome, while the archbishop, on his part, dispatched two messengers to submit the affair to the consideration of the pontiff. The pope's letter confirmed his former resolution, declaring, that the church, and all its revenues, belonged to the successors of St. Peter; and that emperors and kings had no right to give the investiture of benefices to the clergy, or to exact homage from them. Some of the arguments adduced in defence of this position were either blasphemy or nonsense: "How abominable is it," said he, "for a son to beget his father, and a man to create his God? and are not priests your fathers and your gods?" But this formal declaration was contradicted by the oral testimony of the king's bishops; who asserted, that Paschal had privately expressed to them his acquiescence in their master's claim, but had not given it under his hand, lest other princes should insist upon the same privilege. Anselm and his messengers regarded this story as a designed pervarication, prompted by the king; but the first time the primate appeared at court, he required him in a peremptory tone to do him homage according to ancient custom, or leave the kingdom; adding, "I will suffer no subject to live in my dominions who refuses to do me homage." The archbishop boldly replied, "I am prohibited by the canons of the council of Rome to do what you require. I will not leave the kingdom, but stay in my province, and perform my duty; and let me see who dares to do me any injury." Immediately he left the court, and returned to Canterbury. Soon after, the king granted him permission to make a journey to Rome, in order to learn the pope's final pleasure. He was attended to the sea-coast by crowds of people of all ranks, whom his austere piety and zeal for the church had attached to his interest. From Rome the archbishop retired to Lyons, and afterwards to his monastery at Bec in Normandy. The king, still desirous of an accommodation, sent a message to invite Anselm into England; and upon receiving information that he was ill at the abbey of Bec, went in person into Normandy to settle every remaining point of difference between them. Anselm recovered from his indisposition, and embarked for England, where he was received with singular expressions of a joyful welcome. The queen herself even travelled before him on the road, and gave orders for his accommodation. The popularity of this prelate may be imputed principally to the severity of his manners, and to the zeal with which he opposed abuses, and encouraged superstitious austerities among the clergy and laity. He rigorously enforced clerical celibacy; and was the first who prescribed this absurd, unnatural, and mischievous practice in England. By one canon of a national synod, held by him during his disputes with the monarch, at Westminster, in 1102, it was determined that no priest should marry; and those who were already married, were commanded to put away their wives. By another canon, it was decreed that the sons of priests should not be heirs to their father's churches. By a third, marriage is prohibited to those who are within the seventh degree of

kindred; and the twenty-sixth canon forbade the worship of fountains, which was probably a relic of druidical superstition. Anselm was ever a violent opposer of all innovation, even in articles of dress and ornament; and preached zealously against the long and curled hair then coming into fashion; and his authority and eloquence had such influence, that the young men universally abandoned that ornament, and appeared in cropt hair, which was recommended to them by the sermons of the primate. One of his adherents writing to him about this time, concluded his letter by saying, that religion was ruined by his absence; that seducery and wearing long hair, which he seems to have regarded as equal crimes, were become very common, and nobody had the courage to reprove them.

In a council held at Whitfuntide, A. D. 1108, at which the king and principal clergy, with Anselm at their head, were present, it was resolved to enforce the canons made six years before, relative to the celibacy of the clergy. Ten others were also added, by which all priests were commanded to put away their wives instantly; not to suffer them to live on any of the lands belonging to the church; never to see them except in cases of great necessity, and in the presence of two or three witnesses. Those who put away their wives were ordered to abstain from meat for forty days, and to perform certain penances; but those who refused to put away their wives were to be excommunicated, and their goods, together with the persons and goods of their wives, were to be forfeited to the bishop of the diocese. These ecclesiastical and wicked decrees afford sufficient proof, that it was then found no easy task to dissolve the natural and virtuous affection that subsisted between the clergy of England and their wives.

One of the last disputes in which Anselm was engaged, was with Thomas elect of York, who, hoping for the death of the primate, delayed to come to Canterbury to receive consecration; but he was at length obliged to submit, make the usual professions of obedience, and render to his superior the accustomed homage. This, in fact, is the only material occurrence mentioned during the three last years of Anselm's life. This celebrated prelate died at Canterbury on the 20th of April 1109, in the 67th year of his age, and the 16th of his primacy.

The superstitious reverence which was paid to the memory of Anselm, and the characteristic credulity of the age, are shewn in the account of his miracles recorded by John of Salisbury. He relates, that while he was living, a Flemish nobleman was cured of a leprosy by drinking the water in which Anselm had washed his hands in celebrating mass: that he extinguished fires, calmed tempests, and healed diseases, by making the sign of the cross: that two soldiers were cured of an ague by tasting crumbs fallen from the bread which he had been eating: that by prayer to God, he produced a spring of excellent water at the top of a hill for the relief of certain villagers: and that a ship in which he sailed, having a large hole in one of her planks, nevertheless took in no water as long as the holy man was on board. The same author adds, that miracles were wrought at Anselm's tomb after his death: that one born deaf, dumb, and blind, obtained his hearing, speech, and sight, by paying his devotions at his tomb: that a soldier was cured of the dropy by winding the saint's girdle about his body; and that the same girdle was successfully applied to the assistance of women in child-birth.

Without examining the powers of Anselm as a saint, his merit as a man may be fairly estimated, if, with great allowance for the narrow prejudices of a monastic education, and for principles and habits generated by a debasing system of superstition, we give him credit for honest zeal, and manly resolution,

resolution, in support of what he conceived to be the cause of religion. Considering the period in which he lived, Anselm was a learned man. He contributed to the introduction of the scholastic method of writing, in which the subtleties of logic were applied to theology. Among his metaphysical works is a treatise on the existence of God, in the manner afterwards resumed by Des Cartes.

The largest edition of his works, which are very numerous, is that published by Father Gerberon, at Paris, in 1675. It is divided into three parts. The first contains dogmatical tracts, entitled, "Monologia." The second contains practical and devotional pieces. The third is composed of his letters. See Biog. Brit. Gen. Dict. Hume's and Henry's Hist. of Great Britain.

ANSELM'S art. See ART.

ANSELM of Paris, an Augustine monk, was born in 1025, and devoted almost his whole life to genealogical and biographical researches. His "Palace of Honour, or Historical Genealogies of the illustrious House of France, and of several noble families of Europe," was published in French at Paris, in 1647, in two vols. 4to. His "Genealogical and Chronological History of the House of France, and of the great Officers of the Crown," was first published at Paris, in 4to. in 1694; but the author, dying this year, did not complete his design. Fourni enlarged this work, and republished it in two volumes folio, in 1711; and it has since been continued by the Augustine fathers, Auge and Simplicien; and in 1726, &c. it was published in nine volumes folio. Biographers have been much indebted to this collection. Nouv. Dict. Hist.

ANSELMUS, *De Janua*, flourished in the thirteenth century. Aitric supposes he was of the faculty of medicine at Montpellier: that he was in repute in his time, is proved by the notice taken of him by Lanfranc, and afterwards by Gui de Chauliac, who recommended his practice in certain cases; but there are no works now remaining bearing his name.

ANSER, in *Astronomy*, a small star, of the fifth or sixth magnitude, in the Milky Way, between the Swan and Eagle: first brought into order by Hevelius.

ANSER *Americanus*. See TOUCAN.

ANSER, in *Natural History*, a species of VIBRIO in the *vermes infusoria*. It is elliptical, with a long neck and tubercle on the back. Gmelin. This kind is found in water where duck-weeds grow: it is between the vibrio proteus and vibrio falx, and is chiefly distinguished by the protuberance on the back. The body is elliptical, round, without any lateral inequality, and full of molecules; the hind part is sharp and bright, the forepart produced into a bending neck, which is longer than the body; the apex even and whole, blue canals passing between the marginal edges, and occupying the whole length of the neck: in one of those canals a vehement descent of water to the beginning of the trunk may be perceived. The motion of the body is slow, that of the neck is more lively and flexuous, and sometimes spiral. See Adams, Microf.

ANSER, in *Ornithology*, a species of ANAS, or duck, called in England the grey-lag, or wild goose, and generally admitted as the origin of the domestic goose. The character of this species is, bill semi-cylindrical; body above cinereous, beneath paler; neck streaked. Linnæus, Gmelin, &c. The length of the bird is usually about two feet nine inches, breadth five feet, weight ten pounds. The bill is large and elevated, yellowish flesh colour, with the nail white. The head and neck are cinereous, mixed with dirty yellow; neck striated downwards; back and primaries dusky, the last tipped with black; shafts white; secondaries black, edged with white; lesser coverts dusky, edged with white;

breast and belly whitish, clouded with ash colour; rump and vent white; middle feathers of the tail dusky, tipped and edged with white; the outmost almost entirely white; legs flesh-coloured; claws black. Penn. Arct. Zool. Lath. Gen. Syn. &c.

"This species," says Dr. Latham, "inhabits the fens of England; and it is believed, does not migrate, as in many countries on the continent, as they are not only met with in the summer, but also known to breed in Lincolnshire, Cambridgeshire, and other places: they have seven or eight young, which are often taken, and easily become tame. They however, unite into flocks during the winter season, as numbers are met with together. On the continent they are migratory, changing place in large flocks, often five hundred or more: in this case the flock is triangular in shape, with one point foremost; and as the goose which is first is tired soonest, it has been seen to drop behind, and another to take its place. In very small flocks, however, they are sometimes seen to follow one another in a direct line. Geese seem to be general inhabitants of the globe: they are met with in Iceland; and on the continent, from Lapland to the Cape of Good Hope; they are frequent in Arabia, Persia, and China, as well as indigenous to Japan; and on the American continent from Hudson's bay to South Carolina. Our voyagers meet with them in the Straits of Magellan, Port Egmont in Falkland Isles, and Terra del Fuego; also in New Holland, though not at New Zealand, as we find capt. Cook making the inhabitants a present of a pair in order to breed." Gen. Syn.

The same author remarks, that the grey-lag goose, in a state of domestication, varies in colour from the wild ones, though much less so than either the mallard or cock, being ever found mere or less verging to grey; though in all cases the whiteness of the vent and upper tail coverts is visible, and very often those parts are quite white, especially in the males. See GOOSE, *domestic*.

ANSERES, in *Ornithology*, the third order in the Linnean arrangement of birds. The character, according to that author, is, the bill smooth, covered with skin, and broadest towards the tip: feet formed for swimming, toes palmated, and connected by a membrane; shanks compressed and short. The body is fat, and flesh rather rancid. These live chiefly on the water, and feed on plants, fish, frogs, worms, &c. The nest is generally formed on the ground; the mother takes little care of the young; and they are frequently polygamous.

The birds of this order are divided into two sections, one having the beak denticulated, or toothed, and the other being destitute of these teeth: the genera of the first section are anas, mergus, phaeton, and plotus; and those of the second section, rhyncops, diomedea, aptenodya, alca, procellaria, pelicanus, larus, sterca, and colymbus.

ANSERIFERA, in *Conchology*, a species of LEPAS. The shell is compressed, and has five valves, which are striated, and seated on a pedicle. Gmelin. This kind inhabits the American and Atlantic seas.

ANSERINA, in *Botany*. See POTENTILLA.

ANSERIS, in *Entomology*, a species of PEDICULUS found on both the wild and tame goose; it is filiform, pale, with black dots on the margin. Linnæus, Fabricius, Redi, &c.

ANSERIS, in *Natural History*, is also a species of FASCIOLA in the *Vermes intestina*. The body is oblong-oval; beneath, two rows of opposite papillæ, with approximate pores. Froelich, Gmelin, &c. Found in the rectum of the common goose.

ANSERIS is also the specific name of a creature in the TÆNIA genus, that infests the intestines of the domestic goose. It is minute and very narrow, the anterior part capillary. Goetz and Gmelin.

ANSES. See ANSER.

ANSIANCE, in *Geography*, a people of the island of Madagascar, towards the isle of St. Mary.

ANSIBARII, or ANSIVARII, in *Ancient Geography*, the name of a people of Germany, mentioned by Tacitus. According to this historian, they were driven, in the time of Nero, from their own territory by the Chauci, and then took possession of certain lands, previously occupied by the Frisians, which had belonged to the Romans, and used as pasture for their horses and cattle. In this acquisition, they were conducted by Boioacalus, a person of distinguished reputation, and of a proved fidelity to the Romans. When the Romans demurred in allowing them to possess these lands, Boioacalus pleaded the merit of 50 years service; and he remonstrated, that the territory was large, and applied to no useful purpose; that an unhappy people, driven from their own habitations, might be accommodated without encroaching on wide tracts, in which the Roman horses and cattle might range; that humanity forbade their suffering men to perish, whilst beasts were amply provided for; that it was incompatible with religion to devote to deserts and solitude parts of the earth which were designed by the gods for the use of men; and that such parts as had no possessor were free and common to all. Then lifting up his eyes to the sun and other celestial luminaries, he asked them, how they could bear to behold a desolate soil, and if they would not, in justice, command the sea to swallow up usurpers, who thus engrossed the earth? To this spirited remonstrance, Avitus, the Roman commander, indignantly replied, that the weakest must submit to the most powerful; and that as the gods had entrusted the Romans with sovereign judgment, they could not permit any other judges to interfere. At the same time, lands were privately offered to Boioacalus, in recompence of his long attachment to the Romans. This offer the brave general considered as the price of his honour, and as a bribe for betraying his people, and he rejected it with disdain and indignation, alleging, "We may want a place to live in, but a place to die in we cannot want." Upon this the Ansibarii invited the neighbouring nations into a confederacy against the Romans, but they were awed by the Roman generals and their forces; so that at length these unhappy people, applying in vain for settlements in neighbouring territories, were under a necessity of making long and various peregrinations, which terminated in their utter destruction. Tacit. *Annal.* lib. xiii. c. 53—57. These people have been known under the other denominations of *Amsivarii*, *Ampsvarii*, and *Ampscarii*. Some have thought that their name is derived from *Anser*, the *Ems*, and *baner*, a German word, which signifies *to inhabit*.

ANSIKO, or ANZIKO, called also MAKOKO, in *Geography*, a kingdom of Africa, is bounded on the west by the river Umbre, which runs into the Zaire, the kingdom of Wangua and the Amboes, who border on Loango; on the north by some deserts of Nubia; and on the south by the provinces of Congo, called Songo and Soada. This country has several mines of copper; it produces a great quantity of sanders wood, both red and grey; and it abounds with rhinoceroses, lions, and other wild beasts. The inhabitants have neither fixed lands nor inheritance; they neither sow nor reap, but live like the wandering Arabs, and subsist by plunder and slaughter. They are said to be the remains of the Gages, who came originally from Sierra Leona, but being weakened by their marches and battles, they were unable to return, and reduced to the necessity of residing, principally, in the kingdom of Anliko, and also on the south-east of Angola. In their undertakings and exploits, they are valiant and intrepid, and altogether regardless of life. Their language is barbarous, and difficult

to be acquired, even by the inhabitants of Congo. Their food is said to be human flesh, and human bodies are hung up for sale in their shambles. Conceiving that they have an absolute right to dispose of their slaves at pleasure, their prisoners of war are fattened, killed, and either eaten, or sold to butchers. It is also said, that discontented slaves offer themselves for food to their masters; and that persons of the nearest relation feed upon each other without the least horror. They have no graves for the dead, who are devoured as soon as they have expired. Persons of the principal distinction wear red and black caps of Portuguese velvet, and those of inferior condition, of both sexes, go barefooted, and are naked from the waist upwards. In order to preserve their health, they anoint their bodies with a composition of pounded white sandal-wood and palm oil. The king of Anliko, or the great Macoe, is esteemed the most powerful monarch of Africa, and his dominion extends over 13 kingdoms. The zimbis, or shell silver found at Loango and Angola, is the current coin of the country, and exchanged by the natives for slaves from Nubia, and also for salt, silk, glass, linens, and other merchandises. The arms of these people are battle-axes, and small but very strong bows, adorned and strengthened with serpents skins, and furnished with strings made of supple and slender shoots of trees, like reeds, which never break, and short arrows of hard and light wood. In the use of their bows and arrows, they are so dextrous, that they kill birds flying, and discharge as many as 28 arrows from the bow before the first falls to the ground. Besides their bows and battle-axes, they have also daggers in serpent-skin scabbards, which they carry in ivory belts. With respect to religion, they are idolaters; worshipping the sun as their chief deity, whom they represent under the form of a man, and the moon under that of a woman; and an infinite number of inferior deities, each man having a peculiar idol to whom he offers sacrifices, and whom he constantly invokes in dangerous enterprises. They practise circumcision, but from what motives, whether religious or otherwise, it is not known. These barbarous people are much extolled for their singular fidelity and loyalty, so that they will sacrifice their lives in defence of their princes, or of their friends and allies. *Mod. Un. Hist.* vol. xiii. p. 266, &c.

ANSLO, or OPSLO, a sea-port town of Norway, in the prefecture of Aggerthuys, upon the bay of Anflo. See CHRISTIANIA.

ANSON, GEORGE, LORD, in *Biography*, an eminent English naval commander, was the third son of William Anson, Esq. of Shuckborough in Staffordshire. He was born in 1697. The navy being Mr. Anson's choice, he went early to sea; and in the year 1716, having passed regularly through the inferior stations, he was made second lieutenant of his majesty's ship the *Hampshire*; and in 1724, he was raised to the rank of post-captain, and to the command of the Scarborough man of war. Between this time and 1733, he went, with ships under his command, three times to South Carolina, where he acquired considerable property, and erected a town bearing his name, the country around which has been ever since called Anson County. Between 1738 and 1739, he made a fourth voyage to the coast of Guinea and to America, in the course of which, by his prudence, he engaged the French to desist from interrupting the English Guinea trade, without coming to acts of hostility.

On the breaking out of the Spanish war in 1739, Mr. Anson was pitched upon as a proper person to command a fleet destined to attack the Spanish settlements in the Pacific Ocean. He set sail in September 1740, with a squadron of five men of war, a sloop, and two victualling ships. The whole business of fitting out this expedition had been managed

waged with extreme negligence and incapacity, which rendered the exertion of all the commander's talents necessary. After a long and tedious voyage, he arrived at Madeira, thence he proceeded to St. Catherine's on the coast of Brazil, and afterwards to St. Julian in Patagonia. In doubling Cape Horn, he experienced prodigious difficulties from storms and tempestuous weather: some of his fleet were separated from him, of which only a small part ever rejoined him. At length he arrived at the island of Juan Fernandes, where he refitted, assisted with his own hands in landing the sick sailors, and for the benefit of future navigators, sowed the seeds of a variety of garden vegetables and fruit-trees. Thence he proceeded to the coast of Peru, and took the rich town of Païta; which, on the refusal of the Spaniards to ransom it, he was obliged, according to the practice of war, to reduce to ashes. When the English were about to embark, one of their company was missing, who, however, soon arrived, and acknowledged, that by taking too copious a dose of brandy, he had fallen into a profound sleep, from which he was awakened by the scorching heat of the town on fire. Upon opening his eyes, he was amazed to behold on the one hand all the houses in a blaze, and on the other, the Spaniards and Indians near him. The greatness and suddenness of the terror instantly brought him back to a state of sobriety, and gave him presence of mind to push through the thickest of the smoke, and thus escape the hands of the enemy. This was the only instance of neglect of duty through the effects of liquor, which might have been obtained in almost every warehouse in the town. On this coast, Commodore Anson took some valuable prizes, on board of which were several passengers of distinction of both sexes; his treatment of whom was to honourable, and consistent with the most delicate decorum, that it left the most favourable impressions of himself and his country. He afterwards sailed to the coast of Mexico; thence with a view of intercepting the annual Acapulco ship, he took his departure across the Pacific Ocean, with his own vessel the Centurion, and the Gloucester. In this passage the Gloucester became leaky, and was abandoned; and the united crews, reduced by sickness, with difficulty reached Tinian, one of the Ladrones. Here while the commodore and the greater part of his crew were on shore, the Centurion was by a strong gale driven out to sea; and so little prospect was there of her being able to reach the island again, that much labour was spent in fitting up a small vessel found on the island, Anson himself taking the axe like a common sailor. The only occasion in which marks of emotion broke through the uniform equanimity of his demeanor, was when he received news of the Centurion's coming again in sight. From Tinian he went to Macao; and in returning from Macao, he took a rich Manilla galleon: but at the moment of victory he had a call for the exertion of all his courage and presence of mind, in consequence of a fire which broke out near the Centurion's powder-room, but which his orders, given with all the calmness of one conversant with danger in every shape, soon got under. He sailed back to Canton with his prize; and there exhibited equal dexterity and firmness in transacting affairs with the Chinese, and maintaining the rights of his own country. Returning from thence by the Cape of Good Hope, he arrived at Spichead on the 15th of June 1744, having completed the circumnavigation of the globe, and brought back great riches taken from the enemy, though unforeseen disasters had defeated some of the principal purposes of the enterprise. Thus was the expedition finished, after having by its event strongly evinced this important truth, that though prudence, intrepidity, and perseverance united, are not exempted from the blows of adverse fortune, yet in a long series of transactions, they

usually rise superior to its power, and in the end rarely fail of proving successful.

In a few days after his return, Mr. Anson was made rear-admiral of the blue; and in a short time after a commissioner of the admiralty, and rear admiral of the white; and in the year 1746, vice admiral. During the winter of 1746 and 7, he was appointed to the command of the channel fleet; and in the following May he captured, off Cape Finisterre, six men of war bound from France to the West and East Indies, laden with warlike stores and merchandise, and four East-Indiamen.

By this successful enterprise, he defeated the pernicious designs of two hostile expeditions, made a considerable addition to the force and wealth of our own kingdom, and thus converted into a public benefit, the intended means of a public calamity. M. St. George, one of the French captains, in allusion to the names of two ships (L'Invincible and La Gloire) which had been taken, said, when he presented his sword to the conqueror; "*Monsieur, vous avez vaincu L'INVINCIBLE, et LA GLOIRE vous suit.*"

For this and other important services, he was with great propriety, in the June following, raised to the English peerage by the title of Lord Anson, baron of Soberton in the county of Southampton. And on the occasion, his lordship made choice of a motto very happily adapted to the dangers he had gone through, and the successes he had obtained, NIL DESPERANDUM. On the 25th of April 1748, he married the eldest daughter of Lord Hardwicke, at that time lord high chancellor of Great Britain: this lady died without issue on the first of June 1760.

Lord Anson had frequently the honour of convoying the late king from England to Holland. The first time was in the year 1748; and ever after he constantly attended his majesty on his going abroad, and on his return to this kingdom. In July 1749, his Lordship was made vice admiral of Great Britain; in 1751, he was preferred to be first commissioner of the Admiralty in the room of Lord Sandwich; and in the years 1752 and 1755, he was one of the lords justices of the kingdom during his majesty's absence. Under him, on the prospect of a war with France, the squadrons were fitted out with great promptitude; and that more success did not attend them was owing to accidents. He was exposed to some censure in consequence of the loss of Minorea at the beginning of the war 1755; and in the following year he resigned his post. On a parliamentary inquiry, however, he, and the persons with whom he had acted, were acquitted of all blame respecting Minorea. In the year 1757, he was again placed at the head of the admiralty board, where he continued during the remainder of his life, which included almost all the glorious periods of that war.

The last time he commanded a fleet was in 1758, when he covered the expedition against the coast of France, and kept the enemy's fleet in port. In 1761, he was raised to the principal naval dignity, that of admiral and commander in chief of the fleet, for the purpose of bringing over the present queen of England, whom, after a rough and tedious passage, he landed on the 7th of September. In February 1762, he accompanied the queen's brother to Portsmouth to shew him the arsenal, and the fleet that was then on the point of sailing, under Sir George Pocock, for the Havannah. Lord Anson, in attending the prince, caught a violent cold, under which he languished for three months. At length it settled on his lungs, and was the immediate occasion of his death. Full of honours and reputation, he died at Moor Park, Hertfordshire, on the 6th of June 1762, leaving his whole property to his brother, Thomas Anson, Esq. of Staffordshire.

Lord Anson was one of his majesty's most honourable

privy council, an elder brother of the Trinity House, and a governor of the Charter House. He was remarkably assiduous at the Admiralty Board, and very ready in making naval dispositions of every kind, and in appropriating the proper strength and proper sort of ships to the different services. Among the various and distinguished merits of this eminent person, was that of having bred up several excellent officers, who were afterwards renowned for signal services achieved for their country. He may, in general, be said to have been a true friend and liberal patron to men of real merit and capacity in his profession. Till later voyages had multiplied the circumstances of the globe, "to have been round the world with commodore Anson," was esteemed a great and honourable distinction to a seaman. *Biog. Britan. Gen. Biog. Dict. Walter's Account of Anson's Voyage.*

ANSON, in *Geography*, an interior county of North Carolina in Fayette district, having Mecklenburgh county to the north, and Bladen and Cumberland counties on the east. It contains 513 inhabitants, including 828 slaves.

ANSON'S ISLE, the *Banka* of Bougainville, an island of the Pacific Ocean, being one of the groupe called *SOLOMON ISLES*. S. lat. 5° 15'. E. long. 153° 30'.

ANSPACH, or *OXOLBACH*, a marquisate or principality of Germany, in the circle of Franconia, bounded by the principality of Bayreuth, and the bishopric of Bamberg and Wurtzburg. The country is mountainous and sandy, but in general it is fertile, and produces considerable quantities of corn and tobacco, and along the Mayn good wine. It has good pastures, and the breed of cattle is excellent. The chief mines are those of iron, those of other kinds being neglected. It has several medicinal springs. Anspach, together with Bayreuth, maintains a population of 320,000 on 2,320 square miles. The principal rivers are the Retzat, Under or Rednitz, the Altmuhl, the Jagst, the Wormitz, the Tauber, and the Mayn. It has 16 boroughs, and 17 market towns, the principal of which are Anspach, Swabach, Kornburg, Cadolzburg, Roth, Gunzenhausen, Wassertrudingen, Windt bach, Feuchtwang, Creiltheim, Colmberg, and Uffenheim. The reigning margrave of this principality has a seat and a voice in the council of the princes of the empire, and is also co-suzerain prince of the circle of Franconia.

ANSPACH, a city of Germany, the capital of the above-mentioned marquisate, situate on the river Retzat, about 13 miles south-west of Nuremberg. This city was rebuilt and enlarged in 1710; it has a public library established in 1738, and a good cabinet of medals and curiosities. N. lat. 49° 14'. E. long. 10° 42'.

ANSPESSADES, or *LANSPESSADES*, in the *French Military*, a kind of inferior officers in the foot, below the corporals, and yet above the common sentinels.

The word is formed of the Italian *lancia spezzata*, q. d. *broken lance*; which was occasioned hence, that they were originally disbanded *gendarmes*, who, for want of other subsistence, sued for a place of some distinction in the infantry. There are usually four or five in each company.

ANSTRUTHER, in *Geography*, a sea port town of Scotland, and a royal borough, situate in the eastern part of the county of Fife, towards the German sea. It is divided into two towns, *East* and *West* (which are royal boroughs) by a small river: the harbour is capable of receiving only small vessels, employed principally in the fishery of the place. N. lat. 56° 12'. West. long. 2° 16'.

ANSWER, in *Law*. See *REJOINDER*.

ANT, in *Entomology*, the common English name of the *formica* of Linnaeus, and synonymous with emmet. That destructive creature termed *fatalis* is also called an ant. See *FORMICA*, and *TERMES*.

This is an insect extremely injurious to pasture lands and

gardens; in the former, by throwing up hills, and, in the latter, by feeding on the fruit, &c. The best methods of keeping them from trees, are those of having the earth round them constantly dug up; and the application of saw-dust, coal-ashes, or other matters of the same kind, about their roots. The same purpose may also be effected by covering the bottom part of the trees with tar; but as this substance is prejudicial to trees, night-soil may perhaps answer better, as it is found to destroy them when spread upon, or put into the little hills which they throw up. A liquor, prepared by boiling rain water with black soap and sulphur, has lately been made use of by M. Tatin, for destroying these animals, it is said, with considerable success. Where this liquor is employed, care should, however, be taken that the ground where they inhabit be perfectly saturated with it.

ANT-BEAR, or ANT-EATER, in *Zoology*. See *MYRMECOPHAGA*.

ANT-EGG is a name popularly given to a kind of little white baills found in the banks or nests of ants, ordinarily supposed to be the ova of this insect. These are not properly the eggs of ants, but the young brood in their incipient state; when they appear like vermicles or little worms, wrapped up in a film or skin, composed of a sort of silk, which they spin out of themselves in the manner of filk-worms and caterpillars. At first they appear motionless, and after a few days, they manifest some symptoms of flexion and extension; then they seem yellowish and hairy, and in the form of small maggots which they assume, they continue to grow till they are almost as large as ants. After having passed their metamorphosis, and when they appear in their proper shape, they exhibit a black speck near the anus, which Mr. Leewenheek and also Mr. Gould imagine to be their faeces or digested food.

Sir Ed. King opened several of these vulgarly reputed eggs, in some of which he found only a maggot in the circumstances as above described; while in another, the maggot had begun to put on the shape of an ant about the head, having two little yellow specks, where the eyes were to be. And in others, a farther progress was observed, the included maggot being furnished with every thing to complete the shape of ant, but wholly transparent, the eyes only excepted, which were as black as bugles. Lastly, in others, he took out every way perfect and complete ants, which immediately crept about among the rest.

The true ants eggs are the white substance which, upon opening their banks, appears to the eye like the scatterings of fine white sugar, or salt, but very soft, and tender. Examined by a microscope, it is found to consist of several pure white appearances in distinct membranes, all figured like the lesser sort of birds eggs, and as clear as a fish's bladder. The same substance is found in the bodies of the ants themselves. This spawn, when emitted, they lie in multitudes on, to brood; till in some time it is turned into little vermicles, as small as mites, commonly called ant-eggs. See *FORMICA*.

ANT-HILLS are little hillocks of earth, which the ants throw up for their habitation and the breeding of their young.

These hills are very detrimental to the farmer, depriving him of as much land as the hills cover, which may, in many cases, be computed at a tenth part or more of his grafs lands; and in some places, where negligence has suffered them to multiply, almost half of it has been rendered useless in this way. In order to remove nuisances of this kind in lands, it has been a custom in some places at the beginning of winter, and often when the weather was not very cold, to dig up the ant-hills, three or four inches below the surface of the ground, and then to cut them in pieces, and scatter the fragments about. But this practice only disseminates the ants, instead of destroying them, as they hide

hide themselves among the roots of the grafs for a little time, and then collect together again upon any little eminence, of which there are generally great numbers ready for their purpose; such as the circular ridges round the hollows where the hills stood before. It is therefore a much better method to cut the hills entirely off rather lower than the surface of the land, and to let them lie whole at a little distance with their bottoms upwards; as by this means the ants, which are known to be very tenacious of their abodes, continue in their habitations, until the rains, by running into their holes of communication, and stagnating in the hollows formed by the removals of the hills, and the frosts, which now readily penetrate, destroy them. If a little foot were sown on the places, and washed in with the rains, it would probably contribute greatly to the effect intended. The hills, when rendered mellow by the frosts, may be broken and dispersed about the land, or removed for the purpose of forming into compost with dung, lime, or other substances. By this method of cutting the hills one other advantage is gained, the land soon becomes even and fit for mowing. In wet seasons, heaps of sandy particles are formed by these insects among the grafs, called by labourers *sprout-hills*, which quickly take off the edge of the scythe. These, which are very light and compressible, may be conveniently removed by frequent heavy rolling in the early spring months. In the rural economy of Norfolk, a practice of cutting and burning the ant-hill: that are formed on grafs land is mentioned by Mr. Marshall. The process is, to cut them up with a heart-shaped sharp spade or shovel, in irregular lumps of from ten to fifteen inches diameter, and from two to five or six inches thick. These are to be turned the grafs side downwards, until the mould side is thoroughly dry, and then to be set the grafs side outwards, until they are dry enough to burn. The fire may be kindled with brush wood, and kept smothering, by laying the sods or lumps on gradually, as the fire breaks out, until ten or fifteen loads of ashes are raised in one heap, which the workmen there complete for a shilling or eighteen pence each load of ashes. The places from which the hills have been removed may be sown with grafs seeds. Besides the destruction of the ant, this is a ready, though by no means an economical way of raising manure.

But in the sixteenth volume of the *Annals of Agriculture*, Mr. Young recommends the method of rolling down the ant-hills, instead of cutting them, as the best practice; and says, that he rode over a large pasture, which he should not have known had ever been infested with these hills, if he had not been assured that it was once covered with them. No other method had been used but that of repeated rollings with a very heavy roller.

ANT *lin.* See *FORMICA-LEO*.

АНТ, *myrk*, the name given by Lister and Ray, to a peculiar species of ant, which is of the number of the perfumed insects. It is found on dry banks, and so much smaller than the common ant, that it needs no other distinction. Those of this species which are without wings are of a yellowish colour, and when bruised or crushed emit a sharp and acid smell, as the common ant does; but those which have wings are coal-black, and these, instead of the four smell of the others, emit a perfume not to be endured for its strength. The smell of all the perfumed insects goes off in keeping; and these little creatures, after they have been dead and dry some time, are found to smell less strongly, but much more agreeably. *Phil. Trans.* N^o 77, or *Abr.* vol. ii. p. 792.

АНТ, *visiting*. At Paramaribo, a Dutch colony in the province of Surinam, there are ants which the Portuguese call *visiting-ants*; they march in troops; and as soon as they appear, all the coffers and chests of drawers are laid open, which they clear of rats, mice, and a peculiar sort of insect

in that country called *cockerlaes*, and of other noxious animals. If any one chance to molest them, they fall upon him, and tear in pieces his stockings and shoes. Their visits are rare; and they do not sometimes appear for three years. *Templeman's Obs.* vol. i. p. 36.

ANTA, in the *Ancient Architecture*, a square column, or pilaster, placed at the corners of the walls of temples and other edifices.

These took their name, according to M. Perrault, from the preposition *ante*, *before*, because placed before the walls and coins of buildings, to secure or strengthen them. The *ante* stood out on the wall, with a projecture equal to one-eighth of their face, provided there were no ornament that had a greater projecture; but it was a rule, that the projecture of the antæ should always equal that of the ornaments.

There are also antæ at doors and gates. Festus confines their use to this last place.

Vitruvius calls those that have but two faces out of the wall angular antæ, to distinguish them from others which have three faces disengaged, and which are placed at the ends of the walls of porticos. See *ANTICUM*.

ANTA, or HANTE, in *Geography*, a small kingdom or province on the gold-coast of Africa, is bounded on the north by the country of Adom, on the north-east by Mampoo, by Axim on the west, and on the south and south-east by the ocean. Its extent from east to west is about ten leagues, the country is mountainous, and covered by large trees, among which are situated many fine villages. Anta was formerly powerful and populous, inhabited by a bold and rapacious people, who greatly annoyed the Europeans by their frequent incursions; but by continual wars with Adom and other neighbouring districts, they are now enfeebled, and the country is almost depopulated. The land is well watered, the vallies are rich and extensive, and the productions, which are abundant, are rice, the best maize, sugar-canes, yams, and potatoes. This country is the most healthy of any along the coast; so that different writers have observed, that the number of deaths here bears no proportion to that in any other of the territories on the coast of Guinea. The principal villages of this country are Bourtury or Botro, Boyera or Petre Grand, Pando, Tokorari, which surpasses all the others in extent and beauty, Sokonda, Anta, and Sama. See the several articles. The king of Anta has fixed his residence four miles from the Dutch fort, as he thus enjoys the protection of the Europeans, and is in some measure secured from the apprehensions occasioned by the incursions of the Adomese. *Mod. Un. Hist.* vol. xiii. p. 401, &c.

ASTA, in *Zoology*. See *TARIR*.

ANTAB, in *Geography*, a town of Syria, 42 miles south of Aleppo.

ANTACÆUS, in *Ichthyology*, a name first given by the Greek writers Ælian and Strabo, to the *ichthyolla piscis*, the singlafs fish, or *huso*; and afterwards by Jonston and others, not only to this fish, but to the common STURGEON.

ANTACHATES is used by some naturalists for a kind of bituminous stone of the nature of amber, though of a different colour, which in burning yields a smell like myrrh.

ANTACIDS, in the *Materia Medica*, is used by some writers to denote medicines proper to correct and resist acid humours.

Antacids are chiefly of the alcalious kind.

Under the class of *antacids* come, 1. Absorbents, as chalk, magnesia, cornu cervi utrum, coral, sea-shells, hæmatites, and steel-slings. 2. Obtundents, as oils and fats. 3. Immutants, as lixivious salts and soaps.

ANTACRIDES denote medicines suited to correct acrimony, either in the whole system, or in particular parts of it. See *ACRIMONY*.

ANTÆ, in *Ancient Geography*, a people placed by Procopius and Jornandes near the mouth of the Danube.

ANTÆOPOLIS, so called from Antæus, overcome by Hercules, a town of Egypt in the Thebaid, on the east side of the Nile; was the capital of the Nome *Antæopolites*, about 32 miles above Panopolis, and about the same distance below Nicopolis. The Thebaid, after the age of Constantine, was divided into two provinces; and Antæopolis became the metropolis of the first Thebaid, and had bishops. This city contained the magnificent temple, which the Egyptians, according to Diodorus Siculus, built in honour of Antæus. No part of it is now remaining but the portico, supported by huge columns, and covered with large stones, one of which may be distinguished, thirty feet long by five wide. The ceiling, painted with gold and azure, has preserved the liveliness of its colours. The Turks have converted it into a stable, where they collect their herds. On the ruins of Antæopolis is now built a miserable burgh called *Gaua el Kebire*. Savary's Travels, vol. i. p. 560.

ANTÆUS, in *Entomology*, a species of SCARABÆUS that inhabits America. The thorax has three horns, the middle one the longest, and simple; head unarmed; wing-cases very smooth. Fabricius, Jablonky, and Gmelin. The female has no horns.

ANTÆUS, in *Fabulous History*, a gigantic king of Libya, said to be the son of Neptune and Terra, and of the enormous stature of 64 cubits. In his contest with Hercules, he was repeatedly overcome, and laid on the ground half dead; but as often as he touched the earth, he obtained assistance from his mother, and acquired fresh strength. Hercules, therefore, found it necessary to raise him from the ground, and suspending him in the air, squeezed him to death. This Antæus is said to have built the town of Tingis on the straits of Gibraltar, where he was interred. The Greek geographers pretend that this Antæus founded Antæopolis in Upper Egypt; and Diodorus Siculus informs us, that Osiris assigned to him the government of Libya and Ethiopia. But it is not easy to determine how the Egyptians should raise to the rank of their gods the Grecian Antæus. It is probable, however, that the temple in which Antæus was honoured by the ancient inhabitants of Egypt, was ruined; and that in process of time the Greeks, under the reign of the Ptolemies, substituted for the worship assigned to the Egyptian Antæus, that of the giant of the same name, slain by Hercules.

ANTÆUS, in *Ancient History*, was probably the same with Atlas; and they are represented by ancient writers as two of the first kings of Mauritania. They were both the sons of Neptune, who reigned over Mauritania, Numidia, and a great part of Libya; and they both ruled over a great part of Africa, particularly Tingitania. Hercules defeated and slew Antæus, in the war in which he dispossessed Atlas of Libya. Atlas and Antæus invaded Egypt, and contended with Hercules in the wars with the gods, and were both vanquished by him. Antæus, as well as Atlas, was famed for his knowledge of the celestial sciences; and from this circumstance it may reasonably be inferred, that they were, under different names, the same king of Mauritania. Antæus, in his wars with Hercules, commanded an army of Egyptians and Ethiopians, and behaved with great resolution and fortitude. By means of powerful reinforcements of Libyan troops, he cut off a great number of Hercules's men; but that celebrated commander, having at last intercepted a strong body of Mauritanian or Libyan forces, that were sent to the relief of Antæus, gave him a total overthrow, and put him and the best part of his troops to the sword. This decisive action put Hercules in possession of Libya and Mauritania, and consequently of all the riches

of those kingdoms; and hence arose the fable, that Hercules, finding Antæus, a giant of an enormous size, with whom he was engaged in single combat, had recourse to the artifice mentioned in the preceding article for putting him to death. Hence likewise may be deduced the fable, intimating that Hercules took the globe of Atlas upon his own shoulders, overcame the dragon that guarded the orchards of the Hesperides, and made himself master of all the golden fruit. The golden apples so frequently mentioned by the old mythologists, were the treasures that fell into the hands of Hercules upon the defeat of Antæus; the Greeks giving the oriental word ΣΝΣ, *riches*, the signification affixed to their own term *μᾶλα*, *apples*. After the most diligent and impartial examination of all the different hypotheses of historians and chronologers, relating to Atlas and Antæus, there is no one that appears so little encumbered with difficulties as that of Sir Isaac Newton. According to this illustrious author, Ammon, the father of Sefac, was the first king of Libya, or that vast tract extending from the borders of Egypt to the Atlantic Ocean; the conquest of which country was effected by Sefac during his father's life. Neptune afterwards excited the Libyans to a rebellion against Sefac, and slew him; and then invaded Egypt, under the command of Atlas and Antæus, the son of Neptune, Sefac's brother and admiral. Not long after, Hercules, the general of Thebais and Ethiopia, for the gods, or great men of Egypt, reduced a second time the whole continent of Libya, having overthrown and slain Antæus near a town in Thebais, from that event called Antea, or Antæopolis. Such is the opinion of Sir Isaac Newton, who endeavours to prove, that the first reduction of Libya by Sefac happened a little above a thousand years before the birth of Christ, as the last, by Hercules, occurred some few years after. *Anc. Un. Hist.* vol. xvi. p. 160.

ANTAGONIST, formed from *αντι*, *against*, and *αγωνίζω*, *I contend*, among the *Ancients*, denotes an adversary in battle. In this sense the word is rather used in speaking of sportive combats, or games, than of serious fighting.

ANTAGONIST also denotes one of the parties in literary disputes.

ANTAGONIST *muscles*, in *Anatomy*, are those which have opposite functions. Such are the *flexor* and *extensor* of any limb, the one of which contracts it, and the other stretches it out; and also the *abductors* and *adductors*. Solitary muscles are those without any antagonists; as the heart, &c.

ANTALGIC, from *αντι*, and *αλγος*, *pain*, an epithet given by some writers to medicines proper for abating pain. In this sense antalgics amount to the same with ANODYNES.

ANTALIS, in *Conchology*, the name given by Argenville to the species of dentalium, called ENTALIS by Linnæus.

ANTALKALINES, in the *Materia Medica*, signify medicines suited to correct alkaline salts, or alkaline matters in the whole body, or in particular parts. Dr. Cullen observes (*Mat. Med.* vol. ii. p. 423.), that no alkaline salt, in its separate state, ever exists in the blood-vessels of the living human body. He accordingly explodes the doctrine of Dr. Boerhaave, who treats "De Morbis ex Alkali spontaneo," as incorrect and erroneous, and leading to no occasion for the use of antalkalines; and he adds, that the only occurrence requiring them is a very rare one, that of a pure alkali being thrown in by mistake or accident into the stomach; and the means of taking off its irritation by acids is sufficiently obvious. It is farther to be remarked, that as the alkali, in any noxious quantity, cannot have been introduced without hurting the mouth, fauces, and œsophagus, it is always necessary, in such cases, along with the acids, to employ the large use of diluents and demulcents.

ANTAMBA,

ANTAMBA, in *Zoology*, an animal of Madagascar, probably the same with the engoi of Congo, is a variety of the leopard, as large as a dog, with a round head; and, according to the relations of the negroes, is like a leopard, and devours both men and cattle. It is found only in the most desert parts of the island.

ANTANACLISIS, from *αντι* and *αντικλιω*, *repercutio*, *I strike again*, a figure in *Rhetoric*; whereby the same word is repeated, but in a different signification—As, “Let the dead bury the dead.” “Dum vivimus, vivamus.” This figure carries with it a poignancy; and when it appears natural and easy, discovers a ready turn of thought.

ANTANAGOGE, from *αντι*, and *αναγωγη*, *reortion*; a figure in *Rhetoric*, when, not being able to answer the accusation of the adversary, we return the charge, by loading him with the same or other crimes; which is usually called **RECRIMINATION**.

ANTANDRO, in *Geography*, a town of Asiatic Turkey, in the province of Natolia, 12 miles west north-west of Adramitti.

ANTANDROS, in *Ancient Geography*, a town of Asia Minor, in Mysia, according to Strabo, who places it on the north side of the gulf of Adramyttium. Stephanus Byz. says, that the Cimmericians possessed it during a century. According to Strabo, these people, conducted by Lygdamis, made this town their place of arms. Servius says, that Antandros was founded by the inhabitants of Andros, after they were driven from their own island on account of their sedition. Others say, that the Thracians, having made Polydore a prisoner, obtained this city as the price of his ransom. Some authors place it at the foot of Mount Ida; and allege, that it gave name to the small chain of mountains extending from Troy to the sea. See **ANDROS**.

ANTANI, a people who inhabited Caria.

ANTANISOPHYLLUM, in *Botany*. See **BOERHAAVIA**.

ANTAPHRODISIAC, from *αντι*, and *Αφροδις*, *Venus*; an epithet given to medicines which diminish the semen, and check or extinguish the incitements to venery. It is doubtful whether there be any medicines of specific power for this purpose; and if there be any which have these effects, it is by answering particular indications, under the titles of which they should only be mentioned, and not under a general term of no defined operation.

ANTAPOCHA, in the *Civil Law*, denotes one's acknowledgment in writing of money paid, in the way of rent, pension, interest, or the like incumbrance. Such instrument, or antapocha, the debtor gives upon making payment to the creditor, to serve as a proof of the charge or incumbrance for futurity, and exclude any claim of prescription against the payment of it. The *antapocha* differs from the *apocha*, in that this latter is given by the creditors to the debtor, the former *vice versa*.

ANTARADUS, in *Ancient Geography*, a town of Syria, commonly called **TORTOSA**, was situated over-against the ancient **ARADUS**, to the right of the river Eleuthera, at a small distance from the sea. In the fourth century, about A. D. 330, it continued to be known by its old name, as appears from the “*Itinerarium Hierosolymitanum*,” which, with its other name *Constantia*, given to it by its restorer Constantius, were dissolved some centuries afterwards, in, or perhaps before, the time of the croisades. Shaw's Trav. p. 266.

ANTARCTIC Pole denotes the southern **POLE**, or end of the earth's axis. The word is composed of *αντι*, *contra*, and *αρκτος*, *ursa*, *bear*; as being opposite to the arctic pole. The stars near the antarctic pole never appear above our horizon.

ANTARCTIC circle, is one of the lesser circles of the sphere, parallel to the equator, at the distance of $23^{\circ} 30'$ from the south pole. It takes its name from its being opposite to another circle, parallel likewise to the equator, and at the same distance from the north pole, called the **ARCTIC circle**.

ANTARCTICA, in *Entomology*, a species of **SPHEX**, about the size of the common wasp. It is black, with ferruginous legs and antennæ. Gmelin. Inhabits the Cape of Good Hope.

ANTARCTICA, in *Ornithology*, a species of **PROCELLARIA** that is found within the antarctic circle. It is brown above, beneath bluish white; tail white, black at the tip; legs lead colour. Gmelin. This is the antarctic petrel of Forster and Cook; petrel antarctique, ou damier brun, of Buffon; and petrel brun et blanc of Bongaino. It is about the size of a large pigeon, and the length is sixteen inches, of which the bill is one inch and an half, and is brown with a black tip; the second quill feathers are white, with dark brown tips; the quills are dark brown, with the inner webs of some next the body white. These birds have been met with in flights of twenty or more, by navigators, in S. lat. $61^{\circ} 36'$.

ANTARCTICA, is also a species of **APTENODYTES**, called by Forster the antarctic pinguin. The beak is black, legs reddish, and a black line on the throat. Gmelin.

The length of this bird is twenty-five inches; the weight eleven pounds and an half. Bill nearly three inches in length, black, and the under mandible somewhat truncated; irides pale yellow; upper parts of the body black, beneath glossy white. Under the chin is a narrow blackish streak passing backwards towards the hinder part of the head, and somewhat bent about the region of the ears. Wings above blue-black, the lower margin and inside white; tips black. Tail cuneiform; the feathers, or rather bristles which compose it, black, and thirty-two in number. The feet, which are reddish, or rather flesh colour, have the soles black. Latham, &c.

This species inhabits the South Sea, from 48° to the antarctic circle; and is frequently found on the icy mountains and islands in those regions, according to Forster, Ellis, and other naturalists and navigators.

ANTARCTICUS, in *Entomology*, a species of **TABANUS** that inhabits America. It has four brown stripes across the eyes, and the flanks of the legs are white. Fabricius and Gmelin.

ANTARES, in *Astronomy*, the Scorpion's Heart; a fixed star of the first magnitude, in the constellation **SCORPIO**.

ANTASTHMATICS, in the *Materia Medica*, denote medicines that are supposed to cure asthma; or, in general, to relieve difficult breathing.

ANTASTROPHE, from *αντι*, and *στρω*, *I turn*; in *Rhetoric*, a species of **ANTEPOSITION**.

ANTAVARE, in *Geography*, a province of Madagascar, is situated to the north of Matatane, in $21^{\circ} 30'$ of S. lat. and bounded by the province and cape of Manoufi. It is watered by the river Mananzari, whose source is in the mountains of Ambohitsmene, or red mountains, situate about 12 leagues farther north-west, and which runs south-east and east. Antavare is extremely fertile in rice, yams, bananas, sugar-canes, and honey, of which wine is made; and it abounds in cattle and goats, and all sorts of fowls and provisions. The French discovered in this province gold dust by means of the negroes, who offered it for sale.

ANTE, in *Geography*, a river of France, which runs into the Dive at Calibœuf, in the department of the Calvados.

ANTE, a town and port of Africa, in Guinea, three leagues from the cape of Three Points.

ANTEA, or **ANTEIS**, *Ampus*, in *Ancient Geography*, a town of Gallia Narbonensis, almost to the north of Forum Vocorum. The Roman way from Forum Julii to Reis Apollinarian, passed by Antea.

ANTEAMBULONES, from *ante*, *before*, and *ambulo*, *I walk*, in *Antiquity*, a kind of state servants, who walked before their masters to clear the way and keep off the crowd.

The *sermula* used by these was *Dote beum de vino meo*.

ANTECANIS is used, by some *Astronomers*, to denote the constellation otherwise called *Canis Minor*, or the star *Procyon*. It is thus denominated as preceding, or being the forerunner of the *Canis Major*, and rising a little before it.

ANTECEDENT, in the schools, something that precedes or goes before another, in respect of time or place.

The word is compounded of *ante*, *before*, and *cedere*, *to go*. In which sense it stands opposed to *subsequent*.

ANTECEDENT, in *Grammar*, the word to which a relative refers.

ANTECEDENT, in *Logic*, denotes the first proposition of an *enthymeme*, or of an argument which only consists of two members. In opposition to this, the latter is called the *consequent*.

Thus, in the argument, *cogito, ergo sum, I think, and therefore I exist*; *cogito* is the antecedent: being thus called, because it precedes the *ergo*, or the *copula*, of the argument.

ANTECEDENT of a RATIO, in *Mathematics*, denotes the first term, or that which is compared with the other.

Thus, if the *ratio* be *a : b*, or of *a* to *b*, *a* is said to be the antecedent.

ANTECEDENT signs, in *Medicine*, are such symptoms of disorder as appear before a distemper is so formed as to be reducible to any particular class, or proper denomination.

ANTECEDENTS, in *Rhetoric*, are such things as being once allowed, others necessarily or very probably follow. This is one of the sixteen topics or common places enumerated by Cicero and Quintilian.

ANTECEDENT decree, in *Theology*, is a decree preceding some other decree, or some action of the Creator, or the provision of action. It is a point much controverted, whether predestination be a decree antecedent to faith, or subsequent to it.

ANTECEDENT will, or *desire*, is that which precedes some other will or desire, or some knowledge or provision. Thus some divines say, God by a sincere, but antecedent desire, wills all men to be saved; that is, this sincere desire of God precedes, and does not suppose, the knowledge of their faith and repentance.

ANTECEDENT necessity. See **NECESSITY**.

ANTECEDENTIAL METHOD, in *Mathematics*, is a branch of general geometrical proportion, or universal comparison; and is derived from an examination of the antecedents of ratios, having given consequents, and a given standard of comparison, in the various degrees of augmentation and diminution, which they undergo by composition and decomposition. This method was invented by Mr. James Glenie, and published by him in 1793; and this method, he says, he always used instead of the fluxional and differential methods, and which is totally unconnected with the ideas of motion and time. See the author's treatise on the subject, and also his *Doctrine of Universal Comparison, or General Proportion*, 1789, upon which it is founded. See **CALCULUS, Antecedental**.

ANTECEDENTIA, among *Astronomers*. When a planet appears to move westward, contrary to the order or course of the signs, as from Taurus towards Aries, it is said to move in *antecedentia*.

On the contrary, when it goes eastward, or forward, from Aries towards Taurus, it is said to move in *consequentia*.

ANTECESSOR, one that goes before, or that leads another. See **PRECURSOR, PREDCESSOR, &c.**

The term is particularly used, in some universities, for a public professor, who teaches or lectures in the civil law.

ANTECESSORS, or **ANTECURSORIS**, in the ancient art of *War*, is an appellation given to a party of horse, dispatched before the *agmen* or body of an army, partly by way of intelligence, and partly to choose out a proper place for encamping on, as well as the most convenient roads for the soldiery to travel in. They amount to the same with what the Greeks call *prodromi*.

ANTECHAMBER, or **ANTICHAMBER**, formed of *ante*, *before*, and *camera*, *a chamber*; an outer chamber before the principal chamber of an apartment, where the servants wait, and where strangers stay, till the person to be spoken with is at leisure.

ANTECHRIST. See **ANTICHRIST**.

ANTECUA, or **ANTEGUA**, in *Ancient Geography*, a town of Spain in Bætica, south-east of Hispalis, possessed, according to Ptolemy, by the Antrigones.

ANTECURSORES. See **ANTECESSORS**.

ANTEDATE, a spurious date, prior to the true date of a writing, instrument, act, deed, or the like.

Antedates, in *Commerce*, are of a very dangerous consequence in matters of trade. To *antedate* is to set down a false date: to date from a day prior to that on which the business is transacted, the note or bill drawn, or letters written, &c.

In France it was formerly the ill custom to have blank orders on the backs of bills of exchange, that is, to indorse them merely with a name, so that they could easily be antedated: which in case of failures was liable to cause very great abuses. But by the regulations for commerce of 1683, it is ordered that the signatures on the backs of bills of exchange shall not serve for orders, unless dated; and antedates are punished as forgery.

ANTEDILUVIAN, or **ANTIDILUVIAN**, formed of *ante*, *before*, and *diluvium*, *deluge*, something that existed or happened before the **DELUGE**.

Dr. Burnet and Dr. Woodward differ very widely about the Antediluvian world; the former imagines its face and appearance to have been smooth, equable, and in all respects different from what we now find it to be. The latter, on the contrary, endeavours to prove, that the face of the terraqueous globe before the deluge was the same as it is now, *viz.* unequal, distinguished into mountains and dales, and having likewise a sea, lakes, and rivers; that this sea was salt, as ours is; was subject to tides; and possessed nearly the same space and extent that it now does; and that the *Antediluvian* world was stocked with animals, vegetables, minerals, &c. that it had the same position, in respect of the sun, which ours now hath, its axis not being perpendicular, but inclined, as at present, to the plane of the ecliptic; consequently that there were then the same succession of weather, and the same vicissitudes of seasons as now. See **EARTH**.

In the sense of the definition, those generations that existed from Adam till Noah's flood, are called *Antediluvians*; and those that have descended from Noah to the present time, are called *Postdiluvians*. Although the regular succession of the several patriarchs from the creation to the deluge, or from Adam to Noah, may be deduced without difficulty from the sacred writings, it is not so easy to settle the chronology of this period. Moses has not precisely marked the time of the various transactions that occurred before

the flood, but he has contented himself with merely setting down the years of the fathers' age, in which the several descendants of Adam, in the line of Seth, were begotten, and the length of their respective lives; and therefore, in this period, nothing more can be done than to ascertain the years of the lives and deaths of those patriarchs, and the distance of time from the creation to the deluge. This, indeed, might easily be done, if there were no varieties in the several copies of the writings of Moses, to which we have now access, which are the Hebrew, the Samaritan, and the Greek version of the Septuagint: but these differ

considerably from one another; and hence learned men, as they have preferred one copy or the other, are much divided in their opinions concerning the first ages of the world. In order to enable our readers to judge of the variations of the three copies above mentioned, in this period, we shall subjoin a table extracted from the Ancient Universal History, in which the corresponding numbers of each will appear; and we shall also add those of Josephus, as they have been corrected by Dr. Wells and Mr. Whitton; a correction which became indispensable on account of the corruptions that have been introduced into the present copies of that historian.

A TABLE of the Years of the Antediluvian Patriarchs.

Their ages at their sons birth.	Heb. Sam. Sept. Jof.				Years they lived after the sons birth.			Length of their lives.		
	Heb.	Sam.	Sept.	Jof.	Heb.	Sam.	Sept.	Heb.	Sam.	Sept.
Adam, -	130	130	230	130	800	800	700	930	930	930
Seth, -	105	105	205	105	807	807	707	912	912	912
Enos, -	90	90	190	90	815	815	715	905	905	905
Cainan, -	70	70	170	70	840	840	740	910	910	910
Mahalaleel, -	65	65	165	65	830	830	730	895	895	895
Jared, -	162	62	162	62	800	785	800	962	847	962
Enoch, -	65	65	165	65	300	300	200	365	365	365
Methufelah, -	187	67	167	187	782	653	802	969	720	969
Lamech, -	182	53	188	182	595	600	565	777	653	753
Noah was aged, } at the Flood, }	600	600	600	600						
To the Flood,	1656	1307	2262	1556						

To this Table it will be necessary, in order to explain the consequence of these variations, to add separate chronological tables, shewing in what year of his contemporaries the birth

and death of each patriarch happened, according to the computation of each of the said three copies.

A Chronological TABLE of the Years of the Patriarchs, according to the Computation of the Hebrew.

	Years of the world.	Years of Seth.	Years of Enos.	Years of Cainan.	Years of Mahalaleel.	Years of Jared.	Years of Enoch.	Years of Methufelah.	Years of Lamech.	Years of Noah.
Adam created, -	1									
Seth born, -	130									
Enos born, -	235	105								
Cainan born, -	325	195	90							
Mahalaleel born, -	395	265	160							
Jared born, -	460	330	225	135	65					
Enoch born, -	622	492	387	297	227	162				
Methufelah born, -	687	557	452	362	292	227	65			
Lamech born, -	874	744	639	549	479	414	252	187		
Adam dies, -	930	800	695	605	535	470	308	243

Jared, Methufelah, and Lamech, die	1307									
The Flood,						847		720	653	600

To the varieties exhibited in the two last tables, others might be added, by admitting the various readings of some numbers in the Samaritan and Septuagint; for as to the Hebrew copies, there is here a constant agreement among them.

The manuscript from which the Samaritan Pentateuch was published, agrees exactly with the Samaritan numbers given by Eusebius. But St. Jerom tells us, that, in his time, there were some Samaritan copies which make Methufelah 187 years old at the birth of Lamech, and Lamech

182 at the birth of Noah, just as the Hebrew does. Now if these numbers be approved as the true original numbers, the interval from the creation to the flood will be 1556 years; differing from the Hebrew computation but 100 years in the age of Jared at the birth of Enoch: and if this last be allowed to be a mistake of the transcriber, by his dropping a number, and writing 62 instead of 162, as has been suspected, the Samaritan will be perfectly reconciled with the Hebrew, and all difference between them vanish.

ANTEDILUVIAN.

Scaliger, on the authority of an old Samaritan chronicle, having at the end a table of the years of the patriarchs to the time of Moses, would correct two of the Samaritan numbers in Eusebius; viz. instead of 65, the age of Mahalaleel when he begat Jared, he thinks it should be 75; and instead of 67, the age of Methufelah when he begat Lamech, he would have it 77. By which alterations he reckons 20 years more to the flood than Eusebius and the manuscript; that is, 1327; but as he acknowledges the table whereon he grounds these corrections, contains some great absurdities, it seems unreasonable to oppose it to the joint authority of Eusebius and the Samaritan manuscript.

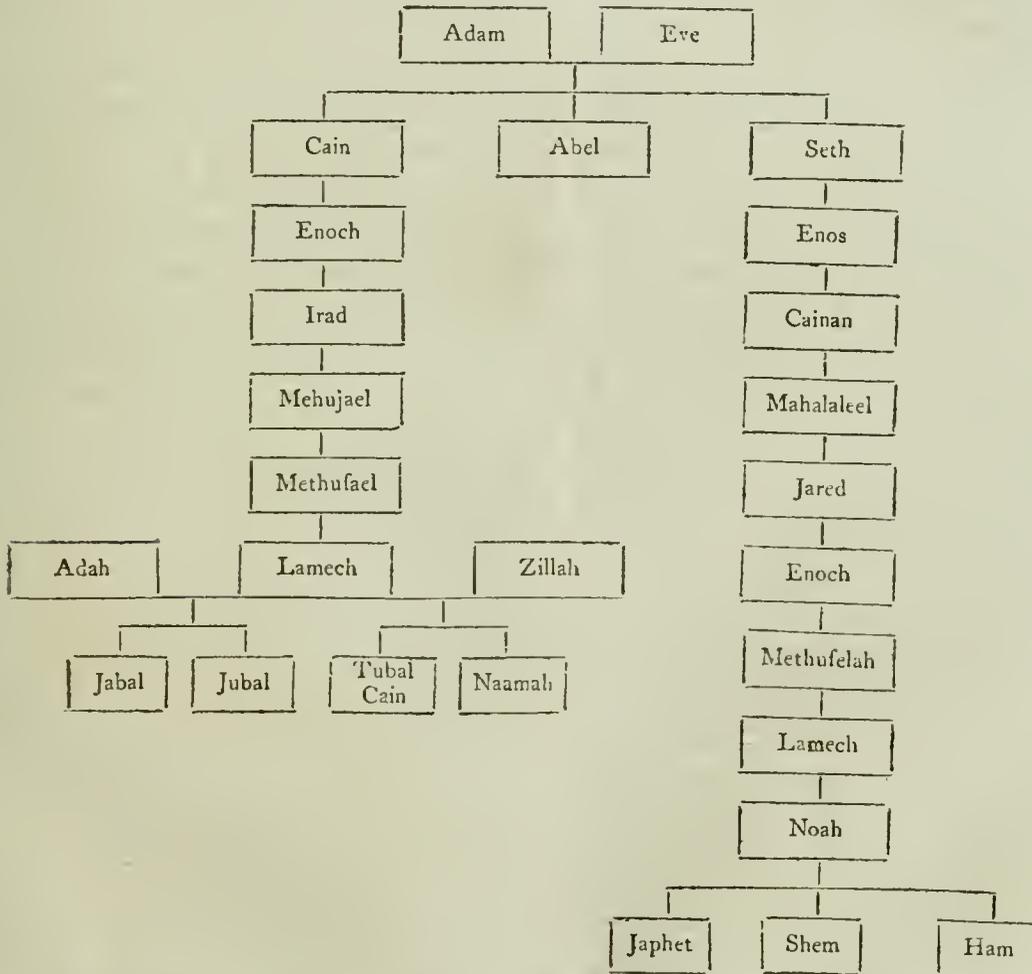

As to the Septuagint, in the common editions of that version, the age of Methufelah at the birth of Lamech is 167; and consequently the sum of this period, according to them, is no more than 2242. But in this case Methufelah will outlive the flood 14 years; and we may well wonder, with Eusebius, where he was preserved. To obviate this objection, we are told, that, in some copies, Methufelah is said to have lived but 782 (not 802) years after the birth of Lamech, and no more than 949 in all. But the Alexandrian manuscript entirely takes away the difficulty, by giving the same number in this place with the Hebrew.

Pezron is of opinion, that the age of Lamech at the

birth of Noah should be but 182, as it is both in the Hebrew and in Josephus; supposing, with St. Austin, that the present number is the error of the scribe, who first copied the original Septuagint manuscript in Ptolemy's library. So that he computes 2256 years to the flood. And, if this correction be admitted, and one more mentioned also by St. Austin, viz. that Lamech lived 505 years after the birth of Noah, and not 565, as in the present copies, there will then remain no other difference between the Septuagint and the Hebrew than 600 years added to the ages of the six patriarchs when they begat their sons; and Methufelah will, conformably to the Hebrew and Samaritan, die in the year of the flood.

The chronology of the learned archbishop Usher has been followed in the calculations of this period; and they may, with very little trouble, be reduced to that of the Samaritan or Septuagint, by those who prefer the accounts of those copies.

As in the course of this work we shall collect, under separate articles, the leading particulars which sacred history has recorded concerning the principal patriarchs, of the Antediluvian world, it is needless to enlarge in this place. It will be sufficient to observe, that the whole progeny of Adam, of whom we have any mention in scripture, were the descendants of Cain and Seth, and the following genealogical table exhibits their succession.

Sacred history is chiefly confined to the line of Seth, and shows few particulars concerning that of Cain, so that no conjectures can be formed how long he or any of his descendants lived. The whole of what we know is, that Lamech, the fifth in descent from him, married two wives, Adah and Zillah, which connection furnishes the first known instance of polygamy: that by the former he had two sons, Jabal, who was the first that dwelt in tents and fed cattle, and Jubal, the inventor of music; and by the other, a son named Tubal-Cain, who found out the art of forging and working metals. Zillah likewise brought him a daughter named Naamah, who is supposed to have invented spinning and weaving. For other particulars, see LAMECH. The posterity of Cain became in a very great degree degenerate and wicked; whilst, on the other hand, the descendants of Seth were as eminent for their piety and virtue. In process of time, however, or after seven generations, according to Josephus, they also became corrupt and profligate; and every kind of wickedness overspread the earth. At length the race of man became incorrigible, and all the means which Providence ordained for awakening and reclaiming them were ineffectual; so that it pleased God, in just displeasure and after signal forbearance, to exterminate the whole species, Noah and his family excepted, by the deluge.

Of the Antediluvian period some accounts have been transmitted to us by those ancient authors who have recorded the Phœnician, Babylonian, and Egyptian antiquities. Sanchoniatho (who is supposed by some to have been contemporary with Gideon, or with David; whilst others deny the existence of such a person, and consider his history as a fiction of Philo Biblius for discrediting Josephus's book against Apion) wrote the Phœnician antiquities. His history commences with the origin of the world and of mankind; but as it was written with a view of apologising for idolatry, he deduces the history, not from Adam in the line of Seth, but in the idolatrous line of Cain, nor does he make the least mention of the deluge. The first pair of mortals with whom his history begins, are called by Philo, his translator, Protogonus and Æon. Their issue were denominated Genus and Genea, and they dwelt in Phœnicia. From Genus sprung Phos, Phur, and Phlox, that is, light, fire, and flame. These found out the method of producing fire by rubbing pieces of wood against each other, and taught men its use. Their sons were of enormous height and bulk, and gave to the mountains of which they took possession their own names of Cassius and Libanus, Antilibanus and Brathys. From these again, in the fifth generation, proceeded Memrumus and Hypsuranius, who were so denominated by their mothers, who lived in a brutal state of prostitution. Hypsuranius inhabited Tyre, and there invented the art of making huts with reeds and rushes, and the papyrus. He quarrelled with his brother Ufous, who was the first inventor of a covering for his body, made of the skins of wild beasts; and he also made a raft of boughs, and ventured upon it into the sea. He likewise consecrated two rude stones or pillars to fire and wind, and worshipped them, pouring out to them the blood of such wild beasts as had been caught in hunting. Afterwards, however, stumps of wood and pillars were also consecrated and worshipped as deities. In the next generation succeeded Agreus and Haliæus, the inventors of the arts of hunting and fishing, from whom the names of huntsmen and fishermen were derived. These begot two brothers, who formed the seventh generation, and who discovered iron and the method of forging it; one of these was called Chryfor, the same with Hephæstus or Vulcan, and exercised himself

in words and charms, and divinations: he found out the hook, bait, and fishing line, built light boats, and was the first man that sailed; so that after his death he was worshipped as a god, and called Zeus Michius, or Jupiter the engineer; and some say, that his brothers invented the art of making bricks. From this generation descended two brothers, one called Technites, or the Artist, and the other Genius Autochthon, or the home-born man of the earth. These found out the art of mingling stubble or small twigs, with the clay of which they made bricks and tiling. One of their posterity, in the ninth generation, was called Agrus, field, and the other Agrouerus or Agrotæ, husbandman, who had a statue much worshipped, and a temple carried about by one or more yoke of oxen, in Phœnicia; and among those of Byblus he is called by way of eminence, the greatest of the gods. These first made courtyards about houses, fences, and caves or cellars. Husbandmen and such as use dogs in hunting, derive their origin from these: and they are also called Aletæ, and Titans. From these succeeded, in the tenth generation, Amynus and Magus, who taught men to form villages, and to feed flocks. Of Amynus and Magus were descended Misor and Sydee; and the son of Misor was Taautus or Thoth. The Protogonus and Æon of the Phœnician genealogy, were, without doubt, Adam and Eve; and Misor, the Mizraim of Moses. From Protogonus to Misor, Sanchoniatho reckons 11 generations; and from Adam to Mizraim, Moses makes 12: so that Sanchoniatho falls short of Moses only by one generation, which is owing to his not having recorded the flood. In this age there was one Eliun, importing in Greek Hypsilus, the most high; and his wife was named Beruth, who dwelt about Byblus; and by him was begotten one Epigeus, or Autochthon, whom they afterwards called Uranus, heaven. He gave his name to the element which is over us, and on account of its excellent beauty, is called heaven; and he had a sister of the same parents, called Ge, the earth, and by reason of her beauty, the earth was denominated from her. Hypsilus, the father of these, being slain by wild beasts, was consecrated, and his children offered sacrifices and libations to him. But Uranus, taking the kingdom of his father, married his sister Ge, and had by her four sons; Hus, who is called Chronus or Saturn; Betylus; Dagon, who is Siton, or the god of corn; and Atlas: but by other wives, Uranus had a numerous issue.

The Babylonian antiquities were collected by Berosus, who was by birth a Chaldæan, and lived in the time of Alexander the Great. He gives a series of ten kings, who reigned in Chaldæa before the flood, and computes their reigns by Sari or decads of years; making the whole sum 1200, or more accurately, 1100 years, which is a number that offers no violence to the Mosiac chronology. As these ten successions correspond to the ten generations that elapsed between the creation and the flood, the first king, whose name was Alorus, has been supposed to be the same with Adam; and Xisuthrus, the same with Noah. Alorus pretended to dominion by divine right, and maintained that God himself had declared him the pastor of the people; a prerogative that peculiarly belonged to Adam. Alasparus, the second king, was succeeded by Amelon, or Amelarus, of the city of Pantibibla, probably the Sipphara of Ptolemy, and supposed by Sir Isaac Newton to be the Sepharvaim of Scripture. After Amenon and Metalarus, who were both of Pantibibla, and the successors of Alasparus, arose Daonus, an inhabitant of the same city, and a shepherd. The seventh prince, called Euedereschus, was of the same city; the eighth or ninth were of another city, called Laranchi; and

ANTE-DILUVIAN.

the last of these; Ohartes or Ardates, was succeeded by his son Xifathrus, in whose time the great deluge happened. See DELUGE.

Berosus ascribes the origin of the arts and sciences among the Antediluvians to the following circumstance. There appeared, says he, out of the Red Sea, at a place near the confines of Babylonia, a certain irrational animal, whose name was Oannes. His body resembled that of a fish, and beneath his head another grew; his feet were like those of a man, and proceeded from the fish's tail, and he had a human voice. This animal conversed with men in the day, and communicated the knowledge of letters, arts, and sciences; he taught men to dwell together in cities, to erect temples, to introduce laws, to acquire geometry, and to gather seeds and fruits; and in short, he imparted to mankind whatever was necessary and convenient for a civilized life. When the sun set, this animal, which was of the amphibious kind, retired into the sea, and stayed there during the night. This animal not only delivered his instructions by word of mouth, but wrote concerning the origin of things, and of political economy. Other authors have also mentioned this Oannes, with some trivial difference in their accounts. Hyginus also writes, that Euahanes, a name not very different from Oannes, came out of the sea in Chaldæa, and explained astrology. According to Abydenus, a second animal, called Annedotus, and resembling the demi-god Oannes, arose out of the sea in the reign of Amelon; and in the time of Daonus, four such animals arose from the sea, and their names were Euedocus, Eneugumus, Eneubulus, and Anementus; and under Euedereschus there appeared another animal, like the former, called Odacon. All these explained more particularly what Oannes had delivered in a more summary and concise manner.

The Egyptians have also a series of kings, who, as they pretend, reigned in Egypt before the flood; and their account begins in the same year with that of Berosus. They had an ancient chronicle, extant among them not many centuries ago, which contained 30 dynasties of princes who ruled in that country, by a series of 113 generations, through an immense interval of 36,525 years, during which period Egypt was successively governed by three different races, *viz.* the Auritz, the Mestrai, and the Egyptians. Manetho, a writer somewhat later than Berosus, and whose remains furnish the ancient Egyptian history, has not adopted this extravagant number of years, though he has probably been led into errors in chronology by this old chronicle, which nevertheless some have supposed to have been a composition of later date than his time. This writer begins his history with 16 dynasties or reigns of princes; of whom the first seven were called gods, and the other nine demi-gods; these, he says, reigned 1985 years.

The knowledge we are able to deduce from the scriptures, the only source of authentic intelligence on this subject, concerning the religion, arts and sciences, and policy of the Antediluvians, is very limited and imperfect, and depends more upon conjecture than upon certain conclusions from a detail of facts. Their religious rites, we know, consisted of sacrifices, both of the fruits of the earth and of animals; but it is not agreed, whether the blood and flesh of the animals, or only their milk and wool were offered. See SACRIFICE. Some have endeavoured to prove, that all the patriarchs from Adam had stated places, and both annual and weekly times set apart for divine worship, and also a separate maintenance for the priests; but these particulars, though they may be true, cannot be proved from the scripture. See САВВАТН. The arts and sciences, as we

may naturally suppose, made but slow progress during the period to which we now refer. It appears that the art of working metals was discovered by the last generation of the line of Cain, and music, which they might have been supposed to practise for their pleasure, was not brought to any perfection (if indeed it was actually invented) before the same generation. Some have supposed, that the science of astronomy was cultivated by the Antediluvians; but this opinion is probably owing to a misapprehension of Josephus: but if it was known, the progress they made in it, or indeed in any other science, was inconsiderable. It has been even doubted, whether or not letters were known before the flood. See LETTERS and WRITING. As to their politics and civil constitutions, we can only say, that the patriarchal form of government was probably the first that was adopted; but this was set aside, when tyranny and oppression began to take place; and this change occurred much sooner, as we have reason to believe, among the race of Cain than that of Seth. Their communities were few, and consisted of much larger numbers of people than those which were formed after the flood; and it has been questioned, whether after the union of the two great families of Seth and Cain, there was any distinction of civil societies, or diversity of regular governments at all. It is more likely, that all mankind formed one great nation, living in a kind of anarchy, divided into several disorderly associations; which was almost the natural consequence of their having but one common language, and must have greatly contributed to the general corruption, that could not otherwise have so universally overspread the Antediluvian world. For this reason chiefly, as soon as the posterity of Noah were sufficiently increased, a plurality of tongues was miraculously introduced, in order to divide them into distinct societies, that they might not be so easily debauched for the future. See CONFUSION OF TONGUES, and DISPERSION.

The Antediluvian world was, probably, stocked with a much greater number of inhabitants in proportion to the extent in which we may suppose it to be habitable than the earth, in its present state, is perhaps capable of containing or supplying. This increase of population seems naturally to follow from the great length of their lives, exceeding the present standard of life in the proportion of at least ten to one; the Antediluvians must, accordingly, in any long space of time, double themselves, at least, in about the 10th part of the time in which mankind do now double their number; for they began to procreate as early, and left off as late, in proportion, as men do now; and the several children of the same father seem to have succeeded as quickly one after another as they usually do at this day; and as many generations, which are but successive with us, were contemporary before the flood, the number of people living on the earth at once, would be sufficiently increased to answer any defect which might arise from other circumstances not considered. So that, if we make a computation on these principles, we shall find, that there was a considerable number of people in the world at the death of Abel, though their father Adam was not then 130 years old, and that the number of mankind before the deluge would easily amount to above 100,000 millions, even according to the Samaritan chronology; that is, to 20 times as many as our present earth has, in all probability, now upon it, or can well be supposed capable of maintaining in its present constitution. It is now generally owned, as the result of good observations, that mankind double themselves in about 360 or 370 years; or, allowance being made for all excepted cases, such as wars, famines, &c. in about 400 years. So that allowing the period for doubling mankind from the
creation.

creation to the deluge to be ten times shorter by reason of their so much longer lives; if we have a series of 40 numbers, beginning at two, for so many God created at first, and doubling themselves in 40, or for convenience, in 41 years, at a mean, or one age with another, till the deluge, we shall, in some degree, obtain the sum total of mankind at the deluge, and also in the several ages before that time; though this period of doubling must still have been much shorter in the earliest, and longer in the latest times of the interval; which computation Mr. Whiston, who has furnished these observations has given in the following table.

Number of mankind.	Years of the world.	Years of doubling.	Series.
4	2	2	1
8	6	4	2
16	12	6	3
32	20	8	4

Mr. Cockburn, in his Treatise on the Deluge, has made several objections to the principles upon which the above table is calculated, for which we must refer to the author's own account. This author has computed two tables, exhibiting the increase of mankind in the Antediluvian world; the first on the supposition of their doubling themselves in 50 years, and the other in 40 years, and both beginning at the year 500, when there could not be fewer than 100 married or marriageable persons descended from Adam and Eve.

Years of the World.	Number of Mankind.
500	200
550	400
600	800
650	1,600
700	3,200
750	6,400
800	12,800
850	25,600
900	51,200
950	102,400
1,000	204,800
1,050	409,600
1,100	819,200
1,150	1,638,400
1,200	3,276,800
1,250	6,553,600
1,300	13,107,200
1,350	26,214,400
1,400	52,428,800
1,450	104,857,600
1,500	209,715,200
1,550	419,430,400
1,600	838,860,800
1,650	1,677,721,600
1,700	3,335,443,200
1,750	6,710,886,500
1,800	13,421,772,800
1,850	26,843,545,600
1,900	53,687,091,200
1,950	107,374,182,400
2,000	214,748,364,800
2,050	429,496,729,600

This table is calculated at the long interval of 50 years, that it may appear that even by under-rating the number of mankind, there would be so many millions born into the world before the deluge came, that they would be obliged to spread themselves over the face of the earth, though but one half of the sum total of 429,496 millions had been alive at the time of the deluge; but as the interval here allowed may appear to be too long for the time of doubling, the second is calculated at the interval of 40 years, which comes nearer to the truth of the case, though even this may exceed the time of doubling.

Years of the World.	Number of Mankind.
500	200
540	400

1,260	104,857,600
1,300	209,715,200
1,340	419,430,400
1,380	838,860,800
1,420	1,677,721,600
1,460	3,355,443,200
1,500	6,710,886,400
1,540	13,421,772,800
1,580	26,843,545,600
1,620	53,687,091,200
1,660	107,374,182,400
1,700	214,748,364,800
1,740	429,496,729,600
1,780	858,993,459,200
1,820	1,717,986,918,400
1,860	3,435,973,836,800
1,900	6,871,947,673,600
1,940	13,743,895,347,200
1,980	27,487,790,694,400
2,020	54,975,581,388,800

The author, allowing for all obstructions and deficiencies in the course of nature, and for all casualties and accidents, reduces the former number to one-half, viz. to 27,487,790,694,400, that is, 27 billions, or millions of millions, four hundred and eighty-seven thousand, seven hundred and ninety millions, six hundred and ninety-four thousand, and four hundred. This he supposes to be the whole number of those who were born into the world before the deluge, or during an interval which he states at 2256 years. He then allows for those who died before the deluge, and on this account reduces the above number again to one-half, and states the whole number of mankind alive upon the earth at the time of the deluge to have been no more than 13,743,895,347,200, that is, 13 billions, or millions of millions, seven hundred and forty-three thousand eight hundred and ninety-five millions three hundred and forty-seven thousand and two hundred; a number far exceeding that of the present inhabitants of the whole earth. The first of the above tables is brought down no lower than to the year 2050, and the second to the year 2020, though there remain by the first 206, and by the second 236 years to the flood; the reason of which is, that in the last 200 years of the world, mankind would not increase in any measure equal to what they had done in the preceding years, though regularly the increase should have been much greater; because violence was then great in the earth, and thousands, yea millions, might have been cut off by untimely deaths; for which cause the destruction of the world was determined 120 years before the flood came.

For the longevity of the Antediluvians, and the probable causes of it, see LONGEVITY.

It has been a question much debated, whether or not flesh was permitted to be eaten before the deluge. By the permission given expressly to Noah for that purpose, after the flood, and God's assigning vegetables only for food to man, as well as beast, at the creation, one would imagine it was not lawful before; yet others have supposed, that it was included in the general grant of dominion given by God to Adam over the animal creation; and the distinction of beasts into clean and unclean, which was well known before the flood, is alleged as a strong argument on this side, and which it is not easy to answer. On the other hand it is urged, that if flesh were eaten before the flood, it does not appear that there was any occasion to renew this grant after it, which grant, specifying distinctly animal food, contradistinguished from vegetable, respected not Adam only, but all his posterity. It is farther urged, that the distinction

between clean and unclean, respected animals offered in sacrifice in the Antediluvian world; as appears from this circumstance, that upon the grant of animal food to him and his descendants, which was posterior in time to the sacrifice, there is not the least mention of any distinction between clean and unclean with respect to food, but the contrary. The distinction of clean and unclean with regard to food, was introduced by the law of Moses, and differed from that of sacrifices; as there were several creatures clean for food which were not to be offered in sacrifice. Others contend, that if it be alleged that this distinction was used proleptically, it is a mere subterfuge; and to suppose it made solely to distinguish what was lawful or unlawful to be sacrificed, and not what might or might not be eaten, is little better; it being the custom to offer to God such fruits and animals as were fit for food and sustenance, and not such as were of no use or benefit to mankind in this respect. Shuckford's Connection, &c. vol. i. book i. p. 1—57. Anc. Un. Hist. vol. i. p. 21—72.

ANTEJURAMENTUM, from *ante*, before, and *juramentum*, oath, or PRÆJURAMENTUM, by our ancestors also called *juramentum calumnie*, in *Law*, an oath which both the accuser and the accused were anciently obliged to make before any trial or purgation. The accuser was to swear that he would prosecute the criminal; and the accused was to make oath on the very day that he was to undergo the ordeal, &c. that he was innocent of the fact of which he was charged. If the accuser failed, the criminal was discharged; if the accused, he was understood to be guilty, and was not to be admitted to purge himself by the ordeal.

ANTEJUSTINIANEAN, an appellation sometimes given to the ancient Roman law, as it stood before the time of the emperor Justinian.

Tribonian has been often condemned for suppressing the writings of the Antejustinianean lawyers. Schulting, a celebrated professor at Leyden, has a dissertation on the equity of this censure. Fabricius gives a catalogue of the ancient Antejustinianean lawyers. Schulting has published a collection of the Antejustinianean writers.

ANTELIA, in *Ancient Geography*, a town of Asia, in Armenia.

ANTELIUS, or ANTHELIUS, in *Ancient Writers*, denotes an idol placed over the doors of houses, supposed to have the guardianship, or protection of them.

The word is originally ἀντιλιος, q. d. against the sun, as being exposed to it.

ANTELMI, JOSEPH, in *Biography*, a French writer of Ecclesiastical History, was a canon of Frejus, in Provence, in the 17th century. He published, in 1680, a Latin "Dissertation, Historical, Chronological, and Critical, on the church of Frejus." He also wrote a critical inquiry concerning the author of the creed, commonly called Athanasius's, with other tracts, abounding with curious research. He died, a victim to immoderate study, at the age of 49, in the year 1697. Nouv. Dict. Hist.

ANTELOPE, ANTILOPE, in *Zoology*, a genus of the *Mammalia Pecora*, in the Linnæan system by Gmelin; the characters of which are, that it has concave horns, turned upwards and round, annulated, i. e. furrowed with prominent rings, or spiral and permanent. The lower jaw has eight broad fore-teeth; the upper jaw none; and there are no tusks in either. To these characters Mr. Pennant adds, that the inside of the ears is marked lengthways with three feathered lines of hair, and that the limbs are of a light and elegant form. The antelope forms an intermediate genus between the deer and the goat; though arranged with the latter by Linnæus, in his former editions, and by several other naturalists: but Gmelin, in imitation of Pennant, Erxleben,

and Pallas, has referred them to a distinct genus. In the form of their bodies they agree with deer, and in the texture of their horns, which have a core in them, they resemble the goats; they have all gall-bladders, distinct lachrymal gutters, or pits under the eyes; a plait of the skin divided into several cells in the groins; brushes of hair on the knees, and beautiful black eyes. In general their flesh is excellent, as they feed on the tender shoots of trees, though some species have a rank hircine or musky flavour, which probably results from the qualities of the plants on which they feed. None of the numerous species of this genus are found in America; they are mostly confined to Asia and Africa, inhabiting the hottest regions of the Old World, or the temperate zones near the Tropics. None of them, except the chamois and saiga, are found in Europe. They chiefly inhabit hilly countries, though some reside in the plains; and some species form herds of two or three thousand, while others keep in small troops of five or six. These animals are elegantly formed, active, restless, timid, shy, and astonishingly swift, running with vast bounds, and springing or leaping with surprising elasticity; they frequently stop for a moment in the midst of their course to gaze at their pursuers, and then resume their flight. The chase of these animals is a favourite diversion among the eastern nations; and the accounts that are given of it supply ample proofs of the swiftness of the antelope tribe. The greyhound, the fleetest of dogs, is usually outrun by them; and the sportsman is obliged to have recourse to the aid of the falcon, which is trained to the work, for seizing on the animal, and impeding its motion, that the dogs may thus have an opportunity of overtaking it. In India and Persia, a sort of leopard is made use of in the chase; and this animal takes its prey not by swiftness of foot, but by its astonishing springs, which are similar to those of the antelope; and yet if the leopard should fail in its first attempt, the game escapes. The fleetness of this animal has been proverbial in the country which it inhabited from the earliest times: the speed of Afabel (2 Sam. ii. 18.) is beautifully compared to that of tzchi, which Shaw, in his Travels, translates antelope, and not roe, as it is in our text; and the Gadites were said to be as swift as the roes upon the mountains. We may add, that the disciple restored to life at Joppa was supposed to have been called Tabitha, i. e. Dorcas, or the Antelope, from the beauty of her eyes; and it is still a comparison in the east; so that *aine el ezazel*, or "You have eyes of an antelope," is used as the greatest compliment that can be paid to a fine woman. Authors enumerate 29 species. 1. *Antelope leucophaea*, blue antelope, with recurved, roundish, and annulated horns, and of a bluish colour. This is the blauer-bock of Kolben, boue-chamois of Journal Historique, and blue antelope of Pennant. It inhabits the country to the north of the Cape of Good Hope; is larger than the fallow deer or buck; its colour, when alive, is a fine blue, of a velvety appearance, but when dead changes to a bluish grey, with a mixture of white; beneath each eye is a large white mark, and the belly is white. This species, according to Pennant, from the form of the horns, which are sharp-pointed, taper, and arcuated, bending backwards, and marked with 20 prominent rings; and also from the length of the hair, seems to connect the goat and antelope kinds. 2. *A. Leravia*, lerwee, with wrinkled horns, bent backwards, distant in the middle, and approaching each other at the base and points, having a remarkable tuft of hair on the nape of the neck, and of a reddish colour. This is the antelope kob of Erxleben; the kob or little brown cow of Buffon; the fish-tall or lerwee of Shaw's Travels; and the Gambian antelope of Pennant. It inhabits Africa, chiefly about the rivers Gam-

bia and Senegal; it is about the size of the fallow-deer, and is remarkable for the tuft of hair on the nape of the neck, and for having long brushes of hair on the knees of the fore-legs. The horns are surrounded with eight or nine rings. 3. *A. Rupicapra*, chamois; see CHAMOIS. 4. *A. Dama*; see NANGUIR. 5. *A. Redunca*; see NAGOR. 6. *A. Tragocamelus*; see BIGGEL and TRAGOCAMELUS. 7. *A. Picta*; see NYLGHAU. 8. *A. Saiga*; see SAIGA. 9. *A. Gutturosa*; see TZEIRAN. 10. *A. Subgutturosa*, Persian antelope, with horns bent in form of a lyre; the upper parts of the body of a brownish ash colour, the under parts pure white, and a yellowish white stripe along each side. It inhabits Persia between the Caspian and Euxine seas. In size and habit it resembles the roe, lives in large flocks, and subsists chiefly on the artemisia pontica; the horns are above 13 inches long, and smooth at the points; the throat has at the fore-part a protuberance, and the knees are furnished with brushes. The female brings forth in May. The flesh is reckoned very good. 11. *A. Pygarga*, *A. dorcas* of Pallas; cervicapra of Houttuyn, Linn. ed. Belg.; and suggested, not without hesitation, by Gmelin to be the koba of Buffon, and mountain antelope of Russel's Aleppo; klip-springer or spring-buck of Sparrman; white-faced antelope of Pennant, with the horns bent like a lyre; the general colour a hoary-red, and a blood-red or bright bay neck, a deep red band along the sides, white buttocks, and a white face. This species is about five feet four inches long, and three feet high at the shoulders; inhabits the countries to the north of the Cape of Good Hope, runs swiftly, bounding from rock to rock, is caught with difficulty, and its flesh is much esteemed. The horns bend outwards in the middle, and approach at the points; those of the males have each six or seven rings on the lower part, and those of the females have no rings. 12. *A. Saltans*, springer antelope, with slender horns, twice contorted, and annulated half way, the general colour a pale brown, the chest, belly, insides of the limbs, buttocks, and half way up the back are white, and a broad chestnut coloured band along the sides. This animal, if it be different from the preceding species, with which it agrees in the form of the horns and disposition of the dark-coloured bands, inhabits the Cape of Good Hope. It is rather less than a roebuck; and migrates annually from the interior parts of the country, in small herds; continues near the Cape for two or three months, and then retreats towards the north in herds of many thousands. Herds of many hundred thousands periodically migrate, in seven or eight years, from the north, probably compelled to leave their haunts in the Terra de Natal by the excessive drought of that region, and spreading over the whole country of Caffraria, which they desolate, without leaving a blade of grass. In their migrations, they are attended by lions, hyænas, and other wild beasts, to which they afford prey. The Hottentots call them the lions' flocks of sheep. Their flesh is excellent; and with other antelopes, they furnish the venison of the Cape. From their prodigious bounds, they are denominated spring-bucks; and when alarmed, they have the power of expanding the white space about the tail into a circular form, which assumes again its linear shape when the animal is tranquil. Pennant. Masson in Phil. Trans. vol. lxvi. p. 310. 13. *A. Dorcas*; see DORCAS. 14. *A. Kevella*; see KEVEL. 15. *A. Corinna*; see CORINE. 16. *A. Bubalis*, the CERVINE Antelope of Pennant; which see. 17. *A. Koba*; see Koba. 18. *A. Gnu*; see GNU. 19. *A. Oryx*; see PASAN. 20. *A. Oreotragus*, African antelope, with very straight, tapering, and sharp-pointed horns, slightly wrinkled at the bases. It inhabits Africa; has a reddish head, the upper parts of the body greenish-yellow, and the under parts of a whitish ash-colour; the tail is very short.

short. 21. *A. Gazella*, capra bezoardica; or bezoar goat of Syst. Nat. ed. 12.; *Hircus bezoardicus* of Brisson, &c.; animal bezoardicum of Ray; animal ignotum of Gesner; gazella of Belon and Prosper Alpinus; algazel of Pennant and Buffon, with very long, wrinkled, slender, upright, tapering, and sharp pointed horns, which are slightly bent inwards at the ends. It inhabits India, Persia, Egypt, and Ethiopia; runs swiftly up hill, but slowly on plain ground; is gregarious, and is easily tamed; the general colour of the fur is red, with a white breast and belly: the real oriental bezoar, of a greenish and bluish colour, and when recent, of a very powerful aromatic odour, is frequently found in the fourth stomach of this species, chiefly in that of males and full grown animals, and more rarely in the stomachs of females or younger individuals. 22. *A. Leucoryx*; see LEUCORYX. 23. *A. Orcas*, Indian or elk antelope; see COUDOU. 24. *A. Scripta*, or harnessed antelope; see GUIB. 25. *A. Grimmia*, or Guinea, antelope; see GRIMM. 26. *A. Pygmaea*, or royal antelope; see GUEVEI. 27. *A. Sylvatica*, wood antelope, wood goat, or bosch-bock of Sparrman; with horns smooth, somewhat spirally twisted, annulated at the bases, and marked with several longitudinal ribs, the ends being taper and sharp pointed. It inhabits chiefly the woods near the Cape of Good Hope, and lives in pairs. It is about three feet high, the upper parts of the body are brown, the forehead white, two white spots on each cheek, a large white spot under the throat, and another at the bottom of the neck; the breast and hinder part of the belly are white, and there are several white spots on the thighs and flanks; the tail is very short, and a short mane runs along the neck and ridge of the back; the whole fur is longish and coarse. The female has no horns. 28. *A. Strepticeros*, or striped antelope; see CONDOMA. 29. *A. Cervicapra*, Indian, common, or brown antelope; see LIDMEE.

Professor Pallas, in his travels through different provinces of Russia and northern Asia, has described the method of hunting the antelope, which is the principal amusement of the Tonguses, who inhabit the heaths of Daouria beyond the lake Baikal. They choose for this purpose the level and open tracts, situated near a mountain, a river, or a forest. In autumn, at which season their horses are most vigorous, they form companies of 150 or 200 hunters, all on horseback, attended by led horses. Each has a trained dog; and they are armed with bows and arrows. This chase commonly lasts several days. When arrived at the rendezvous, they send before three or four sharp-sighted huntsmen to get a view of the game from the heights or mountains; who stop to wait for their companions as soon as they perceive the antelopes. When the troop comes in sight, the scouts make signals to them, or by some evolutions of their horses signify the place in which the antelopes feed, and the course that must be taken in order to come up with them. The troop then breaks into several divisions, and the hunters separate to the distance of 60 or 80 fathoms from each other, in order to form a great ring. Those on the wings advance towards the pasturage of the herd, and endeavour to conceal themselves behind the heights till the animals are surrounded: the ring then closes. When the antelopes, at the approach of the hunters, attempt to escape, the men rush on them, chase them from one party to another, terrifying them with their shouts and the whistling of their arrows, which, for that purpose, are furnished with a button of bone, perforated beneath the head. In this manner they kill all that they can reach. This chase is more successful when the scene of it lies near a river or a mountainous forest, as the antelopes or heath-goats never take to the water, though long and furiously harassed, but rather strive

to escape by sudden and vast leaps through the troops of their pursuers. They are almost equally shy of forests. They are no sooner hunted into a wood, than they are so bewildered among the trees as not to be able to move a hundred paces, but run their heads against every tree, and soon fall breathless. Pallas, Travels, tom. i. p. 402. tom. iii. p. 204.

ANTELUKAN, from *ante* and *lux*, *light*, in Ecclesiastical Writers, is applied to things done in the night, or before day. We find frequent mention of the antelucan assemblies, *caus antelucani*, of the ancient christians in times of persecution for religious worship.

ANTELUZIA, from *ante*, and *ludus*, *game*, in Antiquity, a day of show or parade preceding the circuses, wherein the preparations made for those solemnities were exposed in great form and pomp.

ANTEMETICA, in the *Materia Medica*, denote medicines suited to cure a preternatural vomiting.

ANTEMNA, in *Ancient Geography*, a town of Italy to the north or north-east of Rome. Although it was built in the territory of the Sabines, it was founded by a colony from Alba, and comprised in the division called Ancient Latium. According to Varro, its name, derived from *ante annem*, denoted its position, which Cluvier and M. d'Anville assign at the confluence of the Anio and Tiber. Its inhabitants were called *Antemnates*; and in the fourth year of Rome, they contended with the Romans, and were totally vanquished by them, and their city was destroyed. They afterwards became citizens of Rome.

ANTEMURALE, from *ante*, and *murus*, *wall*, in Middle Age Writers, denotes a kind of outer wall environing the other walls and works of a place, and preventing the too near access of the enemy to them.

This is also called by *Isidore*, *promurale*, as being *pro munitione muri*, for the defence of the wall.

In some writers we find it denominated *antepectoralis muris*, in other *anpis*.

ANTEMURALE is also used to denote any work without-side the rampart or wall of the place.

In this sense, antemurale amounts to the same with what we otherwise call *OUTWORK*.

ANTEMURALE, is also used, in Ecclesiastical Writers, for the vestibule or entrance of the *presbyterium*, or *BEMA*.

ANTENATUS, from *ante*, and *natus*, *born*, is used, in some *Law Writers*, for the first-born, or eldest son, answering to what we call *aîné*.

ANTENATUS, is also sometimes used for a son, the issue of a former marriage. In which sense, antenatus amounts to the same with *privignus*.

ANTENATI, in the modern *English History*, is chiefly understood of the subjects of Scotland, born before king James the First's accession to the English crown, and alive after it. In relation to these, those who were born after the accession were denominated *POSTNATI*. The antenati were considered as aliens in England, whereas the postnati claimed the privilege of natural subjects.

ANTENCLEMA, *αντικλημα*, in *Oratory*, is where the whole defence of the person accused turns on criminating the accuser. - Such is the defence of Orestes, or the oration for Milo, *Occisus est sed latro. Exsecutus sed raptor*. See *RECRIMINATION*.

ANTENICENE, in Ecclesiastical Writers, denotes a thing or person prior to the first council of Nice.

We say the antenicene faith, antenicene creeds, antenicene fathers.

ANTENNÆ, in *Entomology*, are those delicate moveable horns with which the anterior part of the heads of insects are invariably furnished. These are peculiar to this order of beings, and are easily distinguished from the tenta-

culc of vermes, in being crustaceous; and from the palpi of insects, by their situation being nearer the mouth, though not by their number, as naturalists formerly imagined, for they are not a six nor a ten, as is commonly thought, but are usually four in number, as Linnæus mentions; but in most lepidopterous insects, when accurately considered, only amount to two; and the same may be observed of the libellulæ, phalangæ, and several others; while, on the contrary, in the cancer, scyllarus, allacæ, ganumarus, and some other genera, the number of them is six. Fabricius. The antennæ in all insects, or at least with the exception of a few of the apterous kinds that have four, and some six, rarely exceed two. Both the antennæ and palpi are of the utmost consequence in the systematic arrangement of insects, as will be noticed hereafter.

For the want of a more appropriate term in the English language for the antennæ of insects, they are sometimes called the horns, and sometimes the feelers; the latter of which is by no means applicable, since it confounds them with the palpi, which are the true feelers. Of the purposes for which nature has designed the antennæ we are ignorant; some have conjectured, that they are the organs of smell or hearing; and others have supposed they are appropriated to a feeling more delicate than our own, and sensible to the least motion or disturbance in the ambient fluid in which they move. In form and size they vary extremely in different insects, and even generally in the two sexes of the same species, as is fully exemplified in the phalæna genus.

Andrew John Bladh, a pupil of Linnæus's and author of the paper in the seventh volume of Linnæus's *Amoenitates Academicæ*, called *Fundamenta Entomologiæ*, characterises the different structure of the antennæ of insects in the following manner.

SETACEÆ, *setaceous*, are those which gradually taper towards the point, and resemble a bristle.

FILIFORMES, *filiform*, such as are of an uniform thickness throughout, like a thread.

MONILIFORMES, *moniliform*, are filiform like the preceding, but consisting of a series of round knobs, like a necklace of beads.

CLAVATÆ, *clavated*, club shaped, or increasing gradually from the base to the extremity.

CAPITATÆ, *capitated*, club-shaped like the former, but the last articulation larger than the rest, and forming a kind of capital or head.

FISSILES are capitatæ, but have the capitulum divided horizontally into three or four laminæ or plates, as in the scarabæi, &c.

PERFOLIATÆ are likewise capitatæ, but have the capitulum divided horizontally, and connected by a kind of thread that passes through their centre.

PECTINATÆ, so called from their resemblance to a comb, though they more properly resemble a feather, having usually lateral appendages on both sides, as in phalæna, &c.

ARISTATÆ, such as have a lateral hair, which is either naked or furnished with lesser hair, as in some muscæ, &c.

The terms *breuioræ*, *longioræ*, and *mediocres*, are occasionally employed in speaking of the length of the antennæ, and of course imply whether they are shorter, longer, or of the same length as the body. See *ENTOMOLOGÏA*.

ANTENNATOR, a species of *ICHNEUMON* that inhabits Cayenne. It is pale yellow, crown, back of the thorax, tail, and tip of the wings black. Fabricius and Gmelin.

ANTENNELLA, a name given by some to phalæna lucella (*tinea*) of Gmelin. Vide Wien. Schmetterl. p. 135. n. 19.

ANTENNINA, in *Natural History*, a species of *SER-TULARIA*, having denticles verticillate, in fours, and fetaceous; vesicles obliquely truncated; stems rather simple. Linn. Gmelin. This is coralina allaci corniculorum æmula of Ray and Petiver. *Mulca marinus secundus* of Dodon. Pempt. &c. *Myriophyllum non ramosum* of Ginann. &c. Inhabits European coasts.

ANTENOR, in *Entomology*, a species of *PAPILIO* that inhabits India. Wings tailed; both surfaces black with white spots; and a marginal row of red lunated spots on the posterior pair. Fabricius. Gmelin. Donovan's Insects of India, &c.

ANTEOR, in *Ancient History*, a Trojan prince, of whom various fabulous narrations are recorded. He is supposed to have been a son of Laomedon, and younger brother of Priam. Homer represents him as one of the prudent counsellors who advised the restoration of Helen, and giving satisfaction to the Greeks. Some later writers have charged him with betraying Troy to the enemy. However that be, he was spared in the massacre: and Virgil in his *Æneid* has adopted a story concerning him, that, after the destruction of Troy, he led a colony of Veneti, a people of Paphlagonia, into Italy, near the mouth of the Po, where expelling the Euganei from their lands, he settled in them, and founded Padua. From this emigration the name of the Veneti is said to be derived. The pretended tomb of Antenor, discovered in the thirteenth century, is manifestly fictitious. His wife Theano, the daughter of Ciffæus, king of Thrace, was priestess of Minerva. Gen. Biog.

ANTENUPTIAL, something that precedes marriage.

In this sense we say, *antenuptial promises*, *antenuptial presents*, *antenuptial covenants*, *antenuptial fornication*, &c. Neolladius has a treatise, *De Pactis Antenuptialibus*.

ANTEPAGMENTA, or **ANTIPAGMENTA**, in the *Ancient Architecture*, the jambs of a door, or lintels of a window. The word is used for the entire *chambranle*, i. e. the door-case or window-frame.

ANTEPENULTIMA, or **ANTEPENULTIMATE**, in *Grammar*, the third syllable of a word, reckoning from the latter end; or the last syllable except two.

The word is compounded of the preposition *ante*, *before*, and *penultima*, *last but one*, or *pen ultimam*.

It was upon this syllable that the Greeks placed their acute accents, and also on the last and last but one; but they never placed the accent before the antepenultima. See *ACCENT*. The *Antepenultima* of a dactyle is always long.

ANTEPILANI, among the *Ancient Romans*, denote the hastati or principes of a legion.

They are supposed to be thus called because ranged before the triarii, who were also called pilani.

Some will have the word to be a corruption for *ante-fignani*.

ANTEPILEPTICS, in *Medicine*, denote a quality in remedies, whereby they prevent, diminish, or cure epileptic fits.

The practice of classing the articles of the materia medica according to the diseases or parts of the body they are supposed to cure, is unscientific, and now disused.

There are many medicines which diminish irritation in the nervous system; such as opium, castor, musk, valerian, spiritus ætheris vitæ comp. &c. which for the sake of abridging medical language, we call **ANTISPASMODICS**, all which are antiepileptics. Many absurd articles, calculated to excite disgust and horror, may be found in old authors, as specifics in this very common and formidable disease: the human skull, secundines, and blood; lizards, frogs, and the dung of various animals, rank high in these writers: at present, the

the metallic salts, the calces of metals, and some of the vegetable poisons, together with a suitable regimen, are principally relied on. See EPILEPSY.

ANTEPOSITION, from *ante*, and *pono*, I place, a grammatical figure, whereby a word which, by the ordinary rules of syntax, ought to follow another, comes before it. As when, in Latin, the adjective is put before the substantive, the verb before the nominative case, &c.

Anteposition stands opposed to postposition. One case or species of this figure is called by a particular name, *antastrophe*.

ANTEPREDICAMENTS, **ANTEPRÆDICAMENTA**, in *Logic*, certain previous matters, requisite to a more easy and clear apprehension of the doctrine of **PREDICAMENTS** or **CATEGORIES**.

Such are definitions of common terms; as equivocal, univocal, &c. See **DEFINITION**, **DIVISION**, &c.

They are thus called, because treated by Aristotle, before the predicaments: that the thread of the discourse might not afterwards be interrupted.

ANTEQUERA, in *Geography*, a well built town of Spain in the kingdom of Grenada, divided into two parts, the *higher* and the *lower*. The former is situated upon a hill much above the rest, has a fortified castle, and is occupied by the nobility; and the latter is in a fertile plain, watered by a number of streams. It has a collegiate church, four parishes, fourteen convents of monks, and eight of nuns, and about 13,000 inhabitants. The mountain on which part of the town is situated, yields a quantity of salt; and at a small distance is a fountain of water, which is said to cure the gravel. In the neighbourhood are also excellent quarries of stone for building. It is 26 miles north-north-west from Malaga, and 54 west from Grenada. N. lat. 37° 6'. W. long. 4° 40'.

ANTEQUERA is also a town of New Spain in America, in the province of Guaxaqua, 30 leagues south-east from Guaxaqua.

ANTERIDES, in the *Ancient Architecture*, denote buttresses erected to support a wall.

These are sometimes called *antes*, sometimes *crisma*, and by the Greeks *επιστοιχια*.

Anterides answer to what the modern builders call counterforts and archbutants; the Italians *barbican*, and *speroni* or spurs.

ANTERIOR, or **ANTERIOUR**, formed of the preposition, *ante*, before; something before another, chiefly in respect to place. In which sense the term amounts to the same with *prior*, and stands opposed to *posterior*.

ANTERIOR Ramus. See the article **RAMUS**.

ANTIERNACHA, **ANDERNACH**, in *Ancient Geography*, a town of Gaul, belonging to the *Rupeni*, and situate at the confluence of the *Moselle* and *Rhine*. See **ANDERNACH**.

ANTEROS, in *Mythology, the son of *Venus* and *Mars*, one of the two *Cupids* who were the chief of the number. They are placed at the foot of the *Venus* of *Medici*. This is represented with a heavy fullen look, agreeably to the poetical description of him, as the cause of love's ceasing. The other was called *Eros*. Ovid. Rem. Amor. V. verse 549 to 576.*

ANTEROTES, a name given by some of the ancient writers on gems to a species of the *amethyst*. Some have imagined they meant by it a sort of *opal*; but *Pliny* expressly contradicts this, making the *anterotes* the fifth kind of **AMETHYST** in value. *Plinii Hist. Nat. lib. xxxviii, ch. 40.*

ANTES, in *Architecture*. See **ΑΝΤΑ**.

ANTESIGNANI in the Roman armies, a kind of soldiery posted before the eagles, and other ensigns of the legions, whence their appellation.

The *antesignani* stand contradistinguished from the *subsignani*, who were ranged in the same line with the ensign; and from the *postsignani*, who were placed behind them. *Cæsar* and *Livy* mention the *antesignani* as the first line, or first body, of heavy armed troops. The *velites*, who used to skirmish before the army, were also called *antesignani*.

ANTESIGNANI was a denomination given to those inferior officers, called *campi doctores*, who instructed the troops in their exercise.

ANTESIGNANUS, **PLTER**, in *Biography*, an industrious grammarian, was born at *Rabasteins* in *Languedoc*, and flourished in the sixteenth century. He published a Greek grammar, which passed through several editions, and a treatise on universal grammar; but his most esteemed publications were his editions of *Terence's* comedies, in which he took pains to facilitate the learning of the Latin language. The epistle to this work was dated at *Lyons* in 1556. His industry also appears in his "Thematis Verborum investigandi Ratio," and his "Praxis Præceptorum Linguae Græcæ," annexed to several Greek grammars. "Let others," says he, "affect the reputation of learning: I honestly and truly own, that I have to the utmost of my power devoted my labours to the useful purpose of forming and assisting the studies of boys." Gen. Dict.

ANTESINISTRA, a name given by the augurs to those thunderbolts, or birds, which proceeded from the south and passed to the east, and which were thought to afford unfavourable presages. *Virgil* calls by this name a crow, *Eclog. ix. 15*, according to *Servius*:

"Antesinitra cava monuisset ab ilice cornix."

ANTESTARI, in *Roman Antiquity, denoted to bear witness against any one who refused to make his appearance in the Roman courts of judicature, on the day appointed, and according to the tenor of his bail. The plaintiff finding the defendant after this breach of his engagement, was allowed to carry him into court by force, having first asked any of the persons present to bear witness. The person asked to bear witness in this case expressed his consent by turning his right ear, which was instantly taken hold of by the plaintiff, and this was to answer the purpose of a *subpœna*. The ear was turned upon this occasion, says *Pliny*, as being the seat of memory; and therefore the ceremony was a sort of admonition to the party to remember his engagement.*

ANTESTATURE, in *Fortification*, a small retrenchment, made of *palisadoes*, or sacks of earth set up in haste, to dispute with the enemy the remainder of a piece of ground part whereof had been already gained.

ANTEVERTA, or **ANTEVORTA**, and **POSTVERTA**, or **POSTVORTA**, in *Mythology, deities worshipped among the Romans: the first, called also *Prorsa*, or *Porrina*, was supposed to know past events, and was invoked to repair injuries that had already occurred; and the second, being acquainted with futurity, was supplicated to prevent evils that might happen.*

ANTEVIRGILIAN HUSBANDRY. See **ANTIVIRGILIAN**.

ANTHALIUM, among the *Ancients*, a root growing in dry places, and about the bigness of the fruit of the medlar; it was dug up for food, and esteemed very pleasant and wholesome.

ANTHANA,

ANTHIANA, or ANTHENA, in *Ancient Geography*, was a city of Peloponnesus, and one of the 100 towns of Laconia, according to Stephanus Byz. It is said to have derived its name from Anthe, the son of Neptune, who was killed by Cleonenes, the brother of Leonidas.

ANTHEDON, a town of Bœotia, placed by Pausanias, and after him by M. d'Anville, a little to the north of Mount Messapius, and owing its name to its elevated situation. In the midst of this city was a temple of the Cabiri, and near it the sacred wood of Ceres, and the temple of Proserpine, with her statue in white marble; it had also a temple and statue of Bacchus. The poet Anthes, who composed hymns, was, according to Plutarch, a native of this city. Imperial Greek medals were struck here in honour of Caracalla.

ANTHEDON, or AGRIPPIAS, a town of Palestine, in the country of the Philidines, upon the borders of the sea, to the south-west of Gaza. Herod gave it the second name in honour of Agrippa, his friend, and the favourite of Augustus.

ANTHELIA, a town of Messenia, which Homer mentions, and which had been promised to Achilles by Agamemnon. In Strabo's time it bore the name of Thuria.

ANTHELA, a town or burgh of Greece, near the straits of Thermopylæ. According to Herodotus (lib. vii. 176), it was near the river Phœnix, and watered by the Aſopus.

ANTHELION, from *αντι* and *ηλιος*, *sun*, in *Physics*, signifies a mock or spurious sun; and denotes a meteor, not very common, of a luminous appearance, somewhat resembling the sun, seen through clouds, bigger, sometimes four or five times, than the solar disk. In its most refulgent state, it is as yellow as the sun: but the lucid tract surrounding it is of a paler yellow or whitish cast, interspersed sometimes with a few reddish or subfuscous spots. The most received opinion relative to the formation of this kind of meteor attributes the phenomenon to a multitude of minute icy or snowy particles suspended in the air, and either refracting or reflecting the solar rays in such a manner, as to multiply the image of the sun. But the theory of antelia, for want of a proper number of observations, seems not yet to be brought to such a degree of satisfaction, as by every lover of physiology could be desired. The instances of them are but rare. See *Phil. Trans.* vol. liii. Part. i. N^o 16. An. 1761. See HALO and PARHELION.

ANTHELIX, in *Anatomy*, the inner circle of the auricle: thus called from its opposition to the outer circuit, called the HELIX.

ANTHELMIA, Indian PINK.

ANTHELMINTICS, in the *Materia Medica*, medicines good to destroy worms.

The word is compounded of *αντι*, *contra*, against, and *ελμινθες*, a worm.

There are two principal kinds of worms which infest the human stomach and bowels; the flat or tape worm; and worms of various sizes, which are round, somewhat like earth-worms. The former is called TÆNIA, the latter ASCARIS, lumbricus, &c. See *Memoirs of Med. Soc. Lond.* vol. v.

The presence of worms in the primæ viæ generally arises from weak digestion; and therefore the cure of DYSPEPSIA will generally destroy the worms. Particular kinds of worms, however, require particular anthelmintics, which will be found under those heads. See ASCARIDES, &c.

Two or three grains of calomel, with one of salt of steel, taken in treacle, for two or three mornings, and then a brisk purge of rhubarb and jalap, ten or fifteen grains of each, is the best general vermifuge.

ANTHEM, from *αντι*, and *υμνος*, a hymn. In our church service, any psalm or portion of scripture, set in florid counterpoint, different from chanting in our cathedrals, and from metrical psalmody in our parish-churches, is called an anthem, whether for one, two, three, or more voices. Anthems, in our choral service, are distinguished by the epithets solo, verse, or full anthems. *Solo anthems* have frequently symphonics or ritornels for particular stops on the organ. In *verse-anthems*, there are solo parts for voices of different registers or compass, and different sides of the choir. A *full anthem* is in constant chorus, except at the leading off a fugue, or new point of imitation. *Anthems* for a single voice, in the Romish church, are called *motets*. At the latter end of the 17th century and beginning of the last, the *motetti* of Bassani, the master of Corelli, were in great favour in England, as well as Italy. In ecclesiastical history, anthems are styled *Αντιφωνοι υμνοι*, from *αντι*, *contra*, and *φωνη*, *vox*, *sonus*. Antiphonal singing implies singing from side to side, alternately, as the psalms are chanted in our cathedrals. St. Ignatius, a disciple of the apostles, according to Socrates the ecclesiastical historian, was the author of this kind of singing in the Greek church, and St. Ambrose introduced it into the Roman.

There is in the Brit. Mus. an admirable collection of solo, verse, and full anthems, and services, compiled by Dr. Tudway, of Cambridge, for the Earl of Oxford, in six huge vols. fol. (N^o 7337). Dr. Green began to collect our best cathedral music from the time of the reformation, to the middle of the last century; but he dying before any great progress was made in the work, it was carried on with great judgment and spirit by his worthy scholar and successor, Dr. Boyce, and engraved and published, in a correct and splendid manner, in three vols. large fol. 1760, 1768, and 1773. This useful publication has been resumed and carried on since the decease of Dr. Boyce, by Drs. Arnold and Dupuis.

The solo anthems of Purcell, Drs. Crofts, and Green, are elegantly printed, and in constant use in our cathedrals. It is hoped that the solemn and dignified style of the fathers of our church music, Tallis, Bird, and Gibbon, will long be regarded as a model for our services and full anthems, as that of Palestrina continues to be, for the best composers, a *capella*, in Italy.

Anthems were first introduced into the reformed service of the English church in the beginning of the reign of queen Elizabeth.

ANTHEMIS, in *Botany*, supposed from *ανθηω*, *florere*, having an abundance of flowers, a genus of plants of the chamomile kind. Lin. G. 970. Jussieu 185. Linnæan class and order, *syngenesia polygamia superflua*; natural order, *compositæ discoideæ*, and of the *corymbifera* of Jussieu. Its general characters are, that it has a *calyx* common, hemispherical, consisting of numerous linear subequal scales; *corolla* compound radiate; florets in the disk hermaphrodite and tubular, those in the radius female, and more than five; the former are funnel-shaped, five-toothed, erect, the latter ligulate, lanceolate, and sometimes three-toothed. In the hermaphrodite florets the *filaments* are five, capillary, very short, supporting cylindrical tubular *antheræ*. *Germen* oblong, *style* filiform, *stigmata* two, reflex; *seeds* solitary, receptacles chaffy, convex.

Nineteen species of this genus are described, of which five are natives of Britain. 1. *A. cota*, which bears a very large flower, and the *palea* or chaff between the florets is rigid and prickly: it is a native of Spain, growing in ploughed fields; annual. 2. *A. altissima*, grows three feet in height; leaves pinnatifid, compound, with pointed teeth: it grows wild

in the south of Europe; annual. 3. *A. maritima*, with stems prostrate, branches smooth; leaves pinnate, fleshy, cut into small teeth; calyx and peduncles pubescent; a native of the south of France, and also of Britain. 4. *A. tomentosa*, with stems a foot high, one flowered, leaves tomentose; the two outer divisions of the corolla larger than the others: a native of the south of Europe. 5. *A. mixta*, with leaves simple, jagged, toothed: a native of France and Italy; annual. 6. *A. alpina*, with leaves tooth-pinnated, entire, linear; stem villose, one-flowered; florets of the radius striated, three-toothed. See Jacq. Fl. Aust. vol. v. t. 30: a native of Italy; perennial. 7. *A. chia*, with leaves pinnatifid, jagged, peduncles naked, subvillose: a native of the Levant. 8. *A. nobilis*, with root perennial, stems trailing, hairy; leaves bipinnate, pinnulae two or three-cleft, pointed, hairy; flowers solitary; calyx hairy, with broad, shining, membranaceous edges; florets of the circumference somewhat elliptical, entire, or with two or three teeth, those of the centre yellow: this is the common chamomile; it grows wild in many parts of England, and flowers in July and August. See Woodv. Med. Bot. t. 108. 9. *A. arvensis*, with stems erect, much branched; leaves bipinnatifid, hairy; peduncles tomentose, terminal, one-flowered; disk yellow; florets of the radius white, three-toothed; receptacle conical: it is a common annual weed among corn, and therefore called corn-chamomile; it flowers in June and July. See Eng. Bot. 602. 10. *A. austriaca*, with stems upright, branched, scarcely a foot high; leaves bipinnate: flowers solitary, disk yellow, radius white; seeds naked: a native of Austria. 11. *A. cotula*, with stems much branched, smooth; leaves bipinnatifid, smooth, of a light green colour; disk of the flower convex, yellow: radial florets white: this, from its ungrateful smell, is called stinking chamomile, or May-weed; it is very common, and flowers in June and July, annual. Curt. Fl. Lond. fasc. v. t. 61. 12. *A. pyrethrum*, with stem simple, trailing, scarcely a foot high, one-flowered; leaves bipinnate, segments linear, pointed: florets at the centre yellow, those of the circumference white, and purple on the under side: it is perennial, and flowers in June and July; it is called Spanish chamomile, or pellitory of Spain. 13. *A. valentina*, with stem branched, leaves pubescent, tripinnate, bristle-shaped; calyx villose: a native of Spain. Miller, fig. 73. 14. *A. repanda*, with leaves simple, alternate, obtuse; flowers terminal, globose: a native of Spain and Portugal. 15. *A. trinervis*, with stem erect, simple; leaves smooth, coloured; peduncles terminal, one-flowered: a native of South America. 16. *A. americana*, with leaves triternate, peduncles terminal, longer than the branch: a native of America. 17. *A. tinctoria*, with stem erect, angular, about a foot and a half high; leaves bipinnatifid, smooth, lacinate pointed; flowers of a bright golden colour; ox-eye chamomile: it is a native of Sweden and Germany, and also of Britain, flowering in July and August. See Flor. Dan. t. 741. 18. *A. arabica*, with stem upright, proliferous, round, purplish; leaves singly and doubly pinnatifid; one flower terminates the stem; it is large, and of a beautiful golden colour. See Smith, Spicil. 20. This handsome annual plant is a native of Arabia. 19. *A. odorata*, with leaves pinnatifid at the tip, calyx membranaceous: a native of the Cape of Good Hope, where it was discovered by Mr. Masson in 1774.

Medicinal Properties. The common chamomile, species 8, and the pellitory of Spain, species 12, are both articles of the materia medica, in the London and Edinburgh pharmacopœias. Both the leaves and flowers of the former have a strong, though not ungrateful smell, and a very bitter nauseous taste; but the latter are preferred, being bitterer, and considerably more aromatic. The flowers readily give out

their virtues to water, and also to rectified spirit. They possess the stomachic and tonic qualities usually ascribed to simple bitters, having very little astringency, but a strong, aromatic, penetrating odour, from which they are also judged to be carminative, emmenagogue, antispasmodic, and anodyne. They have been successfully employed for the cure of intermittents, as well as of fevers of the irregular nervous kind, accompanied with visceral obstructions, for which we have the authority of sir John Pringle. That chamomile flowers have been effectually substituted for Peruvian bark, we have the testimony of several respectable physicians, among whom we may notice Dr. Cullen, who recommends them to be given, conjoined with an astringent, to prevent their tendency to produce diarrhœa. A watry infusion of these flowers is frequently used for the purpose of exciting vomiting, or for promoting the operation of emetics. Externally they are directed in the *decoctum pro fomento*; they are also ordered in the *decoctum pro enema*. Murray, ap. Med. vol. i. p. 130. Woodville, Med. Bot. vol. ii. p. 103.

From the aromatic and stimulating qualities of the root of the pellitory of Spain, there can be no doubt that it might be found an efficacious remedy, and equally valuable as an internal medicine with many others of this class now constantly prescribed. Its use, however, has been long confined to that of a masticatory, for on being chewed or long retained in the mouth, it excites a glowing heat, stimulates the excretories of the saliva, and thereby produces a discharge which has been found to relieve tooth-achs and rheumatic affections of the face; in this way too, it is recommended in lethargic complaints, and paralytic of the tongue. Woodv. Med. Bot. vol. ii. p. 287.

ANTHEMIS, or ANTHEMUSA, in *Ancient Geography*, one of the names of the isle of Samos, according to Pliny.

ANTHEMIUS, in *Biography*, and *History*, emperor of the west, was a native of Constantinople, and descended from an ancient, illustrious, and wealthy family. His name was derived from his grandfather by the mother's side, Anthemius, prefect of the east, and the excellent prime minister of Theodosius the younger. Having married Marciana, the only daughter of the emperor Marcian, he was successively advanced to the chief dignities, and had some claim to the empire itself. He was consul A. D. 455, and afterwards patrician and general, in which office he gained a victory over the Huns on the banks of the Danube. Being nominated by the emperor Leo I. to terminate the interregnum in the west, Anthemius left Constantinople with a splendid retinue, and entered Rome with universal acclamations, where he was inaugurated A. D. 467. Soon after this event, he married his daughter to Ricimer, the powerful commander of the barbarians. His government was too feeble to protect Gaul from the inroads of the Visigoths, who defeated a body of British troops sent for by Anthemius to protect his subjects, unused to military operations. In the discord that arose between the emperor and Ricimer, the latter fixed his residence at Milan, and exercised an independent sovereignty over that part of Italy; and marching with an army of Burgundians and Suevi, brought with him Olybrius, whom he destined for the empire. Anthemius, faithfully supported by the senate and citizens of Rome, resisted a siege of three months; but at length Ricimer took the capital by storm, and discovering Anthemius in his place of concealment, caused him to be massacred. Anc. Un. Hist. vol. xiv. p. 429—433. Gibbon's Hist. vol. vi. 193, 194. 217, 218.

ANTHEMIUS, a celebrated architect in the time of Justinian, was a native of Tralles in Asia Minor, and employed by him in the construction of various edifices, and particularly

particularly the church of St. Sophia in Constantinople, when on this occasion formed the design, and directed the operations of 10,000 workmen, whose payment in pieces of five silver was never delayed beyond the evening. Anthemius was also a sculptor, a mathematician, and an experimental philosopher. He is said to have so well imitated an earthquake, as to frighten out of his house one Zeno, a rhetorician, who had offended him. At another time the friends of Zeno, as they sat at table, were dazzled by the incredible light which flashed in their eyes from the reflecting mirrors of Anthemius. Theophrastus describes the artifice of these burning glasses, which he had read in a mathematical treatise of Anthemius, intitled, "Περὶ παραδόξων μηχανημάτων," Of Wonderful Machines; which treatise has been published, translated, and illustrated by M. Dupuys, a scholar and a mathematician. Mem. de l'Acad. des Inscriptions, tom. xvii. p. 371—451. Gibbon's Hist. vol. vii. p. 113.

ANTHEMUSIA, in *Ancient Geography*, a town of Asia, in Mesopotamia, mentioned by Pliny, Strabo, and Tacitus; situate to the south-east of Samosata, and nearly east from Zeugma, and separated by a chain of mountains from Edessa to the north-east. An imperial Greek medal of this city was struck in honour of Caracalla.

ANTHENA, a town of the Argolide, in Cynuria.

ANTHERÆ, in *Botany*, a term used by some authors for the yellow or ruddy globules in the middle of certain flowers, as of lilies, saffron, &c.

Some confine the antheræ to the yellowish globules in the middle of rosetts. These are held more assurgent than the rest of the plant.

Others apply the name antheræ to those little tufts or knobs which grow on the tops of the stamina of all other flowers; more usually called APICES.

The antheria or apex of the stamen, in the Linnæan system, is a principal part of the male organ of generation in plants, and contains within it a fine powder, called *pollen*, or *farina seminans*, declined for the impregnation of the *germen*, and which, when come to maturity, it discharges.

ANTHERICUM, said to be derived from ἄθος *anthos*, i. e. *flower of the hedges*. Lin. G. Pl. n. 422. Gertn. 16. Phalangium, Jussieu, 52. Class, *hexandria monogynia*; natural order of *coronarie* and of *asphodeli* of Jussieu. Its generic characters are as follows: *Calyx* none; *corolla*, petals six, oblong, obtuse, spreading; *stamina*, filaments subulate, erect; *antheræ* small, incumbent, four-furrowed; *pistillum*, germen obscurely triangular; *style* simple, of the length of the stamina; *stigma* obtuse, triangular; *capsule* ovate, smooth, three-furrowed, three-celled, three valved; *seeds* numerous, angular. There are more than thirty species of this genus, many of which are very difficult to ascertain. The only species which is a native of Britain is the *A. serotinum*, the *A. ossifragum* and *calyculatum*, being by Dr. Smith now referred to other genera. 1. *A. floribundum*, with leaves flat, smooth, linear-lanceolate, acute; scape simple, raceme many-flowered, cylindric, compact; petals spreading; stamina smooth: a native of the Cape of Good Hope, from whence it was sent by Mr. F. Masson, and introduced into the Royal Garden at Kew, in 1774; it flowers in March and April. 2. *A. serotinum*, with root perennial, consisting of oblong curved bulbs; stem or scape erect, smooth, round, commonly one-flowered; radical leaves exceeding in height that of the stem, semicylindrical, nerved, narrow from the base, those of the stem alternate, short; petals elliptical, equal, nerved, white on the inside, externally reddish; stamina smooth; it grows on high mountains among rocks in several parts of Europe: in Britain it has only been found

in Wales. Jac. Flor. Austr. 5. t. 38. It flowers in June. 3. *A. gracicum*, with leaves flat, scape simple, flowers corymbed, filaments woolly; a native of the Levant. 4. *A. planifolium*, with leaves flat, scape and filaments woolly: it is a native of Portugal, flowering in April. 5. *A. revolutum*, curled flowered anthericum, with leaves flat, scape branched, corolla revolute: it is a native of the Cape of Good Hope; and was first cultivated here by Mr. Miller, in 1731. 6. *A. ramosum*, branching anthericum, with leaves linear subulate, flat; scape branched, peduncles solitary, corolla flat, pistils straight: it is a native of Sweden, Swisserland, Austria, the south of France, &c. and was first cultivated in England by Gerard, about the year 1597. 7. *A. elatum*, tall anthericum, with leaves flat, scape branched; flowers scattered, white: it is a native of the Cape of Good Hope, flowering in August and September. 8. *A. triflorum*, three-flowered anthericum, with leaves channelled, sword-shaped, scape simple, bractæa remote, three-flowered: it is a native of the Cape of Good Hope, and introduced into the King's Garden at Kew, in 1782, by George Winch, Esq. 9. *A. canaliculatum*, channelled anthericum, with leaves rather fleshy, hairy, sword-shaped-triquetrous, channelled; scape simple: this is also a native of the Cape: it flowers in April. 10. *A. albucoides*, striped flowered anthericum, with leaves linear, channelled, smooth, with a cartilaginous edge; scape simple: a native of the Cape, flowering in August; it was discovered by Mr. F. Masson, in 1788. 11. *A. hiliago*, grass leaved anthericum, with leaves flat; scape perfectly simple; corolla flat; pistillum bending down. Jac. Hort. i. t. 83. Fl. Dan. t. 616: it is a native of Germany, France, and Denmark; cultivated here, in 1597, by Gerard. 12. *A. liliastrum*, Savoy anthericum, with leaves flat; scape perfectly simple; corolla bell-shaped, white; stamina bending down: the French call this species St. Bruno's lily; it grows wild on the mountains of Swisserland and Savoy. 13. *A. spirale*, without leaves; scape four inches high, filiform, spiral, bearing three or four flowers; a native of the Cape. 14. *A. frutescens*, shrubby anthericum, with leaves fleshy, columnar; stem shrubby: a native of the Cape; first cultivated in Chelsea garden, in 1702. 15. *A. alooides*, aloe-leaved anthericum, with leaves fleshy, subulate, flattish: a native of the Cape; cultivated by Dr. Sherrard, in 1732. 16. *A. asphodeloides*, glaucous-leaved anthericum, with leaves fleshy, subulate, semi-columnar, upright, stiff; flowers yellow: a native of the Cape; cultivated by Mr. Miller, in 1759. 17. *A. annuum*, annual anthericum, with leaves fleshy, subulate, columnar; scape subracemed; flowers yellow: a native of the Cape; cultivated by Mr. Miller, in 1748. 18. *A. hispidum*, hairy-leaved anthericum, with leaves fleshy, compressed, rough; flowers white: a native of the Cape, and sent to the King's Garden at Kew, by Mr. F. Masson, in 1774. The preceding five species have all fleshy leaves, but those that follow are sword-shaped. 19. *A. calyculatum*, see TORFIELDIA. 20. *A. ossifragum*. See NARTHECIUM. 21. *A. japonicum*, with leaves sword-shaped, convolute, smooth; scape branched, angular; flowers racemed, reddish: a native of Japan, China, and Java. 22. *A. filiforme*, thread-leaved anthericum, with leaves filiform, rather cylindric, rough; filaments smooth: it is perennial, flowering in April: a native of the Cape, and introduced here by Mr. F. Masson, in 1774. 23. *A. flexifolium*. 24. *A. muricatum*. 25. *A. latifolium*. 26. *A. cauda-feis*. 27. *A. triquetrum*. 28. *A. ciliatum*. 29. *A. falcatum*. 30. *A. contortum*. 31. *A. scabrum*. 32. *A. squameum*. The above ten species are all Cape plants, and mentioned in the Supplementum Plantarum, but unknown in this country. They were all but the last discovered by Thunberg. 33. *A. cirratum*, with leaves lanceolate, flattish; scape panicled: a native of New Zealand.

34. *A. adenanthera*, with leaves linear, ensiform, connate at the base; a gland between the filament and anther: a native of New Caledonia.

Propagation and Culture. All the species except the seventeenth are perennial, and are usually propagated by offsets taken during the summer or autumn. Those plants which do not throw out suckers freely, may be propagated by seeds, sown in the spring or autumn, in a warm situation, on a bed of light sandy earth. When the leaves decay, the roots should be broken up and transplanted. If the winter prove severe, they should be defended from the cold by covering the bed with straw, or what is better, old tan, from a hot bed. Thus treated, they will be strong enough to flower in one year, and in autumn may be taken up, and planted in the borders of the flower-garden, where they will live several years, if the roots be well defended from the frost. Some of the species, as the 7th, must be housed in winter, or placed under a hot-bed frame, which is to be preferred to a common green-house. See Martyn's Miller's Dict.

ANTHERINUS, in *Entomology*, a species of *CRYPTOCERPHALUS*, in Gmelin's arrangement. It is black, with two ferruginous bands. This is *tenebrio pedicularis* of the tenth edition of the Linnæan *Systēma Naturæ*, and *meloe antherinus* of the twelfth edition of the same work, and the *Fauna Suecica*. Fabricius places it in his genus *Iagria*, in the *Species Insectorum*: this insect is very small, lives on flowers, and runs fast.

ANTHESPHORIA, in *Antiquity*, a feast celebrated in Sicily, in honour of Proserpine. The word is derived from *ανθος*, *flower*, and *φερω*, *I carry*, in relation to Pluto's having forced away that goddess when she was gathering flowers in the fields. Yet Festus does not ascribe the feast to Proserpine; but says it was thus called, because ears of corn were carried on this day to the temples. Anthesphoria seems to be the same thing with the *floriferum* of the Latins, and answers to the *harvest-home* among us.

Anthesphoria were also celebrated in the temple at Argos, in honour of Juno Antheias; according to Pausanias, in the *Corinthiaca*.

ANTHESTERIA, was a feast celebrated by the Athenians in honour of Bacchus.

The most natural derivation of the word is from *ανθος*, *flor*, a *flower*; it being the custom at this feast to offer garlands of flowers to Bacchus.

Some are of opinion it took its name from the month *Anthesterion*, in which it was celebrated. Others pretend, that this was not the name of any particular feast, but that all the feasts of Bacchus were called *anthesperia*.

The *anthesperia* lasted three days, the eleventh, twelfth, and thirteenth days of the month; each of which days had a name suited to the proper office of the day, and during which the masters served their slaves at table. The first day of the feast was called *ανθισια*, i. e. opening the vessels, because on this day they tapped the vessels, and tasted the wine. The second day they called *χοος*, *congii*, the name of a measure, containing the weight of a out ten pounds: on this day they drank the wine prepared the day before. The third day they call *κηφοι*, *kettles*: on this day they boiled all sorts of pulse in kettles; which, however, they were not allowed to taste, as being all to be offered to Mercury.

ANTHESTERION, in *Ancient Chronology*, the sixth month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our November and beginning of December. Neapolis, a commentator on the *Fasts* of Ovid, says, that it answered to the end of February and beginning of March. The Macedonians called it *Defion*

or *Defion*. In this month the Athenians and other people of Greece celebrated feasts in honour of the dead.

It had its name from the festival *ANTHESTERIA* kept in it.

ANTHIAS, in *Ichthyology*, a species of *LABRUS*, very concisely described by Gmelin, after Artedi, as being entirely reddish, "totus rubescens." This is *Anthea* of Rondel, and according to Catesby, found in Carolina; it is also said to inhabit the south of Europe, and to have the gill covers serrated. Some have supposed this fish to be a perch.

ANTHISTIRIA (*Ανθιστιρια*, *floralia*, an Athenian festival observed in honour of Bacchus), in *Botany*, an exotic plant, of a grass-like appearance, belonging to the class *polygamia monoecia*, and natural order, *gramina*. The essential generic character is, that the *calyx* is cleft at the base into four equal divisions or valves. *Anthistiria ciliata* is the only species of the genus hitherto discovered.

ANTHIUS, **FLOWERED**, in *Mythology*, a furnace given to Bacchus, at Athens, and also Patras in Achaia; because the statues of this god were covered with a robe charged with flowers.

ANTHOCEROS, a small cryptogamous plant, of the order *alge*. Lin. Gen. 1201. In the *male* flower the *calyx* is sessile, cylindrical, entire; anther very long, subulate, two-valved; in the *female*, the *calyx* is cut into six divisions, and contains three seeds. 1. *A. punctatus*, with the fronds undivided, indented, dotted: a native of Britain, growing on heaths and moist shady places. 2. *A. laevis*, with smooth, undivided, indented fronds. 3. *A. multifidus*, with bipinnated linear fronds. See Hedwig's *Figures and Flor. Dan.* 396.

ANTHOINE, **NICHOLAS**, in *Biography*, was born at Brien in Lorraine, of Roman Catholic parents, and educated in the college at Luxemburg, and also under the Jesuits at Triers and Cologne. Conceiving a dislike to the church of Rome, he embraced the Protestant religion; and such was his zeal in his new profession, that he endeavoured to proselyte his relations. In pursuing his theological studies, he became a convert to Judaism, and solicited the Jews in several cities to admit him among them as a proselyte, but his application was ineffectual. Returning to Geneva, he made an external profession of Christianity, but privately performed his devotions as a Jew. He was at length admitted into the ministry of the reformed church; and appointed by the synod of Burgundy, to be minister of the church of Divonne in the country of Gex. Here he was suspected, and became insane; but upon the recovery of his understanding, he was committed to prison. After some time, he was brought to his trial; upon which he avowed himself a Jew, and besought God that he might die in the Jewish religion. The result was his condemnation by the council, who, in 1632, sentenced him to be strangled and burnt; and he was executed on the day of his condemnation. His sentence expressed, that "laying aside all fear of God, he was guilty of apostacy and high treason, having opposed the Holy Trinity, denied our Lord and Saviour Jesus Christ, blasphemed against his holy name, renounced his baptism to embrace Judaism and circumcision, and perjured himself, which are great and horrid crimes, &c." Anthoine left several pieces written with his own hand, such as several prayers, that are said to be composed in a strain of great devotion, though he introduces in them no mention of Jesus Christ; a small paper, containing eleven philosophical objections against the Trinity; a confession of his faith in twelve articles, which are as follow. *viz.* that there is only one God, without distinction of persons;—that there is

no other way of salvation, without fulfilling the law of Moses;—that circumcision is of perpetual obligation, and also the sabbath, and also the distinction of clean and unclean meats;—that sacrifices will be restored, and the temple and city of Jerusalem rebuilt;—that the true Messiah is to come, and that he will be a glorious, holy, and just king, and restore the kingdom of Israel;—that there is no imputation of Adam's sin;—that there is no predestination, by which God has decreed to save some persons and to damn others, but that men shall be rewarded and punished according to their actions;—that no person can make satisfaction for us, but that if we sin there is room for repentance;—and that the New Testament is not agreeable to the Old. Gen. Dict.

ANTHOLOGION, a church-book in use among the Greeks. It was called *ανθολογιον*, q. d. *florilegium*, or a collection of flowers. The anthologion is a sort of breviary or mass-book, containing the daily offices addressed to our Saviour, the Virgin, and the principal saints; with other common offices of prophets, apostles, martyrs, pontiffs, and confessors, according to the Greek rite. See BREVIARY, MASS, and OFFICE.

ANTHOLOGY, **ANTHOLOGIA**, a discourse or treatise of flowers, or of beautiful passages from any authors. Thus called from *ανθος*, *flor*, a flower, and *λογος*, *sermo*, discourse; though others choose rather to derive it from *ανθος*, *flor*, a flower, and *λεγω*, I gather; and use it to signify a collection of flowers.

ANTHOLOGY is frequently used for a collection of epigrams of divers Greek poets.

ANTHOLYZA (*Ανθος*, a flower, and *λυσσα*, madness), in Botany, Lin. Gen. 58. class *triandria monogynia*; natural order *enfata*; and *irides* of Jussieu.

Generic Character. Calyx, spathes two-valved, alternate, imbricated, permanent; corolla, petal one, gradually dilated, from the tube into a compressed ringent throat; upper-lip straight, slender, very long, furnished with two short divisions at the base; under-lip shorter, trifid; stamina, filaments long, slender, under the upper lip; antheræ acute; pistillum, germen inferior; style filiform; stigma trifid, capillary, reflex; per. capsule roundish, three-cornered, three-celled, three-valved; seeds many, triangular.

Ess. generic Character. Cor. tubular, irregular, recurved; caps. inferior.

Species. 1. *A. ringens*, narrow-leaved antholyza, with lips of the corolla divaricated, throat compressed; it grows two feet high, producing red flowers cut into six unequal segments, and appearing in June; cultivated by Mr. Miller in 1759. 2. *A. plicata*, plaited-leaved antholyza, with leaves plaited; stem branching hirsute; corolla ringent, shorter than the stamina; a native of the Cape, and discovered by Thunberg and Masson. 3. *A. cunonia*, scarlet-flowered antholyza, with corolla somewhat butterfly-shaped, the two outer lobes of the five-parted lip broader and ascending. Miller, fig. 113. and Bot. Magazine, 343. A native of the Cape and Persia; cultivated by Miller in 1756; it flowers in May and June. 4. *A. ethiopica*, broad-leaved antholyza, with corolla incurvate; the two alternate lobes of the five-parted lip spreading, large, lanceolate: its flowers are scarlet, and appear in May and June; cultivated by Mr. Miller in 1759. This and the preceding species very much resemble the gladiolus. 5. *A. meriana*, red-flowered antholyza; with corolla funnel-shaped; leaves linear sword-shaped: the flowers have long tubes, of a copper colour on the outside, but of a deeper red within; appearing in April or May. Bot. Magazine, 418. Cultivated by Miller in 1756. See fig. 276, Miller. 6. *A. meriana*,

dwarf antholyza, with corolla funnel-shaped, leaves linear; the flowers are of a pale red, larger than those of the preceding species. Curt. Bot. May 411. The seeds were brought from the Cape in 1754. Both this and the *meriana* differ much from all the other species of antholyza, and ought perhaps to constitute another genus. 7. *A. lucidior*, with radical leaves filiform at the base, broad, tubulate, furrowed at the top; stem simple, leafy, spiked, a foot and a half high; flowers oblong, a little bent, purple above, cut into six unequal lanceolate parts. This, as well as the other six species, are natives of the Cape of Good Hope.

Propagation and Culture. As these are very ornamental plants, much attention has been given to their cultivation. They do not always ripen their seeds in this country, and are therefore frequently propagated by offsets, which their bulbous roots send forth in great abundance. Miller says, "the seeds should be sown soon after they are ripe, for if they are kept out of the ground till the following spring, they often miscarry, or at least remain a year in the ground before they grow. If the seeds are sown in pots of light earth, and plunged into an old bed of tan, which has lost its heat, and shaded in the middle of the day in hot weather, the seeds will come up the following winter; therefore they must be kept covered with glasses to screen them from cold, otherwise the young plants will be destroyed. These may remain in the pots two years, if the plants are not too close, by which time they will have strength enough to be planted each into a separate small pot filled with light earth. The time for transplanting these roots is in July or August, when their leaves are decayed. In summer, the pots may be placed in the open air, but in winter they must be removed and placed under a hot-bed frame, for they are not very tender; but where any damp arises, it is very apt to occasion a mouldiness upon their leaves. The roots shoot up in autumn, and the flowers begin to appear in May; the seeds ripen in August, and soon after their leaves and stalks decay: the roots may then be taken up, and kept six weeks or two months out of the ground, so that they may be easily transported from one country to another at that time." See Martyn's Miller's Dictionary.

ANTHON, in Geography. See VILLETTE D'ANTHON.

ANTHONY, FRANCIS, in Biography, the son of — Anthony, goldsmith, who held a lucrative place in the Jewel Office under queen Elizabeth, was born in London in the year 1550. After passing through the usual steps, he was sent to Cambridge, where he graduated in the year 1574. Having applied himself diligently to the study of medicine, particularly of chemistry, and invented a panacea, which he called Aurum Potabile, he returned to London, and commenced practitioner of physic, but without obtaining a licence from the College. He was therefore summoned before them, and interdicted practising, Goodall says, for incapacity; and on his proving refractory, was committed by them to the Compter-prison. He was, however, soon after released, on his submitting to the college, and paying them a fine of five pounds. Two years after, Dr. Taylor and two other members of the college, accused him of occasioning the death of sundry persons, to whom he had given his medicine. Against this charge he defended himself, in 1610, by a work intitled, "Medicinæ Chymicæ et veri Potabilis Auri assertio," "by no means (Aikin says) devoid of learning and art, although in the present state of chemistry and medicine, it would be thought destitute of solidity." This was answered by Dr. Matthew Gwynne, in a tract called "Aurum non Aurum, sive adversaria in assertorem Chymicæ, sed veræ Medicinæ desertorem Fran. Anthonium." It is curious to find this

this writer calling upon the king to prohibit the sale of the medicine, lest the business of the physician, surgeon, and apothecary should be ruined. This at least shewed it possessed considerable efficacy. This produced from the inventor, in 1616, an apology in defence of his medicine, written in English, in which, besides some popular arguments in favour of the idea of an universal medicine, there is a large collection of attested cures. He had now acquired such a degree of popularity, and so many powerful protectors, that the College did not think it prudent, it would seem, to prosecute him farther. He is said to have been liberal to the poor, and to have lived hospitably in his house in Bartholomew-cloze, where he died, aged 74, on May 26th, 1623. There is a monument erected to him and his son John, who succeeded him in the sale of his medicine, in the church of Bartholomew the Great, in London. Charles, his second son, removed to the town of Bedford, where he practised physic with considerable reputation and success.

ANTHONY, or *Antony*, St. the first institutor of the monastic life, was born at Coma, a village of Egypt, in the lower parts of the Thebais, in the year 251 (252, Cave). Some have said, that though born of wealthy parents, he was wholly illiterate; while others affirm, that he could read and write in the Coptic, which was his native tongue. At the age of 18, he was left in possession of a large estate, which, under the impulse of a fanatical spirit, he sold, distributing the produce of it among the poor, and devoting himself to religion in a state of solitude and poverty. After a long and painful noviciate among the tombs, and in a ruined tower, he boldly advanced into the desert, three days' journey to the eastward of the Nile, discovered a lonely spot, which possessed the advantages of shade and water, and fixed his last residence on Mount Colzim, near the Red Sea; where an ancient monastery still preserves the name and memory of the saint. Before his settlement at Colzim, and during the persecution of Maximin, in the year 311, he left his solitary retreat, and visited Alexandria, for the purpose of administering consolation to those who were suffering in the Christian cause. During the latter part of his life, in the year 355, he took another journey to this city, at the request of Athanasius and other Catholic prelates, to assist them in defending the faith against the Arians; where he is said to have supported his fame with discretion and dignity. Declining to accept an invitation from the emperor Constantine to visit Constantinople, he returned to his cell, and there lived to the advanced age of 105 years. The venerable patriarch beheld the numerous progeny, which had been formed by his example and lessons to that kind of monastic seclusion and mortification, which superstition may deem meritorious, but which an enlightened and benevolent philosophy must pronounce absurd and mischievous. The prolific colonies of monks multiplied with rapid increase on the sands of Libya, upon the rocks of Thebais, and in the cities of the Nile. To the south of Alexandria, the mountain and adjacent desert of Nitria were peopled by 5000 anachorets; and the traveller may still investigate the ruins of 50 monasteries, which were planted in that barren soil by the disciples of Anthony. But "what honour can be due to the memory of the fanatic who laid the foundation of an institution, which has alienated millions of human beings from the first duties and the first enjoyments of society?" Anthony left his cloak to Athanasius, and his hair-cloth to two brethren who were with him at his death. Seven letters, written originally in Egyptian, and translated into Latin, abounding more with piety than eloquence, with some other pieces, ascribed to this proto-monk, may be found in the "Bibliotheca Patrum." Cave's

Hist. Lit. vol. i. p. 220. Gibbon's Hist. vol. vi. p. 241, &c. See MONK.

ANTHONY, *St. of Hainault*. The order of St. Anthony in Hainault, was instituted by Albert, duke of Bavaria and earl of Hainault, Holland, and Zealand, in 1382, on designing an expedition against the Turks and Moors. The ensign of the order was a collar of gold made like an hermit's girdle; at the centre thereof hung a crutch, and a small bell of gold.

ANTHONY, *St. of Æthiopia*. The order of St. Anthony in Æthiopia. After the death of St. Anthony the hermit, who died in 357, many of his disciples remaining near Æthiopia, followed his example and manner of life; and their successors lived in great austerity in the desert, and were called Anchorites till the year 370; when John, emperor of Æthiopia, erected them into a religious order of knighthood, under the title and protection of St. Anthony, patron of his empire. Being thus instituted, they received St. Basil's rule, and lived in monasteries; their habit was black, with a blue Cross Tau. Philip VII. son to the *Founder*, enlarged their lands and privileges, and added a bordure of gold to the badge of the blue cross. In Italy, France, and Spain, there was formerly a sort of monks that had the title of Knights of St. Anthony, which observed the rule of St. Augustine, and they wore a plain cross like that in Æthiopia; but the principals of those wore a double St. Anthony's cross of blue satin, the one above the other. Their chief seat was at Vienne in Dauphine, of which place the General of the Order bore the title of abbot; the monastery being erected, in 1207, in honour of St. Anthony, whose body was translated thither from Constantinople. The badge of this order was a Cross flowery azure, the base point thereof couped, and the whole edged with gold.

The friars of this order came into England in the reign of king Henry III. and had one house at London, and another at Hereford.

It is said that, in some places, these monks assume to themselves a power of giving, as well as removing the *ignis sacer*, or ERYSIPELAS; a power which is usefully employed for keeping the poor people in subjection, and extorting alms.

ST. ANTHONY'S *Fire*. See ERYSIPELAS.

ANTHONY, *St. Island of*, in *Geography*, the most northern of all the Cape Verd islands, lying in N. lat. 18°, and divided from St. Vincent by a clear and navigable channel, about two leagues broad. This island stretches from north-east to south-west, and abounds with high mountains, whose tops are constantly covered with snow, and generally hid in the clouds. On the north side is a good road for shipping, and a supply of fresh spring water. The inhabitants are chiefly Negroes, amounting in number to about 500, under the protection of the Portuguese. The island produces a variety of fruits, oranges, lemons, palms, melons, bacovas, pomegranates, and the sugar-cane. The potatoes and melons are particularly excellent, and much sought after by mariners.

ANTHONY *Cave's Island*, an island in the Pacific Ocean. S. lat. 3° 10'. E. long. 152° 50'.

ANTHONY'S *Falls*, St. lie in the river Mississippi, about ten miles north-west of the mouth of St. Pierre river, which joins the Mississippi from the west, and are situated in N. lat. 44° 50'. They were so named by father Louis Hennipin, who travelled into those parts about the year 1680, and was the first European ever seen there by the natives. The whole river, 250 yards wide, falls perpendicularly above 30 feet, and forms a very agreeable cataract. The rapids below, in the space of about 300 yards, render the descent apparently greater, when viewed at a distance. In the middle of the falls is a small island, about 40 feet square, in which

grow a few hemlock and spruce trees. These falls are so peculiarly situated, that they may be approached without any intervening hill or precipice; and the scene around them is uncommonly beautiful. At a little distance below the falls is a small island, about $1\frac{1}{2}$ acre, on which grow a great number of oak trees, all the branches of which are loaded, at the proper season, with the nests of eagles, where they are secure from the attack both of man and beast.

ANTHONY'S Kill, a western water of Hudson's river; the mouth of which is seven miles above that of Mohawk river, with which it likewise communicates at the east end of Long Lake.

ANTHONY'S Nose, a point of land in the highlands, on Hudson's river, in the state of New York; from which to Fort Montgomery on the opposite side, a large boom and chain was extended in the late war, at an expence of 70,000l. sterling. It was partly destroyed by general Clinton in 1777. This is also the name of a point of a mountain on the north bank of Mohawk river, about 30 miles above Schenectady. The stage road runs about this point.

ANTHOPHYLLUM, in *Natural History*, a species of MADREPORA, found in the Mediterranean. The stalk is simple and ovate; star terminal, hemispherical, and concave, with radiated lamellæ, which are thickest at the bottom. Gmelin, Esper, &c.

ANTHOPHYLLUM, is also a name given by Rumphius to madrepora ranea of Linnæus. *Vide Anthophyllum faxcum*. Rumpf. amb. vi. p. 245.

ANTHORA, in the *Materia Medica*, a medicinal plant, of the *aconite* kind, having yellow flowers, resembling helmets; growing chiefly on the mountains in Switzerland and Savoy. See **ACONITUM**.

This is otherwise called *antithora*, as being reputed an antidote against the *thora*; sometimes *aconitum salutaris*; in English, the *helmet-flower*.

The root, *anthora radix*, has been chiefly in use. It holds a place in the catalogues of the *Materia Medica*, but is not kept at this time in the shops. It is of a dusky brown without and whitish within, of a warm bitterish taste, and is reputed a cardiac and alexipharmic, much of the same qualities with **CONTRAYERVA** root; on which account some also denominate it the *German contrayerva*, though it now only obtains in a few officinal compositions.

ANTHORISMUS, in *Rhetoric*, denotes a counter definition or description of a thing.

Thus, if a plaintiff urge, that to take any thing away from another, without his knowledge or consent, is a theft; this is called *οπος*, or definition. If the defendant reply, that to take a thing away from another, without his knowledge or consent, provided it be done with design to return it to him again, is not theft; this is an *ανθορισμος*.

ANTHOS, in its original Greek, signifies flower; but by way of excellency is appropriated to rosemary, so as to express only that plant.

ANTHOSPERMUM (*Αθος* and *σπρισμα*, *flower-seed*), in *Botany*, Linn. Gen. 1164. Class, *polygamia dioecia*; natural order, *stellata*; and *rubiacea*, Juss.

Generic Character. MALE. *Calyx*, perianth one-leaved, conical, quadrifid beyond the middle; divisions ovate-oblong, revolute, obtuse; *corolla* none; *stamina*, filaments four, capillary, erect, the length of the calyx, inserted into the receptacle; *antheræ* twin, oblong, four-cornered, erect.

FEMALE. *Calyx* and *corolla* as in the male; *pisillum*, germen inferior, ovate, four-cornered; styles two, recurved; *stigmata* simple.

Essen. Generic Character. *Calyx* four-parted; *corolla* none;

stamina four; *pisillum* two; germ. inferior; male and female in the same, or a distinct plant.

Species. 1. *A. ethiopicum*, amber-tree: it bears male and hermaphrodite flowers on distinct plants; a beautiful ever-green shrub, with smooth polished leaves, which emit a very fragrant odour on being rubbed between the fingers. 2. *A. ciliare*, with root perennial, woody, much branched; leaves ciliated, narrow, lanceolate; flowers axillary, sessile. 3. *A. herbaceum*, with leaves six, polished; stem herbaceous. This has the appearance of a galium. All these species are natives of the Cape of Good Hope.

Propagation and Culture. All these plants may be easily propagated by cuttings during the summer months; they will take root in a border of light earth, provided they are watered and shaded as the season may require; or if these cuttings are planted in pots, and placed in a moderate hot-bed, they will take root sooner. Afterwards they should be taken up, and planted in pots filled with light sandy earth, and exposed to the open air till October, when they ought to be removed into the conservatory. See Miller's Dict. by Matya.

ANTHOXANTHON. See **RUMEX maritimus**.

ANTHOXANTHIUM (*Αθος* and *ξανθος*, *yellow flower*), Lin. Gen. 42. class, *diandria digynia*; natural order, *gramina*, or grasses.

Generic Character. *Calyx*, glume one-flowered, two-valved; valves ovate, acuminate, concave, the inner one larger; *corolla*, glume one-flowered, two-valved, of the length of the greater valve in the calyx, each valve emitting an awn from the lower part of the back, one of them jointed; *nectary* two-leaved, very slender, cylindrical; leaflets fubovate, embracing; *stamina*, filaments two, capillary, very long; *antheræ* oblong, forked at both ends; *pisillum*, germen oblong; styles two, filiform; *stigmata* simple; *pericarpium*, glume of the corolla grows to the seed; seed one, pointed at both ends.

Essen. generic Character. Glume two-valved, one-flowered; glume of the corolla two-valved, acuminate; seed one.

Species. 1. *A. odoratum*, sweet vernal grass, with spike oblong-ovate; flowers longer than the awn, on short peduncles. This is an early grass, and grows about a foot high; it may be easily distinguished from all the other grasses which are natives of this country, by having only two stamina; its fragrance is also very remarkable, giving that pleasant smell discovered in new-mown hay. See Eng. Botany, 647. 2. *A. indicum*, with spike linear; flowers sessile, shorter than the awn; culm, or stem, a foot high, jointed; leaves broad, short, spike very narrow: a native of the East Indies. 5. *A. erinitum*, with culm high, smooth; panicle long, spike-shaped; with awns long, spreading, loose: a native of New Zealand.

ANTHOXANTHUM aculeatum. See **CRYPISIS**.

ANTHOXANTHUM paniculatum. See **FESTUCA spadicca**.

ANTHRACIS, in *Natural History*, a word used for a gem by the ancients, but in several different senses; all which seem evidently to refer to the cat's eye, or *asteria* kind.

Many of the ancients also have called the **HEMATITES**, or blood-stone, by this name, because of its being of the colour of a burning coal.

ANTHRACOLITE (of Kirwan), in *Mineralogy*. See **COAL**.

ANTHRACOSIS, in *Surgery*, is a disease affecting the eye or its appendages, which more commonly bears the appellation of *Anthrax*, *Carbo*, or *Carbuncle*. This disorder may, however, be seated in any other external part of the body; and there is no good reason why its name should be altered, when it affects the eye. See **CARBUNCLE**.

ANTHRAX, in the *Natural History of the Ancients*, was a word used by the most early writers for the substance we now call pit coal, and *libanthrax*. Theophrastus plainly tells us, that the substance strictly and properly called *anthrax* (for they also knew a gem by the same name, used in a metaphorical sense) was an earthy fossile substance, which was broken in pieces to be used, and kindled well, and burnt almost like wood-coals, and was used by the smiths. See **COAL**.

ANTHRAX Morio, in *Entomology*, a name given by Scopoli to the musca morio of Linnæus. *Vide* Scop. ent. Carn. 971.

ANTHRAX, in *Surgery*, a circumscribed tumour seated in the common integuments, and readily becoming gangrenous. For a more particular description of this complaint, see **CARBUNCLE**, which is synonymous. The distinction which some persons have made between *anthrax* and *carbo* is not founded in nature.

ANTHRENUM, in *Entomology*, a genus of coleopterous insects in Gmelin's arrangement of the *Systema Naturæ*, comprehending seven species, *viz.* *pimpinellæ*, *serophulariæ*, *muscorum verbasci*, *vagus*, *glaber*, and *sufcus*. The character of the genus is, antennæ clavate; club solid; palpi unequal, filiform; maxilla membranaceous, linear, and two-cleft; lip entire.

ANTHRIBUS, a name given by Geoffroy to the *Cryptcephalus Cricceis* of Gmelin.

ANTHRISCUS, in *Botany*. See **CHÆROPHYLLUM** and **SCANDIX**.

ANTHROMETRICA machina. See **ANTHROPOMETRICA**.

ANTHROPODÆMON, in *Ancient Writers*, a demon conceived under the figure or appearance of man.

ANTHROPOGLOTTUS, in *Natural History*, something that has a tongue or speech resembling that of a man.

The parrot kind are denominated *anthropoglotti*, on account of their broad, thick and muscular tongues, by which they are enabled to speak, and to roll their meat from side to side under the edges of their bills.

ANTHROPOGRAPHIA, a description of man; more particularly of the structure of his body, and the parts thereof.

ANTHROPOLATRÆ, in *Ecclesiastical History*, a title given to the Nestorians, on account of their believing Christ to be a mere man, yet paying him the honour of a God.

ANTHROPOLATRIA, the paying divine worship or honours to a man. *Anthropolatria* is supposed by some to have been the most ancient species of **IDOLATRY**.

ANTHROPOLITES, in *Natural History*, a term denoting petrifications of the human body; as those of quadrupeds are called *zoolites*. See **PETRIFFACTION**.

ANTHROPOLOGY, compounded of *ἄνθρωπος*, *man*, and *λόγος*, *discourse*, a discourse or treatise upon man, or human nature; considered as in a sound or healthy state.

Anthropology includes the consideration both of the human body and soul, with the laws and effects of their union; as sensation, motion, &c.

It is particularly used, in *Theology*, for a way of speaking of God after the manner of men; by attributing human parts and passions to him; as eyes, hands, ears, anger, joy, &c. We have frequent instances of *anthropology* in holy scripture; by which we are only to understand the effect, or the thing which God does, as if he had hands, &c.

ANTHROPOMANCY, compounded of *ἄνθρωπος*, *man*, and *μανθία*, *divination*, a method of divination, performed by inspecting the *viscera* of a person deceased: the emperor Heliogabalus practised this method of divination. The same is related by Cedrenus and Theodoret of Julian II.

who, in his nocturnal sacrifices and magical operations, destroyed a number of young children, for the purpose of inspecting and consulting their entrails. The Scythians were addicted to this barbarous practice; and Strabo informs us, that it prevailed amongst the ancient inhabitants of Lusitania.

ANTHROPOMETRIA, a description of the human body, with its several parts and members, according to the three dimensions, length, breadth, and thickness, both considered in themselves, and comparatively to each other.

ANTHROPOMETRICA machina, a name which Sanctonius gave to his weighing-chair, contrived for measuring the quantity of *insensible PERSPIRATION*.

ANTHROPOMORPHIA, derived from *ἄνθρωπος*, *a man* and *μορφή*, *form*, in the Linnæan system of nature, a denomination formerly given to the primates class of animals which had the greatest degree of resemblance to the human form.

ANTHROPOMORPHITE, formed of *ἄνθρωπος*, *man* and *μορφή*, *shape*, in a general sense, one who attributes to God the figure of a man.

ANTHROPOMORPHITES, in *Ecclesiastical History*, were a sect of ancient heretics, who, taking every thing spoken of God in the scriptures in a literal sense, imagined he had real hands, feet, &c. The passage they chiefly insisted on was that in Genesis, where it is said, that God made man after his own image.

Even philosophers, for want of a better acquaintance with metaphysics, seem to have fallen into *anthropomorphism*, representing God much after the manner of a human soul, without considering the difference between a finite and infinite being; limited, and absolute perfections. Wolfius has laboured hard to avoid this rock, by having the difference still present to his mind, and proceeding according to the ancient rule, *Quæ de Deo dicuntur ἄνθρωποπαδως, ea intellige Θεοομοιωτως*.

The whole sect of Stoics held God to be corporeal: and, not to mention Tertullian, Lactantius and others among the fathers, Hobbes and his followers assert the same among ourselves. Leibnitz charges sir Isaac Newton and his followers with representing God under the conditions of a man; but with what justice it would be hard to say.

Those who held the contrary, *viz.* that God is incorporeal, and without any bodily form, the anthropomorphites branded by the name of *Origenists*, because Origen taught how to allegorize those expressions.

Epiphanius calls the *Anthropomorphites*, *Audiani*, or *Odiani*, from *Audius*, the supposed founder of the sect; who lived about the time of Arius, in Mesopotamia. St. Augustine calls them *Vadiani*.

This system was revived in the year 939.

ANTHROPOMORPHOUS, something that bears the figure or resemblance of a man. Naturalists give instances of anthropomorphous plants, anthropomorphous minerals, &c. These generally come under the class of what they call *lusus naturæ*, or inosfers.

Anthropomorphous stones make a species of those called figured stones.

ANTHROPOMORPHOUS, is an appellation more peculiarly given to **MANDRAGORA**, or mandrake.

ANTHROPOPATHY, compounded of *ἄνθρωπος*, *man*, and *πάθος*, *passion*, a figure, expression, or discourse, whereby some passion is attributed to God, which properly belongs only to man.

Anthropopathy is frequently used promiscuously with *anthropology*; yet, in strictness, they ought to be distinguished as the genus from the species. *Anthropology* may be understood of any thing human attributed to God; but *anthro-*

anthropopathy, only of human affections, passions, sensations, &c.

ANTHROPOPHAGI, compounded of the Greek *ανθρωπος*, *man*, and *φαγον*, *edere*, to eat, people who feed on human flesh.

The Cyclops, the Lestrygons, and Scylla, are all represented in Homer as anthropophagi, or man-eaters; and the female phantoms, Circe and the Syrens, first bewitched with a show of pleasure, and then destroyed. This, like the other parts of Homer's poetry, had a foundation in the manners of the times preceding his own. It was still in many places the age spoken of by Orpheus:

“When men devour'd each other like the beasts,
Gorging on human flesh.—”

Some remains of the usage subsisted much longer, even among the most civilized nations, in the practice of offering human sacrifices.

History gives us divers instances of persons driven by excess of hunger to eat their own relations. Others commence anthropophagi out of revenge and hatred; there are many instances of soldiers, who in the heat of battle have been carried to such excess of rage, as to tear their enemies with their teeth.

The violence of love has sometimes produced the same effect as the excess of hatred. The *Tapuii* eat the bodies of their friends and nearest relations to preserve them from worms and putrefaction, thinking they do not only hereby afford them an honourable grave, but even a new life, a kind of revivification in themselves. Artemisia did something like this, when she swallowed the ashes of her dead husband, Mausolus. Among the Eistedonian Scythians, when a man's father died, his neighbours brought him several beasts, which they killed, minced, and mixed up with the flesh of the deceased, and made a feast.

Among the Massageti, when any person grew old, they killed him and ate his flesh; but if the party died of sickness they buried him, esteeming him unhappy.

Idolatry and superstition have occasioned the eating more men, than both love and hatred put together. There are few nations but have offered human victims to their deities; and it was an established custom to eat part of the sacrifices they offered.

This practice has prevailed more or less in different parts of the globe, in more modern times. The Caribbees used to make eunuchs of their children, in order to fatten and eat them. Garcilasso de la Vega mentions a people in Peru, who were accustomed to fatten and eat the children produced by their female captives, whom they kept as concubines for that purpose; and when the mothers had done breeding, they themselves were killed and eaten. The virtues whereby the Tououpinambos believed they merited Paradise, were revenge, and eating abundance of their enemies. Herrera speaks of great markets in China, that were furnished wholly with human flesh for the better sort of people.

The Jagos, and the subjects of the great Macoco, are said to be anthropophagi. This prince is very powerful, having several kings for his vassals; his court is so numerous, that there are two hundred men butchered every day to supply the table; part of this number are criminals, the rest slaves furnished in the nature of tribute. See *ANSIKO*.

It appears pretty certain from Dr. Hawkesworth's Account of the voyages to the South Seas, that the inhabitants of the island of New Zealand, a country unfurnished with the necessaries of life, eat the bodies of their enemies. It appears also to be very probable, that both the wars and anthropophagia of these savages take their rise, and owe their

continuance, to irresistible necessity, and the dreadful alternative of destroying each other by violence, or of perishing by hunger. See vol. iii. p. 447, and seq. and vol. ii. p. 389, &c.

Mr. Marsden, in his account of Sumatra, informs us, that the Battas, a people of that island, are anthropophagi. They do not eat human flesh to satisfy hunger, because other food is wanting, or as a gluttonous delicacy, but as a mode of shewing their detestation of crimes by an ignominious punishment, and as an indication of revenge and insult to their enemies. The objects of this savage repal are the prisoners taken in war, and offenders convicted and condemned for capital crimes. When sentence is pronounced, the unhappy object is tied to a stake; and when mortally wounded by lances thrown at him by the assembled multitude, they rush upon him as in a rage, cut pieces from the body with their knives, dip them in a dish, previously prepared, of salt and lemon-juice, slightly broil them over a fire, and then swallow the morsels with a kind of savage enthusiasm. In some cases, they tear the flesh from the carcass with their mouths. Some say that they do not eat the bodies of their enemies slain in battle; but though the practice be not general, instances of it occasionally occur.

M. Petit has a learned dissertation on the nature and manners of the anthropophagi. Among other things, he disputes whether or not the anthropophagi act contrary to nature? The philosophers, Diogenes, Chryssippus, and Zeno, followed by the whole body of Stoics, held it a very reasonable thing for men to eat each other.

According to Sextus Empiricus, the first laws were those made to prevent men from eating each other, as had been done till that time. The Greek writers represent anthropophagia as universal before Orpheus. To shew farther, that anthropophagia is not contrary to nature, a modern author urges, that cats, dogs, rabbits, and other animals feed on each other. Pliny, after Aristotle, affirms, that swans eat each other; and the bees also eat their *nympha*, which are their young. The Dutch, in Nova Zembla, saw bears devour each other; and the like has been observed of the fish kind: the *tiburones*, according to Ovid, are caught with a hook baited with their own flesh. Leonardus Florentius having fed a hog with hog's flesh, and a dog with dog's flesh, found a repugnancy in nature to such food; the former lost all its bristles; the latter its hair; and the whole body broke out in blotches.

It may be said, that whether the dead body of an enemy be eaten or buried, is a matter perfectly indifferent; but whatever the practice of eating human flesh may be in itself, it certainly is, relatively, and in its consequences, most pernicious. It manifestly tends to eradicate a principle, which is the chief security of human life, and more frequently restrains the hand of the murderer, than the sense of duty, or the dread of punishment. If even this horrid practice originates from hunger, still it must be perpetual from revenge. Death must lose much of its horror among those who are accustomed to eat the dead; and where there is little horror at the sight of death, there must be less repugnance to murder. See some farther observations on this subject, equally just and ingenious, by Dr. Hawkesworth, *ut supra*.

Some carry their respect for dead bodies to a great length. M. Petit does not think it lawful for anatomists to dissect human bodies in order to learn their structure, except those of condemned criminals, and such as are denied the rites of burial. The Arabs went farther; notwithstanding all their curiosity, and desire to be acquainted with the human structure, they could never be induced to make one dissection; but were contented to borrow all their knowledge of this kind from the Greek physicians.

Some maintain it impossible, whatever precaution is used, to prevent the ingress of the parts of dead bodies into our food and drink. Add, that if we do not feed on our own species, we feed on plants and animals which derive a great part of their nutriment from us. Whence the impossibility of the RESURRECTION of the same body has been inferred.

ANTHROPOPHAGIA, the act or habit of eating human flesh.

This is pretended by some to be the effect of a disease, which leads people affected with it to eat every thing alike. Some choose only to consider it as a species of PICA.

The annals of Milan furnish an extraordinary instance of anthropophagia. A Milanese woman, named Elizabeth, from a depraved appetite, like what women with child, and those whose *menfes* are obstructed, frequently experience, had an invincible inclination to human flesh, of which she made provision by enticing children into her house, where she killed and salted them; a discovery of which having been made, she was broken on the wheel and burnt in 1519.

ANTHROPOSCOPIA, the art of judging or discovering a man's character, disposition, passions, and inclinations, from the lineaments of his body.

In which sense anthroposcopia seems to be somewhat more extensive than PHYSIOGNOMY, or METOPOSCOPY.

Otto has published an "*Anthroposcopia, sive judicium hominis de homine ex lineamentis est raris*."

ANTHROPOSOPHIA, the science of the nature of man, and his structure and composition, both internal and external.

In this sense, anthroposophia amounts to much the same with the medical *physiology* or *anatomy*.

ANTHROPOTHYSIA, in *Ancient Writers*, denotes the offering of human victims.

The anthropothyia was a frequent practice among the ancients. Some have imagined that the sacrifice of Abraham was the first instance. Many reasonings and disquisitions have been founded on this supposition; by which the severity of Abraham's trial is thought by some to have been somewhat exaggerated. Human sacrifices were in use among the Gentiles before that time; practised by kings as well as by private persons; nay by entire nations, as the Egyptians, Phœnicians, Canaanites, &c.

ANTHUMON, in the *Materia Medica of the Ancients*, a name given to the EPITHYMUM, or *dodder*, growing upon THYME.

ANTHUS, in *Ornithology*, a name by which Aldrovand and some other authors have called that species of the OENANTHE LOXIA, called the *chleris* or green finch.

ANTHYLLA, in *Ancient Geography*, a town of Egypt, situate, according to Herodotus, in a plain, nearly west of the Canopic branch, and north-west of Naucratis.

ANTHYLLIS. See ARENARIA, ASPALATHUS, CAMPHOROMA, CRESSA, EBENUS, POLYCARPON, POLYCNEMUM, SALSOLA, and TEUCRIUM.

ANTHYLLIS *Valentina*. See FRANKENIA.

ANTHYLLIS (*Ανθυλλίς*, *floris lanugo*, a downy flower), in *Botany*. Lin. Gen. 864. Juss. 355. Gærtn. 145. Class, *diadelphica decandria*; natural order of *papilionaceæ* or *leguminosæ*.

Generic Character. Calyx, perianth one-leaved, ovate-oblong, swelling, villose; the mouth five-toothed, unequal, permanent; *corolla* papilionaceous; banner longer than the wings, the sides reflex, claw the length of the calyx; wings oblong, shorter than the banner; keel compressed, of the length of the wings; *stamina*, filaments connate, rising; antheræ simple; *pisillum*, germen oblong; style simple; stigma

obtusè; *perianthium*, legume roundish, concealed within the calyx, very small, bivalve; *seeds* one or two.

Essen. generic Character. Calyx swelling; legume roundish, concealed.

Species. 1. *A. tetraphylla*, four-leaved anthyllis or kidney-vetch; with leaves pinnate, with four lobes; flowers lateral: an annual, the spontaneous growth of Spain and Italy; it flowers in the open border in July. Curt. Bot. Mag. 108. 2. *A. vulneraria*, kidney vetch, lady's-finger, with leaves pinnate, unequal; head double; root woody, perennial; stems decumbent, hairy; leaves lyrato-pinnate; flowers yellow. There is a variety with red flowers: a common native of Britain, flowering in July and August. This plant is recommended as an excellent pasturage for sheep. Figured in Eng. Bot. 104, and Flor. Dan. 988. 3. *A. montana*, mountain kidney-vetch, with leaves pinnate, equal; head terminal; flowers oblique; stems four to six inches high; flowers pale, streaked with a deep purple; they appear early, and the seeds ripen in July: a native of the south of Europe. 4. *A. cornicina*, with leaves pinnate, unequal; heads solitary; stem seven or eight inches high; flowers of a pale yellow colour, appearing in May and June: it is a native of Spain, annual. 5. *A. lotoides*, with leaves three-parted; calyces prismatic, fascicled, of the length of the legumes, half a foot high; leaves alternate, distant; flowers about nine, of a deep sulphur colour: a native of Spain, annual. 6. *A. Gerardi*, with leaves pinnate, unequal; peduncles lateral, longer than the leaf; heads leafless: grows wild on the sea coast of Provence. 7. *A. quinqueflora*, with leaves ternate, linear; head five-flowered; it bears yellow flowers: a native of the Cape of Good Hope. 8. *A. involuerata*, sub-herbaceous; with leaves ternate, stipuled, sword-shaped; flowers in a head, yellow: a native of the Cape. 9. *A. linifolia*, with leaves ternate, sessile, ensiform; flowers in a head: it rises eight feet high. 10. *A. barba jovis*, with leaves pinnate, equal, tomentose; flowers in a head Miller. t. 41. f. 2. A shrub ten or twelve feet high, bearing yellow flowers, which appear in June: a native of France, Spain, Portugal, &c. 11. *A. heterophylla*, with leaves pinnate; floral leaves ternate; a small shrub, bearing minute flowers in pairs: a native of Spain and Portugal. 12. *A. visiflora*, with leaves digitate-pinnate; calyces shaggy, viscous; head of five or six flowers, which are yellow: discovered at the Cape of Good Hope by Sparman. 13. *A. cystifoides*, downy-leaved anthyllis, with leaves ternate, unequal; calyx woolly, lateral; a low shrub with yellow flowers, appearing three or four together on the sides of the branches: a native of Spain and the South of France; cultivated by Miller in 1759. 14. *A. germanica*, lavender-leaved anthyllis, with leaves ternate, sub-peduncled; calyces naked; a shrub five or six feet high; flowers yellow, in small clusters at the side of the branches: a native of the most southern parts of Europe. 15. *A. erinacca*, prickly anthyllis, a spinose shrub, with simple leaves; it somewhat resembles gorse or whin: a native of Spain and Portugal; cultivated by Miller in 1759. 16. *A. tragacanthoides*, with leaves pinnate, equal, tomentose; petioles spinose; flowers in racemes. It has a shrubby stem about a span high, and bears purple flowers; a native of Mount Lebanon. 17. *A. indica*, with leaves pinnate, equal, smooth, racemes oblong, sub-terminating; a large shrub, with white flowers: it is a native of the mountains of CochinChina.

Propagation and Culture. Most of the herbaceous species may be propagated by seeds, sown either in the autumn or spring in a bed of light earth, and transplanted at a proper age in the place where they are to remain. The shrubby species are commonly propagated either by seeds or cuttings; if by seeds, they should be sown in the autumn in pots filled with light earth; and placed under a frame in winter, to protect:

protect them from frost. The following spring the plants will rise; and when they are strong enough to be removed, they should be each planted in a small pot filled with light earth, and placed in the shade till they have taken new root; after which, they may be put along with other hardy exotic plants, in a sheltered situation, till October, when they must be removed into shelter. See Miller's Gardener's Dict. by Martyn.

ANTHYLLOIDES. See SALSOLA.

ANTHYPNOICA, in the *Materia Medica*, medicines suited to dispel sleep.

ANTHYPOCHONDRIACA, medicines adapted to the cure of hypochondriasis.

ANTHYPOMOSIA, in *Ancient Writers*, an oath taken by a prosecutor or accuser, declaring that the absence of the party accused is not for any just cause, and therefore demanding that judgment may no longer be delayed on that account.

ANTHYPOPHORA, in *Rhetoric*, a figure whereby we covertly obviate a reason or objection.

In this sense anthypophora stands opposed to *hypophora*, e. gr. if the *HYPOPHORA* be, grammar is very difficult to obtain; the anthypophora may be, grammar is indeed a little difficult to obtain, but then its use is infinite.

ANTI, *Αντι*, is a preposition used in composition with several words in Greek, Latin, English, &c. in different senses. In English, it sometimes signifies before; as in *antichamber*, a place before the chamber. In which case it has the same meaning with the Latin *ante*, *before*.

Sometimes, again, it signifies *contrary*, or *opposite*; and is then derived from *αντι*, *contra*, *against*. In this latter sense, the word makes part of the name of various medicines, to denote some peculiar or specific virtue in them against certain diseases: such, e. gr. are *antivenereals*, *antiscorbutics*, *antinephritics*, &c.

The preposition is frequently, however, omitted on these occasions, without any alteration of the sense; as in *nephritics*, *arthritics*, *asthmatics*, &c.

ANTI, in *Matters of Literature*, is a title given to divers pieces written by way of answer to others, whose names are usually annexed to the *anti*.

See the *Anti* of M. Baillet; and the *Anti-Baillet* of M. Menage: there are also *Anti-Menagiana*, &c. Cæsar the dictator wrote two books by way of answer to what had been objected to him by Cato, which he called *Anti-Catones*; these are mentioned by Juvenal, Cicero, &c. Vives assures us, he had seen Cæsar's *Anti-Catones* in an ancient library.

ANTIAGES, a term used by some writers for the glands and kernels, more commonly called *TONSILS* and *ALMONDS of the ears*.

ANTIADIAPHORISTS, compounded of *αντι*, *contra*, *against*, and *αδιαφορος*, *indifferent*, opposite to the *ADIAPHORISTS*, a name given in the fourteenth century to the rigid Lutherans, who disavowed the episcopal jurisdiction, and many of the church-ceremonies retained by the moderate LUTHERANS.

ANTIANA, *Seczia*, in *Ancient Geography*, a town of Pannonia, placed by M. D'Anville north of Teutoburgium.

ANTIBACCHI, an island of the Red Sea.

ANTIBACCHIUS, in the *Ancient Poetry*, a foot, consisting of three syllables; the two first of which are long, and the third short.

Such are the words *κάνταρέ*, *σῆριζῆ*, *ἔλλῆνες*.

It is so called, as being contrary to the *BACCHIUS*, the first syllable whereof is short, and the two last long. Among the ancients, this foot is also denominated *Palimbacchius*, and

Saturnius; and, by some, *Proponticus*, and *Theffalrus*. Diom. III. p. 475.

ANTIBARBAROUS, a title given to several works levelled against the use of barbarous terms and phrases, chiefly in the Latin tongue.

Eratmus, Nizolius, and Cellarius, have published "*Antibarbara*" Noltemus has given us a Lexicon "*Antibarbarum*," consisting of observations made by the grammarians of late ages in relation to the purity and corruption of Latin words. Sixt. Amama has given an "*Antibarbarus Biblicus*," wherein he pretends to have discovered seven sources of the barbarisms which have been introduced in late ages into the BIBLE. Peter du Moulin used the title "*Antibarbarus*" for a book against the use of an unknown tongue in divine service.

ANTIBARIS, in *Ancient Geography*, a town of Servia, taken by Perigord, general of Manuel, emperor of Constantinople, in 1143.

ANTIBES, in *Geography*, a sea-port town of France, in the department of the Var, and chief place of a canton, in the district of Grasse. The place contains 5,270, and the canton 14,171 inhabitants; the territory includes 165 kilometres and 19 communes. In the first ages of Christianity, it was the see of a bishop, but removed by pope Innocent IV. to Grasse, in 1250, because the piratical Moors of Africa and Spain frequently sacked the town, and plundered the inhabitants. The harbour is small, nor is the trade considerable. N. lat. 43° 5'. E. long. 7° 50'.

ANTIBIBLOS, in the *Civil Law*, an instrument or signature, whereby the defendant owns he has received the libel, or a copy of it, and notes the day whereon he received it. This is usually done on the back of the LIBEL.

ANTICADMIA denotes a species of mineral CADMIA, sometimes also called *pseudo-CADMIA*.

It takes the denomination anticadmia, not as being opposite in quality to the cadmia, but because it is used as a substitute for it.

ANTICACHECTICA, in the *Materia Medica*, medicines adapted to the cure of cachexy.

ANTICARDIUM, in *Anatomy*, &c. that hollow part under the breast, just against the heart, commonly called the pit of the stomach; called also *serobiculus cordis*.

The word is compounded of *αντι*, *contra*, *against*, and *καρδια*, *cor*, *heart*.

ANTICASIUS, in *Ancient Geography*, a mountain opposite to Mount Calius, at no great distance from Antioch.

ANTICATARRHAL, an epithet given to medicines prescribed for catarrhs.

ANTICATEGORIA, in *Oratory*, denotes a recrimination or mutual accusation; where the two parties charge each other with the same crime.

Apollodorus considers the anticategoria as two several causes or actions.

ANTICAUSOTICS, among *Physicians*, denote medicines against burning fevers. In this sense, Juncker has given the description of anticausotic syrup.

ANTICHAMBER; see ANTECHAMBER.

ANTICHORUS, in *Botany*; class *ostandria monogynia*; natural order of *columnifera* and of *tiliaceæ* of Juss. Lin. Gen. Reich n. 508. Juss. 250.

Generic Character. Calyx, perianthium four-leaved, very much expanded; leaflets lanceolate, acuminate, deciduous; corolla, petals four, obovate, obtuse, the length of the calyx; *stamina*, filaments setaceous, erect, shorter than the corolla; antheræ roundish; *pyllium*, germen superior, ovate; style cylindrical; stigma obtuse; *pericarpium*, capsule subulate four

four-celled, four-valved; seeds very many, truncated, in four rows.

Essential generic character. Calyx four-leaved; petals four; capsule superior, four-celled, four-valved; seeds very numerous. There is only one species of this genus, viz. *A. depressus*, which is a small procumbent annual, not exceeding three or four inches long, with alternate branches, bearing yellow flowers: it is a native of Arabia.

ANTICHRESIS, in the *Civil Law*, a covenant or convention, whereby a person borrowing money of another engages or makes over his lands or goods to the creditor, with the use and occupation thereof, for the interest of the money lent. This covenant was allowed of by the Romans, among whom usury was prohibited: it was afterwards called MORT-GAGE, to distinguish it from a simple engagement, where the fruits of the ground were not alienated, which was called *VIT GAGE*.

ANTICHRIST, compounded of *anti*, *contra*, *against*, and *χριστος*, *Christ*, in a general sense, denotes an adversary of Christ, or one who denies that the Messiah is come. In this sense, Jews, infidels, &c. may be said to be *Antichrists*.

The epithet, in the general sense of it, is applicable to any power or persons acting in direct opposition to Christ or his doctrine. Its particular meaning is to be collected from those passages of Scripture in which it occurs. Accordingly it may either signify one who assumes the place and office of Christ, or one who maintains a direct enmity and opposition to him. See bishop Hurd's *Introd. to the study of the Prophecies*, vol. ii. p. 10.

ANTICHRIST is more particularly used for a tyrant who is to reign on earth toward the end of the world: to make the ultimate proof of the elect: and to give a signal instance of the divine vengeance, before the last judgment.

The Bible and the fathers all speak of Antichrist as a single man; though they also assure us, that he is to have divers precursors, or fore-runners. Yet many Protestant writers apply to the Romish church, and the pope, who is at the head of it, the several marks and signatures of Antichrist enumerated in the Apocalypse; which would rather imply Antichrist to be a corrupt society, or a long series of persecuting pontiffs, than a single person: or, rather, a certain power and government, that may be held for many generations, by a number of individuals succeeding one another. The Antichrist mentioned by the apostle John, 1 Ep. ii. 18. and more particularly described in the book of Revelation, seems evidently to be the same with the *Man of sin*. &c. characterised by St. Paul in his second Epistle to the Thessalonians, chap. ii. And the whole description literally applies to the excesses of papal power. Had the right of private judgment, says an excellent writer, been always adopted and maintained. Antichrist could never have been; and when that sacred right comes to be universally asserted, and men follow the voice of their own reason and consciences, Antichrist can be no more.

A late writer (see Kett's *History, the Interpreter of Prophecy*, vol. ii.), after collecting the principal prophecies relating to Antichrist, infers from them, that a power, sometimes represented as the little horn, the man of sin, the Antichrist, the beast, the harlot, the star falling from heaven, the false prophet, the dragon, or as the operation of false teachers, was to be expected to arise in the Christian world to persecute and oppress, and delude the disciples of Christ, corrupt the doctrine of the primitive church, enact new laws, and establish its dominion over the minds of mankind. He then proceeds to shew, from the application of prophecy

to history, and to the remarkable train of events that are now (1799) passing in the world, how exactly popery, Mahometanism, and infidelity correspond with the character given in Scripture of the power of Antichrist, which was to prevail a certain time for the especial trial and punishment of the corrupted church of Christ. Upon this system, the different opinions of the protestants and papists, concerning the power of Antichrist, derived from partial views of the subject, are not wholly incompatible with each other. With respect to the commonly received opinion, that the church of Rome is Antichrist, Mede and Newton, Daubuz and Clarke, Lowman and Hurd, Jurieu, Vitringa, and many other members of the protestant churches, who have written upon the subject, concur in maintaining, that the prophecies of Daniel, St. Paul, and St. John, point directly to this church. This was likewise the opinion of the first reformers; and it was the prevalent opinion of Christians, in the earliest ages, that Antichrist would appear soon after the fall of the Roman empire. Gregory the Great, in the sixth century, applied the prophecies concerning the beast in the Revelation, the man of sin, and the apostacy from the faith mentioned by St. Paul, to him who should presume to claim the title of universal priest, or universal bishop in the Christian church; and yet his immediate successor, Boniface III. received from the tyrant Phocas the precise title which Gregory had thus censured. At the synod of Rheims, held in the tenth century, Arnulphus, bishop of Orleans, appealed to the whole council, whether the bishop of Rome was not the Antichrist of the apostles, "sitting in the temple of God," and perfectly corresponding with the description of him given by St. Paul. In the eleventh century, all the characters of Antichrist seemed to be so united in the person of pope Hildebrand, who took the name of Gregory VII. that Johannes Aventinus, a Romish historian, speaks of it as a subject in which the generality of fair, candid, and ingenious writers agreed, that at that time began the reign of Antichrist. And the Albigenses and Waldenses, who may be called the protestants of the twelfth and thirteenth centuries, expressly asserted in their declarations of faith, that the church of Rome was the whore of Babylon.

The papists imagine they view in the prophetic picture of Antichrist, imperial Rome, elated by her victories, exulting in her sensuality and her spoils, polluted by idolatry, persecuting the people of God, and finally falling like the first Babylon; whilst a new and holy city, represented by their own communion, filled with the spotless votaries of the Christian faith, rises out of its ruins, and the victory of the cross is completed over the temples of paganism. This scheme has had its able advocates, at the head of whom may be placed Bossuet bishop of Meaux, Grotius, and Hammond. Some writers have maintained, that Caligula was Antichrist; and others have asserted the same of Nero. But in order to establish the resemblance, they violate the order of time, disregard the opinions of the primitive Christians, and overlook the appropriate descriptions of the apostles.

It is observed by an ingenious writer, that the term "Antichrist" is used by the apostle John, and by no other sacred writer. He first mentioned it in a period which he called "the last hour;" and this, says he, can admit of no tolerable interpretation, except that of the last period of the Jewish state, just before the destruction of Jerusalem, when the Roman army was actually in Judæa. The apostle refers to some prophecy of Antichrist, who should appear before the dissolution of the Jewish state; "Ye have heard," from the gospels of Matthew, Mark, and Luke, "that Jesus, sitting

with his disciples, of whom I was one, on the mount of Olives, foretold the destruction of Jerusalem, and said, 'When ye shall see Jerusalem compassed with armies, then know that the desolation foretold by Daniel is nigh; and then false Christs shall arise, to seduce, if it were possible, even the elect.' Matt. xxiv. Mark, xiii. Luke, xxi. "Ye have heard that Antichrist shall come. Even now there are many Antichrists; whereby we know, that it is the last time." It was natural to ask, who these Antichrists were, and by what mark they who had not the gift of discerning spirits, as the apostles had, might know them? To this reasonable inquiry, the apostle answers by saying, "Every spirit that confesseth not that Jesus Christ is come in the flesh, is not of God; and this is that spirit of Antichrist, whereof you have heard that it should come, and even now already is it in the world." The sense of the apostle seems to be explained by himself in his second epistle, where he again describes an Antichrist. It was a teacher of a doctrine: it was a doctrine concerning Christ; but it was not the doctrine of Christ, which he himself taught. The doctrine of Christ had in it both the Father and the Son; but the doctrine of Antichrist, by not including both, had not God; that is, had not a right notion of the kingdom of God, either as it had been among the Jews, or as it was to be, after the coming of Jesus in the flesh, among both Jews and Gentiles; one dispensation of truth, virtue, and social love throughout the world. If it be inquired further, whence came these Antichrists? The apostle says, they were none of us, apostles; they went out from us. This must mean, that Antichristian teachers either withdrew from the apostles, or from the doctrine which they taught. It is too evident, that they did not withdraw from their persons; they followed them; they mixed in their churches; they taught there another gospel; they drew the attention of the people from virtue, and fixed it on ceremonies and secular glory. John calls Antichrist a deceiver; and by deceit this party prevailed. John foresaw the whole, and pointed out the place where this iniquity would fix its seat, and for ages try to conceal its ignorance and barbarity under such splendid ensigns of secular glory, as never fail to dazzle, to intoxicate, and to enervate mankind. When Rome boasts of her antiquity, she boasts of a true fact. There is a fine expression of Paul to the Galatians, which teaches readers to consider such Antichrists as abortives, exhibiting a sort of unformed Christianity. Robinson's Hist. of Baptism, p. 625.

After the point had been maturely debated at the council of Gap, held in 1603, a resolution was taken thereupon to insert an article in the confession of faith, whereby the pope is formally declared to be Antichrist. Pope Clement VIII. was stung to the life with this decision; and even king Henry IV. of France was not a little mortified, to be thus declared, as he said, an imp of Antichrist.

F. Malvenda, a Spanish Jesuit, has published a large and learned work, *De Antichristo*, in thirteen books. In the first he relates all the opinions of the fathers with regard to Antichrist. In the second, he speaks of the time when he shall appear; and shews, that all the fathers, who supposed Antichrist to be near at hand, judged the world also was near its period. In the third, he discourses of his origin and nation; and shews, that he is to be a Jew, of the tribe of Dan: this he founds on the authority of the fathers, on that passage in Genesis xlix. *Dan shall be a serpent by the way*, &c. on that of Jeremy viii. 16. where it is said, *The armies of Dan shall devour the earth*; and on the Apocalypse, chap. vii. where St. John, enumerating all the tribes of

Israel, makes no mention of that of Dan. In the fourth and fifth books, he treats of the signs of Antichrist. In the sixth, of his reign and wars. In the seventh, of his vices. In the eighth, of his doctrine and miracles. In the ninth, of his persecutions; and, in the rest, of the coming of Enoch and Elias, the conversion of the Jews, the reign of Jesus Christ, and the death of Antichrist, after his having reigned three years and a half.

Hippolitus, and others, held that the devil himself was the true Antichrist; that he was to be incarnate, and make his appearance in human shape before the consummation of things.

How endless are conjectures! Some of the Jews, we are told, actually took Cromwell for Christ, while some others have laboured to prove him Antichrist himself. Passius assures us he saw a folio Book in the Bodleian library, written on purpose to demonstrate this latter position.

ANTICHRISTIANISM, a state or quality in persons or principles, which denominate them *Antichristian*, or opposite to the kingdom of Christ, and the genius and spirit of his religion.

ANTICHRISTIANS properly denote the followers or worshippers of Antichrist.

ANTICHRISTIANS are more particularly understood of those who set up, or believe in a false Christ, or Messiah.

ANTICHTHON, in its primitive astronomical sense, denotes a kind of globe or earth resembling ours, and like it supposed to be moving round the sun, but invisible to us, because on the opposite side of the sun, that luminary is still exactly interposed between this other earth and ours.

In this sense it is, that Pythagoras and his disciples asserted an antichthon; for which we have the testimonies of Aristotle, Plutarch, &c.

By reason of the perfection of the number ten, they concluded there must be just so many spheres; and as our senses only discover nine, viz. the seven planets, the sphere of the fixed stars, and our earth, they imagined a tenth opposite to ours.

Some of the fathers, who endeavoured to accommodate the doctrine of the heathen philosophers to those of Christianity, assert that this Pythagorean earth is no other than the heavens of the righteous.

Thomasius has a dissertation on the Pythagorean antichthon.

ANTICHTHONES, in *Geography*, are those people who inhabit countries diametrically opposite to each other.

The word is compounded of *επι*, *contra*, and *χθων*, *terra*, *earth*. They are sometimes also called, by Latin writers, *antigenæ*.

In which sense, antichthones amount to much the same with what we more usually call *antipodes*.

ANTICHTHONES is also used, in *Ancient Writers*, to denote the inhabitants of contrary hemispheres.

In which sense antichthones differs from *antocci*, and *antipodes*.

The ancients considered the earth as divided by the equator into two hemispheres, the northern and southern; and all those who inhabited one of those hemispheres, were reputed antichthones to those of the other.

ANTICIMOLIS, or ANTICINOLIS, in *Ancient Geography*, a small island of the Euxine sea, situate opposite and near to the town of Cimolis or Cinolis, on the northern coast of Paphlagonia, to the east of the mouth of the river Æginetis.

ANTICIPATION, from *ante*, *before*, and *capio*, *I take*,
the

the act of preventing, or being before-hand with a person or thing; or of doing a thing before the time.

Anticipating a payment, denotes the discharging it before it falls due.

ANTICIPATION is also used, in a *logical* sense, for a presumption, prejudice, or preconceived opinion.

This is also denominated *preconception*, *presentation*, or *instinct*.

ANTICIPATION, in a *medicinal* sense, is applied to diseases, wherein some of the symptoms which regularly belong to some future period, appear in the beginning; or the word may be understood of those diseases, which having their accesses and remissions at stated hours, gain in point of time, and finish their period sooner than ordinary.

In this sense, *anticipation*, or *anticipated* diseases, by the Greeks called *προληπτικοι*, stand opposite to *υστερητικοι*, which come after the time.

ANTICIPATION, in the *Epicurean Philosophy*, denotes the first idea, or definition of a thing, without which we can neither name, think, doubt, or even inquire, concerning it.

This is otherwise denominated *PRENOTION*.

Anticipation, in this sense, makes the second of Epicurus's criterions of truth.

ANTICIPATION is also used by Shaftsbury, in speaking of painting, to denote the expression of some future action, resolution, or the like.

ANTICIPATION. This word, and *suspension*, in speaking of discords, were first used as technical terms, in *Music*, we believe, by Rameau; and as they are English words as well as French, they may be usefully adopted.

A sound is said to be *anticipated*, when a composer wishes a note to be heard before its time, in plain counterpoint. The same passage will explain both these terms. *Anticipation* in the treble, requires suspension in the base, and *à contra*.

The image shows two staves of music. The top staff is labeled 'Anticipation' and the bottom staff is labeled 'Suspension'. Both staves show a sequence of notes with a final note that is either anticipated or suspended relative to the other staff.

There are several kinds of *anticipation* in music: first, in passing-notes, of which no notice is taken in the base; but this must be done diatonically, not by distant intervals or leaps. Secondly, when the chord is struck on a rest, before the base. Thirdly, in serious and fundamental discords that are to be regularly prepared and resolved, the anticipation in the treble is striking the second before it becomes a third, by the descent of the base. And *anticipation* in the base, or inferior parts, is when the base rises before the treble falls; as from the eighth to the seventh, or tenth, (octave of the third,) to the ninth. The following are examples, in notation, of the several kinds of *anticipation*, in treble and base. See *SUSPENSION*.

Anticipation by Passing-Notes, or which no notice is taken in the Bass.

Passing-Notes in the Bass, unnoticed in the Treble.

Passing-Notes in the Treble.

Passing-Notes in the Bass.

Anticipation. Suspension.

Suspension. Anticipation.

See *PASSING-NOTES*.

ANTICIPATION, in *Rhetoric*, a figure otherwise called PROLEPSIS.

ANTIQU, in *Sculpture* and *Painting*, denotes a fantastical composition of figures of different natures, sexes, &c. as men, beasts, birds, flowers, fishes, and even things merely imaginary, or which have no existence in the nature of things.

Antiqu amounts to much the same thing with what the Italians call *grotesco*, and the French *grotesque*.

ANTICLIMAX, from *anti*, and *κλιμαξ*, *gradation*, in *Rhetoric*, is a figure, whereby the progress of a discourse descends from great to little, and this is sometimes regarded peculiarly agreeable by such a concord between the sense and sound as may contribute to make diminutions appear still more diminutive. Horace affords a striking example.

“Panturient montes, nascitur ridiculus mus.”

ANTICNEMION, from *anti*, and *κνημιον*, *tibia*, the *shin-bone*, in *Anatomy*, denotes the shin, or the fore prominent part of the *tibia*.

This is otherwise called *αεχιβα*, by the Latins *prima tibia*, or *anterior tibia*, and stands opposed to the *fura*, or calf of the leg, sometimes called *ocrea*.

ANTICOLICA, in the *Materia Medica*, medicines suited to cure the colic.

ANTICOLIS, in *Ancient Geography*, a people of interior Lybia, according to Ptolemy.

ANTICONDYLI, a people placed by Stephanus Byz. in Bœotia, supposed by him to be originally Phrygians.

ANTICOSTI, in *Geography*, a barren uninhabited island, in the mouth of the river St. Lawrence. This island has no harbour, but is covered with wood, and excellent cod is found on the shores. N. lat. 49° 10' to 49° 52' W. long. 61° 42' to 64° 4'.

ATICRAGUS, in *Ancient Geography*, a mountain of Lycia.

ANTICTERIC Spirit, in *Pharmacy*, is obtained by distilling one ounce and a half of spirit of turpentine with half a pound of rectified spirit of wine, with a gentle heat; and then separating the oil that swims above in the receiver from the saturated spirit, which is to be preserved for use. Some have imagined, that this combination of oil of turpentine with ardent spirit will furnish a solvent for biliary calculi. Hence the origin of the name; but though this effect may be produced by a copious application to the calculi in a glass vessel, yet it is not to be expected when the spirit reaches them in the course of the circulation.

ANTICUM, in *Architecture*, a porch before a door; also that part of a temple which is called the outer temple, and lies between the body of the temple and the portico. It is sometimes called *ante*.

ANTICUS, *ferratus minor*. See SERRATUS.

ANTICUS, *peroneus*. See PERONEUS.

ANTICUS, *tibialis*. See TIBIALIS.

ANTICYRA, now ASPRO SPITIA, in *Ancient Geography*, a city in Phocis, in a small isthmus which joins a peninsula in the gulf of Corinth. Pausanias supposes, that this was the city called by Homer *Cyparissa*. This place was famous for its hellebore, and was resorted to by sick persons for the benefit of this medicine, which was prepared by an excellent recipe; and hence the adage, “*naviget Anticyram*,” Hor. Pliny relates, that the philosopher Carneades, and Livius Drusus, tribune of the people, availed themselves of this remedy. Pausanias distinguishes two kinds of hellebore, and says that it grew among the rocks which encompassed the city. This place was

adorned with many statues of brass. Above the port was a temple consecrated to Neptune; and this city had gymnasia, baths, and other curiosities, which Pausanias has particularly described. The inhabitants of Anticyra were twice driven from their city; once by Philip, son of Amyntas, and a second time by Titus Flaminius, the Roman general, as a punishment for their attachment to Philip king of Macedonia. Some traces of the buildings, from which it received its present name *Aspro-Spitia*, or white houses, still remain. The port, which is land-locked, is frequented by vessels for corn.

ANTICYRA was also a town of Greece, belonging to Thebais, near the mouth of the Spercheus, at an equal distance from Mount Oeta and the Maliac gulf. Strabo says, that its environs produced better hellebore than that of Anticyra in Phocis, but that the latter was prepared in a better manner.

ANTICYRA was also the name of another town belonging to the Western Locrians.

Some writers have mentioned an island of this name among those of the Ægean sea; but as neither Pliny nor Gellius mention its situation, there was probably no such island.

ANTIDACTYLUS, from *anti*, and *δακτυλος*, *dactyle*, in *Poetry*, a name given by some to a kind of poetical foot, which is the reverse of a dactyl, as consisting of three syllables, whereof the first two are short, and the last long.

ANTIDÆMONICI, from *anti*, and *δαιμων*, *dæmon*, in *Ecclesiastical History*, a sect who denied the existence of devils or evil spirits; also all spectres, incantations, witchcrafts, &c.

ANTIDALEI, in *Ancient Geography*, a people placed by Pliny in Arabia Felix.

ANTIDESMA, from *anti*, and *δεσμος*, *vinculum*, excellent for making ropes, in *Botany*, class *dicoccia pentandria*, Linn. Gen. 1110. Gært. 39. *Gen. character*, male; *calyx* p. five-leaved; *leaflets* oblong, concave, *corolla* none; *stamina*, filaments five, capillary, longer than the calyx, equal; *antheræ* roundish, semibifid. Female, *calyx* as in the male, permanent; *corolla* none; *pisfil* germen superior, ovate; *style* none; *stigmata* five, obtuse; *perianthium* a drupe roundish, one-celled, crowned with the stigmata, and having a furrowed shell; *seed* none. *Species* 1. *A. alexiteria*, a middle-sized tree, with leaves resembling those of the lemon, ever-green flowers in racemes; fruit red and acid like the barberry: it is common in Malabar, where its fruit is esteemed for its pleasant cooling quality; the bark is used for making ropes. 2. *A. acida*, leaves obovate, spikes solitary, and either axillary, or terminating very short lateral branches. It is a native of the East Indies. 3. *A. scandens*, leaves palmate, ferrate; stem climbing without tendrils; filaments of the male flowers short, terminated by erect antheræ, gaping at the tip. A native of China, near Canton.

ANTIDICOMARIANITES, from *αντιδικος*, *adversary*, and *Μαρια*, *Mary*, in *Ecclesiastical History*, a sect of ancient Christians who thought that the Holy Virgin did not preserve a perpetual virginity, but that she had several children by Joseph after our Saviour's birth.

These are otherwise called *anticommaritæ*; and *anticommarites*, and *anticommarianists*; sometimes also *antimariani*. The opinion was grounded on some expressions of our Saviour, wherein he mentions his brothers and his sisters; and on that text of St. Matthew, wherein he says, that Joseph knew not Mary till she brought forth her first-born son.

The anticommarianites were the disciples of Helvidius and Jovinian, who appeared in Rome towards the close of the fourth century.

ANTIDINICA, in the *Materia Medica*, medicines suited to cure giddiness.

ANTIDORON, in *Ecclesiastical Writers*, a name given by the Greeks to the consecrated bread, out of which the middle part, marked with a cross, wherein the consecration resides, being taken away by the priest, the remainder is distributed, after mass, to the poor.

On the sides of the antidoron are impressed the words, *Jesus Christus vicit*. The word is formed from *δορον*, *donum*, a gift, as being given away *loco muneris*, or in charity. The antidoron is also called *panis presanctificatus*.

Some suppose the antidoron to be distributed in lieu of the sacrament, to such as were prevented from attending in person at the celebration; and thence derive the origin of the word, the eucharist being denominated *doron*, *gift*, by way of eminence.

ANTIDOSIS, from *αντι*, and *δίδωμι*, *I give*, in *Antiquity*, denotes an exchange of estates, practised by the Greeks on certain occasions with peculiar ceremonies, and first instituted by Solon.

When a person was nominated to an office, the expence of which he was not able to support, he had recourse to the antidosis, that is, he was to seek some other citizen of better substance than himself, who was free from this and other offices; in which case the former was excused. In case the person thus substituted denied himself to be the richest, they were to exchange estates, after this manner: the doors of their houses were close shut up and sealed, that nothing might be conveyed away; then both took an oath to make a faithful discovery of all their effects, except what lay in the silver mines, which by the law was excused from all imposts: accordingly, within three days, a full discovery and exchange of estates were made. Potter, *Archeol. lib. i. cap. 15*.

ANTIDOTARY is used by some writers for what we more usually call a **DISPENSATORY**.

We have *antidotaries* extant of several authors, as those of Nicolaus, Meuse, Myrepsus, Rhafis, &c.

ANTIDOTE, a remedy taken either to prevent or cure some contagious, malignant, or other dangerous disease. The word is borrowed from *αντι*, *against*, and *δίδωμι*, *I give*, as being something given against poison, either by way of cure or preservative.

ANTIDOTE, is also used to signify a medicine taken to prevent the ill effects of some other; for instance, poison.

In which sense the word has the same signification with alexipharmic, alexiterial, and counterpoison.

The Indian physic consists much in the use of antidotes, *viz.* the root *mungo*, and the viper stone; both held sovereign against the bite of the *cobras de capello*, and other venomous creatures.

ANTIDOTE is also used, in a more general sense, for any compounded medicine.

In which sense, Peter Damian speaks of a person who in his whole life never took an antidote.

ANTIDOTE is also used in a less proper sense for any remedy against any disease, chiefly if it be inveterate, and arise from some ulcer or abscess.

ANTIDOTE is also used for a perpetual form of medicines, otherwise called *opiates*, or more properly **CONFECTIONS**.

ANTIDOTE is also *mystically* applied to the philosopher's stone.

ANTIEN. See **ANCIEN**.

ANTIDYSENTERICA, in the *Materia Medica*, medicines suited to cure dysentery.

ANTIETAM CREEK, in *Geography*, a creek of America in Maryland, rises by several branches in Pennsylvania, and empties into Potowmac river, three miles south-south-east from Sharpsburgh. Elizabeth and Frank's towns stand on this creek; and it has also a number of mills and forges.

ANTIFEBRILIA, in the *Materia Medica*, medicines suited to cure fever.

ANTIGARECA, in *Geography*, an island near the west coast of the peninsula of India, in the tract called "the Pirate's Coast;" 10 leagues north of Gharia.

ANTIGENIDES, in *Biography*, a famous musician of antiquity, was, according to Suidas, a native of Thebes in Bœotia, and the son of Satyrus, a celebrated flute-player, who, as we are informed by Ælian, was so charmed with the lectures of Aristotle, that, upon retiring from them, he said, "If I do not break my flute, I hope I shall have my head cut off." Antigenides, after the example, and by means of the instructions of his father, and also of Philoxenus, became eminent in the same art; and is said to have brought it to a greater degree of perfection than any musician of his time. Suidas says, that he was flute-player in ordinary to Philoxenus, and that he accompanied him in the musical airs which he had set to his own verses. He had also disciples of the first class who were attached to himself; and he was caressed by the most celebrated princes. Pericles invited him to Athens, and committed his nephew, Alcibiades, to his tuition in the art of flute playing. According to Athenæus, Antigenides played upon this instrument at the nuptials of Ipnierates, when that Athenian gentleman espoused the daughter of Cotys, king of Thrace; and Plutarch ascribes to him the power of transporting Alexander to such a degree, by his performance of the Harmatian air, at a banquet, that he seized his arms, and was on the point of attacking his guests. Highly, however, as he was esteemed, he regarded public favour as a precarious possession, and was never elated by the applause of the multitude. He endeavoured to inspire his disciples with the same sentiments; and to this purpose he is said to have consoled an eminent performer, who received little applause from his audience, by saying, "the next time you play, it shall be to me and the Muses." Antigenides was so fully persuaded of the bad taste of the common people, that one day, hearing at a distance a violent burst of applause to a player on the flute, he said, "there must be something very bad in that man's performance, or those people would not be so lavish of their approbation." Antigenides was the author of many novelties on the flute. He increased the number of holes, which extended the compass of the instrument; and, probably rendered its tones more flexible, and capable of greater variety. This musician had great occasion for flutes upon which he could easily express minute intervals and inflexions of sound; since, according to Apuleius, he played upon them in all the modes; the Æolian and the Ionian, the one remarkable for simplicity, and the other for variety; the plaintive Lydian; the Phrygian, consecrated to religious ceremonies; and the Dorian, suitable to warriors. His innovations extended even to the robe of the performer; and he is said to have been the first who appeared in public with delicate Mithian slippers, and a robe of saffron colour, called "croceoton." Plutarch has preserved a bon-mot of Epaminondas, relative to Antigenides. This general, upon being informed, in order to alarm him, that the Athenians had sent troops into the Peloponnesus, equipped entirely with new arms, asked, "whether Antigenides was disturbed when he saw new flutes

States in the hands of "Telis?" who was a bad performer. *Burney's Hist. of Music*, vol. 1. p. 418--422.

ANTIGNANA, in *Geography*, a town of Asia, two miles and a half north-west of Pedena.

ANTIGUCA, or ANTIGONIA, a town of European Turkey, 60 miles south of Jussfa.

ANTIGONE, daughter of Oedipus and Jocasta, is celebrated by the ancient tragedians as a model of filial and fraternal virtue. She accompanied her father in the voluntary exile to which he was condemned, and conducted him in his wanderings after he had lost his sight; and when her brother Polynices was killed in the fatal war of Thebes, she ventured to counteract the inhuman order of Creon, and to pay funeral honours to his exposed corpse. The tyrant commanded her, for this offence, to be starved to death in prison; but she eluded his barbarous sentence, by strangling herself to death; and Hemon, the son of Creon, who was her lover, killed himself upon her lifeless body. *Gen. Biog.*

ANTIGONE, in *Fabulous History*, the daughter of Laomedon, boasted of being more beautiful than Juno; and was transformed by this goddess into a stork.

ANTIGONE, in *Ornithology*, a species of ARDEA. The head is naked, collar papilous, and red; body cinereous; primary quill feathers black. Linnaeus, Gmelin, &c. This is the Indian crane of Latham, and grus orientalis indica of Brisson and Klein. According to Pennant and Latham, it inhabits the Mongolian deserts; from whence it migrates into that part of the Russian dominions which lies beyond Lake Baikal, keeping chiefly within the plains below the rivers Onon and Arun, which is the western extremity of the Gobeon plain.

This bird is larger than the common crane, being in height five feet; the bill is of a greenish yellow, dusky at the tip; irides bright reddish hazel; crown of the head bare and white; on each side of the head, about the ears, is a bare white spot; the rest of the head, and a small part of the neck, covered with a fine red skin, and is also destitute of feathers; the plumage of the bird is ash-colour, lightest about the neck; the quills are black; tail and secondaries ash-colour; those nearest the body are pointed at the ends, longer than the quills, and hang over them; the legs and bare space above the knee are red; the claws white; the middle and outer toe connected by a membrane as far as the first joint. *Lath. Gen. Syn. v. p. 38.*

There is a variety of this species found also in the East Indies, β grus torquata, and grue à collier of Buffon, which is four feet three inches and an half in length; bill long and black; the head and neck, for above half its length, are almost naked, being covered with a reddish-white down; round the middle of the neck is a collar of red; the lower part of the neck, and rest of the body, bluish ash-colour; on the rump is a tuft of stowing feathers, which hang over the ends of the wings and tail, as in the common crane; the tail is black, legs dusky.

ANTIGONEA, in *Ancient Geography*, a city of Macedonia in Mygdonia, founded, according to Stephanus Byz., by Antigonus, the son of Gonatas. This was also the name of a city of Epirus, placed by Steph. Byz. in Chaonia, and by M. d'Anville south-east of Apollonia, and near Celydnus. Another, in Arcadia, was founded on the ruins of the ancient Mantinea, and this name had superseded the other by the adulation of the Greeks, who gave it the name of King Antigonus.

ANTIGONIA, a city of Troas, probably the same with that which was called Alexandria. This name was

also given, according to Strabo, to Nieza, a city of Bithynia. Antigonis was also a city of Syria, upon the Orontes. Diodorus Siculus informs us, that it was built by Antigonus, and that it was 170 stadia in circuit, and that it was designed for the residence of the governors of Egypt and of Syria; but when Seleucia was built, he destroyed Antigonis, and removed the inhabitants to this city. There was also a city of the same name in Asia Minor, in the vicinity of Cyzicus, or rather a fortress, about 50 stadia from the sea. Antigonis was also an island of the Thracian Bosphorus, now called *Isola del principe*. This was also the name of a city of Macedonia, in the Chalcidic territory, in the Thermanic gulf, now the gulf of Thessalonica. It is called Antigneia.

ANTIGONIA, in *Geography*, an island of the Portuguese, in the Æthiopic gulf, near that of St. Thomas, called by them *Iha da principe*.

ANTIGONIS, in *Ancient Geography*, a country of Greece, in Attica.

ANTIGONUS, in *Ancient History and Biography*, one of Alexander's chief generals, was the son of Philip, a Macedonian nobleman. Upon the division of the Macedonian empire, after the death of Alexander, Pamphylia, Lycia, and Phrygia Major were assigned to him; but Perdiccas, who assumed regal power, and who derided the talents and high spirit of Antigonus, determined to take him off; and with this view formed and encouraged various accusations against him. Antigonus, whilst he appeared to submit to Perdiccas, and prepare for his trial, retired with his son Demetrius into Greece, in order to avoid the danger that threatened him, and put himself under the protection of Antipater and Craterus. After the death of Perdiccas, when the provinces were again divided by Antipater, Lycia and Caonia was added to those which Antigonus had originally possessed; and he was appointed to the command of the troops that were destined to act against Eumenes, who was now reputed a public enemy. Eumenes was at first totally routed, through the treachery of Apollonides, general of his horse; and compelled to retire into the castle of Nora, which was situated on an inaccessible rock, and very strongly fortified. The place was invested by Antigonus, but he soon found that it was impossible to reduce it by force; and he therefore contented himself with erecting a strong wall about it, and leaving a sufficient number of troops to guard it, and marched against Alcetas and Attalus, who had raised a considerable force for the succour of Eumenes. Having taken the one and reduced the other to the alternative of surrendering or destroying himself, which latter mode of escape he preferred; their troops were dispersed, and Antigonus had leisure to concert those plans of ambition which he determined to accomplish. Upon receiving the news of the death of Antipater, he resolved to seize Asia. In order to facilitate the execution of his projects, he removed all the governors of provinces who were not in his interest, and endeavoured to secure friends in whose constancy and valour he might confide. With this view, he solicited the concurrence of Eumenes; but this faithful commander having contrived to make his escape from the castle of Nora, assembled an army, and was appointed the royal general in Asia. After several advantages which he gained over the army of Antigonus, he was at length delivered by treachery to his enemy, and put to death. Having thus removed the principal obstacle to his progress, he soon vanquished lesser difficulties; and making himself master of the immense treasures of Susa, he marched forward to Babylon, of which Seleucus was governor. Seleucus escaped, and entered

entered into a league with Ptolemy, Lyfimachus, and Cassander, in order to reduce the power of Antigonus, and secure themselves in their possessions; but in the mean while Antigonus seized the provinces of Syria and Phœnicia. In consequence of a diversion given by Cassander to his arms, Ptolemy recovered Syria, and defeated Demetrius, his son, who had been sent to oppose him. Antigonus, however, who was then in Phrygia, hearing of this disaster, hastened his march over mount Taurus to join his son, and recovered all the provinces which he had lost. Emboldened by his success, he formed a design of subduing the Nabath Arabs, who inhabited the deserts bordering on Judæa. To this service his general Athenæus was appointed; but after having surprised Petra, and possessed himself of its treasures, he was followed by the Arabs; and his whole army, indulging themselves in their imagined security, was cut off, with the exception only of 60 horse, who made their escape. Upon this Antigonus sent his son Demetrius against the Arabs, but he could only succeed so far as to bring them to a kind of composition, with which he was obliged to be satisfied, and to return. He was afterwards sent against Seleucus, who had recovered the province of Babylon, but which he was now obliged again to abandon; and the result of this expedition was, that the confederates made a treaty with Antigonus, and surrendered to him the possession of the whole of Asia, upon condition that the Greek cities should remain free. The treaty was soon broken; and Ptolemy made a descent in Lesser Asia, and some of the islands of the Archipelago, which was at first successful; but he was defeated in a sea-fight by Demetrius, who took the island of Cyprus, and also a great number of prisoners. Such was the effect of these successes on the mind of Antigonus that he assumed the title of king, and conferred the same on his son; and from this period (ante Christ. 306) properly commence his reign in Asia, and also the reigns of Ptolemy in Egypt, and those of the other captains of Alexander in their respective territories. Antigonus now formed the design of driving Ptolemy out of his Egyptian dominions, and for this purpose he prepared a powerful army and fleet, putting himself at the head of the former, and committing the command of the latter to his son Demetrius. This expedition, however, proved unsuccessful, and the design was abandoned. The reduction of Rhodes was the next object to which the attention of Antigonus was directed; but the enterprise was difficult of execution; and Demetrius having made a favourable treaty with the inhabitants, obeyed the summons which he received to assist the Athenians against Cassander. This was followed by a new confederacy on the part of Cassander, Seleucus, and Lyfimachus, against Antigonus and his son; and in order to resist it, they combined their forces, and marched with a powerful army to Phrygia. Here they met Seleucus and Lyfimachus with a force nearly equal; and there ensued the decisive battle of Ipsus, of the event of which Antigonus seemed to have some presentiment; for in the prospect of it he appeared thoughtful and melancholy, and was frequently silent; and, contrary to his usual manner, was slow in his resolutions, consulted much with Demetrius, and as he was reviewing his troops, recommended him to the officers as his successor. His usual confidence, therefore, seems to have forsaken him. On the morning of the battle, as he was rising from a fall with some difficulty, he exclaimed, "Immortal gods! grant me victory, if it be your will; but if not, let me fall in battle, and not survive my fading glory." Whilst the battle was advancing, the king was deserted by a number of traitors, who went over to the enemy; and at length he

was overpowered by a shower of arrows, and thus terminated his life in the 84th year of his age, ante Christ. 301.

The character of Antigonus was that of a soldier of fortune, brave, active, sagacious, of insatiable ambition and avarice, and too heedless of the means by which these passions were gratified. He had also other better qualities; and towards the close of his life he became more mild and tolerant, and endeavoured by good will to retain the subjects whom he had acquired by force. In all private concerns he was strictly just; and to his brother, who wished him to hear in his cabinet a cause in which he was a party, he replied, "No, my dear brother; I will hear it in the open court of justice, because I mean to do justice." Concerning the weight and duties of his office, he frequently uttered philosophical sentiments; and when addressed by Hermodotus, a Greek poet, and one of his flatterers, with the title of a god, and the offspring of the sun, he remarked, that his chamberlain well knew the contrary. At another time, when he was complimented upon his recovery from sickness, he said, "This disease was sent to apprise me, that being a mortal, I should not grasp at any thing above a mortal." As an apology for his extortion, to which he was urged by his exigence, and when he was reminded that Alexander acted differently, "True," said he; "Alexander reaped Asia, and I only glean it." With regard to his domestic conduct, and the harmony with which he lived with his wife and family, Antigonus was peculiarly distinguished: and such was his affectionate confidence in his son Demetrius, that, though he was a youth of splendid talents and considerable ambition, he admitted him as an associate both in his title and government; and Demetrius approved himself not only the dutiful son, but the loyal subject and attached friend. *Anc. Un. Hist. vol. vii. p. 443—479. vol. viii. p. 1—7.*

ANTIGONUS GONATAS, so called from the place of his birth, was the son of Demetrius Poliorcetes, and grandson of the preceding Antigonus, and distinguished by his prudence and mildness more than by his valour. His hereditary claims to the dominions of Demetrius, which comprehended several cities of Greece and the kingdom of Macedon, involved him in various contests, in which he alternately succeeded and was defeated. After the death of Sophenes, and the evacuation of Macedon by the Gauls, he asserted his claim, which he had before done without effect against Ptolemy Ceraunus; but on this occasion he was opposed by Antiochus Soter; the event of the contest was favourable, and he was restored to his possessions. He afterwards established himself by defeating the Gauls, who made an irruption into his kingdom; but was himself expelled by Pyrrhus, king of Epirus. He afterwards recovered a great part of Macedon; and followed Pyrrhus to the neighbourhood of Argos. But the inhabitants wished neither of the contending princes to enter their city. Pyrrhus acquiesced, and at the same time challenged Antigonus to determine the contest by single combat. To this challenge Antigonus replied; "That in making war, he used not only arms, but time; and that if Pyrrhus was weary of life, there were many ways to death, which lay directly before him." Pyrrhus, in a conflict that ensued, was slain: and when the son of Antigonus brought the head of the vanquished prince to his father in triumph, Antigonus thrust his son from him with disdain; "Barbarous wretch!" says he, "dost thou think, that he whose grandfather was thus slain, and whose father died a captive, should rejoice at such a sight?" Then covering the head with his robe, he bedewed it with his tears, and ordered the body to be fought, and burned with all the funeral

ral honours due to a king. When Helenus, the son of Pyrrhus, was brought to him by the same son, who had treated his captive kindly; "Well my son," said Antigonus, "this is better than you did before; however, you have done less than your duty still, because you have suffered a person of his quality to approach me in that thread-bare coat, which is not a disgrace to him, but to our victory." Having entertained Helenus with respect, and comforted him for the loss of his father, he set him at liberty. He also extended his favour to the principal officers in the army of Pyrrhus, and incorporated the troops they commanded in his own. In the closing years of his life and reign he governed his subjects in Macedonia, recovered to him from the Gauls by his son Demetrius, in peace; and enlarged his authority, and conciliated the attachment of the people both to himself and to his descendants. On occasion of the siege of Thebes, in the earlier period of his life, he remonstrated with his father on account of the loss of so many lives for an object so inconsiderable. Nevertheless, he was eminently distinguished by filial affection and respect to his father; for when he was made prisoner by Seleucus, he offered himself as hostage to procure his liberty; and not succeeding, wore deep mourning, and declined participating in any festivities, while his father remained in prison; and on the news of his death, he prepared a fleet, with which he failed to meet his ashes, which he received with the utmost sensibility and respect. One of the least honourable transactions of his life, was his gaining possession of the citadel of Corinth by means of a stratagem, the success of which threw him into a phrenzy of joy; and of the power which he acquired by this event, he made use in augmenting his dominions in Greece, and supporting the petty tyrants against the free states. The Achæans, under their illustrious chief Aratus, vigorously opposed him, and at length recovered Corinth; but Antigonus, indisposed to war, pursued his course of artful and peaceable policy. After a reign of 34 years, and having attained the age of above 80 years, he died, ante Christ. 343, and was succeeded by his son Demetrius II. *Anc. Un. Hist. vol. viii. p. 53—62.*

ANTIGONUS DORON, *q. d. will give*, so called because he was more ready to promise than to perform, succeeded his brother Demetrius II., whose widow he married, in the throne of Macedon; and was distinguished by his great talents in maintaining peace at home, and prosecuting war abroad; by his reputation for justice; by clemency towards his enemies; and by affability and kindness towards his friends. The Achæans invited him into Greece, to aid them in counteracting the power of Cleomenes, king of Sparta, who was himself assisted by the Ætoliens. The citadel of Corinth was put into his hands; and Aratus, who was now become a friend to the Macedonians, was distinguished by his respectful attention. Whilst the greater part of his army was absent, he declined an engagement with Cleomenes; but as soon as his forces arrived, he totally defeated him at Selasia; and by this victory, became master of the hitherto unconquered city of Sparta, which, however, he treated with great lenity, and left free. He then made a precipitate march back into Macedonia, in order to resist the Illyrians, who had, during his absence, invaded that kingdom. In his return, he restored the little republic of Tegea; and arriving at Argos, during the celebration of the Nemæan games, he received many testimonies of respect from the Grecian states. The deliverance of his country cost him his life; for in a battle with the Illyrians, though victory was decisive and complete in favour of the Macedonians, the king fell a sacrifice, not to the sword of the

enemy, but to the exertion he used in straining his voice during the engagement, and to a spitting of blood that was the consequence of this exertion. This soon terminated in his death, ante Christ. 221. Having, died, as he had lived, in the service of his country, he appointed for his successor Philip, his brother's son, to whom he had acted the part of a kind and faithful guardian. *Anc. Un. Hist. vol. viii. p. 63—66.*

ANTIGONUS, king of the Jews, the son of Aristobolus II., was established on the throne of Judæa by the assistance of the Parthians. Soon after his accession, he caused the ears of his uncle Hyrcan, the high priest, to be cut off, that he might be incapacitated for the office; but Herod, who had betrothed, and afterwards married, Mariamne, the grand-daughter of Hyrcan, invaded Jerusalem, and at length, after a siege of six months, took it by storm. With this event, which happened ante Christ. 37, ended the reign of the Asmoneans, which had continued 129 years, from Judas Maccabæus to Antigonus, the last male of that race who bore the regal title. Sosius, governor of Syria, who commanded the Roman forces, and who had assisted Herod on this occasion, having presented a crown of gold to the temple, left Jerusalem, and conveyed Antigonus in chains to Antony; by whom he was, at the earnest solicitations of Herod, put to a shameful death in the third year of his reign. *Anc. Un. Hist. vol. iii. p. 159.*

ANTIGONUS CARYSTIUS, a philosopher and historian, flourished under the Ptolemies Lagus and Philadelphus, about 300 years before Christ. He wrote several lives of philosophers, an heroic poem, entitled, "Antipater," mentioned by Athenæus, and other works; but none are extant, except *Ἱστοριῶν παραβολῶν Συναγωγῆς*, a collection of wonderful stories concerning animals and other natural bodies, compiled from various authors. This work was first published by Xylander, with a Latin version, at Basil, in 568, 8vo.; and reprinted at Leyden, by Menrsius, in 619, 4to. *Fabric. Bib. Græc. lib. iii. c. 27. § 8. tom. ii. 672.*

ANTIGONUS SOCHÆUS, a Jew, was born at Socho, on the borders of Judæa, flourished in the time of Eleazer the high priest, about 300 years before Christ, and was a disciple of Simeon the Just. Offended at the innovations, which were introduced by the patrons of the traditionary institutions, and particularly at the pretensions which were made to meritorious works of supererogation, by which men hoped to establish a title to extraordinary temporal rewards, he strenuously maintained and taught, that men ought to serve God, not like slaves for hire, but from a pure and disinterested principle of virtue. This refined doctrine, opposed by Antigonus merely to the expectation of a temporal recompence for works of religion and charity, was misinterpreted by his followers, and extended to the rewards of a future life; and particularly by Sidæe and Baithofus, two of his disciples, who taught that no future recompence was to be expected, and consequently that there would be no resurrection of the dead. This doctrine they taught to their followers; and hence arose, about 200 years before Christ, the sect of the Baithofæi, or Sadducees. *Brucker, Hist. Philos. by Enfield, vol. ii. p. 172.*

ANTIGRAPHE, from *αἰτι*, and *γραφα*, *I write*, in *Antiquity*, denotes a law suit about kindred, whereby a person claimed relation to such or such a family.

The *antigraphæ* appears to have been the same with *παρακαταβολῆς*.

ANTIGRAPHUS, in *Antiquity*, an officer of Athens, who kept a counterpart of the *apodeicti*, or chief treasurer's accounts,

accounts, to prevent mistakes, and keep them from being falsified. Potter Arch. lib. i. c. 14.

ANTIGRAPHUS is also used, in *Middle Age Writers*, for a secretary or chancellor. He is thus called, according to the old glossarists, on account of his writing answers to the letters sent to his master. The antigraphus is sometimes also called *archigraphus*; and his dignity *antigraphia*, or *archigraphia*. Du-Cange.

ANTIGRAPHUS is also used in Isidorus for one of the notes of sentences, which is placed with a dot to denote a diversity of sense in translations.

ANTIGRAPHUS is also applied, in *Ecclesiastical Writers*, to an ABBREVIATOR of the papal letters. In which sense the word is used by pope Gregory the Great in his Register.

Of late days, the office of *antigraphus* consists in making minutes of bulls from the petitions agreed to by his holiness, and renewing the BULLS after engrossing.

ANTIGUA, called also ANTEGO, in *Geography*, one of the Antilles or Caribbee islands, belonging to Britain, and lying about 20 leagues east from St. Christopher's, and 10 north-east from Montserrat; and being about 50 miles in circumference, is reckoned the largest of all our Leeward islands. It contains 59,838 acres of land, of which about 34,000 are appropriated to the growth of sugar, and pasture annexed; its other principal staples are cotton-wool and tobacco; and in favourable years it furnishes great quantities of provisions. Antigua was one of the Caribbee islands discovered by Colon, in his second voyage, and is said to have been planted by the English in 1632. The first regular grant of it was made by Charles II. about 1663, to William lord Willoughby of Parham. The French were masters of this island for a few years, but in 1668 it was restored to the English by the treaty of Breda. It owes its chief prosperity to the attention of colonel Christopher Codrington, who, in 1674, removed from Barbadoes to Antigua; and having been appointed captain-general and governor of all the Leeward Islands, made this the seat of his government. He applied his knowledge in sugar-planting with such good effect and success, that others, animated by his example, and assisted by his advice and encouragement, adventured in the same line of cultivation. The climate of Antigua is hotter than that of Barbadoes, and so subject to hurricanes, that if it were not for the convenience of its situation and harbours, it would probably be uncultivated and desert. Its soil is of two different kinds; the one, a black mould on a substratum of clay, which is naturally rich, and in favourable seasons, when unchecked by the droughts to which the island is subject, very productive. The other is a stiff clay on a substratum of marl; less fertile than the former, and abounding with a kind of grass which is not capable of being eradicated, so that many estates once profitable, are now covered with it, and so impoverished, as to become either pasture land or utterly abandoned. Exclusively of such deserted land, and such part of the island that is altogether unimproveable, the whole of it may be said to be under cultivation. It is not easy to ascertain an average return of the crops; because they vary to such a degree, that the quantity of sugar exported from this island in some years is five times greater than in others. In 1779, were shipped 3,382 hogheads, and 579 tierces, and in 1782 the crop was 15,102 hogheads, and 1,603 tierces. Mr. B. Edwards is of opinion, that the island has progressively decreased both in produce and in white population. It appears from the returns to government in 1774, that the white inhabitants of all ages and sexes were 2,590, and the enslaved negroes 37,808; and 17,000 hogheads of sugar of

16 cwt. are reckoned a good saving crop; which is about a hoghead of sugar per acre for each acre that is cut.

Antigua is divided into six parishes and 11 districts, and contains six towns and villages: *viz.* St. John's, the capital, Parham, Falmouth, Willoughby Bay, Old Road, and James Fort, of which the two first are legal ports of entry. No island in that part of the world can boast of so many excellent harbours; the principal of which are English harbour and St. John's, both well fortified; and at the former, the British government has established a royal navy-yard and arsenal, and conveniences for careening ships of war. The governor of the Leeward Islands is generally stationary at Antigua; in hearing and determining causes from the other islands, he presides alone; but in causes arising in Antigua, he is assisted by his council; and by an act of assembly of this island, confirmed by the crown, the president, and a certain number of the council may determine chancery causes, during the absence of the governor-general. The other courts of this island are a court of king's bench, a court of common pleas, and a court of exchequer. The legislature of Antigua is composed of the commander in chief, a council of 12 members, and an assembly of 25. This legislature presented the first example of the melioration of the criminal law, respecting negro slaves, by giving the accused party the benefit of a trial by jury; and allowing, in the case of capital conviction, four days between the time of sentence and execution. The military establishment generally consists of two regiments of infantry, and two of foot militia, besides the force raised in the island. The Moravians have been active in their endeavours to enlighten the minds of the negroes, and to lead them into the knowledge of religious truth; and the number of converted negro slaves under the care of the brethren, at the end of the year 1787, was 5,465. St. John's lies in N. lat. 17° 4' 30". W. long. 62° 9'. Edwards's West Indies, vol. i. p. 437—455.

ANTIGUGLER, is a crooked tube of metal, so bent as easily to be introduced into the necks of bottles, and used in decanting liquors, without disturbing them. For this purpose the bottle should be a little inclined, and about half a spoonful of the liquor poured out, so as to admit an equal quantity of air; let one end of the bent tube be stopped with the finger, whilst the other is thrust into the body of the liquor near to the bubble of air already admitted. When the finger is taken off, the bottle will have vent, and the liquor will run out steadily and undisturbed. See SIPHON.

ANTIHECTICS, in the *Materia Medica*, remedies against hectic disorders.

ANTIHECTICUM *Poterii*, in *Pharmacy*, a celebrated chemical preparation, made of equal quantities of tin and chalybeated regulus of antimony, by melting them in a large crucible, and putting to them, by little and little, three times the quantity of nitre: the detonation being over, the whole is to be washed with warm water till no saltness remains.

This was formerly esteemed a very penetrating medicine, making way into the minutest passages, and searching even the nervous cells; whence its use in hectic disorders, from which it derives its name. It was accordingly recommended in heaviness of the head, giddiness, and dimness of sight, from whence proceed apoplexies, and epilepsies; and in all affections and foulnesses of the viscera of the lower belly; and also in the jaundice, dropsies, and all kinds of cachexies. Quincy adds, that there is scarcely a preparation in the chemical pharmacy of greater efficacy in most obstinate chronic distempers. But Neumann observes, that it has no claim to

antihætic virtues, nor indeed to any salutary operation; and it is now generally disregarded. See Neumann's Chem. Works, p. 89, and 138.

It is also called *antimonium diaphoreticum joviæ*. There are divers methods of preparing it, given by Wedelius, Ettmüller, &c. A learned author speaks of it as fatal to consumptive persons. Junker says of it, that in hætic fever, it is rather injurious than salutary. Gmelin's Apparatus Medic. vol. i. p. 235.

ANTILOGOMENA, in *Scripture Criticism*, an expression denoting doubtful, but acknowledged by most to be genuine, one of the three classes into which Eusebius has distributed the books of the New Testament; the other two are homologoumena, i. e. of undoubted authority, and notha or spurious. To this class he refers the epistles ascribed to James and Jude, the second of Peter, with the second and third of John, whether they were written by the evangelist, or by another person of the same name. He is of opinion that these books may be received as genuine productions of the Apostolic age, even if they were not written by the evangelists. Euseb. Eccl. Hist. lib. iii. c. 2.

ANTILEXIS, from ἀντιλεγω, *I contradict*, in *Antiquity*, denotes a new trial granted in the Athenian judicatories, where judgment had before passed against a party for non-appearance.

ANTILIBANUS, in *Ancient Geography*, a chain of mountains in Cælo-Syria, which ran parallel to the other chain denominated Libanus, and both extended from south to north. Antilibanus was to the east, and commenced nearly to the north of Upper Galilee, from which it was separated by mount Hermon, and reached almost to Heliopolis, where it terminated; and thus a distinction is established between Libanus and Antilibanus, though the scriptures call them both by the same common name, Lebanon. The long valley that was situated between these two chains of mountains was called Cælo-Syria. These mountains are now inhabited by those semi-christians called Druses. The Jordan has its source in these mountains.

ANTILLARUM, in *Conchology*, a species of NERITA, very frequent on the shores of the Antilles islands. The shell is sub-globose and black; within white, grooved, and striated; vertex obtuse; and both pillar and outer lip rugose and denticulated. Gmelin.

ANTILLARUM, in *Ornithology*, a species of FALCO, described in L'Histoire des Antilles, tom. ii. p. 252, under the name of Mansfenny, after Buffon; and likewise called le faucon des Antilles by Brisson, Orn. i. p. 361. This is the falco Antillarum of Gmelin, who says it is brown, crown black, and belly white; and Mansfenny of Latham, who characterises it specifically as having the body totally brown. This bird has the shape and plumage of an eagle, but is smaller, being not much bigger than a falcon, and has legs and claws double the size in proportion to those of the falcon tribe. It is found in the Antilles or Caribbee islands, and feeds on small birds, snakes, lizards, &c.

ANTILLES, in *Geography*, a denomination differently applied by various geographers. The term is applied by Hoffman (Lexic. Univ.), to the Windward or Charibbæan islands only; and he says, "dicuntur Antilæ Americæ quasi ante insulas Americæ, nempe ante majores insulas sinûs Mexicanî". Rochfort and Du Tertre explain the word nearly in the same manner; whilst M. D'Anville applies the name to those islands only which are *anti-insula*, or more immediately opposed to, or situated against the continent. Thus he terms Cuba, Hispaniola, Jamaica, and Porto-Rico, the *Great Antiles*; and the small islands of Aruba, Curaçoa, Bonair, and Margarita, and some others near the coast of Caraccas on the southern peninsula, the *les*; altogether ex-

cluding the Charibbæan islands. The Spanish historians plainly prove, that the word *Antilia* was applied to Hispaniola and Cuba, before the discovery either of the Windward islands, or any part of the American continent. This appears from a passage in the first book of the first decad of Peter Martyr, bearing date from the court of Spain, Nov. 1493, eight months only after Columbus's return from his first expedition: "Ophiram insulam sese reperisse refert, sed cosmographorum tractu diligenter considerato, *Antilia* insulæ sunt illæ et adjacentes aliæ; hanc Hispaniolam appellavit, &c." The cluster of islands, denominated the Antilles, is usually divided into Great and Small. They lie from 18 to 24 degrees of N. lat. and are by many geographers distinguished into Windward and Leeward islands; and they lie in the form of a bow, stretching from the coast of Florida north to that of Brazil south. The Greater Antilles have usually been made to comprehend Cuba, Hispaniola, Jamaica, and Porto-Rico; and the Les to include Aruba, Curaçoa, Bonair, Margarita, and some others near the coast of Terra Firma. See each under its proper head. See also CARIBBEES.

If we examine, says M. Buffon, the position of the Antilles, beginning with the island of Trinidad, which is the southernmost, it is impossible to doubt but that Trinidad, Tobago, the Grenades, St. Vincent, Martinico, Marigalante, Antigua, Barbadoes, and all the adjacent isles, once formed a chain of mountains, which extended from south to north, like Newfoundland, and the country of the Esquimaux. The direction also of the Antilles from east to west, if we begin with Barbadoes, and pass on to St. Bartholomew, Porto-Rico, St. Domingo, and Cuba, is nearly the same with the coasts of Cape Briton, Arcadia, and New England. All these islands lie so contiguous, that they may be regarded as a continued belt of land, and as the most elevated parts of a country now occupied by the sea. These islands, therefore, he considers as relics of ancient continents, that seemed to unite the old continent with America. Buffon's Works, by Smellie, vol. i. p. 316., vol. ix. p. 192.

ANTILLON, in *Geography*, a town of Spain, in Navarre, five leagues from Balbatro.

ANTILOCHUS, in *Entomology*, a species of PAPILIO that inhabits North America. The wings are tailed, and yellow both above and beneath, with black bands and margin; tail white, and as long as the wings. Linnæus, Fabricius, &c. This is *papilio caudatis maximus striis umbrisque nigris* of Pevier mus. p. 50. n. 505.

ANTILOGARITHM, the COMPLEMENT of the LOGARITHM of a sine, tangent, or secant; and it is found by beginning at the left hand, and subtracting each figure from 9, and the last figure from 10.

ANTILOGY, ἀντιλογία, q. d. *contrary saying*, a contradiction between two expressions or passages in an author.

Tirinus has published a large index of the seeming *antilogies* each other, but which are all explained and reconciled by him, in his comments on the Bible. Dom. Magri, a Maltese of the Oratory in Italy, has attempted the like; but he has done little more than rehearse what occurs of that kind in the principal commentators.

ANTILOIMICA, in the *Materia Medica*, medicines which preserve against the plague.

ANTILOPE, in *Entomology*, a species of LUCANUS that inhabits Africa, and is described in the Stockh. Transf. 1787. The jaws are exerted, and bimarginated on the interior side; upper margin two-toothed, lower margin five-toothed. Swederus, Gmelin: found in Sierra Leona; it is brown, and rather smooth.

ANTILOPE, in *Zoology*, See ANTELOPE.

ANTILUTHERANS, in *Ecclesiastical History*, a sect or party among the ancient reformers, who maintained opinions, chiefly in relation to the eucharist, different from those of Luther.

Such were Carolostadius and his followers, called also *Sacramentarians*; and those of Zuinglius, denominated *Zuinglians*.

The sect of Antilutherans, at first confined within narrow bounds, in a few years time subdivided into six or seven inferior sects; and ere long into an infinite number, more variously denominated.

ANTILYSSUS *pulvis*, in *Medicine*, is composed of equal parts of the LICHEN cinereus terrestris, & piper niger. It is reckoned useful in preventing the RABIES canina. Phil. Trans. N^o 448.

The pulvis antilyssus of Hill, composed of half a scruple of alum, half an ounce of chalk, three drams of bole-armoniac, one dram of the root of helenium, and six drops of oil of aniseed, is commended by Heysham for preventing hydrophobia. Med. and Philos. Com. Edinb. vol. i. p. i. Lond. 1777-8.

ANTIMACHUS, in *Biography*, a name applied to three Greek poets, of whom the most celebrated was the son of Hipparchus, a native either of Claros or the neighbouring Colophon, who flourished in the 93d Olympiad, about 408 years before Christ. He was reckoned one of the six most famous Greek poets; and he is ranked by Quintilian next to Homer, at a great distance, in heroic poetry. His great work was a "Thebaid," or an epic poem on the war of Thebes. It is said that it consisted, before the seven chiefs were brought to the siege, of 24 books; and at a public recital of his piece, all his auditors, except one, deserted him: but this one was Plato; and Antimachus declared, that he would read on, as Plato alone was equal to the whole audience. When his fame was almost forgotten, the emperor Adrian endeavoured to revive it, and to give him the priority to Homer; but a Roman emperor could not do this. Antimachus wrote a poem to Lyde, supposed to be either his wife or his mistress, the celebrity of which may be inferred from the mention of it by Ovid:

"Nec tantum Clario Lyde dilecta poetæ."

"More lov'd than Lyde by the Clarian bard."

Nothing of this writer has reached modern times. Vossius, Gen. Biog.

ANTIMACHUS, in *Entomology*, a species of PAPILO that inhabits Africa. The wings are indented, long, and black; interior pair spotted with rufous; disk of the posterior pair rufous, radiated, and marked with black spots. Fabricius, &c.

ANTIMACO, MARK ANTONY, in *Biography*, a learned Italian, was born at Mantua about the year 1473. He spent five years at Greece in the study of the Greek language; and on his return opened a school at Mantua for the study of this language and of polite literature, which became famous. He pursued the same employment at Ferrara, where he died in 1532. Antimaco translated several pieces from the Greek, which were printed at Basil in 1540, together with an oration in praise of Grecian literature. He also wrote Latin poems. Tiraboschi, Gen. Biog.

ANTIMENSIVM, a kind of consecrated table-cloth, occasionally used in the Greek church, in places where there is no proper altar.

F. Goar observes, that in regard the Greeks had but few consecrated churches, and that consecrated altars are not things easy to be removed; that church has, for many ages, made use of certain consecrated stuffs, or linens, called antimensia, to serve the purposes thereof.

ANTIMENSIVM, in the *Greek Church*, answers to the *altare portabile*, or portable altar, in the Latin church. They are both only of late invention, though Habertus would have them as old as St. Basil. But Durant and Bona do not pretend to find them in any author before the time of Gregory and Charlemagne.

ANTIMENSIA is also applied to other tables, used in offices of religion, besides those whereon the eucharist is administered: such, e. gr. are those whereon the host is exposed, &c. The origin of the antimensia is described by Meuschen: when the bishop had consecrated a church, the cloth which had been spread on the ground, and over the communion-table, was torn in pieces, and distributed among the priests, who carried each a fragment away, to serve to cover their tables in their churches and chapels. Not that it was necessary that such cloths should be laid on all tables, but only on those which either were not consecrated, or at least whose consecration was doubted of.

ANTIMENSIUS, an ancient officer in the Greek church, whose business it was to introduce and place the communicants at the eucharist.

Some have imagined that he had the care of the *antimensia*. But this rather belonged to the office of great *scenophylax*. He is otherwise called chief of the *antimensii*.

ANTIMERIA, from *αντι*, and *μερος*, a part, in *Grammar*, a figure whereby one part of speech is used for another: e. gr. *velle suum cuique est*; for *voluntas sui cuique est*; also *populus late rex* for *populus late regnans*.

ANTIMERIA, in a more restrained sense, is a figure whereby the noun is repeated instead of the pronoun.

The antimeria is frequent in the Hebrew, and is sometimes retained in our version of the Old Testament; accordingly, e. gr. *Hear my voice, ye wives of Lamech, for my wives*. Gen. ch. iv. ver. 23.

ANTIMETABOLE, in *Rhetoric*, a figure which sets two things in opposition to each other.

The word is compounded of *αντι*, against, and *μεταβολη*, from *μεταβαλλω*, I shift, or transfer; i. e. a shifting, or setting two things over against each other.

This figure is twice exemplified in an apophthegm of Musonius; which, on account of its excellence, is called *aureum monitum*, the golden maxim or precept:

Ἐάν τι πράξης καλὸν μετὰ πόνου, ὃ μὲν πόνος ἄρχεται, τὸ δὲ καλὸν μένει, Ἐάν τι ποιήσης αἰσχερὸν μετὰ ἡδονῆς, τὸ μὲν ἡδὴ ἀρχεται, τὸ δὲ αἰσχερὸν μένει.

In English thus:

"Allowing the performance of an honourable action to be attended with labour; the labour is soon over, but the honour immortal: whereas, should even pleasure wait on the commission of what is dishonourable, the pleasure is soon gone, and the dishonour eternal."

ANTIMETATHESIS, from *αντι*, and *μετατιθημι*, I transfer, in *Rhetoric*, is the inversion of the parts or members of an ANTITHESIS. Such is that of Cicero, in Verrem, lib. iv. cap. 52. "Compare this peace with that war; the arrival of this governor with the victory of that general; his profligate troops with the invincible army of the other; the luxury of the former with the temperance of the latter: you will say, that Syracuse was founded by him who took it; and taken by him, who held it when founded."

ANTIMILO, in *Geography*, a small desert island of the Archipelago, a few miles north-west of Milo, and like it appearing volcanic.

ANTIMISIUM, in *Antiquity*, a table placed before the Roman tribunal or judgment-seat.

What relation this has to the *antimensia* in the Greek church

church, does not appear. Some writers confound them together as the same thing.

ANTIMONARCHICAL, from *αντι* and *μοναρχικος*, *μονος*, alone, and *αρχη*, dominion, something that opposes or stands against monarchy or kingly government.

Antimonarchical is frequently used in the sense of republican.

ANTIMONARCHIST, a person who maintains antimonalarchical principles.

Buchanan, Milton, Hottoman, Languet, Ludlow, Sidney, and others, are celebrated antimonalarchists.

ANTIMONARCHOMACHI, from *αντιμοναρχος*, and *μαχη*, contest: *antimonarchomachist*, is used by some political writers to denote maintainers of monarchical or absolute power vested by divine right in the persons of princes. In which sense, *antimonarchomachi* stand opposed to *monarchomachi*.

King James the First, Salmasius, Peter du Moulin, bishop Bramhall, Albericus Gentilis, Ziegler, William and George Barclay, Bochart, &c. have distinguished themselves in the class of monarchomachists. Acker has treated professedly of the monarchomachists and antimonalarchomachists.

ANTIMONIALS, in *Medicine*, denote preparations of antimony, or remedies whereof antimony is the basis or principal ingredient.

Antimonials are chiefly of an emetic tendency; though they may be so qualified as to become either cathartic or diaphoretic, or even only alterative. See *WARD'S Pill*.

An antimonial cup, made either of glass of antimony, or of antimony prepared of salt-petre, though a substance indissoluble by the stomach, will give a strong cathartic or emetic quality to any liquor poured into it, without any diminution of its own weight.

ANTIMONIATED, something tinged with the qualities, or resembling the appearances of antimony.

Dr. Woodward speaks of a kind of striated, or antimoniated lead ore.

ANTIMONY, *Στιβιον*, *Στιβιον*, *στυβιον*, Gr. *Stibium* *Furbason*, Lat. *Spießglas*, *Spießglanz*, Germ. *Spießglas*, Swed. *Spießglas*, Dan. *Pisgotz*, Hung. *Antimoine*, Fr. *Antimonio*, Ital. *Antimonia*, Russ. *Protus*, *leo ruber*, *plumbum nigrum*, *balneum regis*, *lupus metallorum*, Alchem.

Antimony is a brittle metal, of a brilliant white colour; fusible at a moderate red heat; and at a higher temperature, with access of air, it exhales a white inodorous vapour. It is soluble in nitro-muriatic acid, and precipitable from its solution of a white colour by distilled water, and of a deep brick-red by sulphuret of ammonia (volatile liver of sulphur.)

§ I. Ores of Antimony.

The antimonial ores have not as yet been analysed with sufficient accuracy to clear up all doubts as to the nature of their contents; an arrangement of them must, therefore, as yet principally depend on their external characters. We shall follow the example of Weidenmann, Emmerling, &c. in dividing them into several species, though probably the whole may be reduced to the native, the sulphurated, and the oxydated.

Sp. I. Native antimony. *Gediegen Spießglas*, Germ. *Antimonium nativum*, Werner. *Antimoine natif*, & *A. blanche ou arsenicale*, Delisle, Haüy, and Born.

Has a light tin-white colour, with an occasional shade of yellow. Occurs massive, disseminated, or kidney-shaped. Is internally of a brilliant metallic lustre. Its fracture is either striat or curved foliated. The fragments are usually

large or small grained; seldom conchoidal. It is soft, approaching to half hard, and of considerable specific gravity.

It melts with ease on charcoal before the blowpipe, exhaling a white arsenical fume, and readily amalgamates with mercury.

By the analysis of Mongez the younger, it appears to be a native alloy of antimony and arsenic, in the proportion of about 96 of the former to 4 of the latter.

Native antimony is a mineral of very rare occurrence; it was first found in 1748, by Schwab, in the silver mines of Sahla in Sweden, with a gangue of calcareous spar; and has since been detected by Sage imbedded in quartz in the mines of Allemont in Dauphiné.

Sp. II. Sulphurated A.—Grey antimonial ore. *Graues Spießglaserz*, Germ. *Mine d'Antimoine gris ou sulfureuse*, Delisle. *Antimoine sulfuré*, Haüy.

Of this ore there are three varieties, the compact, foliated, and striated.

Var. 1. Compact. *Dichtes graues Spießglaserz*, Germ. *Antimonium mineralizatum griseum densum*, Werner.

The colour of this is lead grey, passing into steel-grey, and tarnishes blue or purple on exposure to the air. It occurs massive or disseminated. Is of a metallic lustre, shining or little shining. Its fracture is small-grained uneven. It flies, when broken, into irregular blunt-cornered fragments. Is soft, gives a bright metallic streak, and is of considerable specific gravity.

It melts with great ease before the blowpipe, and burns with a blue flame, exhaling a copious white sulphurous vapour.

It is the scarcest of the sulphurated antimonial ores, and is found principally with quartz and spathose iron ore at Braunndorf in Saxony, Goldkronach in Bayreuth, Auvergne in France, and Majurka in Hungary.

Var. 2. Foliated. *Blättriges graues Spießglaserz*, Germ. *Antim. mineraliz. griseum lamellosum*, Werner.

This differs from the former variety in the following particulars. Colour, light steel-grey. Fracture fine grained foliated, sp. gr. 4. 36. Occurs in quartz at Braunndorf, and at Nagyag in Hungary.

Var. 3. Striated. *Strahliges graues Spießglaserz*, Germ. *Antim. mineraliz. grif. radiatum*, Werner.

Its colour is light steel-grey, passing into a blackish grey, azure blue, golden yellow, and other splendid iridescent tints. It occurs disseminated, or in glandular mamillated and stalactitic masses or crystallized. The primitive form of its crystals has not yet been ascertained. Haüy has shewn that they are most easily and neatly divisible in one direction only, parallel to their axes; other natural joints are, however, discernible by the varying reflection of light from these surfaces when held before a candle. The only crystalline form that has hitherto been determined, is a compressed hexahedral prism, terminated by obtuse tetrahedral pyramids with trapezoidal surfaces (*antimoine sulfuré sexoedronal* of Haüy). See crystallographical plates, fig. 206. Incidence of *n* on *s* 134°; of *l* on *l'* 106° 30'; of *l* on *s* 146°. Born also mentions specimens from Hungary and Norway of truncated tetrahedral prisms. The surface of the crystals is generally marked longitudinally, with delicate striæ, and possesses much lustre. The internal lustre both of the amorphous and crystallized kinds is metallic and bright, or little shining. Its fracture is striated either broad or narrow, radiating, diverging, or implicated. When broken, it flies into irregular prismatic, or long granular fragments. Is soft and brittle. Specific gravity from 4.13. to 4.51. Its component parts, according to Bergman, are,

74 antimony,
26 sulphur.

100

The Hungarian antimony also contains a small variable proportion of gold.

This is the commonest of all the antimonial ores: it is procured at Kremnitz and Tefobanya in Hungary, at Draviza in the Banat, Braunsdorf in Saxony, the Black Forest in Swabia, Pereta in Tuscany, Lubillac in Auvergne, and Corawall in England; also in Spain, Mexico, and Siberia. The splendid iridescent specimens come principally from Hungary.

Sulphurated antimony is sometimes confounded with oxyd of manganese; it may, however, be easily distinguished by the great ease with which it is fusible even in the flame of a common candle: it differs also from native antimony in exhaling, when heated, a sulphureous, and not an arsenical odour; in being of a darker colour, and leaving a dark grey trace when rubbed on paper.

It is found, for the most part, in primitive mountains, in micaceous schistus, and clay porphyry, mixed with pyrites and oxyds of iron: the gangue is sulphated barytes in Hungary, but elsewhere, for the most part, quartz; also, though rarely, chalcedony fluor and calcareous spar.

Sp. III. Plumose antimony. *Federerz, Silber Federerz*, Germ. *Mine d'argent grise antimoniale*, Delisle. *Antimoine sulphuré argentifere*, Haüy. *Antimonium plumosum mineralizatum argentiferum*, Born. *Antimonium mineralizat. griseum plumosum*, Werner.

The colour of plumose antimony is steel-grey, passing into greyish black, lead, or smoky grey: by exposure to the air, it tarnishes to an iridescent blue or yellow. It occurs in slender minute capillary crystals investing the surface of quartz and other minerals with a delicate brittle down or wool: the crystals are sometimes scarcely visible to the naked eye, and so implicated with each other, as to appear like an amorphous crust. According to Delisle, the form of the crystals is that of a compressed hexahedral prism, terminated by dihedral summits with pentagonal faces; the longitudinal striæ, however, are generally so strongly marked as to obscure the sides of the prism. Its lustre is semi-metallic, more or less glimmering. The fracture is confusedly fibrous, and the fragments are indeterminate. It is brittle: sp. grav. 3.57. Before the blowpipe it emits a smoke that deposits a white and yellow powder on the charcoal, and the residuum then melts into a black slag. No accurate analysis has yet been made of it; but, according to Bergman, it consists of antimony, iron, arsenic, sulphur, and sometimes silver.

This substance is ranked by many mineralogists among the silver ores; but improperly, as the proportion of silver is casual and variable, and never exceeds $3\frac{1}{2}$ or 4 per cent.

It is met with in the Saxon mines, especially that of Himmelfurt near Freyberg; also at Stöllberg in the Hartz, and Schemnitz in Hungary.

Sp. IV. Red antimony. *Rothes Spießglaserz*, Germ. *Soufre doré natif strié*, et *Kermes mineral natif*, Delisle. *Antimoine hydro-sulfuré*, Haüy. *Antimonium auripigmento mineralizatum*, Cronstedt. *Antimonium mineralizatum rubrum*, Werner.

The colour of red antimony is a deep crimson approaching to blood red, sometimes, though seldom, clouded with iridescent blue. It occurs generally in minute short hair, or needle-form crystals, radiating or implicated: sometimes also it is found massive or disseminated. Its lustre is vitreous,

little shining. Its fracture is fine, and irregularly diverging fibrous. It is opaque, brittle but somewhat elastic: sp. grav. 4. to 4.7.

Before the blowpipe it melts easily and evaporates, exhaling a slight sulphureous odour.

The only mineral with which it is liable to be confounded is the red silky oxyd of copper: this last, however, is of a brighter colour, and dissolves with effervescence in nitrous acid, giving it a green tinge; the red antimony, on the contrary, is not dissolved, but becomes covered with a whitish crust. No accurate analysis has yet been made of this ore; from its colour it was formerly supposed to contain arsenic and sulphurated antimony: according to Sage, however, it is a native mineral kermes. Thus much is certain, that it is met with in the crevices, and investing the surface of the common sulphurated antimony, and appears to be this in an advanced state of natural decomposition: the amorphous or massive variety is frequently studded with small crystals of native sulphur, in the form of rhomboidal octahedrons.

It is met with at Braunsdorf in Saxony, Malazka and Kremnitz in Hungary, and Allemont in Dauphiné.

Sp. V. White antimony. *Muriated antimony*, Kirwan. *Weißes Spießglaserz, Spießglanzspat*, Germ. *Muriate d'antimoine*, Born. *Antimoine oxydé*, Haüy. *Antimonium mineralizatum album*, Werner.

The colour of white antimony passes from snow-white through greyish and yellowish white into ash grey. It is seldom found massive, often radiating like zeolite, but generally crystallized in small and long quadrilateral prisms or rectangular tables, which are accumulated together in bundles or cells. The surface of the crystals is plain, or longitudinally striated, and bright shining or specular. Internally this mineral is much shining, or shining with a vitreous lustre passing into pearly. Fracture striat foliated. It flies when broken into irregular, not particularly sharp-cornered fragments. Is translucent, soft, brittle, and heavy.

In whole crystals it decrepitates before the blowpipe; but when powdered, it melts quietly and without difficulty, giving out a white smoke, and by degrees totally evaporates. Between two coals it is reducible to the metallic state.

From the analysis of Klaproth, it seems to consist of antimony and muriatic acid; but the acicular variety from Dauphiné afforded Vauquelin,

86 oxyd of antimony,
3 oxyd of iron and oxyd of antimony,
8 silic,
3 loss.

100

This beautiful, but uncommonly rare fossil, was first discovered in 1782, by Mongez the younger, at Allemont in Dauphiné, mixed with native antimony: afterwards, in 1787, by Röslér at Przißram on the surface of galena: it occurs also at Malazka in Hungary, with the red and sulphurated antimony.

Sp. VI. Yellow antimony. *Supposed phosphorated antimony*, Kirwan. *Phosphate d'Antimoine*, Fr. *Gelbes Spießglaserz*, Germ. *Antimonium mineralizatum flavum*, Werner.

The colour of this is orange or wax yellow, or yellowish white, passing into black when tarnished. It occurs in long striated needleform crystals, or quadrilateral tables. It is shining, and when black has a metallic lustre. Is soft, flexible, and heavy.

Before the blowpipe it neither flames nor smokes, but melts easily into a brittle slag, containing a small tin-white bead

A N T I M O N Y.

head of metal. It has not been analysed. This mineral was first discovered by Count Rafumawfky, in a vein of sulphurated antimony at Fincigny in Savoy, and has since been found at Malazka in Hungary.

Sp. VII. Antimonial ochre. *Spießglasker*, Germ. *Antimonium ochraceum*, Werner.

Its colour is blew or lemon yellow, and yellowish grey. Occurs massive, disseminated or incrusting. Is dull; of a fine earthy fracture; soft, brittle, and heavy.

Before the blowpipe it becomes white, volatilizes, but does not melt. It effervesces strongly with borax, and is partially reduced. It has not yet been analysed, but is supposed by Karsten to be an oxyd of antimony.

It is found at Briantbrunn near Freyberg, and in Hungary, mixed with sulphurated and red antimony.

Emmerling, vol. ii. Wiedenman, Handbuch, &c. Lenz, Versuch. &c. vol. ii. Haüy, Traité de Mineralogie, vol. iv. Delisle, Crystallographie, vol. iii. Kirwan's Mineralogy, vol. ii.

§ 2. *Assay and Analysis of Antimonial Ores.*

All the antimonial ores are easily reducible before the blowpipe on charcoal; and by a continuation of the heat, they exhale a dense smok of a white or yellowish colour, with little or no arsenical odour, and deposit yellowish flowers, or white needleform crystals, on the surface of the charcoal: these appearances are, however, liable to considerable modification on account of the variable proportion of lead, arsenic, sulphur, &c. that are usually mixed with the antimony. A more certain, therefore, though not so expeditious a method of ascertaining the presence of this metal, is to reduce 200 grains of the ore to fine powder, and digest it in a moderately diluted nitro-muriatic acid, in which the nitrous is not more than one-third of the muriatic part. The clear liquor, after slow digestion for an hour, is to be decanted and reduced by evaporation to about half its bulk, and then poured into a large quantity of distilled water: a copious white precipitate immediately takes place of antimonial oxyd, which when edulcorated and mixed with an equal weight of crude tartar, is to be put into a small lined crucible fitted with a cover, and by a moderate red heat the oxyd will be reduced into a metallic button.

The analysis of antimonial ores presents no particular difficulties, except such as are common to all minerals in which arsenic enters. The following are the substances which have been found mixed with antimony, *viz.* iron, silver, lead, copper, arsenic, and sulphur; to which must be added, flint and alumine, as composing the stony gangue, which cannot always be entirely separated previous to analysis.

(a) Let 500 grains of the ore be reduced in an agate mortar to an impalpable powder, and afterwards mixed in a flask with 1500 grs. of pure nitrous acid of sp. gr. 1.25, and 1000 grs. of distilled water; digest the mixture at a temperature considerably less than boiling, for an hour, then pour off the clear liquor, and add nitrous acid equal to half the quantity first used; digest this for a few minutes, and add by degrees, during the remainder of the digestion, half as much distilled water as acid; then pour off the clear liquor, and wash the residue with distilled water.

(b) Add together the two nitrous solutions and the washings, and drop in a saturated solution of muriated soda as long as any precipitate takes place, and allow it to stand for a few hours; pour off the liquor, and boil the precipitate in a little distilled water; filter and edulcorate. Add the washings to the liquor.

(c) The precipitate (b), consisting of muriated silver, and probably a little arsenic, being dried in a heat just inferior to its fusion, is to be weighed, and reduced in a small crucible by twice its weight of pearlash: 75 parts of silver denote 100 of muriated silver, and if the produce of metal is less than that obtained by calculation, the deficiency may be let down as arsenic.

(d) The nitrous solution (b), containing a great excess of acid, is to be reduced to only a slight excess by the addition of potash or soda; and is then to be treated with nitrated barytes for sulphuric acid: the sulphat of barytes thus produced, contains the sulphur of the ore oxygenated by the nitrous acid. This being separated, add a saturated solution of sulphated soda, as long as any precipitation takes place. This is sulphated lead.

(e) The residue of solution (d), being evaporated to dryness, is to be mixed with soap, and heated in a subliming flask, the arsenic will thus be obtained in a metallic state.

(f) Upon the insoluble residue (a) digest two or three ounces of nitro-muriatic acid, composed of nitrous acid 1, muriatic acid 5, water 3. By this the antimony, iron, and copper will be dissolved, together with a little alumine and flint. Separate this from the undissolved residue, and pour the liquor into three or four times its quantity of distilled water, and the oxyd of antimony will be precipitated. Separate this by filtration, wash, and add the washings to the other liquor: 130 parts of oxyd of antimony well dried denote 100 of metal.

(g) Evaporate the fluid (f) to a small bulk, and superaturate it with caustic ammoniac, the iron and earths will be precipitated, and the copper will be held in solution, giving it a blue colour. Separate the precipitate by a filter; and add sulphuric acid to the ammoniacal liquor till it becomes acidulous, then precipitate the copper by a bar of clean iron.

(h) The precipitate (g) being digested with a little caustic potash, the flint and alumine will dissolve, leaving the oxyd of iron behind.

(i) The undissolved residue of (f) being dried and weighed, is to be ignited to drive off the sulphur, the quantity of which is denoted by the loss of weight after ignition. What remains is earth and a few atoms of metallic oxyd, which being fused with black flux, will reduce the oxyd, and render the earths soluble in water.

(k) The sulphated lead (d) is to be reduced by fusion with tartar, and the oxyd of antimony also by the same method: being then weighed separately, as much pure lead is to be added as will make the lead twice the weight of the antimony. The metals being melted together are to be divided into two equal parts, and subjected to cupellation; if any silver remains, its amount is to be added to that of (c). Bergman's Ess. Klaproth's Analytical Essays. Kirwan's Mineralog. vol. ii.

§ 3. *Reduction of Antimonial Ores.*

The grey or sulphurated antimony is the only one of this metal that is found in sufficient abundance for the purposes of manufacture, and the treatment that it undergoes is extremely simple. The larger pieces of the earthy or stony matter of the gangue being first picked out, the remainder is coarsely bruised, and subjected to a low red heat in close vessels: the sulphurated metal then melts on account of its very easy fusibility, leaving the impurities behind. This process is usually performed in a crucible, whose bottom, perforated with a number of small holes, is inserted into another

other

other crucible. (See Chemistry, Plate iv.) A. B. *fig. 15*, or connected with the lower crucible by means of a pipe, *fig. 16*. In each apparatus the ore is put into the upper crucible, which serves the purpose of a filter, by detaining the stony impurities, while the melted metal flows into the lower receptacle. *Fig. 17, 18, 19, 20, 21, 22*, are plans and sections of the furnaces generally made use of. This method, however, of extracting the ore is far from being the most economical possible, on account of the length of time necessary to charge a multitude of crucibles, the expence of replacing those that are broken, and the extra quantity of fuel required when the ore is not in immediate contact with the flame. On this account some of the founderies in Hungary and France have altogether discarded the crucibles, and melt the antimony in mass by a reverberatory furnace, taking care to keep the surface of the metal covered with charcoal to prevent oxydation. *Fig. 23 and 24* are a plan and section of such a furnace. The rough ore being placed in the bed A, and covered with charcoal, is gradually brought to a state of fusion; and the plug at B being then withdrawn, the melted metal flows into the receptacle C. *Fig. 25, 26*, represent another kind of furnace for the same purpose made use of at Ramée in La Vendée. The sulphurated antimony thus obtained is remelted, and cast into loaves or cakes, forming the common or crude antimony of the shops.

§ 4. *Regulus of Antimony.*

The sulphurated ore of the preceding section having been long known by the name antimony, the term regulus of antimony was employed to designate the pure metal: in the reformed nomenclature, on the other hand, the former of these substances is called sulphuret of antimony, and the latter simply antimony. This ambiguity it is of consequence to be aware of, and we shall endeavour to avoid it as much as possible by using the term regulus of antimony wherever by so doing the sense may be made clearer.

The substance from which the regulus is prepared, whether in the large way for the purposes of commerce, or in the laboratory, is universally the native sulphuret. This consists of antimony and sulphur in the proportion, according to Bergman, of 74 of the former to 26 of the latter. Numerous methods have been proposed by different chemists for the separation of the metal, all of which may be conveniently arranged under the three following general heads. I. Reduction by roasting. II. Reduction by scorification. III. Reduction by dry parting or precipitation.

I. Reduction by roasting.

The native sulphuret of antimony being previously separated by fusion from all earthy impurities, as described in § 3, is to be pulverized and spread thinly on the floor of a reverberatory furnace or muffle, to be freed from its sulphur by roasting. At the commencement of the process the fire must be managed with particular care, and the temperature ought scarcely to be greater than what is necessary for the fusion of tin, otherwise the antimony will clog, and even melt, so as to require being removed from the fire, and again pulverised: as soon as the fumes of sulphur become visible to the eye, in the form of a light lambent blue flame, it is a proof that the heat is sufficient; and the ore should now be continually stirred with a tobacco-pipe, or any other earthen rod. In a short time the antimony will begin to oxydate, and assume a greyish earthy appearance; the fire may then be raised a little, to hasten the evaporation of the sulphur; and thus the operator may go on gradually increasing the heat as the ore will bear it; and continually

stirring it, so as to expose fresh surfaces to the air. When the ore is moderately red-hot, and ceases to give out a sulphureous vapour (which will not be till after some hours), the roasting is finished. By this means an ash grey oxyd is obtained; still, however, not entirely free from sulphur, weighing from 30 to 36 per cent. less than the original sulphuret.

In order to obtain the regulus from this grey oxyd, the common way is to mix it with half its weight of crude tartar, and expose it in a covered crucible to a full red-heat; the tartar will thus be decomposed, its carbonaceous part serving to deoxygenate the antimonial oxyd; and its alkaline base combining with the sulphur still contained in the ore, forms sulphuret of potash, by which a portion of antimony is held in solution, while the rest of the regulus, by its superior specific gravity, unites into a mass at the bottom of the crucible. The quantity of regulus obtained by this means in the large way, is from 66 to 70 per cent. on the oxyd; but the produce depends essentially on the accuracy with which the roasting has been performed: if much sulphur still remains in the oxyd, a large proportion of the metal will be dissolved in the sulphurated alkaline scoria. Kunkel's method appears to be more economical, and better in every respect: he mixes the roasted oxyd with oil or fat and a little powdered charcoal, puts the mixture into a crucible to melt, and as soon as the regulus begins to shew itself, injects by degrees some powdered nitre, in the proportion of an ounce to a pound of antimony: the matter in thin fusion being poured out, a pure regulus is obtained in much greater quantity than by the common way. Most of the sulphurated ores, as those of lead and copper, are reduced to the metallic state after roasting by a simple carbonaceous addition, by which means the product of metal is greater than if an alkaline flux was made use of, and the whole expence of the flux is saved. Induced, therefore, by these motives and analogies, a series of experiments was undertaken by Haffenratz, Vauquelin, and Buillon la Grange, to obtain the regulus of antimony by cheaper means than the use of tartar or nitre. For this purpose different parcels of the roasted grey oxyd were mixed with charcoal powder, with tallow and with pitch, and exposed in covered crucibles to a reducing heat; being then withdrawn, and the contents of each examined, nothing was found in the crucibles but a little carbonaceous matter, and a few minute globules of antimony, the rest being evaporated. Some grey oxyd was then mixed with, 1. equal parts of lime, alumine, and silix; 2. equal parts of sulphat of barytes, chalk and clay; 3. with common salt; 4. with sulphat of soda; and the materials being strongly heated, they were all found converted into yellow glasses, but not a particle of regulus could be perceived. The above four mixtures, with some charcoal rubbed up into them, were next treated as before: vitreous scoriae were obtained, but no greater quantity of regulus than when charcoal alone was made use of. Lastly, some of the same grey oxyd being fluxed with half its weight of tartar, yielded a perfect button of pure antimony. Hence it appears, that potash, and probably alkalies in general, exert some specific action on antimonial oxyd, which induces it to become much more fixed while converting into regulus, than when mere carbonaceous matter is employed.

II. Reduction by scorification.

This, although the most expensive and inaccurate method of procuring the regulus of antimony, is generally preferred in the laboratory to every other on account of its expedition. For this purpose the antimonial sulphuret is reduced to a fine powder,

powder, and mixed with nitre and tartar; a crucible being then made red hot, successive spoonfuls of the mixture are gradually projected into it till the vessel is nearly filled; being then covered, and a full red heat applied for half an hour, the contents are either poured out into a greased iron cone, or suffered to cool in the crucible; a pure regulus is thus obtained, covered with a mass of saline scorix. In this process the acid of the nitre is decomposed, and is employed in acidifying the sulphur and partly oxydating the antimony, while the carbonaceous matter of the tartar serves to deoxydate the metal, and in some degree also to decompose the sulphuric acid; hence the scorix consist of the potash of the nitre and tartar, partly united with sulphuric acid, forming sulphat of potash, and partly with sulphur, forming sulphuret of potash, which last also holds in solution a considerable proportion of the antimony.

If the quantities of nitre and tartar are large compared with that of the crude antimony, nearly the whole of the metal will be taken up by the scorix. According to Lemery, sixteen ounces of sulphurated antimony, mixed with the same weight of nitre and also of tartar, yielded no more than five ounces and a half of regulus. Whereas sixteen ounces of crude antimony, twelve ounces of tartar, and six ounces of nitre, afforded six ounces and one dram of regulus. The usual proportions are four parts of crude antimony, with three parts of tartar, and one and a half of nitre. Some advise to detonate the nitre and tartar together, before the antimony is added, but this is decidedly a bad way, as the use of the nitre is not to alkalize the tartar, but to oxygenate the sulphur. A greater proportion of regulus than usual would probably be obtained by mixing the antimony and nitre alone, and not adding the tartar till after the detonation had taken place.

III. Reduction by precipitation.

This is effected by fusing the antimonial sulphuret with any other metal whose affinity for sulphur is greater than that of antimony, in which case the sulphur combines with the added metal, while the regulus of antimony collects in a button at the bottom of the crucible. The metals capable of thus decomposing the sulphurated antimony are iron, copper, lead, silver, and tin, whence originated five varieties of antimonial regulus, known among the alchemists by the names of martial, venereal, saturnine, lunar, and jovial. As equal parts of these metals require different quantities of sulphur for their saturation, a greater or less proportion of them is necessary for a given weight of crude antimony: thus two parts of this last substance are decomposed by one part of iron, by two parts of copper, or by four parts of lead.

In order to prepare the martial regulus (for all the others are now become obsolete), a number of formulæ are given by Lemery, Beaumé, and other practical writers, the relative merits of which can only be duly appreciated by a comparison of the quantity and purity of the regulus with the expence of time, of fuel, and of nitre, required in its preparation. The following are those which seem best worth notice:

1. Take eight ounces of horseshoe nails, and heat them nearly to whiteness in a crucible, then add, by degrees, sixteen ounces of coarsely pulverized antimonial sulphuret; cover the crucible and keep up the fire; in a few minutes the mixture will be in perfect fusion, at which time, add little by little, three ounces of nitre, a slight detonation will take place, and the whole will be brought to a state of perfect fusion; then pour it into an iron cone, heated and greased, and strike the sides of it gently as the mass becomes solid to favour the precipitation of the regulus. When cold it

will be found to consist of a button of antimony, weighing about ten ounces, covered with an alkaline ferruginous scorix, from which it is readily separated by a blow with a hammer. This regulus, however, is far from pure, containing both iron and a little sulphur; it is therefore to be remelted, and mixed while in fusion with two ounces of crude antimony and three ounces of nitre; after all detonation has ceased, pour it into an iron cone as before, and separate the regulus from the scorix. Remelt the regulus and project upon it by degrees three ounces of nitre. Separate this regulus from the scorix, and melt it again once more with three ounces of nitre; heat it strongly and rapidly, and pour the whole into a cone; there will be obtained about eight ounces of a beautiful stellated regulus, covered with yellowish white scorix. In this process the whole of the materials employed are eighteen ounces of crude antimony, eight ounces of nails, and twelve ounces of nitre; four separate fusions are required, and the product is eight ounces of regulus.

2. Pulverize and mix together 16 ounces of crude antimony, 12 ounces of tartar, 10 ounces of nitre, and eight ounces of iron filings; project it by degrees into a red hot crucible, a strong detonation will take place, and the mass will enter into fusion; keep it at a full heat for a few minutes, and then pour the whole into an iron cone; when cold, there will be found beneath the scorix a pure stellated martial regulus, weighing about six ounces.

3. Heat in a crucible till they are white hot, five ounces of horseshoe nails, and then add 16 ounces of crude antimony, coarsely pounded; the two will presently melt down together, and as soon as the mass is in very liquid fusion, project at several times one ounce of pulverized nitre; during each projection there will be a detonation, and when the last has ceased, increase the heat for a few minutes, and then take out the crucible and allow it to cool gradually; there will be found at the bottom of the vessel a perfectly pure martial regulus.

In the reduction of antimonial sulphuret by iron, the success of the experiment depends much upon the temperature; a high heat briskly applied, and of short continuance, so as to bring the whole into very liquid fusion, is far preferable to an inferior heat of longer continuance: since the regulus separates more completely from the scorix, and the proportion of metal, lost by evaporation, is not nearly so considerable.

The antimony obtained by roasting or scorification, by proper care, may be rendered absolutely pure; but the martial regulus, though purified so as to exhibit the stellated appearance on its surface, which is usually reckoned characteristic of purity, is, in fact, an alloy of antimony and iron; hence it is harder and more difficultly amalgamable than the former; and when reduced to fine powder, is, according to Lemery, attracted by the magnet.

§ 5. External Characters and Physical Properties of Reguline Antimony.

This metal, when perfectly pure, is of a dusky white colour, between that of tin and iron; it appears to be absolutely destitute of ductility, and may easily be reduced in a mortar to a fine powder; it is moderately hard, and may be cut without much difficulty by a common knife. Its fusibility is not quite so great as that of zinc, since it requires to be made red hot before it flows. Its specific gravity, according to Bergman, is 6.86; but by the later experiments of Brisson, amounts to 6.7021. Its fracture is usually broad foliated, but sometimes the facets are so minute as to give it almost a granular appearance; in general the slower it is cooled, the broader will be the plates of which it

is composed, but this rule is not without its exceptions. Antimony is one of the most easily crystallizable of all metals, and this tendency is shewn in a striking manner by the appearance of a radiated star, or of pinnated leaves, like those of fern, with which the convex surface of a mass of antimony that has been allowed to cool slowly is generally covered. It was this circumstance that induced the alchemists to pay so much attention to antimony; by their heated imaginations every thing singular was considered as a type or mysterious hint, and thus confounding sacred with profane, they denominated this appearance, which in truth is only the result of a confused crystallization, the eastern star that was to conduct the sages (themselves) to the cradle of their king, i. e. to the method of making gold, the king of metals. These rays or branches are merely superficial as Lemery demonstrated, by making transverse sections of various masses of stellated regulus. If a crucible, furnished with a plug at the bottom is filled with melted antimony, and the fluid part allowed to run out by withdrawing the plug as soon as a crust is formed on the surface of the metal, there will be found under the crust various crystalline groups, consisting of cubes, of lengthened rectangular parallelepipeds, or ramifications, made up of small octohedrons implanted in each other, and frequently aggregated into a trihedral pyramid, with furrowed sides. The primitive crystalline form of antimony has hitherto eluded the sagacity of Havy: it is divisible at the same time parallel to the faces of a regular octohedron, and of a rhomboidal dodecahedron.

§ 6. *Oxyds of Antimony.*

The action of air and moisture at the usual temperature upon reguline antimony is scarcely perceptible, as it remains a long time without even tarnishing, and the oxydation is never more than merely superficial. By a low red heat, however, and the contact of air, this metal is gradually converted into a greyish white oxyd, volatile at a higher heat, and capable of being more completely oxygenated. When antimony is brought quickly to a bright red heat, and then exposed to the air, it is rapidly converted into a white oxyd, which being volatile, exhales in the form of a dense smoak from the surface of the melted metal, and condenses in the upper and cooler part of the crucible into beautiful crystalline needles of a snowy or silvery white; which have obtained the name of argentine flowers of antimony, or snow of reguline antimony. As this crystallized oxyd is not easily obtained in a common crucible, we shall mention the method of preparing it as given by Beaumé. "Place a wide cylindrical earthenware tube closed at one end in a wind furnace, so that it shall remain in a slanting direction, with the open end protruding a little way through a hole or door in the side of the furnace; and to prevent the inside of the tube from being too much cooled, an earthenware stopper must be prepared to fit loosely into the open mouth of the tube.—The apparatus being properly put together, light the fire, and when the bottom of the tube is red hot, introduce the antimony in small pieces, and close the mouth of the tube with the stopper. The metal being melted, will begin in a short time to smok, and the crystalline oxyd will be deposited in the upper part of the tube, from which it may be scraped from time to time with a clean iron spoon. The first portions are generally yellowish on account of a small quantity of sulphur contained in the metal; this, however, is soon burnt off, and the succeeding flowers are of a pure brilliant argentine white colour." Although antimony is not combustible at so low a temperature as zinc, yet, at a white heat, with access of air, it burns with a white flame, throwing out copious vapours of white oxyd. Another

pretty experiment on the inflammation of antimony, was discovered accidentally by Cit. Gillet. Place a small piece of antimony on a bit of charcoal, and fuse it by the blowpipe; when it is boiling hot, shake it gently out so that it may fall three or four feet through the air; it presently divides into a few globules, which immediately take fire, and explode when they reach the ground like fireworks.

The crystalline oxyd, like the other white oxyds that we shall have occasion to notice in the next section but one, appears to be a saturated combination of antimony and oxygen in the proportion, according to Thenard, of 80 of the former to 20 of the latter; in many of its properties it resembles the metallic acids; it is soluble, though but sparingly, in water, has a decided taste, forms a crystallizable salt with potash, from which it may be separated by the action of any of the stronger mineral acids. When heated by itself in a porcelain tube, it may be reduced nearly to the metallic state; the first impression of the fire converts it into a yellow oxyd, very easily fusible into glass, and containing 0.19 of oxygen; afterwards, as the heat increases, it assumes a reddish brown tint, and holds only 0.16 of oxygen; at length it arrives at the state of black oxyd, wanting only to be deprived of 0.02 of oxygen, to return to the metallic form. Oxyd of antimony, by hasty fusion in a crucible, is converted into a vitreous mass, which, when transparent, is of a yellowish orange colour, and is called *glass of antimony*; and when opaque, is of a brown colour, and has hence obtained the name of *liver of antimony*. These preparations, however, must not be confounded with the glass and liver of antimony, as procured from the sulphuret of this metal.

§ 7. *Action of Acids on Antimony.*

1. The *sulphuric acid*, when cold, appears to exert no action on antimony; but when boiling hot, it is decomposed by this metal, a copious extrication of sulphureous acid gas takes place, accompanied by violent effervescence; and if the mixture is distilled to dryness in a retort, a small quantity of sulphur sublimes, and a mass of white antimonial oxyd is at the bottom of the vessel. When the process is stopped short of desiccation, there remains in the retort a white bulky, soft, and moist mass, and this, when washed with a little water, occasions a copious deposit of white oxyd, while the clear liquor becomes diluted sulphuric acid, holding in solution a small portion of antimony; a larger quantity of water added to this liquor, precipitates what remains of antimonial oxyd. The action of heat also has the same effect, for while evaporating it becomes turbid without forming crystals; the same takes place on the mixture of any alkaline solution. If the unwashed sulphated oxyd of antimony is mixed with common salt and distilled, the result is oxymuriat, or butter of antimony.

2. *Sulphureous acid*, whether hot or cold, has no effect whatever on reguline antimony; it will, however, decompose most of the acid salts of this metal, especially that formed by muriatic acid. If sulphureous acid is added to a solution of muriated antimony, a white powder is thrown down of an acrid and harsh taste, which appears to be a true insoluble sulphite of antimony, decomposable with extrication of the sulphureous acid by the sulphuric, or by mere heat in close vessels; the residue of this last operation is a reddish brown matter, soluble in fixed alkali, and again precipitable by the muriatic acid in form of kermes or hydrofulphurated oxyd of antimony.

3. *Nitric acid*, especially the yellow, is speedily decomposed on antimony, even in the cold. During the mutual action of these two bodies, a large disengagement of nitrous gas takes place, and the metal is converted into a white oxyd so rapidly, as sometimes to cause actual inflamma-

A N T I M O N Y.

tion. In its eager absorption of oxygen, a great analogy subsists between antimony and tin; for not only the nitric acid, but even the water that is mixed with it, are decomposed by the antimony; the azot of the former, and the hydrogen of the latter of these fluids, combine together during their nascent state, and produce ammonia, which with the undecomposed acid, forms nitrated ammonia, the crystals of which salt, thus unexpectedly occurring, have sometimes been mistaken for nitrat of antimony. If the white oxyd, resulting from this chemical action, is mingled, before it has been washed, with lime or caustic alkali, antimoniocal gas will be disengaged. The greatest part of the antimoniocal oxyd remains uncombined at the bottom of the vessel; a very small quantity, however, is taken up by the supernatant acid; but even this little is precipitated by water, by evaporation, and by mere standing for a few days. The white nitrous oxyd is fully saturated with oxygen, of which it contains, according to Theuars, about 30 per cent. It is considered as one of the most refractory and irreducible of the metallic oxyds, which it certainly is when treated with the common fluxes; but when rubbed with a little regulus of antimony, and heated in a close vessel, it becomes in succession yellow, orange, brown, and then black; containing only about two per cent. of oxygen, as is related of the argentine flowers in the former section.

4. *Muriatic acid*, when assiled by heat, is capable of dissolving a small proportion of antimony; part of this, however, is again deposited in the form of a white oxyd as the liquor cools: by evaporation it may be brought to crystallize in small acicular deliquescent needles. The oxyd of antimony is more easily soluble in muriatic acid than the metal itself, and also in greater proportion: it crystallizes, according to Monnet, in brilliant plates, like the boracic acid, and is decomposable by water.

5. The *oxygenated muriatic acid*, when in the form of gas, exerts a very striking action on reguline antimony: if this metal, previously reduced to a fine powder, is thrown by small quantities at a time into a vial filled with the acid gas, each parcel will be found to take fire, and burn with a white flame, throwing out, at the same time, a number of bright sparks, and thus forming a most beautiful shower of fire. The antimony is converted into a white muriated oxyd. The liquid oxymuriatic acid changes the metal into a powdery oxyd, but holds a very small quantity of it in solution; no doubt on account of the great proportion of water, which even the most concentrated liquid oxymuriatic acid necessarily contains. If a solution of either the muriat or oxymuriat of antimony be gently evaporated nearly to dryness, and afterwards exposed in a retort to a low sand heat, a thick oleaginous liquid will come over, that by cooling concretes into a soft mass, called, from its consistence, by the ancient chemists, *butter of antimony*; the above, however, is not the actual method of preparing this salt in the laboratories; it is more expeditiously made by taking advantage of the superior affinity which antimony has over mercury: for this purpose some reguline antimony is well mixed in a mortar with twice or two and a half times its weight of oxymuriated mercury (corrosive sublimate); during trituration, much heat is extricated, the evidence of a chemical action between the two substances: the mixture being put into a wide necked retort, with a suitable receiver adapted, is exposed in a sand bath to a gentle heat. During the first half hour, a small quantity of a clear liquid passes into the receiver, which is afterwards followed by a thick liquor that concretes by cooling in the receiver, and often in the neck of the retort into a white mass; this is the *butter of antimony*. A moderate fire is

kept up till nothing more comes over, at which time the receiver is unluted, and emptied of its contents; there remains in the retort fluid mercury with some muriated oxyd of antimony. By continuing the distillation at a greater heat, the mercury is volatilized, and collect'd in a liquid state in the receiver. It is to be remarked, however, that there are two objections to this process; the one, that if the mercurial salt is in too great proportion, a little of it will rise with the butter of antimony, and be dissolved in it; the other objection is, that if too little oxymuriat is used, the produce will be much diminished, as a considerable proportion of the antimony will be merely in the state of muriated oxyd. The best way, therefore, of preparing this salt, is to mix the unwashed sulphat of antimony (1. § 7.) with common salt and black manganese, and distil the whole to dryness.

The London Pharmacopœia orders the sublimed muriat to be made thus. Mix together one part of crocus of antimony with two parts of decrepitated salt; put the mass into a glass retort, and add one part of sulphuric acid; then distil, and what comes over is butter of antimony.

Butter of antimony, though solid at the usual temperature of the atmosphere, liquefies at a very gentle heat, and by slow cooling crystallizes in large parallelepipeds. It is intensely caustic, destroying the organization both of animal and vegetable substances; by exposure to the air and light it becomes coloured, and deliquesces into a thick oleaginous fluid. When dropped into distilled water, it is for the most part decomposed, and a copious white precipitate is thrown down, which is little else than a perfect oxyd of antimony. This, after being washed and dried, forms the *powder of ALGAROTH*, or *mercurius vite*. The clear liquor separated from the precipitate still holds a little antimoniocal oxyd in solution, as is obvious from a further precipitation taking place on the addition of an alkali.

Scheele has given the following method of preparing powder of algaroth, in an essay of his on this very subject. To two parts of sulphurated antimony add three of nitre, and detonate the mixture in a hot crucible; pulverise the mass, and stir in one part of this to three of water, with one of sulphuric acid, and one of common salt. Let the whole digest together for twelve hours in a sand bath, and strain it through a cloth; separate the clear liquor, and add to the residue more salt and diluted sulphuric acid, which digest and filter as before. Mix the two liquors together, and pour them into a large quantity of boiling water; a white precipitate immediately takes place, and this, when washed and dried, is the powder of algaroth.

If to any quantity of sublimed muriat of antimony an equal weight of nitric acid is added, the liquor becomes highly coloured, copious orange-coloured fumes are disengaged, and a considerable degree of heat is excited; after a while, a white magma of oxyd is deposited. If before the latter effect takes place, the liquor is evaporated to dryness, a pure white oxyd remains behind; and this being three times more abstracted with fresh nitric acid, and afterwards heated moderately red in a crucible, assumes the appearance of a pulverulent mass, white at the surface, and rose-coloured beneath; this being ground in a mortar, so that the white and coloured parts may be thoroughly mixed, is known in the shops and old pharmacopœias by the name of *bezoar mineral*; and, in fact, is nothing more than a perfect oxyd of antimony, holding, perhaps, a very small portion of the acid.

6. *Nitro-muriatic acid* is the best solvent of reguline antimony; if the acid is made moderately warm, and the metal put in by small pieces at a time, taking care not to add

A N T I M O N Y.

add a second till the first is completely dissolved, it may be thus charged with a considerable proportion of antimony, only a small part of which is deposited by cooling. This, however, like all the preceding antimonial solutions, is almost wholly decomposed by the addition of distilled water. A piece of iron or zinc also causes a precipitation of a black oxyd (§ 6.), almost in the metallic state, which, according to Theuars, when dried at a low temperature, acquires the properties of a pyrophorus, inflaming spontaneously by contact with the air.

7. The *fluoric, boracic, and carbonic* acids, have no action on reguline antimony; they are capable, however, of combining with its oxyds, forming salts, the particular properties of which have not been examined.

8. The action of all the *metallic acids* on antimony, except the arsenic acid, is wholly unknown: and for this see *ARSENIAL of Antimony.*

9. The *vegetable acids* produce no other effect on metallic antimony, except blackening its surface; they dissolve, however, its oxyds without much difficulty, forming salts, a few only of which have been properly examined: these we shall proceed to particularise.

10. The *antimoniated tartar, or emetic tartar*, is the most important of the combinations of antimony with the vegetable acids. It was first prepared by Adrian Mynsicht, in 1631; and from that time to the present, has attracted the notice of chemists and physicians. Bergman, in his admirable essay on Emetic Tartar, was the first who gave any thing like a consistent account of the rationale, and the various chemical affinities concerned in its preparation; and the subject has of late been finally elucidated by the able and sagacious experiments of Theuars.

The tartareous acid, the acidulous tartrate of potash (or cream of tartar), and the tartrate of potash (soluble tartar, or tartarized tartar), are each capable of dissolving and combining with oxyd of antimony; an inquiry, therefore, into the chemical properties of emetic tartar, necessarily includes the consideration of the above different menstrua, and thus renders it a very complicated affair.

Pure tartareous acid and boiling water, digested on any of the oxyds of antimony, except that which is saturated with oxygen, as the diaphoretic antimony, may be made to take up one-third or one-fourth part of its own weight; and the solution, when concentrated by evaporation, and allowed to cool gradually, usually deposits a few crystalline grains, but is for the most part converted into a brownish gelatinous mass, which, at a red heat, is charred, and the antimony contained in it is partly extricated in the form of a white smoke, and partly reduced to metallic grains.

A solution of tartrate of potash, at a boiling temperature, takes up at least as much oxyd of antimony as tartareous acid is capable of dissolving; the liquor becomes slightly alkaline, and upon evaporation, yields a number of crystalline grains.

A solution of tartareous acidulum, or cream of tartar, being boiled with any of the simple oxyds, or sulphurated oxyds of antimony, dissolves a considerable quantity; and by evaporation and cooling, deposits elongated octahedral crystals of emetic tartar.

The taste of this triple salt is slightly harsh and metallic; it reddens vegetable blues; it effloresces in the air, loses its transparency, becomes of a dead white, and is then pulverulent: it requires for its solution about 40 times its weight of boiling water, and nearly twice as much at the common temperature. Sulphuric acid precipitates from it a sulphated oxyd of antimony, leaving the cream of tartar pure; the alkalies, both pure, and carbonated, decompose it in part only, a loose white oxyd being

precipitated by the first, and by the second, a carbonated oxyd, which, in a short time, crystallizes in the form of divergent rays. If either tartareous acid, or tartrate of potash, is added to the solution of emetic tartar previously to pouring in the alkali, there will be no precipitate; for the tartrate of potash produced by the alkaline addition, or already existing in the fluid, immediately dissolves the antimonial oxyd; and for the same reason, a simple solution of emetic tartar cannot be wholly decomposed by any quantity of alkali; and hence probably have arisen the great seeming differences in the proportion of its constituent parts, as the salt has been analysed by means of a pure alkali, a carbonated alkali, or other re-agents. According to Theuars, the crystals of emetic tartar, from whatever antimonial oxyd they are prepared, and whatever has been the proportion of ingredients employed, contain in a given weight precisely the same quantity of antimony, of tartareous acid, of potash, and water; and even the degree of oxydation of the metal is also invariable. His method of analysing this salt, is first to ascertain its water of crystallization, by drying in a heat just not sufficient to decompose it; secondly, to dissolve the emetic tartar, and precipitate the antimony by sulphurated hydrogen; thirdly, to ascertain the tartareous acid by dropping in acetite of lead; fourthly, to determine the quantity of potash by igniting the residue, and extracting the alkali by dilute nitrous acid. By a very careful analysis, conducted in the above manner, he found 100 parts of emetic tartar to contain 38 oxyd of antimony, 34 tartareous acid, 16 potash, and 8 water, besides 4 loss. But the tartareous acidulum, which supplies both the acid and alkali to the emetic tartar, contains 57 tartareous acid, 33 potash, and about 10 water and loss; or 70 tartrate of potash, and 20 tartareous acid in excess. Hence it follows, that there is a greater excess of tartrate of potash in cream of tartar over the acid, than exists in the emetic tartar; and this excess of tartrate of potash is found in the mother water, in which the crystals of the emetic are decomposed; when, therefore, the whole is evaporated to dryness, as is often the case in the preparation of emetic tartar, there is a portion of antimoniated tartrate of potash superadded, which, no doubt, modifies its effect, and produces variations, which are unjustly charged to the emetic tartar. Another objection to evaporating the whole mass to dryness without separating the crystals, is, that the tartrate of lime which exists in a variable proportion in all cream of tartar, according to Vauquelin, is also mingled with the antimonial salt, and weakens its operation. To make, therefore, emetic tartar uniformly of the same strength, select an antimonial oxyd somewhat below the maximum of oxydation, and digest it in a hot saturated solution of cream of tartar, taking care that the oxyd shall be rather more than enough to saturate the salt (if the grey oxyd from the sulphuret of antimony is made use of, or even the common glass of antimony, as these are not already sufficiently oxydated, there will be a decomposition of water, and a small quantity of kermes will be formed); when the liquor refuses to take up any more antimony, filter and evaporate till a pellicle begins to be formed; allow the solution to cool, and select all the octahedral and tetrahedral crystals that are deposited; wash them in cold water, and again dissolve in hot water, and crystallize. For the particular formulae of the different pharmacopœias, see § 12.

11. The only remaining antimonial salts of any consequence, are the oxalat and acetite of antimony; and we are as yet acquainted with very few particulars even concerning these. The oxalat of antimony is easily formed, and concretes into small crystalline grains; these are soluble in wine, giving it an emetic quality; and this preparation has

A N T I M O N Y.

been used by some medical men instead of the common antimonial wine. The acetite of antimony being known before the discovery of emetic tartar, was recommended for the same uses to which the former is now applied, by Angelo Sala. Neither the oxalat, nor the acetite, however, of this metal appear to be possessed of any superiority over the emetic tartar, and are now, we believe, wholly disused.

§ 8. Action of Neutral Salts on Antimony.

Muriat of soda is said to be in part, at least, decomposable by antimony at a red heat; but the experiments on this subject are contradictory, and require to be performed afresh with care and exactness.

Sulphat of potash (and probably all the alkaline sulphats), is decomposed without any difficulty. This was first shewn by Monnet; he fused together in a crucible two parts of sulphated potash, and one of antimony; the metal disappeared, and he obtained a yellow, semi-vitrified mass, intensely caustic, of antimoniated sulphuret of potash; which, when washed with warm water, depolished, by cooling, a hydro-sulphurated oxyd of antimony. The metal, therefore, in this case, became oxydated at the expence of the sulphuric acid; and the sulphuret of potash resulting from this combined with the metallic oxyd, rendering it partly soluble in hot water.

Oxymuriat of potash has a very powerful action on antimony, as it has indeed upon all the easily combustible metals: if equal parts of this salt, and antimony previously reduced to a fine powder, are mixed together, and struck briskly on an anvil, or any suitable hard body, a remarkably loud and vehement detonation takes place: if the mixture, instead of being struck, is poured into sulphuric acid, or rather if the acid is poured upon the powder, a hissing noise is produced, red sparks are emitted, and the metal is converted into an oxyd.

Nitre and antimony, in equal parts, or two parts of the former to one of the latter, being thrown into a red-hot crucible, detonate with a vivid flame, the acid of the nitre is decomposed, and the metal is completely oxygenated. The white mass remaining in the crucible being pulverised and digested in hot water, is separated into two parts, one soluble, and the other insoluble: the latter of these was formerly considered as a pure oxyd of antimony, but Theuars has shewn, that it contains about one-fifth of potash, intimately united with the oxyd, which appears to act the part of an acid: it was formerly known by the name of *reguline diaphoretic antimony*, but appears, in fact, to be a kind of *antimonite of potash*, rendered insoluble by an excess of oxyd; the soluble part differs from the other merely in the proportion of its ingredients, being an *antimoniated potash*, crystallizable and decomposable, with precipitation of its oxyd, by any of the mineral acids. As, however, this is generally prepared from the sulphuret of antimony, we shall refer the reader for further particulars to the next section.

§ 9. Sulphuret of Antimony—Glas of Antimony—Kermes, &c.

1. Sulphuret of antimony may be prepared artificially, by pulverizing a pound of reguline antimony, and mixing with it eighteen ounces of flowers of sulphur; this being put into a crucible, and brought to a low red heat, melts into an uniform mass, of the weight of about two pounds, which, when cold, exhibits a striated appearance, exactly similar to the native grey sulphuret (§ 3.), and is possessed of all the same physical and chemical properties; hence, for cheapness sake, all the preparations from the antimonial sulphuret are made with the native ore, just separated by fusion from the stony and earthy matters that it is mixed with, which is

known in commerce by the name of *crude antimony*, or *antimony of the shops*.

2. If the sulphuret of antimony is exposed to a red heat, with access of air, most of the sulphur is volatilized, and a small but variable proportion of the metal is carried up at the same time: this operation being performed in a melting-pot, surmounted by a series of aludels, the vapour as it rises, is condensed in the form of a light pulverulent substance, called *flowers of antimony*. The flowers, at the beginning of the process, are of a greyish yellow colour, and consist of sulphur, with antimony, either in the metallic state, or at least very little oxydated; the next portions are orange-coloured, and those which rise towards the end of the operation, are almost yellow, and consist of little else than pure sulphur. What remains behind at the bottom of the melting-pot is a greyish ash-coloured oxyd, still holding a little sulphur: among the old chemists it was known by the name of *grey calx of antimony*; by the moderns it is called the *grey sulphurated oxyd of antimony*. It is most commonly prepared by slow roasting of the crude antimony in a flat dish or reverberatory furnace, and the sulphur and metal that are volatilized with it are allowed to escape. See § 4.

3. The grey sulphurated oxyd, when urged by a sufficient degree of heat, forms a transparent glass, possessing, according to circumstances, every shade of colour from light yellow to the deepest hyacinthine red; this is the *glas of antimony*, or, according to the modern nomenclature, the *vitreous sulphurated oxyd of antimony*. In order to prepare this, any quantity of the grey oxyd is put into a crucible, and kept at a full red or low white heat till it enters into perfect fusion; soon after this has taken place, the end of a clean tobacco pipe should be dipped in it; and if the matter that adheres to the pipe is transparent, and may be drawn into a thread like common glass, it has been heated sufficiently: the crucible is then to be removed from the fire, and its contents are to be poured on a compact flat stone or plate of copper. When the glass has become solid, it should be removed into a covered vessel, as it cracks and flies while cooling.

It sometimes happens in making the glass of antimony, that the grey oxyd begins to melt as soon as it is red hot, and continues limpid like water, without acquiring the property of drawing into threads like glass: at other times, on the contrary, even the long continuance of a white heat will do no more than bring it to a pasty consistence. In the former case, the glass is of an unusually deep colour; in the latter of a very light colour. This inequality arises from a difference in the grey oxyd; if it has been too little roasted, it flows with the first impression of the heat, but when more completely oxydated and desulphurated, it proves very refractory: this last, however, may be remedied by throwing in a little crude antimony in powder, which will immediately determine its fusion and vitrification; and in this case there are always found at the bottom of the crucible a few grains of very pure regulus of antimony.

If the previous desulphuration has been very slight, the oxydation also will have proceeded but a little way; and the glass produced, though possessed of a vitreous fracture, is perfectly opaque, and of a dark liver colour, hence it has obtained the name of *liver of antimony*: the same name, however, has been given to a preparation of crude antimony and nitre, which will be mentioned presently.

4. The action of acids upon the sulphuret of antimony is upon the whole so similar to their action on the regulus, as described, § 7, that it will only be necessary to point out the circumstances in which they differ. In general, the metallic part of the sulphuret is more easily dissolved and retained

retained

ANTIMONY.

tained by acids than the mere regulus is, and the sulphur of the compound is not at all or very little acted upon. The sulphuric and nitric acids are decomposed with considerable energy, on pulverized sulphuret of antimony; sulphureous acid in one case, and nitrous gas in the other, being copiously disengaged, the metal is oxydated, and remains intimately mixed, though no longer combined with the sulphur, very little of it being actually dissolved by these acids. The muriatic acid, even when cold, will decompose a large quantity of sulphuret, during which process there is a considerable extrication of sulphurated hydrogen; if the mixture is heated, the whole of the metal enters into solution, leaving the sulphur at the bottom unaltered; a small portion, however, both of the sulphur and metallic oxyd is dissolved in the hydrogen, and escapes in a gaseous form; for Bergman observed, by performing this experiment in a vessel with a long narrow neck, that the sulphurated hydrogen, in its passage through, deposited a little kermes, or hydrofulphurated oxyd of antimony. The best menstruum, however, for crude antimony, is a nitro-muriatic acid, composed of one part nitric, and three parts muriatic acid; the metallic oxyd is entirely taken up, part of the sulphur is carried off by the hydrogen gas, another part is acidified and mixes with the other acids, and the remainder, about 26 per cent. is left at the bottom of the vessel in form of a white powder. In § 7, we have given an account of the original method of preparing the butter of antimony by sublimation of the regulus with corrosive mercurial muriat: the same antimonial salt may be obtained by using sulphuret of antimony, but instead of obtaining the mercury in a metallic state, it is combined with the sulphur of the antimony into a violet-coloured mass, which, at a full red heat sublimes, and is deposited in the upper and cooler part of the vessel, in needle-form crystals of cinnabar, hence called *cinnabar of antimony*.

5. The fixed alkalies are capable by the dry way of combining with sulphurated antimony, forming several important preparations. If 15 ounces of pulverized crude antimony, 12 ounces of decrepitated sea salt, and 3 ounces of tartar, are mixed together, and fused in an earthen crucible, there will be found, on breaking the vessel when cool, that it contains two substances; the upper is of a lighter colour than the other, and consists of the salt with a little sulphur; the inferior substance is very heavy, opaque, of a black colour, and on being broken, exhibits a shining vitreous fracture: it has obtained the name of *medicinal regulus*, though improperly, being a simple alkalized sulphuret of antimony, in which the metal is probably uncombined with oxygen, and nearly saturated with sulphur. A similar preparation to this is the *ruby of antimony*, or *magnesia opalina*, differing, however, in containing less sulphur, and in the metal being perhaps more oxydated. It is prepared by mixing equal parts of muriated soda (sea salt), nitre, and crude antimony, and fusing the whole in a crucible; there is a large quantity of scoria in this as in the former process, and underneath them is a compact vitreous mass transparent in thin shivers, and, if well made, of a deep, somewhat smoky-red colour, and brilliant semi-metallic lustre. Neither of these preparations is deliquescent or soluble in water, on account of the small proportion of alkaline salt that they contain. By increasing, however, the dose of alkali, the mass becomes soluble; thus, if to one part of sulphurated antimony we add two parts of pure dry pearl ash, we obtain by fusion a compact reddish-brown mass of alkaline sulphuret of antimony, and a little of the metal in its pure reguline state is found at the bottom of the crucible. If the whole of the antimony is required to be dissolved in the sulphurated alkali, as is the case in the preparation of kermes, it is requisite to add to the above ingredients about

one-twentieth of their weight of sulphur. Hence it appears, that the sulphur of the crude antimony is divided between the metal and the antimony, in the compound ratio of their weights and their respective affinities for sulphur, in consequence of which some of the antimony is entirely desulphurated, and remains in an uncombined state, while the remainder being only partially desulphurated, unites into one mass with the sulphurated alkali. If this alkaline sulphuret of antimony, coarsely powdered, is boiled in pure water, nearly the whole is held in solution as long as the liquor continues hot, so that it may be passed hastily through a filter; but in proportion as the liquor cools, a copious precipitation takes place of a bulky, flocculent substance, whose colour is a deep brick-red approaching to that of the kermes insect, whence it has been called *kermes mineral*: after the deposition of kermes has ceased, the liquor being separated from it by a filter, is of a wine-yellow colour; and upon the addition of any acid, a still further precipitation is brought about, of an orange yellow powder, which is called the *golden sulphur of antimony*. Kermes may also be prepared in the humid way, as was first shewn by Lemery in the year 1707. Since that period a multitude of processes have been published by the French chemists for the preparation of this substance; none of them, however, appear to be essential improvements of Lemery's original method; and as this has received the high sanction of the observant and accurate Beaumé, we shall select it for the use of our readers. Put into a clean iron pan five or six parts of pure liquid fixed alkali, with fifteen or twenty parts of water; set it over the fire to heat, and as soon as it has begun to boil, stir in some well levigated sulphuret of antimony, equal in weight to one-sixteenth of the alkali; stir the mixture well, and when it has boiled for a minute or two, throw the whole on a filter, so that the clear liquor may pass through while hot; a large quantity of kermes will be deposited while it cools, which, after being separated from the alkaline solution, is to be washed first in cold, and then in hot water, till the water comes off quite insipid; the powder being then dried in the shade by a gentle heat, and levigated and passed through a fine sieve, is to be kept in a well-closed phial for use. The alkaline liquor, when it has ceased to deposit kermes, may be made to yield the golden sulphur, by saturating it with dilute sulphuric acid. In this process by the humid way, as in the other by the dry way, a partition of the sulphur takes place between the alkali and the metal, by which a portion of this last is left undissolved in the form of a grey powder; and this, by simple fusion in a crucible, is reduced to a mass of regulus. According to the French chemists, both the kermes and golden sulphur are *hydrofulphurated oxyds of sulphuret of antimony*: and Theuars, in his experiments on the antimonial oxyds, has given the following as the result of his analyses of these two substances, viz. Kermes mineral contains,

72.760 brown oxyd of antimony,
20.298 sulphurated hydrogen,
4.156 sulphur,

97.214
2.786 lbs.

100.000

Golden sulphur contains,

68.3 orange oxyd of antimony,
17.877 sulphurated hydrogen,
11 to 12 sulphur.

98.177

The theory concerning their formation is, that the alkaline antimonial sulphuret coming into contact with water, decomposes it; that the oxygen of the water combines with the sulphurated metal, while its hydrogen dissolves some of the sulphur with which it is in contact, and unites to the sulphurated metallic oxyd in different proportions, according to the different degrees of oxydation of these oxyds: that when the antimony is the least oxydated, it unites with the greatest quantity of sulphurated hydrogen, and becomes insoluble in alkali, forming the kermes; and, on the other hand, when more oxydated, it unites with less sulphurated hydrogen, and remains dissolved in the alkali till precipitated thence by an acid, forming the golden sulphur. Kermes may also be made by passing sulphurated hydrogen through a solution of muriat of antimony; and this among others is adduced as a proof of the kermes containing the metal in an oxydated state. Notwithstanding, however, the excellent experiments of Berthollet and Theuars on this subject, many very strong objections may, in our opinion, be urged against their theory: to enter into them at full length would be inconsistent with the plan of this work, but we shall resume the subject when treating of the *Metallic Hydrosulphurets*.

6. The nature of the preparations resulting from the mutual action of nitre and sulphurated antimony, depends very much on the proportion which the nitre bears to the other ingredient. The nitrous acid is consumed in acidifying the sulphur and oxydating the antimony; and the alkaline base of the nitre unites with the sulphur, if any remains, with the sulphuric acid forming sulphat of potash, and with the metallic oxyd. When the nitre considerably exceeds the antimonial sulphuret, as in the preparation of diaphoretic antimony, the sulphur is entirely oxygenated, and partly escapes in the form of sulphureous acid gas, while the remainder, with part of the alkali, forms sulphat and sulphite of potash; the metal also is completely oxygenated at the expence of the nitre; and the oxyd hence resulting, combines with the potash in two proportions; that portion which is united to a large quantity of alkali is rendered soluble, and the other remains insoluble. Hence when the result of the above process is lixiviated with hot water, we find dissolved in the liquor, and may obtain, in a crystalline form, sulphat and sulphite of potash, some undecomposed nitre, and antimonite of potash; the undissolved residue, or diaphoretic antimony, consists of the perfect oxyd of antimony combined with about a fifth of potash.

When the nitre and crude antimony are in equal proportions, only part of the sulphur is acidified, and the metal is at a low state of oxydation; by the action of warm water the mass is divided into an insoluble and soluble portion; the first, called *crocus metallorum*, seems, like the glass of antimony, to be merely a sulphurated oxyd; the latter consists of kermes, of golden sulphur, and sulphat of potash. For further particulars see § 12.

§ 10. *Phosphuret of Antimony.*

Pelletier, in his *Essays on Phosphorus*, has given the three following processes for combining antimony with that highly inflammable substance. 1. To one ounce of regulus of antimony add an equal weight of glass of phosphorus, and one dram of charcoal; pulverize the whole well together, and fuse the mixture in a covered crucible; the result is a white metallic mass of phosphorated antimony, very brittle, with a lamellar fracture, and nearly cubical fragments. When a little piece of it is put upon lighted charcoal, and exposed to the action of the blowpipe, it emits, at the moment of fusion, a faint green flame, and then volatilizes like pure antimony, in the form of white flowers.

2. Equal parts of regulus and glass of phosphorus furnish by fusion a metallic mass, whose fracture displays minute facets, and in every other respect is similar to No. 1. 3. A phosphuret of antimony, with the same properties as the former, may also be prepared by projecting on the melted regulus small pieces of phosphorus. In this case, however, the crucible must be removed from the fire immediately after the last portions are thrown in, otherwise by a continuance of the heat it would be all volatilized.

The phosphurets of antimony are not applied to any use, and the above are all the facts which we are possessed of concerning them.

§ 11. *Alloys of Antimony.*

1. *Antimony with gold.* See GOLD.
2. *Antimony with platina.* See PLATINA.
3. *Antimony with silver.*

According to Lemery, one ounce of reguline antimony and three drams of expelled silver, being fused together in a strong heat, yielded an alloy of the same weight as the original materials, and similar to common regulus of antimony, but more compact, and not so brittle. Gellert (*Chymie Metallurg.*) relates, that 181 grains of silver being fused with 255 grains of reguline antimony, the alloy was found to have lost during the process 115½ grains; the remainder was very brittle, and in colour similar to regulus of antimony: its specific gravity was = 8.44. But the sp. gr. of the silver being = 9.1, and that of the antimony being = 6.7, the sp. gr. of the alloy, supposing the whole loss of weight to have been antimony, ought to be = 7.56. Therefore the sp. gr. of this alloy is greater than the mean of its constituent parts. It is made no use of.

4. *Antimony with copper.*

These two metals mixed together in nearly equal proportions, form a hard brittle alloy, of a violet colour internally, which is not very soon affected by exposure to the air. Gellert, having mixed together 314 grains of copper, sp. gr. = 8.7, with 464 grains of reguline antimony, sp. gr. = 6.7, obtained an alloy whose sp. gr. was = 8.02. During the fusion there was a loss of 43½ grains; and putting the whole of this to the account of the antimony, the sp. gr. of the alloy ought, by calculation, to have been = 7.49. The sp. gr. therefore of this alloy is greater than the mean of its constituent parts. It is made no use of.

5. *Antimony with iron.*

The general properties of antimony with a very small proportion of iron, or *martial regulus*, may be found above in § 4. Gellert having mixed by fusion 115½ grains of iron, sp. gr. = 8.0 with 173 grains of reguline antimony, obtained an alloy of 63 grains less by weight than the materials. It was brittle, of an ash colour, and contained specks like rust of iron. Its sp. gr. was = 6.92. Now supposing the loss of weight to be placed to the account of the iron, the density of the alloy ought to be = 7.05; its sp. gr. therefore is less than the mean of its ingredients. This alloy was wholly unaffected by a powerful magnet, except one or two particles which appeared to be iron. It is not made any use of.

6. *Antimony with mercury.* See MERCURY.

7. *Antimony with tin.*

These two metals being mixed together in nearly equal proportions, form a moderately hard, very brilliant, and brittle alloy, capable of receiving an exquisite polish, and not easily tarnished; it has therefore been occasionally manufactured into speculums for telescopes. Gellert mixed together by fusion 231¾ grains of tin, sp. gr. = 7.36, with 231¾ grains of antimony; 77 grains were lost in the process, and the alloy was = 6.94 sp. gr. Supposing the whole loss to be

ANTIMONY.

be attributed to the tin, the density of the compound ought to be = 7.0; its sp. gr. is therefore less than the mean of its ingredients.

8. *Antimony with lead.*

This is the most important of all the alloys of antimony, it being the material of which the common types for printing are made. In proportion as the lead exceeds the other ingredient, will be the ductility of the mass; and the lead may be hardened, and its fusibility unimpaired by so small a proportion of antimony as not to injure its ductility. Gmelin found that equal parts of the two metals produced a porous brittle alloy; one part antimony, and two lead, afforded a more compact metal, but still brittle; one part antimony and three lead, gave a homogeneous metal ductile under the hammer, and much harder than lead: one part of antimony gave to eight of lead an increase of fusibility, hardness and colour, without materially injuring its malleability. According to Gellert, $386\frac{1}{2}$ grains of lead, sp. gr. 11.7, being fused with 333 grains of antimony, experienced a loss of 101 grains. The alloy was brittle, and presented a granular somewhat shining fracture; its sp. gr. was = 9.17; and even if the whole loss of weight is attributed to the antimony, the density by calculation ought to be = 9.12. The mass is therefore of a greater sp. gr. than the mean of its ingredients.

9. *Antimony with zinc.*

Equal parts of the two metals being fused together, formed a homogeneous brittle mass of a light ash colour; the loss of weight was about one-sixth of the whole; as however both these metals are very volatile, it is impossible to say with any certainty what proportion of the loss is to be attributed to each; the sp. gr. of the mass was rather less than that of the antimony, which is the lighter of the two. It is not used.

10. *Antimony with bismuth.*

According to Gellert, equal parts of the two metals being fused together, lost $\frac{1}{3}$ of their weight, and produced an alloy of a lighter colour than bismuth, and very brittle, displaying in its fracture a cubical structure like that metal; the sp. gr. of the mass was = 8.96; whereas, supposing the $\frac{1}{3}$ of loss to have been sustained by the bismuth, the heavier of the two, its density by calculation ought to have been only = 7.94. Not used.

Concerning the combination of the other metals with antimony nothing is as yet known, except merely that cobalt unites easily with antimony, and manganese with great difficulty, and very imperfectly.

§. 12. *The medicinal Virtues, and pharmaceutical Preparations of Antimony.*

This metal affords several of the most valuable articles of the pharmacopœia; and as it has for so many years engaged the attention of chemists and alchemists (of whom a large number have ever been zealous to add to the resources of the healing art), we possess an almost infinite variety of antimonial preparations, all of them valuable as medicines, all enjoying many virtues in common, but a few out of the number recommending themselves peculiarly to the medical practitioner from the uniformity of their composition, or from a greater tendency to one mode of operation rather than another, whereby particular indications in the cure of diseases may be fulfilled.

The first and most unquestionable operation of antimony on the human body is that of an emetic. This operation appears to be always in direct proportion to the activity of the antimonial in every other respect; and it exists in the highest degree in those preparations that are almost too virulent

to be given internally with safety in common cases. Antimonials excite to vomit very speedily, and their action is continued on the stomach for a considerable time; hence they are of a peculiar service, either where any acrid or poisonous matter has been taken which requires to be speedily and effectually removed; or in such cases as incipient fever, where, along with the clearing of the first passages, the physician wishes to prolong the mechanical action of vomiting, so as to induce a relaxation on the skin, and complete perspiration.

The operation of antimony is also extended to the intestinal canal, and hence it proves considerably *purgative*; and this effect takes place, either when the dose has been greater than necessary, merely to produce vomiting; or when the stomach has escaped the action of this powerful mineral. In order to secure the purgative, and prevent the emetic operation of antimony, it is advisable to unite it with some of the usual aperient medicines, whose operation it will thus assist in a considerable degree.

Antimony appears to promote almost all the excretions, and to quicken and stimulate the action of the absorbent vessels. It is therefore eminently *diaphoretic* (or promoting perspiration); *expectorant*, and often *diuretic*. It frequently happens that a single one of the antimonial preparations may be made to produce each of these effects by varying the dose, increasing it to render it a vigorous emetic or cathartic; and diminishing it when the gentle and more gradual operation of a diaphoretic or expectorant is to be secured.

A long continued course of antimonials, in the mildest form, wherein the direct operation of this metal is scarcely at any one time to be detected, has been found of essential service, both in various obstinate cutaneous complaints, and to produce that change of constitution and supposed resolution of internal obstruction, which entitle a medicine to the (somewhat ambiguous) character of *alterative* and *deobstruent*.

We shall now proceed to take notice of those preparations of antimony which are actually in use, or which have acquired a certain reputation in medicine.

Antimonium preparatum (*Pharm. Lond. & Edin.*). This is nothing but the crude antimony or native black sulphuret, prepared for medicinal use simply by triture to an impalpable powder, edulcoration with water, and subsequent drying. In this native mineral the proportion of the sulphur to the metallic part is so large, as to render it almost entirely inert, at least with regard to any sensible operation. It is sometimes, however, though rarely, employed in cutaneous complaints; and formerly it was used in the preparation of decoctions of sarsaparilla, guaiacum, and the other sudorific woods; a quantity of the mineral being tied up in a loose cloth, and suspended in the vessel in which the decoction was preparing; but as scarcely the minutest portion of the antimony could be dissolved by this process, it has properly been omitted.

The crude antimony still, however, is retained in veterinary practice; and it may be given to many animals in doses of several ounces without any apparent operation.

It is likewise the material from which all the other antimonial medicines are prepared, directly or indirectly.

Antimonium vitrefactum (*Pharm. Lond.*), *vitrum antimonii* (*Pharm. Edin.*), Glass of antimony.

To prepare this, the crude antimony is roasted on a tile or other shallow vessel, with a very slow fire, and frequent stirring, till all the sulphur is expelled which can be separated in this method. What remains is a grey powder, which is to be melted in a crucible and an intense fire into a yellowish vitrescent mass, to be poured out on a warm copper or iron plate, and when cold reduced to a very fine powder.

A N T I M O N Y.

powder. This preparation is an oxyd of antimony not at its highest point of oxydation, and still retaining a small portion of sulphur, which it is impossible to separate by mere heat. When well prepared it is pretty uniform in its nature, and is a very violent medicine, operating even in small doses as a strong emetic and cathartic. It is scarcely ever employed internally, but is the basis of the emetic tartar, and the antimonial wine, in the London Pharmacopœia.

Vitrum antimonii ceratum (Pharm. Edinb.).

Take one ounce of glass of antimony in fine powder, add it to one dram of yellow wax melted in an iron vessel, heat them gently together for a quarter of an hour, with constant stirring; pour out the mass when cold, and reduce it to powder.

The glass of antimony here incorporates with the wax, and changes its colour from lemon yellow to brown in the process. The wax appears to lessen in a very great degree the activity of the antimony, so that this medicine may be given with safety, and has been much recommended in dysenteries and other bowel complaints. It is rejected from the London pharmacopœia; but retained in those of Edinburgh, Amsterdam, and some others.

A great variety of preparations have been made from the crude antimony by the intermedium of nitre. The operation of this salt on the metallic sulphuret when dephlagrated together, is first to consume the sulphur, and afterwards, if the quantity be sufficient, to oxydate the metal to the highest point. It is remarkable, that the perfect oxyd of antimony, entirely divested of sulphur, and fully saturated with oxygen, appears almost as inert as the crude sulphuret of antimony itself, whilst in the intermediate states of desulphuration, and oxydation, many very active medicines are found.

Of these the two following alone are now retained, the first with a smaller proportion of nitre, the latter fully saturated.

Crocus antimonii (Pharm. Lond. & Edin.). Crocus of antimony, also called crocus metallorum, safran des metaux, and hepar or liver of antimony, by foreign writers.

To prepare this, take one pound of crude antimony, one pound of nitre, and one ounce of common salt, mix them accurately, and project them, a spoonful at a time, in a large crucible heated red hot; when the whole is dephlagrated, increase the fire so as to melt the mass, and pour it out. When cold it will be found to consist of two parts, the upper a whitish saline scoria, to be separated from the lower, which is the crocus of antimony. This is to be rubbed to a fine powder, and repeatedly washed with warm water, till it comes off from the powder quite insipid.

The crocus of antimony is a very violent emetic and purgative, and is seldom employed internally except in farriery. When washed it appears to have the greatest resemblance to the glass of antimony above described, and it is reserved for similar purposes, that is, as a basis for the tartar emetic and some other of the antimonial preparations.

When prepared in the large way, it would appear that it is not necessary to heat the vessel in which the mixture is fired, the heat excited by the dephlagration being sufficient to fuse the whole to the requisite degree. The whitish scoria here produced consist of sulphat of potash (formed by the potash of the nitre and the sulphuric acid, generated by the dephlagration of the sulphur), of the sea-salt, and probably of a portion of uncombined alkali, with some particles of the metallic sulphuret that may have escaped the action of æbe nitre.

Antimonium calcinatum (Pharm. Lond.), *antimonium*

ustum cum nitro (Pharm. Edin.), *calx antimonii*, or diaphoretic antimony.

This is prepared, according to the London college, by projecting gradually in a hot crucible a mixture of one part of crude antimony with three parts of nitre, raising the heat after dephlagration, and continuing it for half an hour; and when cold, pulverizing and edulcorating it.

The Edinburgh college direct one part of the grey powder left after roasting crude antimony for the glass of antimony, to be dephlagrated with only an equal weight of nitre, to be heated for an hour, and afterwards reduced to powder and washed till insipid.

These two preparations are, however, essentially the same, and consist of the oxyd of antimony left after the sulphur has been entirely dissipated by the nitre, itself having been oxydated to a high degree by the same dephlagration.

As the intention of using so much nitre in the first method is to consume the whole of the sulphur as well as to oxydate the metal, it is obvious that a much less quantity of this neutral salt will be sufficient where so much of the sulphur has been driven off by roasting, as is the case in the second method. Formerly a distinction was made between the pulverized oxyd taken before, or after washing; in the first instance being termed *antimonium diaphoreticum nitratum*; and in the second, *antimonium diaphoreticum lotum*; the former, as it contained an alkaline salt, was deliquescent to a certain degree, and required to be preserved in a close vessel. It is now, however, disused, the *washed* alone being retained.

The diaphoretic antimony, owing probably to its high state of oxydation, is mild in its effects, and may be taken in large doses, without producing sickness or purging. It is naturally white and in a pulverulent state, the antimonial oxyd not being truly vitrified in the process, as it is in the preparation of the crocus of antimony, but only involved in the alkali of the nitre, from which it is separated by washing.

The several washings of this substance contain a mixture of sulphat of potash, with part of the nitre undecomposed, and the naked alkali, all holding in solution a certain quantity of antimonial oxyd.

If this compound liquor is decomposed by an acid, the metallic oxyd precipitates in the form of a white powder, which has been called the *cerusse of antimony*, or *materia perlata*; but if the liquor is merely evaporated to dryness, part of the salts crystallize together with metallic oxyd, and form the *nitrum sibiatum*, or *antimoniated nitre of Stahl*. These latter preparations are now in disuse.

Some other antimonial medicines have been prepared with different proportions of antimony and nitre, forming oxyds, all of which act in a similar manner upon the human body, but with different degrees of energy. It should seem that the middle point with regard to the proportions of antimony and nitre, that is, equal parts of each, furnishes the most active antimonial oxyd, which is the crocus; and the medicinal power seems to diminish in proportion as either of these ingredients is used in excess. Thus the completely oxydated metal, the diaphoretic antimony, is possessed of but little activity; and on the other hand, the *crocus antimonii medicinalis*, formed by dephlagrating eight parts of antimony with one of nitre, and consequently but partially desulphurated, is equally mild in its operation.

The *crocus antimonii mitior*, the proportions of which are two parts of antimony to one of nitre, is another medicine now in disuse, which appears to be more active than the last mentioned, but milder than the common crocus.

A N T I M O N Y.

The *emeticum mite antimonii* of Boerhaave is made by employing one part of antimony to two of nitre, and is a mild and safe medicine.

Another antimonial oxyd, formerly employed in medicine, is prepared by dephlagrating the *regulus* of antimony with twice or thrice its weight of nitre, and this has also been termed by some the *cerussa antimonii*.

The nitre here, having no sulphur to engage it, acts entirely on the metal, and reduces it to the state of a perfect oxyd, which, when washed, resembles in every respect the washed diaphoretic antimony made with the black sulphuret and three times its weight of nitre. The *regulus*, however, does not require more than its own weight of nitre for this preparation; all the rest is superfluous.

Regulus antimonii medicinalis, vel febrifugum Craanii, an antimonial remedy much recommended by many of the German physicians, and introduced in the former pharmacopœias of Edinburgh, Brandenburg, Strasburg, and others of celebrity, but now disused.

This, which is improperly termed a *regulus*, is prepared by fusing together five parts of crude antimony with four of common salt and one of salt of tartar. On cooling, two substances are found in the crucible, an upper scoria, containing the sea-salt, the alkali, and part of the sulphur, and the lower, a reddish mass composed of the greater part of the metal, deprived of a portion of its sulphur by means of the alkali, and thus rendered more active as a medicine than the crude antimony. It is this lower reddish mass which is the *medicinal regulus*. The use of the common salt seems to be merely to assist the fusion.

Regulus antimonii. The methods of preparing the true *regulus* of antimony have been already mentioned. This metal used formerly to be cast in the form of a cup, and, owing to its slight degree of solubility in various menstrua, a powerful emetic liquor was prepared simply by filling the cup with wine, and suffering it to stand for some hours. At the same time the cup had lost so little of its weight that it would continue to give the same properties to fresh portions of wine for years, or almost centuries, without being corroded through.

In like manner the *regulus* cast into the form of pills would produce the emetic or purgative operation to any number of persons in succession, and hence they were called *perpetual pills*.

These preparations are now, however, discontinued.

Vinum antimonii. (*Pharm. Lond.*) Instead of the *regulus*, the glass of antimony is now employed as the basis of this medicated wine. One ounce of this, in fine powder, is to be digested for twelve days with frequent agitation, in a pint and a half of white Lisbon wine.

This is a very valuable antimonial, principally employed in doses of from ten to sixty drops as a diaphoretic. The quantity of the metal taken up by the wine is extremely small, but is liable to vary in proportion to the acidity of this menstruum, which is one inconvenience attending its use.

Vinum antimonii tartarificati. (*Pharm. Lond. and Edin.*) In the former dispensatory it is directed to be made by dissolving forty grains of emetic tartar in two ounces of boiling water, and afterwards adding eight ounces of white Lisbon wine.

In the latter, twenty-four grains of emetic tartar are simply dissolved in a pint of the wine.

The nature and preparation of the celebrated *kermes mineralis*, or *pulvis carthusianus*, have been already explained; this is at present laid aside, and in its place the London and

Edinburgh pharmacopœias have adopted the precipitate, formed from a liquid solution of sulphuret of antimony in caustic alkali, by the addition of an acid, instead of by mere cooling, as is the case with the *kermes*: this is the

Sulphur antimonii precipitatum vel auratum, the golden sulphur of antimony.

To prepare it, boil for three hours two pounds of crude antimony with four pounds of the aqua kali puri (or caustic lye), diluted with three pounds of distilled water; strain it while hot through a linen cloth, and immediately add gradually dilute vitriolic acid, sufficient to precipitate the sulphurated antimony, which is of a fine golden colour. Wash it well with warm water, and dry in a gentle heat.

The golden sulphur is of a lighter colour than the *kermes*, the latter being generally of a brown or brick red. Both of them consist principally of sulphur, but holding in solution a certain quantity of the metal which renders them emetic or purgative when taken in doses of several grains. The golden sulphur is never used with a view of acting violently or by any sensible operation, but it is employed (often combined with mercury) as a gentle alterative, with a view of keeping up a constant perspirable state of the skin, and determining a gentle increase to the several emunctories. Hence its use in various obstinate cutaneous complaints, and other chronic disorders.

The only solutions of antimony in acids employed in medicine are the *muriated antimony*, more commonly known by the name of *butter of antimony*, and the *antimoniated tartaric of potash*, or the *tartar emetic*. The chemical nature of each of these interesting preparations has been already described.

The *muriated antimony* is much too acrid and violent to be employed for internal purposes. It is used externally as a caustic, especially in farriery. The *powder of algarobis*, or the antimonial oxyd, precipitated from this salt by water alone, or by an alkaline solution, is used by several chemists as the basis of the emetic tartar.

Antimonium tartarificatum vel tartarus emeticus. (*Pharm. Lond. and Edin.*) To prepare this most valuable medicine according to the London Pharmacopœia: take one pound and a half of crocus of antimony in fine powder, two pounds of cream of tartar, and two gallons of water, boil them together in a glass vessel for a quarter of an hour, strain the liquor through paper, and set it by to cool: the crystals that form are the emetic tartar.

The Edinburgh college directs: first, to add some of the *muriated antimony* to hot water, holding salt of tartar in solution, to collect the white precipitate thus formed, and edulcorate it thoroughly: next to add nine drams of this precipitate, and two ounces and a half of cream of tartar, in fine powder, to five pints of water, and to boil the whole till the tartar is dissolved; afterwards to evaporate the liquor in a glass vessel, till a pellicle appears on its surface, and to set it by to crystallize.

The emetic tartar is by much the most valuable of all the antimonial preparations; its composition renders it sufficiently soluble in simple menstrua, and as it is almost entirely insipid, and as the requisite dose is in all cases comparatively small, it may be given with great ease to children, or wherever there would be a difficulty of getting down bulky medicines. In doses of from one to about three grains it proves emetic, and often purges even after the stomach has been emptied: in smaller quantities, or mixed with various other medicines, and especially with those that correct its emetic property, it fulfills the other intentions with which antimonials are given; and with proper precautions it is always safe, manageable, and highly to be depended on.

When prepared in the same way, it is generally very uniform in its nature, but it is liable to some variation, when different antimonial oxyds are used; an inconvenience it would be of great importance to prevent.

The last of the antimonial medicines that we shall mention, is the *pulvis antimonialis* (*Pharm. Lond.*), or the *antimonium calcareo-phosphoratum*. (*Pharm. Edin.*)

To prepare it. Take equal parts of crude antimony and hartshorn shavings, mix them together, and throw them into a wide iron pan, heated fully red, and stir them constantly till they acquire an ash-colour; then take them out, reduce them to powder, fill a coated crucible with it, and lute over the top another crucible, inverted, and with a small hole at the bottom, to serve as a cover: then raise the fire gradually to a full white heat, and keep it in this state for two hours; when cold, take out the contents, reduce them to a molt subtile powder, and it is the *pulvis antimonialis*.

This preparation is intended as a substitute for the JAMES'S POWDER, one of the molt celebrated empiric medicines in this or any other country, the value of which has long been established by the molt unequivocal testimony. We shall refer the reader to this article for an account of the ingenious analysis made by Dr. Pearson of this powder, and published in the *Philosophical Transactions*, whereby it is proved to be a mixture of an oxyd of antimony with the earth of bones, or calcareous phospat; and hence the *pulvis antimonialis* has been employed as a substitute.

This preparation is given in doses of one to five or six grains, or even more, and is employed peculiarly in removing general fever, by means of perspiration. It is never intentionally given in such large doses as to prove emetic; but it is generally supposed, that the genuine James's Powder may be taken in larger doses than the antimonial powder, without exciting sickness.

We may add, that Mr. Chenevix, (in the *Philosophical Transactions* for 1801) has given the following ingenious method of preparing this medicine in the moist way, which removes every cause of variation which may take place whenever the oxyd of a metal so volatile as antimony is in certain states, is subjected to intense and long-continued heat. The following is the simple process: "Dissolve together, or separately, in the least possible portion of muriatic acid, equal parts of the white oxyd of antimony, formerly called algaroth powder (made by dropping the butter of antimony into water), and of phospat of lime; pour this solution gradually into distilled water, previously alkalized by a sufficient quantity of caustic ammonia: a white and abundant precipitate will take place, which, well washed and dried, is the proposed substitute for James's Powder."

In this process, the antimony and the phospat of lime are precipitated from their solution in muriatic acid at the same instant, the former by means both of the ammonia and the water in which it is dissolved, and the latter merely by this alkali. Hence, the inventor gives the useful caution to pour the mixed muriatic solutions *into the alkaline liquor*, and not to add the latter to the former; in order that the precipitation of the antimony and the phosphate of lime may be confentaneous, and therefore in uniform proportion from first to last. The muriatic acid simply dissolves phospat of lime, and does not decompose it, and therefore it is separated unchanged from its solution by the ammonia. If it be wished to prepare this powder with a stronger dose of antimony, it is only requisite to increase the proportion of muriated antimony to the muriated calcareous phospat, before the precipitation is made.

We shall only add to this short review of the various antimonial preparations used in pharmacy, that several other pre-

parations, slightly varying from those which we have mentioned, have been at times recommended by several eminent men, and have had a certain vogue; but it does not appear that any thing further can be expected from any other change in the preparation of antimonial medicines; and those which we already possess, form some of the molt valuable articles of the *Materia Medica*.

§ 13. *Uses of Antimony.*

The uses of antimony are not very numerous; it is of high value in medicine, and is employed, in combination with other metals, in the manufacture of printers' types, and specula for telescopes. Its oxyds are used in colouring glass; the sulphuret is employed in scurifying copper and other metals which are found mixed with gold; hence it was called by the alchemists *balneum regis*, or *balneum solis*.

The native antimony, at first, was of service only in the composition of paint. Scripture describes it to us as a sort of paint, with which the women blacken their eye-brows. Jezebel understanding that Jehu was to enter Samaria, painted her eyes with antimony, or, according to the Hebrew, "put her eyes in antimony."

At this day the women of Syria, Arabia, and Babylonia, anoint and blacken themselves about the eyes; and both men and women put black upon their eyes in the desert, to preserve them from the heat of the sun, and the piercing of its rays. M. D'Arvieux tells us, that the Arabian women border their eyes with a black colour made of *tuty*, which the Arabians call *rebel*. They draw a line of this kind of blacking without the corner of their eyes, to make them appear larger. Isaiah, in his enumeration of the several ornaments belonging to the daughters of Sion, has not forgot the needles which they made use of in painting their eyes and eye-lids: nor has this practice escaped the lash of Juvenal.

"Ille supercilium madida fuligine tinctum
Obliqua producit acu, pingitque trementes
Attollens oculos."

Ezekiel, describing the irregularities of the Jewish nation, under the idea of a debauched woman, says, that she bathed and perfumed herself, and that she anointed her eyes with antimony. Job shews sufficiently how much antimony was in esteem, by calling one of his daughters a vessel of antimony, or a box to put paint in, *cornu sibirii*. Tertullian and St. Cyprian have declaimed very warmly against this custom of painting the eyes and eye-brows.

ANTINE, in *Biography*, a Benedictine monk, was born at Gonireux, in the diocese of Liege, in 1688, and published several useful works of an historical kind. In 1736, he published the five first volumes of a new edition of "Du Cange's Glossary," with valuable corrections and editions. He also bestowed much pains upon "Bouquet's collection of French Historians," and on "The Art of verifying Dates," published in 4to. in 1750, and reprinted, with enlargements, in 1770. Nov. Dict. Hist.

ANTINOE, or ANTINOOPOLIS, now called *Enfene* by the Arabs, in *Ancient Geography*, a city of Upper Egypt, on the east side of the Nile, was built near the ruins of Abydus, where the Egyptians worshipped the god Besa, and revered his oracles; and became the capital of a nome or prefecture. The oracle of Besa was famous in the time of Ammianus Marcellinus, who says that all the neighbouring people went to consult him, and assembled at a certain period to celebrate festivals in his honour. Hence the Arabs call Antinoe the city of the Magi. This city was built in consequence of a shameful passion, which ill disguised the appearance of gratitude affected by Adrian, its founder.

This

This prince, renowned for his political and military talents, was, at the same time, contemptible on account of his passion for Antinous, the perfection of whose form is proved by one of the finest statues bequeathed to us by antiquity. Adrian, equally superstitious and depraved in his manners, while he was in Egypt with his court and army, consulted the oracle of Bêsa, which declared, that he was threatened with great danger, unless a person that was dear to him, and by whom he was beloved, was immolated for his preservation. Antinous offered himself for the victim, and the emperor had the cruelty to accept the sacrifice. The beautiful and generous Antinous precipitated himself from the summit of a rock into the Nile, and Adrian thought to efface his ingratitude and infamy by building, in honour of his favourite, whom he likewise regarded as his deliverer, a city which, under the name of Antinoe or Antinoopolis, has perpetuated at once his barbarous cruelty, and his criminal passion. This city he embellished with all the most valuable productions of art. The statues of Antinous were here considered as sacred images; and the emperor not only erected temples in honour of him, but instituted games and sacrifices, and regulated the worship that was to be paid to his memory. Savary says, that this city was half a league in circumference, and that two principal streets, 45 feet wide, intersecting each other at right angles, traversed its whole extent. The others were narrower, but equally straight. The two largest terminated by four gates, some of which still subsist; the handsomest has three vaulted entries; that of the middle is 40 feet high by 22 in width, and 20 thick; the other two are smaller. Each of the façades of this edifice is ornamented with four pilasters in bas relief, the Corinthian capitals of which, with the leaf of the Acanthus, have a considerable projection. This beautiful gate was surrounded by eight Corinthian columns, of the same height with itself. One only has escaped the ravages of time, and of men; the rest are either mutilated or destroyed; but the pedestals remain entire. Besides this edifice, one discovers in different quarters of the town, heaps of rubbish, which announce temples or palaces destroyed. If we may judge from the distances of the pedestals along the streets, they were bordered by a colonnade, which formed a portico on each side, and allowed the inhabitants to walk sheltered from the sun. Besides these embellishments, one of the squares was ornamented with four large pillars of the Corinthian order, three of which have perished, their bases only remain. The fourth is preserved, and is about 50 feet high. The shaft is composed of several stones. On the first is carved an ornament of oak leaves. On the pedestal is a Greek inscription, half effaced, which dedicates it to the emperor Alexander Severus.

The vestiges of the city, says Sonnini, excite regret for its destruction. The extent of ground, strewed with the most beautiful remains of antiquity, threw him into admiration and astonishment. In the time of Vansleb and of Paul Lucas, there were existing piers of architecture altogether entire, which he could not find. What appeared to him most remarkable was a triumphal arch, or magnificent gate, decorated with fluted pillars; its front was 50 yards in length; and he has given a drawing of it. On the other side of the mountain which terminates, towards the east, the site of the ancient Antinoopolis, are to be distinguished many apertures in the rock, which led to grottoes, that were burial-places or catacombs. The mosque of the village which is near the city, the appearance and population of which form so striking a contrast with the superb edifices and elegance of the ancient city built by Adrian, contains a tomb, and the relics of a saint, from whom this place has

obtained the name of *Sheick Abadé*; and this saint, though regarded by the Mahometans as a zealous defender of the koran, was, at the same time, claimed by the Christians as one of their bishops, who enjoyed the painful honour of martyrdom at *Infiné*. Towards the end of the fourth century, this city is said to have been peopled by Christians. Palladius assures us, that it had 12 convents of virgins, and several others inhabited by monks. It is now occupied by the worst people and most determined banditti and robbers in Egypt. Savary's Letters, vol. i. p. 552. Sonnini's Travels in Upper and Lower Egypt, p. 517.

ANTINOËIA, in *Antiquity*, annual sacrifices, and quinquennial games, in memory of Antinous the Bithynian.

They were instituted at the command of Adrian the Roman emperor, at Mantinea in Arcadia, where Antinous was honoured with a temple and divine worship. They were also celebrated at Argos.

ANTINOMIANS, in *Church History*, denote those who maintain the law of no use or obligation under the gospel dispensation, or who hold doctrines that clearly supersede the necessity of good works and a virtuous life.

The Antinomians took their origin from John Agricola, about the year 1538, who taught that the law is no wise necessary under the gospel; that good works do not promote our salvation, nor ill ones hinder it; that repentance is not to be preached from the decalogue, but only from the gospel.

This sect sprung up in England, during the protectorate of Oliver Cromwell; and extended their system of libertinism much farther than Agricola, the disciple of Luther. Some of their teachers expressly maintained, that as the elect cannot fall from grace, nor forfeit the divine favour; the wicked actions they commit are not really sinful, nor are to be considered as instances of their violation of the divine law; and that consequently they have no occasion either to confess their sins, or to break them off by repentance. According to them, it is one of the essential and distinctive characters of the elect, that they cannot do any thing which is either displeasing to God, or prohibited by the law.

Luther, Rutherford, Schlusfelburgh, Sedgwick, Gataker, Witfius, Bull, Williams, &c. have written refutations; Crisp, Richardson, Saltmarsh, &c. defences of the Antinomians; Wigandus, a comparison between ancient and modern Antinomians.

The doctrine of Agricola was in itself obscure, and perhaps represented worse than it really was, by Luther, who wrote with acrimony against him, and first styled him and his followers Antinomians. Agricola stood on his own defence, and complained, that opinions were imputed to him, which he did not hold. Nicolas Amsdorf fell under the same odious name and imputation, and seems to have been treated more unfairly than even Agricola himself. It is rather hard to charge upon a man all the opinions that may be inferred from things that have hastily dropped from him, when he himself disavows such inferences.

ANTINOMY, ANTINOMIA, derived from *αντι*, *contra*, and *νομος*, *lex*, a contradiction between two laws, or between two articles of the same law.

ANTINOMY, sometimes also signifies an opposition to all law. Whence a sect of enthusiasts, who are for carrying gospel liberty above all moral regards, and who slight the motives of virtue as insufficient to salvation, are called Antinomians; and sometimes Anonians.

ANTINOUS, in *Astronomy*, a part of the constellation AQUILA, or the eagle.

ANTINOUS, in *Mythological History*, a Bithynian youth,

youth, the favourite of Adrian, and the object of his unnatural and detestable passion. Some have said, that he fell accidentally into the Nile, as he was sailing on that river with the emperor, and was drowned. Dio Cassius assures us, that he was sacrificed in the manner already related under ANTIQOE. The emperor, whatever was the occasion of his death, bewailed him, says Spartian, with all the tenderness and weakness of a woman lamenting the death of her husband. To soothe in some measure his grief, he desired the Greeks to rank him among the gods, which they accordingly performed; so that in a short time all the Eastern provinces were filled with statues, temples, and chapels, consecrated to this new divinity. It was even pretended, that he uttered oracles; but his answers were commonly thought to have been composed by Adrian. The Astrologers, having discovered, or pretended to discover a new star, gave out that it was Antinous. Adrian caused the body of his beloved catamite to be buried with the utmost magnificence, built a city on the spot, and converted his tomb into a temple, where he was said to work miracles; which we find exposed and ridiculed by the Pagans themselves.

ANTINOUS, in *Sculpture*, a very famous Roman antique statue; originally in the collection of cardinal Alexander Albani: it is at present in the gallery of antiques, in the museum at Paris.

This statue is in marble; it is a standing figure of a young man, entirely naked; the head looks downwards, with a melancholy air; this is in every respect a highly finished and beautiful performance.

There are nearly as many statues of Antinous as of the Venus de Medicis; and they are very similar to each other: the hair is always disposed in the same manner, covering the forehead nearly as low as the eyebrows; and they all resemble one another in conveying a melancholy idea to the mind.

Mr. Richardson supposes that the vast number of these statues may be attributed to the nobility of Rome, who probably might make court to the emperor Adrian, by having statues of his favourite Antinous.

Among the different statues referred to, was one of late in the yard of the palace of the grand duke at Florence. There were two in the Villa Mattei; another in the garden of the Belvidere, found in Adrian's baths by Leo. X. Another fine statue of Parian marble, formerly broken to pieces, but well put together, stood in the Villa of Cassali, on Monte Caelio. The pieces of this statue had been made use of by the Goths to build a wall with, at the demolishing of which, they were found and put together. All the statues of this Villa had been treated in the same manner.

There is also a number of very fine busts of Antinous; among which, was one twice the size of life in the palace Farnese, at Rome; another in the palace Giustiniani; besides many others.

ANTIO, or ANZIO, *Capo*, in *Geography*, a promontory of Italy, in the ecclesiastical state, between port Ostia and the gulf of Gaeta. It has a fortified tower, and a convenient port. It takes its name from the ancient *Antium* in its vicinity.

ANTIOCH, in *Ancient Geography*, a city of Syria, was built in memory of his father Antiochus, by Seleucus Nicator, on the river Orontes, about 20 miles from the place where that river empties itself into the Mediterranean; being equally distant from Constantinople and Alexandria in Egypt, or about 700 miles from each. It soon became, and continued to be for many ages, the metropolis of the east, for the Syrian kings, and afterwards the Roman governors, who presided over the affairs of the eastern provinces, chose it for their place of residence; and in the Christian times, it

was the see of the chief patriarch of Asia. It ought also to be particularly mentioned, that the disciples of Christ were first called Christians at Antioch, and this Chrysolom specifies as the distinguishing prerogative of this city above all others; and he has celebrated this honour in a distinct homily on Acts XI. Here also the gospel was preached to Grecians who were incorporated into the Christian church. Here also Barnabas and Saul were sent out by the church, under the direction of the Holy Ghost, to travel through Pagan cities, to give light to the Gentiles, and to publish Jesus for salvation to the ends of the earth. We cannot forbear observing, that the Gospel acquires credibility from its having been first taught in the most populous, enlightened, and learned cities, never shunning the public eye, but challenging full examination; and that in those cities it obtained numerous converts by conviction, without the aid of force or fraud. Antioch was particularly honoured by the Jews, on account of the jus civitatis, which Seleucus Nicator had given to them in that city, together with the Greeks and Macedonians; and which, according to Josephus (*Ant. lib. xii. c. 13.*), they retained in his time. This metropolis of Syria was afterwards known by the name of Tetrapolis, being divided, as it were, into four cities, each of them having its proper wall, besides a common one, which enclosed them all. The first of these cities or quarters was built by Seleucus Nicator; the second by those who repaired thither on its being made the capital of the Syro-Macedonian empire; the third by Seleucus Callinicus; and the fourth by Antiochus Epiphanes. At the distance of about four or five miles was a place called *Daphné*, and reckoned a suburb of Antioch. Here Seleucus planted a grove, and in the midst of it erected a temple, which he consecrated to Apollo and Diana. To this place the inhabitants of Antioch resorted for their pleasures and diversions; and thus it became at last so infamous, that "to live after the manner of Daphné," was used proverbially to express the most voluptuous and dissolute mode of living. Daphné was formerly of such note, that the metropolis was distinguished by it, and denominated *Antioch near Daphné*.

Antioch, though it continued for 1600 years, as Pliny calls it, the queen of the East, was frequently in danger of being overwhelmed by earthquakes to which its situation exposed it, or of being ruined by its enemies. About 144 years before Christ, the disorders and tumults occasioned by the licentious and tyrannical conduct of Demetrius, the sovereign of Syria, terminated in a general revolt of the inhabitants of Antioch; and Demetrius was under a necessity of seeking assistance from Jonathan, one of the Maccabees, for the purpose of chastising the mutineers. Having obtained 3000 men, he resolved to disarm them, and issued orders for this purpose. This measure inflamed their resentment, and produced an insurrection, so that 120,000 men invested the palace in order to kill the king. The Jews slew to disengage him, dispersed the multitude with fire and sword, burnt a great part of the city, and killed or destroyed very nearly 100,000 of the inhabitants. Upon the destruction of the Syrian empire by the Romans, Antioch submitted, and remained for a long time under their dominion. About the year 115, in the reign of the emperor Trajan, Antioch was almost utterly ruined by one of the most dreadful earthquakes which history records. Trajan himself escaped with difficulty, and not altogether unhurt, through a window of the room in which he had retired; and he afterwards contributed largely towards restoring its ancient splendour. In the year 155, it suffered very much by a fire, the damage of which was repaired by Antoninus Pius. Upon the revolt of Avidius Cassius, the Roman general,

general, about the year 176, the inhabitants of Antioch took part with him, and thus incurred the resentment of Marcus Aurelius, who issued a severe decree, forbidding all shows and public diversions, and even the exercise of all municipal offices; but upon their repentance he pardoned their offences, restored their privileges, and visited their city before he left the province. In the year 194, they were again deprived of their privileges by the emperor Severus, for joining Niger, and subjected, as a mere village, to the authority of Laodicea; but by the intreaties of his son Caracalla, then an infant, he mitigated their punishment.

Upon the decline of the Roman power, Antioch became an object of contention between the Romans and the nations of the East; and accordingly, when Sapor, king of Persia, over-ran Syria and other provinces, the city of Antioch was surprised whilst the idle multitude was fondly gazing on the amusements of the theatre; its splendid buildings, private and public, were either pillaged or destroyed; and the numerous inhabitants were put to the sword, or led away into captivity. This sack of Antioch is assigned, by the decisive testimony of Ammianus Marcellinus, to the reign of Gallienus; though other historians refer it to that of Valerian, some years before. Upon the division of the Roman empire by Constantine, in 331, it was afflicted with a very grievous famine, and relieved by the liberality of the emperor, who sent thither 30,000 bushels of corn. In 347, Constantine II. caused a harbour to be erected at Seleucia for the convenience of Antioch, which was executed at a very great expence. It suffered from famine in the reign of Julian, and also in that of Theodosius the Great, at which latter period the distress of famine was aggravated by a plague. On occasion of a tax imposed in 387, by Theodosius, the people were much enraged; and the cruelty of the governor, in restraining and punishing their sedition, induced many of them to abandon their dwellings, and to retire with their wives and families to the neighbouring mountains. Some of them, however, returned; and to these St. Chrysostom preached some of those admired homilies now in our possession; and these homilies are said to have had a great effect in reforming the licentious and dissolute. Theodosius, when he heard of this tumult, commanded the city to be destroyed, and the inhabitants to be put indiscriminately to the sword; but the order was revoked; and he contented himself with inflicting a punishment similar to that of Severus at a former period. Numbers, however, were condemned; and St. Chrysostom interposed to obtain for them a respite. At last a general pardon was obtained, and the city was restored to its former privileges. Antioch suffered from earthquakes in the years 458 and 526; but when Chosroes, king of Persia, invaded Syria in 540, the city, disdainful of offers of an easy capitulation, was taken by storm, the inhabitants slaughtered with unrelenting fury, and the city itself delivered to the flames; those who escaped were carried into Persia, and sold as slaves. Having again recovered, in a great degree, its former splendour, it was visited with an earthquake, A. D. 587, by which 30,000 persons lost their lives, and the city was almost wholly destroyed. In 611, it was seized by Chosroes II.; but "the aged metropolis, so often overturned by earthquakes and pillaged by the enemy, could supply but a small and languid stream of treasure and blood." In 638, Antioch was reduced by the Saracens, and ransomed with 300,000 pieces of gold: but "the throne of the successors of Alexander, the seat of the Roman government in the east, which had been decorated by Cæsar with the titles of free, and holy, and inviolate, was degraded, under the yoke of the caliphs, to the secondary rank of a provincial town." It was re-

covered by the Greeks under Nicephorus Phocas and John Zimisces, in the 10th century, and again restored as a permanent and useful accession to the Roman empire. But the civil dissensions in the empire afforded to the Turks an opportunity of seizing upon Antioch, as well as the whole kingdom of Syria; and from them it was taken by the crusaders, A. D. 1098. In 1262, it was taken by Bibars, sultan of Egypt, and then its glory terminated.

Antioch, called by the Arabs *Antakia*, anciently so renowned, is now no more than a ruinous town, the houses of which built with mud and straw, and consisting of narrow and miry streets, exhibit every appearance of poverty and wretchedness. It is situated on the southern bank of the Orontes, at the extremity of an old decayed bridge, and is covered to the south by a mountain, upon the slope of which is a wall built by the crusaders. The distance between the present town and this mountain may be about 400 yards; and the intervening space is occupied by gardens and heaps of rubbish.

Antioch, however, seems to be better calculated than Aleppo, which is become the metropolis of these eastern parts, to be the emporium of the Europeans. By clearing the mouth of the Orontes, which is six leagues lower down, boats might be towed up that river, though they could not fail up, as Pococke has asserted, its current being too rapid. The natives, who never knew the name Orontes, call it, on account of the swiftness of its stream, *El-Aafi*, that is, the rebel. Its breadth at Antioch is about 40 paces. Seven leagues above the town it passes by a lake abounding in fish, and especially in eels. Many of these are salted every year; but the quantity is not sufficient for the numerous fasts of the Greek christians. We no longer hear at Antioch either of the grove of Daphné, or of the voluptuous scenes of which it was the theatre.

The walls of each quarter of Antioch, as well as those which surrounded the whole, are still remaining; but as the houses are destroyed, the four quarters appear like so many inclosed fields.

The plain of Antioch, though the soil of it is excellent, is uncultivated, and abandoned to the Turkmans; but the hills on the side of the Orontes, particularly opposite to Serkin, abound in plantations of figs and olives, vines and mulberry trees, which are planted in quincunx, and exhibit a beautiful landscape. N. lat. 36° 20'. E. long. 37° 5'. Anc. Un. Hist. vol. viii. p. 115. Rollin's Anc. Hist. Crevier's Hist. of the Roman Emperors. Gibbon's Hist. vol. i. p. 438., ii. p. 361., iv. 123. 146., v. 59. 64., vii. 313. 417., viii. 220., ix. 417., x. 90., xi. 64. Volney's Travels in Egypt and Syria, vol. ii. p. 154.

There were many other ancient cities which bore the name *Antiochia*. Stephanus, de Urbibus, and Eutathius, in Dionys. p. 170, enumerate 14; and others, particularly Appianus in Syriacis, mention 16 cities distinguished by this appellation. Of these we may mention, Antioch of Pisidia, as it was usually denominated, though it was situated in Phrygia, near Pisidia, or in the northern part of Pisidia; this was a Roman colony, and called also *Cæsarea*. It is mentioned by Strabo and Ptolemy; and also by St. Luke, Acts xiii. 14. Another was of Caria, situate on the Meander river, at the confluence of this with the Corinthus, north-west of Aphrodisius. According to Stephan. Byz. it was also called Pythopolis, and Nyssa or Nyssa; which, according to Strabo, was near Tralles. This was built by Antiochus, the father of Seleucus, and was a bishop's see. Another was of Cilicia, in that part called Trachea, on the borders of the sea, at the foot of Mount Cragus. Steph. Byz. is mistaken in placing this city near the Pyramus, which

which watered Cilicia Campestris. There was also another town of this name in Cilicia, situate on the Sarus, and anciently called Adana; but Antiochus Epiphanes gave it his name, about 171 years before Christ. It was famous under the emperor Titus Antoninus, and distinguished by honorary titles. The Itineraries place it 27 Roman miles from Tarsus, and 18 miles from Mopsuestia. Another Antiochia was situated in Mesopotamia, at the foot of mount Masius, according to Strabo, and the same with Nisibis. A city of this name is placed by Steph. Byz. between Cœlosyria and Arabia; and Berkelius says, it was the same with Gadara. Another Antiochia was situated in the province of Syria, called Comagene, at the foot of mount Taurus, to the west of Samosata, and at a distance from the Euphrates, where Pliny places it. Antiochia was also the name of Edeffa. Pliny places a city of this name in Sittacene, which Hardouin supposes to be that which Ptolemy calls Apollonia. Another Antiochia was in Margiana, called Alexandria, after the name of its original founder, but re-established by Antiochus, son of Seleucus, who gave it his own name. Antiochia was also, according to Pliny, an island at the entrance of the Thracian Bosphorus. Stephanus Byz. says, that there was also a city of this name in Scythia.

ANTIOCHA, in *Entomology*, a species of PAPILO that inhabits South America. The wings are black, with two white bands on the anterior pair. Fabricius, Gmelin, &c. Papiilio clytia of Cramer is considered as a variety β of this species.

ANTIOCHE, PERTUIS DE, in *Geography*, a channel in the Atlantic, on the French coast, near the northern part of the island Oleron, and on the southern of the isle of Rhé.

ANTIOCHETTA, a town of Asiatic Turkey, on the coast of Caramania, and nearly due north from the western end of the island of Cyprus. It is a bishop's see. N. lat. $36^{\circ} 8'$. E. long. $32^{\circ} 15'$.

ANTIOCHIA, a town of South America, in the kingdom of Popayan.

ANTIOCHIAN *secta*, or *academy*, a name given to the fifth academy, or branch of academies.

It took the denomination from its being founded by Antiochus, a philosopher contemporary with Cicero.

The Antiochian academy succeeded the Philonian. As to points of doctrine, the philosophers of this sect appear to have restored that of the ancient academy, except that in the article of the criterion of truth, Antiochus was really a Stoic, and only nominally an Academic. After his time, the professors of the academic philosophy were dispersed by the tumults of war, and the school itself was transferred to Rome. See ANTIOCHUS.

ANTIOCHIAN *epocha*, in *Chronology*, a method of computing time from the proclamation of liberty granted the city of Antioch, about the time of the battle of Pharsalia.

ANTIOCHIS, in *Ancient Geography*, a tribe of Greece, in Attica.

ANTIOCHUS SOTER, in *Ancient History and Biography*, was the son of Seleucus Nicator, by Apama, the daughter of Artabazus the Persian; and took possession of the empire of Asia, on his father's death, and held it for 19 years. He is chiefly recorded in history on account of his passion for Stratonice, his mother-in-law. Fearing to disclose his attachment, he fell into a lingering disease, which endangered his life. But the affection of his father induced him to employ the celebrated physician, Erasistratus, to discover the cause of his disorder, and to administer necessary relief. The physician soon perceived, by the changes of his pulse and countenance whenever Stratonice entered the room, the occasion of his complaint; and he pretended to the father, that Antiochus was in love with his wife, and at the same

time expressed his concern, that his malady admitted of no cure. Seleucus remonstrated, and strongly urged the physician to preserve the life of his son by yielding to his wishes. "Would you do so (said Erasistratus) provided Stratonice were the object of his affection?"—"Most willingly," replied the king.—"The cure then (rejoined Erasistratus) is in your own power:" and when he disclosed to him the secret. Seleucus fulfilled his promise, and resigned the beautiful Stratonice to his son, together with a considerable part of his dominions; and caused them to be crowned king and queen of Upper Asia. Upon the death of his father, he succeeded to the whole empire, and resided at Antioch. Having surrendered his pretensions to Macedon in favour of Antigonus Gonatus, on his marrying Phila, the daughter of Stratonice by Seleucus, he afterwards defeated the Gauls, who had settled in Lower Asia, whence he obtained from these provinces the title of *Soter*, or *Saviour*. He himself was afterwards defeated by Eumenes king of Pergamus; and after this defeat returned to Antioch, where he put one of his sons to death, for raising disturbances in his absence; and at the same time proclaimed the other, called Antiochus, king of Syria. He died soon after in the year before Christ 261. *Anc. Un. Hist.* vol. viii. p. 125.

ANTIOCHUS THEOS, or *God*; so called by the flattery of the Milesians, for delivering them from Timarchus; was the son of the preceding Antiochus by Stratonice, and succeeded his father in the sole possession of all his dominions. In the third year of his reign, a bloody war broke out between him and Ptolemy Philadelphus, king of Egypt, on occasion of an insult offered to Apame, sister of Antiochus, and widow of Magas king of Cyrene and Lybia. During this war, the Parthians revolted, and putting themselves under the conduct of Arfaces, drove out the Macedonians; and thus laid the foundation of the Parthian empire, which at length became formidable not only to all the Princes of the East, but even to the Romans. The Bactrians also, under Theodotus, and the other nations in those parts, shook off the Macedonian yoke, and elected princes of their own; and thus Antiochus lost all the provinces of his empire lying beyond the Euphrates. In these circumstances of desertion and distress, Antiochus concluded a treaty of peace with Ptolemy, on the condition of divorcing his former wife Laodice, who was his own sister by the father, and marrying Berenice, the daughter of Ptolemy, and settling the crown upon the male issue of that marriage. The nuptials were solemnized with extraordinary magnificence at Seleucia. Within two years after this marriage Ptolemy died, and Antiochus repudiated Berenice, and restored Laodice, who embraced this favourable opportunity of securing the succession to her son. With this view, she caused Antiochus to be poisoned, and employed Artemon, who much resembled him in his voice and features, to be placed in his bed, the body of her deceased husband being secretly conveyed away. To complete this stratagem, Artemon strongly recommended his dear Laodice and her children to the lords that visited him. Accordingly, in the name of Antiochus, supposed to be still alive, orders were issued that all his subjects should obey his beloved son Seleucus Callinicus, and acknowledge him for their lawful sovereign. The crown being thus secured, the death of the king was publicly declared, and Callinicus, without opposition, ascended the throne. Antiochus died in the year before Christ 246, after a reign of 15 years. Laodice finished her infamous career by the murder of Berenice and her son. *Anc. Un. Hist.* vol. viii. p. 127.

ANTIOCHUS *the Great*, so called on account of his illustrious actions, was the son of Seleucus Callinicus, and succeeded his brother Seleucus Ceraunus, in the year before Christ

A N T I O C H U S .

Christ 225. After the troubles with which his reign commenced, and which were terminated peaceably by his activity, his attention was engaged by the revolt of his uncle Achæus, who usurped the sovereignty of Asia Minor; and by a contest with Ptolemy Philopator, king of Egypt, for the recovery of Cœlosyria. He first resolved on a war with Ptolemy, which, after several advantages gained by him, terminated by a defeat in the decisive battle of Raphia, in the year before Christ 217, which obliged him to abandon all his conquests, and to withdraw, with the remains of his shattered army, to Antioch. The result was a negotiation for peace, which Antiochus obtained, on the condition of surrendering to Ptolemy the whole of Cœlosyria and Palestine. His next object was Achæus, whom he obliged to quit the field, and to shut himself up in the castle of Sardis; but he was at length delivered up by treachery to Antiochus, who, whilst he compassionated the misfortunes of a man to whom he was indebted for his crown, ordered him to be beheaded, and thus put an end to the war of Asia. Antiochus was now at liberty to pursue his plans for the reduction of those provinces in the east, which had shaken off the Syrian yoke. Accordingly he recovered Media and Parthia, and reduced Syringis, the capital of Hyrcania. Arsaces, however, was a formidable enemy; and he therefore made overtures to him for putting an end to the war; the consequence of which was, that it was agreed by treaty, that Arsaces should hold Parthia and Hyrcania, on condition of his assisting Antiochus to recover the other provinces which had revolted. He also, in a similar manner, concluded a peace with Euthydemus king of Bactria. After this pacification, he crossed Mount Caucasus, and entered India, where he renewed his alliance with Sophaganeus king of that country; and having marched through Arachosia, Drangiana, and Carmania, he returned by Persia, Babylonia, and Mesopotamia, to Antioch, after a successful expedition of seven years, and with the surname of *Great*, which he had acquired, and which he might have retained, with the reputation annexed to it, till his death, if he had not unfortunately engaged in a war with the Romans.

Soon after the return of Antiochus, Ptolemy Philopator died, and was succeeded by his son Ptolemy Epiphanes, a child of five years. The youth of the sovereign of Egypt presented to the ambitious views of Antiochus objects which were too alluring to be resisted. This, he thought, was a favourable opportunity, not only for recovering his lost provinces, but for seeking further aggrandisement. Accordingly he entered into a treaty with Philip king of Macedonia, in virtue of which they were to deprive the infant king of his dominions, and to divide them: Philip was to have Caria, Lybia, Cyrene, and Egypt; and Antiochus all the rest. Antiochus, having settled these preliminaries, marched into Cœlosyria and Palestine, and soon subdued them. But it so happened, that at this time Scipio had concluded the second Punic war; and the fame of the Romans was every where spread. The guardians of the young king, incited by the celebrity of the Roman name, sent an embassy to Rome, imploring the protection of that republic, and offering the guardianship of their king, and the regency of the kingdom during his minority. The Romans acceded to the proposal, and immediately signified their compliance to Antiochus and Philip, requiring them to desist from invading the dominions of their pupil, and threatening war upon them for his protection. Aristomenes, an old experienced officer, was appointed the young king's minister, and he deputed Scopas to levy troops in Ætolia, for the service of his master. These troops marched, during the absence of Antiochus, into Palestine and Cœlosyria, in

order to recover those provinces; but after some success, Antiochus returned, defeated Scopas, with the loss of the greatest part of his army, and obliged him to surrender Sidon, into which he had retired, with the whole garrison. Antiochus was cordially received by the Jews; and on his approach to Jerusalem, treated with the utmost respect and hospitality. In return, Antiochus granted them many privileges and favours. Antiochus proceeded from Palestine to Asia Minor; and as he sailed with a formidable fleet along the coast of Cilicia, Pamphylia, Lycia, and Caria, many of the maritime cities of those provinces voluntarily submitted to him. He then sailed to Ephesus, made himself master of it, and took up his winter-quarters there. In the mean time Smyrna, Lampascus, and other Greek cities of Asia, which at that time enjoyed their liberty, concurred in imploring the protection of the Romans, who were at last prevailed upon to exert themselves in restraining the progress of Antiochus. But during this embassy, Antiochus crossed the Hellespont, and seized all Thracian Chersonesus. The succour which these cities solicited was delayed, and much time was lost in ineffectual negotiation; till at length, in the year before Christ 195, Hannibal besought the protection of Antiochus, and engaged him to make war on the Romans. Antiochus strengthened himself by new alliances; having married his daughter Cleopatra to Ptolemy king of Egypt; and Antiochis, his second daughter, to Ariarathes king of Cappadocia. After fruitless embassies between him and the Romans, he formed the fatal resolution of commencing a war with them. Hostilities were mutual, and success for some time was doubtful; but the fleet of Antiochus having been defeated by that of the Romans, and his troops having been withdrawn from the Hellespont, the two Scipios, Cornelius and Africanus, found a free passage into Asia. The king was alarmed, and made proposals of accommodation to the Romans, which, although very advantageous to them, were rejected. He also offered, without ransom, the son of Africanus; and the grateful father acknowledged his obligations, by desiring him not to hazard a battle before his return to the army. But a decisive engagement took place at Magnesia, in Lower Asia; Antiochus was completely vanquished, in the year before Christ 190: and compelled by the circumstances to which he was reduced, to sue for peace. The terms were his giving up all his pretensions on Europe, limiting his Asiatic dominions to the country beyond Mount Taurus, and paying the expenses of the war. The surrender of Hannibal was also stipulated, but he had made his escape. The Syrian monarch did not long survive this humiliation: the manner of his death is not so satisfactorily ascertained. Jerom, on the authority of Strabo, says, that having plundered the temple of Jupiter Belus, in the province of Elemais, he was slain in an insurrection of the people. Aurelius Victor relates, that he gave himself up to every kind of dissolute pleasure; and that he was killed at an entertainment by one of his guests, whom he had insulted. He died, however, in the year before Christ 187, in the 37th year of his reign, and 52d of his age; and he is highly commended by most of the ancient historians for his humanity, clemency, and liberality. Till the 50th year of his age, his prudence in counsel, and courage in action, were such as to command success, and entitle him to the appellation of "Great;" but after that age, he was less wise and valiant, and less prosperous. His conduct in the war with the Romans, the contempt with which he received the wise counsels of Hannibal, and the ignominious peace which he was forced to accept, obscured all the glory of his former expeditions. The prophecies of Daniel, from the 10th verse of the 11th chapter to the 19th, inclusive,

clusive, relate to the actions of this prince, and were all fully accomplished. *Anc. Un. Hist.* vol. viii. p. 139—191.

ANTIOCHUS EPIPHANES, a younger son of Antiochus the Great, succeeded his brother Seleucus, in the year before Christ 176. It was one article of the humiliating treaty of Maguesia, that this prince should be sent to Rome as a hostage; and there he was detained for 13 years, till he was exchanged for his brother's son Demetrius. In his way home, his brother Seleucus was poisoned by Heliodorus, who usurped the crown. But aided by Eumenes, king of Pergamus, and Attalus that king's brother, he drove out the usurper, and ascended the throne. His conduct was foolish and extravagant to an extreme degree; and besides the frantic follies with which he was chargeable, he was addicted to drunkenness, squandered away large sums of money in riotous excesses; and in his mad frolics, scattered handfuls of money among the populace, crying out, "Let him take it to whom fortune gives it." This odd and extravagant conduct, of which many singular instances are related, made his subjects regard him as a madman; whence, instead of "Epiphanes, or the Illustrious," the title which he assumed on being settled on the throne, they used to style him "Epimanes" that is, "the Madman." Soon after his accession, a demand was made by the administration of Egypt for the restoration of Cœlosyria and Palestine; and this demand occasioned a war between the two crowns. Antiochus determined to anticipate the preparations made in Egypt, by a commencement of hostilities, and by an actual invasion of the country; and, at the same time, he sent a splendid embassy to Rome to justify his conduct, and to conciliate the favour of the senate. In his first expedition, he routed the Egyptians, and wintered at Tyre. In a second campaign, in the year before Christ 170, he reduced the whole country, except Alexandria, and gained as much by his clemency as by his arms. On this occasion, Ptolemy Philometer fell into the hands of the conqueror; and the Alexandrians, considering him as lost to them, placed upon the throne his younger brother Ptolemy Euergetes, called also Physcon; and made attempts to recover their country from the Syrians. Antiochus was thus induced to make a third expedition into Egypt, and advanced directly to Alexandria, with the design of besieging it. In this danger, Ptolemy Euergetes, and his sister Cleopatra, sent an ambassador to Rome to supplicate assistance. The senate determined to give them relief, and accordingly sent an embassy into Egypt for the purpose of terminating the war: and the instructions of their ambassadors were, to order the contending princes to suspend all hostilities, and to put an end to the war, on pain of forfeiting the friendship and alliance of the Romans. Antiochus, in the mean time, had made a pacification with Philometor, and engaged to restore him to the possession of his dominions, Pelusium excepted. He then returned to Antioch; but during his absence, the two royal brothers agreed, under the influence of Cleopatra's mediation, to reign jointly, and to renounce their dependence on Antiochus. This produced a fourth expedition into Egypt; and the Syrian king was hastily marching towards Alexandria, after having reduced the greatest part of the country, when he was met by the three Roman deputies. The decree of the senate was announced to him, and he desired some time for deliberation. Popilius, one of the deputies, drew a circle with a rod, which he held in his hand, round the king, and informed him that he expected a peremptory answer before he left that ring. Antiochus hesitated for a few minutes, and then declared his readiness to comply with the requisition of the republic. The three deputies gave him their hands, and Popilius renewed his former

familiarity with him. Antiochus was probably not a little exasperated, though he was obliged to submit; for on his return from Egypt, he visited Jerusalem, and with extreme cruelty compelled the Jews to violate the principles of their religion and worship at the heathen altars which he had caused to be erected. In a former expedition, he had taken Jerusalem by storm, plundered and despoiled the temple, and abolished the Jewish ritual. These violences, which are related in the books of the Maccabees, occasioned the new revolt of Mattathias and his sons; which for a long time filled that country with bloodshed, and despoiled the whole power of Syria.

With a view of further ingratiating himself with the Romans, he celebrated their subjugation of the kingdom of Macedon under Perseus, by causing games to be exhibited at Daphné near Antioch, with a pomp and magnificence which even in that luxurious part of the world had never before been witnessed. The king's conduct was so extravagant and absurd on this occasion, that Tiberius Gracchus, the Roman envoy at his court, informed the senate, that they need be under no apprehensions from any design which he could form. Nevertheless, on a revolt of Armenia and Persia, he left part of his army under Lyfias to reduce Judæa, and marched with the rest against Artaxias, the Armenian king, whom he defeated and took prisoner. From Armenia he marched into Persia, and slew to Elimais, of the immense wealth of which he had received information, with a design to plunder both the city and the temple. Here he was repulsed with the greatest ignominy; and mortified at the disgrace he suffered, he withdrew to Ecbatan in Media. But news arriving of the defeat of Nicanor and Timotheus, two of his generals in Judæa, he hastened towards Babylonia; and was met in his passage by two messengers, who gave him an account of the defeat of Lyfias, and that the Jews had retaken the temple, thrown down the images and altars which he had erected, and restored their former worship. These tidings exasperated him beyond measure; and he determined to march in person against the Jews, and threatened to extirpate the whole nation. He had scarcely uttered these words, when he was seized with an excruciating pain in his bowels, which no remedy could cure or alleviate. He resolved, however, to proceed, till at length he was obliged to halt at a town called Tabæ, on the confines of Persia and Babylonia, in the year before Christ 165, where he expired, after languishing for some time in the most dreadful agony both of mind and body, in the 12th year of his reign, and 39th of his life. The 11th chapter of Daniel, from the 20th verse to the end, wholly relates to this Antiochus. *Anc. Un. Hist.* vol. viii. p. 195. 213.

ANTIOCHUS EUPATOR, was the son of the preceding, and placed on the throne at the age of 9 years, on the death of his father, by Lyfias; though the deceased monarch had appointed Philip, his prime minister, for his guardian. Philip retired into Egypt; and Lyfias prosecuted the war with the Jews which Epiphanes had begun; but the large army which he conducted thither was defeated by Judas Macca-

bæus. From another expedition into Judæa, and the siege of Jerusalem, he was recalled by the intelligence, that Philip had taken possession of Antioch, and seized on the government. Lyfias made peace with the Jews; and having marched against Philip, defeated him, and put him to death. In the mean time the Roman senate had assumed the tutelage of the young king, and sent a commission of guardianship into Syria, with orders to burn all the decked ships, and disable the war-elephants. Octavius, who was appointed chief of this commission, and who executed his orders with great insolence,

A N T I O C H U S.

solence, was killed in a popular tumult at Laodicea; and buried with great pomp by Lyfias, who dreaded the indignation of the senate, and sent ambassadors to Rome for his own exculpation. At this time Demetrius, the son of Seleucus Philopator, who had the best right to the crown, but who was kept at Rome as a hostage, contrived to make his escape: and arriving in Syria, was received every where by the people as their lawful sovereign. Lyfias and the inoffensive Eupator were delivered by their own soldiers to Demetrius, who ordered them both to be put to death, in the year before Christ 162, after the young prince had reigned between two and three years. The author of the first book of the Maccabees says, they were taken prisoners by the soldiers of Demetrius, and by them put to death, without any orders from Demetrius. *Anc. Un. Hist.* vol. viii. p. 212. 221.

ANTIOCHUS SIDETES, or the *Hunter*, was the second son of Demetrius Soter, and succeeded to the throne, vacated by his brother Demetrius Nicator, after the expulsion of Tryphon the usurper, by the interest of Cleopatra, the wife of Demetrius, whom he married, and the assistance of Simon, high priest of the Jews, in the year before Christ 138. After his accession, he reduced all those cities of Syria which had rendered themselves independent during the intestine troubles. He then made war with the Jews, besieged Jerusalem, and compelled Hyrcan, who had succeeded his father Simon, to purchase a peace, on the condition of paying tribute. He then entered Parthia, with a motley multitude of cooks, singers, women, and other ministers of luxury, much more numerous than his soldiers, defeated Phraates, and regained the provinces which he had separated from the Syrian empire. But his troops being dispersed into distant winter-quarters, the oppressed people, joined by the Parthians, conspired to attack them all in one day; and Antiochus, and every man under his command, were destroyed. Others say, that he could not survive the disgrace of being vanquished in battle, and that he put an end to his own life. This happened in the ninth year of his reign, before Christ 130. Although Antiochus was addicted to intemperance and amusement, he is represented as a prince possessing many good qualities, a lover of justice, and inclined to clemency. Phraates, on viewing his dead body, is said to have exclaimed, "Your wine, Antiochus, and your too great confidence, have brought you to this untimely end. You thought you could have swallowed the kingdom of Arfaces in your cups." *Anc. Un. Hist.* vol. viii. p. 242—245.

ANTIOCHUS GRYPUS, or *hook-nosed*, was the son of Demetrius Nicator by Cleopatra; and on the death of his brother Seleucus, whom his mother, jealous of her power, caused to be murdered, was recalled by her from Athens, where he had been sent for his education, and proclaimed king of Syria, in the year before Christ 123, to the exclusion of Alexander Zebina, who had usurped the throne, and whom Grypus afterwards put to death. Cleopatra had advanced Grypus to the throne, with a view of reserving the authority to herself, and of allowing him the mere title of king. But when he began to manifest an inclination to govern independently of his mother, she determined to transfer the crown to a younger son, and to dispatch this by poison. For this purpose, she prepared a bowl, and presented it to the young king on a day when he returned hot and weary from the chase. But as he was forewarned of her purpose, he desired her to take the first draught; and on her refusal, he summoned the lords of his court, communicated to them the information he had received, and then said, that the only mode by which she could exculpate her-

self, was to drink what she had prepared for him. She drank, and presently expired. After her death, Antiochus enjoyed the sovereignty of Syria for eight years without disturbance; but there arose a rival, *viz.* Antiochus the Cyzicene, the son of Cleopatra by Antiochus Sidetes. The consequence of this rivalry was a civil war, which terminated in the division of the kingdom. Having thus settled their difference, they both devoted themselves to voluptuousness and debauchery, and totally neglected both their private and public concerns. This negligence on their part gave John Hyrcan an opportunity of making conquests upon Syria; and the subsequent disagreement of the two brothers afforded occasion for several cities to assert their independence. At length Grypus was assassinated by one of his own subjects, in the 45th year of his age, in the year before Christ 97, after having reigned, according to Josephus, 29, and according to Porphyrius, 26 years. Cyzicenus, some years after, was defeated and slain by his nephew Seleucus. *Anc. Un. Hist.* vol. viii. p. 248—253.

ANTIOCHUS, a monk of Seba in Palestine, of a very superstitious complexion, lived towards the beginning of the seventh century; and wrote a summary of the christian doctrine, intitled "The Pandect of the Holy Scriptures," in 130 homilies. In the preface, he mentions the capture of Jerusalem by Chosroes, king of Persia; and relates the cruelties inflicted on the monks of Palestine; and in an annexed poem, he laments in doleful strains the loss of a precious fragment of the true cross, which, among other spoils, was carried away by the Persians. The work is published in Greek and Latin, in the additions to the "Bibliotheca Patrum." *Fabric. Bib. Grec.* l. v. c. 34. § 3. t. ix. p. 260. *Mosheim Eccl. Hist.* vol. ii. p. 174. 179.

ANTIOCHUS, a Stoic philosopher, was a native of Ascalon, a disciple of Carneades, and the last preceptor of the Platonic school in Greece. He flourished about 100 years before Christ. Cicero (in *Brut. et de Nat. Deorum.* l. i. c. 7.) mentions him with respect as one of his instructors, and as the author of an ingenious treatise upon the Academic sect; in which he shewed that the Peripatetics and Stoics differed more in words than in real opinion. He also maintained, that the doctrines of the Stoics were to be found in the writings of Plato. Cicero also professes to admire his eloquence and the politeness of his manners; and Lucullus took him as his companion into Asia and to Rome, in which city he enjoyed the friendship of many illustrious men. Plutarch (in *Lucull.*) mentions a treatise of his "On the Gods;" and Stephanus Byz. says, that he was the ornament of his country, and gives him the appellation of a "swan." None of his writings are extant. He resigned the academic chair in the 175th Olympiad, or in the year before Christ 80. *Brucker's Hist. of Philos.* by Enfield, vol. i. p. 254.

ANTIOCHUS, was a contemporary with Galen. He is said to have lived nearly an 100 years, and to have enjoyed his faculties to the last. This was attributed to an abstemious and careful regimen, which he adopted as soon as he became advanced in years.

ANTIOCHUS, in *Entomology*, a species of PAPILIO that inhabits China. The wings are entire, roundish, black; with a broad yellow-brown band continued across the upper surface of all the wings. *Fabricius, and Donovan's Insects of China.*

ANTIODONTALGICUS, a new insect, described by professor Gerbi, in a small work published at Florence in 1794; so called from its property of allaying the tooth-ach. It is a kind of curculio, and found on a species of thistle, *carduus spinosissimus*, which is perhaps a variety of

the cmeus. Its flowers, when analysed, gave the acid of salts, the muriatic acid, oxalate of lime, extractive matter, and a very little resin. The insect eats not only the parenchyma, but also the vessels and fibres of the leaves. It is of a length figure, covered below with short yellow hair, and above with golden, yellow velvety spots. Its coreclet is variegated with specks, and the covering of its wings with specks and stripes. It has a short proboscis, and somewhat resembles the *cureulio villosus* of Geoffroy. Its larva represents a sort of ichneumon. If 12 or 15 of these insects, in the state of larva, or when come to perfection, be bruised and rubbed slowly between the forefinger and thumb, until they have lost their moisture; and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases, sometimes instantaneously. A piece of shamoy leather will answer the same purpose with the finger. If the gums are inflamed, the remedy is of no avail. Other insects possess this property of curing the tooth-ach: such as the *carabus ferrugineus* of Fabricius; the *coccinella septem-punctata*, or lady-bird; the *chrysomela populi*, and the *chrysomela sanguinolenta*. This property seems to belong to several kinds of the coleoptera.

ANTIOPA, a species of *PAPILIO* that inhabits Europe. The wings are angulated, black, with a whitish border. Linn. Faun. Suec. Fabricius, &c. This is *papilio maxima nigra*, alis utrisque limbo lato albo cinctis of Ray, &c.; and is known by the English name of Camberwell beauty butterfly. The dark colour of the wings inclines to a rich purple-brown, the external border to yellowish; and it has an intermediate black stripe, with a row of blueish spots, and two long yellowish spots on the anterior margin of the first wings. It is produced from a black spinous larva, that is marked on the back with a row of ferruginous spots, and feeds on the willow. It is remarkable, that the insects of this species found in England have the external border of a paler colour than those found in other parts of Europe, though in other respects they are perfectly similar. Donovan's British Insects, vol. iii. p. 47.

ANTIOPE, in *Fabulous History*, the wife of Lycaus king of Thebes, who, being deflowered by Jupiter in the form of a satyr, brought forth Amphion and Zethus. Another Antiope was queen of the Amazons; and, with the assistance of the Scythians, invaded the Athenians, but was vanquished by Theseus.

ANTIOPIA, in *Ancient Geography*, an ancient town of Palestine, in the tribe of Naphtali, towards the frontier of Aser, between Tyr and Bethsaida. It was once a principal city of the Canaanites, but is now reduced to a miserable village.

ANTIPACHSU, in *Geography*, a small island on the coast of Epirus, over against the gulph of Arta, between Corfu and Cephalonia.

ANTI-PÆDO-BAPTISTS, derived from *anti*, against, *παις*, *παιδος*, child, and *βαπτισμα*, baptize, whence *βαπτισμος*, is a distinguished denomination given to those who object to the baptism of infants; because, they say, infants are incapable of being instructed, and of making that profession of faith which entitles them to this ordinance, and an admission into church communion. See ANABAPTISTS and BAPTISTS.

ANTIPAGMENTS, *Antipagmenta*. See ANTEPAGMENTS.

ANTIPAPINIANUS, *αντιπαπινιος*, a title given by the Greek lawyers to the fourth part of the Digest, including four books, beginning with the title *De pignoribus*.

This is otherwise called *antipapianus*.

The antipapianus was thus denominated, not as being in-

tended in opposition to Papinian, but because it was to serve in the schools of the civil law in lieu of the books of that lawyer, pursuant to an edict of the emperor Julian; so that the antipapinian was so far from being a refutation of Papinian, that it was only a substitute for his writings, which were not so proper for the use of the younger sort of students.

ANTIPARALLELS, in *Geometry*, are those lines which make equal angles with two other lines, but in opposite directions. Thus, if AB and AC (*Plate 11. Geometry. fig. 27.*) be any two lines, and FC and FE be two others intersecting them in such a manner, that the angle B be equal to the angle E, and the angle C equal to the angle D, then BC and DE are antiparallels, with respect to AB and AC; and these latter are antiparallels with regard to the two former. It is a property of these lines, that each pair cuts the other into proportional segments, if they be taken alternately. *viz.* AB: AC:: AE: AD:: DB: EC, and FE: FC:: FB: FD:: DE: BC. M. Leibnitz, however, calls those lines antiparallels, which cut two parallels so, that the outward angle being added to the inward one, the sum may be equal to a right angle.

ANTIPARALYTICA, in the *Materia Medica*, medicines suited to cure the palsy.

ANTIPARASTASIS, from *anti* and *παρυστασις*, of *παρυστημι*, I exhibit, in *Rhetoric*, a reply to an opponent, by allowing part of his argument, and denying the rest, *e. gr.* "you may print whatever you please, provided the public suffer no prejudice from it; but you must not, if it does."

ANTIPAROS, in *Geography*, an island in the Archipelago, opposite to Paros, and separated from it by a strait about seven miles wide. This is the ancient *Oliaros*, which was established by a colony of Sidonians. It is narrow and long, extending in a direction from north-east to south-east; and, according to Tournefort, about 16 miles in circumference; its soil is tolerably fertile, and produces for its own supply wheat, barley, wine, sesamum, and some legumes; but the most considerable production, and that which enables the inhabitants to pay their imposts, is cotton. What renders Antiparos particularly famous is the grotto, which penetrates into its bosom to a very great depth; and which, according to the relations of the Greeks, communicates beneath the waters with some neighbouring islands. Magni, an Italian traveller, who first discovered this subterraneous grotto, has given an account of it; Tournefort has also described it with great exactness; and M. de Choiseul Gouffier has given some very beautiful drawings of it in his "Voyage Pittoresque de la Grèce." We first find a rustic cave, about 30 feet wide, divided by some natural pillars; between which the ground slopes gently, and then more precipitately to the bottom of the cavern. At last the descent is by a ladder to the grotto itself, which is about 300 fathoms below the surface of the earth; and it appears to be about 40 fathoms high, and 50 wide. It is full of large and beautiful stalactites, hanging from the roof, and covering the floor. Olivier (Travels, p. 121.) queries, whether it ought to be considered as a quarry, from which marble has been extracted for a length of time, or as an immense cavity, such as naturally exist in most calcareous mountains.

ANTIPAS-HEROD. See HEROD.

ANTIPASCHA, in *Ecclesiastical Writers*, denotes the first Sunday after Easter; otherwise called *DOMINICA in albis*.

ANTIPATER, in *History* and *Biography*, was a native of Idumæa; and, having acquired wealth and influence in the Jewish state, joined the Pharisees against Aristobulus the high

high priest, in favour of his brother and competitor Hyrcan. He also engaged Aretas, the Arabian king, to invade Judæa, where he was strengthened by Hyrcan's party; and totally defeated Aristobulus, who was forced to fly into Jerusalem, and avoid the event of a close siege. In these circumstances Aristobulus applied to the Romans for succour; and Scarus, the Roman general, was induced by a considerable bribe to threaten Aretas, and thus to induce him to lead his army out of Judæa. He was afterwards overtaken by Aristobulus, and defeated with great slaughter. When Pompey arrived in Syria, in the year before Christ 63, the two brothers, Aristobulus and Hyrcan, appeared before him, and urged their respective pleas; but the decision was deferred, and Aristobulus departed in disgust. When Pompey entered Judæa, he summoned Aristobulus, who had raised a considerable army, to appear and to answer for his conduct; but being dissatisfied with the terms of conciliation that were proposed to him, he fled with haste to Jerusalem, and was soon followed by Pompey, who laid siege to the city, and, after an obstinate resistance, took it. On this occasion, 12,000 of the besieged were slaughtered by the Romans, besides many more who died by their own hands. During this horrid scene, the priests never intermitted the divine service in the temple; and at last suffered themselves to be butchered before the altar, with as much meekness and constancy as the victims they were then offering. Hyrcan was restored to the pontifical dignity, with the specious title of prince, though from thenceforth tributary to Rome; but he was wholly divested of his regal power, and forbade to resume either the diadem or royal style, or to extend his territory beyond the old borders of Judæa. Aristobulus and his two sons, Alexander and Antigonus, together with his two daughters, were taken by Pompey to Rome, as captives to adorn his triumph. The indolence of Hyrcan led him to commit the management of his affairs to Antipater, who artfully contrived to ingratiate himself with the Romans, and to promote the aggrandizement of his own family. With these views he gave successive assistance to Scarus, Gabinius, and Cassius, the Roman generals who commanded in those countries. He also facilitated the capture of Pelusium by the succours which he afforded to Julius Cæsar, and he was one of the foremost in scaling it, when this city was taken by assault. Mithridates, in a letter to Cæsar, acknowledged that his successes were owing to the co-operation and valour of Antipater; and in recompence of his service, Cæsar gave him considerable polls in the army, and made him procurator or lieutenant of Judæa, and citizen of Rome. Antipater, having accompanied Cæsar to Tyre, where he embarked for Sicily, returned to Jerusalem, and exerted himself in restoring the Jewish government to its ancient model, and repairing the walls and fortifications. He also made his eldest son Phasael governor of the metropolis, and appointed his second son, Herod, governor of Galilee. This growing power, however, excited the envy and jealousy of the principal Jews; and at length Malichus, who had been of the same party with Antipater, and who had concurred with him in the support of Hyrcan's interell, resolved to take him off by treachery. Antipater, being apprized of his design, retired beyond Jordan, and put himself in a posture of defence; but Malichus contrived by various protestations to remove his suspicion, and to effect a reconciliation with him; and Antipater, by his interest with Marcus, governor of Syria, prevented his being put to death. The jealousy and envy of Malichus were smothered, but not extinguished; and he embraced the first convenient opportunity that offered of bribing the butler of the high priest to poison him with

a glass of wine, whilst with an armed force he seized upon the government of Jerusalem. This event happened in the year before Christ 43. *Anc. Un. Hist.* vol. iii. p. 127 - 147.

ANTIPATER, the Macedonian, was a person of noble birth, and distinguished by his natural talents and excellent education. He was the friend and disciple of Aristotle, learned, and a lover of learning; magnificent in his actions, but plain in his dress and behaviour, never varying his habit during the whole time of his government, but appearing like a private person when he gave law to kings. Philip of Macedon selected him as his minister, and confided in him as his friend. "I have slept soundly," said he; "for Antipater was waking." And Alexander, referring to his plain garb, replied to those who observed to him, that all his great officers, except Antipater, wore purple; "True; but Antipater is all purple within." During the absence of Alexander, on occasion of his expedition into Asia, the government of Macedon was given to Antipater; and he was supported even against the interference of Olympias, Alexander's mother. He also maintained the tranquillity of all Greece; and marching with a considerable force against Agis III. king of Sparta, who had united several of the Grecian states against the Macedonians, he defeated the Spartan king, and by a single action terminated the war.

After the death of Alexander, when the empire was divided by a general council summoned by Perdiccas, the government of the European provinces was assigned to Antipater, as general of the army in that continent. In consequence of an edict of Alexander, which directed all the cities of Greece to recall their exiles, Antipater was soon engaged in a war, in which the Athenians were particularly active, and in which they were at first successful; so that they compelled him, after a defeat, to retire to Lamia, a strong city, near the field in which their armies had been engaged. But Antipater, receiving assistance from Asia, was rescued from confinement, and the siege being raised, he was joined by Craterus, and thus enabled to defeat the confederate Greeks. Athens, on his approach, was compelled to submit at discretion; and he abolished the popular government there, and established that of Solon, leaving a Macedonian governor in the place. He also settled the rest of the Grecian states on a similar plan of equity and moderation; and so much to general satisfaction, that he was honoured as the father and protector of Greece. Upon his return to Macedon, he directed his arms, in conjunction with his son-in-law Craterus, who had married his daughter Philla, against the Ætolians, the only persons that had refused to be comprehended in the peace, and effected their purpose. They afterwards entered into a league with Ptolemy, and passed over into Asia, in order to control the power of Perdiccas, who had assumed the sovereignty. But Perdiccas being soon after slain in Egypt, Antipater was sent for to the army in Syria, and declared the sole protector of kings, and invested with sovereign power. Antipater next proceeded to make a new division of the provinces, and then returned to Macedon, his own province, with the kings, leaving the army satisfied with his proceedings. Soon after his return to Macedon, he was attacked by a dangerous disease, which, at his advanced age, left him little hope of life. In his last moments he behaved with the same firmness and the same regard to his reputation which he had manifested in all the actions of his life. His great offices of protector and governor of Macedon he bequeathed to Polysperchon, the eldest of Alexander's captains then present; and his eldest son, Cassander, he merely appointed to be a chiliarch or colonel of a thousand

men. To Polyperchon he gave a council suggested by the experience of his life: "Never, on any account to suffer a woman to interfere in affairs of state." He died at the age of 80, in the year before Christ 318. *Anc. Un. Hist.* vol. vii. p. 454., vol. viii. p. 16. Rollin's *Anc. Hist.* vol. iv. p. 374., vol. v. p. 119—151.

ANTIPATER, was bishop of Bostra, an Arabian church, and flourished towards the end of the fifth century. He wrote a refutation of Eusebius's Apology for Origen, fragments of which are preserved in the acts of the second council of Nice. *Fabr. Bib. Græc.* l. v. c. 34. § 7. t. 9. p. 274

ANTIPATER, LELIUS COELIUS, a Roman historian, who lived in the time of the Gracchi, was the author of a history of the second Punic war, of which Brutus wrote an abridgment. He is often mentioned by Cicero. The emperor Adrian preferred Antipater to Sallust, probably for the same reason that he preferred Ennius to Virgil, because he was an admirer of the ancient Roman language. Fragments of this historian were published by Riccoboni in 1568, and reprinted with fragments of other historians, by Antony Angustin, at Antwerp, in 1595. *Voss. de Hist. Lat.* l. i. c. 8.

ANTIPATER of Sidon, or of Tarsus, a stoic philosopher, and also a poet commended by Cicero and Seneca, flourished about the 175th Olympiad, or 80 years before Christ. He was the disciple and successor of Diogenes the Babylonian; and his chief opponent was Carneades.

ANTIPATER, an ancient physician of the sect of the methodists, died, as Galen relates, of a tubercle in his lungs. The tubercle occasioning an intermission of his pulse, which continued several months, Galen, from this circumstance, predicted that his death would be sudden, which accordingly happened.

ANTIPATHES, among the *Ancient Naturalists*, was used to express any stone or gem, which, according to their superstitious ideas of the virtues of gems at that time, was supposed to have a power of resisting the force of enchantments. Pliny mentions a very valuable gem, called by the ancients antipathes for this very reason; and the black coral had the same name on the same account.

ANTIPATHES, in *Natural History*, the name of a genus in the ZOOPHYTA order of VERMES, the character of which, according to the Linnæan system, is, animal growing in the form of a plant; stem within horny, with small spines; base expanded; the outside covered with gelatinous flesh, and numerous polypiferous warts. The species of the genus are, spiralis, ulex, subpinnata, myriophylla, elopecuroides, cupressus, orichalcea, dichotoma, clathrata, fabellum, pennacea, ericoides, and fœniculacea; which see respectively.

ANTIPATHY, compounded of *αντι*, *contra*, *against*, and *παθος*, *passion*, in *Physiology*, a natural enmity or aversion of one body to another. In which sense the word stands opposed to SYMPATHY. Such an aversion is commonly said to be between the salamander and the tortoise, the vine and the elm, the toad and the weasel, the sheep and the wolf, the olive and the oak, &c. *Phil. Trans.* N^o 339.

In a more restricted and proper sense, antipathy denotes that natural aversion and detestation which an animated and sensitive being feels with regard to some object that is presented to it, either in reality or in imagination; and the cause of which is mysterious and inexplicable. Such are some of the antipathies mentioned in the last paragraph; and such also is the aversion to which some persons are conscious under the apprehension or at the sight of particular

objects, as cats, mice, spiders, serpents, eels, &c. and which produces, whatever be the cause of it, sensible and apparent effects. Many instances of antipathies that have been recorded are, perhaps, no better than fables; and a severe examination would reduce them to the large class of vulgar errors. There are also fictitious aversions, which have no other source besides affectation, and a pretended delicacy of nerves, which is more frequently feigned than real. Of those other antipathies, the existence of which is capable of being ascertained, and which produce sensible and undisputed effect, it is not difficult to assign a cause without recurring, with the Peripatetics, to any occult qualities inherent in bodies. In the credulous period of infancy, with what pains and industry are the minds of children impressed with the sense of the noxious qualities of particular animals, such as serpents and other reptiles; and how easily do they associate the ideas they are thus led to entertain of some objects, with others that resemble them in their visible form or general properties? When an aversion thus imbibed in early life, or in consequence of some trivial act or injury, concurs with a feeble frame and irritable state of the nervous system, it will serve to account, with sufficient satisfaction, for the antipathies of advanced age, without recurring to any occult qualities and latent principles, which are mere names for unknown and unascertained causes of particular effects. The antipathy which some persons have to eels, may be traced to the resemblance which these fishes bear to serpents, and to the dread of these reptiles that has been betimes implanted and cherished. There are other antipathies with regard to food or liquor of any particular kind, which have proceeded from a defective and faulty conduct of indulgent and ill-judging parents in early life, or from some natural unsuitableness to the taste or digestive faculty of children. "To what then are those antipathies of which we have heard so much reducible? Either to legendary tales, or to aversions against objects which we believe dangerous; or to a childish terror of imaginary perils; or to a disrelish, of which the cause is disguised; or to a ridiculous affectation of delicacy; or to an infirmity of the stomach: in a word, to a real or pretended reluctance for things, which are either invested, or supposed to be invested with qualities hurtful to us. Too much care cannot be taken in preventing or regulating the antipathies of children; in familiarising them with objects of every kind; in discovering to them, without emotion, such as are dangerous; in teaching them the means of defence and security, or the methods of escaping their noxious influence; and when the rational powers are matured by age, in reflecting on the nature of those objects which we fear, in ascertaining what has been told concerning their qualities, or in vigorously operating upon our own dispositions to overcome those vain repugnances which we may feel."

Some think that the term antipathy can only be applied to any certain purpose, when used with the restriction of modern philosophers; among whom it signifies no more than a *vis centrifuga*, or repelling power.

ANTIPATHY is sometimes also used in a *moral* sense, to denote a contest between the mind and the body, or between reason and inclination.

ANTIPATHY, in *Painting*, relates wholly to the colouring part of that art, and which may be more properly expressed by *contrast*, *degradation*, &c. Blue and crimson are by mixing changed into purple, as blue and yellow are into green, or red and yellow into an orange colour: these mixtures may be said to be kind to, or to harmonize with each other. If red and green, yellow and purple, or blue and orange colours, be united by admixture, they not only destroy

stroy the character of the colours, but they also destroy most completely the brilliancy of the several tints employed. Hence we may say, that purple has an antipathy to yellow, green to red, and orange to a blue colour. The union of these antipathies degrades the colours more or less, according to the proportion in which they are used: these degradations, however, are of the greatest use in the hands of a skilful artist, without which his pictures would resemble the crudeness of paintings upon glass, rather than be imitations of nature. Although the skilful use of these antipathies prevents a too glaring and gaudy effect, yet there is danger on the other hand, if they are not used with great judgment and delicacy, that the picture may sink into coldness, stupidity, and flatness. It is upon the knowledge of these three colours, blue, red, and yellow, and their proportion to each other as antipathies, that the whole art of colouring depends, which requires more study and application, and an eye of nicer discernment, than may be generally supposed. The nicer antipathy can hardly be applied to the arrangement of the parts which compose a picture, as the colours of garments, &c. without affectation; the expressions in more common use convey ideas with less ambiguity, such as contrast, union, harmony, discord, &c.; and the two last, although they are, in strict propriety, musical terms, yet have been adopted, and very aptly applied by painters, who well understood their signification as relative to their art, as well as to that of a musician. We should not have inserted the term antipathy, as applied at all to painting, but on account of its being found among some writers on that art, and that our readers might not be disappointed when seeking its explanation.

ANTIPATRIA, in *Ancient Geography*, a town placed by Pliny in Macedonia, towards the south, in Elymiotis, upon the Celydnus, to the north-west of Adrianopolis. Livy, speaking of its capture by the Romans, says, that it was situated in a narrow defile.

ANTIPATRIS, or *Capharsaba*, formerly called *Capharsalema* (1 Maccab. vii. 31.), a town of Palestine, placed by Reland and M. d'Anville in Samaria, to the east of Apollonia, on the sea-coast. It was of little repute till it was rebuilt by Herod the Great in the plain of Capharsaba, which, according to Josephus, was watry and fit for plants, with a river and a grove encompassing the city. It was 18 miles from Jerusalem, and in the way to Cæsarea Palestina, (Acts, xxiii. 31.), and within the borders of Samaria and the half tribe of Manasseh. Herod called it Antipatris, in honour of his father Antipater.

ANTIPELARGIA, among the *Ancients*, a law, whereby children are obliged to furnish necessaries to their aged parents. The *ciconia*, or stork, is a bird famous for the care it takes of its parents when grown old. Hence, in some Latin writers, this is rendered *lex ciconiaria*, or the stork's law. Puffavant has published a dissertation *De Antipelargia*, Basil, 1672, 4to.

ANTIPERISTALTIC, in *Anatomy*, a motion of the intestines producing a contrary effect to that which the peristaltic motion naturally occasions. The latter, in a state of health, determines the residue of the alimentary matter downwards towards the anus; whilst the former, being the consequence of disease, urges the contents of the intestines upwards into the stomach. See *PERISTALTIC Motion*.

The word is derived from *αντι*, against, *πειρι*, about, and *σπλιτικος*, that which hath the power of compressing.

ANTIPERISTASIS, in *Philosophy*, the action of two contrary qualities; one whereof is supposed, by its opposition, to excite and heighten the force of the other.

The word is formed of *αντι*, contra, against, and *πριστασις*,

to stand round, or to restrain; q. d. *circumobfistentia*, or the renitency against any thing that surrounds or besets another.

Antiperistasis is usually defined, "the opposition of a contrary quality, whereby the quality it opposes becomes heightened or increased: or the action whereby a body attacked by another, collects itself, and becomes stronger by such opposition: or it is an increase of the activity of one quality, caused by the opposition of another."

Thus, cold, say the school-philosophers, on many occasions, exalts the degree of heat, and dryness that of moisture. Thus it is, say they, that quick-lime is set on fire by the effusion of cold water; and so water becomes warmer in winter than in summer by antiperistasis; and to the same cause it is owing, that thunder and lightning are excited in the middle region of the air, which is continually cold.

This antiperistasis was a principle of great use and extent in the Peripatetic philosophy.

Mr. Boyle has canvassed this doctrine thoroughly, in his *History of Cold* (Works by Birch, vol. ii. p. 659.). It is certain, that *a priori*, or considering the reason of the thing abstracted from the experiments alleged to prove an antiperistasis, it appears highly absurd; since, according to the course of nature, one contrary ought to destroy, not to strengthen another.

In effect, not only reason, but experiment also, concludes against the notion of an antiperistasis: the leading argument urged in behalf of it is, the heating of quick-lime in cold water; now how astonishing the laziness and credulity of mankind, who have so long and generally acquiesced in what they might so easily have found to be false! for if, instead of cold water, the lime be quenched with hot water, the ebullition will always be far greater than if the liquor were cold.

As to the refreshing coldness which subterraneous places afford in summer, it may be denied that they are then really colder than in winter; though, if the contrary were allowed, it would not necessarily infer an antiperistasis. The smoking of waters drawn from deep places in frosty weather, does not necessarily infer such water to be warmer than at other times when it does not smoke, since that effect may proceed, not from the greater warmth of the water, but from the greater coldness of the air. For a man's breath in a cold summer, or in mild winter weather, becomes very visible; the cold ambient air suddenly condensing the fuliginous steams discharged by the lungs; which in warm weather are readily diffused in imperceptible particles through the air. See **COLD** and **EFFLUVIA**,

ANTIPHARMACA, in the *Materia Medica*, medicines suited to resist poison.

ANTIPHATES, in *Entomology*, a species of **PAPILIO** found in America, and described by Fabricius, from a specimen in the British Museum. The wings are tailed, white; margin brown, fasciated with white; posterior pair, beneath yellowish at the base, and fasciated with black. This is the specific character, to which it is added, that the exterior margin has seven white bars; the tail is very much elongated, ovate, and black; the black bands on the base of the posterior wings two in number, and apex of the wings white, with a few black dots.

ANTIPHELLOS, or **ANTIPHELLUS**, in *Ancient Geography*, a town of Asia Minor, in Lycia, took its name probably from the town of Phellus, which was situated at a small distance to the north. The small island of Cisthenes lay opposite to it.

ANTIPHERNA, among the ancient Greeks, denoted a kind of settlement made on a wife in case of surviving her husband, as an equivalent for her dowry.

This word seems to answer to what in our law is called a JOINTURE.

ANTIPIIIII, in *Ancient Geography*, a place of Africa in the Mareotic, mentioned by Ptolemy, and also by Strabo.

ANTIPIILOGISTICA, in the *Materia Medica*, medicines or remedies suited to resist, diminish, or cure inflammation, or an inflammatory state of the system.

ANTIPIION, in *Biography*, an Athenian orator, was born at Rhamnus in Attica, and hence called the *Rhamnusium*. He was instructed by his father Sophilus in rhetoric, and was deemed not inferior in eloquence to Themistocles, Aristides, Pericles, or Gorgias, his immediate predecessors; and he was preceptor in this art to Thucydides, who mentions him as an eminent orator. Quintilian (Inst. l. iii. c. 1.) informs us, that he was the first who wrote precepts on oratory; and Ammianus Marcellinus (l. xxx. c. 4.) says, that he first introduced the practice of pleading for money. Plutarch, as well as Thucydides, represent him as an energetic and persuasive orator, of fertile invention, and ingenious in adapting himself to the prejudices and interests of his auditors. Philostratus (de Sophist. l. 1.) describes him as possessing peculiar powers for soothing the minds of his hearers, and alleviating grief. Plato, however (in his Menexenus) treats his talents with contempt, and makes Socrates employ him in opposition to Aspasia; but Socrates, it should be remembered, had been insulted by the sophists, and particularly by Antiphon. His talents, as it is observed to his dishonour, were employed in establishing the tyranny of the four hundred in Athens; and, as Plutarch says, he was, for this offence, condemned and executed as a traitor, and his body thrown out of the walls of the city, in the first year of the 92d Olympiad, or 412 years before Christ. Others have given a different account of the manner of his death. Sixty orations under his name were formerly extant, but there now remain only 16; of which the subjects are criminatory, for murder or manslaughter, or defensive in similar causes. Fabricius and other critics think that they are genuine, though their authenticity has been questioned by others. They have been edited, with the orations of Æschines, Lyfias, &c. by Aldus at Rome, in folio, in 1513; by H. Stephens, in 1575; and in 8vo. by Minutius, at Hanau, in 1619. Plutarch. de Vita x. Oratorum, apud op. tom. ii. p. 832. Fabr. Bibl. Græc. l. ii. c. 26. § 2. t. i. p. 884.

ANTIIPHONALLY, from *anti*, *contra*, and *φωνη*, *voice*, in respect of church music, imports as much as alternately, or anthem-wise.

The Greeks have a method of singing *antiphonally*, *antiphonatum*, called by them *αλληλοφωνω*, wherein two persons sing together, and then are silent, and so on.

ANTIIPHONARY, *antiphonarium*, a service book which contained all the invitatories, responsories, collects, and whatever else was said or sung in the choir, except the lessons. This is otherwise called *responsorium*, from the responses therein contained. The author of the Roman antiphonary was Pope Gregory the Great.

This is a book containing, in Gregorian notes, the anthems and hymns of the Romish church. The Abbé Feytaud, in correction of Rousseau, says that the book only which contains the *anthems* is styled the *Antiphonarium*. When the psalms and hymns are understood to be included, it is called *vesperal*; when it contains the chants of the mass, it is termed *gradual*. The processional book contains the benediction, station, and processional chants. The funeral chants occupy the *ritual*.

We also find mention of nocturnal and diurnal *antiphonaries*, for the use of the daily and nightly offices; summer

and winter *antiphonaries*; also *antiphonaries* for country churches, &c. By the provincial constitutions of archbishop Wincellessa, made at Merton, A. D. 1305, it is required that one of these should be found in every church within the province of Canterbury.

The use of these, and many other popish books, was forbidden by the 3d and 4th of Edward VI. c. 10.

ANTIIPHONY, *ANTIIPHONA*, the answer made by one choir to another, when the psalm or anthem is sung alternately between two.

ANTIIPHONY, sometimes denotes a species of psalmody, wherein the congregation, being divided into two parts, repeats the psalms, verse for verse, alternately.

In this sense, antiphony stands contradistinguished from *symphony*, where the whole congregation sings together.

Antiphony differs from *responsorium*, because in this latter the verse is only spoken by one person, whereas in the former, the verses are sung by the two choirs alternately. The original of antiphonal singing in the western churches is referred to the time of St. Ambrose, about the year 374. That father is said to have first introduced it into the church of Milan, in imitation of the custom of the eastern church, where it appears to be of greater antiquity, though as to the time of its institution, authors are not agreed. It was most probably introduced at Antioch.

St. Ignatius, who, according to Socrates (E. H. l. vi. c. 8.), had conversed with the apostles, is generally supposed to have been the first who suggested to the primitive christians in the east the method of singing psalms and hymns alternately, or in dialogue: dividing the singers into two hands or choirs, placed on different sides of the church. Socrates, and several of the fathers, pretended, that it was revealed to St. Ignatius by a vision, in which he had seen choirs of angels praising the Holy Trinity in this manner by singing alternate hymns. The custom soon prevailed in every place where christianity was established. But Theodoret (E. H.) l. ii. c. 24) informs us, that this manner of singing was first practised at Antioch. Suidas, under the word *χορος*, says, that the choirs of churches were, in the time of Constantine, the son of Constantine the Great (who reigned from 337 to 361) and of Flavian, bishop of Antioch, divided into two parts, who sung the Psalms of David alternately; a practice, he adds, that began at Antioch, and was thence dispersed into all parts of the christian world. Indeed, it seems, that many of the primitive christians had not any more sublime conceptions of the celestial employment, or the joys of the blessed, than that they were eternally singing. The ancient hymn, "Te Deum laudamus," still retained in the church, appears to have furnished the poet Dante with a model of the 28th canto of his "*Paradiso*;" where, under three different hierarchies, consisting each of three choirs or choruses, the heavenly host of cherubim and seraphim are singing perpetual hosannahs. Milton has also assigned them the same employment:

" ——— Their golden harps they took;
Harps ever tun'd, that glitter by their side
Like quivers hung, and with preamble sweet
Of charming symphony they introduce
Their sacred song, and waken raptures high:
No voice exempt, no voice but well could join
Melodious part, such concord is in heaven."

Paradise Lost, book iii.

See Burney's Hist. of Music, vol. ii. p. 10.

ANTIIPHONY is also used to denote the words given out at the beginning of the psalm, to which both the choirs are to accommodate their singing.

ANTIPHONY, in a more modern sense, denotes a kind of composition made of several verses extracted out of different psalms, adapted to express the mystery solemnized on the occasion.

ANTIPHONA ad introitum, that anciently sung in the introit of the mass.

ANTIPHONA invitatoria, that repeated at the psalm *Venite exultemus*.

ANTIPHONÆ majores, those seven used to be sung in the time of Advent, at the Magnificat, and during the seven days before Christmas.

ANTIPHONÆ processionales, those sung at processions.

ANTIPHONÆ rogationes, those rehearsed at rogations.

ANTIPIHRASIS, derived from *αντι* and *φρασις*, of *φραζω*, I speak, in Rhetoric, a sort of figurative expression, which has a contrary meaning to what it carries in appearance. Or, a kind of irony, wherein we say one thing, and mean the contrary.

Sanctius defines antiphrasis to be a form of irony, whereby we say a thing, by denying what we ought rather to affirm it to be: as when we say, "it did not displease me;" or, "he is no fool;" meaning, "I was pleased with it: or "he is a man of sense." On this principle the antiphrases ought to be ranked among the figures of sentences, and not among those of words.

It is a common error, to make antiphrases consist in single words; as when we say, that the *Parææ* are thus called by antiphrasis, because they spare nobody, "*PARCÆ, qui nemini parcunt.*" St. Jerom, in his epistle to Riparius against Vigilantius, says, he ought rather to be called "*Dormitantius per antiphrasin,*" than Vigilantius, because he opposed the christians holding wakes at the tombs of the martyrs.

Sanctius holds it improper to call these antiphrases; because *phrasis* is not applicable to a single word, but signifies *orationem, aut loquendi modum*.

ANTIPIHRASICA, in the *Materia Medica*, medicines adapted to resist and cure phthisis or consumption.

ANTIPIHUS, in *Entomology*, a species of *PAPILIO* that greatly resembles *P. Polydorus*, but is still a distinct insect. The wings are tailed, black on both surfaces, with seven lunated red spots on the posterior pair. Fabricius, and Donovan's Insects of India.

ANTIPIINO, in *Geography*, a town of Russia, in the province of Saratov on the Volga, 100 miles south of Saratov.

ANTIPIEURITICA, in the *Materia Medica*, medicines suited to cure pleurisy.

ANTIPIODAGRICA, medicines suited to cure the gout.

ANTIPODES, from *αντι*, against, and *πους, ποδος*, a foot, in *Geography*, a relative term, denoting such inhabitants of the earth as live diametrically opposite to one another.

The Antipodes are those who live in parallels of latitude equally distant from the equator, the one toward the north, the other to the south; and under the same meridian, though 180°, or just half of that meridian, distant from one another.

The Antipodes have nearly the same degree of heat and cold; and the same length of night and day; but at contrary times: it being midnight with one, when it is noon with the other; and the longest day when it is the shortest with the other.

Again, as the horizon of any place is 90° distant from its zenith, the Antipodes have the same HORIZON. And hence, when the sun rises to one he sets to the other.

Plato is said to have first started the notion of Antipodes

and likewise to have given them the name: as he conceived the earth to be of a spherical figure, it was easy for him to infer, that there must be Antipodes.

Many, and particularly Lactantius and Augustine, ridiculed the notion. These fathers are strangely perplexed to think how men should hang pendulous in the air, with their feet uppermost, as he thought they must do in the other hemisphere.

This perplexity was owing to their not considering, that the lowest point, with regard to the inhabitants of our earth, is the centre; and that the terms *up* and *down* are relative, and merely signify farther from or nearer to the centre, to which all heavy bodies gravitate. If we traversed the globe, we should, in every part of it, have the sky over our heads, and our feet towards the centre; and we should every where call it *up* over our heads, and *down* under our feet; although the same right line which is *down* to us, if continued through and beyond the opposite side of the earth, would be *up* to the inhabitants on the opposite side. Our Antipodes may as well imagine, that we stand with our heads hanging downwards, as we conceive that this is their pendulous position; but if we changed places, we should find that we stood equally upright and firm wherever we were. Nay, the fact is, that we, who are now on what we are ready to call the uppermost side of the earth, and so wonder how another, in the situation of our Antipodes, can stand securely on the undermost side, with his head hanging downwards, shall be carried by the revolution of the earth, in the space of 12 hours, to the situation where our antipodes now are, although we shall be as far from them as before; and when we arrive there, we shall find no difference as to our manner of standing; but we shall then see the opposite half of the heavens, and imagine that they have moved half round the earth.

If we may believe Aventine, Boniface, archbishop of Mentz and legate of pope Zachary, the eighth century, declared a bishop of that time, called Virgilius, heretic, for maintaining that there was such a thing as Antipodes.

But this piece of history is controverted by the authors of the *Mem. de Trevoux*: as having been made use of, it seems, by some persons, to shew that the church has been mistaken in its decisions.

As to the sentiments of the primitive Christians with regard to the Antipodes, some, rather than admit the conclusions of the philosophers, absolutely denied the whole, even the demonstrations of the geometers relating to the sphericity of the earth: which is Lactantius's way. Instit. lib. iii. cap. 24. Others only called in question the conjectures of the philosophers; which is St. Augustine's method, *De Civit. Dei*, lib. xvi. cap. 9. After putting the question, whether there ever were nations of the cyclopes, or pigmies, or of people whose feet stood outward, &c. he comes to the point of Antipodes, and asks, "whether the lower part of our earth be inhabited by Antipodes?" He made no doubt of the earth's being round, nor of there being a part diametrically opposite to ours, but only disputes its being really inhabited. And the considerations he suggests for that purpose are just enough, as that they who asserted Antipodes had no history for it; that the lower part of the earth may be covered with water; and that to place Antipodes there, of a different origin from us (as must have been the opinion of the ancients, since they thought it impossible to go from our world to theirs), is to contradict scripture which teaches, that the whole race descended from one man. Such are the sentiments of that father. It may be added, that the Christian fathers were not the only persons who disputed the truth of the Antipodes. Epicurus and Lucretius had

had done it before them, at the end of his first book, v. 1063, &c. See also Hierarch, lb. De Facie in Oibe Lunæ; and Ptery, who relates the opinion, lb. in cap. 5.

ANTIPOLES, in *Ancient Geography*, now ANTIPES, a city of Gaul, near the river Varus, in Narbonensis Secunda, situate on the Mediterranean; built and colonized, according to Strabo, by the Marseilles, from whose authority it was withdrawn by a decree of the Roman senate, in the time of Augustus. Others say, that it was taken by them from the Ligurians of Gaul, called Degates. It was once very considerable, and had a port, a theatre, and many public monuments. See ANTIPES.

ANTIPOPE, a false or pretended pope; or one that is, or is pretended to be, irregularly elected in opposition to another.

Cædres gives the history of no less than twenty-four schisms in the Romish church, caused by antipopes; some took their rise from a diversity of doctrine or belief, which led different parties to elect each their several pope; but the greater part from dubious controverted rights of election, the fruits of chicanery and ambition.

ANTI-PORTICO is used by some for a vestibule, or porch, at the entrance of an edifice.

ANTI-PRAXIA, from *anti* and *πραξια*, *I perform*, in the *Ancient Physic*, denotes a contrariety of functions, temperaments, &c. in different parts of the body; invented to account for that contrariety of symptoms which frequently concur in hypochondriac cases, when, e. gr. the liver is charged with being immoderately hot, and the stomach excessively cold.

The moderns, particularly Etmüller, refute the notion of an antipraxia, on this principle, that the blood circulating duly through the whole body, warms all the parts, as well the stomach as liver proportionably. To which some advocates for the ancient system object, that this is confounding the preternatural state with the natural.

ANTI-PREDICAMENTS, in *Logic*; see ANTE-PREDICAMENT.

ANTI-PROBABILISM, the doctrine or system of those who hold it unlawful to follow the less probable opinion in opposition to the more probable one.

There have been vigorous advocates for antiprobabilism; for even among its greatest enemies, the Jesuits, F. Gilbert has a treatise in favour of antiprobabilism, viz. "Antiprobabilismus, seu tractatus theologicus fidelem totius probabilismi stateram continens," &c. Par. 1703, 4to.

ANTI-PROBOLE, in *Rhetoric*, a figure whereby the defendant adopts or admits the charge brought against him by the prosecutor.

E. gr. supposing the prosecutor's *επιβολη* to be, "Titus has killed Caius;" the defendant's antiprobole may be, "I have killed him, but undesignedly."

ANTI-PROPEMPTICON, in *Poetry*, a poem wherein a person going a journey addresses himself to his friends. Such is that of Ovid, lib. i. Trist.

"Cum subit illius tristissima noctis imago," &c.

It is opposed to PROPEMPTICON.

ANTI-PROTASIS, in *Rhetoric*, a solution of the PRO-TASIS.

ANTI-PSARA, in *Geography*, a small island in the Grecian Archipelago, two miles from the island of Ipsara.

ANTI-PSORA, from *anti* and *ψωρα*, *itch*, in *Pharmacy*, remedies proper against the itch.

ANTI-PTOSIS, a figure in *Grammar*, whereby one case is put for another.

The word comes from *anti*, *pro*, and *πτωσις*, *casus*.

ANTI-PYRETICA, from *anti* and *πυρ*, *fire*, or ANTI-FEBRILIA, among *Physicians*, an appellation given to medicines against fevers.

ANTI-PYRGOS, or ANTI-PYRGUS, in *Ancient Geography*, a part of Africa belonging, according to Ptolemy, to Marmotica.

ANTIQUA, in *Entomology*, a species of PHALÆNA that inhabits Europe. The anterior wings are ferruginous, with a white lunated spot in the posterior angle. Female apterous. Linnæus, Fabricius, &c.

ANTIQUANUS, or rather ANTIQUANUS, in *Ornithology*, a species of Lanius, having a long wedge-shaped tail; above yellowish rufous; beneath white; head, bill, wings, legs, and upper side of the tail black. Gmelin. This is the antiquan shrike of Latham, and pie-greife d'Antique of Sommerat. It inhabits Panay, one of the Philippine islands, but chiefly about Antigue, one of the provinces thereof. Its size is that of the red-backed shrike; bill large and black; the upper mandible very long, and extremely incurved; irides dusky; head black; back yellowish rufous; throat and breast white; quills and bastard wing coverts black; the wings reach only to the beginning of the tail, which is very long and wedge-shaped; the two middle feathers are wholly black; the others black above, and reddish beneath, with a rufous spot at the tip; legs dusky black. Latham.

ANTIQUARE, among Roman lawyers, properly denotes the rejecting of a new law, or refusing to pass it.

In which sense, *antiquating* differs from *abrogating*; as the latter imports the annulling of an old law, the former the rejecting of a new one. See A.

ANTIQUARE is also used for a law's growing obsolete, or into disuse, either by age or non observance.

ANTIQUARIUM, among the *Ancients*, denoted a place or apartment, wherein their antique monuments were preserved.

ANTIQUARTIUM is used by some modern practitioners, for a specific against the quartan ague.

Hence some call the Jesuits bark *antiquarium Peruvianum*. Wedelius also speaks of an *essentia antiquaria*.

The *antiquarian* of Riverius is a preparation of *mercurius dulcis*, *aurum fulminans*, sulphur of antimony, and scammony.

ANTIQUARY, ANTIQUARIUS, a person who studies and searches after monuments and remains of the ancients; as old medals, books, statues, sculptures, and inscriptions: and, in general, all curious pieces that may afford any light into antiquity.

Formerly there were several other kinds of antiquaries. The LIBRARI, or copyists, i. e. those who transcribed in fair legible characters, what had been before written in the notes, were called by this name. They were also denominated *calligraphi*. They were also employed in repairing books injured by age.

In the chief cities of Greece and Italy, there were other persons of distinction, called *antiquaries*, whose business it was to show strangers the antiquities of the place, to explain the ancient inscriptions, and to give them all the assistance they could in this way of learning.

This was, doubtless, a very curious and useful institution, and might well deserve to be re-established. Pausanias calls these antiquaries *επιγραφαί*. The Sicilians call them *mythologi*.

There was an ancient college of antiquaries erected in Ireland by Ollamh Fodhla, 700 years before Christ, for the composing a history of that country. And to this, say the Irish historians, it is owing that the history and antiquities of that kingdom may be traced back beyond those of most other nations.

Foundations of this kind have often been wished for, and sometimes also attempted, in England.

Sir H. Spelman speaks of a society of Antiquaries in his time, to whom his treatise of the terms, written in the year 1614, was communicated, he himself being one of the number.

The society was founded in 1572, by archbishop Parker, Camden, sir Robert Cotton, Stowe, and others. Application was made, in 1589, to queen Elizabeth for a charter, and a house wherein they might hold their meetings, erect a library, and the like. But by the death of that princess, their application proved abortive. Her successor, king James I. was far from favouring their design.

In the year 1717, this society was revived again, since which time no interruptions having happened, it is at present in a very flourishing condition; consisting of many learned and ingenious men, of the nobility, gentry, clergy, &c. whose business, as members, is to discover the antiquities of their own, as well as those of other nations.

This society was incorporated by the king's charter, in the year 1751, by the name of the President, Council, and Fellows of the Society of Antiquaries of London; their council consists of twenty-one persons, ten of whom are annually changed: the election of members is by ballot, a certificate signed by three or more fellows being previously exhibited for six ordinary successive meetings, except in the case of peers, members of the privy council, and judges, who may be proposed by a single member, and ballotted for the same day; and the choice is determined by a majority of two-thirds. Every member pays an admission-fee of five guineas, and two guineas a year, or an additional sum of twenty-one guineas. They have weekly meetings on Thursday, from seven of the clock in the evening till nine. This society began to publish its discoveries, &c. in 1770, under the title of "Archæologia."

A similar association was founded in Edinburgh, in 1780, and received the royal charter in 1783. See SOCIETY.

ANTIQUARY is also used, by *Ancient Writers*, for the keeper of the antiquarium, or cabinet of antiquities.

This officer is otherwise called *archæota*, or *antiquary*, of a king, a prince, a state, or the like.

Henry VIII. gave John Leland the title of his antiquary, a title which, says the author of his life, no body ever enjoyed besides himself. But the restriction, we suppose, was only intended to be understood in respect of the kings of England. M. Schott, we find, had the title of antiquary to the king of Prussia; P. Pedruzzi, that of antiquary to the duke of Parma; M. Gallant resided some time in Turkey, under the title of antiquary of the king of France. The university of Oxford have still their antiquary, under the denomination of *custos archivorum*. The kings of Sweden have been at great expences in order to illustrate the antiquity of their country, having established an academy of antiquaries with this single view.

The office of the ancient Irish antiquaries was to preserve the genealogies of the kings of Ireland, to correct the regal tables of succession, and deliver down the pedigree of every collateral branch of the royal family.

P. Labbe and Petavius have published pieces expressly concerning the apparatus of antiquaries.

ANTIQUATA, in *Conchology*, a species of ARCA, that inhabits the Mediterranean, Indian, and American seas. The shell is obliquely heart-shaped, with many unarmed grooves. Linnæus, Gmelin, &c. This kind is rather large, white, and covered with a hairy epidermis; a compressed prominent angle in the anterior slope.

ANTIQUATA, a species of CHAMA, found in the Atlan-

tic, American, and Indian seas. The shell is rather heart-shaped, grooved longitudinally, and striated transversely. Linnæus. It is spotted with brown or ferruginous, and has from nineteen to twenty-two ribs; the margin is dentated; beaks inflected back; and a deep clofed fissure before. Gmelin, &c. Adanson calls this shell *ajar*.

ANTIQUATED, ANTIQUATUS, something obsolete, or grown out of date or use.

ANTIQUÉ, ANTIQUUS, in a general sense, something that is ancient.

ANTIQUÉ is chiefly used among architects, sculptors, and painters; who apply it to such pieces of buildings, sculpture, painting, &c. as were made at the time when the arts were in their greatest perfection among the ancient Greeks and Romans; viz. from the age of Alexander the Great to the time of the irruption of the Goths into Italy, under Alaric, in the year 400.

In this sense the word stands opposed to *modern*. Thus we say, an *antique* building, or a building after the *antique*; an *antique* bust, or bas-relievo; the *antique* manner, taste, &c.

The science of antiques is also called by Spon ARCHÆOGRAPHIA.

Under this is included the knowledge of ancient coins, medals, inscriptions, buildings, statues, sculptures, MSS. vessels, weights, measures, &c.

ANTIQUÉ is sometimes also contra-distinguished from *ancient*, which denotes the lesser degree of antiquity, when the art was not in its utmost purity.

Thus *antique architecture* is frequently distinguished from *ancient architecture*.

Some writers also use the compound, ANTIQUO-MODERN, in respect of the old Gothic churches, and other buildings, to distinguish them from those of the Greeks and Romans.

ANTIQUÉ, more especially applied to *Painting*, designates such works of the ancient painters as were produced before the destruction of the Roman empire. It appears very certain, that painting was but in an infantile state among the Assyrians and Egyptians, as it was and still continues to be among the Persians and Chinese, which is known from the accounts we have received, and the specimens which are extant; but it is thought extraordinary, that there should remain any degree of uncertainty with us respecting the state of painting among the ancient Greeks and Romans, when it is allowed that statuary, the twin sister-art, should have prevailed in so wonderful a degree, as to astonish the world with the excellent works which were produced by them, and remain the noble monuments of their superior skill, the unrivalled objects of admiration, the patterns of imitation, and the standards of excellence. It has, however, been the subject of controversy with respect to the degree of excellence to which the ancient painters carried their art; the following observations are by sir Joshua Reynolds.

"From the various ancient paintings which have come down to us, we may form a judgment with tolerable accuracy of the excellencies and defects of art among the ancients. There can be no doubt, but that the same correctness of design was required from the painter as the sculptor; and if the same good fortune had happened to us in regard to their paintings, to possess what the ancients themselves esteemed their master-pieces, which is the case in sculpture, I have no doubt but we should find their figures as correctly drawn as the Laocoon, and probably coloured like Titian. What disposes me to think higher of their colouring than any remains of ancient painting will warrant, is the account which Pliny gives of the mode of operation used by Apelles,

that over his finished picture he spread a transparent liquid like ink, of which the effect was to give brilliancy, and at the same time to lower the too great glare of the colour: *Quod absoluta opera atramento illinebat ita tenui, ut id ipsum reperculsi claritatis colorum excitaret.—Et tum ratione magna ne colorum claritas oculorum aciem offenderet.* This passage, though it may possibly perplex the critics, is a true and artist-like description of the effect of glazing or scumbling, such as was practised by Titian and the rest of the Venetian painters; this custom, or mode of operation, implies at least a taste of what the excellence of colouring consists, which does not proceed from fine colours, but true colours; from breaking down those fine colours which would appear too raw, to a deep-toned brightness. Perhaps the manner in which Corregio practised the art of glazing was still more like that of Apelles, which was only perceptible to those who looked close to the picture, *ad manum intuenti demum appareret*; whereas in Titian, and still more in Bassan and others his imitators, it was apparent on the slightest inspection: artists, who may not approve of glazing, must still acknowledge, that this practice is not that of ignorance. Another circumstance that tends to prejudice me in favour of their colouring, is the account we have of some of their principal painters using but four colours only. I am convinced the fewer, the cleaner will be the effect of those colours, and that four are sufficient to make every combination required; two colours mixed together will not preserve the brightness of either of them single, nor will three be as bright at two: of this observation, simple as it is, an artist, who wishes to colour bright, will know the value. In regard to their power of giving peculiar expression, no correct judgment can be formed; but we cannot well suppose that men, who were capable of giving that general grandeur of character which so eminently distinguishes their works in sculpture, were incapable of expressing peculiar passions. As to the enthusiastic commendations bestowed upon them by contemporaries, I consider them as of no weight. The best words are always employed to praise the best works; admiration often proceeds from ignorance of higher excellence. What they appear to have most failed in is composition, both in regard to the grouping of their figures, and the art of disposing of the light and shadow in masses. It is apparent that this, which makes so considerable a part of modern art, was to them totally unknown.

“If the great painters had possessed this excellence, some portion of it would have infallibly been diffused, and have been discoverable in the works of the inferior ranks of artists, such as those whose works have come down to us, and which may be considered as on the same rank with the paintings that ornament our public gardens. Supposing our modern pictures of this rank only were preserved for the inspection of connoisseurs two thousand years hence, the general principles of composition would be still discoverable in those pictures; however feebly executed, there would be seen an attempt to an union of the figure with its ground, some idea of disposing both the figures and the lights in groups. Now, as nothing of this appears in what we have of ancient painting, we may conclude that this part of the art was totally neglected, or more probably unknown.

“They might, however, have produced single figures, which approached perfection both in drawing and colouring; they might excel in solo (in the language of musicians), though they were probably incapable of composing a full piece for a concert of different instruments.” Reynolds’s Notes upon Frenoy, note 37, verse 350.

ANTIQUE, in *Sculpture*, a statue, busto, basso-relievo, or other work, the production of ages prior to the fall of the

Roman empire; a term chiefly applied by sculptors to the works of the ancient Greeks and Romans.

The statues of the ancients were very numerous, chiefly arising from their custom of deifying and erecting statues in honour of almost all the heroes and celebrated characters among them. But the Romans seem to have surpassed the Greeks in the number of their Gods. “There was no place in Rome,” Livy observes, “which was not full of gods and sacrifices;” and for this reason, Quartilla says, “our country is so full of deities, who honour it with their presence, that it is more easy to find a god than a man.”

Antique sculpture is universally supposed to be far superior to the productions of modern times: it is certain, that the best antiques greatly surpass modern sculpture in general; but it is equally true, that the best modern works exceed by far the majority of the ancient. And here it may not be improper to remark, that the different casts in plaster, and specimens in marble which are brought to England from abroad, are carefully selected from the mass of productions; and therefore an Englishman is not usually aware of the deficiencies that are attached to the bulk of the works which remain abroad.

One considerable advantage which antiques possess above modern productions is, that they are in general works of much longer time. It was in many instances among the ancients considered sufficient for one sculptor to have executed four or five statues in the course of his life; hence we find, that the most celebrated marbles of antiquity are finished to a degree that will bear the closest inspection, and will appear equally complete in all the different lights in which they may chance to be placed. Another advantage of the antique above the modern is, that they are the works of artists, who were continually in the habit of viewing nature half or quite naked, owing to the scanty cloathing of the lower orders of people in the climates of Greece and Italy: the artists were able to study these fine examples of nature while in action, as running, wrestling, boxing, and playing at the several athletic games and exercises of those times; and especially in the gymnasia or public places, where the youths performed their various feats quite naked. Here all the different motions and beautiful play of the muscles, together with an amazing variety of postures and attitudes, were exhibited to the attentive observer; and with a dignity, truth, grace, and expression, that can never be imitated by those mercenary models, that sell their ignoble nakedness to the artists in our modern academies. The clothing also of those days, being light and scanty, did not confine and disfigure the body, as unfortunately is the case in modern times. They had also, if report be true, peculiar advantages in the statues of some of their goddesses; as it has been asserted, that even the modest women of those days considered themselves honoured by being allowed to sit as models for a goddess: and that in consequence of this, noblemen of the first distinction would bring their daughters to the artist for that purpose; report has also gone so far as to state, that not less than four hundred young women of the first rank and greatest beauty stood to the sculptor who executed the Venus de Medicis.

In many instances, the ancients seem to have bestowed as much labour on the subordinate parts of their statues as on the principal; hence we very often find the fingers, toes, nails, ears, and hair as highly finished as the face or body; whereas, modern sculptors in general are apt to bestow their labour upon the more important parts, to the neglect of the inferior. But in many other instances the ancients neglected, to a very inexcusable degree, what they conceived to be of subordinate consideration: the following remark in one of the lectures of sir Joshua Reynolds, is a sufficient evidence

of this fact. "The ancient sculptors," says he, "neglected to animate the features, even with the general expression of the passions. Of this, the group of the boxers is a remarkable instance; they are engaged in the most animated action with the greatest serenity of countenance;—this frequent deficiency in ancient sculpture could proceed from nothing but a habit of inattention to what was considered as comparatively immaterial."

But it is nevertheless proper to remark here, that the ancients in their bustos, where the face became the principal object of attention, excelled to a great degree; and undoubtedly surpass modern sculptors by far: their treatment of the human countenance, displayed in the beauty and dignity of some of their heads and bustos, is beyond description: they were acquainted to the smallest nicety with the feat of every expression, and were perfect masters of the art of bringing each into full effect.

Simplicity is a great characteristic of antique sculpture in general: this principle is attached not only to the attitudes of their figures, but to the disposition of the drapery, the hair, and every lesser attribute: scarce an instance of the *outré* or extravagant is to be found among the finer antiques. But this principle, however beautiful, was often carried too far; and in many instances rendered their works stiff and uninteresting, which may certainly be considered the chief defect of antique sculpture. The ancients, in order to preserve dignity and majesty in the statues of their gods, heroes, emperors, philosophers, and other great characters, often placed the head and body of the statue in an upright position, which in very many instances bordered upon stiffness; and by purposely avoiding every trifling turn or angle in the drapery that might tend to destroy its simplicity, they were sometimes drawn into the opposite error: we therefore find in many instances, though each fold may be beautiful in itself, that their draperies are composed of a continued repetition of long and straight lines.

There is a subordinate mistake attached to many of the best as well as to the inferior antique statues; where, in order to strengthen them, the stump of a tree, or a piece of rock is introduced, as incorporated with the flesh of the limb against which it is placed; whereas, it is evident that some drapery or other disguise should be thrown over the support, to conceal an effect so awkward and unnatural.

There was also a great degree of false taste among the ancients, manifested in their custom of introducing metallic eyes, and working the heads, hands, and feet of some of their statues in marble of a different colour from the other parts of the figure; but this mistake does not belong to their principal and most celebrated works.

For some account of the chief antique statues, see the following articles:

Adonis.	Faunus.	Meleager.
Amazone.	Flora.	Melpomene.
Antinous.	Ganymede.	Mercury.
Antonine Column.	Gladiator.	Narcissus.
Apollo.	Hercules.	Niobe.
Ariadne.	Juno.	Poppea.
Bacchus.	Jupiter.	Trajan Pillar.
Ceres.	Laocoon.	Torso.
Cicero.	Livia.	Venus.
Cleopatra.	Marcus Aurelius.	Urania.
Cupid.	Mars.	
Discobolus.	Marsyas.	

See also SCULPTURE and STATUE.

ANTIQUENSIS, or ANTIGUENSIS, in *Entomology*, a species of APIS that inhabits the islands of Antigua. It is

hairy and black; thorax and anterior part of the abdomen yellow. Fabricius and Gmelin.

ANTIQUENSIS, rather ANTIGUENSIS, is also a species of MUTILLA that inhabits Antigua, and is described by Fabricius and Gmelin. It is red, abdomen black at tip, and streaked with white.

ANTIQUITY, ANTIQUITAS, is used to denote the times or ages past long ago.

Thus we say, the heroes of antiquity, the marks or footsteps of antiquity, monuments of antiquity, &c.

ANTIQUITY is also used to denote the works or remains of ancient times. See MONUMENT, REMAINS, RUINS, &c.

Thus we say, a fine curious piece of antiquity; Italy, France, and England, abound in antiquities.

ANTIQUITY is also used to denote the great age of a thing, or its duration from times of old.

In this sense we say, the antiquity of a kingdom, a custom, or the like; most nations lay claim to an antiquity much greater than they can truly warrant. The present age may be said to be the antiquity of the world; which was but new in what are commonly called the ancient days, according to the received chronology.

There are great disputes concerning the antiquity, or age of the world.

Aristotle carried it even to eternity; Parmenides, Pythagoras, and the Chaldeans, were of the same opinion: but the generality of philosophers, as well as divines and historians, have always held an origin of it; though where to fix that origin is the difficulty. The different systems of the chronology of the Greeks, the Egyptians, the Jews, the Hebrew Text, and the Septuagint version of Scaliger, of Pezron, of sir Isaac Newton, &c. to say nothing of the Chinese annals, leave the point infinitely embarrassed.

Dom. Pezron thinks he has merited well of the public by adding 2000 years to the age of the world, which had been taken from it by Scaliger and others; but this did not hinder F. Martianay from entering a prosecution against him in the archbishop's court of Paris for heresy. His crime was following the Heathen rather than the Hebrew chronology, in which however he was preceded by the generality of the fathers and primitive writers of the church; among whom it appears to have been a common practice, to make 5500 years between the creation and the incarnation. In reality, the Jews are charged with having corrupted their chronology; by which the moderns have been misled.

Some have proposed to trace out the antiquity of the earth, by an observation of the saltiness of the sea; others by observing the elevation of the bottom of the sea, or the growth of its strata. One mark or proof of antiquity has been started by Rudbeck, which he pretends to have carried to a demonstration; it is taken from the thickness of a certain black crust, called in the Swedish tongue, *mat-iorden* and *swart-myllan*, which covers the surface of the earth, being formed of a mixture of rotten grass and other herbs, with dust and a kind of mud, which the melted snow leaves behind it. According to this antiquary, there are at least 500 years requisite to form an inch thick of this crust, which in many places of Sweden is found to be upwards of seven inches thick, where urns have been dug up full of bones and ashes. From whence it follows, according to this author, that it is upwards of 3500 years since burning the dead was practised in Scandinavia.

Recupero, the historiographer of Ætna, suggests an argument in favour of the antiquity of the earth from the several strata of lava that have issued at different times from this mountain. A stream of lava, which Diodorus Siculus relates to have burst out in the time of the second Punic war,

is covered at this day only with a very scanty soil; and in digging pits and wells, several strata of lava have been discovered with earth to a considerable thickness over the surface of each stratum; in one instance, seven distinct surfaces of this kind were pierced; and allowing 2000 years for the interval between two eruptions, the lava that composed the first or lowest stratum, must have flowed from the mountain above 14,000 years ago. Brydone's Tour, &c. vol. i. p. 131.

But this argument is very fallacious, because we learn from sir William Hamilton's remarks on the soil of Naples, that since the first eruption of Vesuvius, which destroyed the ancient town of Herculaneum in the year 79, there have been six eruptions of lava, forming as many different strata, with veins of good soil between them. Phil. Transf. vol. lxi. N^o 1. See ΑΤΣΑ.

There is scarce a nation under heaven but lays claim to a greater degree of antiquity than the rest of its neighbours: the Scythians, the Phrygians, the Chaldeans, Egyptians, Greeks, Chinese, &c. pretend each to have the honour of being first inhabitants of the earth: several of these nations, lest they should be outstripped in their pretensions by any of the rest, have traced up their origin to ages long before the received account of the creation. Hence the appellations *aborigines, indigenæ, terrigenæ, antelunares*, &c. The Athenians were not ashamed to pretend to be *autochthones*; and what is most remarkable, Socrates himself gives them this ridiculous appellation, which, as some others of the philosophers have wisely observed, only put them on a level with ants and grasshoppers. Mem. Acad. Infer. tom. vii. p. 408.

The Chaldeans pretend to astronomical observations of 470,000, or 473,000 years; they mention the precise king who reigned over them at the time of the deluge, whose name was Xisuthrus, and attribute to him several things which we ascribe to Noah.

The Chaldaic antiquities of Berofus are lost, except a few fragments which have been collected by Jos. Scaliger, and since more fully by Fabricius. Annus of Viterbo, a Dominican monk, towards the close of the fifteenth century, would not suffer us to want such a treasure, but officiously went to work, and forged a Berofus out of his own brain, which he published at Rome in 1498. The monk went farther; and from the same mint soon after produced Manetho's supplement to Berofus, from the time of Ægyptus king of Egypt, to the origin of the Roman state. The mischief is, Manetho lived before Berofus; this anachronism alone had sufficed to betray the cheat.

St. Augustine laughs at the folly of the Egyptians, who pretend to observations of the stars above 100,000 years old: in effect, no people appear to have been warmer in the contest for antiquity than those of Egypt. They pretend two periods of time; one shorter, during which the throne of Egypt had been filled by men; the other almost infinite, wherein gods and demi-gods had worn the crown. From Isis and Osiris to Alexander they reckoned a space of 23,000 years, the time before that, while the gods reigned, made 42,984 years more; the whole duration from the beginning of their monarchy amounting to 65,984. De Civ. Dei, lib. xviii. c. 40.

The computation of their dynasties, as given by Manetho, a writer of their own (of whom we have extracts in Syncellus, taken from Julius Africanus and Eusebius), extends to 5530 years before Alexander's time; and the Egyptian chronicle, cited by the same Syncellus, goes farther, reckoning 36,525 years. Diogenes Laertius makes no less than 48,863 years from the reign of Vulcan. Yet the Scythians,

the Phrygians, the Ethiopians, and some others, still insisted on their priority to the Egyptians; and in the judgment of many seem to have carried their point. Justin, after Trogius, gives the precedency to the Scythians; and affirms, that they were always allowed to have been before the Egyptians.

It is no wonder that their catalogues should be ridiculously incredible, when the Egyptians made their first kings reign 1200 years a-piece; and the Assyrians theirs about 4000.

But the Chinese is esteemed the most ancient monarchy in the universe; having cultivated the sciences from the earliest ages, and subsisted at least these 4000 years with the same laws, manners, and usages.

Some indeed have called in question the truth and authenticity of the Chinese annals; yet we find them confirmed, at least as high as 660 years before Christ, by the annals of Japan. At worst, the Chinese antiquities stand on as good a footing as those of either Greece or Rome. Their annalists, both for order and chronology, are not inferior to any of those ancients so much admired among us; but far surpass them in point of antiquity, and have a better title to be credited, as having written by public authority, which can be said of few Greek or Roman pieces, except perhaps the Capitoline Marbles, which are not properly a history.

We have no inconsiderable confirmation of the truth of the Chinese account, from an ancient observation of a grand conjunction of the planets under Chuen-Hio, emperor of China, related by Martinius. That prince lived 2513 years before Christ. M. Kirchius has defended the observation against Cassini, and shewn a conjunction must really have happened at the time mentioned by the Chinese annals.

But the authenticity of this observation, and the whole of the Chinese chronology, has been attacked by an ingenious author, Mr. Costar.

Dionysius Halicarnassus has traced the Roman antiquities, Josephus the Jewish antiquities, Berofus the Chaldaic antiquities, Sanchoniathon the Phœnician antiquities, Manetho and Marsham the Egyptian antiquities.

The Phœnician antiquities of Sanchoniathon are preserved in part by Eusebius. We have an English translation of Sanchoniathon, with notes, by bishop Cumberland, and a continuation from the canon of Eratothenes. Lond. 1720, 8vo.

Dionysius gave his book the title of Roman Antiquities, on account of the curious inquiries he had made concerning the origin of the Romans, by tracing them back to the remotest ages. For fidelity as well as instruction he is generally preferred to Livy; his accounts are more ample, and his facts described with more particulars; he gives a full idea of the Roman ceremonies, the worship of their gods, sacrifices, manners, customs, discipline, policy, courts, laws, &c.

To the class of supposititious antiquities belong the Hetrurian antiquities, pretended to have been found by Scornelli near Volaterra; and published in 1636, by Curtius Inghiramus, who is generally supposed to have been the forger of them. A great number of fictitious names of ancient authors are cited in this book to give the better face to the cheat; but the style betrayed it. Allatius and Ernestius early detected the imposture. Fabr. Bibl. Lat. lib. iv. cap. 13.

The British antiquities, before Cæsar's invasion, are utterly dubious, not to say fabulous. Old chronicles speak of Samothæ, the son of Japhet, as the founder of the British monarchy; Albion, a descendant of Cham, invaded it three hundred years after; and about 600 years after this, Brute, grandson

grandson of Æneas, came and took possession of the island in the year of the world 2880, giving it the name which it still retained when Cæsar made his attempt. This is Geoffroy of Monmouth's system of the antiquities of the British nation, which the generality of our historians admit, for want of a better. It has been defended by A. Thomson of Queen's College, in the preface to his English translation of that writer.

It must not be forgot that the Irish also pretend to be the most ancient of all nations; they trace their origin without interruption up to Japhet. But the Scots still dispute their priority with them, holding themselves to be an elder branch of the Scythians, the first of men.

The antiquity of religion has been often urged as a proof of the truth of it. Jews, Gentiles, Christians, Protestants, Papists, have all in their turns made use of the argument from antiquity. It is indeed of the inartificial kind; and comes rather under the denomination of a presumption than a proof: on the whole, it seems to have served the cause of error as much, if not more, than that of truth.

ANTIQUITY is more peculiarly used to denote the ceremonies, customs, and usages, which obtained in ancient times, either with regard to persons, places, or things.

Antiquities, in this sense, are usually divided into sacred, political, military, literary, and domestic; sometimes only into civil and ecclesiastical.

ANTIQUITIES, *sacred*, those relating to the religious worship, discipline, and belief of ancient times and people. These may be subdivided into Heathen, Christian, and Mahometan, &c.

Reland has a treatise expressly on the sacred antiquities of the Jews: Struvius on those of the Romans; Lakemacher on those of the Greek; and Stillingsfleet on those of the British churches.

Fabricius has given two plans of a thesaurus or body of antiquities; the one of Hebrew antiquities, after the manner of Grævius and Gronovius: the other of ecclesiastical antiquities, divided into twelve books. He gives the names and titles of 156 authors to be included in the first, and 101 authors for the second.

ANTIQUITIES, *Christian*, those which relate to the ancient state of the Christian church.

These are the same with what we otherwise call *ecclesiastical antiquities*.

The Magdeburg centuries are looked upon by protestants as a library of Christian antiquities.

Mr. Bingham has published a learned system of Christian antiquities.

As a principal branch of Christian antiquities, we may reckon,

ANTIQUITIES, *Biblical*, the notices of ancient laws, ceremonies, events, &c. occurring in the scriptures.

These make a branch of ecclesiastical antiquities, and bear a near relation to the Jewish, &c. antiquities.

Some pretend to deduce most of the heathen antiquities from the Bible; others, as Spencer, &c. take the contrary course, and deduce the antiquities of the Bible from those of heathenism.

To interpret Scripture, it is absolutely necessary regard be had to the heathen antiquities alluded to in them, and these not only such as are directly aimed at or approved, but also such as are purposely opposed.

Dr. Cave has published a treatise of apostolical antiquities, "Antiquitates Apostolicæ;" or the Lives, Acts, &c. of the Apostles, Evangelists, &c. Lond. 1674, fol. 1684, and 1686.

ANTIQUITIES, *civil*, all that belong not to the head of *ecclesiastical*.

ANTIQUITIES, *political*, those relating to the origin of states, governments, magistrates, and laws.

ANTIQUITIES, *national*, those employed in tracing the origin, ancient actions, usages, monuments, remains, &c. of some nation or people.

Gronovius has given a collection of the chief writers on the Greek antiquities; Rouse, Pfeiffer, Bos, Brunings, and bishop Potter, have given shorter systems; the last is the best esteemed, though found too short by some in what relates to the religion, the gods, vows, and temples of Greece. A system of this kind has been lately published (*viz.* 1801), by Mr. Harwood, in 8vo.

The best system of Roman antiquities yet extant is that of Rolius, with Dempster's notes.

We have compendiums and introductions to the Roman antiquities by Hoepfner, Nieuport, Godwin, Cantelius, Basil, Kennet, Adam, &c.

Heineccius has given a collection of Roman antiquities for illustration of civil law; and Briffonius another, drawn from the books of the civil law; Gravina's *Origines Juris Civilis* is excellent on this subject.

A body of the writers on the Roman antiquities hath been published by Grævius, and another of those on the Greek antiquities by Gronovius, both under the titles of *Theauri*.

A supplement to the former has been published by Salengre and Polenus. Danet and Pitiscus have also published lexicons of the Roman antiquities. Varro's books of Roman antiquities are entirely lost, excepting some fragments, preserved by St. Augustine.

ANTIQUITIES, *parochial*, those confined to the limits of one or more parishes, and conversant chiefly in what relates to the tithes, revenues, &c. of the churches.

Dr. Kennet has published a learned and curious work under the title of "Parochial Antiquities," attempted in the history of Ambrosden and Burchester, and other adjacent parts in the counties of Oxford and Bucks. Oxf. 1695, 4to. See Phil. Trans. N^o 220.

ANTIQUITIES, *literary*, those relating to matters of learning and study; a principal branch of these, are,

ANTIQUITIES, *academical*, the origins, usages, &c. of the ancient academies, schools, colleges, and other literary societies. These bear a near relation to scholastic antiquities, and make a branch or division of literary antiquities. Herm. Conringius has given a body of academical antiquities, and Ursinus a treatise on the scholastical antiquities of the Hebrews. Montfaucon, count Caylus, Winckelman, Iken of Bremen, &c. ought to be mentioned as collectors of antiquities of various kinds.

ANTIQUUS, JOHN, in *Biography*, an historical painter, was born at Groeningen, in 1702, and was instructed in the art of painting on glass, which he practised to the age of 20 years; but being desirous of learning the art of painting in oil, he sought improvement in France and Italy, and at Florence was retained in the service of the grand duke for six years. At this period, he painted a grand composition of the "Fall of the Giants," which, as to disposition and design, shewed equal judgment and taste. He made several journeys to Rome, and in every part of Europe through which he travelled, left memorable proofs of his genius and fine execution; and he is ranked among the best artists of his time. Pilkington.

ANTIQUUS, in *Conchology*, a species of MUREX. The beak is patulous; shell oblong, with eight roundish whorls. Linn. and Gmelin. This species inhabits the northern seas

of Europe, and is admitted as a British shell. There are three supposed varieties of it figured by Seba, Martin, and Lister: and the *murex carinatus* of Pennant has been considered as an accidental growth of the same species; but the last is certainly distinct. *Wid. Don. Brit. Shell.*, p. 119.

The shell is from four to six inches in length, of a yellowish colour, finely cancellated with transverse striae and longitudinal plaits; it has two or more angular ridges along the whorls, which are tuberculated.

ANTI-RATIONALISTS, a name sometimes given to divines, who in matters of religion are for hounding reason, and making it bend to faith, asserting that the absurdity of a thing is no reason for rejecting it.

In this sense, the rigid Calvinists and adherents to the synod of Dort have been denominated anti-rationalists, on account of the doctrine of absolute predestination, &c. The Roman Catholics are also entitled to the same appellation, on account of the doctrine of transubstantiation. M. Bayle took shelter in the system of the anti-rationalists, the better to combat the Christian doctrines of the origin of evil, providence, &c. But this, like other offensive appellations, has been very indiscriminately applied; it has been uncandidly used as a term of reproach; and reason, the first endowment conferred on mankind by their Creator, though unduly depreciated by some, has been extravagantly extolled by others, who have been enabled to extend and improve the exercise of it, especially in the province of religion, by the extraordinary communications of a divine revelation.

ANTI-RHODUS, in *Ancient Geography*, a small island situate within the port of Alexandria, in Egypt, whither Antony retired in despair, after the battle of Actium. After the example of Timon the misanthropist, he withdrew from intercourse with mankind, and called this reclusive habitation *Timonium*.

ANTIRRHEA, in *Botany*. See **CUNNINGHAMIA**.

ANTIRRHETICUM, from *ἀντι* and *ῥησις*, *I speak*, in *Literary History*, denotes a refutation of some book, author, or opinion. In this sense we also meet with the word *antirrhetis*.

ANTIRRHINUM, in *Botany* (*ἀντι*, *æqualis*, and *ῥίς*, *nasus*). *Quod fructu sit vituli narium simile*; hence it has been called *calves-snout*; class *didynamia angiospermia*. *Linn. Gen.* 750. *Gærtn.* 53. *Juss.* 120. Snap-dragon, or toad-flax; natural order, *personate*.

Generic Character. *Calyx* perianth five parted, permanent; divisions oblong, the two lower more gaping than the others; *corolla* monopetalous, ringent; tube oblong, gibbous; limb bilabiate; upper lip bifid, reflex on the sides; lower limb trifid, obtuse; palate convex, usually closed by a promiency between the lips, arising from the under lip; *nectary* at the base of the corolla produced downwards, prominent; *filamina*, filaments four, two of which are shorter; *antheræ* converging; *pollinillum*, germs roundish; style simple, of the length, and in the situation of the filamina; stigma obtuse; *pericarpium*, capsule roundish, two-celled; seeds numerous.

Essential gen. Character. *Calyx* five-leaved; *corolla* with the base produced downwards and nectariferous; *capsule* two-celled.

Fifty-two species of this plant are described, only eight of which, according to Dr. Smith, are the spontaneous growth of this country.

Species. *Leaves angular. 1. *A. cymbalaria*, ivy-leaved toad-flax; leaves heart-shaped, five-lobed, alternate; stalks procumbent; the root is perennial, from which issue long, decumbent, spreading stalks, bearing violet-coloured small flowers, with a yellow palate: it is a native of Britain, growing on crevices of rocks and old walls; hence this plant is well adapted for the

ornament of rock work; it flowers from June till October. Figured in *Curt. Flor. Lond. fasc. t. 47. Eng. Bot.* 501. 2. *A. pilifera*, hairy-leaved toad-flax, leaves kidney shaped, very hairy, alternate; stalks procumbent; the edge of the leaves divided into nine or ten obtuse crenulate lobes: a native of the Alps. *Jac. Obs. ii. t. 48.* 3. *A. elatine*, sharp-pointed toad-flax, or fluellin, leaves hastate, alternate; stalks procumbent; calyx and leaves hairy; corolla yellow; upper lip purple underneath: a British annual, growing in fields, and flowering from July till October. *Curt. Flor. Lond. fasc. i. 46. Eng. Bot.* 692. 4. *A. spurium*, round-leaved toad-flax, or fluellin, leaves ovate alternate; stalks procumbent; this plant is hairy; the upper lip of the corolla is yellow, the under purple: it is an annual British plant, growing among corn, and flowering from July till September. *Curt. Flor. Lond. fasc. iii. 37. Eng. Bot.* 691. 5. *A. cirrhosum*, tendrilled toad-flax, leaves hastate, alternate; stems spreading; petioles tendrilled; stems filiform, very branching; peduncles axillary, one-flowered; corolla bluish, with a whitish palate spotted with purple; annual: a native of Egypt; introduced in 1777, by Dr. Joseph. Nich. de Jacquin. *Jac. Hort. t. 82.* 6. *A. Ægyptiacum*, Egyptian toad-flax, leaves hastate alternate; stem erect, and much branched; this very much resembles the third species; it is an annual plant, a native of Egypt.

**Leaves opposite. 7. *A. triphyllum*, three-leaved toad-flax, leaves ternate, ovate; an annual plant, rising with an upright branching stalk, more than a foot high; leaves oval, in threes, sometimes in pairs, flowers yellow, with saffron-coloured lips: a native of Sicily; a variety of this has a purple standard and spur: this species has been cultivated here since 1640. 8. *A. triornithophorum*, leaves in fours, lanceolate; stem erect, branching; flowers peduncled; it grows more than five feet high, bearing large purple flowers: a native of Portugal and America. 9. *A. purpureum*, purple toad-flax, leaves quaternate, linear; stem erect, flower-bearing, spiked; a perennial plant, rising two feet high: it is a native of Italy; and cultivated in the Oxford garden, in 1648. *Curtis Magaz.* 99. 10. *A. versicolor*, leaves linear-lanceolate; the lower ones ternate; stem erect, spiked; it resembles the *A. linaria*, or common toad-flax, except that the upper lip is whitish, and the flowers racemose: a native of the south of Europe, and introduced, in 1777, by Monf. Thouin. *Jac. Ic. rar. t. 116.* 11. *A. repens*, leaves linear, glaucous, verticillated, or scattered; stem panicled; calyx smooth, of the length of the spur; corolla of an ash-coloured white; under lip streaked with purple: a perennial British plant, flowering from July till September. 12. *A. monspessulanum*: this, according to Dr. Smith, is the same plant as the repens. 13. *A. sparteum*, branching toad-flax, leaves subulate, channelled, fleshy, the lower ternate; stem panicled; corolla very smooth; stem about a foot high, smooth, erect, stiff; flowers racemose, yellow, with a tinge of red at the palate: a native of Spain, and introduced in 1772, by M. Richard. *Curt. Bot. Mag.* 200. 14. *A. bipunctatum*, dotted toad-flax, leaves linear, smooth, the lower quaternate; stem erect, panicled; flowers spike-headed; an annual from four to eight inches high, bearing yellowish flowers, spotted with brown on the lower lip: a native of France and Spain; introduced by M. Thouin in 1777. 15. *A. tristis*, dark-flowered toad-flax, leaves linear, scattered, the lower opposite: nectary subulate; flowers subsessile; stem eight inches long, decumbent; flowers of a dark purple. *Curtis Magaz.* 74: a native of Spain; introduced in 1727, from Gibraltar, by sir Charles Wager. 16. *A.*

16. *A. supinum*, procumbent toad-flax, leaves subquaternate, linear; stalk diffusid; flowers racemed; spur straight: a native of France and Spain; cultivated by Miller, in 1728. 17. *A. arvense*, yellow corn toad-flax, leaves sub-linear, lower quaternate; calyx hairy, viscid; flowers spiked; stem erect, a span high; the colour of its flowers varies blue and yellow; according to Hudson, it is a native of Britain. 18. *A. pelliferianum*, violet-coloured toad-flax, stem-leaves linear, alternate; root leaves lanceolate, ternate; flowers corymbed; an annual, eight inches high, with purple flowers: a native of France and Italy. 19. *A. saxatile*, rock toad-flax; leaves lanceolate-linear, scattered villose; the inferior quaternate; stem decumbent; flowers spiked; a perennial, with yellow flowers, having two orange spots on the palate: a native of Spain. 20. *A. viscosum*, clammy snap-dragon, root leaves quaternate, lanceolate; stem-leaves linear, alternate; calyx villose; about eight inches high: a native of Spain; introduced by M. Thouin, in 1786. 21. *A. multicaule*, many-stalked toad-flax; leaves quinate, linear, fleshy; flowers headed; an annual plant, about a foot high, with several stems, bearing either deep yellow, or sulphur-coloured flowers: a native of the south of Europe; and cultivated by Miller, in 1731. 22. *A. glaucum*, leaves quaternate, subulate, fleshy; stem erect; flowers spiked; a small annual, with yellow flowers; spurs pale, or streaked with blue; a native of the south of Europe. 23. *A. alpinum*, alpine toad-flax, leaves quaternate, linear-lanceolate, sea-green; stem diffuse; flowers racemed, spur straight; perennial; it has a stem about five inches high; flowers of a fine violet-purple colour, and of a deep yellow in the middle. Curtis Mag. 207. A native of the Alps. 24. *A. bicorne*, horned toad flax, leaves opposite, ovate-oblong, serrate; stem erect; flowers racemed; capsules two horned; it grows a foot and a half high, bearing blue flowers, with a yellow mouth: a native of the Cape; and introduced by Mr. F. Masson, in 1774; annual. 25. *A. villosum*, leaves all opposite, ovate, villose; stem simple; flowers opposite, lateral; a perennial with yellow flowers; introduced by Sir Francis Drake, in 1786; a native of Spain. 26. *A. originifolium*, leaves mostly opposite, oblong; flowers alternate; an annual, polymorphous plant, varying with lanceolate leaves. It grows wild on the Pyrenées; it was introduced by Lee and Kennedy, Hammersmith. 27. *A. pinnatum*, leaves opposite, pinnatifid; stem erect; flowers racemed: found at the Cape, by Thunberg.

***Leaves alternate. 28. *A. minus*, least toad-flax; leaves mostly alternate, lanceolate, obtuse; stem very much branched, spreading; calyx longer than the spur; stem erect, branched, villose, viscid; flowers small, violet coloured, with the under-lip white, and palate yellow, growing on axillary peduncles; it is a British perennial plant; found in corn fields and sandy pastures. Curtis, Lond. 541. 29. *A. dalmaticum*, leaves alternate, heart-shaped; stem clasping; stem woody, three feet high; flowers large, yellow, axillary; a native of Crete. 30. *A. hirtum*, leaves lanceolate, flaggy; flowers spiked; the upper leaf of the calyx largest; an annual, rising with a single stalk a foot and a half high; flowers of a pale yellow colour, with dark stripes, and deep yellow lips. Miller received the seeds of this species from Madrid, Jac. ic. rar. t. 117. 31. *A. genistifolium*, broom-leaved toad-flax, leaves lanceolate acuminate; panicle slender, flexuose; stem erect, much branched, three feet in height; flowers of a bright yellow colour, in loose spikes, and resemble those of the Linaria (33.); perennial or biennial: a native of Siberia, Aultria, Switzerland, &c.; cultivated by Dr. Sherard, in 1732. Jacquin Flor. Aust. t. ii. f. 244. 32. *A. junceum*, rush-like toad-flax, leaves linear, alternate; stem panicled, slender; flowers racemed; upper-lip of the

flowers white, with blue streaks; lower a pale yellow: found in Spain; introduced by M. Thouin, in 1780. 33. *A. linaria*, common yellow toad-flax, leaves lanceolate-linear, crowded; stem erect, spiked; calyx smooth, shorter than the spur: it is a common well-known plant, which, from the colour of its flowers, is vulgarly called *butter and eggs*. Woodv. Med. Bot. supp. 221. Eug. Bot. 658. 34. *A. linifolium*, leaves lanceolate, three-nerved; flowers racemed; peduncles distant, shorter than the bractæ; flowers yellow; spur the length of the flower; it grows wild on the sea-coasts of Italy; perennial. 35. *A. chalepense*, white-flowered toad-flax, leaves linear-lanceolate, alternate; flowers in racemes; calyx longer than the corolla: stem erect; an annual plant, growing two feet high; the flowers are small, white, with long spurs, produced singly, almost extending over the whole branches: a native of Italy; and cultivated in the Oxford garden, in 1680. 36. *A. reflexum*, leaves ovate, smooth; peduncles axillary, fruit-bearing, elongate, recurved; stem procumbent; this annual plant rises with filiform procumbent stems, seven inches high, bearing white flowers, with a yellow mouth, placed on solitary peduncles; it grows near Messina; and was discovered in Barbary, by Brander. 37. *A. pedunculatum*, leaves linear remote; flowers panicled; peduncles longer than the leaf, stiff, upright; stems seven inches high, branching; flowers yellow, streaked with blue: a native of Spain. 38. *A. lagopodioides*, leaves scattered, soft, recurved at the tip; spikes ovate, villose; stems herbaceous, nearly a foot high; leaves lanceolate-linear; flowers small, yellow with two orange spots within the palate: a native of Siberia.

****No leaves. 39. *A. aphyllum*, a capillary scape; this is a very singular plant, resembling a kind of moss (splachnum); no part of it produces any leaves: found near the Cape by Thunberg.

****Corollas gaping, or tail-lefs. 40. *A. majus*, great toad-flax, or snap-dragon; flowers without tails, in spikes; calyces obtuse, villose; stem from one to two feet high; leaves lanceolate or ovate; flowers violet, lower lip white, mouth yellow, spur very short pointed: a British annual, growing in sandy ground, and flowering from June till August. Eng. Bot. 129. 41. *A. orontium*, lesser toad-flax, corolla without a tail; flowers subspliked; calyces digitate, longer than the corolla; stem erect, a foot high; leaves lanceolate; corolla a pale purple; lips rose-coloured; palate yellow; spur very short, obtuse; this much resembles the preceding species; it is a British annual, affecting a sandy and calcareous soil, and flowering from July till August. Curtis, Lond. iv. 45. 42. *A. papilionaceum*, corolla tail-lefs; flowers axillary; calyx papilionaceous; leaves fleshy; leaves ovate, entire, alternate; calyx five-leaved; upper lip of the corolla bifid, lower trifid: a native of Persia. 43. *A. asarina*, heart-leaved toad-flax, corollas without tails; leaves opposite, heart-shaped, crenate; stems procumbent; a low, trailing annual; flowers of a dingy purple colour above; below greenish: a native of Italy and the south of France; cultivated in 1669, by Jacob Bobart. 44. *A. molle*, woolly-leaved toad-flax; corollas without tails; leaves opposite, ovate, tomentose; stems procumbent; flowers white villose; upper lip streaked with red: a native of Spain; cultivated by Miller, in 1748. 45. *A. unilabiatum*, corollas without tails, furnished with two calluses; leaves alternate, pinnate; stem panicled: found near the Cape, by Thunberg.

*****Corollas gaping. 46. *A. bellidifolium*, daisy-leaved toad-flax, root leaves tongue-shaped, toothed, marked with lines; stem-leaves parted, entire; flowers very small, in a long spike, which frequently contains one hundred flowers; it is a biennial or triennial, with a branched stem, two feet high: a native of the south of Europe; and cultivated in England, in 1629. 47. *A. Cal-*

nalese, Canada toad-flax, leaves linear, alternate; lower lip of the corolla spreading out, flat; an annual, with a sili-form stem, about a foot high; flowers racemose, alternate: a native of Virginia. 48. *A. micranthum*, small-flowered toad-flax, stem herbaceous, erect; lower leaves quaternate, upper alternate; flowers very small; spur short, interior; an annual, with very small blue flowers, having a white palate; they are axillary, distant, solitary, terminating the stem: a native of Spain, near Madrid. 49. *A. reticulatum*, leaves linear, channelled, scattered; those on the radical shoots generally in fives; flower-stalks shorter than the bractæ; flowers thrice as long as the calyx; spur conical, acute, a little curved, twice the length of the peduncle, yellow, streaked; upper lip erect; segments acute, divaricate, streaked; before expansion purple, changing to a blood-red, and afterwards violet-coloured; it is perennial, with herbaceous branched erect stems, having its radical shoots prostrate, and producing only one flower on each peduncle placed alternately: discovered at Algiers, whence it was sent to the royal garden at Paris, by professor Desfontaines. Its seeds were transmitted to Dr. Smith by M. Thonin; and from these seeds several plants were produced, in Chelsea garden, by the care of Mr. Fairbairn. Smith, ic. rar. fasc. i. t. 2. 50. *A. pygmaeum*, dwarf toad flax, leaves sagittate; peduncles capsulaceous; stems wand-like, prostrate; leaves an inch long upon long foot stalks; calyx extremely small; flowers yellow, little, each upon solitary axillary peduncles. 51. *A. argineum*, lower leaves in fours, linear; flowers in racemes; the upper leaflet of the calyx twice as long as the others; it is annual, having several wand-like stems nearly upright, and linear-lanceolate glaucous leaves; flowers in a terminal raceme, which contains about 30 or 40; these are yellow, and commonly their lower and upper lips are bluish; spur of the length of the flower, recurved and variegated above, with violet-coloured streaks; this species varies into what Linnæus has termed *peloria*, with from one to five spurs on different flowers on the same plant: it is a native of Spain. 52. *A. hexandrum*, leaves opposite, cordato-ovate, ferrate; peduncles axillary, one-flowered. Flor. Aut. n. 235. A native of the island of Otaheite in the South Seas. The five last species are to be considered as new, none of them being noticed by Murray in the fourteenth edition of the "Syllena Vegetabilium," published in 1784.

Propagation and Culture. The various species of snap-dragon are raised from seeds, which may be sown in April or May, or in Autumn: all the varieties of the 40th species, sown late in spring, may in July be planted out in borders, where they will flower the following spring; or they may be sown early in the spring, for flowering in the autumn of the same year; but in this case the plants are not so likely to withstand the winter; and if the autumn prove bad, they will not perfect their seeds. Any of the perennial snap-dragons may be propagated by parting the roots, or by cuttings, which, during the summer months, will readily take root. They are all pretty ornaments in a garden, and requiring very little culture, are rendered more acceptable. The antirrhinums are hardy plants, and will in general resist the cold of our winters; but the tenderer species, or those that are natives of warm climates, should be planted in pots, and removed into shelter, or placed under a hot-bed frame during frosty weather. The soil and situation in which the different species grow in a wild state, should always be considered, and their culture adapted accordingly; a dry gravelly or sandy soil well suits the 40th species and several others, especially those that are natives of Britain; and should these be planted in a rich moist soil, they become very luxuriant in a short time, but are very liable to rot in autumn or winter. Many of these plants are permitted to scatter their seeds, and thus suffered to propagate

themselves, the young plants only requiring thinning where they come up too close, and removing any weeds with which they may be encumbered. See Miller's Dictionary, by Martyn.

The *A. linaria*, or common toad-flax, is the only plant of this genus to which any medicinal virtues have been ascribed: its leaves, which have a bitterish and somewhat saline taste, are reported to be diuretic and cathartic; hence they have been recommended in dropsies and other disorders requiring copious evacuations. This plant has also been used as a resolvent in jaundice and other visceral obstructions; but it has chiefly been valued as an external application in hæmorrhoidal affections, employed in the various forms of ointment, fomentation, and cataplasm. An unguentum de linaria is to be found in the Wirtemberg, Brandenburg and Danish pharmacopœias. Linnæus (Flor. succ.) says, this plant is used as a poison for flies. See Murray, vol. ii. p. 183. Woodville, Med. Bot. vol. iv. p. 25.

ANTIRRHIUM, in *Ancient Geography*, a promontory and small town of Loeris, at the entrance of the Corinthian gulf, opposite to Rhium, whence its name.

ANTI-SABBATARIANS, a modern religious sect, who oppose the observance of the Christian Sabbath.

The great principle of the anti-sabbatarians is that the Jewish Sabbath was only of ceremonial not moral obligation: and consequently is abolished by the coming of Christ. See SA.ATH.

ANTISAGOGE, in *Rhetoric*, a figure differing little from that called CONCESSION. The following passage from Cicero is an instance of it: "Difficilis ratio belli gerendi; at plena fidei, plena pietatis; et sic dicas, magnus labor, multa pericula proponuntur; at gloria ex his immortalis est consecutura."

ANTI-SCEPTIC, something opposed to the reasonings and system of Pyrrhonists, or sceptics.

ANTISCII, compounded of *ἀντι*, against, and *σκια*, a shadow, in *Geography*, denominates people who dwell in the opposite hemispheres of the earth, and whose shadows at noon fall in contrary directions.

Thus the people of the north are antiscii to those of the south. The one project their shadows at mid-day towards the arctic pole; and the others towards the antarctic pole.

The antiscii are very often confounded with the ΑΝΤΩΕΣΙ, though the former term is more general than the latter. The antiscii stand contradistinguished from *periscii*, &c.

ANTISCI is sometimes also used, among *Astrologers*, for two points of the heavens, equally distant from the tropics. Thus the signs Leo and Taurus are held antiscii to each other.

ANTISCORBUTICS, in the *Materia Medica*, medicines proper for the cure of the scurvy.

ANTISEPTIC, from *αντι*, and *σπυρος*, putrid, of *σπυρα*, to putrify, an appellation given to such substances as resist PUTREFACTION.

We have some curious experiments in relation to antiseptic substances by sir John Pringle, who has ascertained their several virtues. Thus, in order to settle the antiseptic virtue of salts, he compared it with that of common sea-salt; which being one of the weakest, he supposes equal to unity, and expresses the proportional strength of the rest by higher numbers, as in the following table.

Salts, their antiseptic virtue.

Sea salt	-	1	Saline mixture	-	3
Sal Gemme	-	1 +	Nitre	-	4 +
Tartar vitriolated	2		Salt of hartshorn	4 +	
Spiritus Mindereri	2		Salt of wormwood	4 +	
Tartarus Solubilis	2		Borax	-	12 +
Sal diureticus	-	2 +	Salt of amber	-	20 +
Crude Sal Ammoniac	3		Alum	-	30 +

In this table the proportions are marked in intercal numbers; only to some there is added the sign +, to shew, that these salts are possessed of a stronger antiseptic virtue than the number in the table expresses, by some fractions; unless in the three last, where the same sign imports, that the salt may be stronger by some units.

Some refinous and other substances even exceed the antiseptic virtues of the neutral salts; thus myrrh, assa-fœtida, terra Japonica, and aloes, are at least twelve times more antiseptic than sea-salt. Two grains of camphor are equivalent to sixty grains of that salt. An infusion of a few grains of Virginia snake-root, in powder, exceeds twelve times its weight of sea-salt. Chamomile flowers have nearly the same extraordinary quality. The Jesuits bark has it also. Besides these, pepper, ginger, saffron, contrayerva-root, are twelve time more antiseptic than sea-salt. Dried sage, rhubarb, the root of the wild valerian, mint, angelica, ground ivy, fena, green-tea, red roses, wormwood, mustard, and horse-radish, were likewise found more antiseptic than the standard.

To the class of antiseptic medicines may likewise be added fermented liquors, acids, spirits, and even those plants called anti-acids, and erroneously supposed halteneis of putrefaction, particularly horse-radish. Now vegetables possessing this virtue are the more valuable, in that, being usually free of acrimony, they may be taken in much greater quantities than either spirits, acids, resins, or even the neutral salts.

Antiseptics are prescribed in all putrid, malignant, and pestilential cases. It is to be remarked, however, that different kinds of them are to be given in different diseases, and even in different stages of the same disease. Thus, the bark is a specific in a gangrene, when the vessels are relaxed, and the blood resolved or disposed to putrefaction; but will fail, if the vessels are too full, or the blood be too thick. It must be confessed, however, that inferences drawn from the effects of antiseptics on dead putrescible matter, may mislead us considerably in their application to the living human body. The putrescent tendency of the fluids, supposed to be present in scurvy and contagious fevers, cannot be obviated by the most powerful antiseptics alone, but will often yield to substances scarcely antiseptic in the lowest degree. On the contrary, gangrene, though generally treated with astringents and antiseptics conjoined, has often been arrested by animal food and volatile alkali.

From the great antiseptic virtue of alum, the bark, and other astringents, it should seem, that astringent had no small share in the cure of disorders termed putrid; and, indeed, the very nature of putrefaction consists in a separation or disunion of the parts. But as astringents are improper to be administered in many cases, contrayerva-root, snake-root, camphor, &c. may supply their place; which, though highly antiseptic, have very little, or any, of an astringent quality. Pringle's Obs. on the Diseases of the Army. See Dr. Macbride's Essay on the respective Powers, &c. of Antiseptics.

ANTISEPTIC substances, in Agriculture, are such substances as have a tendency to resist the putrefaction and decay of animal and vegetable matters, when united with them, either beneath the soil or upon its surface, and in the dung or compost heap. Aluminous and vitriolic substances are mostly of this kind; and likewise the astringent principle of different vegetable matters.

ANTISIGMA, among the *Ancient Grammarians,* signifies one of the notes of sentences affixed to those verses whose order was to be changed.

ANTISPASMODICS, in the *Materia Medica,* are me-

dicines proper for the cure of spasms and convulsions. Heat, especially alternating with cold; æther, wine, spirits, opium, balsam of Peru, and the essential oils of many vegetables, are the principal articles of this class of medicines. Opium excels, for its immediate effects. Peruvian balsam, in many instances, produces more lasting benefit than opium, and sometimes succeeds where opium fails. As *antispasmodics,* the essential oils differ in this from opium, that they act more on a particular part than on the system in general, and have no soporific effect. Where the strictures are produced by inanition, and a defect of vital heat, spasms are removed by those medicinal means that restore the *vis vitæ,* such as warmth, appropriate food and drink, pure airs, cordials, aromatics, and the cheerful passions.

The other *antispasmodics* will be found under the particular diseases, to which they have been applied with the greatest success; see Hysteria, Tetanus, Convulsions, &c.

ANTISPASTUS, a poetical foot, consisting of four syllables, whereof the first is short, the second and third long, and the fourth short.

ANTISPODIUM. See *SPIDIUM.*

ANTISSA, in *Ancient Geography,* was, according to Strabo, in ancient times, an island, and thus called, because it was opposite to Lesbos, then known by the name of Issa; but having offended the Romans, it was depopulated by Labco, and the inhabitants were transplanted to Methymna.

ANTI-STANCARIANS, in *Church History,* a sect of German protestants that opposed the doctrine of Stancarius, who asserted that justification was the sole effect of Christ's human nature, exclusive of his divinity.

ANTISTASIS, in *Oratory,* a defence of an action, from the consideration, that if it had been omitted, worse would have ensued. This is called by Latin writers *comparativum argumentum*: such e. gr. would be the general's defence, who had made an inglorious capitulation, that without it the whole army must have perished.

ANTISTASIS, in *Antiquity,* denotes the gibbous part of the liver in the Grecian victims.

ANTISTES, from *ante,* before, and *stis,* I stand, in *Ecclesiastical Writers,* a title usually given to bishops, though sometimes also to priests or presbyters. Among the ancient Romans, antistes was an appellation given to the chief or first orders of the priests in the provinces.

In which sense, *antistes* stands distinguished from *pater* and *magistri*.—In the more usual sense, notwithstanding, *antistes* denotes the same with *sacerdos*.

There were also females of this quality under the title of *antiste*.

ANTISTHENES, in *Biography,* an Athenian philosopher, and the founder of the Cynic sect, was born about the 90th olympiad, or the year before Christ 420. His first attention was directed to military exploits, and he acquired fame by his valour in the battle of Tanagra. But changing his object, he studied the art of rhetoric under Gorgias, and then prosecuted the attainment of more substantial wisdom under Socrates; and such was the ardour of his mind, that though he lived at the Piræum, which was distant 40 stadia from the city, he was a daily attendant on the instructions of this admired preceptor. The virtuous manners of Socrates, and the noble independence of his spirit, attracted his notice and esteem; and he determined to make the character of his teacher the object of his imitation. Whilst he was a disciple of Socrates, he discovered his propensity towards severity of manners by the meanness of his dress, and frequently appeared in a thread-bare and ragged cloak. His master perceiving that he took pains to expose,

rather than to conceal his tattered drefs, ſaid to him; "Why ſo oſtentatious? through your rags, I ſee your vanity." (Ælian, lib. ix. c. 6.) After the death of Socrates, Antiftihenes, by a reaſonable jeſt, hiſked the deſerved puniſhment of his perſecutors, Melitus and Anytas. When ſome young men came from Pontus to Athens for the purpoſe of attending upon Socrates, they were introduced to Anytas by Antiftihenes, who aſſured them, that he far exceeded Socrates in wiſdom. By this ſarcaſtic encouragement the reſentment of the Athenians againſt thoſe who had diſgraced their city by the baniſhment of ſo excellent a man, was inflamed; and the conſequence was the ſpeedy exile of Anytas, and the death of Melitus. In the ſchool eſtabliſhed by Antiftihenes, and called Cynofurgum, or the temple of the white dog, he ſedulouſly inculcated, both by precept and example, a rigorous diſcipline. In order to accommodate his manners to his doctrine, he wore a coarſe cloak, ſuffered his beard to grow, and carried a wallet and ſtaff, like a wandering beggar. His diet alſo was of the moſt ſimple kind, and he refrained from every kind of effeminate indulgence. In his diſcourſes, he cenſured the manners of the age with a degree of harſhneſs, which procured him the ſurname of "The Dog." He alſo expreſſed the utmoſt contempt for pleaſure, as the greateſt evil, and declared, that he would rather be mad, than addicted to a voluptuous manner of living. Towards the cloſe of his life, the gloomy caſt of his mind, and the moroſeneſs of his temper, ſo increaſed, as to render him troubleſome to his friends, and an object of ridicule to his enemies. In his laſt illneſs he was fretful and impatient; tired of life, and yet loth to die. When Diogenes, at that time, aſked him, whether he needed a friend, Antiftihenes replied, "where is the friend that can free me from my pain?" Diogenes preſented him with a dagger, ſaying, "Let this free you;" but Antiftihenes answered, "I wiſh to be freed from pain, not from life." He paid little reſpect to the gods and to the religion of his country; nevertheless, he ſeems to have entertained juſt notions concerning the Supreme Being. In his book, which treats on phyſics, ſays Cicero (De Nat. Deor. lib. i. c. 13.), he obſerves, that "The Gods of the people are many, but the God of nature is one." For the doctrine inculcated by Antiftihenes, ſee CYNICS. The following maxims and apophthegms are aſcribed to him: "As ruſt conſumes iron, ſo doth envy conſume the heart of man." "That ſtate is haſtning to ruin, in which no difference is made between good and bad men." "The harmony of brethren is a ſtronger defence than a wall of braſs." "A wiſe man converſes with the wicked, as a phyſician with the ſick; not to catch the diſeaſe, but to cure it." "A philoſopher gains at leaſt one thing from his manner of life, a power of converſing with himſelf." "The moſt neceſſary part of learning is to unlearn our errors." "The man who is afraid of another, whatever he may think of himſelf, is a ſlave." Antiftihenes being told that a bad man had been praifing him, ſaid, "What fooliſh thing have I been doing?" He wrote many books, of which Diogenes Laertius has given a long liſt; but none are extant, except two declamations, under the names of Ajax and Ulyſſes, which are publiſhed in the collection of ancient orators by Aldus, in 1513; by H. Stephens, in 1575; and by Canter, with a Latin verſion, as an appendix to his edition of Ariſtides, printed in folio at Baſil, in 1566. Suidas. Fabr. Bibl. Græc. lib. ii. c. 23. §. 32. tom. i. p. 830. Brucker's Hiſt. Phil. by Enſ. vol. i. p. 296.

ANTISTITIUM, is a term uſed in ancient chronicles for an abbey or monaſtery.

ANTISTIUS, in *Biography*, a phyſician whoſe name

is only known from his having been called on to examine the wounds of Julius Cæſar, after he had been aſſaſinated in the Capitol, forty-three years before the commencement of the Chriſt era.

ANTISTROCHON, from *αντι*, and *τροχων*, letter, a grammatical figure, whereby one letter is uſed inſtead of another: as *oli for illi*. This is otherwiſe called *antiphron*, by ſome writers.

ANTISTROPHE, a kind of dance in uſe among the ancients; wherein they ſtepped ſometimes to the right and ſometimes to the left, ſtill doubling their turns or converſions.

The motion towards the left, they called *antistrophè*; from *αντι*, againſt; and *τροπη*, of *τροπω*, I turn.

It was cuſtomary among the Greeks, on ſome occaſions, to dance round the altars, whiſt they ſung the ſacred hymns, which conſiſted of three ſtanzas, or parts; the firſt of which, called *ſtrophe*, was ſung in turning from eaſt to weſt; the other, named *antistrophè*, in returning from weſt to eaſt. Then they ſtood before the altar, and ſung the epode, which was the laſt part of the ſong—Hence,

ANTISTROPHE is alſo uſed in *Lyric Poetry*, in ſpeaking of the ODE, which is uſually divided into the *ſtrophe*, *antistrophè*, and *epode*.

The *antistrophè* is a kind of echo, or replication to the *ſtrophe*; and the *epode* is a lancheing out from them both.

ANTISTROPHE is alſo a figure in *Grammar*, whereby two terms or things, mutually dependant one on another, are reciprocally converted. As if one ſhould ſay, "the maſter of the ſervant, and the ſervant of the maſter."

ANTISTROPHE, in *Rhetoric*, the ſame with what is more commonly called EPISTROPHE.

ANTISYLLOGISM, in *Logic*, a fyllogiſm, which infers a contrary concluſion to that of another SYLLOGISM.

ANTITACTÆ, or ANTITACTICI, in *Antiquity*, a kind of Gnoſtics, who owned that God, the Creator of the univerſe, was good and juſt; but aſſerted, alſo, that one of his creatures had created evil, and had engaged us to follow it, in order to ſet us in oppoſition to God the creator; and that it becomes our duty to oppoſe this author of evil, in order to avenge God of his enemy.

Hence the name; which is derived from *αντιτακτω*, I oppoſe.

ANTITAUROS, in *Geography*, a chain of mountains in Cappadocia, paſſing from the ſouth-weſt to the north-eaſt, and extending from mount Taurus to the Euphrates. The inhabitants of the country now call it Rhoam-Taura.

ANTITHENAR, in *Anatomy*, from *αντι*, againſt, and *θενη*, the palm of the hand, is the name given by Riolanus to the muſcle, commonly named in England *abductor indicis manus*, to which refer. Winſlow alſo calls by this name, the *abductor pollicis pedis*, which ſee.

ANTITHESIS, from *αντιθεσις*, I oppoſe, in *Rhetoric*, a ſetting two things together by way of oppoſition to each other, that the different qualities of each may appear the more ſtrongly.

Such is that of Cicero, in the ſecond Catilinarian; "On the one ſide ſtands modeſty, on the other impudence; on the one fidelity, on the other deceit; here piety, there ſacrilege; here continency, there luſt," &c.—Such alſo is that of Auguſtus to ſome ſeditious young men; "Audite juvenes ſenem, quem juvenem ſenes audivere."—Such again is that of Seneca; "Curæ læves loquantur, ingentes ſtupent." And that of Virgil;

"Flectere ſi nequeo ſuperos, Acheronta movebo."

St. Auguſtine, Seneca, Salvian, and many other ancient writers.

the Antiates; whose ships they partly conveyed into the arsenal of Rome, and partly burnt, and with their beaks, or rollers, they adorned the pulpit erected in the forum, hence called *rylva*. Horace refers to a famous temple of Fortune in this place, l. i. od. 35.

“O Diva, gratum quæ regis Antium,” &c.

Caligula and Nero were born in this city; and Suetonius says, that the former proposed to retire thither after he had massacred the principal persons of Rome, and the latter assigned it as a place of retreat for the veteran soldiers. Tacitus informs us, that Nero was at Antium, when news was brought to him of the conflagration of Rome, which Suetonius charges upon himself. In Christian times, Antium became the see of a bishop; but it is now extinct.

ANTIXENI, a people of India, who, according to Pliny, lived on the other side of the Indus.

ANFLER, among *Hunters*, the first of the pearls that grow about the bur of a deer's horn. There are also *fur-antlers*, *brow-antlers*, &c.

ANTLESTORF, in *Geography*, a town of Germany, in the archduchy of Austria, six miles east of Entzerstorff.

ANTLIA, an ancient machine, supposed to be the same with our pump.

Hence the phrase, in *antliam condemnari*, according to the critics, denotes a kind of punishment, whereby criminals were condemned to drain ponds, ditches, or the like.

ANTÆCI, in *Geography*, those inhabitants of the earth who live under the same meridian, and at the same distance from the equator; the one toward the north, and the other toward the south.

The word is formed of *αντι*, *contra*, and *οικου*, *I inhabit*.—The *Antæci* are contradistinguished from the *Periæci*, and they are frequently confounded with the *Antiscii*.

Hence the *Antæci* have the same longitude, and equal latitudes, only of a different denomination; and, of course, they have precisely the same hour of the day and night, but opposite seasons: when it is 12 o'clock in the longest summer's day with one, it is 12 o'clock of the shortest winter's day with the other; and hence the night of the one is equal to the day of the other.

ANTOING, a town of the Netherlands, in the circle of Hainault, near the Scheldt, 1½ league S. of Tournay. It is the chief place of a canton in the district of Tournay, and department of Jemappe. The place contains 1,567, and the canton 14,849, inhabitants; the territory comprehends 125 kilometres and 19 communes.

ANTOMOSIA, from *αντι* and *ομοσ*, *I swear*, in *Ancient Writers*, an oath taken by both the parties in a criminal accusation; whereby the accuser charges the other with the fact, and the accused in his turn denies the same.

In which sense, *antomosia* amounts to the same with *diomosia*, though some distinguish between the two, restraining *antomosia* to the oath of the person accused, whereby he engages to make no other than a fair defence; and *diomosia* to the prosecutor's oath, whereby he swears that his accusation is justly founded.

Others will have *antomosia* properly denote a law-suit about things to which there are no witnesses, and which can only be decided by the oaths of the parties. Others again will have it to be, where the accused party alleging sickness for his non-appearance, the prosecutor takes an oath that the sickness is only feigned, upon which the judges proceed to sentence.

ANTONA, in *Ancient Geography*, a name given by Tacitus (*Vit. Agricol.*) to a British river, concerning which antiquarians are not agreed. Some writers, as Camden, Carte, &c. appropriate the name to the Nan of North-

amptonshire, others to the Wye; and Whitaker (*Hist. Marcherellæ*, c. 12.) to the Avon of Warwick. Other writers contend for the Southampton river, to which, according to Camden, the name of Anton was applied, and from which he deduces the appellation of Haute-Seyre for Hampshire, and Hanton for Southampton.

ANTONNACUM, or ANTONNACUM, a town of the Treveri, now Andernach, below Coblentz. See *ANDERNACH*.

ANTONELLO DA MESSINA, in *Biography*, a painter of history and portrait, was born at Messina in 1426; and was the first of the Italian masters who understood the art of painting in oil, the secret having been communicated to him by John Van Eyck of Bruges. In order to obtain it, he visited Flanders, and so effectually recommended himself to Van Eyck by his affability and ingenuity, as well as by a present of some fine Italian designs, that Van Eyck disclosed to him the whole mystery; and Antonello soon acquired an eminence almost equal to that of his instructor. From a principle of gratitude he continued in Flanders as long as Van Eyck lived; and, after his death, settled at Venice, where he painted several pictures, that were universally approved, as the subjects were well designed, the figures beautifully drawn, and the whole very delicately finished. He communicated the secret to a painter, named Domenico, from whom Andrew Del Castagno obtained the knowledge of it; and from him the art of painting in oil gradually became known, and generally practised through all Italy. He died at Venice at the age of 49. Pilkington.

ANTONGIL BAY, in *Geography*, lies on the east side of the island of Madagascar, in S. lat. 16°, and E. long. 49° 2'.

ANTONIA TOWER, or *Fortress*, was situated in Jerusalem, at the N. W. angle of the temple, founded by Hyrcanus, on a steep hill; and so elevated, that it commanded the temple. Herod enlarged and fortified it, and gave it the name of Antonia, instead of Baris, by which it was known when Hyrcanus occupied it, in honour of Marc Antony. It communicated with the temple by an arcade, and when the Romans had possession of the country, they kept a garrison in this tower; and by commanding the temple from this fort, they were masters of the city by means of the temple. It was taken by Titus, who thus became master of the temple and of the city.

ANTONIAN Water, in the *Materia Medica*, the name of a medicinal water of Germany, remarkably pleasant to the taste, and of service in many cases as a medicine.

This water, if mixed with any acid liquor, raises a considerable effervescence; and, when mixed with Rhenish wine and sugar, which is a common way of drinking it, makes a great hissing and bubbling, and becomes turbid and milky. If powder of galls be added to it, it suffers no change, but remains limpid and colourless; whence it is plain that it contains no iron nor vitriol. Syrup of vitriol mixed with it turns the whole green, whence it is plain that it contains an alkali: and if oil of tartar be added to it, it becomes turbid and milky, and precipitates a white sediment; whence it appears that there is either common salt or a calcareous earth in it. If it be exposed some time to the air in an open vessel, it, like all the other mineral waters, loses its pungent taste and pellucidity, becoming turbid and vapid. A quart of it evaporated with a very gentle heat, leaves two scruples of a very dry sediment, which being separated by another solution, is found to be one-half of an alkaline salt, and the other a calcareous earth. Oil of vitriol mixed with the salt produces a great effervescence; and a penetrating scent arises like that produced by the mixing of oil of vitriol and common salt. Hence it appears, that these waters contain

tain a small portion of an alkaline salt, a larger portion of sea-salt, and a yet larger of a calcareous earth, and with these a very considerable quantity of a subtle and penetrating mineral spirit.

It is a very temperate water, not too strongly operating either by stool or urine; and hence it is a very proper drink for persons in chronic and in many acute cases, either alone, or mixed with wine, to supply the place of malt liquor, which is proper but in very few illnesses. A long use of it alone may also prove of considerable service in hypochondriac cases.

ANTONIANO, SILVIO, in *Biography*, a cardinal and learned man of the 16th century, was born at Rome in the year 1540; and, at the early age of 10 years, distinguished himself by extemporaneous productions in verse. Having given various proofs of his singular talents in this way, he was taken under the protection of the duke of Ferrara, who provided him with excellent masters to instruct him, assigned him a pension, and established a professorship of belles lettres, with which he was honoured at the age of 17 years; and on this occasion he pronounced some orations, which were afterwards published. When cardinal de Medicis succeeded to the popedom, under the name of Pius IV., he sent for Antoniano to Rome, and made him Latin master and secretary to his nephew, cardinal Borromeo. He was also appointed professor of polite literature in the college at Rome; and discharged this office with such reputation, that he had for his auditors not only a prodigious number of people, but even 25 cardinals. He was afterwards chosen rector of the same college. At the death of Pius IV., he was chosen secretary of the sacred college by Pius V.; and occupied this post for 25 years. Clement VIII. made him secretary of the briefs, afterwards his chamberlain, and finally a cardinal. He fell a sacrifice to intense study, in his 63d year. Antoniano is said to have written with such ease and correctness, that he never made a blot or erasure; and his manners were so irreproachable, that he is said never to have transgressed the bounds of the strictest chastity. He left a variety of works both in prose and verse; of which the principal are, "De Christiana Puerorum Educatione;" "Dissertatio de Obscuritate Solis in Morte Christi;" "De Successione Apostolica;" "De Stylo Ecclesiastico seu de conscribenda Ecclesiastica Historia;" "De Primatu Sancti Petri;" "Lucubrationes in Rhetoricam Aristotelis, et in Orationes Ciceronis." It is also said that he had a share in the catechism of the Council of Trent. Gen. Dict.

ANTONIDES, J. VANDER GOES, an eminent Dutch poet, was born of an abaptist parents, at Goes in Zealand, in the year 1647. After a tolerable education, he was apprenticed to an apothecary: but the fame of Vondel and some other poets of his country, led him to cultivate his natural talent in this way. He began with translations from the best Latin writers, and then launched into original composition. His tragedy upon the conquest of China by the Tartars, intitled "Trazil," was followed by "Bellona in Chains," which was highly applauded by the best judges. But his capital work was entitl'd "Y Stroom," or the River Y, which forms the port of Amsterdam. This recommended him to M. De Bufero, deputy in the college of admiralty, who procured for him the place of secretary in that department. Soon after he had been thus raised from his obscure situation, he married a clergyman's daughter, who had a taste for poetry; but abandoning the Muses, and devoting himself to the duties of his office, he soon died of a consumption in the flower of his age, in 1684. He had proposed, and begun a life of St. Paul, but left only a few fragments of it.

His works were published, in 4to. at Amsterdam, in 1714, under the inspection of Mr. Hoogstraten, one of the masters of the Latin school. Gen. Dict.

ANTONIENBERG, in *Geography*, one of the highest points of the Swiss Alps, in the Valais.

ANTONINE COLUMN, in *Architecture and Sculpture*. See COLUMN.

ANTONINUS PIUS, or *Titus Aurelius Fulvius Boionius Antoninus*, a Roman Emperor, was born at Lanuvium or Lavinium, in the vicinity of Rome, A. D. 86; and descended from virtuous and honourable ancestors at Nismes in Gaul. Both his grandfathers, and his father, were consuls. After the death of his father, his education was completed in the house of his maternal grandfather, Arrius Antoninus. At an early age he conciliated the affection of all his relations, so that when they died, he was distinguished by their bequests, and became rich; and as he advanced to maturity, he combined, in a very eminent degree, all the virtues of the heart with a gentle and majestic countenance, a cultivated understanding, a commanding eloquence, and an exemplary conduct. In his sentiments and actions he was guided by moderation; and he was perfectly free from affectation and vain glory. Having attained the consulate A. D. 120, he was afterwards one of the four consulars appointed by Adrian to govern Italy, and became proconsul of Asia; where, by the mildness of his authority, and the affability of his manners, he engaged the affection and attachment of persons of all ranks and parties. On his return to Rome, he was admitted into the council of Adrian; nor did the emperor pursue any measure of consequence without his advice. He married Anna Faustina, the daughter of Annius Verus; and though he was not very happy in his choice, he behaved with singular respect to the father, comforting him in his old age, and supporting him with his arm when he came into the senate; and hence it is said, he obtained the surname of *Pius*. By this marriage he had two sons, who died young; and two daughters, one of whom, named Faustina, was married to Marcus Aurelius, afterwards emperor. Upon the death of Ælius Verus, Adrian determined upon the adoption of Antoninus; and having overcome his reluctance to undertake so great a charge as that of the Roman empire, he declared his nomination in the presence of a council of the principal senators, on the 25th day of February, A. D. 138, and immediately made him his colleague in the proconsular and tribunitian authorities. He also caused him to adopt the son of Verus, an infant of seven years of age; and Marcus Annius, afterwards Aurelius, who was about 17 years old. Upon the death of Adrian, July 10, A. D. 138, or, as some say, A. D. 139, Antoninus succeeded to the throne, amidst the congratulations of the senate, and to the universal satisfaction of the Roman people. His accession was marked by the usual titles and honours conferred on the Roman emperors; to which the senate added that of *Pius*, either from the circumstance already mentioned, or on account of the respect with which he treated the memory of his predecessor. Although the pacific reign of Antoninus affords little variety of incident, it is nevertheless to be regretted, that we derive our direct information of this reign from a confused and obscure historian, Capitolinus; the records of Dio Cassius having been lost. From the testimony of this historian, however, it appears, that, after his accession to the empire, he pursued the same course of conduct which he had done whilst he was a private person; fixing the attachment of his friends, and conciliating his enemies; consulting the senate on every transaction of importance, and frequently giving an account to the people of all his actions

and negotiations. Such was his general conduct, that M. Aurelius was convinced, by his example, that a prince might lead a private life even in a court. He reduced most of the impolls and tributes, and enjoined his collectors to exact them without severity; observing, that he rather chose to be poor, than that his coffers should be filled at the expence of an oppressed people. Soon after his accession, he distributed the greatest part of his private estate among the indigent citizens; and when the empress Paulina repined at his liberality, he told her, that a prince ought to have no private interest, no private property, and nothing in view but the public welfare. He was judicious in the choice of the governors of provinces; and, it is said, that he never promoted an undeserving person to any employment or honour. The pensions of useless persons were abolished, and he alleged, that he could not bear to see the state impoverished by those who did it no service, but lived idly upon the labours of others. But though he was sparing of the public money, no one ever charged him with avarice, as he was exhibiting daily evidence of an unbounded generosity. He never would accept legacies from such as had children; and he ordered the estates of criminals condemned for extortion to be restored to their heirs, after having rendered satisfaction to those whom they had pillaged. He also extirpated the whole tribe of informers; and upon any misfortune that happened to any city or province, he was ready to lessen their tribute or taxes. Antoninus every where favoured men of learning, encouraged the education of youth, and spent considerable sums in providing for the children of indigent parents. Although he was not addicted to building, he raised several stately edifices in Rome and its vicinity. He caused a port to be made at Caieta or Gæta; repaired that of Terracina; finished Adrian's magnificent mausoleum; built a stately palace at Lorium in Etruria, about ten miles from Rome, where he had been educated; and he contributed large sums towards repairing several ancient buildings in Greece, Ionia, Syria, and Africa. It is probable that Nimes was indebted to him for those magnificent decorations that still distinguish it, the amphitheatre and aqueduct. Having declared at the commencement of his reign, that he would not spill the blood of any senator, he religiously observed his engagement; so that when one was convicted of parricide, he contented himself with banishing him, after he had confessed his crime. When Attilius Tatianus and Priscianus were accused of conspiring against his life, and after the latter had destroyed himself, and the former was banished, he took the son of the survivor under his care, and brought him up as if he had been his own child; nor would he suffer any inquiry to be made after their accomplices, observing to the senate, who urged him to it, "I do not care the world should know by how many persons I am hated." In the exercise of jurisprudence, he issued three decrees which manifest a laudable spirit of equity. The first was, that no one should be again prosecuted on a charge of which he had been once acquitted:—the second, that the children of a person become a Roman citizen, who were not so themselves, should not, as in former times, forfeit their inheritance to the treasury:—and the third, that a woman prosecuted for adultery by her husband, should have a right to recriminate. He also issued rescripts in favour of the Christians, to protect them from popular rage and legal injustice. One of these, addressed to the people of Asia Minor, is preserved by Eusebius (E. H. l. iv.), and it bears testimony to their character. So pacific was his disposition, that he never engaged in any war which he could avoid; and was often heard to say, "that he had rather save one citizen than destroy a thousand enemies."

Some commotions, however, arose in various parts of the empire; but they were suppressed, without much difficulty, by his lieutenants. In Britain, the incursions of the Brigantes were suppressed; and the boundaries of the Roman province were extended, by building a new wall to the north of that of Adrian, from the mouth of the Elbe to that of the Tweed.

Antoninus, by his temper and conduct, gained the affections, not only of his own people, by whom he was revered as their father and protector, but of those who were the avowed enemies of Rome. Such was the influence of his known character, that a letter addressed by him to the king of Parthia, induced him to decline a meditated invasion of Armenia, and to disband his troops. The kings of Hyrcania, Bactria, and India, sent ambassadors to him, court- ing his friendship and alliance. Pharasmanes, king of Iberia, paid him a visit in person at Rome; and the Lazi, the Armenians, the Quadi, and several other nations, readily received such persons as he was pleased to appoint for their rulers, though they were not then subject to the empire. Antoninus is by some historians compared, and by others even preferred, to Numa, on account of the tranquillity which Rome enjoyed during the greatest part of his reign; and his extraordinary care of all things belonging to the worship of the gods, and to religion.

Some persons have thought that he extended his indulgence to the empress Paulina, whose life was dissolute, to an improper and culpable extreme. After she died, she was honoured with divine worship, priests, temples, and statues of gold and silver; games were also instituted to her honour; and her statue was carried, by his express order, amongst those of the other gods, at the Circensian sports.

Soon after his advancement to the throne, Marcus Aurelius was distinguished by his favour; for he married him to his daughter Faustina, and declared him Cæsar; nor had any reason to regret the honours he conferred upon him, and the confidence he reposed in him. In this state of domestic and public tranquillity, Antoninus attained his 74th year; and being seized with a fever at one of his country seats at Lorium, he closed his life, in the month of March, A. D. 161. He foresaw the event, and summoned the principal officers of state to attend him; and in their presence confirmed his choice of Marcus Aurelius as his successor, and caused the imperial ensigns to be carried to him. In the state of derangement, occasioned by his fever, his thoughts were evidently directed to the republic; and he deprecated the anger of the kings whom he supposed hostile to it. In a lucid interval, he gave as a watchword to the prætorian tribunes, "Equanimitas;" and then placidly expired, after a reign of 22 years seven months and 26 days. His funeral was conducted with pomp and magnificence; his remains were deposited in the tomb of Adrian; he was ranked by the senate among the gods; a temple was built to his honour; and priests, sacrifices, and annual sports were instituted. His death, though at an advanced age, was the subject of universal lamentation; and so highly honoured was his memory, that succeeding emperors chose to bear the name of Antoninus, as the most popular appellation they could assume. Marcus Aurelius and the senate consecrated to his memory a sculptured pillar, which still subsists, as one of the principal ornaments of Rome, under the name of the *Antonine Column*. *Anc. Un. Hist.* vol. xiii. p. 294—309. *Crevier's Hist. of the Emperors*, vol. vii. p. 198—245. *Lardner's Works*, vol. vii. p. 388—395.

ANTONINUS, MARCUS ANNIUS AURELIUS, one of the most illustrious of the Roman emperors, was born in the year

A N T O N I N U S.

of Rome, 874, A. D. 121, during the second consulship of his grandfather, L. Annius Verus; and descended from an honourable family of Suceubis or Ueubis, of Beticæ, supposed to be related to that of Adrian. He was distinguished by the patronage and favour of Adrian in his early years; and at the age of six years he advanced him to the rank of knighthood, at eight admitted him into the college of Salii, and at length adopted him into the imperial family, so that his succession to the empire was secure. The Emperor used to call him M. Annius Verissimus, on account of his great sincerity. When he was adopted, he took the names of M. Ælius Aurelius Verus, Aurelius being an appellation peculiar to the family of Antoninus, and Ælius belonging to that of Adrian, into which Antoninus had been adopted. Upon his accession to the empire he assumed the name of Antoninus; and he is usually distinguished from his predecessor by the prenomens of Marcus, or surname of Philo-sophus, which was given him by the unanimous consent of historians, and not by any decree of the senate. The care of his education in his infancy was devolved on his paternal grandfather, Annius Verus; and in his maturer years, he was brought up in the palace, and instructed under the direction of Adrian, in all the arts that pertain both to the body and mind; eloquence and poetry, however, engaged little of his attention, for his thoughts and time were devoted to philosophy; and more especially to that kind of philosophy that tended to regulate the temper and conduct. His principal masters were Herodes Atticus, and Cornelius Fronto, Greek orators: and above all, Junius Rusticus, who joined to an illustrious birth an hereditary taste for the stoical philosophy. Such was his proficiency under these instructors, that at the age of 12 years he assumed the philosophical gown. To his intense study he added the austerities of the profession to which he was devoted; and by unwearied application and strict regimen he prejudiced his health. With the gravity of a philosopher, however, he blended no part of the severity; his address was agreeable and engaging to all with whom he had any intercourse; he was virtuous without pride, modest without timidity, and grave without melancholy. To his masters he was respectful and grateful; he honoured them living and dead; and kept their images of gold, with those of his household gods, in his domestic chapel; and offered up chaplets of flowers and victims at their tombs. At 15 years of age, he put on the manly gown, and soon afterwards was appointed præfect of the city. About this time he manifested his disinterested generosity, by surrendering to his only sister, Annia Cornificia, all his father's effects. His adoption into the Aurelian family, by Antoninus Pius, took place in his 17th year; but such was the superiority of his mind to all distinctions of this nature, that the honour produced no change in his disposition and mode of life, nor in the course of his studies. After his adoption, he was appointed quæstor; and immediately upon Adrian's death, Antoninus married him to his daughter Faustina, advanced him to the dignity of Cæsar, and conferred upon him, in quick succession, a variety of civic honours. He was appointed chief of one of the centuries of Roman knights, had a household assigned him, was twice consul, and received the tribunitial and præconsular authorities. Such was the emperor's confidence in him, that he was called to all his public councils, and he gave away no office without his advice and approbation; and such was Aurelius's attachment to the emperor, that, during almost 23 years, he never slept apart from him more than two nights either in town or country.

Of the disinterestedness of Aurelius, we have a singular instance on his first accession to the throne. L. Aurelius

Commodus, the son of that Verus whom Adrian had adopted, had been joined with Marcus Aurelius in the adoption of Antoninus, and equally intended for the succession. But Antoninus, on account of the errors and vices of his youth, had excluded him from any share in the sovereignty, and appointed Aurelius heir to the empire; and, upon the death of Antoninus, the senate confirmed his purpose. Aurelius, however, procured Commodus to be declared his colleague, promised him his daughter Lucilla in marriage, and ordained that he should take his own original name of Verus, by which name he was afterwards known. In the first year of Aurelius's reign, Faustina was delivered of male twins, one of whom died under age, and the other was Commodus, who succeeded his father in the empire, disgraced his elevation, and became notorious for every kind of profligacy. About the same time, the public tranquillity was disturbed in Germany, Great Britain, and Parthia; but the most important events were, the invasion of Armenia by Vologeses, king of the latter country, and his irruption into Syria. Verus proceeded to the east, rather making a tour of pleasure than conducting a military expedition, and took upon him the supreme command. After four years the war terminated in a treaty, which restored the king of Armenia to the throne; and though Verus was an object of contempt, on account of his luxurious disposition, to foreign nations, and had little personal share in the honour of bringing the war to a termination, he was dignified with the title of "Imperator" by the army, and other pompous appellations. During the course of this war, he married Lucilla; and, on his return to Rome, both emperors were united in the triumph, and a cordial harmony subsisted between them. The character of these two emperors was, however, essentially different. Verus was debauched and extravagant; and if we except cruelty, in the exercise of which he was restrained, he exhibited all the follies and vices of the worst of his predecessors. Aurelius, on the other hand, was a philosopher on the throne; and exhibited a pattern of every private and public virtue. He distinguished himself more than any former emperor had done, by his respect and deference to the senate, and by his attention to the happiness of the people. He would not touch the money in the treasury, without the express permission of the senate: "Every thing," said he, "belongs to the senate and people; we have nothing which we do not hold of you; the very palace we inhabit is your property." When he was under a necessity of patiently enduring those vicious habits which he could not reform by gentle means, he used to say, "We cannot make men as we wish them to be: we must take them as they are, and do the best with them that lies in our power." So determined was Aurelius in resisting exactions, that he checked the rapacity of his soldiers at a moment of victory, by telling them, "All that is given you beyond your due must come from the blood of your parents and relations." In a time of public distress, he preferred selling the furniture of his palace, and the rich wardrobe of his wife, to increasing the burden of the provinces. Although he did not wholly abolish, he restrained the expence of public exhibitions: and he softened the cruelty of the combats of the gladiators, by substituting less hurtful arms in the room of those that were destructive. Lenity was the chief foible of his character; and yet he ever manifested a strict regard to justice. He expedited the decision of legal processes, increased the number of days on which the courts were to sit for the dispatch of business, and followed the example of his predecessor in his improvement of jurisprudence. The right of succession of children to their mothers was made by him

a part of the Roman law, and he appointed a particular prætor for the guardianship of minors.

The close of the life and reign of this tranquil prince was disturbed by the hostilities of the Marcomanni and other German tribes; and when a peace had been concluded with the Partians, their hostilities, which had become formidable, demanded attention. In the year 166, the two emperors having levied an army, left Rome together, and wintered at Aquileia. Antoninus had prepared for the conflict that was expected, by a variety of religious ceremonies, which he thought might tend to render the deities propitious, whilſt they manifested his own attachment to the forms of religion which superstition had devised and sanctioned. Till the death of Verus, in the year 169, nothing decisive seems to have occurred. Worthless as his character was, Antoninus prostituted upon him divine honours; and in his memoirs, he speaks of him with undue respect, and in a manner that is not very compatible with the reproach which he cast upon him in his address to the senate. In the following year, the emperor, who was now sole possessor of power, returned to Pannonia, and vigorously opposed the Marcomanni, who had advanced as far as Aquileia. During a contest which detained Antoninus in these parts for five years, he had many opportunities for the exercise of fortitude and patience, and for the practice of those lessons which he had studied in his youth. The most celebrated event which occurred in this period, was a victory obtained by the emperor in person over the Quadi, the consequence of a sudden storm of rain, hail, and lightning, which disconcerted the barbarians, and was regarded as miraculous. Antoninus and the Romans ascribed it to an interposition of Jupiter and Mercury, but the Christians attributed it to the effectual prayers of a legion of Christians who served in the army, hence called the *thundering legion*. See a more particular account under that article. Pannonia was at length delivered from the incursions of the barbarians; to whom territories were assigned on the confines of the empire. The subjugation of the Marcomanni was delayed by the revolt of Avidius Cassius, who assumed the purple in Syria; and who obtained support in consequence of a rumour of the emperor's death, which he contrived to circulate. This rebellion was soon quelled by the officers of Cassius, who conspired against him, and killed both himself and his son. Such was the magnanimity of the emperor on this occasion, that, having obtained the papers of Cassius, he committed them to the flames without reading them. After the suppression of this insurrection, Antoninus made a progress through the east, and was accompanied by Faustina, who died in this journey, after a short illness. In her licentious conduct she rivalled the infamous Messalina; and yet, such was the stoical insensibility of her husband, that he paid her divine honours after her death. This conduct on the part of the emperor, either betrays great want of penetration, or offers an inexcusable insult to decorum and good morals. Whilſt the emperor visited Syria, Egypt, and Greece, in the year 176, he was initiated at Athens, in the Eleusinian mysteries, and he conferred various privileges on this seat of philosophy. On his return to Rome, after an absence of eight years, he obtained a triumph on account of his conquest of the Marcomanni, and profusely distributed largesses among the people. After two years, he marched again towards the Danube, where the war with the Marcomanni was renewed; and in this expedition he was accompanied by his son. Before his departure, it is said that, in compliance with the request of the people, who wished him to instruct them in the secrets of philosophy, he gave public lectures for three days; and the report of adulation adds, that he de-

livered similar lectures in some of the capitals of the provinces. In this new war Antoninus was successful, and was for the 10th time honoured with the title of "Imperator." After an absence of two years, he fell ill at Vindobona, now Vienna, in Austria, apparently of a pectus ail disease which prevailed in the army, and died on the 7th day, March 17th, A. D. 180, U. C. 933, at the age of 59 years, and after a reign of somewhat more than 15 years. His death was universally lamented; he was deified by the acclamation of the senate and people; his image was kept in the private houses of the Romans among their deities, and he who had not one was deemed inauspicious; his worship of him continued above 100 years; and Dioclesian gloried in honouring him as one of the principal deities.

Marcus Aurelius, notwithstanding all the good qualities by which he was distinguished, and the mildness and clemency which perhaps on some occasions he carried to a blameable excess, persecuted the Christians. He was undoubtedly prejudiced against them, and in his own book, (xi. 3.), censures very unreasonably what he ought to have approved (as the excellent Dr. Jortin remarks, Discourses concerning the Truth of the Christian Religion, p. 57)—their readiness and resolution to die for their religion. The ground of this censure is particularly examined by Dr. Lardner; and he ascribes it partly to the Christians refusing to join in the common worship of the Heathen deities, and to the freedom of their reflections upon the philosophers; partly to their surpassing even the stoics in patience under all kinds of sufferings; and partly to the emperor's bigotry, both in religion and philosophy, which often misleads the judgment, and induces persons of the best disposition to act contrary to the laws of equity on some occasions. Of the persecutions in this reign, which were numerous and severe, and which have led the ancients to reckon Aurelius among the persecuting emperors, we must seek the cause in the stoical and hard-hearted philosophy which he had embraced; in his attachment, real or dissembled, to the religion of his country, and to the established worship of the gods against which Christianity militated; and perhaps principally to the instructions and investigations of the philosophers, who frequented his court, and who cherished in his mind an enmity against the Christians. Whatever motives influenced the conduct of Aurelius, the Christians were under great discouragements during his reign. In that period were published many apologies, as the second of Justin Martyr, those of Tatian, Athenagoras, Apollinaris of Hierapolis, Melito of Sardis, and Theophilus of Antioch. In this period were also many martyrs; some of great distinction, as Justin, Polycarp, and the martyrs of Lyons, with their aged bishop Pothinus.

Aurelius was a writer; and his "Meditations," written in Greek, have reached our time. The most valued editions are those with Gataker's notes, particularly that of Cambridge, 4to., 1652; of London, 4to., 1697; and of Utrecht, folio, 1698. In order to form a true judgment of these meditations, with respect to their meaning and spirit, they should be read, not as detached moral maxims or reflections, but as connected with, and founded upon, the principles of stoicism. The leading feature in the character of Aurelius was goodness of heart: but it was not accompanied with a comprehensive understanding and sound judgment. "His philosophy was not free from pedantry and ostentation. We want in him the manly sense of Trajan, and the simple virtue of Antoninus Pius; yet he will ever stand high among the friends and benefactors of mankind; and will afford a memorable example of philosophy strictly maintained upon a throne." ANTONIO, NICHOLAS, was born at Seville in Spain, in 1617; and having studied law in the university of Salamanca, became agent-general for the king of Spain, at Rome. He is known as the author of a celebrated work in Spanish literature, intitled "A Catalogue of Spanish Authors," to the compilation of which he devoted several years in the royal monastery of Benedictines at Salamanca; and for the completion of which, as well as the gratification of his taste for letters, he purchased 30,000 volumes. The work was completed in four volumes folio, and printed at Rome in 1696. It is copious, correct, and methodical; and is now scarce. He also wrote in Latin a treatise "On Exile," which was published at Antwerp in 1659. Antonio died in the year 1684. Gen. Biog.

ANTONIO, *Port*, in *Geography*, a bay or harbour on the north-east coast of the island of Jamaica, two leagues west-north-west from north-east point.

ANTONIO *Island*. See ST. ANTHONY'S *island*.

ANTONIO, *St. Cape*, lies in a small deep bay, about two leagues north-west from Cape St. Martin's, on the coast of Valencia, in the Mediterranean, belonging to Spain.

ANTONIO, *St. Port*, lies in the island of Lemnos, in the Archipelago, between two hills, appearing at sea like two islands; 12 leagues north-west from Mitylene, or Lesbos.

ANTONIO *Viana*, is a shoal due west of Cape Negro, on the coast of Africa, 80 or 90 leagues from the shore, which is very dangerous, and should be carefully avoided.

ANTONIO, *St. Cape*, is the extreme western point of the island of Cuba, in the West Indies. N. lat. 21° 45'. W. long. 84° 10'.

ANTONIO, *St. Fort*, lies on the coast of Brazil, within the north point of the river Paraba. S. lat. 21° 25': called Point Lucena, and the rendezvous of the Brazil ships for Europe.

ANTONIO DE SUCHITEPEC, *St.*, a town in Mexico, or New Spain, on the coast of the Pacific Ocean. N. lat. 15°. W. long. 93° 5'.

ANTONIO, *St.*, the capital of the province of Apachiera, in New Mexico.

ANTONIO, a town in the province of Navarre, in North America, on a river which runs south-west into the gulf of California.

ANTONIO DE CABO, *St.* a town of Brazil, in South America, near Cape St. Augustine, subject to the Portuguese, where they manufacture a considerable quantity of sugar. S. lat. 8° 34'. W. long. 35° 22'.

ANTONIO, *St.* a town of New Mexico, on the west side of Rio Bravo river, below St. Gregoria. It is also the name of a town on the river Hondo, which falls into the gulf of Mexico, north-east of Rio de Brava.

ANTONIoTTO, GIORGIO, in *Musical Biography*. See GIORGIO.

ANTONIUS, MARCUS, the *Orator*, in *Biography*, was the greatest ornament of the Antonian family. Having obtained the quaestorship of the province of Asia, he had proceeded to Brundisium, when he was informed that he was accused of incest; and that the cause lay before Cassius the praetor, who was a very severe judge. Declining to avail himself of the privilege belonging to those who were absent in the service of the commonwealth, against whom no accusation could be preferred, he hastened back to Rome, and submitted to a trial, in which he was honourably acquitted. Whilst he was praetor, Sicily fell to his lot, and he cleared the seas of the pirates which infested those coasts. He was

consul in the year of Rome 653, before Christ 101, and was very active in suppressing the tumults excited by the tribune Sextus Titus. His conduct, whilst he was governor of Cilicia, obtained for him the honour of a triumph. In order to improve his talents for eloquence, he put himself under the instruction of the principal teachers of rhetoric, both at Athens and Rome. On his return to Rome, he performed the office of censor, and gained a cause against Duronius, who had from revenge preferred an accusation of bribery against him. He was highly admired and esteemed on account of both his talents and conduct; but unfortunately fell a sacrifice in the tumults occasioned at Rome by the factions of Marius and Cinna. The soldiers who were dispatched to discover his retirement and to kill him, were so overpowered by his address that they were unable to execute their commission; and the commanding officer, observing that they hesitated, and enraged that his orders were not complied with, became himself the assassin. His head was afterwards exposed before the rostrum, which he had adorned with his triumphal spoils. This happened in the year of Rome 667, before Christ 87. Marcus Antonius was one of the greatest orators of Rome; and in the judgment of Cicero, it was owing to him and to Crassus, that Italy was the rival of Greece in the art of eloquence. He makes him one of the principal interlocutors in his "Dialogue on Oratory;" and in his "Treatise on famous Orators," describes at length his character as a speaker. His distinguishing qualities were force, earnestness, acuteness, variety, readiness, and copiousness, and he excelled as much in action as in language. His memory was singularly retentive; and though he began to speak without any seeming preparation, he was always so much master of his subject, that the judges seemed not sufficiently prepared to answer him. In his defence of Marcus Aquilius and others, he moved the judges, by the tears he shed, and by exhibiting the scars on the breast of his client, to such a degree, that he gained his cause. Although a tract of his on oratory had got abroad surreptitiously, he never suffered any of his pleadings to be published; alleging that whenever it would have been better that any thing had not been said, it might not be proved against him. Cicero, de Oratore, lib. ii. c. 47. &c. Apud Oper. tom. i. p. 254, ed. Olivet.—De Claris Oratoribus, c. 30, 31, &c. Oper. tom. i. p. 416, &c. Pro Cluentio, c. 50. Oper. tom. v. p. 88. Valer. Max. lib. vii. c. 3. Gen. Dict.

ANTONIUS, MUSA, physician to the emperor Augustus. Having had the good fortune to restore the emperor to health, from a tedious and dangerous complaint, which his other physicians had attempted in vain, he was loaded with riches, and was allowed the liberty of wearing a gold ring, a privilege only granted to personages of the first rank. This privilege was afterwards granted to other physicians at Rome, in compliment to Antonius.—The medicines he used in the cure of Augustus are said to have been principally cooling herbs, to which he added the use of the cold bath, at that time but little known. He was skilful, Haller says, in the knowledge of medicine, and many of his compositions continued to be used to a very late period. Bib. Med. Pract.

ANTONNE, in *Geography*, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Perigueux, on the Ille; five miles east of Perigueux.

ANTONOMASIA, compounded of *anti*, for, and *νομα*, name, a figure in *Rhetoric*, whereby a noun appellative is used instead of a proper name, or *vice versa*. Thus we say, the Philosopher, instead of Aristotle; the Orator, for Cicero; the Apostle, for St. Paul; the Prophet,

for Moses, &c.—Thus also we call a voluptuous person, a Sardanapalus, &c. And thus the French say, Henry the Great, meaning Henry IV. of France.

ANTONOW, in *Geography*, a town of Poland, in the palatinate of Minsk, 16 miles south-south-east of Mozyr.

ANTONY, a town of France, two leagues S. of Paris.

ANTONY, MARK, MARCUS ANTONIUS, the *triumvir*, in *Biography and History*, was grandson of the celebrated orator of that name, and son of Antonius, surnamed *Cretenfus*. His mother's name was Julia, of the Cæsarian family, a lady of distinguished merit. He was born in the year before Christ 86, and educated under his mother's direction. But, following the example of his father, he launched out at an early age into the excess of riot and debauchery. His comely person, lively wit, and insinuating address, recommended him to Curio, who encouraged and supported his licentiousness, and involved himself on his account in a debt of 50,000 pounds. On this occasion Cicero was requested to appease the anger of Curio's father; and having prevailed with him to pay his son's debts, he advised him to enjoin on his son the surrender of all intercourse with Antony. This laid the foundation of an early aversion in Antony to Cicero, which was increased by his forming intimate connection with the enemies of Rome. He afterwards attached himself to the profligate Clodius; but conceiving a dislike of him, and dreading the termination of the measures he was pursuing, he went to Greece with a view of improving himself in eloquence and the military art. Here he was invited to serve under the proconsul Gabinius, and obtained the command of the cavalry in his expedition into Syria, where he signalized himself by his valour in a complete victory over the Jews, and in his attempts to restore Ptolemy to the throne of Egypt. When Pelusium was taken, Ptolemy ordered the inhabitants to be put to death; but Antony interposed, and by his influence saved their lives. He afterwards performed several glorious actions, by which he gained the reputation of a great general. Upon the breaking out of the civil war, he joined Cæsar's party, and was created augur and tribune of the people; but becoming obnoxious to the senators, he was driven out of Rome, and sought an asylum in the camp of Cæsar, in Gaul. Having complained, that the tribunes of the people were not permitted to speak freely, and that those who appeared in favour of equitable measures were in danger of losing their lives, Cæsar marched immediately into Italy; and on this account Antony as been considered as the promoter of the civil war among the Romans. When Cæsar had made himself master of Rome, he assigned to Antony the government of Italy and the supreme command of the army, whose attachment he engaged, whilst he incurred the charge of oppressing the people. Such was the reputation he acquired by the effectual assistance which he gave to Cæsar, that he was appointed to the command of the left wing in the battle of Pharsalia, whilst Cæsar himself led the right. When Cæsar, after the victory over Pompey, was made dictator, Antony was appointed general of the horse, which office he retained for a whole year, though the usual period of it was only six months. In the exercise of this office he was tyrannical and intolerant; and his general conduct was so dissolute and licentious, that Cæsar treated him with coldness, and did not admit him to be his colleague in the consulship at this time; as he died two years after, in the year before Christ 44, when he himself was consul the fifth time. His restoration to favour was the recompence of the most profligate adulation and servility, and his conduct in office was so base as to accelerate the fall of his patron. At the festival of the Lupercalia, he thrice tempted Cæsar with the offer of a regal diadem, which was as

often refused by Cæsar, to the great satisfaction of the multitude. This attempt at royalty was soon succeeded by the conspiracy which deprived Cæsar of his life. Antony escaped by the interposition of Brutus; and afterwards contrived, by his art and eloquence, to procure a confirmation of Cæsar's acts, and to oblige the conspirators to fly from Rome. The government of Antony, after Cæsar's death, was for some time absolute; and he seemed to aspire to the sovereign power which Cæsar had possessed. His contemptuous treatment of Octavianus, the heir of Cæsar, however, threw him into the arms of the senate, and defeated his own ambitious projects. Having failed in his various attempts for regaining him, Antony levied forces and retired to Cisalpine Gaul, of which he had been appointed governor, and laid siege to Mutina, now Modena, which was occupied by Decimus Brutus. For this conduct he was declared a public enemy; and the two consuls, Hirtius and Pansa, accompanied by Octavianus, were sent against him. In the battle which ensued, the two consuls lost their lives, but Antony was defeated, and the whole republican army was at the disposal of Octavianus. Antony was compelled to leave Italy, and to march his troops over the Alps, which he conducted with a fortitude that did him honour. Having arrived in Gaul, he attached the soldiers of Lepidus to his interest; and they induced Lepidus to join him. Strengthened also by the troops of Plancus and Pollio, he returned to Italy with a large army. At Bologna, Antony and Lepidus had an interview with Octavianus, who abandoned the senate; and here they agreed on the partition of the Roman empire. They also concurred in that detestable proscription, of which the first sanguinary measure was the death of Cicero, against whom Antony had conceived an inveterate hatred on account of the condemnation of Lentulus the second husband of his mother, and the Philippic which he had pronounced against himself. The usurpers proceeded to Rome, and filled the city with rapine and murder; and Antony enjoyed the base satisfaction of fixing the head and right hand of the illustrious Roman orator upon the rostra, which had so often witnessed the triumphs of his eloquence.

After having completed the destruction of their enemies in Rome, Antony and Octavianus marched into Macedonia, against Brutus and Cassius; the latter of whom, after a defeat at Philippi, put an end to his own life; and, in a second battle, Brutus fell in the same manner. It is recorded, as an instance of generosity on the part of Antony, that when Lucilius, who was mistaken by the Thracians for Brutus, surrendered himself in order to give his friend an opportunity of escaping, Antony commended his fidelity, and embraced him as a friend; and also, on viewing the dead body of Brutus, his sensibility was affected, he threw over it his own rich mantle, and ordered it an honourable funeral. At Athens in Greece, whither Antony next proceeded, he endeavoured to ingratiate himself with that city, by expressions of regard, and he frequented its public schools and gymnasia. In Asia, he indulged his taste for splendour and voluptuousness; and, though he shewed some lenity to the friends of Brutus who fell into his hands, he plundered several cities, and bestowed the wealth he thus collected on his parasites and buffoons. In Cilicia he summoned the famous Cleopatra, queen of Egypt, to give an account of her conduct, which had given offence to the triumvirs. The interview was singularly splendid; and the queen advanced with confidence, not doubting that, as in her youth she had enslaved Cæsar and Pompey, she would be able, by her charms and the art which experience had taught her, to captivate the heart of Antony. The intercourse terminated as she expected. The triumvir was completely subdued, took the queen with him to Alexandria, and

and indulged in dissipation and luxury, which made him regardless of every important concern. In the mean while, Fulvia, the widow of Clodius, whom Antony had married before the death of Cæsar, quarrelled with Octavianus, and assembling some legions at Præneste, commenced hostilities. Before Antony could reach Italy, the war had terminated in favour of Octavianus; and the death of Fulvia, who is thought to have concerted this war for the purpose of detaching Antony from Cleopatra, made way for completing a reconciliation with Octavianus, by the marriage of Antony with his sister Octavia, to whom the brother was affectionately attached, and who was a lady of an excellent and amiable character. On this occasion, Antony and Octavianus, the two principal of the triumvirate, agreed on a new partition of the Roman empire; and by virtue of this partition, Codropolis, a town of Illyricum, being fixed as the boundary of their dominions, the whole that lay west of this place was allotted to Octavianus, and the whole that was situated to the east belonged to Antony; so that the former had Dalmatia, the two Gauls, Spain, and Sardinia, and the latter all the eastern provinces as far as the Euphrates. Africa was assigned to Lepidus. It was also agreed that Antony should make war upon the Parthians; and Octavianus reduce Pompey, if he refused to submit to reasonable conditions. Antony, after this business was amicably settled, spent the winter at Athens with Octavia, and dispatched his lieutenant Ventidius into Asia, to check the incursions of the Parthians. The success of Ventidius roused the jealousy of Antony, and he determined to leave Athens and to march into the east. When he arrived, he dismissed his lieutenant, who was besieging Samosata, and sent him to Rome to demand of the senate and people the honours of a triumph. Antony, having offended his soldiers by dismissing Ventidius, and raising the siege without much honour, returned to Octavia at Athens, and soon afterwards sailed to Italy, at the request and for the assistance of Octavianus, in order to overpower by their united counsels and forces their rival, Pompey. Antony came as far as Brundisium; and not finding Octavianus there at the time appointed, he returned to Athens. However, when Octavianus was reduced by Pompey to great danger, Antony assembled a large fleet, and sailed for Italy. But the two ambitious triumvirs, jealous of each other, disagreed; and Octavia, by a conference with her brother, in the presence of Mæcenas and Agrippa, and by earnest entreaties, prevailed with him to meet Antony, and to compromise the differences that subsisted between them. In this office of prudence and affection she succeeded; and after an accommodation, Antony departed once more for Syria. Octavia accompanied him to Coreyra, but from thence returned to Italy. Upon Antony's arrival in Syria, he invited Cleopatra, and bestowed upon her all Phœnicia, Cœlosyria, Cyprus, and a great part of Arabia and Judæa. His profusion offended the Roman people, and they censured his conduct on account of his scandalous connection with Cleopatra. After these extravagant grants, he marched with a large army against the Parthians, which only served to render his retreat the more ignominious. The Romans justly attributed the misfortunes of this fatal expedition to his passion for Cleopatra, and they were also particularly incensed by his conduct towards Artabazes, king of Armenia, whom he seized in a treacherous manner, and led in triumph to Alexandria. Having been induced by the crafty queen to order Octavia not to pursue her journey into Syria, but to return to Rome; he accompanied Cleopatra to Alexandria, and passed the winter with her in every kind of pomp, luxury, and voluptuousness. Octavianus availed himself of the general resentment against Antony, and preferred to the senate and people several articles of accusation

against him. A war between these two triumvirs became inevitable: but Antony, instead of making necessary preparations, appointed the isle of Samos for the place of general rendezvous; and summoned thither players and musicians, and all the ministers of riotous luxury. From Samos he afterwards sailed for Athens, where he pursued the same course of luxury and dissipation: and in order to testify his resentment against Octavianus, he solemnly divorced Octavia, and ordered her to be expelled from his house at Rome. Many of his friends abandoned him. War was declared against the Egyptian queen; and Antony was deprived of his consulate and government; and the reason assigned for it was, that he suffered himself to be ruled by a woman. Each party collected its forces; and the Ambrazian gulf, between the islands of Coreyra and Cephalonia, became the scene of contest. The famous battle of Actium ensued: and this was fought at sea, against the advice of Antony's best officers, and chiefly through the persuasion of Cleopatra, who was proud of her naval force. In the midst of the action, Cleopatra, with her 50 gallees, took to flight, and Antony followed her in a small vessel, and thus overwhelmed his character in perpetual ignominy. After an obstinate resistance on the part of the soldiers, though abandoned by Antony, and at length by their principal officers, they surrendered to Octavianus, and were incorporated in his legions. Antony, thus defeated and disgraced, vented his resentment against Cleopatra; but they were soon reconciled; and he pursued his course to Libya, where he had stationed a considerable body of troops: but on his arrival, he found that they had deserted to Octavianus. Distracted with disappointment and vexation, he returned to Egypt, and lived for some time in gloomy solitude: but Cleopatra by her arts drew him to her palace, and he resumed his former voluptuous life. Hither he was pursued by Octavianus: and though on his approach to Alexandria, Antony made a successful sally against the invader; yet, deserted by the Egyptian fleet, by his own army, and betrayed, as he suspected, even by Cleopatra, he sunk down in despair. His first frantic effort was directed against the queen, who had been the cause of all his misfortunes: but she fled from her palace and escaped: he then desired one of his own servants to dispatch him; but the faithful Eros stabbed himself, and fell down at the feet of his master. Antony, emboldened by this act of heroism, fell on his own sword: but as the wound did not immediately prove mortal, he sought Cleopatra in her place of retirement and safety; and being drawn up to the tower in which she lodged, by ropes, he expired in her arms, in the 56th year of his age, and in the year before Christ 30. He was magnificently interred by Cleopatra; but at Rome his statues were demolished, and his memory was declared infamous.

Antony left seven children by his three wives; two sons by Fulvia; two daughters by Octavia, who by their alliances gave three emperors to Rome; and two sons and a daughter by Cleopatra, whom he had lawfully married after his divorce from Octavia. Of these children Octavia took the most laudable care; and at length the daughter of Cleopatra was married to Juba king of Mauritania.

Antony was neither a great nor a good man: he wanted that vigour of understanding which entitled him to a place in the first class; and his love of pleasure, his want of principle, as well as his meanness and cruelty, exclude him from the second denomination. He has had, however, his partisans and admirers; and, it must be allowed, possessed a generosity of disposition which raised him above his rival, the cold and crafty Octavianus. Plutarch in Anton. apud. oper. tom. i. p. 915—957. ed. Francf. Anc. Un. Hist. vol. xi. and vol. xii. Gen. Dict.

ANTONY, *St. the hermit.* See ANTHONY.

ANTONY of *Lebrisa*, or *Antonius Nabifensis*, a Spanish writer, was born at Lebrisa in Andalusia, in 1444, and contributed to the revival of literature in Spain. He still studied at Salamanca; and acquired farther knowledge in the university of Bologna. Besides classics and polite literature, he was acquainted with the mathematics, law, medicine, and theology, and might have been justly classed among the most learned men of his age. After his return to Spain, he taught grammar at Salamanca for 28 years; and at Alcalá, under the patronage of cardinal Ximenes, he taught till his death. Here he employed himself in publishing a polyglot edition of the bible. As historiographer to the king, he published, in 1509, two decades of the history of Ferdinand and Isabella, which are to be found in the work intitled "Hispania Illustrata." His dictionary of the Latin, Greek, and Hebrew languages, was printed at Grenada in 1545. He also wrote notes upon several Latin classics, and upon Aristotle's Rhetoric; a Treatise on Weights and Measures; a cosmography; a law dictionary; a medical dictionary; Commentaries on the Scriptures, &c. He died in 1522. Cave, Hist. Lit. Appendix, vol. ii. p. 209. Nouv. Dict. Histor.

ANTONY of *Messina*. See ANTONELLO.

ANTONY of *Padua*, a monk of the order of St. Francis, was born at Lisbon, in 1195. A desire of obtaining the crown of martyrdom induced him to sail for Africa; but being driven on the coast of Italy, he devoted himself in that country to the study of theology, and became an eminent preacher. The fraternity of Flagellants is said to have owed its origin to his sermons. Pope Gregory XI. used to call him "the Ark of the Covenant, and the Depository of sacred Learning." He was successively a teacher at Montpellier, Toulouse, and Padua; where he died, in 1231, at the age of 36 years. His works, consisting of sermons, commentaries, and a moral concordance to the bible, were published at the Hague, in 1641. Nouv. Dict. Histor.

ANTONY of *Pratovecchio*, in Tuscany, was educated at Florence, and distinguished himself in the 15th century, by his attempt to form a new code of feudal law. The emperor Sigismund created him count and counsellor of the empire, and charged him with the execution of this undertaking. The result was a treatise, entitled "A Course of Feudal Law," and published in the year 1428. Although the emperor, under the influence of the lawyers, who envied the reputation of Antony, refused his imperial approbation of this new code, it was afterwards granted by Frederic III. Antony also wrote "Commentaries on the Decree of Gratian," and a "General Repertory" or Lexicon of Jurisprudence. He died at Bologna about the year 1464. Gen. Biog.

ANTOSIANDRIANS, in *Ecclesiastical History*, a sect of rigid Lutherans, who oppose the doctrine of Osiander, relating to justification. These are otherwise denominated *Osiandro-mastiges*.

The Antosiandrians deny that man is made just, with that justice wherewith God himself is just; that is, they assert, that he is not made essentially, but only imputatively, just; or, that he is not really made just, but only pronounced so.

ANTRAIGUE, in *Geography*, a town of France, in the department of the Ardeche, and chief place of a canton, in the district of Privas, ten miles west of Privas. The place contains 1521 and the canton 7401 inhabitants: the territory includes 187½ kilometres and 8 communes.

ANTRAIN, a town of France, in the department of the Ille and Villaine, and chief place of a canton, in the district of Fougères, seven leagues north-north-east of Rennes, and

four south east of Dol. The place contains 1375 and the canton 13,252 inhabitants: the territory includes 220 kilometres and 10 communes.

ANTRIM, a county of Ireland, in the province of Ulster, lying at the north-eastern extremity of the island, and being one of the most respectable in point of culture and population. It is washed on its northern and eastern sides by the north channel, which divides Ireland from Scotland. On the west, Lough Neagh and the river Bann form a natural boundary, except for about five or six miles near the sea. On the south-east, it has a large estuary, called Carrickfergus Bay, or the Lough of Belfast; and on the south lies the county of Down, from which it is partly separated by the river Lagan. Its greatest length from north to south is 44 miles (56 English), and its greatest breadth 24 (30½ English), containing 387,200 Irish plantation acres (622,059 English), and being about 605 (or 972 English) square miles. The number of houses, according to an official return made to the House of Commons, in 1791, is 30,314, from which we may estimate the population at about 170,000. The number of parishes is 74, of which 42 only have churches, all of them, except one, in the diocese of Down and Connor. This county returns five members to the Imperial parliament; namely, two knights of the shire, and one each for the towns of Carrickfergus, Belfast, and Lisburn. The face of the country, especially in the northern and eastern parts of it, is very mountainous, and there are several extensive bogs, some of which have been improved, and others are very improveable. There is also a tract of very rough and high hills on the west of Belfast; of which Mr. Arthur Young observes, that to their summits they consist of exceedingly good loam, and such as might be improved into good meadow. Of the mountains, Devis near Belfast, Slenish in the middle, and Knocklayd in the northern part of the county, are the most considerable. The richer and more fertile parts of it are well cultivated, producing fine crops, especially the southern extremity, which is in a high state of beauty and improvement. The linen business extends throughout the whole county, in a manner which seems peculiarly favourable to the morals and happiness of the people. The farms are generally very small, and chiefly in the hands of weavers, who make the web at their own houses, and on their own account, and then carry it to the nearest market-town, where it is purchased by the bleacher. They grow their own flax, and generally have a patch of oats, some potatoes, and a cow, which supply them with their usual diet. The rivers of this county are generally small, but very numerous: the principal ones are, the Lower Bann, a broad and rapid stream, by which all the waters of Lough Neagh are discharged into the sea; and the Lagan, which passes by Lisburn, and a little below Belfast flows into Belfast Lough. The northern coast of this county is remarkable for its basaltic pillars, an account of which will be found in the article relating to the Giants' Causeway, where they are most conspicuous. The stupendous promontories of Bengore and Fairhead (the *Robogdium* of Ptolemy), in particular, are in a great measure composed of these pillars. The eastern coast has many little bays, on which are villages inhabited by fishermen. At the south east is a little peninsula, called Island Magee, which is improperly represented in most maps as an island, though connected with the main land by an isthmus of more than a mile broad. The inhabitants of this county had from an early period a considerable intercourse with the adjoining parts of Scotland; and some Scotch families settled in it, previously to the encouragement given by James I. The countess of Antrim, of the family of M'Donnell, descended from one of these, has in her possession, according to Mr. Young, 173,000 acres in this

this county, which are let on very long leases for 8000l. per annum, and relet for 64,000l.

At present the greater part of the inhabitants are of Scotch extraction, and most of them continue attached to the Presbyterian form of worship. The assizes, elections, &c. for the county are held at Carrickfergus, but the quarter sessions at Antrim. Dr. Beaufort's Memoir; Mr. Young's Travels in Ireland; Dr. Hamilton's Letters respecting the Coast of Antrim.

ANTRIM, a town in the county of the same name in Ireland, pleasantly situate on a small stream, called the Sixmile-Water, which a little below the town empties itself into the north-eastern extremity of Lough Neagh. This was a populous, thriving place, but was injured some years ago by the desire of the proprietor to increase his influence in the election of members of parliament. It still partakes the benefits of the linen manufacture; and the fine yard-wides are chiefly bleached and finished in the neighbourhood of this town, Lisburn, and Belfast. Amongst the dissenting ministers of this town were Mr. Abernethy and Dr. Duchal, so well known by their writings, both of whom afterwards removed to Dublin; and from it that presbytery took its name, which first advocated the cause of religious toleration in the north of Ireland. At a place called Steeple, near Antrim, is one of those round towers peculiar to Ireland. See ROUND TOWERS. In the streets of this town, a smart engagement took place on the 7th of June, 1798, between 6000 insurgents, and some detachments of the regular troops and yeomanry, in which the former were defeated with considerable loss. Lord O'Neil, a nobleman much respected, received a wound from a pike, of which he soon after died. Distance from Dublin 8½ miles. W. long. 6° 6' N. lat. 45° 42'.

ANTRIM, or ANTERIM, a township of Hillsborough county, New Hampshire, in America, having 528 inhabitants, incorporated in 1777, 7½ miles west from Portsmouth, and as many north-west from Bolton.

ANTRODOCIO, a small town of Italy, in the kingdom of Naples, situate in Abruzzo Ulterior, on the small river Velino, between Aquila and Rieti.

ANTRON, in *Ancient Geography*, a town of Greece, in that part of Thessaly, called Phthiotis, situate at the entrance of the Pelasgic gulf. It was famous for furnishing apes of a large size. This town existed in the time of the Romans; and in the war against Perseus, the consul Licinius, in the year before Christ 171, obtained it by treaty.

ANTROS, a small island of France, at the mouth of the Garonne, where was erected the tower of Cordouan, which served as a light-house to vessels that entered this river, in passing to Bourdeaux.

ANTRUM *Genæ*, in *Anatomy*, a large cavity in the bone of the upper jaw, which communicates with the nostrils. It was thus called by Casserius, but by Dr. Highmore *antrum maxillæ superioris*. It is also frequently called *antrum Highmorianum*. For a further account of this cavity, see the description of the superior maxillary-bone.

ANTRUM *Pylori*, is a term which has been employed to express the concavity in the great curvature of the stomach, as it approaches the pylorus.

ANTRUM *Maxillare*, *Diseases of the*, in *Surgery*. The cavity of the cheek bone is liable to inflammation and abscess. The bone itself may become carious, and be followed with very distressing consequences. Insects will sometimes be generated within this sinus, and produce the most excruciating pain for years together.

We have already had occasion to notice the treatment of abscesses in the maxillary sinus, to which we therefore refer our readers. See ABSCESS, INFLAMMATION, CARIES, and DISEASES OF THE TEETH.

ANTRUM, in *Geography*, a mountain of Switzerland, in the Valais, which is a part of the Alps, that may be passed from the Valais into the Milanese.

ANTRUSTIO, in *Antiquity*, q. d. *qui in truste dominica est*, a name given in the Salic law to the king's vassal, for whose death that law imposed a composition of 600 sous. Montefq. Sp. of Laws, vol. ii. p. 406.

ANTULLY, in *Geography*, a town of France, in the department of the Saône and Loire, and chief place of a canton, in the district of Autun, five miles south-east of Autun.

ANTWERP, or ANTORFF, in French *Anvers*, and in Spanish *Amberes*, the capital of a marquisate in Brabant, called the Marquisate of Antwerp, and also the Marquisate of the Holy Roman Empire; situate in a large plain on the eastern side of the Scheld, which is sufficiently deep and wide for admitting vessels of great burthen to the quay; and vessels may be brought by means of canals cut through the town to unload at the doors of the warehouses. It ranks the third city in Brabant; it is large and well built, and contains 22 squares, and more than 200 streets, which are straight and broad; and one of them, called the Merc, is so wide, that six carriages may pass it abreast. At the head of this street is a crucifix of brass 33 feet high. The cathedral church is a beautiful and elegant building; but in the course of the last war it was robbed of its richest ornaments, or the pictures of Rubens, which are now placed in the Louvre gallery at Paris. The Stadt-house and the Exchange are also magnificent structures. The latter built in 1531, is the first building of that kind in Europe, and on the model of this were built the exchanges of London and Amsterdam. Its pillars are of blue marble, and carved, but every one of them in a different style. Antwerp, towards the end of the 15th century, when the commerce of Bruges declined, and the English fixed their staple in it, became one of the most celebrated trading towns that ever existed. There were two circumstances in particular, that contributed to the great increase of its commerce and riches; one was the grant of free fairs for commerce, two of which lasted six weeks, and hither merchants resorted from all parts of Christendom, with their merchandize, custom free; and at these fairs great concerns were managed, not only in merchandize, but in bills of exchange with all parts of Europe: the other was, Portugal's bringing over in immense quantities, the rich produce of India, first to Lisbon, and thence to Antwerp, as to a kind of half-way port between the northern and southern parts of Europe. This drew the German and other merchants to settle at Antwerp; and after the archduke Maximilian had, about the year 1499, brought Bruges into subjection, the merchants of that city removed to Antwerp. In 1543, it was enlarged for the third and last time, and encompassed with new walls, built of fine hewn stone, and beautifully adorned. At this time it contained, according to the computation of Guicciardin, 100,000 inhabitants. When the emperor Charles V. wished to introduce the infernal tribunal of the inquisition into this city, about the year 1550, he was awed by the information, that the English merchants would leave the city and country; and this remonstrance proved effectual; for upon inquiry the emperor found, that the English merchant adventurers maintained or employed at least about 20,000 persons in Antwerp alone, besides 30,000 more in other parts of the Netherlands. At this time this city, and Hamburgh, possessed the principal commerce of the northern and middle parts of Europe; but after the Union of the seven United Provinces, in 1579, the commerce of Antwerp began to decline; and this misfortune was accelerated by the persecutions of the duke d'Alva, and the sack of the town by the duke of Parma, in

1585, which forced its inhabitants to seek an asylum in Holland, and particularly at Amsterdam, whither its trade, in consequence of the entire command of the Scheld, was transferred. The loss of their trade led them to direct their attention to painting, jewellery, or banking, which they have profecuted with success and reputation; and they have also had a considerable manufactory of tapeltry and lace. The future trade and prosperity of this city must depend on the restrictions or enlargements to which the navigation of the Scheld shall be subject. This city is the see of a bishop; and besides the cathedral, it has several other fine churches. As to the fortifications of the city, it is encompassed by a wall, planted with rows of trees on each side, and of such breadth as to admit two carriages abreast; and it is also defended by a pentagonal citadel, erected by the duke d'Alva, in 1568, which commands the town and the neighbouring country. The magistracy of this city is elected out of the seven patrician families, and consists of two burgo-masters and 18 echevins, besides inferior magistrates. Among its privileges, there is one, by which every person born in it becomes a citizen, though both his father and mother were foreigners.

One of the most remarkable sieges which history records, was that of Antwerp by the duke of Parma in 1585. In later times, after the battle of Ramillies, it surrendered to the duke of Marlborough. In 1746, it was taken by the French, but restored to the house of Austria at the treaty of Aix-la-Chapelle. It was taken by the French in 1792, and evacuated in the beginning of 1794; but in July of the same year it surrendered again to the republican troops. The navigation of the Scheld was declared free in August 1794. This city is 25 miles north of Brussels, and 75 south of Amsterdam. By the new arrangement since the revolution, it is the principal place of a district in the department of the Deux Neuthes; the place contains 61,800, and the canton 66,480 inhabitants; the territory includes 10 kilometres, and five communes. N. lat. 51° 13' 15". E. long. 4° 22' 45".

ANTYX, from ἀντιξ, in *Antiquity*, the outermost round or circumference of a shield.

ANUA, in *Ancient Geography*, a town of Palestine, in the tribe of Zebulon, mentioned by Eusebius and Jerom. This was also the name of a town in the tribe of Ephraim, on the borders of that of Benjamin.

ANVARI, or ANVERI, in *Biography*, one of the most famous of the Persian poets, was born in a village of Khorasan, in the 12th century. He studied as a poor scholar, at the city of Thous, in the college called Mansuriah. As the equipages of sultan Sanjiar chanced to pass by, he inquired into the name and condition of a person who appeared so well dressed and mounted, and being told that he was one of the sultan's poets, he became desirous of excelling in an art that was so much honoured and encouraged, and the next day presented to the sultan a poem in praise of him. The prince approved it, and immediately attached the author to his person. To him belongs the reputation of having been the first who rescued the Persian poetry from impurity and licentiousness; and he acquired such renown, that the surname of the king of Khorasan was conferred upon him. Between him and the poet Raschidi there was carried on a singular kind of contest; as they were in opposite interests, and the latter was shut up in a fortress besieged by Sanjiar, they made war upon each other by means of missile pieces of verse, fastened to the points of arrows. Anvari was much addicted to astrology; and he predicted a storm which was to happen on the day of the conjunction of the seven planets in the year 1185, but the day proved singularly serene. His enemies took this occasion to ridicule him, and the sultan re-

primanded him. Thus mortified and abused, he retired first to Meru, and then to Balk, where he wrote a poem in which he renounced astrology, and all its predictions. He died at Balk about 1200. D'Herbelot *Bibl. Orient.* p. 110.

ANVAT, in *Ancient Geography*, a town in the island of Taprobana, according to Ptolemy.

ANUBINGARA, a town also in the same island.

ANUBIS, in *Mythology*, a deity worshipped among the Egyptians, the Greeks, and the Romans. Ovid mentions this deity, when he says to Isis, (*Amor. lib. ii. eleg. 13.*)

“Per tua filtra precor, per Anubidis ora verenda.”

The head of this deity was that of a dog, and in Egypt especially he was regarded as the faithful companion of Osiris and Isis, and received divine honours. Temples and priests were consecrated to him; and his image was borne in all religious ceremonies. His temples were denominated *Anubidea*. This kind of worship seems to have commenced in Egypt, by consecrating an animal to Anubis, as was the custom with regard to other deities. Soon afterwards they substituted the figure of a dog for that of Anubis himself, and then annexed the head of this animal to a human body, as an emblem of the new deity. Thus he is represented in the ruins of the ancient temples of Egypt, as well as on bronzes and marbles in the collections of antiques. Diodorus Siculus (*lib. i.*) says also, that the god called Anubis is represented with the head of a dog. Virgil, Ovid, Lucian, and the ancient fathers of the church represent him under this form, and Virgil (*Æn. lib. viii.*) and Ovid (*Metamorph. lib. ix. v. 692.*) denominate him the “Barker Anubis.” Cynopolis, the present Minieh, situated in the lower Thebais, was built in honour of Anubis. The priests celebrated his festivals there with great pomp, and consecrated the dog to him, as a living representation of him. This city of dogs, says Strabo, (*lib. xvii. tom. ii. p. 1116.*) is the capital of the Cynopolitan prefecture. These animals are fed there with sacred aliments, and religion has decreed them a worship. The medals of this city bear upon them the figure of a man with a dog's head. But though Cynopolis was the centre of the worship of Anubis, the whole of Egypt adopted it; and to this purpose Juvenal says, *Sat. xv. v. 8.*

“Oppida tota canem venerantur.”

From the universality of the worship of this deity proceeded the respect which the Egyptians manifested for dogs. This strange worship, however, was not confined to the banks of the Nile. The Greeks adopted it not only in the time when the Ptolemies blended the worship of Greece with that of their new subjects, but in the more remote periods of the Greek history. When Rome had adopted the ceremonies of Egypt, the emperor Commodus, in celebrating the Iliac feasts, shaved his head, and carried the god Anubis. His statue was either of massive gold or gilt, as well as the attributes that accompanied it. Even the name of Anubis, derived according to Jablonski (*Panthæon Egypt.*) from *nub, gold*, and *annub, gilt*, signifies gilded.

But what was the signification of this emblematical deity? What is the natural meaning concealed under it? Plutarch, in his *Treatise of Isis and Osiris* (*Oper. tom. ii. p. 368.*), explains this. “The circle which touches and separates the two hemispheres, receiving the name of horizon, is called Anubis. He is represented under the form of a dog, because that animal watches night and day.” St. Clement of Alexandria, well informed concerning the mystic theology of the Egyptians, favours this explication. The two dogs, says he, (*Strom. v. tom. ii. p. 671.*) the two Anubis are the symbols of two hemispheres, which environ the terrestrial globe. He adds in another place; others pretend,

that these animals, the faithful guardians of men, indicate the tropics, which guard the sun on the north and the south, like porters. According to the former of these interpretations, the priests, regarding Anubis as the horizon, gilded his statue, to denote that this circle, receiving the first rays of the sun, appears sparkling with brightness on his rising; and that at his setting he reflects his last rays upon the earth. In their sacred fables they said, that Anubis was the illegitimate son of Osiris. In fact, he only gives to the earth a borrowed light, and never can be esteemed like Horus, as the father of the day, or as the legitimate offspring of Osiris. We may add, that the visible horizon turning with the sun, is his inseparable companion. According to the latter explication, which makes Anubis to represent the tropics, he is also the faithful guardian of Isis and Osiris. In reality, the course of the sun and of the moon is contained between the circles in which the solstices occur, without deviating from them. These limits assigned by the author of nature, might therefore, in hieroglyphic language, be represented by a divinity with the head of a dog, who seemed to oppose their passage on the side of the two poles. The other opinion, however, seems to be more natural, and more analogous to the ideas of the priests. Upon the whole it is not unreasonable to imagine, that Anubis was, at first, only a symbolical image, invented by astronomers, to convey a sensible expression of their discoveries; that afterwards the people, accustomed to see it in their temples, which were the depositaries of science, adored it as a deity; and that the priests favoured their ignorance by connecting it with their religion. The worship of Anubis introduced that of the dog, which became his emblem. Almost all the gods of the Gentiles have originated in this manner. Before the invention of writing, men made use of hieroglyphics or imitative figures to convey their ideas; those hieroglyphics remained in their sanctuaries, and the priests alone preserved the knowledge of them. In the end, these allegorical signs no longer represented the real meaning of things to vulgar understandings, but the exterior forms and figures only, which became the objects of superstition. Savary's Letters, vol. ii. p. 488—495.

Siris or Osiris (says Bruce, Travels into Abyssinia, vol. i. p. 412.) was not the sun, but Sirius or the dog-star, represented under the figure of a dog, because of the warning he gave to Atbara, where the first observations were made at his heliacal rising, or his disengaging himself from the rays of the sun, so as to be visible to the naked eye. He was the "Latrator Anubis," and his first appearance was figuratively compared to the barking of a dog by the warning it gave to prepare for the approaching inundation of the Nile. This, he thinks, was the first hieroglyphic; and Isis, Osiris, and Tot, were subsequent inventions relating to it. In this opinion he is confirmed by considering, that in the city of Axum, once a large city, there is not any other hieroglyphic besides that of the dog-star.

At Rome they had many statues of Anubis, the principal of which are two in the Villa Albani, and one in the Barberini palace. Anubis is frequently represented in pictures, &c. with a dog's head, holding in one hand a branch of palm, and in the other a caduceum, or Mercury's wand.

ANUBUS, in *Entomology*, a species of SPHINX that inhabits Surinam, and is figured by Cramer. The anterior wings are sub-ferruginous, posterior wings black with a row of whitish spots. Fabricius. A black spot in the middle, and a large brown spot with a few streaks near the margin of the anterior wings.

ANUCHTA, in *Ancient Geography*, a town of Asia, in Susiana, according to Ptolemy.

ANVERS, D', HENRY, earl of Danby, in *Biography*, is here introduced, as being founder of the botanic garden at Oxford. In the year 1622, he purchased five acres of land in the vicinity of Oxford, which he took care to stock with numerous foreign as well as indigenous plants; and having erected hot-houses and other necessary buildings, gave it to the university in 1631. He also endowed it with an annual rental, for the support of a gardener and proper assistants; and of a botanical professor, to teach the science to the students of the university. Dr. Sherard augmented the estate of the garden, by a donation of 500l., to enable the curators to enlarge the conservatory; and presented them with a large number of exotic plants, and a handsome collection of books on the subject of botany.

ANVERSA, in *Geography*, a town of Italy in Naples, five miles west of Solmona.

ANUI BOLSCHE, a river of Siberia, which runs into the Kolima, eight leagues east of Niznei Novimskoi.

ANUI Sachoi, a river of Siberia, which runs into the Kolima, nine leagues east of Niznei Novimskoi.

ANVIL, a smith's utensil, serving to place the work on, to be hammered or forged.

The face, or uppermost surface of the anvil must be very flat and smooth, without flaws; and so hard, that a file will not touch it. At one end there is sometimes a pike, bickern, or beak-iron, for the rounding of hollow work. The whole is usually mounted on a firm wooden block.

Forged anvils are better than those of cast work; and the best have the upper part made of steel. Locksmiths have a smaller kind of anvil, called the *flake*, which is moveable, and placed ordinarily on their work bench. Its use is for setting small cold work straight, or to cut or punch on with the cold chisel or cold punch.

ANVIL Island, in *Geography*, an island of the Pacific Ocean, on the north-west coast of America, so called from the shape of the mountain that composes it, and lying in N. lat. 49° 30'. W. long. 237° 3'.

ANVILLE, JEAN BAPTISTE BOURGIGNON D', in *Biography*, geographer to the king of France, and adjunct-geographer to the Academy of Sciences, was born at Paris, July the 11th, 1697. D'Anville possessed a peculiar talent and disposition for geographical researches; and the principal part of his time was devoted to this kind of employment. Accordingly he collected, from the perusal of ancient and modern authors of various descriptions, such as geographers, historians, travellers, and even poets, materials for his main purpose, which was, the construction of charts, and the accurate adjustment of the situation of different places. At the age of 22, he began to publish some of those charts which have given celebrity to his name. To every chart of importance he annexed an account of the authorities upon which he depended, and of the means by which he obtained necessary information; and this he did not with selfish views, or for the purposes of ostentation, but from a consciousness of the assiduity and extent of his inquiries, and in order to enable others to form a competent judgment for themselves. The success of his investigations, and the reputation he acquired, were owing partly to the natural vigour of his mind, and perhaps principally to his indefatigable study; for he is said to have devoted, for 50 years of his life, 15 hours of every day to study. To this reclusive mode of life it was probably owing, that though he was cheerful, modest, and unassuming, his decisions on the peculiar objects of his study were more positive and dogmatical than they would have been if he had accustomed himself more to the society and conversation of literary men. In the year 1773, the Academy of Sciences appointed him adjunct-

junior-geographer; and though he was then near 80 years of age, he presented several memoirs to that learned body. His known talents for geographical research, and the esteem in which he was held by the learned of all Europe, enabled him to collect an immense and valuable mass of charts of various descriptions, which was purchased by the king of France a few years before his death. Having completed the favourite work of his life, he resigned himself to that decay of his faculties, which might naturally be expected at the close of such a life as his; and after an interval of two years, during which his infirmities increased, he died on the 28th of January 1782, in the 85th year of his age. He married in 1730, and two daughters survived him. His principal works are as follow: "Geographie ancienne abrégée," 1768, 3 vols. 12mo.; to which are annexed the author's maps of ancient geography, and a complete system of this science: "Traité des Mesures Itinéraires Anciennes et Modernes," 1769, 8vo.; "Dissertation sur l'étendue de l'ancienne Jérusalem," 1747, 8vo.; "Mémoire sur l'Égypte ancienne et moderne, avec une Description du Golphe Arabe," 1766, 4to.; "États formés en Europe après la chute de l'Empire Romain en Occident," 1771, 4to. "Notice de l'ancienne Gaule, tirée des monumens Romains," 1761, 4to. To these may be added, a work intitled, "Mesure de la Terre sous l'Équateur," occasioned by the discussion of the oblate figure of the earth, and founded on erroneous principles. Hist. de l'Acad. Royal Paris, 1782. Nouv. Dict. Hist.

ANVILLE, or MILLER'S TOWN, in *Geography*, a town of America, in Dauphine county, Pennsylvania, at the head of Tulphoocken Creek; eighteen miles north-east by east from Harrisburgh, and 65 north-west from Philadelphia.

ANUISKAIA, a fortress of Siberia, 50 miles west-north-west of Biisk. N. lat. 52°. E. long. 93°.

ANUROGRAMMUM, in *Ancient Geography*, a town in the island of Taprobana, according to Ptolemy.

ANUS, in *Anatomy*, is the termination of the intestinum rectum. It is kept contracted and closed by a sphincter muscle, and supported in its situation by two muscles named *levatoris ani*.

ANUS is a name which was absurdly applied to a small hole leading from the third to the fourth ventricle of the brain. It is now called *foramen commune posterius*.

ANUS, *Diseases of the*, in *Surgery*. The complaints which most commonly affect this part of the body, are, EXCRESCENCES, ABSCESSSES, FISTULÆ, PILES or HEMORRHOIDS, PROLAPSES, and IMPERFORATION. Each of these disorders is described in its proper place. It will be only necessary at present to treat of the *artificial anus*.

Artificial anus is a preternatural passage through the abdominal ring, occasioned by an adhesion being formed, after gangrenous hernia, between the upper end of the intestine and the abdominal ring, leaving an orifice, through which, instead of through the natural passage of the anus, the excrements are continually voided. This circumstance occurs when, after a gangrenous hernia has been opened, the gangrenous part cut away, and the excrements evacuated, the intestine does not re-unite. Sometimes it occurs without the assistance, nay, even against the wish of the surgeon, when, for example, his attempt to produce the re-union of the intestine does not succeed; sometimes he must endeavour to promote it, namely, when for a considerable time before he was called in, the fæces have been voided solely through the abdominal ring, whilst nothing has passed through the anus; and consequently there is reason to believe that the lower portion of the intestine is already contracted, or even closed, so that the natural passage for the fæces can no more be re-

stored. Sometimes the surgeon must do all in his power to prevent its production, and endeavour to promote the re-union of the intestine. This is particularly necessary when the intestinal canal has been opened, in consequence of gangrene, at no great distance from the stomach; for example, in the jejunum, as in that case the patient would die from inanition. Sometimes it is arbitrary, whether the surgeon shall promote the formation of an artificial anus, or endeavour to make the intestine re-unite; as when the case is a recent one, and a contraction of the lower portion of the intestine is not yet to be apprehended; and when the gangrenous part is situated at the middle or inferior part of the ileum, or even at the beginning of the colon, so that there is no reason to fear that the patient will fall into a marasmus or wasting, in consequence of the formation of an artificial anus.

When the surgeon wishes to promote the formation of an artificial anus, he must first carefully examine which is the superior portion of the intestine; and this he may, in general, know, by observing through which the excrements are discharged. However, as this is not always a certain mark of distinction, he may let the patient swallow a few spoonfuls of oil, after which he may distinguish the superior portion of the intestine with certainty, by observing from whence the oily discharge proceeds. Through this end of the intestine he then passes a thread, which he fastens with adhesive plaster to the external skin, in order that it may not be drawn back into the cavity of the abdomen. This operation, however, is not often necessary, as both ends of the intestine generally adhere within and behind the abdominal ring. The lower portion of the intestine must then be cleared by glysters and purgative injections; and it may be suffered to lie in the wound, in order to avoid the inconveniences which might arise from returning it into the abdominal cavity. At the end of the cure, a plug of sponge should be introduced into the upper orifice, to prevent its contracting, and occasioning an impediment to the discharge of the fæces.

With respect to the formation of an artificial anus, however, the most rational practice is to leave the whole to nature. The surgeon, in general, has done all that he can when he has opened the gangrenous hernia, separated the gangrenous portion, and evacuated the excrements from the intestines; after which nature either re-unites the intestine, or does not re-unite it, in which case an artificial anus is formed, with regard to which the surgeon has nothing to do besides what has already been mentioned. If the surgeon wishes from the very first to form an artificial anus, he should immediately introduce pledgits into the superior extremity of the intestine, whereby the re-union of the two ends will be prevented.

His next business must be to endeavour to obviate the inconveniences arising from the involuntary discharge of the excrements through an unusual passage, and to keep the parts clean. For receiving the matters discharged, he may fasten a receptacle of horn or strong leather to the body by means of a strap, in such a manner that its orifice rests upon the artificial anus. Dr. Richter (*Abhandlung von den Bruechen. neue Aufg. Goettingen, 1785, page 458.*) proposes, for the same purpose, an elastic rupture-bandage, having a piece of sponge fastened under its head, which covers and closes the artificial anus in such a manner as to prevent both the access of the air and the discharge of the fæces; and to supply the place of a sphincter, without either irritating or rubbing the orifice. Whenever the patient wishes to discharge either fæces or wind, he must take it off. M. Loeffler (*Archiv. der praktischen Arzneykunst, &c.*

&c. Leipzig, 1785, b. i. p. 115.), however, has found the use of this bandage to be attended with some inconveniences, which, he thinks, may be avoided by one of a different construction. In the pelotte of the bandage he directed a hole to be made, an inch in diameter, and a varnished leathern receptacle to be adapted to its outer margin.

As the sphincter is wanting, a prolapsus of the intestine may more easily be produced through an artificial anus than through the natural one. Such a prolapsed intestine may sometimes be easily reduced with the hand; sometimes it is reduced spontaneously, merely by the patient lying down upon his back. When this is not the case, the patient should constantly lie on his back, every exertion of the body should be carefully avoided, and gentle pressure permanently applied, by which means the prolapsus will generally be effected in a longer or shorter space of time: force ought never to be applied, as by too hasty and forcible reduction of the intestine the iliac passion might easily be excited. A prolapsus of the lower portion of the intestine is in general far more difficult to be reduced than that of the upper portion; and frequently it cannot be reduced at all, the intestine being contracted, or even entirely closed, behind the prolapsed part. Such herniæ ought never to be suffered to attain too large a size, as in that case it may become impossible to reduce them; they may particularly also prevent the discharge of the excrements, and occasion the death of the patient. By using an elastic bandage, the head of which is provided on its inner side with a sponge, which covers and gently compresses the artificial anus, both the production of such a prolapsus, and its recurrence after having been reduced, may be prevented. Mr. Lange (*Schmuckers vermischte chirurgische Schriften*, &c. b. ii. p. 298.) has shewn that such a hernia may actually become strangulated. He mentions an instance in which the intestine hung down a foot in length, and was so turgid with blood, that it was impossible to reduce it. He was, therefore, obliged to enlarge the artificial anus and abdominal ring by an incision, after which the reduction was easily performed.

It is always a dubious undertaking to attempt to close up an artificial anus of a pretty long standing, and restore the discharge of the excrements by the natural passage. However, when still some part of the excrements is discharged by the natural anus, when clysters can be thrown in by that passage, especially when the artificial anus is of no long standing, and we can be assured that the lower portion of the intestine is still open, we may make the attempt to close the artificial anus. That even where the artificial anus is already of long standing, the cure is still possible, has been proved by a case related by Mr. Dessault. The disease had already continued for the space of four years, the intestine was protruded out of the body, in the form of a cylinder, nine inches in length; and its membranes were so much thickened and hardened, that it appeared more than temerity to attempt the reduction of so considerable a mass. The patient had discharged nothing from the rectum since he had received his wound; every two or three months, however, he had a stool, by which he voided a whitish hard kind of substance. Mr. Dessault applied a simple bandage over the whole tumor from the top to the bottom, in such a manner that the turns of the bandage applied close over each other, leaving only a small opening at the point, for the purpose of discharging the feculent matter, which consisted of half-digested aliments. When by this means the intestine had been restored to its natural size, on the fourth day, he directed it to be raised up into a perpendicular direction: and having introduced his finger into the orifice of

the intestine, whilst he pressed the intestine itself with his other hand, in order to prevent the protrusion of the parts, he extricated the intestine, so that it now contracted into itself, and consequently the hernia was reduced. The orifice of the intestine, through which the excrements were voided, was closed by means of a plug three inches long, and made of a piece of linen rolled up, which was introduced into the orifice, and secured by means of the common inguinal bandage. His intention with this plug was, that it should be withdrawn twice a day, in order to afford a passage to the fæces; but soon after the reduction of the intestine, stasis was several times discharged through the anus; and soon afterwards fluids; which, in the course of the following days, acquired more consistence, so that on the eighth day the plug was no longer used, but the external orifice merely covered and secured with pledgits of lint, compresses, and the cushion of an elastic bandage: by this means the discharge of the excrements through the preternatural orifice was prevented, and its natural passage by the rectum permanently re-established.

But, in general, the attempt to close up an artificial anus is not unattended with difficulty and danger; and it ought never to be risked, unless when the vicinity of the orifice to the stomach gives rise to inanition, or a consumption, or some other material inconvenience. But even in these circumstances, Prof. Richter thinks we ought to use gentler means of alleviating the symptoms, and with a view to the cure. He recommends to keep the orifice of the artificial anus constantly closed, by means of the bandage above mentioned, whereby the chylous fluids will be detained longer in the alimentary canal, and a greater absorption of the nutritive parts take place; to let the patient take only easily digestible, very nourishing, and fluid aliments; and to avoid whatever might tend to accelerate the passage of the aliments through the intestinal canal. By this means he thinks that the above mentioned inconveniences may generally be remedied.

ANUS, in *Botany*, denotes the posterior opening of a monopetalous flower.

ANUS, in *Conchology*, a species of MUREX in the order of *testacea vermes*, having a veiny shell with membranaceous dilated lips, gibbous reticulate-tuberculate aperture, sinuous and erect at the end. It is the *auris hirsuta* of Rumpf. Mus. t. 24; found in the Mediterranean, and the ocean contiguous to the southern part of Asia: the shell is about three inches long, for the most part brown, with white bands, and an almost triangular aperture. Gmelin.

ANWEILLER, in *Geography*, a town situate in the duchy of Deux Ponts, ceded to France by the treaty of Westphalia; eight miles west of Landau. It is the chief place of a canton in the district of Deux Ponts, and department of Mont-Tonnerre: the place contains 1,841, and the canton 12,690, inhabitants; the territory includes 24 communes.

ANXA, in *Ancient Geography*, the name given by the Romans to CALLIPOLIS.

ANXANUM, LANCIANO, or ANCIANO, a considerable town of Italy, which was the capital of the people called Frentani. It was situate in Latium, near the mouth of the Sagrus.

ANXI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Basilicata, eight miles south-east of Potenza.

ANXUR, in *Ancient Geography*, a town of the Volsci, called by the Greeks and Latins Tarracina, situate at the lower extremity of a small gulf to the east of the Circean promontory. In allusion to its situation on a mountain,

Martial calls it "superbus Auxur." Jupiter $\alpha\zeta\upsilon\rho\sigma$, or the beardless Jupiter, was worshipped in this town; and at the distance of three miles from it were a grove and waters consecrated to the goddesses Feronia, mentioned by Horace, lib. i. sat. 3.

ANYM, a town of Palestine, placed by Joshua in the tribe of Judah; and supposed by Calmet to be the same with Anam or Anem.

ANZABAS, a river of Asia, which, according to Ammanus Marcellinus, was not far from the Tigris.

ANZA, in *Geography*, a river of Italy, which runs into the Tosa near Ugogna, in the principality of Piedmont.

ANZAR, a town of Turkestan, in the vicinity of the northern part of China, where Tamerlane died.

ANZERMA, a town and province of Popayan in South America, situate on the river Coca, and having mines of gold. N. lat. $4^{\circ} 58'$.

ANZIKO. See ANSIKO.

ANZITA, in *Ancient Geography*, a town of Asia, situate on a small river, near the east of the Euphrates.

ANZUQUI, in *Geography*, a town of Japan, in the island of Nihon, upon the eastern side of the gulf of Macao.

ANZUQUAMA, a town of the kingdom of Mino: the territory so called was the paradise of Nabumanga, who went from the sovereignty of Mino to that of Japan.

AOAYS, a town of Spain, in Navarre, on the river Yrate, seven leagues from Pamplona.

AOBRIGA, or AOBRICA, in *Ancient Geography*, a town of Spain, called also Abobrica and Abobriga.

AOCHARA, a town of Africa, in the kingdom of Algiers, between Tenez and Sercelles.

AONIÆ, or AONIANS, in *Ancient Geography*, a people of Bœotia, who jointly with the Hyantes succeeded the Ectenes. At the arrival of Cadmus, according to Pausanias (in Bœot. c. 5.), the Hyantes took up arms to oppose him; but the Aonians submitted, and were afterwards incorporated with the Phœnicians. The Aonians derived their name from Aonia.

AONIA, an ancient name given to Bœotia.

AONIDES, in *Mythology*, the appellation of the Muses, derived from the mountains of Bœotia, where they were particularly honoured, called the Aonian mountains.

AONIS, in *Entomology*, a species of PAPILO (Nymph. Gem.) found in India. The wings are angulated, grey, anterior pair clouded with yellow; a large and small eye-shaped spot above. Cramer, Gmelin, &c.

AORASIA, formed of *a*, *priv.* and $\alpha\rho\alpha\upsilon$. *I see*, denotes invisibility, and was applied by the ancients to the gods; for they apprehended that, in their intercourse with man, they never shewed themselves face to face, but were distinguished, as they retired, by their backs. Thus Neptune, as Homer represents him (Iliad ii.), assumed the form of Calchas in conversing with the two Ajaxes, and was known merely as he withdrew by his majestic gait and step. Venus also, according to Virgil, appeared to Æneas under the form of an huntress; but she discovered herself in her retreat by her radiant head, flowing robe, and dignified movement.

AORISTIA, in the *Sceptic Philosophy*, denotes that state of the mind, where we neither assert nor deny any thing positively, but only speak of things as seeming or appearing to us in such a manner.

The aoristia is one of the great points or terms of scepticism, to which the philosophers of that denomination had continual recourse by way of explication or subterfuge. Their adversaries, the dogmatists, charged them with dogmatizing, and asserting the principles and positions of their sect to be true and certain.

AORISTUS, compounded of α , *privative*, and $\epsilon\rho\iota\zeta\omega$, *to limit*, in the Greek *Grammar*, an indefinite and indeterminate kind of tense, which sometimes expresses the present, sometimes the future, but most frequently the past time.

The Greeks have two aorists; the Latins have none.

Dr. Beattie, in his "Theory of Language," (Part ii. ch. 2.), giving an account of the Greek tenses, omits the second aorist as well as the second future; because he considers them as unnecessary. Some grammarians, he says, are of opinion, that the first aorist signifies time past in general; and the second, indefinite time past; and that the first future denotes a nearer, and the second a more remote futurity. But this he apprehends to be mere conjecture, unsupported by proof; and he inclines rather to the sentiments of those who teach, that the second future and second aorist have no meaning different from the first future and the first aorist; and that they are the present and imperfect of some obsolete theme of the verb; and, when the other theme came into use, were retained for the sake of variety, or, by accident, with a preterite and future signification. In this opinion Lord Monboddo concurs; and he has endeavoured to strengthen it by the testimony of some ancient grammarians. Dr. Browne, in his "Brief Structures on certain Observations of Lord Monboddo respecting the Greek Tenses" (See Transactions of the Royal Irish Academy for 1789, or vol. iii. part ii. p. 11, &c.), has controverted this opinion. Aorists, or indefinites, he observes, are sometimes so called, because they are used for many tenses indifferently, pasts, presents, and futures: sometimes, because they do not mark any precise point of time when an action happened, but only express that it did happen: sometimes, because the verb, when used in these tenses, doth not express whether the action signified be perfected or imperfect. In this last sense he uses the term aorist; and by definite, he means the sense in which the verb expresses the perfection of the action. Having thus defined the meaning which he annexes to the term aorist, he allows that both the aorists are often used, without discrimination, as mere past indefinites; but he maintains, that the first aorist has much more frequently a definite meaning than the second; whereas the second appears in nine instances out of ten to be used indefinitely. Grammarians have observed, that the first aorist is oftener introduced to denote the past perfect time, than their preterperfect tense itself; and hence he argues, that its proper meaning is of a definite nature, and that it is not properly an aorist. Sæntius, he alleges, seems to have been of this opinion, when he calls the second only by the name of aorist. He then proceeds to shew, that such a definite, as he conceives the first aorist to be, was wanting in the Greek language, and is not supplied by the preterperfect; which implies, that the action has been done, and still continues to be done. In the Greek language there must be some other tense for expressing the time of the performance of an action which was perfected at a time past, and has ceased to continue. Dr. Clarke has assigned to this office the tense usually called the preterpluperfect; but in Dr. Browne's opinion, without sufficient authority, as that tense expresses something more. He has recourse, therefore, for this purpose, to the first aorist, the original intention of which was to express the real preterperfect time of philosophical grammar. In the Latin and English languages we have no diversity of tenses, or of single words, to express whether a past action has been done lately, or a long time since. It is only from the tone of the speaker, from the circumstances of the event, or from the context, that we can find out the difference. To supply the defect which these languages labour under, in their *aïve* voice, in not distinguishing, by

different sounds or words, the difference between what was lately perfected, and that which was perfected some time ago; and in the *passive*, in not making this distinction except by the help of auxiliary verbs; the Greeks, according to Dr. Browne, invented their first aorist; and intended by it to indicate the latter, as the preterperfect indicated the former. When Archimedes rushes out of the bath, after having made his celebrated discovery, he exclaims *εὕρηκα*, because he had just at that moment found out and solved the difficulty. But when Nestor (Homer Il. i. v. 260, 261.) speaks of ancient days and ancient heroes with whom he had been conversant, he speaks in the aorist, *αἰρεοσίν ἤπειρ ὑμῖν Ἀνδρασιν ἰμίλιθα*. When Demosthenes supposes the question *τιθῆναι Φιλίππος*; it follows, that if it had been so, and any person had suddenly announced it, he would have replied *τιθῆναι*. But when Chrysis (Il. i. v. 40.) alludes to actions formerly and frequently performed by him, he uses the aorist, "if I have ever crowned your altars or burnt victims," *ἔειψα* and *ἔκην*.

Moreover, the probability that the Greek language had a distinct tense to denote what had lately, or what had long since happened, is augmented by the consideration that they had a tense to express what was soon to come. As they had a "paulo-post future," they might also have had a "paulo ante preterit."

If an action be spoken of which has been often done, the Greeks generally use the first aorist. Thus, in the beginning of the "Cyropedia," where Xenophon reflects how many democracies have been reduced, and how many oligarchies subverted, cases frequent in human affairs, he uses the first aorist: thus also he expresses, in the beginning of the "Memorabilia," his frequent surprize at the errors respecting Socrates; "I have often wondered," in the first aorist. This is also the case in the example of Nestor above mentioned; and in similes, where a comparison is made with something frequently occurring, the first aorist is generally used. In such cases, no particular time at which the action happened is specified, but an action which has often passed is mentioned, without determining any precise time. The second aorist, on the other hand, which generally refers to a particular time, is seldom if ever used to denote a frequentative; although lord Monboddo has assigned this office to this as well as to the first aorist.

To close this article, we may observe, that definite tenses are those which limit both the times of the person and of the action: whereas those tenses which leave the nature of the action wholly undecided, and take no notice whether it be finished or unfinished, are indefinite, or aorists; e. g. "I write," is the aorist of the present tense, "I wrote," is the aorist of the past; and "I shall write," is the aorist of the future.

AORNUS, in *Ancient Geography*, a town of Bactriana, situate to the east of Bactra.

AORNUS was also a place of Epirus, according to Pliny; belonging to the Thresprotia; according to Pausanias; whence issued an exhalation that was fatal to birds which flew over it; and where, it is said, they invoked the dead to predict future events. In this place were a temple and grove consecrated to the Manes.

AORNUS, *Rock of*, a name given to a high mountain of India, situate in the modern district of Bijore, and deriving its name from *α*, priv. and *ορν*, *bird*, expressing its great elevation, which was supposed to be above the flight of a bird. The circuit of it was, according to Arrian, 200 stadia or about 18 or 20 miles; its height about 11 furlongs; and the access to it was only by one narrow path,

cut out of the rock. On the summit was a great extent of arable and pasture land, with springs of water; so that a garrison of 1000 men might subsist, without any extraneous supply. It may be supposed to be somewhat similar to Gwaher, or Rotas Gur, in Bahar. Some have laid, that the Indus passed by Aornus; but this, says Mr. Rennell (Memoir, &c. p. 174.), could not be the case; because the district of Sowhad Proper lies between the Indus and Bijore, according to the Ayeen Acbaree. The siege and capture of this fort were among the most celebrated exploits of Alexander in his Indian expedition. Hercules was said to have attempted it in vain; but Arrian informs us, that this was a groundless report; and that it was a fable, probably invented by some of Alexander's flatterers to magnify his enterprise. Whilst he was preparing for the siege, an old man and his two sons, who had long lived in a cavern of the mountain, offered to shew him a private way of ascending it; and a deputation of light-armed troops, under the command of Ptolemy, was sent to accompany them. As soon as they were safely lodged, they caused a lighted torch to be erected on a pole in their camp, as a signal to Alexander. Alexander, attempting the ordinary passage with a body of troops, was repulsed with great slaughter. But Ptolemy attacking the Indians in the rear, whilst Alexander renewed the assault, a second repulse took place. Upon this Alexander, perceiving that the strength of the Indians depended on the narrowness and declivity of the passage, gave orders to fell a quantity of trees, and to fill the cavities between the plain on which the Indians were encamped, and the highest of his own advanced posts. These measures were at first derided by the Indians; but as soon as they began to feel the effects of the missile weapons of the Macedonians, they proposed terms of surrender. Alexander, suspecting that they merely wanted to gain time, and to make their escape, took the advantage of their descent; and having gained possession of the deserted rock, he then made a signal for the forces to fall upon the flying Indians. The fugitives, hearing their loud shout, were so terrified, that many of them fell from the rocks and precipices, and were dashed to pieces, and the rest were cut off in the roads. *Anc. Un. Hist. vol. vii. p. 398.*

AORSI, a people who, according to Strabo, inhabited the banks of the Tanais. They afterwards extended themselves along the northern parts bordering on the Caspian sea, and carried on a commerce in gold and other articles of merchandize between India and Babylon.

AORTA, formed of *αορτη*, which signifies a *bag*, *chest*, &c. in *Anatomy*, the great artery proceeding from the left ventricle of the heart; from which all the other arteries either mediately or immediately proceed, and by which the whole mass of blood is conveyed to all parts of the body.

The structure, divisions, course and branches of this vessel, are explained under the article ARTERY.

AORTA, *diseases of the*, in *Surgery*. The most common local disorders of this vessel are, ANEURISM, OSSIFICATION, or a thickening and opacity of the semilunar valves of the aorta, interrupting their proper action, and sometimes producing fatal consequences. This artery is likewise subject to INFLAMMATION and ULCERATION, like other parts of the body; but in all these complaints the art of healing affords only palliative means of relief. See POLYPUS of the heart and blood vessels.

AOUS, in *Ancient Geography*, a river of the isle of Cyprus.

Aous is also a name given to the river *Æas*, near Apollonia,

lonia, which rose in the south-east, and discharged itself towards the west into the Ionian sea.

AOUSTA, or **AOST**, in *Geography*, formerly *Augusta prætoria*, a city of Piedmont, situate at the foot of the Alps, on the river Doria. is so called probably from its ancient name, which was given it by Augustus, who sent thither a colony of 3000 of the Prætorian legion. It is the see of a bishop, has several Roman antiquities, such as a triumphal arch, an amphitheatre, &c., and was the birth-place of Anselm, archbishop of Canterbury. It is distant 25 miles north-west from Ivrea, and 50 north-north-west from Turin; N. lat. 45° 38'. E. long. 7° 33'.

AOUSTA, a district of Piedmont, with the title of a duchy, is a valley about 30 miles long, and fertile in pasture and fruit; extending from the pals of St. Martin's, near the frontiers of Yvrèe, to St. Bernard. Its capital is Aoulla, and most of the inhabitants are Goitres.

AOUSTE, a town of France, in the department of the Drome, and chief place of a canton in the district of Crest, situate on the Drome; 15 miles south-east from Valence, and two south-east from Crest.

AOUTA, the name of the paper mulberry-tree at Otaheite, in the South Sea, from which a cloth is manufactured that is worn by the principal inhabitants. The bark of the trees is stripped off, and deposited to soak in running water; when it is sufficiently softened, the fibres of the inner coat are carefully separated from the rest of the bark; they are then placed in lengths of about 11 or 12 yards, one by the side of another, till they are about a foot broad; and two or three layers are laid one upon the other. This is done in the evening; and by the next morning the water is drained off, and the several fibres adhere together in one piece. It is afterwards beaten on a smooth piece of wood, with instruments, marked lengthways with small grooves of different degrees of fineness; and by means of this operation becomes as thin as muslin; and after bleaching it in the air in order to whiten it, it is fit for use. If the cloth breaks in the beating, it is easily repaired by pasting on a patch with a gluten that is prepared from the root of the *pea*, which is done so nicely that it cannot be discovered. This cloth is cool and soft, but as liable to be rent as paper. The colours with which it is dyed are principally red and yellow. The red is a beautiful scarlet, and produced by mixing the juices of two vegetables, *viz.* the fruit of the fig called *matle*, and the leaves of the *cordia sebastina* or *etou*. The yellow is made of the bark of the root of the *marinda citrifolia* called *nono*, by scraping and infusing it in water. The inhabitants of the island also dye yellow with the fruit of the *tamanu*. Hawkesworth's Voyages, &c. vol. ii. p. 210, &c.

AOUTOS, in *Geography*, a town of European Turkey, in the province of Romania, 44 miles west-north-west from Burgas.

AOYCA, a town of Spain, in Navarre, four leagues from St. Estevan, and five from Pampeluna.

APACHES, a people of North America, in New Mexico, who occupy an extensive country under the appellations of Apaches de Parillo, to the south; Apaches de Xilla and de Navaio, to the north; and Apaches Vaqueros, to the east. They are brave, and resolute, fond of liberty, and the inveterate enemies of tyranny and oppression. Ever since their revolt from the catholic king towards the close of the 17th century, they have been the allies, but not the subjects of the Spaniards.

APACHIERA, an audience and province of New

Mexico, whose capital is St. Fe, in N. lat. 36° 30'. W. long. 104°.

APACTIS, ($\Delta\pi\alpha\kappa\tau\iota\varsigma$, *abductus*, from $\alpha\pi\alpha\rho\gamma\omega$), in *Botany*, Thunberg, Jap. 11. Schreb. gen. 808. Juss. 432. Clafs. *dodecaedria monogynia*. Generic Character: *calyx*, none; *corolla* four-petalled; *petals* round sh crenate, concave, unequal, two opposite broader; *filam.* filaments from 16 to 20; *fil.* germen superior; *style* one. Essential character: *cor.* four-petalled; *cal.* none. *Apactis japonica*, the only species of this genus, is a tree growing erect, with numerous branches, which are alternate, round, scabrous, dotted, erect. Leaves alternate, petiolate, ovate, acute, serrate, entire at the base, nerved, smooth, paler underneath, an inch long. Petioles half round, furrowed a quarter of an inch in length. Flowers in racemes, at the ends of the branchlets. Racemes usually ovate, as they advance becoming more oblong. Peduncles villose-scabrous.

APÆDUSIA, from α and $\pi\alpha\iota\delta\iota\alpha$, *infrustration*, denotes ignorance or unskilfulness in what relates to learning and the sciences. Hence also persons uninstructed and illiterate are called *apædeutæ*. The term *apædeutæ* was particularly used among the French in the time of Huet; when the men of wit at Paris were divided into two factions, one called by way of reproach *apædeutæ*, and the other *eruditi*.

The *apædeutæ* are represented by Huet as persons who finding themselves either incapable or unwilling to undergo a severe course of study, in order to become truly learned, conspired to decry learning, and turn the knowledge of antiquity into ridicule, thus making a merit of their own incapacity.

The *apædeutæ*, in effect, were the men of pleasure; the *eruditi*, the men of study.

APAGMA, a term used, by some writers, in *Surgery*, for the thrusting of a bone or other part out of its proper place. But it is more properly used for a fracture of a bone at or near the part whereby it is articulated with another.

APAGOGE, from $\alpha\pi\omega$ and $\alpha\gamma\omega$, *I draw*, or *bear*, in the *Athenian Law*, the carrying of a criminal, taken in the fact, to the magistrate. If the accuser was not able to bring him to the magistrate, it was usual to take the magistrate along with him to the house where the criminal lay concealed, or defended himself.

APAGOGE, in *Logic*. See **ABDUCTION**.

APAGOGE, in *Mathematics*, is something used to denote a progress or passage from one proposition to another; when the first, having been once demonstrated, is afterwards employed in the proving of others.

APAGOGICAL demonstration, is such as does not prove the thing directly, but shews the impossibility and absurdity which arises from denying it.

Hence it is also called, *reductio ad impossibile*, or *ad absurdum*.

APALACHES, or **ST. MARK'S RIVER**, in *Geography*, rises in the country of the Seminole Indians, in East Florida, in N. lat. 31° 30', and runs south-west, through the Apalachy country, into the bay of Apalachy, situate N. lat. 30°. W. long. 83° 53', in the gulf of Mexico, about 15 miles below St. Mark's. After a course of about 135 miles, it falls into the bay, near the mouth of Apalachicola river.

APALACHIAN Mountains, sometimes called the *Alleghany Mountains*, pass through the territory of the United States, from the south west to the north-east. According to the best maps, they commence on the north of Georgia, where they give rise to many rivers that run south to the gulf of Mexico,

Mexico, and to the Tennesse, and others that have their course to the north. The Apalachian chain, from which proceed several collateral ridges, as the Iron, or Bald mountains, the White Oak mountains, and others, extends from thence through the western territory of Virginia, together with its collateral ridges, the breadth of the whole being often 70 miles, and advancing through Pennsylvania, passes Hudson's river, and afterwards rises to a greater elevation, and seems to terminate in the country of New Brunswick. Accordingly, this chain may extend about 900 geographical miles, which is a length unrivalled by any European mountains, except the Norwegian Alps. The collateral ridges are singularly distinct; and a naturalist would at once pronounce that the central or highest must be granitic, the next schistose, and the exterior belts calcareous. The granite seems commonly to consist of white felspar, bluish or rather pellucid quartz, and black mica. The schistose band presents copper ore; and in Canada, lead and silver are said to have been discovered. The limestone contains, as usual, many petrifications, particularly the cornu ammonis, a small scallop shell, and several sorts of corals. The height of the chief summits, which appear to be in the province of New Hampshire, has not been accurately ascertained, but does not probably exceed 3000 feet above the sea; and they are often clothed with forests. Mr. Weld conjectures, that the Peaks of Otter, the highest of the Blue Mountains, are little more than 2000 feet high, and at any rate their height is much inferior to that of Snowdon. Morfe's Amer. Geog. p. 292. Pinkerton's Mod. Geog. vol. ii. p. 552.

APALACHICOLA, a river of America, between East and West Florida, rises in the Apalachian Mountains, in the Cherokee country, within 10 miles of Tuguloo, the upper branch of Savannah river, and from its source to the mouth of Flint river, in a course of 300 miles, bears the name of Chata-Uche, or Chatubooche river. Flint river falls into it from the north-east below the lower Creek towns, in N. lat. 31°. From thence it runs near 80 miles, and falls into the bay of Apalacky, or Apalachicola, in the gulf of Mexico, at Cape Blaize. From its source to N. lat. 33° its course is south-west, and thence to its mouth nearly south.

APALACHICOLA is also the name of the mother town, or capital of the Creek or Muscogulge confederacy, called Apalachicola by Bertram; who describes it as sacred to peace, no captives being put to death or blood shed there; and when a general peace is proposed, deputies from all the towns in the confederacy meet here to deliberate. Whereas the great Coweta town, 12 miles higher up the Chata-Uche river, is called the "Bloody Town," where the Micos chiefs and warriors assemble, when a general war is proposed; and here captives and state malefactors are put to death. Apalachicola is situated one mile and a half above the ancient town of that name, which lay on a peninsula, formed by the doubling of the river, but deserted on account of inundations. The town is about three days journey from Tallassee, a town on the Tallapoosie river, a branch of the Mobile river.

APALACHY COUNTRY extends across Flint and Apalaches rivers in East Florida, having the Seminole country on the north-east. Apalacky, or Apalachya, is also a name applied by some writers to a town and harbour in Florida, 90 miles east of Pensacola, and at the same distance west from Del Spiritu Santo river. The tribes of the Apalachian Indians lie around it.

APALATOA, in *Botany*. See CYCLAS.

APALHAO, in *Geography*, a town of Portugal in Alentejo, containing about 1200 inhabitants.

APALIORIA, an island that lies on the eastern coast of the peninsula of India, in S. lat. 9° 8'. E. long. 79° 40'.

APALUS, in *Entomology*, a genus of the COLEOPTERA insects, with filiform antennæ, equal and filiform palpi, maxilla horny and unidentated, and lip membranaceous, truncated and entire. There is one species, the *ap. bimaculatus*, *pyrochroa bimaculata* of Degeer; found early in the spring in the sandy parts of Sweden.

APAM, in *Geography*, a village of Africa, in the kingdom of Acron, on the Gold Coast, inhabited by fishermen, and fortified by the Dutch in 1697. See ACRON.

APAMA, in *Botany*, a genus of the *polyadelphia polyanthra* class and order: the characters of which are, that the calyx is trilid, no corolla, and the filaments distributed in three ranks. Gmelin mentions one species, *viz. A. dubia*, the *alpany* of Rheed, Malab. vi. p. 51. This is a tree in the East Indies, with ash-green bark and white wood. It is an ever-green, and bears fruit twice a year. With its juice and oil are formed an ointment which cures the itch, and deterges old ulcers. La Mark. Encycl. t. i. p. 91.

APAMATUCK, in *Geography*, a river of North America, in Virginia, runs into the Powhatan.

APAMÆA, or APAMIA, in *Ancient Geography*, a town of Syria, situate in a marshy country, at the confluence of the Orontes and Marfyas, which form a kind of lake, that has no communication with the land but by a small isthmus. It is about 60 miles almost south of Antioch, and about 90 from Aleppo, in N. lat. 35° 6'. E. long. 37° 18'. Its former name was Pharnasca, and the Macedonians called it Peila; and as it was almost wholly surrounded by water, it was denominated Chersonesus. According to Strabo, it was founded by Seleucus Nicator; and derived its name from his wife Apamea, the daughter of Artabazus the Persian. It had its own kings till the arrival of Pompey in Syria; and afterwards the whole country became a Roman province. It was there, says Strabo, that the Seleucidæ had established the school and nursery of their cavalry. The soil of the vicinity, abounding in pasturage, fed no less than 30,000 mares, 300 stallions, and 500 elephants. It is now called *Famia*; and its marshes scarcely afford supply for a few buffaloes and sheep. To the veteran soldiers of Alexander, who here reposed after their victories, have succeeded wretched peasants, who live in perpetual dread of the oppressions of the Turks, and the inroads of the Arabs. Some have supposed this city to have been the present *Hama*. Volney's Travels, vol. ii. p. 298.

APAMEA is also a town of Asia Minor, in Bithynia. It was originally called Myrlea, but destroyed by Philip, king of Macedon, the son of Demetrius, and the father of Perseus; and given to his ally Prusias the Bithynian, who rebuilt it, and called it after his wife's name, Apamea. Such is the account of Strabo. But Steph. Byz. says, that it was founded by Myrtilus, general of the Colophonians; and that Nicomedes Epiphanes, son of king Prusias, called it Apamea in honour of his mother. Others say, that it derived its name from Myrlea, an Amazon. The Romans fixed a colony there called *Colonia Apamena*.

APAMEA *Cibotos*, so called, according to Salmastius, from *κιβωτος*, an ark or coffer, because it was the mart or common treasury of those who traded from Italy and Greece to Asia Minor, was the metropolis of Phrygia, till Constantine's division of the empire. It was situated at the confluence of the Marfyas and Mæander. It was built, according to Strabo, by Antiochus Soter, and so called from his mother Apamea, the wife of Seleucus Nicator. He also removed

removed the inhabitants of the ancient Celenæ, the situation of which is confounded by some writers with that of Apamea, to this city. It is now called *Aphion Kara Hisar*, or the black cattle of Opium, which drug is collected in its environs.

APAMEA was also a city on the confines of Media and Parthia, not far from Rages, and surnamed *Raphane*, or probably as it should have been, *Ragare*.

APAMEA, *Mesene*, is a town of Asia, in Mesopotamia, situate to the south-east upon the Tigris, in a district which lay between the canal and the river, whence the epithet Mesene, because it was in the midst of that small territory now called *Dizgel*.

APAMEA, *Koma*, a town situate at the confluence of the Tigris and Euphrates, to the south of the preceding.

APAMEA, *Cebene*, a town of Asia, on the left bank of the Euphrates, opposite to Zeugma; both founded by Seleucus, and connected by a bridge.

APAMIS, a name anciently given, according to Steph. Byz. to Lampascus.

APAMIS is now the name of the Ancient Apamea, on the Meander, called Mindra, a town of Asiatic Turkey, and the see of a Greek bishop; 100 miles west of Eski-hissar.

APAMMARIS, a town of Asia in Syria, on the banks of the Euphrates, south-east of Hierapolis.

APAN, in *Conchology*, a name given by Adanson to the same shell as Linnæus has since called *PINNA RUDIS*; which see.

APANAGE, APENAGE, APPANAGE, APANNAGE, or APENNAGE, in the *French Law*, the fortune of a king's younger son; or a settled portion of land, &c. assigned for the subsistence of the cadets or younger sons of a sovereign prince. *Nicod* and *Menage* derive the word from *panis*, *bread*, which frequently includes all other sorts of provision necessary for subsistence. Some will have the apanages, at the first institution, to have been only pensions, or annual payments, of a certain sum of money.

During the first and second races of kings, the right of primogeniture and apanages were unknown; but the domains were divided pretty equally among all the children.

Great inconveniences arising hence, it was at length found proper to put off the younger-born with counties, duchies, or other districts; on condition of their paying homage and fealty for the same, and of their reverting, in defect of heirs male, to the crown.

This has happened, accordingly, to the first and second branch of the dukes of Burgundy. The duchy of Orleans was the apanage of the second son of France. The apanage was unalienable; collateral branches did not inherit it. The eldest son alone was heir to the whole apanage: but bound to allow the younger an honourable maintenance.

In France, apanages were of two kinds, *royal* and *customary*; the first only granted to males the king's brothers, exclusive of the females. These are not so properly alienations of the king's demesnes, as dismembering of them. *Customary apanages* were those granted to women. the king's sisters. Joseph Meiers has published a body of all the writers on *apanage* and *parage*, in one volume in folio.

APANORMIA, in *Geography*, a town in the island of Santorin, in the Archipelago; it has a spacious port, in the form of a half-moon; but the sea is so deep as to afford no anchorage.

APANTA, or APANTE, a province of Terra Firma, in

South America, between the lake Parima and the river of the Amizans; to the west of the province of Carapa.

APANTHROPY, in *Medicine*, a term sometimes used to denote a love of solitude, or an aversion from the company of mankind; and is reckoned by some a symptom, and by others a species or degree of melancholy; and it is a bad indication in leucophlegmatic cases.

APANTORA, in *Entomology*, a species of *CANCER* that inhabits Chili. The thorax is ovate, sides denticulated, tail triangular. Molin. and Gmelin.—Obs. legs hairy, tail rather long.

APARA, in *Zoology*, a species of armadillo or dasy-pus. See *DASYPUS*.

APARGIA, in *Botany*. See *HEDYPEROIS*.

APARIA, in *Geography*, a province of South America, in Peru, near the river of the Amazons, where it receives the Curavaya.

APARINE, in *Botany*. See *ASPERUGO*, *GALIUM*, *SHERARDIA*, *VALANTIA*, and *UTRICULARIA*.

APARINES. See *AMMANNIA*.

APARITHMESIS, from *απαριθμω*, *I number*, or *enumeration*, in *Rhetoric*, is a figure, whereby that which might be expressed in few words is branched out into several particulars, to enlarge the idea and render it the more affecting; and sometimes it denotes the answer to the protasis or proposition itself. Thus if the protasis be "appellandi tempus non erat," the aparithmesis is "ac tecum anno plus vixi."

APARTISMENUS, in the *Ancient Poetry*, an appellation given to a verse, which comprehended an entire sense or sentence in itself.

This is sometimes also written *apartemenus*, *i. e.* suspended, as not needing any following verse.

APARTMENT, a portion of a large house, wherein a person may lodge separately; having all the conveniences requisite to make a complete habitation.

The word comes from *apartmentum*, of the verb *partiri*, to divide; or, as some imagine, *a parte mansionis*, making part of a dwelling.

A complete apartment must consist of a hall, a chamber, an antechamber, a closet, and a cabinet or wardrobe.

APATE, in *Botany*. See *LACTUCA*.

APATE, in *Entomology*, a genus of coleopterous insects in the Fabrician system (*Ent. Syst.*); the character of which is, feelers filiform; jaws, one tooth in each; lip membranaceous and truncated; and the antennæ perfoliated. This genus includes some of the Linnæan dermeles, as *capucinus* and *domesticus*; *bostrichus* of Geoffroy and Olivier, as *cornutus* & *bimaculatus*; and *ligniperda* of Pallas, as *tere-bans* & *cornuta*.

Gmelin makes a subdivision of the Linnæan *DERMESTES*, in his edition of the *Systema Naturæ*, according to the number of teeth in the jaws, *maxilla bifida*, and *maxilla unidentata*; the latter he calls *apate*, and it includes several of the species described by Fabricius in his genus of the same name.

APATHY, formed of the privative, *a*, and *παθος*, *passion*, denotes an insensibility; or a privation of all passion, all emotion, or perturbation of mind.

The Stoics affected an entire apathy; their wisdom was to enjoy a perfect calmness or tranquillity of mind, incapable of being ruffled, and above the reach of any sense either of pleasure or pain.

Whilst Epicurus taught his followers to seek happiness in a kind of indolent ease or freedom from labour and pain; Zeno imagined his wife man, not only free from all sense of pleasure,

pleasure, but void of all passions and emotions, and capable of being happy in the midst of torture. That he might avoid the torpid indolence of the Epicureans, he had recourse to a moral institution, which bore indeed the lofty front of wisdom, but which was elevated far above the condition and powers of human nature.

In the first ages of the church, the christians adopted the term apathy to express a contempt of all earthly concerns; a state of mortification, such as the gospel prescribes. Clements Alexandrinus, in particular, brought it exceedingly in vogue; thinking, hereby, to draw the philosophers to Christianity, who aspired after such a sublime pitch of virtue.

Quietism is only apathy disguised under the appearance of devotion.

APATI, in *Geography*, a small town of Hungary in the county of Jarmat, situate on the river Carafna or Tibiser, east of the lesser Varadin, and north-west of Samos. Its territory is fertile in grain and pasturage.

APATIT. *Phospholite* of Kirwan. *Calcareus apatites* of Werner.

This mineral is divided by the German mineralogists into two varieties, the crystallized, and earthy.

I. Crystallized apatit *Gemeiner apatit*, Germ. *L'Apatite commune*, Brochant. *Chaux phosphatée*, Haüy. *Fosforite lamellare*, Napione.

The usual colours of this substance are greenish-white, mountain green, olive green, violet blue, rose-red, and clove brown; more rarely pearl grey, greenish grey, sky blue, Prussian blue, or flesh red. In some crystals several of the colours are combined, other specimens are iridescent.

It is generally found crystallized, but occasionally disseminated; the forms of its crystals are the following:

1. A short regular hexahedral prism, (*Chaux phosphatée primitive* of Haüy), Crystallography (*Pl. xxx. fig. 90*), but this is of rare occurrence.

2. The same prism truncated on its prependicular edges (*Ch. phosph. péridodecaèdre* of Haüy), Crystallography (*fig. 91*). Incidence of ϵ on M = 150° . The sides ϵ are often striated longitudinally.

3. The same prism bevelled on its lateral edges (*Ch. phosph. annulaire* of Haüy, Crystallography (*fig. 92*). Incidence of r on M = $112^\circ 12' 28''$, and on P = $157^\circ 47' 32''$.

4. The same prism exhibiting a combination of the truncatures and bevellings of the two preceding varieties (*Ch. phosph. emarginée* of Haüy), Crystallography (*fig. 93*).

5. The same prism bevelled on the edges as N° 3, and having a quadrangular facet on each of the solid angles of the original prism. (*Ch. phosph. unibinaire* of Haüy). Incidence of s on P = $125^\circ 15' 52''$. Crystallography (*fig. 94*).

These crystals, &c. are commonly small, or very small, being rarely of a middling size; they are almost always grouped one upon the other in an irregular manner, being seldom found single. The surfaces are usually smooth, except the lateral faces of the prisms which are sometimes furrowed with strong longitudinal striæ. Their external lustre is shining, and often brilliant. Internally they are shining, with a vitreous lustre.

The cross fracture (or parallel to the base of the prism) is straight lamellar: in the opposite direction it is uneven fine-granular, sometimes imperfectly conchoidal.

Its fragments are indeterminate, with somewhat sharp edges.

It is usually semitransparent, passing, however, on one hand to transparent, and on the other to translucent.

Its hardness is a little inferior to that of fluor spar; it is brittle, easily broken; sp. grav. = 3.218.

When thrown on hot coals, the apatit gives a greenish phosphoric light. It is infusible, without addition, by the flame of the blowpipe, only losing its colour. It dissolves almost totally in nitric acid. It has been erroneously supposed to become electric by mere heat, not acquiring this property without friction.

According to the analysis of Klaproth, its constituent parts are 55 lime and 45 phosphoric acid, with a little manganese.

It is met with in the tin-mines of Ehrenfriedersdorf and Schneeberg in Saxony, and at Kutteneberg and Schlackenwald in Bohemia, accompanied by fluor spar, quartz, brown spar, wolfram, molybdena, lithomarga, steatite, and cupreous and arsenical pyrites.

This mineral was formerly considered as a felsorl by some authors, as a fluor spar by others; it was also not infrequently ranked among the beryls and aquamarines; hence its old German names of aquamarinfluß, chrysolithfluß, basaltamethyst, &c. The analysis of Klaproth however, in 1788, established its chemical nature; and Werner made a particular species of it, to which he appropriated the name apatit from the Greek *απαταις*, to deceive, on account of its resemblance to substances from which it is essentially different. See SPARGELSTEIN.

II. Earthy apatit. *Erdiger apatit*, Germ. *L'Apatite terreuse*, Brochant. *Chaux phosphatée terreuse*, Haüy. *Fosforite compatta*, Napione.

Its colour is yellowish or greyish white. It occurs massive or earthy, amorphous.

Its fracture is earthy, passing into the fine grained uneven. The fragments are indeterminate, blunt-edged, sometimes wedge-shaped.

It is opaque; half hard, sometimes friable; brittle; easily broken; meagre and harsh to the touch: sp. grav. = 2.824.

On exposure to the blowpipe it yields a phosphoric light and fuses into a white glass; it is also phosphorescent when pulverized and thrown on hot coals; it dissolves in nitric acid, and gives out white vapours when treated with the sulphuric acid.

Its constituent parts, according to the analysis of Berstrand, Pelletier, and Donadei, are,

Lime	59
Silex	2
Phosphoric acid	34
Fluoric acid	2.5
Carbonic acid	1.
Muriatic acid	0.5
Oxyd of iron	1.
	100.0

This mineral is found in beds mixed with quartz, in great abundance in Spain, near Truxillo, in the province of Estremadura. It is used by the inhabitants of the country for building stone, who appear to have been long acquainted with its phosphorescent property. It is to Proust however that the public is indebted for the first scientific account of it. (See his Letter to Darcet, Journal de Physique for April 1783.)

Widenmann's Handbuch der Mineralogie, p. 528. Emermerling,

melius, vol. 1. p. 502. Lenz, Versuch, &c. vol. i. p. 426. Brochant, vol. 1. p. 579. Haüy, Traité de Mineralogie, vol. II. p. 134. Kirwan's Min. vol. 1. p. 128.

APATURIA, in *Antiquity*, a solemn feast celebrated by the Athenians in honour of Bacchus.

The word is usually derived from *απατην, fraud*.

It is said to have been instituted in memory of a fraudulent victory obtained by Melanthus, king of Athens, over Xanthus, king of Bœotia, in a single combat, which they agreed upon, to put an end to a debate between them relating to the frontiers of their countries.—Hence Budæus calls it “fellum deceptionis, the feast of deceit.”

Other authors give a different etymology of this feast; they tell us, that the young Athenians were not admitted into the tribes on the third day of the Apaturia, till their fathers had first sworn, that they were their own children; and that till that time, they were supposed in some measure to be without fathers, *απατορις*: whence the feast, they say, took its name.

Xenophon, on the other hand, informs us, that the relations and friends met on this occasion, and joined with the fathers of the young people who were to be received into the tribes; and that from this assembly the feast took its name; that in *απατηρις*, the *α*, far from being a privative, being here a conjunctive, signifies the same thing with *ομα*, together.

This feast lasted four days: the first day, those of the same tribe made merry together; and this they called *δοπις*: the second day, which they called *ακρησις*, they sacrificed to Jupiter and Minerva: the third day, which they called *κρησις*, such of their young men and maids as were of age were admitted into their tribes: the fourth day they called *επιδορις*.

APATURIAN, a denomination given by Strabo to a temple consecrated to Venus. It was built at Corocondoma, a peninsula between the Euxine sea and the Palus Mæotis. The surname *deceitful*, from *απατην*, was given to Venus, because this deity used artifice in the war of the gods against the giants.

APAULIA, in *Antiquity*, the third day of a marriage solemnity.

It was thus called, because the bride, returning to her father's house, did *απαυλιζεσθαι τω νομφω*, lodge apart from the bridegroom. Some will have the apaulia to have been the second day of the marriage, viz. that whereon the chief ceremony was performed; thus called by way of contradiction from the first day, which was called *περαυλια*. On the day called *απαυλια* (whenever that was), the bride presented her bridegroom with a garment called *απαυλινηρια*.

APAUMEE', in *Heraldry*. The French heralds use this term to express a hand open and extended, so that the full palm appears, as is seen by the hand of Ullier, borne by the baronets of England.

APAVORTEN, in *Geography*, a pleasant and fertile country of Asia, in Mawaralnahra, to the east of the Caspian sea. In this country, Arfaces, the restorer of the Parthian empire, built *Dara* or *Daravum*.

APE, in *Zoology*, one of the four sections into which the numerous race comprehended under the genus, *Simia*, is divided; including such as are destitute of a tail. The other three are *baboons*, *monkeys*, and *sapajous*; to which some have added a fifth, called *sagains*. For the Linnæan generic characters and distribution of the genus *Simia*, see *SIMIA*.

It is the distinguishing character of the *apes*, that they have no tails. Besides, their visage is flat; the teeth, hands, fingers, feet, toes, and nails, resemble those of man; and they walk

naturally erect. This division includes the simiæ or apes, properly so called, of the ancients, which are not found in America. Dr. Gmelin, in his edition of the *Systema Naturæ*, refers to this division the following species, viz. 1. *S. Troglodytes*, or CHIMPANZEE, which Dr. Shaw considers as a smaller variety of the JOCKO, in its less shaggy or more naked state. 2. *S. Salyrus*, or ORAN-OTAN, with the varieties, or two distinct species of this animal, as Dr. Shaw denominates them, the PONGO and the JOCKO. 3. *S. Lar*, long armed ape of Pennant, and grand GIBBON of Buffon, with the varieties of the lesser gibbon and silvery gibbon. 4. *S. Sylvanus*, or PYGMY. 5. *S. Inuus*, Barbary ape, or MAGOT of Buffon. See the several articles.

APE, *Sea*, in *Ichthyology*, the long tailed shark, a species of *SQUALUS*.

APE, *Sea*, in *Zoology*, is also a name given to a very singular animal seen by Mr. Steller on the coast of America, and which is thus described. It was five feet long, with a head like a dog's, erect and sharp ears, large eyes, a sort of beard on both lips, round body, thickell near the head and tapering to the tail, which was bifurcated, the upper lobe the longest: its body was covered with thick hair, grey on the back, and red on the belly. Mr. Steller could discover neither feet nor paws. It was full of frolic, and played a thousand tricks, sometimes swimming on one side, sometimes on the other side of the ship, and looking out with seeming astonishment. It would come so near the ship that it might be touched with a pole; but if any person stirred, it would immediately retire. It often raised one third of its body above the water, and stood erect for a considerable time; then suddenly darted under the ship, and appeared in the same attitude on the other side; and it would repeat this 30 times together. It would frequently bring up a sea-plant, not unlike the bottle-gourd, which it would toss about and catch again in its mouth, playing with it numberless fantastic tricks. Nat. Hist. of Quadrupeds, &c. vol. i. p. 573.

APECHEMĀ, *Απηχημα*, in *Surgery*, the same with *CONTRAFISSURE*.

APEDIA, in *Zoology*, *simia apedia*, little baboon, with short tail, thumbs of the hands close to the fingers, oblong nails on the fingers, and rounded nails on the thumbs, and hairy buttocks. This is said by Linnæus to be of the size of a squirrel; but in a description given in the *Amoenitates Academicæ*, it is said to be as large as a cat. Its general colour is yellowish, the hairs being tipped with black; face brown, with a few feathered hairs; head roundish; ears roundish and naked; tail scarce an inch long. No bare spaces on each side. A native of India, and said to be a lively species. Gmelin queries whether this animal be not a variety of the *simia feiurea*.

APEË, in *Geography*, an island, one of the new Hebrides, about 20 leagues in circumference, situate in the South Pacific ocean. S. lat. 16° 45'. E. long. 168° 31'.

A-PEEK. See ANCHOR.

A-PEIBA, in *Botany*. See AUBLETIA.

APELCHE, or APELSCHERUEL, in *Geography*, a town of the United Netherlands, in the country of Friesland, 12 leagues south of Lewarden.

APELINA, in *Conchology*, a species of *TELLINA*, figured by Chemnitz. It is oval, pellucid, colours changeable, with a white rib in each valve that extends from the hinge to the exterior margin. Gmelin. A variety (*β*) *tellina papyracea alba spengleri* is described by Schroet; this papyraceous white kind, is found with the other in Nicobar.

APELLA,

APELLA, among *Physicians*, a name given to those whose prepuce is either wanting or shrunk, so that it can no longer cover the glans. Some have supposed that Horace uses the word in this sense, when he says, "Credat Judæus Apella, non ego," but Salmaſius and others maintain, that Apella was the proper name of a Jew, and not an adjective, ſignifying "circumciſed."

APELLA, **SIMIA**, in *Zoology*, a ſpecies of ſimia or monkey in the claſs of ſapajous, ſai a gorge blanche of Buffon, and weeper monkey of Pennant; is the long-tailed beardleſs monkey, with prehenſile tail, brown body, black feet, and without calloſities. It is of the ſize of a very ſmall cat; face round, ſwarthy, and fleſh-coloured; general colour of the animal ferruginous brown, deepeſt on the back and outſides of the limbs; tail blackiſh, or in Schreber's figure, annulated with black and whitſh, and well covered with hair; hands and feet duſky; nails flat and round. Shaw. It inhabits Surinam and Braſil, appears as if always weeping, and of a melancholy diſpoſition, but prone to imitation. Pennant ſuggeſts that this was one of the ſpecies of monies which Dampier ſaw in the bay of All Saints, and which were ugly and ſmelled ſtrongly of muſk, kept in large companies, and made a great chattering, eſpecially in ſtormy weather, and reſiding in a ſpecies of tree, bearing a podded fruit, on which they feed.

APELLES, in *Biography*, the moſt famous painter of Antiquity, was born in the iſland of Cos, and flouriſhed in the time of Alexander the Great, in the fourth century. Having been inſtructed in his art by Pamphilus of Amphipolis, he diſtinguiſhed himſelf by his aſſiduity; and from this circumſtance aroſe the proverb; "No day without a line." It was his wiſh, in the exerciſe of his art, to approve himſelf even to the vulgar; accordingly when a ſhoemaker pointed out a defect in a ſhoe which he had painted, he corrected it; but when the ſame artiſan was proceeding to criticiſe the leg of his picture, he came forth from his hiding place, and reproved him in thoſe words, which are become proverbial, "ne futor ultra crepidam." Such was his idea of excellence, that he uſed to write under his pictures, in the imperfect tenſe, "Apelles εποίησεν, faciebat, and not περιποίησεν, fecit." Nevertheless he cenſured Protogenes for not knowing when "to take his hand from his work," an expreſſion which is become proverbial. The characteristic excellence of Apelles in all his performances was "grace," and in this he claimed the pre-eminence. His colouring was chaſte and ſimple; and, according to Pliny, he uſed only four colours. The varniſh with which he covered his pictures was of a peculiar kind, and ſerved to ſoften and harmonize his tints. It is recorded of him, that when he ſaw a Helen painted by one of his pupils with a profuſion of gold and jewels, he ſaid jocoſely to him; "not knowing how to make her handſome, you have made her rich." Apelles was a great favourite of Alexander, and was admitted into very intimate familiarity with him. Alexander would not allow any other painter to take his portrait; and it is related by Pliny, that when he had painted one of the moſt beautiful and beloved of his concubines, Campaſpe, naked, Alexander finding that Apelles had fallen in love with her, generouſly ſurrendered her to him. Apelles was permitted to uſe freedoms with Alexander, the reality of which has been diſputed on account of their ſingularity. When Alexander was one day in his ſhop talking very ignorantly of his art, it is ſaid that Apelles requeſted him to be ſilent, leſt the boys who ground his colours ſhould laugh at him. Apelles painted many pictures of Alexander, but the moſt famous was one, in the character of a thundering Jove, in

the temple at Ephesus. The hand which held the thunder-bolt ſeemed to come out of the canvas, and excite horror in thoſe who beheld it. But the moſt celebrated of all the pictures of Apelles was his "Venus Anaduomene," or riſing from the ſea, and preſſing her wet locks with her hands. The lower part of it was injured by time; but no one ventured to repair it. Another unfiniſhed Venus, of which the head and neck only were executed, was very much admired. Several of his other works were the ornaments of the temples and other edifices in which they were placed. Of the volumes which he wrote on the art, and inſcribed to one of his ſcholars, nothing is extant. Apelles was fond of ſociety, pleaſant in converſation, addicted to pleaſure, and devoted to the fair ſex. It is ſaid that the courteſan Lais was initiated by him into her profeſſion. The time and place of his death are not known. Gen. Diſt.

APELLES was the name alſo of one of the ſect of Marcionites, who flouriſhed about the year 100. Tertullian and ſome others charge him with criminality in his connection with Philomene, a fanatical virgin who pretended to prophetic illuminations; but Rhodon, in Eusebius, bears testimony to his character, as a person venerable for his age and abſtemious courſe of life. Beaufobre and Lardner vindicate him from this aſperſion. Apelles, however, ſeparated from his maſter, and adopted different ſentiments. Whiſt he taught that there is one God, perfectly good, he maintained that this holy and good God, who is over all, created an inferior deity, who was a fiery being, and who made heaven and earth, and all things in this world. He alſo believed that ſouls have ſexes, or at leaſt that bodies derived their ſexes from the ſouls that animated them. Concerning Chriſt, he taught that he aſſumed fleſh, not from the Virgin Mary, but that he formed for himſelf a body out of the four elements; and believing the reality of his crucifixion and reſurrection, it was his opinion, that when Chriſt aſcended, he ſurrendered his body to the elements from which he took it, and returned to heaven. Theſe peculiarities of Apelles are aſcribed to his conferences with Philomene. As he rejected Moſes and the ancient prophets, he maintained that Jeſus was the only perſon who ever came from God. He alſo denied the reſurrection of the body. In other matters he generally agreed with Marcion, and concurred with him in condemning marriage. As to his opinion concerning the ſcriptures of the Old Teſtament, it appears by his writings, as they are cited by Eusebius, Origen and others, that if he did not abſolutely reject the Old Teſtament, he charged upon it contrarieties and contradictions, and he laboured to evince the difficulties that occur in it, if not totally to overthrow its authority. His ſentiments concerning the New Teſtament were probably not different from thoſe of Marcion; as he denied the miraculous conception of Chriſt, it is likely that he rejected at leaſt the beginning of the gospels of St. Matthew and St. Luke. It appears, upon the whole, that he treated the ſcriptures as Marcion did, by receiving part, and rejecting what did not ſuit his purpoſe. And to this purpoſe Epiſtaphanius accuses him with acting, in this reſpect, like a judge, and not like an interpreter of ſcripture. None of Apelles's writings are preſerved, and therefore we muſt depend altogether upon the report of others with regard to his ſentiments. Lardner's Works, vol. ix. p. 437—448. Cave's Hiſt. Lit. tom. i. p. 85.

APELLES, in *Entomology*, a ſpecies of **SCARABÆUS**, found at the Cape of Good Hope. The head is furniſhed with a very ſhort horn; and the wing-caſes are cinereous, with elevated black dots. Fabricius, and Gmelin. This is a ſmall inſect: the legs are yellow and ſpotted with black.

APELLES is also a species of *HESPERIA ruralis*, in the Fabrician system. (Ent. Svll.) The wings are dentated, fulvous, border brown. Under side of the posterior pair marked with rufous silvery-margined bands. Inhabits New Holland. Obs. In the Linnæan system, this is one of the *PAPILIO P. b. ruralis*.

APELLICON, in *Biography*, a peripatetic, was a native of Teos, and lived about 90 years before Christ. He was extremely rich and avaricious: but his peculiar propensity led him to expend his wealth in the purchase of books. This propensity he indulged to such a degree, that his collection consisted of all the most scarce and valuable books that could be purchased or procured by any means, however illicit and dishonourable. Amongst other literary treasures, he at length obtained possession of the libraries of Aristotle and Theophrastus. These libraries had passed, by bequest, into the hands of Nilens of Scepsis, and from him they descended to his heirs. When they were informed that the king of Pergamus, to whose jurisdiction Scepsis was subject, eagerly sought after books, they buried their collection in a cavern, where they lay for more than 100 years, and suffered great damage. Apellicon discovered this treasure, and purchased it at a great price. Upon removing his library to Athens, he caused the writings of Aristotle and Theophrastus to be copied; but the chasms occasioned by the depredation of time were supplied by the transcribers, so that though the copies were made from the originals, they were of course in many respects erroneous and faulty. After Apellicon's death, Sylla seized on all his books, and took them with him to Rome to enrich his own library, and hence erroneous transcripts were communicated to the world. Apellicon himself was more pleased with having the possession of valuable books than with the perusal and study of them; so that Strabo justly calls him a lover of books rather than a lover of wisdom; φιλοβιβλος μαλλον η φιλοσοφος. Strabo Geog. lib. xiii. tom. ii. p. 906, &c.

APELLITÆ, in the *Primitive Church*, denote those who taught in the second century, that Christ left his body dissolved in the air; and so ascended into heaven without it. See **APELLES**.

APENE, ἀρην, chariot, in *Antiquity*, a kind of chariot wherein the images of the gods were carried in procession on certain days, attended with a solemn pomp, songs, hymns, dancing, &c.

The *apene*, or sacred chariot of the Greeks, is called *tenfa*.

It was very rich, made sometimes of ivory, or of silver itself, and variously decorated.

APENNAGE. See **AFANAGE**.

APENNINES, in *Geography*, a chain of mountains or hills of Italy, extending from the Alps to the southern extremity of the kingdom of Naples. At first they are a branch of the Alps, which separates the plains of Piedmont from the sea; so that they commence near Ormea, in the high ridge which now forms the boundary of the French department of the Maritime Alps, and stretch without interruption along both sides of the gulf of Genoa, at no great distance from the sea, giving source to many rivers that flow to the east. In the south of the former territory of Modena, after giving rise to the Panaro, and Reno, they proceed almost due east to the centre of Italy, where they afford sources to the Arno and the Tiber, and thence pass south-east to the extremities of Italy, generally approaching nearer to the Adriatic than to the Mediterranean. These mountains consist, to the south of Bologna, of stratified

grey hard limestone, with a few petrifications. Yet in the Genoese territory and Tuscany, appear not only the beautiful marble of Carrara, but rich serpentine, here called Gabbro, with steatite and asbestos. Granite, consisting of white felspar and green mica, is also found here. Among the animals of the Apennines we may reckon the marmot and the ibex. Pinkerton's Geog. vol. i. p. 631. The Apennines derive their name from Alpen, a Celtic word, signifying a high mountain.

APENNIS, in *Ancient Law*, a deed or instrument made in favour of a person, who has lost the title-deeds to his house or land by fire. Du-Cange.

In such case, an assembly of the people of the neighbourhood being called, and an exact inquiry made before the judge, another instrument was framed to confirm and secure the unhappy person's right.

APENRÅDE, in *Geography*, a sea port town of Denmark, in the duchy of Sleswick, situate at the bottom of a bay in the Baltic sea, surrounded with hills, which form a harbour, both deep and secure. The inhabitants are much employed in fishing, and it is besides a place of considerable trade. N. lat. 54° 52'. E. long. 10° 7'.

APEPSY, in *Medicine*, denotes crudity, or a want of digestion.

The word is formed from the privative particle α, and πepsis, *I concoct*.

Apepsia may be defined a defect in the stomach, which prevents the aliment taken in from affording a proper chyle for supplying the blood and nourishing the body. Abstemiousness and excess are alike causes of indigestion. The method of treatment in the *apepsia* is the same as in the *anorexy*. The *COLUMBO* root is particularly useful, when the stomach is languid, and digestion difficult, &c. It may be given in substance with any grateful aromatic, or in Madeira wine, now and then interposing gentle doses of rhubarb in tincture. A mixture of mustard-seed with the *columbo* root is of great utility in cases of this nature, where acidity and flatulence prevail much in the *prime via*. See Percival's Essays, &c.

APER, **MARCUS**, in *Biography*, a Roman orator in the first century, was a native of Gaul, who distinguished himself by his genius and eloquence, and occupied several important posts in the empire. He was probably the author of the dialogue "On the Corruption of Eloquence," sometimes ascribed to Tacitus or Quintilian, and placed at the end of their works. He died at Rome about the year 85. Gen. Biog.

APER, in *Zoology*, a name given to several species of the *SUS*; as the variety *ferus* of the *sus ferosa*, the *sus tajassu*, the *sus athiopicus*, and the *sus babyrussa*. See these articles, and **BOAR**, and **HOG**.

APER, in *Ichthyology*, a species of **ZEUS** that inhabits the seas about Rome and Genoa. The tail is even, and the body reddish. Linn. and Gmel. Some describe it as having the tail even, body entirely red or reddish, and the beak retracted.

APERÆ, in *Ancient Geography*, a town of Lycia, which became an episcopal see.

APERANTÈS, a people who inhabited *Aperantia*, which was a district of Theffaly, situate towards the south-west, and abounding with mountains, in which was the source of the river Achelous.

APEREA, in *Zoology*, a species of **CAVIA** or **Cavy**, having no tail, and the upper parts of the body being of a reddish ash-colour. This is the *cuniculus brasiliensis*, having

no tail, &c. of Brisson and Ray; the aperea of the Braffilians, so called by Marcgrave, &c.; the cuniculus indicus femina of Aldrovand. This animal inhabits Brazil, in the holes of the rocks, from which it is driven out and taken by little dogs; the colour of the upper part of the body resembles that of the hare; its body is white; the upper lip divided; the ears short and rounded like those of a rat. It moves like the hare, the fore legs being shorter than the hind; it has four toes with short small claws on the fore feet, which are black and naked, and only three on the hind, of which the middle is the longest; its length is about 12 inches; its flesh is like that of the rabbit, but reckoned of a superior flavour; and its manner of living is also very similar. There is a variety, which is the rock cavy of Pennant, of a black colour, mottled with tawny on the back, belly and throat white. It is exactly similar in every respect, except in colour, to the former. The animal called *cori* by Oviedo, Charlevoix, &c. is thought by Buffon to be the same with the aperea. There are many varieties of the *cori* with respect to colour; and they are found in various parts of the West Indies, and on the continent of America.

APERIENS *Os*, in *Anatomy*, a name given by some writers to a muscle of the mouth, called by Albinus *biventer maxillæ inferioris*, and by others DIGASTRICUS.

APERIENS *palpebram reclusus*, is a name that has been given to the muscle more commonly called LEVATOR *Palpebræ*.

APERIENTS, or APERITIVE medicines, from *aperio*, I open, are such as are suited to open obstructed passages; and particularly to restore suppressed excretions or evacuations; and the term is most commonly applied to those that are adapted to open the vessels of the uterus, and thereby to excite the retained, or to restore the suppressed, menstrual flux. The term, however, as variously employed, both with respect to different cases and to different modes of operation, is, without specifying the particular case and operations, extremely improper. Cullen's *Mat. Med.* vol. 1. p. 171. The term aperients in its present use is synonymous with *laxatives* or *purgatives*, which see.

APERISTATON, from *α*, without, and *περιστοι*, unfavourable circumstance, in the *Ancient Physic*, denotes an ulcer of a mild or benign kind, and not attended with any severe symptom.

APEROPIA, in *Ancient Geography*, a small island of the Ægean sea, opposite to the promontory of Buporthmos in the Argolide. It was so called by Pliny.

APERITIONS, in *Architecture*, are the openings in a building; as doors, windows, stair-cases, chimneys, outlets and inlets for light, smoke, &c.

The apertions should be as few as may be; it being a rule, that all openings are weakenings: and they should not approach too near the angles of the walls.

APERTO, *Ital.* in *Music*, open, opposed to *Chiuso*, close.

APERTOR *oculi*, in *Anatomy*, a name given by Spigelius and others to the muscle called the APERIENS *palpebram*, and LEVATOR *palpebræ superioris* by others.

APERTURE, the opening of any thing; or hole, cleft, or vacant place, in some otherwise solid or continuous subject. It comes from *aperire*, to open.

In *Geometry*, aperture is used for the space left between two lines, which mutually incline towards each other to form an angle.

In *Optics*, aperture is the hole next the object-glass of a telescope or microscope, through which the light and image of the object come into the tube, and are thence carried to the eye.

APERTURE is also understood of that part of the object-glass itself which covers the former, and which is left pervious to the rays. See TELESCOPE.

A great deal depends on having a just aperture. To find it experimentally, apply several circles of black smutted paper, each bigger than the other, upon the face of the glass, from the breadth of a straw to such as leave only a small hole in the glass; and with each of these separately view several distinct objects, as the moon, stars, &c.; that through which they appear the most distinctly is to be chosen.

M. Auzout affirms, that he found that the apertures of telescopes ought to be nearly in the subduplicate ratio of their lengths: but Huygens, who first found that the use of apertures conducted very much to one perfection of telescopes, assures us he found by experience, that the aperture of an object-glass, e. gr. of 30 feet, is to be determined by this proportion; as 30 to 3, that is, as 10 to 1, so is the square root of the distance of the focus of any glass multiplied by 30, to its proper aperture; and the focal distances of the eye-glasses are to be proportional to the apertures. A table of apertures for telescopes of various lengths, &c. see under the article TELESCOPE.

The greater or less aperture of an object-glass, it is to be noted, does not increase or diminish the visible area of the object; all that is effected by this is, the admittance of more or fewer rays, and, consequently, the more bright or obscure appearance of the object; but the largeness of the aperture or focal distance causes the irregularity of its refractions. See ABERRATION.

Hence in viewing Venus through a telescope, a much less aperture is to be used than for the Moon, Jupiter, or Saturn, because her light is so vivid and glaring. This circumstance does a little invalidate and disturb M. Auzout's proportion, as is shewn by Dr. Hook. *Phil. Trans.* N^o 4.

APERTURA *tabularum*, in *Ancient Law Books*, signifies the breaking open a last WILL and TESTAMENT.

APERTURA *feudi* denotes the loss of a feudal tenure, by default of issue to him to whom the feud or FEE was first granted.

APESAS, or APESANTUS, in *Ancient Geography*, a mountain of Peloponnesus, in the territory of Nemea.

APETALOUS, or APETALOSE plants, are such as are without, or have an imperfect or stamincous flower. They are so called because they are destitute of those tender fugacious coloured leaves, called *petals*; but consist only of a calyx or cup, and of stamina, or capillaments, or styles. *Phil. Trans.* N^o 186.

The word comes from the privative particle *α*, and *πεταλον*, *folium*, a leaf.

The apetalous kind is subdivided by Ray, 1. Into such whose fruits are not contiguous to their flowers; as in hops, hemp, nettles, spinach, mercury, *palma Christi*, the American physic-nut, &c. 2. Such as have a triquetrous or triangular seed, as the docks, sorrels, arsmarts, knot-grass, snake-weeds. 3. Those which have round, compressed, and otherwise figured seeds, as the pond-weeds, oraches, sea purslane, the blites, the amaranthi, the beets, some kalies, &c.

APETNA, in *Ancient Geography*, a town of Bœtica, near Corduba.

APETOUS, or APETUBES, in *Geography*, a people of South America, in Brasil, occupying the parts in the vicinity of the government of Puerto Saguro.

APEUCTIC, from *απειυχουαι*, I deprecate, in the *Ancient Poetry*,

Poetry, denotes a kind of poem or prayer preferred to God for averting some evil.

In which sense *apudicum* stands contradistinguished from *prosecutum carmen*, which begs for some good, e. gr. *di prohibete minas, di talem avertite casum, et placidi servate pias*.

APEX, the vertex or summit of any thing.

APEX is peculiarly used in *Antiquity*, for a kind of conical cap or covering of the head, wore by the flamen or priests of Jupiter; and also by the Sali, or priests of Mars. This was otherwise denominated *pilus capitiuus*, or *albanus*.

The apex is described as a flitched cap in form of a helmet, with the addition of a little stick fixed on the top, and wound about with white wool.

The ordinary flamen only wore the apex in the time of performing divine service; the flamen dialis always wore it out of doors; for within it was allowed him to be bareheaded. See **APICULUM**.

APEX was also used among the Romans for the crest of a helmet.

APEX, in *Botany*, denotes the point, end, or termination of a leaf, &c. Leaves, with respect to their apices, are called *truncate*, or lopped, when they end in a transverse line; *premorse*, or bitten in the fore-part, when they are very obtuse, and are terminated by unequal notches or incisions; *retuse*, or blunted, when they terminate in an obtuse sinus; *emarginate*, or nicked, when they terminate in a notch; *obtusè*, or blunt, when they terminate as it were within a segment of a circle; *acute*, or sharp, when they terminate in an acute angle; *acuminate*, or pointed, when they terminate in a subulate apex; and *cirrhose*, or clasped, when they terminate in a clasper or tendril. See **LEAF**.

APEX is also used, by *Grammarians*, for a long accent or mark, to denote that a syllable is to be pronounced long. Quintilian condemns the practice of putting the apex on all long syllables; yet in some cases he allows the apex necessary, e. gr. where the different lengths of a syllable distinguish the different senses of a word, as in *malus*, which, as long or short, denotes an *ill man*, or an *apple tree*. See **ACCENT**.

APHACA, in *Botany*. See **LATHYRUS**.

APHACA, in *Ancient Geography*, a town of Syria, between Heliopolis and Biblos, near mount Lebanon. Zosimus (lib. i. c. 58.) informs us, that in this town was a temple of Venus called *Aphacitis*; and near the temple there was a lake, in which the gifts that were presented to the goddess, however light in themselves, sunk to the bottom, if acceptable; but if displeasing, they floated, however heavy, on the surface of the water. Eusebius (in Vit. Const. lib. iii. c. 55.) styles his temple a school of wickedness, in which men prostituted themselves like women, in order to render the goddess propitious by their infamy. The temple was rased to the ground by Constantine the Great, and all its statues destroyed. The name is of Syriac origin, and denotes *embrace*, or *salute*; and hence this Venus was denominated "The Goddess of embraces."

APHÆREMA, one of the three tetrarchies added to Judæa by the kings of Syria.

APHÆRESIS, from ἀφαιρέω, *I take away*, in *Grammar*, a figure whereby something is taken away from the beginning of a word.

Thus *ciconia*, by aphæresis, is written *conia*; *contemnere*, *temnere*; *omittere*, *mittere*, &c.

A like retrenchment at the end of a word is called *apocope*.

APHÆRESIS, in *Medicine*, denotes a necessary taking away or removing of something that is noxious.

In *Surgery*, it signifies an operation whereby something superfluous is taken away.

APIANES (Ἀπιάνης; not apparent from its diminutive size), in *Botany*, parsley-piert. Linn. Gen. 166. Schreb. 223. Juss. 337. Class, *tetrandria digynia*, or *monandria monogynia*; natural order, *senticoza*; *rosacea* of Jussieu.

Generic Character. *Calyx*, perianth one-leafed, tubular, permanent; mouth flat, eight-parted; *corolla* none; *filamina*, filaments four, or one, erect, subulate, very small, placed at the mouth of the calyx; anthers roundish, or one twin; *pisillum*, germ ovate; *style* filiform, inserted into the base of the germen; *stigma* headed; *perianthium* none; *seeds* ovate, acuminate, compressed, contained in the bottom of the calyx. This plant is by Dr. Smith removed to the genus *alebenilla*. Flor. Brit. vol. i. 190. 1. *A. arvensis*, parsley-piert. Hudf. Aug. 72. With. 143. Flor. Dan. 973. A small annual plant, with spreading branched leafy stems; leaves alternate, petiolate, palmato-tripartite, crenate and indented, hairy; calyx eight-toothed, alternately very minute; seeds one or two; it is a common British plant, growing in fallow fields. In most of the old Herbals, it is called parsley break-stone, from its supposed lithontriptic qualities.

APHAR, in *Ancient Geography*, the metropolis of Arabia Felix, situate near a bay on the sea-shore, and not far north from the Promontorium Aromatum. Aphar, according to some authors, was the capital of the Homerites, where the king kept his court. In the Notitia Imperii, Aphar is a river. This place, now called *Al-Fara*, is situated on a river between Mecca and Medina.

APHARA, or **APHERA**, a town of Palestine, in the tribe of Benjamin.

APHARANTES, a people of Libya, who had no fixed habitation.

APHARSATHKITES, a people who were transferred together with the *Apharfites* into Samaria, by Esarhaddon, king of the Assyrians, and who opposed the Jews in rebuilding their temple. Ezra, iv. 9.

APHAS, called by D'Anville *Avas*, a river of Epirus, which ran from north to south in the eastern part of the country, and discharged itself into the Ambracian gulf, at some distance to the east of the Aracithus.

APHASIA, from ἀ, and φημι, *I speak*, in the *Sceptic Philosophy*, denotes a state of doubt, wherein a person not knowing what to determine on, it is best for him to be silent. In this sense *aphasia* stands opposed to *phasis*, under which are included both assertion and negation.

APHEA, in *Mythology*, a goddess worshipped by the Eginete and Cretans. Pindar wrote an ode in honour of her, and she had a temple in the island of Crete. The Cretans confounded her with Diana.

APHEK, in *Scripture Geography*, a name given to several cities. 1. Aphek in the tribe of Judah, was the place where the Philistines encamped, when the ark was brought from Shiloh, which they had taken in battle. 1 Sam. iv. 1, 2, 3, &c. 2. Aphek in the valley of Jezreel, where the Philistines encamped, while Saul and his army were near Jezreel, on the mountains of Gilboa. 1 Sam. xxix. 1, &c. 3. Aphek, a city belonging to the tribe of Asher, near the country of the Sidonians. Josh. xix. 30. xiii. 4. This was probably the same with Aphek of Syria, in Benhadad's kingdom, near which the Syrians were defeated in a battle between Ahab and Benhadad. 1 Kings, xx. 26, &c. It was, perhaps, the **APHACA** near Lebanon.

APHELIA,

APHELION.

APHELIA, from ἀφελιας, *simple*, in *Rhetoric*, is used to denote simplicity of DICTION.

APHELION, from ἀπο, *from*, and ἥλιος, *sun*, in *Astronomy*, that point of the earth's or any planet's orbit, in which it is at the greatest distance from the sun.

Thus, a planet being in A (*Plate I. Astron. fig. 9.*) its utmost distance from the sun S, at the extremity of the greater or transverse axis of the elliptic orbit, is said to be in its aphelion. In the system or supposition of the sun's moving round the earth, the point in which he appears when the planet is in its aphelion, is called *apogee*. The aphelion stands opposed to the perihelion.

The times of the aphelia of the primary planets may be known by their diameters appearing the smallest, and by their moving with the least velocity in a given time. Methods for calculating them, with the results of the computations, have been given by many astronomers; such as Riccioli, *Almag.* Nov. lib. vii. § 2 and 3.; Wolfius, *Elem. Astron.* § 659; Dr. Halley, *Phil. Transf.* N^o 128; sir Isaac Newton, *Princip.* lib. iii. prop. 14; Dr. Gregory, *Astron.* lib. iii. prop. 14; Keill's *Intro. to Astron.* lect. xxii-xxiv. De la Lande, *Mem. de l'Acad.* 1755, 1757, and 1766; and *Astron.* lib. xxii.; and also in the writings of M. Euler, M.

D' Alembert, M. Clairaut, &c. upon *Attraction*. See also Vince's *Astron.* vol. i. p. 130. &c.; and the article PLANET in this Dictionary. The places of the aphelia are stated by different authors as in the following tables.

For the Year 1700, according to KEPLER and DE LA HIRE.

PLANETS.	KEPLER.	DE LA HIRE.
Mercury	♿ 8°. 25'. 30"	13°. 3'. 40"
Venus	♀ 3. 24. 27	6. 56. 10
Earth	♁ 8. 25. 30	* * *
Mars	♂ 0. 51. 29	0. 35. 25
Jupiter	♃ 8. 10. 40	10. 17. 14
Saturn	♄ 28. 3. 48	29. 14. 41

Place of the Aphelia for the Beginning of 1750.

PLANETS.	M. CASSINI.	DR. HALLEY.	M. DE LA LANDE.
Mercury	8°. 13°. 41'. 18"	8°. 13°. 27'. 12"	8°. 13°. 33'. 58"
Venus	10. 7. 38. 0	10. 7. 18. 31	10. 7. 46. 42
Earth	3. 8. 27. 23	3. 8. 28. 43	3. 8. 37. 16
Mars	5. 1. 36. 9	5. 1. 31. 38	5. 1. 28. 14
Jupiter	6. 10. 14. 33	6. 10. 33. 46	6. 10. 21. 4
Saturn	8. 29. 13. 31	8. 29. 39. 58	8. 28. 9. 7

N. B. The place of the aphelion of Herschel, or Georgium Sidus, in 1788, was 11°. 16°. 19'. 30"; and in 1790, 11°. 3°. 29'. 42".

Kepler makes the earth's apogee to have coincided with the equinoctial point ♄, on July 24, in the year 3993 before the Christian era, which, according to some authors, is about the time of the creation. At the same time, he makes the aphelion of Saturn to be ♄ 24°. 28'. 6"; of Jupiter ♁ 23°. 34'. 18"; of Mars ♂ 15°; of Venus ♀ 0°. 0'. 0"; of Mercury ☿ 0°. 0'. 0"; and the apogee of the Moon ♁ 0°. 0'. 0".

None of the aphelia of the planets are at rest; for their mutual actions upon one another keep those points of their orbits in a continual motion; and this is greater or less in the different planets. The course of this motion is in confuentia, or according to the order of the signs; and sir Isaac Newton shews, that it is in the sesquuplicate ratio of the respective distances of the planets from the sun, or as the square root of the cube of the distances. This motion, arising from their mutual attraction, is ascertained by comparing the places settled by the ancient and modern observations; or by comparing the length of an anomalistic with that of a tropical or sidereal revolution.

To find the Motion of the Earth's Apogee. Hipparchus, 140 years before Christ, determined its place to be 2°. 5½°; and by the observations of Waltherus, in 1496, it was found to be 3°. 3°. 57'. 57"; whence the motion of the apogee is 1'. 2¾" in a year, with respect to the equinoctial points. M. de la Caille determined the place of the apogee for the beginning of the year 1749, to be 3°. 8°. 39'; which compared with the observation of Waltherus, gives 1'. 6" for the yearly motion. In the year 1588, Tycho determined the place of the apogee to be 3°. 5°. 30'; and Kepler, in the same year, determined its place to be 3°. 5°. 32". These compared with the observation of Cassini, in the year 1738, who determined its place to be then in 3°. 8°. 19'. 8", give about 1'. 7" for the annual motion. M. de la Caille determined the length of the anomalistic year to be 26'. 33" longer than the tropical year, which makes the motion of the apogee to be 1'. 5½" in a year. Kepler made it 1'. 2"; Ricciolus 1'. 2". 4". 4". in a year. Mayer in his Tables makes it 1'. 6". Dr. Halley makes it 1'. 1"; and Cassini about 1'. 1". 25". M. de la Lande, in his Tables, makes it 1'. 2" as computed by M. de Lambre, from Dr. Maskelyne's observations in 1788; and this determination is most to be depended upon, as made by so eminent an astronomer, from observations which

APHELION.

which are acknowledged to be the best that have been ever made. These motions are in respect to the equinox. If we assume it to be $1'. 2''$, and the precession of the equinoxes to be $50\frac{1}{4}''$, we shall have the real motion of the apogee $11\frac{3}{4}''$ in a year.

To determine the Motion of the Aphelion of Saturn. The place of the aphelion, in 1694, was $8'. 28'. 58''$; but from three oppositions observed in the years 127, 133, and 136, its place for the year 132 was $7'. 24'. 14''. 20''$, which makes the annual motion $1'. 20''$. Tycho found the place of the aphelion on December 19, 1590, to be $8'. 25'. 40''. 51''$, which compared with the observation in 132, gives $1'. 18''. 55''$ for the annual motion. The same observation of Tycho compared with the place of the perihelion on December 12, 1708, in $8'. 28'. 25''. 10''$, gives $1'. 23''. 5$ for the annual motion. If the same observation of Tycho be compared with the place of the aphelion in April 1694, in $8'. 28'. 58''$, it gives $1'. 55''$ for the annual motion. Cassini conjectured from all this, that the motion of the aphelion was quicker now than formerly. He also found the perihelion, in 1708, not so forward by a degree as it ought, when compared with the place of the aphelion in 1694, at the annual movement of $1'. 20''$; from whence he suspected that the orbit had a librating motion, and that there ought to be an equation employed between the two points. The irregularities of Saturn, however, are so great, that we need not wonder at these differences. Kepler makes it $1'. 16''$; Cassini supposes it to be $1'. 18''$; and Dr. Halley $1'. 20''$. M. de la Grange, from calculating the disturbing force of each planet upon the other, has determined the annual motion of the aphelion to be $1'. 6''. 3$. M. de la Place makes it $1'. 6''. 07$, which M. de la Lande has employed in his Tables.

To determine the Motion of Jupiter's Aphelion. According to the observations of Ptolemy, the aphelion was in $\mu\gamma 14^\circ. 38'$ in the year 136; but in 1720 it was in $\approx 9^\circ. 47'$; this gives $57''. 11'''$ for the annual motion. In the year 1590, the place of the aphelion, calculated from the observations of Tycho, was found to be in $\approx 6^\circ. 30'. 43''$; this compared with the observation in 1720, gives $1'. 30''$ for the annual motion. If we compare the places in 136, and 1590, they give $54''$ for the annual motion. This induced Cassini to think, that the motion of the aphelion is accelerated; or that it was subject to some irregularities; he states the motion at $57''. 24'''$; Kepler makes it $47''$; Dr. Halley makes it $72''$; M. Jaurat computed the place of the aphelion in 1590 to be $\approx 7^\circ. 49'. 19''$, and in 1762 in $\approx 10^\circ. 36'. 41''$; from which he found the annual motion to be $58''. 4$. Euler, from the theory of attraction, found it to be $55''$; M. de la Grange, $57''. 2$. M. Wargentin says, that an annual motion of $62''$ best agrees with observation. M. de la Lande has employed $56''. 73$ in his last Tables, according to the theoretical determination of M. de la Place.

To determine the Motion of the Aphelion of Mars. From three oppositions determined by Ptolemy, the place of the aphelion in 135 was found to be $3'. 29'. 24''$; and by the observations made at Greenwich in 1601, 1696, and in 1700, the place was found to be in $5'. 0'. 31''. 34''$ in 1696; hence the annual motion of the aphelion is $1'. 11''. 47''' . 20'''$;

Kepler makes it $1'. 7''$; Dr. Halley makes it $1'. 12''$. From comparing the place, in 1748, in $5'. 1'. 26'. 10''$, with the place in 1592 in $4'. 28'. 49'. 50''$, the motion is $1'$. The mean of these determinations is $1'. 7''. 5$. M. de la Lande supposes it to be $1'. 7''$.

To determine the Motion of the Aphelion of Venus. Cassini has found, from computing the place of the aphelion from the ancient observations, a difference of $15'$, from which uncertainty it is more difficult to determine its annual motion. However, the place, computed from the observations in 136, 138, and 140 (and which he thinks are the most to be depended upon), was found, in 138, to be in $4'. 21'. 29''$; this compared with the observations in 1715, 1716, and 1718, when it was found to be in $\approx 6^\circ. 50'$ in 1716, the annual motion is found to be $1'. 42''. 50''$. From comparing the place in 1596 in $\approx 1^\circ. 54'$ with the place in 1716 in $\approx 6^\circ. 50'$, the motion is $2'. 28''$. Horrox fixed the place of the aphelion in 1639 in $\approx 5^\circ$; this compared with the place in 1716, gives $1'. 26''$ for the motion. By comparing the place of the aphelion in the first Tables of M. de la Lande with the place in Kepler's Tables, the annual motion comes out $2'. 41''. 5$; Cassini makes it $1'. 26''$; and Dr. Halley $56''. 5$. Kepler makes it $1'. 18''$. Amidst so much uncertainty, M. de la Lande thinks it better to depend upon the theory which, according to M. de la Grange, makes it $48''. 5$, and which M. de la Lande employs in his Tables. On account of the small eccentricity, this uncertainty of the place of the aphelion is not of so much consequence, as an error of 1° in the place of the aphelion will never produce an error of $1'$ in the heliocentric longitude.

To determine the Motion of the Aphelion of Mercury. From the observations of the passages of Mercury over the sun in 1661, 1690, and 1697, Cassini determined the place of the aphelion on November 9, 1690, to be in $8'. 12'. 22'. 25''$; and upon supposition that the motion of the aphelion was $1'. 20''$ in a year, he found that it represented the passages very well in 1631, 1672, 1723, and 1736. But as these passages were nearly at the same point of the orbit, it does not sufficiently establish $1'. 20''$ to be the true motion, as it might answer to the same points nearly, but not to other parts of the orbit. We ought not therefore to be surprised, says M. de la Lande, that a motion of $52''. 5$ by Dr. Halley answers equally well to the same observations. Kepler makes it $1'. 45''$. M. de la Lande found, by the greatest equation, that on May 6, 1753, the place of the aphelion was $8'. 13'. 55''$. From comparing this place with the place computed from eight observations of Ptolemy (rejecting six others, two of which did not appear to be reconcilable with each other, and four were too near the aphelion), he found the motion to be $1'. 10''$ in a year, which he constructed his first Tables upon; observing, however, at the same time, that this motion does not agree perfectly with the observations in this century. He has since found that a motion of $56''. 25$ will best agree with observation; and this he has assumed in his last Tables. M. de la Grange makes it $57''$ by theory. The motions of the aphelia here determined are their motions in longitude; if therefore we subtract $50''. 25$ (the annual precession of the equinoxes) from each, we shall get their real motions.

Motion of the Aphelia in One Hundred Years.

PLANETS.	M. CASSINI.	DR. HALLEY.	M. DE LA LANDE.
Mercury	2°. 13'. 20"	1°. 27'. 37"	1°. 33'. 45"
Venus	2. 23. 20	1. 34. 13	1. 21. 0
Earth	1. 42. 55	1. 41. 7	1. 43. 35
Mars	1. 59. 38	1. 56. 40	1. 51. 40
Jupiter	1. 35. 42	2. 0. 0	1. 34. 33
Saturn	2. 9. 44	2. 13. 20	1. 50. 7

According to the calculations of M. de la Grange, the aphelion of the Georgian planet is progressive 3",17 in a year, from the action of Jupiter and Saturn; consequently its motion in longitude is 50",25 + 3",17 = 53",42. He

has also calculated the effect of each planet in disturbing the aphelia of the rest. The following table contains the annual effect.

Annual Motion of the Aphelia.

	MERCURY.	VENUS.	EARTH.	MARS.	JUPITER.	SATURN.
By Mercury	. . .	— 4",30	— 0",42	0",02	0",00	0",00
— Venus	4",14	. . .	+ 5, 20	0, 70	0, 01	0, 00
— Earth	0, 84	— 5, 06	. . .	1, 92	0, 01	0, 00
— Mars	0, 04	+ 1, 18	+ 1, 54	. . .	0, 00	0, 00
— Jupiter	1, 56	+ 6, 38	+ 6, 79	12, 31	. . .	15, 99
— Saturn	0, 08	+ 0, 08	+ 0, 19	0, 70	6, 56	. . .
Real motion	6, 66	— 1, 72	13, 30	15, 65	6, 58	15, 99
Precession	50, 25	50, 25	50, 25	50, 25	50, 25	50, 25
Mot. in long.	56, 91	48, 53	63, 55	65, 90	56, 83	66, 24

M. de la Grange here supposes, as before, the density of Venus to be 1,31, but M. de la Lande makes it only 0,95; for this density, therefore, the second horizontal line must be diminished in the ratio of 1,31 to 0,95. See Vince's Astronomy, vol. 1 c. 14.

APHELLAN, the name of a bright star in the constellation Gemini, marked α.

APHERNOUSLI, in Botany, a species of pine growing wild on the Alps. The timber is large, and the planks made of it are of a finer grain, and more beautifully variegated than deal; and may therefore be applied to many uses. It grows in bleak and barren ground, and most resembles that which is called in England the Weymouth pine.

APHES DOMIN, in Scripture Geography, a place of Palestine in the tribe of Juda, between Socho and Azecha, where the Philistines were encamped whilst Goliath insulted the Israelites.

APHESIS, from ἀφίημι, I remit, in the Athenian Laws, was applied to the case of a person deeply indebted, who

desired the people to remit part of the debt, on account of his disability to make payment.

Voetius has a dissertation expressive on the words *aphesis* and *parefsis*, and their difference.

APHETERIA, in the Ancient Military Art, a kind of engines used in the besieging of towns.

Suidas does not mention their particular form or structure. Aquinas takes them to have been of the projectile kind.

APHIDIODES, in Entomology, a species of ACARUS, of a red colour; the first pair of legs very long, and formed for running; two horns on the posterior part of the abdomen. Linn. Fann. Succ. Fab. This is la tique rouge des pierres à pattes antérieures fort longues of Geoffroy, and is found among stones and rotten wood.

APHIDUM, a species of ICHNEUMON that is produced from several of the European kinds of aphides. It is black, with yellow feet, and antennæ about the length of the body. Geofr. Inf. L'ichneumon des pucerons.

APHILANTHROPY, from α, φίλος, friend, and ἀ-βρωπος man, among Physicians, denotes the state or disorder, wherein

wherein a person has an unnatural disrelish for mirth and society, and indulges solitude and melancholy.

APHIOCEM, a composition made principally of the buds of hemp before they flower. It is much in use among the Arabs, and has the intoxicating quality of **OPIMUM**.

APHIOM, **KARA HISSAR**, in *Geography*, a town of Asiatic Turkey in Natolia, situate on the Mindra, and defended by an elevated castle; 56 miles south from Kutaia. N. lat. $38^{\circ} 35'$. E. long. $32^{\circ} 18'$. See **APAMEA**.

APHIS, in *Entomology*, a very interesting and extensive genus of the **HEMIPTERA** order, in the Linnæan system. It is a tribe of creatures that has, in a particular degree, engaged the attention of naturalists for various reasons: their generation is equivocal, and their instinctive economy differs, in some respects, from that of most other animals, as will appear hereafter.

Linnæus defines the generic character of the aphid thus; beak inflected, sheath of five articulations, with a single bristle; antennæ setaceous, and longer than the thorax; either four erect wings, or none; feet formed for walking; posterior part of the abdomen usually furnished with two little horns. Geoffroy says, the aphides have two beaks, one of which is seated in the breast, the other in the head; this last extends to, and is laid upon the base of the pectoral one; and serves, as that writer imagines, to convey to the head a part of that nourishment which the insect takes, or sucks in, by means of the pectoral beak.

The species enumerated by Linnæus and Gmelin are, longirostris ribis, arundinis, ulmi, papaveris, paltinacæ, pruni, sambuci, solidaginis, cerasi, rumicis, acetosæ, ligustici, lychnidis, capræ, padi, rosæ, hortensis, pieridis, ægopodii, danci, urticata, nymphææ, corni, tilizæ, juniperi, brassicæ, craccæ, lactucæ, fonchi, cirsi, cardui, achilleæ, tanacet, absinthii, millefolii, evonymi, avenæ, fraxini, jaceæ, betulæ, alni, roboris, fagi, quercus, pini, pineti, salicis, vitis, populi, tremulæ, viburni, mali, bursaria, aparinis, urticæ, aceris, atriplicis, pistaciæ, persicæ, polyanthi, falgina, plantaginis, archangelicæ, leucantheni, scabiosæ, fabæ, genistæ, coryli, juglandis, balsamitæ, gallarum, farinosa, xyloltei, and mayeri. The whole of these, and no doubt, many others, are found in different parts of Europe. They infest an endless variety of plants; and it is believed each species is particularly attached to one kind of vegetable only; hence each sort has been hitherto uniformly named after the individual species, or genus of plants, on which it feeds; or if that could not be ascertained, that on which it had been found; for some species are rather uncommon and little known, though others are infinitely too numerous. The aphides are sufficiently known by the indiscriminate term of **PLANT LICE**; they abound with a sweet and grateful moisture, and are therefore eagerly devoured by ants, the larva of coccinellæ, and many other creatures, or they would become, very probably, more destructive to the whole vegetable creation than any other race of insects known.

If Bonnet was not the first naturalist (as is generally acknowledged) who discovered the mysterious course of generation in the aphides, or, as he calls them, pucerons, his experiments, together with those of his countryman Trembley, tended at least to confirm in a most satisfactory manner the almost incredible circumstances respecting it: that an aphid or puceron, brought up in the most perfect solitude from the moment of its birth, in a few days will be found in the midst of a numerous family; and that if the experiment be again repeated on one of the individuals of this family, a second generation will multiply like its pa-

rent; and the like experiment may be many times repeated with the same effect.

“M. Bonnet,” says an ingenious writer, “had repeated some experiments of this kind, as far as the sixth generation, which all uniformly presented the observer with fruitful virgins, when he was engaged in a series of new and tedious experiments, from a suspicion imparted by M. Trembley, in a letter to him, who thus expresses himself: ‘I have formed the design of rearing several generations of solitary pucerons, in order to see if they would all equally bring forth young. In cases so remote from usual circumstances, it is allowed to try all sorts of means; and I argued with myself, who knows but that one copulation might serve for several generations?’ This ‘*subo knovus*’ persuaded M. Bonnet that he had not sufficiently pursued his investigations. He therefore now reared to the tenth generation his solitary aphides, having the patience to keep an exact account of the days and hours of the birth of each generation. He then discovered both males and females among them, whose amours were not in the least equivocal; the males are produced only in the tenth generation, and are but few in number; that these soon arriving at their full growth, copulate with the females, and that the virtue of this copulation serves for ten successive generations; that all these generations, except the first, from fecundated eggs are produced viviparous, and all the individuals are females, except those of the last generation, among whom some males appear to lay the foundation of a fresh series.” Adams *Microsc.*

The history of aphides has also been very copiously treated upon by Dr. Richardson, in a paper printed in the 41st vol. of the *Philosophical Transactions*; nor must we omit another upon the same subject by the late ingenious Mr. Curtis, that appeared in the sixth volume of the *Transactions of the Linnæan Society*.

The tenor of Dr. Richardson’s remarks is briefly this: the great variety of species which occur in the insects now under consideration, may make an inquiry into their particular natures seem not a little perplexing; but by reducing them under their proper genus the difficulty is considerably diminished. We may reasonably suppose all the insects, comprehended under any distinct genus, to partake of one general nature; and by diligently examining any particular species, may thence gain some insight into the nature of all the rest. With this view, Dr. Richardson chose out of the various sorts of aphides the largest of those found on the rose tree; not only as its size makes it more conspicuous, but there are few of so long duration. This sort appears early in the spring, and continues late in autumn, while several are limited to a much shorter term, in conformity to the different trees and plants whence they draw their nourishment.

If, at the beginning of February, the weather happens to be so warm as to make the buds of the rose tree swell and appear green, small aphides are frequently to be found on them, though not larger than the young ones in summer when first produced. It will be found, that those aphides which appear only in spring, proceed from small black oval eggs which were deposited on the last year’s shoot; though when it happens that the insects make too early an appearance, the greater part suffer from the sharp weather that usually succeeds, by which means the rose trees are some years in a manner freed from them. The same kind of animal is then at one time of the year viviparous, and at another oviparous.

These aphides which withstand the severity of the weather,

ther, seldom come to their full growth before the month of April, at which time they usually begin to breed, after twice casting off their exuvia, or outward covering. It appears that they are all females, which produce each of them a numerous progeny, and that without having intercourse with any male insect; they are viviparous, and, what is equally singular, they all come into the world backwards. When they first come from the parent, they are enveloped in a thin membrane, having in this situation the appearance of an oval egg; these egg-like appearances adhere by one extremity to the mother, while the young ones contained in them extend to the other, and by that means gradually draw the ruptured membrane over the head and body to the hind feet. During this operation, and for some time after, the fore part of the head adheres, by means of something that is glutinous, to the vent of the parent. Being thus suspended in the air, it soon frees itself from the membrane in which it was confined; and after its limbs are a little strengthened, is set down on some tender shoots, and left to provide for itself.

In the spring months there appear on the rose trees but two generations of aphides, including those which proceed immediately from the last year's eggs; the warmth of the summer adds so much to their fertility, that no less than five generations succeed one another in the interval. One is produced in May, which casts off its covering, while the months of June and July each supply two more, which cast off their coverings three or four times, according to the different warmth of the season. This frequent change of their outward coat is the more extraordinary, because it is repeated more often when the insects come the soonest to their growth, which sometimes happens in ten days, where they have had plenty of warmth and nourishment.

Early in the month of June, some of the third generation, which were produced about the middle of May, after casting off their last covering, discover four erect wings, much longer than their bodies; and the same is observable in all the succeeding generations which are produced during the summer months, but still without any diversity of sex: for some time before the aphides come to their full growth, it is easy to distinguish which will have wings, by a remarkable fullness of the breast, which in the others is hardly to be distinguished from the body. When the last covering is rejected, the wings which were before folded up in a very narrow compass, are gradually extended in a surprising manner, till their dimensions are at last very considerable.

The increase of these insects in the summer time is so very great, that by wounding and exhausting the tender shoots they would frequently suppress all vegetation, had they not many enemies to restrain them. Notwithstanding these insects have a numerous tribe of enemies, they are not without their friends, if those may be considered as such, who are officious in their attendance for the good things they expect to reap thereby. The ant and bee are of this kind, collecting the honey in which the aphides abound, but with this difference, that the ants are constant visitors, the bee only when flowers are scarce; the ants will suck in the honey, while the aphides are in the act of discharging it; the bees only collect it from the leaves on which it has fallen.

In the autumn three more generations of aphides are produced, two of which generally make their appearance in the month of August, and the third before the middle of September. The two first differ in no respect from those which are found in summer; but the third differs greatly from all the rest. Though all the aphides which have hitherto appeared

were female, in this tenth generation several male insects are found, but not by any means so numerous as the females.

The females have, at first, the same appearance as those of the former generations, but in a few days, their colour changes from a green to a yellow, which is gradually converted into an orange before they come to their full growth: they differ also, in another respect, from those which occur in summer, for all these yellow females are without wings. The male insects are, however, still more remarkable, their outward appearance readily distinguishing them from this and all other generations. When first produced they are not of a green colour like the rest, but of a reddish brown, and have afterwards a dark line along the back; they come to their full growth in about three weeks, and then cast off their last covering, the whole insect being after this of a bright yellow colour, the wings only excepted: but after this change they become of a deeper yellow and in a very few hours of a dark brown, if we except the body, which is something lighter coloured, and has a reddish cast. The males no sooner come to maturity than they copulate with the females, who, in a day or two after their intercourse with the males, lay their eggs, generally near the buds. Where there are a number crowded together they of course interfere with each other, in which case they will frequently deposit their eggs on other parts of the branches.

It is highly probable that the aphides derive considerable advantages by living in society; the reiterated punctures of a great number of them may attract a larger quantity of nutritious juices to that part of the tree or plant where they have taken up their abode. Vide Adams Microf. Phil. Trans. &c.

The observations of Mr. Curtis on the aphides are chiefly intended to shew that they are the principal cause of blights in plants, and the sole cause of the honey-dew. He therefore calls them the aphis, or blighter; and after observing, that in point of number, the individuals of the several species composing it surpass those of any other genus in the country, speaks thus, in general terms, of the whole tribe:

“These insects live entirely on vegetables. The loftiest tree is no less liable to their attacks than the most humble plant. They prefer the young shoots on account of their tenderness; and on this principle often insinuate themselves into the very heart of the plant, and do irreparable mischief before they are discovered. But for the most part, they beset the foliage, and are always found on the underside of the leaf, which they prefer, not only on account of its being the most tender, but as it affords them protection from the weather, and various injuries to which they would otherwise be exposed. Sometimes the root is the object of their choice, which, from the nature of these insects, one would not, *à priori*, expect; yet I have seen the roots of lettuces thickly beset with them, and the whole crop rendered sickly and of little value; but such instances are rare. They rarely also attach themselves to the bark of trees, like the aphis salicis, which being one of our largest species, and hence possessing superior strength, is enabled to penetrate a substance harder than the leaves themselves.”

Mr. Curtis next observes, that as among caterpillars we find some that are constantly and unalterably attached to one or more particular species of plants, and others that feed indiscriminately on most sorts of herbage, so it is precisely with the aphides; some are particular, others more general feeders; and as they resemble other insects in this respect, so they do also in being more abundant some years than others. In 1793, they were the chief, and in 1798,

the sole cause of the failure of the crops of hops. In 1794, a season almost unparalleled for drought, the hop was perfectly free from them, while peas and beans, especially the former, suffered very much from their depredations. Beans, in 1798, were almost wholly cut off by them; indeed they suffer more or less every year by a black species of aphid, particularly the latter crops. To potatoes, and even corn, they prove in some years highly detrimental, and not less so to melons. To plants in stoves, green houses, and frames, where, from the warmth and shelter afforded them, a preternatural multiplication takes place, they prove extremely injurious; and many rare and valuable plants also in the open ground of our botanic gardens fall victims to these general depredators. "Seeing, therefore," says that writer, "that our necessities, as well as luxuries of life, are so materially affected by the insects of this genus, an attempt to ascertain some curious and important facts relative to their history, and to make them more generally known, will not, we trust, be unacceptable. Such inquiries may possibly lead to the means of obviating the injuries they occasion; and if they fail in this, they may tend at least to correct the erroneous notions entertained of blights, not by the vulgar and illiterate merely, but even by persons of education, who may be frequently heard to maintain, that these insects are brought by the east winds; that they attack none but sickly plants; with other notions, all as false in fact as unphilosophical in principle."

In the course of this long but ingenious paper, Mr. Curtis proves, in a satisfactory manner, the truth of his preliminary remarks; and, by a series of experiments, which are necessarily beyond our limits to detail, has discovered some peculiarities in their economy deserving notice: we shall conclude with a brief survey of those most interesting, and refer the more inquisitive reader to the paper at length, in the *Transactions of the Society for 1802*.

Locusts and caterpillars are furnished with strong jaws, by means of which they crop and wholly devour the foliage of plants. The aphid destroys them in a different way. Instead of jaws and teeth, it is provided with a hollow-pointed proboscis, which, when the animal is not feeding, folds under the breast. With this instrument it pierces the plant, and imbibes its juices to support itself; but these juices being essential to the life of the plant, it follows, that when they are drawn off, the plant, exhausted, flags and perishes, being, in fact, literally bled to death by these leech-like animalcules. Yet so tenacious of life are plants in a healthy state, that, in general, they only fall victims to the continued attacks of these insects when in immense numbers. But it most commonly happens, that if they do not wholly destroy a plant, they deface it; and a small number of aphides are sufficient to produce this effect.

Aphides are described by the best authors as being generally oviparous and viviparous at different periods of the same year. Mr. Curtis found, from the 24th of September to the 6th of December following, during which time Fahrenheit's thermometer had been as low as 29, that the aphid *falicis* was constantly viviparous; though, from the inclemency of the weather, very few of these insects, at the period last mentioned, remained on the trees; and those few were soon after entirely cut off by the unusual cold that took place, the thermometer falling to four degrees below 0. Other aphides are oviparous or viviparous, according to the temperature of the air to which they are exposed. In very cold weather they are oviparous, for this obvious reason, that the eggs are capable of resisting cold more powerfully than the young. On the 22d of November, in the same year,

he found a considerable number of eggs, which had been deposited in some auricula plants by a green aphid, which infests plants very commonly, while the same species on a geranium within doors produced young. In mild winters, in the month of January, the same species of aphid has been observed in great numbers on various species of primula without doors, and all the females viviparous. These, and some preceding facts, prove, that all aphides are not oviparous and viviparous at the same season, but that some may be wholly viviparous; that all such as are both oviparous and viviparous do not lay eggs toward the middle of autumn, nor at all during the winter, unless a certain degree of cold takes place.

In the quality of the excrement voided by these insects there is something wonderfully extraordinary. Were a person accidentally to take up a book, in which it is gravely asserted, that in some countries there were certain animals which voided liquid sugar, he would lay it down, regarding it as a fabulous tale, calculated to impose on the credulity of the ignorant; and yet such is literally the truth. Mr. Curtis collected some on a piece of writing paper from a brood of the aphid *falicis*, and found it to be as sweet as sugar; and observes, that were it not for the wasps, ants, flies, and other insects that devour it as quickly as it is produced, it might, no doubt, be collected in considerable quantities; and by the processes used with other saccharine juices, might be converted into the choicest sugar or sugar-candy. The sweetness of this excrementitious substance, the glossy appearance it gave the leaves it fell upon, and the swarms of insects this matter attracts, led him to imagine the honey-dew of plants was no other than this secretion, which further observation has since fully confirmed; and not, as its name implies, a sweet substance falling from the atmosphere. On this opinion it is further remarked, that it neither falls from the atmosphere, nor issues from the plant itself, as is easily demonstrated. If it fell from the atmosphere, it would cover every thing it fell upon indiscriminately, whereas we never find it but on certain living plants and trees. We find it also on plants in stoves and green-houses covered with glass. If it exuded from the plant, it would appear on all the leaves generally and uniformly; whereas its appearance is extremely irregular, not alike on any two leaves of the same tree or plant, some having none of it, and others being covered with it but partially. As far as the writer's observation extended, there never exists any honey-dew but where there are aphides; though such often pass unnoticed, being hid on the underside of the leaf; and wherever honey-dew is observable upon a leaf, aphides will be found on the underside of the leaf or leaves immediately above it, and under no other circumstance whatever. If by accident any thing should intervene between the aphides and the leaf next beneath them, there will be no honey-dew on that leaf: and thus he conceives it is incontrovertibly proved that aphides are the true and only source of honey-dew.

Though no mode of destroying aphides will perhaps ever be devised on a large scale, in the open air, by artificial means, it can be accomplished most effectually when they infest plants in stoves, green houses, and frames, or any situation in which they can be enveloped for a certain time in clouds of smoke. Powders or liquids, however fatal to aphides, must ever be ineffectual, from the trouble and difficulty of applying them, so that they may come in contact with the insects. The smoke of common vegetables, however powerful, is found inadequate to their destruction, and the only one yet employed with success is that of tobacco.

bacco. They may for hours, or even a whole day, be immersed in water, and when taken out some will be living, and many of the rest will revive afterwards; they remain affixed to the plant in water as before, and their bodies assume a luminous appearance from the minute bubbles of air which issue from them. One experiment is mentioned, in which a green-house plant, with the pot it grew in, was immersed in the evening into a tub of water, and in the morning they appeared alive and well. When they are taken from the plant on which they feed, and are kept under water, they do not survive so long; their struggling in that case perhaps exhausts them sooner. It appears therefore, upon the whole, that they are extremely tenacious of life, and that wet is not so hurtful to them as might naturally be imagined.

Some curious remarks on the opinions that prevail respecting blights conclude the paper. Blights, he observes, originate from a variety of causes, the chief of which are unfavourable weather, and insects. Some imagine that the insects which are the cause of them are brought from a distance by easterly winds; and others, that they attach themselves to none but sickly plants; neither of which, so far as the writer has observed, are founded in fact; and he is induced to believe the aphides are by far the most general cause of the diseases distinguished by the name of blights.

APHLASTUM, from α and $\phi\lambda\alpha\sigma\tau\omicron\varsigma$, *frangible*, in the *Ancient Navigation*, a wooden instrument, shaped like a plume of feathers, fastened on the goose's or swan's neck used by the ancient Greeks in the heads of their ships.

The aphiastum had much the same office and effect in a ship that the crest had on a helmet. It seems also to have had this further use, *viz.* by the waving of a party-coloured ribband fastened to it, to indicate from what quarter the wind blew. The aphiastum was the proper ornament of the head, as the acrostolium was of the stern. The Greek aphiastum answered to, and was probably the origin of the Latin aplustre.

APHLE, in *Ancient Geography*, a town of Asia, in Chaldea, situate near the Tigris, where it borders on the Persian gulf.

APHNEUM, a town of Phrygia, near Cyzicum. Steph. Byz.

APHNEUM is also a town of Lydia.

APHONIA, in *Medicine*, the state of a person who is deprived of voice.

The word is compounded of the privative α , and $\phi\omega\upsilon\eta$, *voice*, q. d. a loss of speech or voice.

This is rarely an idiopathic affection, and may arise from a variety of causes; such as cutting the *recurrent nerves* which go to the larynx or glottis, where the voice is formed: or making an aperture into the trachea below the glottis, or any other mechanical injury to the parts.

Any fit may deprive the patient of the use of the organs of speech, as *epilepsy*, *apoplexy*, *paralysis*, or *hysteria*, may become a cause of aphonia.

When a person is suddenly seized with a loss of voice, and no cause appears, it generally indicates the approach of one or other of these attacks.

As all voluntary motion depends on the nerves and muscles of the respective organs, so whatever injures those of the tongue, or any of the other organs subservient to the formation of the voice, may induce aphonia.

Some other causes have been mentioned by medical writers, which are only accidentally so; such as the receding of cutaneous eruptions, inflammation of the tongue and fauces, spasmodic affections, worms, fear or joy, a crumb of bread, or any other extraneous substance sticking in the rima glottidis.

The *prognosis* will vary with the cause; the most obstinate cases are those which depend on a paralytic state of the nerves. As hysteria, worms, or extraneous matters, are commonly soon removed; so a disease depending on them may be deemed easily curable.

The *general indications of cure* are, to restore freedom to the nervous influence when impeded, and integrity to the organs themselves when wounded or otherwise disabled. The first indication is answered by the treatment of PARALYSIS; the second by the practice of *surgery*. *Particular indications* are taken from the cure of those particular diseases on which the aphonia depends, *viz.* HYSTERIA, EPILEPSY, WORMS, SPASM, &c.; which see.

APHORISM, a maxim, general rule, or principle of a science; or a brief sentence, comprehending a great deal of matter in a few words.

The word is derived from $\alpha\phi\omicron\rho\iota\zeta\mu$, *I separate*, q. d. a choice or select sentence.

The term is chiefly used in *Medicine* and *Law*. We say, the aphorisms of Hippocrates, of Sanctorius, of Boerhaave, &c.; aphorisms of the civil law, &c.

APHORISM is used, in *Ecclesiastical Writers*, for the lesser excommunication, by which the delinquent is cut off from the benefit of the sacrament and the prayers of the faithful; but allowed to bear a part in the rest of the service.

APHORISM is also used for a kind of figure in *Rhetoric*, whereby something that has been said is limited and corrected. This is otherwise called *diorismus*.

APHORISTIC, something relating to, or partaking of the nature of *aphorisms*.

The *aphoristic* method stands contradistinguished from the *systematic*, or methodical, as also from the *diexodic*, or discursive way.

The aphoristic method had great advantages, as containing much matter in a small compass; sentiments are here almost as numerous as expressions; and doctrines may be counted by phrases. Every thing is close and pertinent, allowing no room for useless discussions, or for languishing connections and transitions; there is hardly a word to be lost.

APHORMION, in *Ancient Geography*, a place of Bœotia, dependent upon Thespia, which, according to Steph. Byz. was the birth-place of Typhus, who superintended the construction of the ship Argo.

APHOSIATIN, in *Geography*, a part of Romelia in European Turkey, near the Black Sea, and not far from Constantinople to the north.

APHPHADENA, a town of Asia in Mesopotamia, near the Euphrates.

APHRACTI, from α , and $\phi\epsilon\alpha\lambda\omicron\varsigma$, *inclosed*, in the *Ancient Military Art*, denote open vessels, without decks or hatches, furnished only at head and stern with cross planks, whereon the men stood to fight.

The *aphracti*, or open vessels, stood contradistinguished from *cataphracti*, or covered ones.

APHRODISIA, in *Antiquity*, festivals in honour of the goddesses Αφροδίτη , or Venus. There were several of these *Aphrodisiæ* observed with lascivious ceremonies in divers parts of Greece: the most remarkable was that at Cyprus, first instituted by Cinyras, out of whose family certain priests of Venus were elected, and for that reason named *Κυπριαδαί*. At this solemnity several mysterious rites were practised: all who were initiated to them offered a piece of money to Venus as an harlot, and received as a token of the goddess's favour, a measure of salt, and a $\phi\alpha\lambda\lambda\omicron\varsigma$; the former, because salt is a concretion of sea-water, to which Venus was thought to owe her birth; the latter, because she was the goddess of wantonness.

Athenæus (Deipnosoph. l. xiii. c. 6.) informs us, that at Corinth their feasts were celebrated by harlots; and that they who supplicated the goddess were accustomed to promise to devote some women to her, in order to the obtaining of their requests. Erasmus observes in his Adagia, that this city was filled with courtlans; and that the verb *κοινοῦναι*, signified proverbially to surrender themselves to debauchery. See CORINTH.

APHRODISIA is also used for the age of venery, more frequently denominated *puberty*.

APHRODISIA, in *Ancient Geography*, a town of Thrace, to the north of the peninsula which joined the Chersonesus of Thrace to the continent, between Candia to the west, and Heraclea to the east.

APHRODISIA is also a town placed by Stephan. Byz. in Scythia, near the Euxine sea.

APHRODISIACE, in the writings of the ancients, a name given to a gem, supposed, according to the idle traditions of those times, to have a power of procuring love to the person who wore it about him; all the description we have of it is, that it was of a pale flesh-colour; but the stone, as well as its virtues, are wholly unknown to the world at present.

APHRODISIACS, in the *Materia Medica*, denote medicines supposed to be suited to excite the venereal appetite, or to increase the venereal powers. As there are no medicines of specific power for these purposes, the term seems, for the most part, to have been very improperly employed.

In which sense, *aphrodisiaks* stand contradistinguished from *antaphrodisiaks*.

Some authors give the appellation *aphrodisiaca* to the EPILEPSY.

APHRODISIAS, or APHRODISIUM *Promontorium*, in *Ancient Geography*, a promontory of Caria, near Cnidus.

APHRODISIAS, or *Aphrodisium, Gbeira*, is a town of Caria, towards the north-east, at the confluence of the Corfinus and Timelas.

An island of Libya.

Also, an island in the coast of Bætica, near Gades, and afterwards called *Erythia*.

Also, a town of the island of Cyprus, towards the north-east.

Also, an island in the gulf of Caramania, called by its inhabitants, according to Arrian, *Catæa*.

A town of Laconia.

A country of Asia, in the Eolide.

An island, now *Bona*, on the coast of Africa.

Aphrodisias and Aphrodisium were appellations given to several other places, which it is needless to mention.

APHRODISIUS, in *Chronology*, denotes the eleventh month in the Bithynian year, commencing on the 25th of July in our's.

APHRODITA, in *Natural History*, a genus of VERMES in the mollusca order; the character of which is, body creeping, oblong, covered with scales, and both sides furnished with bristly feet; mouth terminal, cylindrical; feelers two, setaceous and annulated; eyes four. Linn. Gmel. There are only nine species described by authors, and which are, aculeata, scabra, squamata, imbricata, plana, lepidota, cirrhosa, violacea, and longa.

APHRODITA *quarta*, is also the name of one of the marine VERMES in Hill. Hist. An. t. 5, and which has been since named by Linnaeus HOLOTHURIA PENTACTA.

APHRODITARIUM, in the *Ancient Pharmacy*, de-

notes a kind of dry medicine, compounded of frankincense, the scales of copper, celus, starch, and pomegranates, mixed in equal quantities.

The name is also given to a kind of *collyrium*, mentioned by Galen.

APHRODITE, in *Entomology*, a species of PAFILIO in the section Nymph. Phal. The wings are dentated, fulvous, with black spots: the under side of the posterior pair is brown, with 24 silver-coloured spots. Fabricius and Gmelin. This is a native of South America.

APHRODITE, in *Mythology*, a name of Venus, derived from *αφροσ*, *foth*, because, according to the poets, Venus is supposed to be produced from the froth or foam of the sea.

APHRODITES, in *Natural History*, a name given by some authors to the finest species of amethyst. See GEMMA *Veneris*.

APHRODITES, in *Ancient Geography*, the name of an island in the Arabian gulf, near Egypt, according to Ptolemy. M. d'Anville supposes that it was the island called *Sufange-ul-Bebri*.

APHRODITOIDES, in *Natural History*, a species of NEREIS found in the Greenland seas. The body is depressed, without furrows; and the peduncles furnished with cirri and papillæ. Gmelin and Fabr. The head is white, eyes and jaws black, tentaculæ four, two cirri in front, body pellucid; anterior part ochraceous yellow, the rest reddish, with two ferruginous lines along the abdomen. Sometimes, though rarely, it is green, with the ferruginous lines on the abdomen, and transverse reddish lines upon the back.

APHRODITOIS, a species of TEREBELLA that inhabits the Indian ocean; it is about a foot and an half in length, and consists of about 148 segments; the peduncles are fleshy, furnished with a cirrus, and two cirri at the head. The specific character is, body round, and gradually tapering towards the posterior extremity; beneath rather depressed, with an obsolete furrow; the first eight segments destitute of branchiæ, those on the three next simple, and the rest becoming gradually larger, and pinnated on one side. Gmelin, &c. This is nereis aphroditois of Pall. nov. act. Petrop, &c.

APHRODITOPOLIS, in *Ancient Geography*, the name given by Pliny and Ptolemy, to two, and, after them, by M. d'Anville, to three towns in Egypt; and each of the two former the capital of a particular nome. *Aphroditopolis*, in the Heptanomia, upon the right of the Nile, at some distance south from Memphis, is the capital of the 36th nome; and M. d'Anville supposes it to have been succeeded by *Asieb*; but Father Siccard imagines that it is *Bercubel*, a small place at a little distance to the south-west.

Aphroditopolis is also a town of Upper Egypt, and the capital of the 42d nome. This town lay to the left of the Nile, a little north of Ptolemais; and it seems to have been that which Pliny calls *Oppidum Veneris*. M. d'Anville supposes that *Iset* now occupies its situation.

Aphroditopolis belonged also to the nome of Hermonthites; and was situated on the left of the Nile, at a small distance north from Latopolis. M. d'Anville assigns it to the place where *Asfan*, or *Asfoun*, now stands.

APHRODITOPOLITES, a nome of Egypt, the metropolis of which is called by Ptolemy *Crocodylorum civitas*.

APHROGALA, from *αφρος*, *foth*, and *γαλα*, *milk*, in the *Ancient Physic*, denotes a kind of whipt cream, or milk, agitated til it be converted wholly into froth.

A P H T H Æ.

The aphrologa is directed by Galen, as proper against hot disorders of the stomach.

APHROLITRUM, in the *Ancient Physic*, denotes the spume or froth of *litrum*; and seems to amount to the same with *aphrenitrum*.

APHRONITRE. See NITRUM.

APHROSELENOS, among *Ancient Naturalists*, a denomination given to the *Selenites*, or *lapis specularis*.

APHTHÆ, in *Surgery*, from *ἄφθρα*, *incendo*, the *thrush*. By this term are denoted clear, white, pale, livid, painful spots, which appear in the mouth, fauces, and neighbouring parts, of various sizes and shapes; and which generally raise themselves into real vesications, filled with a clear or turbid yellow or bluish fluid. They attack every part of the cavity of the mouth, the trachea, œsophagus, stomach, and intestines: sometimes also they are found in the nostrils. Generally they appear at first in small white points, which are always preceded by a very sensible degree of heat in the mouth and breath of the patient, which gradually increase in size; and sometimes in the space of a few minutes, or more slowly, spread themselves farther, become elevated, and form vesications, which are either round or flattish, and stand either single or in groups. In some cases they soon burst open, or separate themselves at their base; and the contained fluid is either quickly discharged, or is absorbed; and they collapse, or wither away, as it were, and the detached cuticle forms wrinkled white spots, which frequently occupy a larger extent of surface. Sometimes they remain longer elevated, the contained fluid grows thick, and they fall off in scales of a darker yellow colour. Sometimes aphtæ are not of a white colour; for when the morbid matter has long continued its ravages in the system before assistance is procured, or if the aphtæ have not been discovered early enough, they are found sometimes ash-coloured, sometimes lead-coloured, blue, and black, according as either the vitiated humours, or the bottom of the sore, appears through the skin.

After a shorter or longer space of time, they generally detach themselves and fall off, upon which a moisture is seen to cover the ulcerated parts. When this becomes greatly accumulated, a salivation is commonly produced. If the parts do not soon become covered with a new skin, they begin to bleed, and to occasion acute pain. This separation sometimes takes place within a few hours, generally within twelve; sometimes also the sloughs remain for several days, and do not fall off at the same time, but one after the other, in different parts.

Frequently they disappear, but as frequently return again, according as there is a larger or smaller quantity of morbid matter which deposits itself in the mouth, and irritates it. Sometimes the internal surface of the mouth becomes covered with a perfectly white crust, produced by the coalescence of the separate aphtæ, whence a variety of inconveniences are produced; for the symptoms of the disease are exacerbated, and at length putrefescence and gangrene supervene, which takes place the sooner if there be fever at the same time present. In this state the patient can take no nourishment, as he cannot swallow even liquids without intolerable pain and anxiety; and should it be possible to get any thing down, it does not contribute to the nourishment of the body, so that the strength of the body wastes away, and death may at length terminate the sufferings of the patient.

Frequently the aphtæ appear as a primary or idiopathic disease; but more commonly they are symptomatic, or concomitants of other diseases. Some have also asserted, that they may be critical, which however is doubtful, or,

if they ever are so, it is only with adults. In the idiopathic aphtæ, the following symptoms are observed: they appear in children from a week to a fortnight old, sometimes also later. The infant becomes uneasy, sometimes sleeps much, sometimes little; he cries a great deal: his voice grows feeble, shrill, and hoarse; his respiration is very quick and difficult; his pulse uncommonly quick and small, with symptoms of irritation; his mouth, tongue, and the other neighbouring parts, are dry and very hot; this heat extends itself over the whole body without perspiration, and the patient becomes languid, feeble, and spiritless. The infant is very eager for the breast, where the mother feels an intolerable heat; but he is unable to suck, on account of the pain excited by the pressure of the nipple, and the exertion of the muscles requisite in the action of sucking; in consequence of which many infants die for want of nourishment, even before the thrush breaks out.

When aphtæ appear as symptoms or concomitants of other diseases, the febrile symptoms become exacerbated; and they are very apt to appear when the patient has been affected with a diarrhœa at the very commencement of the febrile attack. The patient is moreover troubled with constant nausea, a loathing of food and drink, and sometimes also with vomiting. He feels a sense of anxiety and weight at the pit of the stomach and in the thorax, especially if copious and frequent evacuations have preceded. He feels a sensation as if some hard substance stuck in his throat, especially when he swallows any liquid. If evacuations have been administered, and have produced a discharge of much mucus, bile, and other impurities, and the above mentioned symptoms continue, aphtæ certainly make their appearance. Finally, they are frequently prognosticated by a dulness and stupidity of the senses and understanding, during which the patient is much inclined to sleep, but his sleep is attended with a great deal of dreaming.

It is necessary that the physician or surgeon should be well acquainted with these symptoms, from which the appearance of aphtæ may be prognosticated; for whether they be idiopathic or symptomatic, they are always an unfavourable occurrence, and seldom unattended with danger.

When aphtæ actually make their appearance, they are attended besides with the following symptoms: shortly before they break out, or when they do break out, a sensation of heat and intolerable burning is felt in the mouth. The patient feels as if the whole cavity of his mouth were excoriated or ulcerated; and the slightest touch excites the most acute pain in it. If, at the same time the voice becomes hoarse, with a hollow tone, the fever and uneasiness increase, hiccup supervenes, the tongue becomes very red, with a sense of pain deep in the throat, or about the upper orifice of the stomach, we may conclude with certainty that aphtæ have already been formed in the stomach and œsophagus, which will gradually spread themselves higher up, till they appear also in the fauces. These excite singultus and vomiting, especially with infants. The evacuations by stool are very copious; and infants void, together with the other excrements, lumps of undigested milk. With this copious and preternatural alvine evacuation, fever is often combined during several days. As soon as the aphtæ have spread themselves over the whole internal surface of the mouth, they render mastication, suction, and deglutition extremely difficult to the infant, who therefore continually cries; and when he yawns, he is always affected with violent gripping in the belly, which is attended with a rumbling noise. When the aphtæ have completely broke out, they are accompanied also with a variety of symptoms of different kinds, of which we are to form our judgment, partly according to the colour of the aphtæ,

aphthæ, partly according to the symptoms and course of the disease, of which they are symptoms or concomitants.

The morbid matter by which the aphthæ are produced, is to be sought almost solely in the primæ viæ, where it is formed, particularly with new-born infants, when the first indispensably necessary purgation has been neglected, and also when in any other manner, either by the improper diet of the infant, or also by that of the mother or nurse, occasion has been given to the production of impurities in the primæ viæ. It is prejudicial to suffer the infant to sleep on the breast, as he then keeps some of the milk in his mouth, where it easily becomes spoiled.

This disease may also be produced by the infant receiving unwholesome milk. With many infants, therefore, we may prevent the production of aphthæ, by frequently cleansing their mouths, soon after birth, in order that none of the mucus may remain in them; by evacuating the contents of their intestines by proper purgatives; and by keeping them, in general, clean, and giving them wholesome nourishment.

In the cure of the aphthæ, our first object must be to examine whether they be idiopathic or symptomatic, as each species requires a distinct mode of treatment. The most important general indication of cure, is to endeavour to correct and remove the viscid, acrid, and offensive humours. For this purpose we may administer elder-flower tea, demulcent ptisans, with a little lemon-juice, emulsion of almonds, sweet milk, a dilute decoction of oats or barley, whey, &c. When the infant is affected with the aphthæ in his mouth, the mother or nurse should take these remedies; and, at the same time, it will be very beneficial to plunge the hands and feet of the infant frequently into warm water, or to apply either liquid or vapour-baths with elder-flowers, and other emollient herbs, wheat, bran, soap, &c. Emollient glysters, composed with the above mentioned substances, are particularly to be recommended, as the requisite remedies may thus be introduced into the body, without doing any violence to the mouth, fauces, and throat of the infant; besides that, this manner of administering remedies is the best adapted for infants, who generally neither can nor will swallow them.

The use of much animal food, and whatever can increase the alkaline tendency of the fluids, must particularly be avoided in the diet of the patient, as the quality of the morbid matter would thereby be increased. On the other hand, fresh air, a clean and warm chamber, frequent cleaning of the body, bodily motion, both with children and adults, the application of acidulous vapours, and other substances that sheath or neutralize the alkalies, also fixed air, are to be recommended. The diet of the patient ought in general to be liquid and light, but, at the same time, nourishing, consisting of bread-soups, barley-broth, sago, &c. Panada, made with bread, honey, and wine, boiled in water, is also a good article of food; but with respect to the wine, we ought to be very cautious, in order that we may not increase the irritation in fevers of an inflammatory nature, and when there is already too much irritation in the system. We may administer it more plentifully in diseases of debility and malignant fevers; and the same applies to all aromatic and other stimulant substances.

Our most important object here is to diminish the violence of the fever and the febrile heat. If the fever be an intermittent, cinchona, rad. bened., and other bitter and lightly astringent remedies are proper. In nervous, malignant, or putrid fevers, cinchona, contrayerva, arnica, camphor, and acidulous substances are indicated. But most frequently the fever is either of the inflammatory kind, or at

least it is attended with a considerable degree of febrile heat. In this case we may use warm drinks, a decoction of flor. samb. tilix with spir. vitriol. oxymel simpl. whey with tamarinds, cream of tartar, or other acidulous substances, succ. berb. and rub. itæor. diluted with water, emulsion of poppy seeds with nitre or sal. acetosell. essential; or also the following composition: R. Aq. flor. sambuc. tilix ãã ʒij. nitr. depur. ʒj. fyr. rub. idæi, or acetosell. citr. ʒj. M. D. S. A table-spoonful to be taken every two hours. Many of these remedies may be administered in the form of glysters; injections with sour whey are also particularly to be recommended.

Finally, we must moderate the heat by means of external applications, of which the most approved are the following. R. borac. venet. gr. xxx. folv. in aq. rub. idæi ʒij. adde fyr. rub. id. M. D. S. A sponge, a piece of linen, or a brush of lint to be dipt into it, and the mouth cleaned with it. We may also give a tea-spoonful of it every two or three hours internally, with great advantage. We may likewise administer from time to time aq. acetof. with syrup or honey. Also: R. spir. vitriol. ʒij. fyr. violar. ʒij. aq. commun. ʒiv. M. D. S. A table-spoonful to be taken every hour by adults, and a tea-spoonful by infants, also to be used for washing the mouth. We may also administer, particularly to young children, an ounce of house-leek juice (*sempervivum*), with an equal quantity of honey. Or, according to Mr. Starke, R. borac. venet. ʒj. fyr. moror. ʒj. fyr. papav. alb. ʒss. M. D. S. The mouth to be cleaned with a brush dipped in it.

Besides what has been already said, the following directions are particularly to be attended to: as soon as the idiopathic aphthæ appear, it will be very useful to administer a purgative, either of rhubarb or manna, with some neutral salt, or magnesia and rhubarb, with infants; but with adults, tamarinds and some neutral salt, or the infusion of fenna. When there are bilious or other impurities in the intestines, an emetic with tart. emet. is administered in a dose proportionate to the age of the patient; or with children, sulph. aurat. antim. or laxative glysters. If the patient already complains of great pain in the throat and œsophagus, or even in the belly, these remedies are altogether inadmissible. In the symptomatic aphthæ it depends upon the nature of the primary disease whether it shall be proper to administer any evacuant. Emollient and gently laxative glysters, however, will never do any harm. With these remedies the liquid ones first mentioned are to be combined.

When the aphthæ have actually made their appearance, the above mentioned draughts and remedies are to be administered; with children, frequent injections should be used, and the mouth washed with emollient decoctions, or with figs and honey of roses, or some other acidulous syrup, applied by means of a brush. But when it is observed that they extend lower down than the fauces, or even already form crusts and excite pain, they must be moistened, softened, and gently irritated. We may then apply to the aphthæ a decoction of carrots, or the expressed juice of boiled carrots, with honey of roses, by means of a brush; or we may let the patient swallow a tea-spoonful of this remedy in cases of internal aphthæ. Equally beneficial is also a decoction of the brassica rapa sweetened with sugar, or its expressed juice slightly boiled and sweetened with honey, and its efficacy will be increased if we rub down the peel together with the pulp; we may also use the juice expressed from it after having been roasted, mixed with honey of roses. With these remedies we should frequently wash out the mouth of the patient, or let him use them as gargles; and where there are internal aphthæ some of them must be swallowed down.

We may also boil the brassica rapa in veal broth, and let the patient eat it; and he may either drink the broth, or it may be administered in injections. Sem. lin. boiled in water, and mixed with honey of roses, or any other acidulous syrup, as also the compositions with borax, are very serviceable in these cases.

As external remedies we may use those that have just been mentioned with great advantage, as also the following: macerate sage in warm wine, add some honey, and let the patient's mouth be washed with it; this mixture may be applied to the mouths of infants, even though they should bleed; after which the mouth is to be washed again, by means of a brush, with syrup of mulberries, honey of roses, syrup of quinces, or the juice of four cherries, diluted with an infusion of sage, and two or three drops of the spirit of vitriol; or we may use white vitriol dissolved in barley-water, with the addition of honey of roses; and a decoction of rose-leaves with honey has also produced very good effects. The following remedy has likewise been recommended: ℞. mell. commun. ℥j. borac. vener. ℥ij. alum. ult. ℥fs. aq. rosar. ℥fs. M. D. S. To be applied to a brush, and the mouth cleaned with it. Finally, when the crusts will not separate, we may use the following composition: ℞. spir. cochlear. ℥v. succ. citr. press. ℥j. M. For washing the mouth we may use also the decoction of Peruvian bark.

When the apthæ at first appear discoloured and gangrenous, or become so in the course of time, we should use the following composition: ℞. terr. catech. ℥ij. coq. in aq. calc. lbj. ad rem. ℥viii. colct. add. sacch. saturn. ℥fs. mell. rosar. ℥ij. M. D. S. A table-spoonful to be taken every hour, held for some time in the mouth, and swallowed down slowly. Cinchona administered internally, in injections, and mixed with honey of roses, is likewise recommended. The same mode of treatment is to be pursued with the symptomatic apthæ.

When the apthæ slough off, and the parts become raw, sore, bloody, and painful, the following mucilaginous and gently astringent remedies are useful: mucilag. cydon. with aq. saliv. or ℞. aq. rosar. ℥ij. vitell. ovor. N^o ij. syr. papav. alb. ℥j. crem. tart. ℥fs. M. Also borax with syrup of poppies, emulsion of poppy seeds, and even opium triturated with mucilage of quinces, and diluted with water, may be used with advantage. But if the parts appear discoloured, or the pain in general has abated, we may administer the remedies mentioned just before, as they are of a more astringent nature, and tend to check inflammation and gangrene; also whey with vinegar, the juice of lemons and oranges, or oxymel; a decoction of hb. agrimon. & mel. rosar. is recommended, to which acetos. may be added; also Peruvian bark.

When the apthæ have sloughed off, both in the mouth and other parts, which we may know to be the case when any of them are voided by stool; when a sufficient quantity of strengthening remedies has been employed, which may be known by the abatement of the fever, and the absence of morbid matter in the humours; purgatives, and particularly those of a mucilaginous and tonic nature, are necessary; such as tamarinds, manna, rhubarb, or glysters made with these substances, in order that any impurities that may still remain in the stomach and intestines may completely be evacuated.

Sometimes, however, the apthæ, particularly the symptomatic, produce other peculiar symptoms; as in children, when they alleviate the other symptoms of the disease as soon as they make their appearance, in which case we must endeavour to promote the eruption by means of the above-mentioned decoction of brassica rapa, and other similar re-

medies. When the fever becomes of a malignant and putrid nature, cinchona, serpentaria, contrayerva, mullard with some sp. falis and mell. rosar., also butter-milk, are the proper medicines. When they are of a scorbutic or venereal nature, these morbid poisons must be counteracted by the appropriate remedies.

When the bowels are obstructed, we must loosen them by means of emollient glysters with chamomile flowers, decoction of oats, soap, or oil of almonds. Frequently a violent and exhausting diarrhœa comes on, which is to be checked by mucilaginous medicines, such as corn. cerv. gum arabic dissolved in barley water, with the addition of a quantity of saffron; the same end may also be obtained by means of opium, laud. liq. or tinct. opii and syr. passav. which the mother or nurse may also take; and some time after having taken it give the infant breast. Mucilaginous glysters with theriaca and soap are sometimes very effectual. When a troublesome and pernicious salivation comes on, it must first be treated with mucilaginous and gently astringent remedies, such as mucilag. cydon. aq. saliv. &c. and afterwards with stronger, such as a decoction of rad. tormentill. herb. agrimon. or granate with honey of roses.

The hiccup, with which patients are sometimes attacked, frequently ceases spontaneously; however, nourishing-mucilaginous remedies, combined with a little opium, will contribute much to remove it. With a view to restore the patient's strength, mild, light, and mucilaginous substances must be given him, in order that the stomach and bowels may again become used to food; e. g. barley-water, sago, salep, jelly, and even fenegal. When the stomach has become somewhat accustomed to the reception of these substances, the patient may gradually return to his former diet.

With adults, apthæ occur in various kinds of fever, but particularly in those autumnal fevers which commence with diarrhœa or dysentery, when the impurities of the bowels have not only not been evacuated, but have been detained by the medicines that have been used. Such apthæ have sometimes been observed to be epidemic; and they frequently appear in hectic fevers. The prognosis depends upon the nature of the disease which accompanies the apthæ, and the strength of the patient. It is an unfavourable circumstance when, after the apthæ have made their appearance, the fever returns, the pulse grows small and weak, and the appetite is not restored.

This species of apthæ is to be treated like the rest; but when they are accompanied with a putrid fever, we must be very cautious with regard to the use of evacuating remedies: antiseptic and other appropriate remedies should rather be administered, and these combined with the former. When the apthæ have separated, acrid and too stimulant medicines and food, as also cold air and drink, should be avoided; lest the former should excite inflammation or suppuration in the stomach and bowels, and the latter a new swelling of the mouth, and the most dangerous species of angina.

APHTHARTODOCETÆ, in *Ecclesiastical History*, a sect, sworn enemies to the council of Chalcedon.

The name is derived from ἀφθαρτος, *incorruptible*, and δοξα, *I imagine*; and was given them, because they imagined the body of Jesus Christ was incorruptible and impassible, and not capable of death.

They arose among the Eutychians, and made their first appearance in 535.

APHTHONIUS, in *Biography*, a rhetorician of the third century, wrote a work entitled "Progymnasmata Rhetorica," or Rhetorical Exercises; first published in Greek by Aldus, at Venice, in 1508; afterwards with Her-

mogenes and Longinus, in Svo. at Gen. vi. in 1569; and at Upsal, in 1670, by Scheffer, with a translation and notes. To the same author are ascribed Tables, printed with those of Besop, at Frankfort, in 1610. Suidas. Fabr. Bib. Græc. l. iv. c. 31. § 17. t. iv. p. 449.

APHYA, in *Ichthyology*, a species of CYPRINUS that inhabits in shoals the shores of the northern European seas. The body is pellucid; iris red; and the anal fin contains nine rays. Linn. Gmelin. Müll. According to Fauna Suecica, the dorsal fin contains ten rays; pectoral twelve; ventral seven; anal nine; and caudal nineteen. It is from an inch and an half to four inches and an half in length; is long, thick, round, and covered with scales of a moderate size; above the colour is brown, beneath white or red. Flesh white and savory. Upper jaw rather longest, iride of the eye yellow, encircled with red; lateral line along the middle straight; fins cinereous, greenish at the base.

APHYA is likewise a species of COMBUS found in the Nile and Mediterranean sea. The first dorsal fin has six rays; second sixteen; pectoral eighteen; ventral twelve; anal fourteen; and caudal thirteen. Body and fins barred with brown. Linn. Gmel. Art. &c.

APHYLLANTHES, in *Botany*, (*ἄφυλλος ἄνθος*, a flower without leaves). Linn. gen. 408. Schreb. 576. Juss. 44. Class, *hexandria monogynia*; nat. order of *tripetalicæ junce*, Juss.; Gen. character, *cal.* glumes univalve, lanceolate, several, imbricate; *cor.* petals six, ovate, spreading; *claws* slender, erect, converging into a tube; *stam.* filaments setaceous, shorter than the corolla, inserted into the throat, anthers oblong; *pisil.* germ superior, three-cornered, turbinate; *style* filiform, of the length of the filaments; *stigma*s three, oblong; *per.* capsule turbinate, triangular, trilobular; *seeds* ovate. Species 1, *aphyllanthes montpelienis*; root creeping; culms naked, simple, surrounded at the base with sheaths like the rush; glume two-valved, two-flowered. It grows wild near Montpellier, in barren and rocky places. This plant differs solely from the rush in having a corolla.

APHYLLON. See OROBANCHÆ.

APHYLLUS, formed of *α*, *priv.* and *φυλλον*, a leaf, denotes leafless.

APHYTEIA, a plant having neither root, stem, nor leaves (from *α*, and *φυτεω*). Linn. gen. Schreb. 1104. Amœn. Acad. S. 312. Supp. pl. 48. Hydnoa. Thunb. Act. Holm. 1775. 69. Class, *monadelphia triandria*. Generic character, *cal.* perianth monophyllous, semitrisfid, funnel-shaped, large, fleshy, erect, permanent; *corolla*s, rudiments of three petals, growing to the divisions of the calyx; *stam.* filaments connate at bottom, short; *anthers*, convex, cordate, striated; *pisil.* germ inferior; *style*, thickish, short; *stigma*, triangular, channelled; *per.* a berry, one-celled; *seeds*, numerous, netting. There is one species, *viz.* *Aphyteia hydnoa*, a vegetable without leaves, stem, or root; parasitical, terrestrial, consisting of a single fructification, which is four inches over, sessile, coriaceous, succulent; calyx large, with an erect trisfid border, white within, scutiform. The ripe fruit, which is not unpleasant to the smell, is eaten, both raw and roasted, by the Hottentots. Discovered by Thunberg at the Cape of Good Hope.

APHYTEIA, or APHYTIS, in *Ancient Geography*, a town of Thrace in the Pallena, a peninsula south-west of the Thermaic gulf. Plutarch relates, that when Lyfander laid siege to this town, Jupiter Ammon appeared to him, and ordered him to abandon it.

APIAN, PETER, in *Biography* an eminent astronomer and mathematician, called in German *Bienenwitz*, was born at Loifnich in Misnia, and became professor of mathematics at Ingolstadt, in 1524. He wrote several valuable mathe-

matical and astronomical treatises, and enriched astronomy with many instruments and observations. His first work was a treatise on "Cosmography, or Geographical Instruction," which was published in 1530, and several times republished, particularly by Gemma Frisius. In 1533, he constructed, at Nuremberg, a curious instrument, called from its figure, "Folium populi," which shewed the hour of the day by the sun's rays, in all parts of the earth, and even the unequal hours of the Jews. In 1534, he published his "Inscriptiones orbis;" and in 1540, his "Instrumentum sinuum, sive primi Mobilis," with 120 problems. In the same year his principal work, intitled "Astronomicæ Cæsarum," was published at Ingolstadt; and it contains many interesting observations, with the descriptions and divisions of instruments, calculations of eclipses, and the construction of them in plano. In the second part of this work, or the "Meteorologicum Planum," he describes the construction and use of an accurate astronomical quadrant, and he has annexed to it observations of five different comets, *viz.* those of 1531, 1532, 1533, 1538, and 1539, and here he has first shewn that the tails of comets are always projected in a direction opposite to the sun. The elements of the comet of 1532 were nearly the same with those of one observed 128½ years after, *viz.* in 1661, by Hevelius and others; hence Dr. Halley inferred that they were the same comet, and it was expected in the beginning of the year 1789. But astronomers, either through an error of Apian, or from some other cause, were disappointed. Apian was also the author of many other works, among which may be enumerated the "Ephemerides" from 1534 to 1570; "On Shadows;" "Arithmetical Centilogues;" "The Rule of Cos," or Algebra demonstrated; "On Gauging;" "Almanacs;" "On Conjunctions;" "Books of Eclipses;" "The Works of Ptolemy, in Greek;" the Works of Azoph," an ancient astrologer; "The Works of Gebre;" "The Perspective of Vitellio;" "Of Critical Days, and of the Rainbow;" "A new Astronomical and Geometrical Radius, with various uses of sines and chords;" "Universal Astrolobe of Numbers;" "Maps of the World, and of particular Countries," &c. &c. Apian was treated with great respect by the Emperor Charles V., who published several of his works at his own expence, conferred on him the honour of nobility, and presented him with 3000 crowns of gold. Apian, after a life devoted to study and the improvement of science, died at Ingolstadt in 1552. His son Philip, who survived him, was also an eminent astronomer, and taught mathematics both at Ingolstadt and Tubingen. He was born in 1531, and died in 1589. He has left a treatise on "Solar dials," and other writings. Tycho has preserved his letter to the Landgrave of Hesse, in which he gives an opinion on the new star that appeared in Cassiopeia, in 1572. Voss, de Scient. Montucla Hist. Mathem. tom. i. p. 623. Hutton's Math. Dict. Nonv. Dict. Histor.

APIARIA, in *Entomology*, a species of MUSCA. (Linn.) The anterior part of the thorax is yellow; abdomen black at the apex; tips of the wings ferruginous. Gmelin. This kind inhabits Italy, and somewhat resembles musca mystacea. The antennæ are feathered, front of the head, posterior part of the thorax and abdomen, except the apex, black. Wings obscure. Obs. This is SYRPHUS APIARIUS of Fabricius. Spec. Inf.

APIARIUS, a species of ATTELABUS; bluish, upper wings red, and three black bands; Gmelin. This is the clerus, with red wings, and three bluish bands of Fabricius; the clerus nigro-violaceus hirsutus, &c. of Geoff. Clerus ceruleo-violaceus of Degeer; and dermestes apiarius of Schranck. Found in Europe, America, and Siberia.

APIARY,

APIARY, from *apis*, a bee; a garden or place where bees are kept. The ancient as well as modern writers on bees agree in recommending a southern aspect as the most proper for this purpose; as a general rule bee-hives should be placed in situations that are little exposed to the wind, and enjoy as much of the influence of the sun as possible: as wind always retards the bees in their work, while the sun's beams invite them to it. Thus, though it be well known, that bees will thrive well in high and windy situations, a low one is obviously always to be preferred. In the vicinity of the apiary, there should constantly be abundance of flowers, from which the bees may collect their wax and honey. Mr. Bonner, a late writer on the management of bees, observes, that were a choice allowed him where to place his bees, it should be in an easterly situation, a hollow glen by the side of a rivulet, surrounded with abundance of turnips in blossom in the spring, mustard and clover in summer, and heath in the latter end of autumn and harvest; with a variety of other garden and wild flowers in their seasons. It is not, however, to be understood from this, that bees will not thrive unless they are placed in such an advantageous situation, as the contrary can, he says, be proved; for bees have thriven amazingly well in places where they were not within reach of any of the abovementioned flowers: but although they will do well in most situations, and fly far for their food, yet they will thrive far better when situated among or near good pasture, and surrounded with plenty of food, and Mr. Keys properly remarks that the hives should be clear from the droppings of trees and the annoyance of dung-hills, long grass and weeds, as by these means insects are bred which are not only destructive to the bees, but which greatly retard them in the preparation of honey. See **BEE**, and **BEE-HOUSE**.

APIASTELLUM, in *Botany*, the name of two different species of plants with different authors; Dodonæus expressing by it the common baum; and Apuleius the black bryony.

APIASTER, in *Ornithology*, a species of **MEROPS** found in Europe and Asia. The back is ferruginous; abdomen and tail azure green, the two middle tail feathers long; chin yellow. Linn. Gmel.

This is **MEROPS GALILAEUS** of Hasselquist, **ISPIDA cauda molli** of Kramer, **guépier** of Buffon, **schaeghaghli** of Forskal, and common **BEE-EATER** of English writers. Its length is about ten inches, of which the bill is an inch and three quarters. The pervading colours are green and blue, blending into each other; it has a few whitish feathers at the base of the upper mandible, and on the forehead a space of blue green, behind this another of green, and then succeeds the chestnut colour, tinged with green, and becoming paler on the back. From the bill to the back of the head is a black stripe that surrounds the eyes. Under parts of the body blue-green, palest on the belly. Lesser wing-coverts dull green, middle one rufous, and the greater ones an intermediate colour between both green and rufous. The legs are of a reddish brown, and the claws blackish.

It takes the name of bee-eater because those insects are its usual food; but it pursues and devours other kinds, as gnats, flies, and cicadae, on the wing, like the swallows; and at times will eat various kinds of seeds. Ray supposes, from its similarity to the king's-fisher, it may possibly feed on fish. Willoughby tells us on the testimony of Belon, "that its singular elegance invites the boys in the island of Candia, which it inhabits, to hunt for it with cicadae, as they do for those greater swallows called swifts, after this manner; bending a pin like a hook, and tying it by the head to the end of a thread, they thrust it through a cicada, (as boys bait a hook with a fly), holding the other end of the thread

in their hands; the cicada, so fastened, flies nevertheless in the air, which the merops spying flies after it with all her force; and catching it swallows pin and all, wherewith she is caught." Will. Orn.

APIASTRA, or American king-fisher. See **ALCEDO leucorhyncha**.

APIASTRUM, in *Botany*, a name given by the ancients to two different plants of such contrary form and qualities, that it is unlucky they should have given occasion of confounding them together, as mistakes about them might be of fatal consequence. The one of these plants was the poisonous *water-croxyfoot*; which they called apiastrum, because of its having leaves that somewhat resembled smallage. The other apiastrum is the common garden baum, so called by these writers, from their having observed that the bees were very fond of it.

APICALIS, in *Entomology*, a species of **PHALÆNA**, in form and size resembling *phalæna purpuralis*. It is a native of South America, and its specific character is, according to Fabricius, wings deep yellow, with a brown streak, apex obscure purple, with a yellow spot and two white dots on the margin. Obs. In the Linnæan arrangement, this insect belongs to the *pyralis* section of the *Phalæna* genus: Fabricius places it with the *geometræ*.

APICE, in *Geography*, a town of Italy, in the kingdom of Naples, and Principato Citra; seven miles east-south-east of Benevento.

APICES, SUMMITS, in *Botany*, the same with **ANTHERÆ**.

APICILIA, in *Ancient Geography*, a town of Italy, at some distance east of Concordia, in Carnia.

APICIUS, in *Biography*, a name rendered infamous by the gluttony and epicurism of three persons at Rome, to whom it belonged. The most notorious of these lived under Tiberius; and he is recorded as the inventor of several new sauces and delicacies, and as having kept, as it were, a school of gluttony at Rome. Seneca and Martial inform us, that he squandered away in the gratifications of the table an hundred million of sesterces, which, computed by Mr. Raper's rule for Imperial money (see **SESTERCES**), amounts to about 853,601 l. sterling; and when he found, that, after payment of his debts, he should have but a tenth part of this sum, he poisoned himself for fear of starving. Pliny describes him, in reference to some of the dishes of his invention, as "nepotum omnium altissimus gurgis," i. e. the deepest whirlpool of all spendthrifts. Athenæus (*Deipnos*, lib. iv. p. 168.) mentions another Apicius of similar celebrity, who lived about the year of Rome 660, and was the cause of the banishment of Rutilius. The third Apicius lived under Trajan; and having a secret for preserving oysters, he sent some perfectly fresh to the emperor as far as Parthia. A work "De re culinaris," is extant under the name of Cælius or Cæcilius Apicius, which is supposed to have been written at a later period. Crevier's *Rom. Emp.* vol. ii. p. 227 Gen. Dict.

APICULUM, in *Antiquity*, a kind of thread or fillet which the flammens wore, in the heat of summer, in lieu of the **APEX**.

Festus speaks of the *apiculum* as a cover for the *apex*; but the passage seems to be corrupt.

APIDANUS, in *Entomology*, a species of **PAPILIO** found in Surinam. The wings are tailed, blue; the lower ones, beneath brown, varied with blue; a double golden-coloured spot in the anal angle. Fabricius and Gmelin. Obs. In the Fabrician system it belongs to the **HESPERIA** genus; in that of Linnæus and Gmelin, it stands in the **PAPILIO** genus. (Section *Pleb. rural.*) The wings are edged with black and have a ferruginous spot at the base on the under side.

APIANUS, APIDANO, in *Geography*, a river of Europe in Turkey, which runs into the Peneus, near Larissa.

APIFORMIS, in *Zoology*, a species of MUSCA, found in Germany. It is lary and black; thorax at the base, and felt round the abdomen, yellow; tail whitish. See mark. Cinctus. Pupæ footy, gibbous, found in decayed trees. Obs. This belongs to the section that has the hair of the antennæ naked. There is likewise another insect in the same genus called AFFORMIS by Linnæ: it inhabits Germany; is downy; thorax black with white dots and lines; abdomen yellow with black lines.

AFFORMIS, is also a species of SPHINX, in the Linnæan system, and SERIA in that of Fabricius. The wings are transparent, abounded by low white back belts; thorax black, with two yellow spots on each side. Linn. Fab. It lives in the larva state in the trunks of willow trees. This is sphinx scapigea of Scopoli; sphinx crabroniformis, Wien. Schmett. and sphinx apiformis, hornet sphinx, Donov. Brit. Inf. tom. xxv.

APILAS, in *Ancient Geography*, a river of Macedonia, in Picia.

APINA, a town of Italy, in Daunia.

APION, in *Biography*, a learned grammarian and historian, was born at Oasis in Egypt, about the beginning of the Christian æra; and probably derived his name from Apis, the Egyptian deity. The character of Apion, whatever might be his talents or learning, was that of a pedant, who took pains in investigating and ascertaining matters of trifling importance. Accordingly he took infinite pains, and had even recourse to magic, in order to discover the country and family of Homer. He valued himself on having discovered that the two first letters of the Iliad, considered numerically, amounted to 48, and he fancied that the poet had used these letters designedly to express the number of books. Hence he also concluded that the opening of the first poem was last written. His arrogance and ostentation are justly reprehended by Pliny, when he says (Præf. in Nat. Hist.); "a certain grammarian, named Apion, whom Tiberius called the cymbal of the world, but who might more properly be styled the drum of public fame, boasted that he conferred immortality on those to whom he dedicated any of his writings; an arrogant boast which time has refuted; for all the works of Apion are lost; and his name only lives in the writings of others."

Having been admitted to the citizenship of Alexandria, whence he obtained the appellation of Alexandrinus, he was sent to Caligula as chief of the embassy which carried complaints to the emperor against the Jews; and, on the other hand, Philo and several other deputies were commissioned to justify their conduct. Apion executed his charge with much partiality and rigour, and instead of confining himself to the subject in dispute, preferred charges against the Jews of a foreign nature, which merely tended to exasperate the emperor; accusing them of refusing to consecrate images to him, and to swear by his name. He also wrote a work with the express purpose of fixing reproach upon them, which Josephus refuted in a direct reply "against Apion," which he also designed as an apology for his Jewish antiquities. He wrote, moreover, a learned treatise "On the Antiquities of Egypt," in five books, one of which is cited by Tatian. In this work he also treated so largely on the pyramids of Egypt, that Pliny (Nat. Hist. lib. xxxvi. c. 12.) mentions him as a principal authority on this subject. He also wrote "On the luxury of Apicius;" "On the Roman Tongue;" "On the knowledge of metals;" and on "Universal History." Gen. Dict. Nouv. Dict. Histor.

APIOS, in *Botany*, see GLYCINE and EUPHORBIA.

APIRA, or APEIRA, in *Ancient Geography*, a town mentioned by Homer, and supposed to be that called Apera or Adapera. M. d'Anville places it in Galatia, to the west of Tavium, and south of Halys.

APIRÆ, a town of Asia Minor in Lycia, situate near the sea coast of Andriæ, and south east of Myra.

APIS, MUSCA, the bee, or fly, in *Zytronomy*, a southern constellation, containing four stars; the principal of which is marked by the abbe de la Caille, in his catalogue of stars, for 1750, with 185° 30' 44" of right ascension, and 67° 45' 15" of south declination.

APIS, in *Entomology*, a genus of the HYMENOPTERA order in the Linnæan system, and thus defined in his *Système Naturel*, by Gmelin; mouth hard, jaw and lip membranaceous at the apex; tongue inflected; palpi four, unequal, and filiform, antennæ filiform, and short; wings flat; sting of the females and neuter acute and concealed.

The species are numerous, and divided into several families: in the first are these, linguaria, glauca, longicornis, tumulorum, clavicornis, farfarisqua, curvicornis, centuncularis, punctata, cinctæ, bombyleus, muscaria, hæmorrhoidalis, cineraria, anal's hæmorrhousa, mexicana, carbonaria, retusa, rufa, lunata, bicolor, villosa, pubescens, myllæca, tunetana, bicornis, maxillofa, florea, truncorum, floriformis, flavipes, dentata, cordata, varicolor, mellicica, disjuncta, rufipes, thoracica, flavifrons, cunicularia, argillofa, lagopus, musitans, pilipes, plumipes, manicata, florentina, iricos, maculata, flicica, interrupta, varia, rotundata, erythropus, ferruginea, trispinosa, quadridentata, lanipes, cæcitiens, tridentata, fasciata, barbara, conica, sexenctæ, quadricincta, annulata, smaragdula, albipes, ferruginata, bipunctata, cariosa, dimidiata, latipes, violacea, nigrita, caffra, africana, olivacea, carolina, terrestris, cryptarum, ruderata, nemorum, forocensis, horrorum, pratorum, lapidaria, sylvarum, bryorum, agrorum, muscorum, hypnorum, sibirica, fragrans, lincorum, brasilianorum, acervorum, subterranea, maiorum, furinamentis, virginica, hispanica, antiguenfis, americanorum, aestuans, tropica, fenilis, faminuda, alpina, leucorhoufa, chalcoptera, cyanoptera, melanocephala, grisea, collina, floralis, musciformis, lætuosa, degener, vespiformis, agillissima, fuliginosa, arvensis, fulva, * bryorum, convexa, cetii, leucozonias, leucostoma, hirta, bicincta, hemispherica, fulventris, noveboracensis, albifrons, vesparia, fericea, præcox, vespoidea, sphegoidea, minuta, sanguinolenta, leucopus, leucomelas, lutea, acuminata, fusciventris, nigriventris, cinerascens, lefkii, crocata, literata, nebulosa, fulvipes, annuus, fordida, lutescens, armata, denticulata, rufescens, lutulenta, chrysofoma, ochrocephala, ursina, nigricans, cana, triangulum, rostrata, canescens. The whole of this family is distinguished by a five-cleft tongue, and very short palpi; and are with few exceptions strictly apes of the Fabrician system. (Ent. Syst.) Also, for the character of his genus APIS is, *Os lingua inflexa, quinquefida, palpi brevissimi, antennæ filiformes*; and he includes nearly all the same species as Gmelin.

A trisid tongue is the chief criterion of the second section, which is again subdivided into two families, the first corresponding with the ANDRENA genus of Fabricius, and the second with the NOMADA of the same author. The species of the two subdivisions are these: in the first helvola, bicolor, tricolor, ma'abarica, æthiops, quadrifasciata, succincta, cingulata, virefcens, bidentata, gulosa, dichroa, hirtata, ciliata, zonata, marginella, ænea, labiata, cornuta, cærulefcens, maculosa, flavicornis, fascicornis, subvillosa, rubicornis, guttata. And in the second, fœcica, hattorfiana, gibba, fabriciana, variegata, agrellis, tuscicornis, lineata, scutellans, histrio, riparia, squalida, montana, minor, ranunculi, nufuta, tranquebarorum, morio.

“The industry of these little animals (says an ingenious writer), which is as profitable, as curious in itself, will always continue to excite the admiration of the wiser part of mankind.” Swammerdam, Reaumur, Hagllrom, D’Aubenton, Geoffroy, and others, have written their history with great accuracy. Swammerdam, above all, deserves to be read with the greatest attention. To these may be added the names of several later naturalists, who have bestowed uncommon attention upon their economy and manner of life, as will be more fully noticed in the article BEE, a term by which these creatures are better known to the English reader than that of apis.

In this general term it must notwithstanding be observed many creatures are included, which, in the opinion of naturalists, do not belong to the same family, or even genus. This is obvious on the slightest inspection of a few of the species so named; but whether, on the other hand, the characters laid down, by most of those naturalists, for ascertaining the different families and genera, are not rather more capricious than just, deserves consideration. It is certain that no two writers have yet agreed upon the same characters by which they are to be divided into sections, and each seems to have had his own system for their arrangement.

Linnaeus, to whom a comparatively small number of species was known, contended himself with dividing them into two families, one including those with smooth bodies, or with only a few hairs upon them, *apes proprie dictæ*, and the other *bomblinatrices hirsutissimæ*, with bodies very hairy. These subdivisions have been since found too vague and inapplicable for a number of later discovered species, and even for those Linnaeus had described; for, as Scopoli observes, the noise they make in their flight, and the hair on their bodies, increase so gradually, as to render it uncertain where the first family should terminate, or the second commence: and therefore he divides them in a different manner, into two sections, according to the form of the antennæ, which in some were straight, and in others bent, and forming an angle from the base, *antennis rectis*, and *antennis basi inflexis*; but he then perceived the insufficiency of his own system, as it would unavoidably exclude some species with which he was well acquainted, and for that reason he afterwards divided them into three distinct genera, *viz. eucera, apis, and nomada*.

Geoffroy, after Scopoli, gives this character of his *apes*; I. Abeille, antennes brisées, dont le premier anneau est très-long. Ailes inférieures plus courtes. Bouche armée de machoires, avec une trompe membraneuse cochée en dessous. Aiguillon simple et ca pointé. Ventre attaché au corcelet par un pédicule court. Trois petits yeux lisses. Corps velu. And these are divided into two families. Famille 1^e. Abeilles proprement dites. Corpore villosa. Famille 2^e. Abeilles—bourdons. Corpore hirsutissimo. These characters differ only in one exception from the *vespa* genus of the same author, in which, instead of the body being hairy or downy, it is glabrous.

Degeer divides the *apis* into two genera, *apis* and *nomada*: the first he defines, antennæ fractæ articulo primo longiori; os dentibus et rostro flexili fracto; sursumque plicato; alæ planæ; abdomen thoraci petiolo brevi adnexam; aculeus punctorius in abdomine reconditus; oculi reticulati ovales integri. And the second, antennæ clavate vel filiformes articulis duodecim; os dentibus et rostro porrecto vaginâ cartilagineâ cylindricâ; alæ planæ; abdomen petiolatum; aculeus punctorius in abdomine reconditus; oculi reticulati ovales uniti.

The Fabrician divisions of the *apes* are these: BEMBEX,

HYLÆUS, ANDRENA; APIS, EUCERA, and NOMADA. The character of his genus APIS is, os lingua, inflexa, quinquesida; palpi brevissimi; antennæ filiformes. Ent. Syst. (Tongue inflected, five-tooth; feelers very short; antennæ filiform.)

Gmelin, we think, should rather be commended than censured for the cautious manner in which he has adapted the improvements of the latter writer, to that of his great master, Linnaeus; for had he ventured to divide the genera, and destroy the distinctions Linnaeus had laid down, instead of endeavouring to reduce the newly discovered species to his arrangement, he would have incurred more blame than he has for avoiding it. Some may perhaps think he has been cautious to a fault, and not made those alterations that are absolutely requisite; the arrangement unquestionably demands some amendment.

Rocmer, in his “Genera insectorum Linnæi et Fabricii iconibus illustrata,” gives another definition of APIS, to which it is objected, he introduces more characters than are needful; some of them belonging only to certain families, are consequently not general distinctions. APIS os maxillis dentatis, atque *proboſcide inflexa*, vaginâ duabus bivalvibus linguam includentibus. *Capite triangulare*, fronte plana, flexum. *Antennæ sæpe pedatæ*, primo articulo reliquis longiore. *Alæ planæ*, in omni sexu. *Aculeus punctorius reconditus*, retractilis, ferratus, feminis et neutris. *Tarsi quinque articulis*, primo longitudine tibiæ, compresso, ciliato, transversim sulcato. P. 28.

M. Latreille, about six years since, published a work at Paris, intitled, “Précis des caractères généraux des insectes, disposés dans un ordre naturel,” in which the characters are taken from the antennæ, labium superius, mandibulæ, lingua, maxillæ, tubus and palpi. The APIS, which, like Fabricius, this writer places between nomada and eucera, is thus briefly described; APIS, langue de trois piéces. (Organes de la nutrition plus petits dans les mâles.)

The latest treatise on *apes* is that of the Rev. Wm. Kirby, entitled “Monographia Apum Angliæ,” a book we shall advert to more fully hereafter. It is an attempt to divide into their natural genera and families such species of the Linnaean genus APIS as have been discovered in England; but the introductory and collateral remarks take a wider range. By way of illustration, these include many observations on the class *hymenoptera*, to which they belong; and a comparative view of the exotic species analogous to those he describes. Mr. Kirby first reviews the several characters of the genera into which different authors have divided *apes*, and after pointing out imperfections in each, proceeds to offer an arrangement altogether distinct from either.

His two genera are MELITTA, and APIS: the essential character of the first is, *aculeus punctorius; lingua apice brevis, porrecta, planiuscula, vaginâ subcylindricâ*; and of the second, *aculeus punctorius; lingua elongata, inflexa*. To each of these are added an artificial and a natural character. The artificial character of MELITTA is *os proboſcide subcylindricâ, porrectâ linguam brevem, planiusculam, exerente. Antennæ mediæ, aculeatis subelavate articulis 13; maribus filiformis, articulis 14. Oculi laterales, sub ovales, integri. Alæ planæ. Aculeus punctorius, reconditus*. That of APIS is *os proboſcide fractâ, inflexâ, linguam cylindricam, elongatam, exerente. Antennæ mediæ, aculeatis articulis 13; maribus articulis 14. Oculi laterales, sub ovales, integri. Alæ planæ. Aculeus punctorius reconditus*.

After stating these characters of the two genera MELITTA, and APIS, Mr. Kirby proceeds to mention the distinctions which divide them into families; in which his aim, as he observes, has not been so much to fix upon artificial characters,

acters, which often disunite those insects which nature has put together, but to discover whether the all-wise author of nature, who is a God of order, has not subdivided these genera, and impressed certain common characters upon such subdivisions, by which one who studies his works under no influence but a love of truth, and led by a single desire of finding out *his* system, might not be enabled to arrange them according to their natural affinities.

His first step was to place together all those individuals which appeared to agree in habit, adopting the sentiment of Linnæus, that habit would often lend a clue to discover nature. This led him at first to commit many mistakes; for relying solely on habit for the arrangement of species, he often placed the males in one subdivision, and the females in another; he however succeeded to arrange them very nearly according to their natural affinities, and by attending to the proboscis, and external anatomy, was enabled to detect the constant characteristics of the males in these genera, exclusive of their *genitalia*; and by further observations on those he had an opportunity of taking alive, and inspecting these parts, the mistake alluded to was in a manner rectified, and instead of confusion, lucid order now took place in the arrangement. "Thus (says the author) beginning with habit, and ending with anatomy and economy; descending from generals to particulars, and then tracing back my steps from particulars to generals; using both the synthetical and analytical modes of reasoning, as mathematicians speak, by a series of observations and experiments frequently repeated, I was enabled to trace the labyrinth of nature, and, by the assistance of this double *filum ariadneum*, to establish my system upon a sure basis."

The distinctions of these two families are as follow:
 MELITTA.—* *Lingua* obtusâ,—a. *lingua* obtusâ, apice bilobâ.—b. *lingua* obtusâ, apice truncatâ.—* *Lingua* acutâ.—a. *labio* inflexo, emarginato.—b. *labio* appendiculato, appendiculâ inflexâ.—c. *labio* obtusangulo, tuberculo munito.—APIS.—* *Proboscide* laciniis exterioribus nullis.—a. *Antennis* subclavatis in omni sexu.—b. *Antennis* filiformibus in omni sexu.—* *Proboscide* laciniis exterioribus instructâ.—a. *Palpis* exterioribus 5-articulatis. *Labio* subquadrato.—b. *Palpis* exterioribus exarticulatis. *Labio* anticè curvo.—c. *Labio* inflexo, elongato.—1. *Ventre* femineo glabro.—a. abdomine femineo conico, acutissimo.—β. femineo subeylindrico obtuso.—2. *Ventre* femineo hirsuto.—a. *Palpis* omnibus biarticulatis.—β. *Palpis* exterioribus exarticulatis.—γ. *Palpis* interioribus exarticulatis.—δ. *Palpis* exterioribus 4 articulatis.—d. *Proboscide* rectâ, apice subulato-conicâ; palpis exterioribus 6-articulatis.—1. *Laciniis* interioribus involutis, exteriorum longitudine.—2. *Laciniis* interioribus rectis, quàm exteriores brevioribus.—a. *Labio* quadrato inermi.—β. *Labio* emarginato, tuberculo munito.—c. *Proboscide* subinvolutâ, palpis exterioribus exarticulatis.—1. *Corpore* villosulo.—2. *Corpore* hirsutissimo. Each of these families Mr. Kirby illustrates with figures, in his *Tabularum Explicatio*, and refers all the species he describes to their proper situation in his synopsis specierum, in conformity with this system.

From this comparative view of the different arrangements offered by naturalists for the distribution of BEES into distinct genera, subdivisions or families, it evidently appears a task of some difficulty to point out the true and invariable characters by which they may be arranged with the greatest propriety. Mr. Kirby has done much in behalf of a new mode of arranging them; he has pursued this subject with no common assiduity and skill, and furnished us with an admirably curious treatise, the result of his useful and well-directed labours. Of his accuracy in ascertaining, and integrity in delineating the characters he has chosen, there can

be no distrust; and perhaps there can exist but one objection to his mode of arrangement, and that arises from the difficulty in some instances of perceiving them. All his descriptions were taken, as he himself says, from insects viewed under a lens; an advantage no doubt to him in defining those characters with fidelity, but which at once implies that they are minute, and the lamentable errors he points out by that means in the observations of his predecessors on those parts, prove sufficiently they are ambiguous also. Every naturalist will blame Fabricius for having taken his characters too frequently from the mouth, *Instrumenta cibaria*, and other minute and complicated parts; because, except in recent specimens, it is difficult, nay often impossible to ascertain his distinctions of genera and families, without injuring or destroying the very parts he describes, and frequently not then. Mr. Kirby has, we may believe, endeavoured to avoid this error as far as the subject would permit; and we must only regret that in such able hands, some characters less complicated and minute than those sometimes adopted by him, could not have been found for the arrangement of this curious tribe of creatures.

APIS, in *Geography*, a town of Egypt, on the banks of the lake Marcotis, not far south from Marea. It is mentioned by Herodotus; and Pliny says, it is 62 miles from Paratonium. South-east of this town, and at some distance from the sea, was a mountain of the same name.

APIS was also, according to the Scholiast of Apollonius, a small island near that of Crete.

APIS, in *Mythology*, a symbolical deity, worshipped by the Egyptians in the whole country, and particularly at Memphis. It was an ox, having certain exterior marks, in which animal the soul of the great Osiris was supposed to subsist. This animal was preferred to others, as being the symbol of agriculture, which Osiris had found out, and to the improvement of which he was zealously devoted. He was so famous, that all who visited Egypt had the curiosity to see him, and to render him respect and homage. Alexander conducted his army to Memphis, and according to Arrian, sacrificed to all the gods, and more especially to Apis. Pliny says, that when Germanicus was in the east, he consulted Apis; and the same curiosity which induced Augustus to visit Memphis, induced Titus, Adrian, and Septimius Severus, to follow his example. Apis was an object of worship, not merely on account of his divinity, but because he was consecrated in a peculiar manner to the sun and moon; that is, to Osiris and Isis. Suidas and Ammianus Marcellinus mention his consecration to the moon, and Porphyry expressly says, that this animal bore the characteristic signs of these celestial luminaries. The marks or characters, by which this sacred bull was distinguished from others of the same species, were, his black colour, a white square mark upon his forehead, the figure of an eagle on his back, a lump under his tongue resembling a beetle, and a white spot in the form of a crescent on his right side. These marks were obviously the contrivance of the priests, who secretly brought up the calf that was intended for the Apis. This sacred animal was not produced by the ordinary laws of generation. The Egyptians ascribed his birth to celestial fire; and, as Pintareh informs us, the priests pretended that the moon diffused a generative influence; and that as soon as the cow to whom it was imparted took the bull, she conceived an Apis. When a calf was produced in these circumstances, and with the appropriate marks, the priests announced to the people the birth of Apis. Accordingly, says Ælian (de Anim. lib. xi.), they built a temple to the new god, facing the east, in pursuance of the order of Mercury, and nourished

nourished the young calf with milk for four months. At the close of this period, and at the time of the new moon, the priests repaired to his habitation, and saluted him with the name of Apis. He was then placed in a vessel magnificently decorated, covered with rich tapestry and resplendent with gold, and conducted to Nilopolis, a city of the Nile, with hymns and perfumes. Here they kept him for 40 days, and suffered only women to visit and examine him. After the inauguration of the god in this city, he was conveyed to Memphis with the same retinue of priests, followed by a great number of boats sumptuously adorned. From this time he became sacred to all the world. He was superbly lodged, and the place where he lay was mystically called "the bed." The edifice in which he was kept, and which is particularly described by Strabo (lib. xvii.), was situated near the temple of Vulcan; in a court of which he was occasionally presented to gratify the curiosity of strangers; and he might be seen at all times through a window; but it was the office of the priests to produce him to public view. Once a year, say Pliny, Solinus and Ammianus, they presented a heifer to him, which they killed on the same day. This bull, to which supernatural knowledge was ascribed, is said by the priests to have predicted future events by certain signs and motions, which they interpreted according to their own fancy. Pliny says (lib. viii.), that he had two temples called "beds," which served as an augury to the people. When they came to consult him, if he entered into one of these, the omen was favourable; but if he passed into the other, unpropitious. He also gave answers to individuals, by taking food from their hands; and Ammianus says, that he refused that which was offered him by Germanicus; and that this unfortunate victim of the jealousy of Tiberius was soon after poisoned. The worship that was offered to this deity was very solemn. The people assembled to offer sacrifices to him, and oxen were selected for the victims on this occasion. In every part of Egypt feasts were consecrated in honour of him, and particularly in honour of his birth: they were called "Theophania," the apparition of God, and lasted seven days. "What festivals! (says Ælian) what sacrifices take place in Egypt at the commencement of the inundation! At this time all the people celebrate the birth of Apis. It would be tedious to describe the dances, the rejoicings, the shows, the banquets, to which the Egyptians abandon themselves on this occasion, and impossible to express the intoxication of joy which breaks forth in all the towns of the kingdom."—"During the seven days in which the priests of Memphis celebrate the birth of Apis" (says Ammianus), "the crocodiles forget their natural ferocity, become gentle, and do no injury." This sacred bull, however honoured, had a fixed term assigned to his life: at the termination of 25 years, the priests drowned him in the Nile; and as Pliny says, in the fountain of the priests. This number was the product of five by itself, and gave the number of the letters of the Egyptian alphabet, as well as the age of Apis: and this number marked a period of the sun and moon, to which luminaries the bull was consecrated. Hence it has been inferred, that Apis was the tutelary divinity of the established form given to the solar year, which was to consist invariably of 365 days, and of the cycle of 25 years, discovered at the same time. "Nor can it be doubted," says Savary (Letters, vol. ii. p. 472.), "that he had a marked relation to the swelling of the Nile, for it is testified by a great number of historians. The new moon which followed the summer solstice was the zera of this phenomenon."—The crescent on the right side of Apis indicated, according to Ælian, the commencement

of the inundation. "If Apis," continues Savary, "possessed the characteristic signs which proved his divine origin, he promised fertility and abundance of the fruits of the earth. It seems demonstrated, therefore, that this sacred bull, the guardian of the solar year of 365 days, was also regarded as the genius who presided over the overflowing of the river. The priests, by fixing the course of his life to 25 years, and by making the installation of a new Apis concur with the renewal of the period now mentioned, had probably perceived, as the result of long meteorological observations, that this revolution always brought about abundant seasons. Nothing was better calculated to procure a favourable reception of this emblematical divinity from the people, since his birth was a presage to them of a happy inundation, and of all the treasures of teeming nature." The name *Api* in the Coptic language signifies number, and seems to have referred to the number of cubits which marked the increase of the Nile, that was most advantageous for the fertility of Egypt.

When Apis died, he was embalmed and privately deposited in the subterraneous cavern destined for this purpose. If he died a natural death before the expiration of 25 years, the priests publicly proclaimed his death, and solemnly conveyed his body to the temple of Serapis, at Memphis. Strangers were forbidden to approach the temple, and the priests entered it only when Apis was interred. It was then, says Plutarch, that they opened the gates called *Lihé* and *Coeyté* (of oblivion and lamentation), which are said to have made a harsh and piercing sound. On occasion of the death of Apis, Egypt resounded with the cries and lamentations of those who bewailed it, and the whole country put on mourning. To this purpose Tibullius says, (Eleg. i. 8.)

"Te canit atque suum pubes miratur Osirim,
Barbara, Memphiten plangere docta bovem."

Lucian also represents this circumstance in his usual pleasant manner. "When Apis dies, is there any one so enamoured of his long hair as not immediately to cut it off, or to display on his bald head the symptoms of his sorrow?" This distress and mourning continued till the people had obtained another Apis. Darius Hystaspis, being at Memphis on an occasion of this kind, and observing the consternation of the town, offered 100 talents of gold to any one who discovered a new Apis. Polyænus, Strat. vii. Jablonski, in his "Pantheon Egyptiorum," and M. Huet, bishop of Avranches, and some others, have endeavoured to prove, though not with much success, that Apis was a symbolical image of the patriarch Joseph, and appointed for the commemoration of him. But the hypothesis, that Apis and his worship were symbolical of the Nile, and the circumstances attending it, seems to be more probable. The particulars that have been already recited afford a strong presumption to this purpose. The kind of animal that was selected favours this opinion; for rivers were anciently represented by bulls or oxen. Plutarch says expressly (De Iside & Osiride, Oper. tom. i. p. 66.) that the ox was in Egypt the symbol of the earth. All the mystic phenomena that attended the birth, growth, character, death, and worship of Apis, bore an obvious reference to the agriculture of Egypt, and the fertility occasioned by the inundation of the Nile.

Dr. Bryant apprehends that the name of Apis was an Egyptian term for a father, that it referred to the patriarch Noah, and that the crescent, which was usually marked on the side of the animal, was a representation of the ark. Anc. Mythol. vol. ii. p. 420.

Jablonski (*ubi supra*) fixes the zera of the consecration of the

the first Apis at the year 1171 before the vulgar era of Chool; a d, according to the same writer, it ceased at Memphis, under the reign of Thebes, together with that of Sais, at Alexandria; and he assigns a period of 1535 years for its whole duration.

Apis is represented on the Greek medals in the form of a bull, with a flower of the lotos, the water-lily of the Nile, supposed by Microbius to be a symbol of the creation. On the medals of Adrian and Antoninus Pius, struck in Egypt, and on a marble preserved in the cabinet of Odel-chalene, he is delineated with the crescent on his side.

APIS, in *Falubus History*, the son of Phoroneus, second king of Argos, who settled in Egypt, according to the fables of the Greeks, and made himself so famous, that after his death he was ranked among the gods, under the name of SERAPIS.

APIYANI, in *Ancient Geography*, a people of Arabia Felix, according to Pliny.

APITES VINUM, from *απις*, the pear tree; *περυσ*, wine of pears. See PERRY.

APIUM, (perhaps from *Apes*, bees, because these insects are found on it,) in *Botany*, a genus of plants, including parsley, smallage, and celery. Lin. Gen. 167. Schreb. 429. Juss. 219. Chas. *pentandria digynia*; natural or fewer of umbellata, gen. character, *cal. general* umbel of several rays than those of the partial; *general* involucre small, of one or more leaflets; *partial* similar; *proper perianth* obsolete; *cor. general* uniform; *stamules* almost all fertile; *petals* roundish; *inflex*, equal; *filam.* filaments simple; *anthers* roundish; *pist.* germ inferior; *styles* reflex; *stigmas* obtuse; *per.* none; *fruit* ovate, striate, splitting in two; *seeds* two, ovate, striated on one side, plane on the other. Ell. gen. char. *fruit* ovate, striated; *invol.* one-leaved; *petals* equal.—Species 1. *A. petroselinum*, common parsley, stem leaflets linear; involucre minute; the stems are round, smooth, striated. At the origin of the universal umbel there is usually one leaflet, and an involucre of six or eight short folioles, almost as fine as hairs, at the partial umbel. Flowers pale yellow, regular; petals small, long, narrow, acornate, inflex. It is a biennial plant, and generally cultivated for culinary purposes. Linnæus found it growing wild in Sardinia. The varieties of parsley are *α. A. sativum*, common garden parsley. Word. Med. B. t. lxxiii. *β. A. crispum*, curled parsley. *γ. A. latifolium*, large rooted parsley. *δ. A. graveolens* smallage, or wild celery, stem leaves wedge shaped. This is also a biennial plant, rising with a smooth, shining, deeply furrowed stem; leaves alternate, radical, pinnated, ternate; pinnae trifid, gash-ferrate, shining, smooth; umbels axillary; with about fifteen unequal rays; flowers small, white; seeds minute. It grows wild in ditches and marshes, in which state it is acid and fetid. Smith's Flor. B. 535. Miller states the varieties of this plant as follow; *β. A. dulce*, upright celery; *γ. A. rapaceum*, celeriac or turnip-rooted celery; *δ. A. hispanicum*, Portugal celery.

In regard to the medicinal properties of parsley, Doctor Woodville, in his Medical Botany, remarks, that both the roots and seeds are directed to be employed by the London College; the former of which have a sweet taste, accompanied with a slight degree of warmth, or flavour resembling that of a carrot; but that the latter are warmer in taste and more aromatic than any other part of the plant, and also manifest a considerable degree of bitterness. In distillation, three pounds were found to yield above an ounce of essential oil, a great part of which sunk in the fluid. They give out little of their qualities by infusion in watery menstrua, but readily impart all their virtue to rectified

spirit. The roots by distillation in water were ascertained to afford but a very inconsiderable portion of essential oil, not more than two or three drachms from as many hundred pounds. These roots are said to be aperient and diuretic, and have been employed in apozems, to relieve nephritic pains, and obstructions of urine. In this way they have been preferred by Dr. Cullen, without producing any diuretic effect; and this, he thinks, may in some measure be attributed to the loss of their active matter, which they sustain by boiling.

The seeds, like those of many other umbelliferous plants, possess a strong aromatic and carminative power; but as this is inconsiderable, they are now seldom employed. They are stated, it is observed, to have been advantageously made use of externally for removing cutaneous diseases in children, by Con. Mich. Vekinski, in Act. Nat. Cur. vol. 1. p. 287; and by Rosenfeld in Bur's Junkd. ed. 3. p. 533.

The bruised leaves have been successfully made use of as a discutient poultice to various kinds of tumours. We are told, Dr. Woodville says, by Large (Misc. Ver. t. Med. p. 26), that this application has succeeded in scirrhus tumours where cicuta and mercury have failed.

Although parsley is so commonly used at table, it is remarkable, says the above writer, that facts have been adduced to prove that in some constitutions it occasions epilepsy, or at least aggravates the epileptic fits in those who are subject to this disease. It has been supposed also to produce inflammation in the eyes.

APIUM *Macedonicum*. See PUBON.

APIUM *petraeum* and *montanum*. See ATHAMANTA.

APIUM, *Pyrenaicum*. See CRITIMUM.

APIUM, in *Gardening*, comprehends parsley, celery, and smallage, of which there are several species cultivated in the kitchen-garden; as the *A. petroselinum* or common parsley, which has two varieties, the common plane-leaved, and the curled-leaved; the *A. latifolium*, or broad leaved, large-rooted parsley; the *A. dulce*, sweet, or common upright celery; of which the following varieties are cultivated: the common upright, with the stalks of the leaves hollow or fistular; the common upright, with the stalks of the leaves solid, generally known by the names of hollow and solid celery, the *giant upright*, that grows very tall, with a large body of thick fleshy leaf-stalks; the *A. rapaceum*, or turnip-rooted spreading celery or celeriac; and the *A. graveolens*, or smallage; all of which are herbaceous plants, of hardy growth, and of the biennial tribe, or of two years duration, producing only leaves the first year, but attaining perfection for kitchen and other domestic uses. The second spring they however, shoot up stalks, flower, and perfect their seed; and in autumn perish both in root and branch, so that they continue useful only one year, and therefore a fresh supply must be raised annually from seed. Some of the species may, however, be deemed annual, as if sown very early, they run to seed the same year, especially in the celery kind.

Of the *A. petroselinum*, or common parsley, both the varieties are in use; but it is remarked by the authors of the Universal Gardener, that the plane-leaved sort is most commonly cultivated, though many prefer the curled kind, because its leaves are much easily distinguished from the *achusa*, or d's parsley, a sort of hemlock, and a poisonous garden-weed, which, while young, has great resemblance to the common plane-leaved parsley. Besides, the curled parsley, from its having larger and thicker leaves, and being curiously fabricated and curled, so as to show full and double, makes a better appearance in its growth, and is

more esteemed by cooks for the purpose of garnishing dishes, &c. It may, however, be necessary to remark, that this sort, as being only a variety, is liable to degenerate to the common plane sort, unless particular care be taken to save the seed always from the perfect, full curled plants. Both the varieties are propagated by seed sown annually in spring, where the plants are to remain; but the plants, as has been seen, are biennials, rising from seed sown in March, April, and May.

The proper season for sowing the different varieties, is any time from the beginning of February until the beginning of May; but they will grow at almost any time of the year; however, in order to have the plants come into use by the time the old parsley begins to run, it is necessary to sow first about the time just mentioned. The best method for which is in drills, as it will be thus not only more conveniently kept clean and more easily gathered, but have a neater appearance. Where only a sufficiency is required for the supply of a family, it may be sown in single drills along the edges of the borders, or the quarters of the kitchen-garden, the plants thus serving the double purpose of utility and edging; but for the supply of markets, gardeners generally sow it in large plats, either in broad-cast, raking it in, or in shallow drills, at eight or nine inches distance from each other, trimming the earth evenly over it, near half an inch deep, and then lightly raking the surface, to give it a degree of smoothness. Seed of this kind is extremely slow in vegetating, sometimes not appearing in less than a month or five weeks from the period of its being sown.

The chief culture the plants require while growing, is to be kept clean from weeds; and when they grow faster than wanted, which is often the case in private gardens, to be cut down close. This should be constantly practised in autumn, as about Michaelmas, or in sufficient time for the plants to recover before the winter sets in.

In order to save the seed, some rows of the one year old plants must be permitted to stand, and shoot up their stalks, which is done in May and June following, the seed being ripened in July and August.

A. latifolium, or broad-leaved parsley. The propagation of this species is also by seed sown annually in February, March, or April, where the plants are to remain. For this purpose, a spot of light rich earth, in an open exposure, is to be preferred; the seed being sown broad-cast, and raked in, the plants generally appearing in about a month after being sown, and in May or June they require to be thinned and cleared from weeds, which may be performed either by hand or hoe; but the latter is most eligible, as it will stir and loosen the surface of the earth, which may be beneficial to the plants, cutting them out to about six inches distance from each other.

In the latter end of July, the roots will mostly have attained a size proper for use; and may be drawn occasionally; but they seldom acquire their full growth till about Michaelmas.

This is sometimes called *Hamburg parsley*, probably from its being much cultivated about that place.

It is chiefly cultivated and esteemed for its large roots, which are white and carrot-shaped, being long, taper, and of downright growth, often attaining the size and appearance of the middling parsneps; they boil exceedingly tender and palatable, are very wholesome, and may be used in soup or broth, or to eat like carrots and parsneps, or as sauce to both meat.

A. dulce, or the common celery. The method of propagation in all the varieties of this sort is, by sowing the seed in the spring, and when the plants have attained six or eight inches in height, transplanting them into trenches in the

manner described below, in order to be earthed up on each side as they advance in growth, and have their stalks blanched or whitened, to render them crisp and tender.

As plants of this kind continue useful only one year, a fresh supply must be raised annually, as has been already observed.

The proper periods of sowing, if a regular succession of plants be required for eight or nine months in the year, are at two or three different times from the beginning of March till the middle of May. As, for example, if it is intended to have celery for use as early as possible in the summer, as in July, some seed must be sown the first week in March on a warm border; or to bring the plants more forward, in a slender hot bed; or if it be necessary to have it still more early, the middle of February; but as the plants of these very early sowings are apt to pipe or run for seed the same year, before they attain their perfection, a few only need be raised. But for the principal crops, to come in for autumn and winter, as in August or September, and continue in perfection till Christmas or spring, the seed may be sown about the middle or towards the latter end of March, or in the first or second week in April, in a bed of natural earth in an open exposure; and a little more in the latter end of the last named month, or in the first or second week in May, to furnish a still later crop to come in the beginning of November, and continue good until the March or April following; and to have a late crop principally for the spring, it will be necessary that a small portion be sown at the latter end of May; and by putting out some of the plants in shallow trenches about Michaelmas, and in October and November, they may be fit for use in March and April, and continue without running till the middle or latter end of the May following.

As it has been suggested, that the early crop may either be sown upon a warm border of natural earth, or upon a slight hot-bed, it may be observed, that by the latter practice, the plants may be so forwarded, as to be fit to transplant into trenches sooner by three weeks or a month, than those raised in the natural ground; a small bed of about eighteen or twenty inches deep of dung will be sufficient, which may be sheltered either with a small frame, or occasionally with mats supported on arches made with sticks; upon this five or six inches of rich light earth should be laid, the seed being then sown on the surface, and covered near a quarter of an inch deep; when the plants appear, the full air must be freely admitted in mild days, but sheltered with a glass or mats in the nights until they acquire some strength, frequent light waterings being occasionally given: when the plants of either of the sowings are two inches high, some of the finest should be pricked out into a bed of rich earth, in a sheltered situation, three inches apart; or to bring them still more forward, upon a slender hot bed, and occasionally sheltered with mats, giving them water, and occasionally shade, till they have struck root; and if rain do not fall, refreshing them as frequently with water as may be necessary.

As those that were thus first pricked out will, in May or the beginning of June, be generally five or six inches high, some of the strongest of them should be transplanted into trenches, in order to their being blanched. In regard to sowing the main and later crops at several times as have been recommended, make choice of a spot of rich light earth, in an open situation, and let it be neatly dug and divided into one or more beds; but one bed is generally sufficient for private use, which should be three feet and a half wide, the surface being made level and smooth. The seed may then either be sown on the surface, and raked in lightly, or the surface first raked nice, the seed then sown, earth being lifted over it near a quarter of an inch thick; or the bed being first raked smooth as above, the earth may be shoveled with the

back of a rake from off the surface a quarter of an inch deep into the alley; the seed then be sown, and with the rake turned the right way, the earth drawn up on the bed again with a kind of jerk, so that it may spread and cover it equally.

When the plants of these sowings are come up, they should be frequently watered in dry weather, especially while they are young. And when about three or four inches high, the seed-bed should be thinned by pricking out a quantity of the strongest into an open rich spot, properly dug and divided into beds three feet and a half wide, taking an opportunity, if possible, of moist weather, and in rows six inches asunder, and three or four inches distant in each row, water being given, and if dry weather succeeds, occasionally repeated till they strike fresh root; in this bed, they are to remain a month, or five or six weeks, to acquire due strength previous to their being transplanted into trenches, in order for blanching. The same seed-bed will frequently afford three, four, or more different drawings, to prick out in this way, by observing to thin out the largest plants regularly each time, before they draw each other weak by close standing; and by thus pricking them in beds till the ground intended for the trenches is at liberty, they will be advancing in their growth, and be considerably better prepared for setting out, than such as have remained all the time in the seed-bed.

The next business is that of transplanting them into the trenches for the purpose of blanching; the season for which is occasionally from the middle of May till the latter end of October, or even middle of November, according to the forwardness of the plants, the time they are required for use, and the period it is intended they shall continue. When the plants are from about six to ten or twelve inches high, as has been observed, they are of a proper size for transplanting into the trenches.

It is necessary always to make at least three different transplantations, allowing the distance of three or four weeks between each time of planting; but when the plants are required for use as early in summer as possible, and to be continued in spring as late as the middle or latter end of May, it is eligible to plant four, five, or even six different crops, allowing the distance of time abovementioned between the planting of each separate crop; observing that the crops intended principally for spring use be of the latest sown plants, and not planted in the trenches until September, October, and beginning of November.

In making the trenches, chuse a dry rich spot of ground, in an open quarter, and with a line and spade mark and chop out the trenches crossways of the piece of ground, each trench twelve inches, or about one spade breadth wide, and allow a space of three feet between trench and trench, that there may be sufficient scope to have a due portion of mould to earth up the plants to a proper height; the trenches being marked in this manner, proceed to dig them out in order to form the furrow for the reception of the plants, which should be done lengthways to the depth of a moderate spade, or about six or eight inches for the early crops; but the later ones do not require so much, without taking out any shovellings, laying the spits of earth alternately to the right and left in the spaces between, levelling it neatly, and beating up the edges firm and straight; then let the bottom be properly dug and levelled, or if the ground be poor, first spread therein two or three inches depth of rotten dung, and dig it in four or five inches deep.

The trenches being thus prepared, a quantity of the best plants must be drawn, the ends of their roots, and the tops of the straggling leaves trimmed off; then a row planted ex-

actly along the middle of each trench, placing the plants four or five inches distant, a good watering being immediately given out of a pot with the rose on, and which, if showers do not fall, should be repeated every other evening at least, till the plants have taken fresh root.

Only a few of the very early plants, as those sown in February, or early in March, should be planted out at a time, as they are apt to pipe almost as soon as they are blanched, or sometimes before it is fully effected.

When it happens that the plants intended to be planted in autumn, for the late crops, have, by the allotted compartment of ground for their reception not being vacant, stood so long in the seed or pricking-out beds as to have become rank, and drawn each other up weak, it may be proper to retard their running up tall, in order to obtain them of robust growth against October and November, for planting them in shallow trenches; to effect this, it will be adviseable, in August or the beginning of September, either to cut them down low to shoot out again, or transplant them into rows nine inches distant.

Another method of planting and making the trenches, but which is less in use, is with a line and spade to cut or mark out a bed, or rather trench, six feet wide, crossways the ground; then to begin at one end, and proceed to dig out a cavity the above width and length, one spade deep, laying the spits of earth to the right and left, in a ridge along each side of the cavity or trench, beating it up in front that it may not slip down; and when the trench is thus dug, to loosen and level the bottom; and where dung is necessary, to add it, digging it into the bottom four or five inches deep. When more than one of such trenches are to be made, a clear space of six feet must be allowed between trench and trench, to contain the earth dug out, and to have a sufficiency to bring up to the plants afterwards.

The trenches being thus prepared, the plants are to be trimmed as before directed, and then planted, observing that they are here to be planted in rows crossways the trench, about a foot asunder, and in other respects as in the other method.

The plants of this sort, in order to whiten or blanch the stalks, and render them crisp, tender, and of a grateful flavour, require to be earthed up as they rise in height on each side, for which purpose the earth that was dug out of the trenches is to be employed; and when that is expended, that in the spaces between them must be dug out, broken, and applied repeatedly as the plants advance in growth, in this way blanching them from ten or twelve to fifteen or eighteen inches or more in height.

The proper time to begin this work, is when the plants are about ten or twelve inches high, which should be repeated every fortnight or three weeks, as may be necessary, during their principal growth. In performing the work, regard must be had to break the earth, where lumpy, moderately small with the spade: or the first and second earthing may be performed with a large hoe, but afterwards in the principal earthings a spade is to be preferred, and care taken to trim the earth up lightly to the plants, so as not to break the stalks of the leaves, or force the mould into their hearts. The first time, they may be earthed three, four, or five inches, according to the size and height of the plants, observing the same rule at each time, till they are by degrees earthed to twelve inches, but fifteen or twenty are better. By this means, if the soil be rich, those of the main crop that have been planted out in the end of June or in July, sometimes make such progress, that by September or October they may be blanched eighteen inches, or near two feet in length. These earthings are to be continued to the later

crops occasionally, until Christmas, or as long as the plants continue to grow in height during the winter, at which season, as about November and December, it is proper to earth them up pretty near their tops previously to hard frost setting in, which often destroys such plants as are out of the ground, and which, if of considerable duration, would occasion the decay of most of the other parts that are within the earth.

But in the late crops, planted in October or November for spring use, such plants as are of small or low growth, will probably require but little or no earthing till February or March, at which time they should be earthed up moderately, according to their growth, to have them for use in April and May, when the general crops are finished.

In earthing up the plants that are planted in the latter of the above methods, it will be necessary to trim the earth in well between the rows, taking it equally from the different sides; in doing which, it is of advantage, where the plants have attained a large growth, to be furnished with a couple of thin boards, six feet long; which are to be used at the time of earthing, to slip into the spaces between the rows of plants, to keep the stalks and leaves up close just till the earth is put in, placing them close to the plants, and then trimming in the earth between them; and when one space is thus earthed, drawing out the boards, and placing them in the next.

The different earthings should always, if possible, be performed when the plants are dry, as where this circumstance is not attended to, they are apt to become spotted and cankered.

Some of the first earthed-up plants, where they have been planted in the trenches in May, or the beginning of June, will generally be fit to take up in July; for when such early plants are blanched five or six inches in length, it is time to begin to take them up, as they rarely continue long before they begin to pipe and become useless.

But the plants of the main crop will seldom be blanched any considerable length, till the middle or latter end of August, and beginning of September, and will not have acquired their full perfection until October, as observed above. However, where there is much demand for the plants, you may begin to take some up, when they are blanched six or seven inches, as, if properly followed with earthing, they will be daily increasing in length in the blanched part.

In winter, at the approach of very severe frost, it may sometimes be of advantage to cover some of the rows of the main crop with dry long litter to save the plants, and prevent the ground being frozen hard, that the plants may be readily dug up when wanted. And when a hard frost is expected, a quantity of the plants may be taken up for use, and laid in some dry earth in a shed, or other sheltered place.

A. rapaceum, or the turnip-rooted celery. This is likewise propagated by seeds, sown in an open rich spot in March or April, as directed for the common sort; and when the plants are an inch or two high, they are to be thinned to three inches; and at four, five, or six inches in height, transplanted into shallow trenches; previously to which the ground must be dug all over one spade deep, and drills three inches deep and eighteen asunder, made with a hoe, in which the plants are to be set six inches distant.

When they are advanced nine or ten inches in growth, observe the progress of the roots, and if they have acquired a tolerable size, draw earth up to each side of the row of plants, three or four inches high, which, being well watered, will be sufficient to improve the roots. They are generally fit to take up for use in a fortnight or three weeks afterwards.

A. graveolens, or smallage. This is a plant of the weed kind, and but seldom cultivated in the garden. If wanted, it may, however, be easily raised in the spring.

APIVORUS, in *Ornithology*, a species of the *FALCO* genus. The cere is black; feet half naked and yellow; head grey; tail banded with cinereous colour, and white at the tip. Linn.

This is a very variable bird in respect of its colour, and scarcely any two authors agree in describing it. The length of one specimen is twenty-three inches; weight thirty-eight ounces. The bill and cere black; irides golden yellow; head ash-coloured; neck, back, scapulars, and wing coverts deep brown; the chin nearly white streaked with narrow brown lines; fore part of the neck rufous, breast and belly barred with transverse regular bars of rufous brown and white, each feather being white with two bars across it. Tail brown, with two dusky bars, one in the middle and the other near the end. Legs short, yellow, claws black. Lath. Gen. Syn.

One described in the British Zoology about the same size had the chin white, breast and belly of the same colour, marked with dusky spots, pointing downwards; and the tail long, of a dull brown colour, marked with three broad dusky bars, between each of which were two or three of the same colour, but narrower. Another, supposed to be the female, being shot on the nest, is noticed in the supplement of the folio Zoology of Pennant; it was entirely of a deep brown, but had much the same marks on the wings and tail as the male; and the head was tinged with ash colour. Linnæus says, the tail has only one cinereous band across; the side tail feathers are banded with white, and spotted with brown, according to Brisson; and Albin's bird had no bars on the tail.

The honey-buzzard inhabits various parts of the continent of Europe, but is no where common except in the open parts of Russia and Siberia; is seen as far north as Soudonor in Norway; in England is scarcely ever met with.

It feeds on larvae of bees and wasps, and on frogs and lizards; the eggs are of a deep red brown, with ferruginous blotches. This is the *BUTEO APIVORUS* of Ray, la bondrée of Brisson and Buffon, le goiran ou bondrée of Belon, and honey-buzzard of Albin. Pennant, Brit. Zool. and Donov. Brit. Birds, t. 30.

APLANATIC, formed of *α, priv.* and *πλαναω, erro*, in *Optics*, a term applied by Dr. Blair, professor of practical astronomy in the university of Edinburgh, to that kind of refraction discovered by himself, which entirely corrects the aberration of the rays of light, and the colour depending upon it, in contradistinction to the word *achromatic*, which has been appropriated to that refraction, in which there is only a partial correction of colour. After a variety of researches and experiments, detailed at large in a paper read before the Royal Society at Edinburgh, in 1791, and published in the third volume of their Transactions, he discovered a mixture of solutions of ammoniacal and mercurial salts, and also some other substances, which produced dispersions proportional to that of glass, with respect to the different colours; and he proceeded to construct a compound lens, consisting of a semi-convex one of crown glass, with its flat side towards the object, and a meniscus of the same materials, with its convex side in the same direction, and its flatter concave next to the eye; and the interval between these lenses he filled with a solution of antimony in a certain proportion of muriatic acid. The lens, thus artificially adapted, did not manifest the slightest vestige of an extraneous colour. His discovery is undoubtedly valuable and important, and may lead to a very useful improvement in the construction of telescopes. Dr. Blair obtained a patent for his invention of a method of

improving the refracting telescopes, and other dioptrical instruments, in 1791. See ABERRATION and TELESCOPE.

APLEBECK, in *Geography*, a town of Germany, in the circle of Westphalia and county of Mark, three miles south from Dortmund.

APLOGA, a district of the kingdom of Whidah, on the Slave coast in Africa, where is held a regular market for slaves, cows, sheep, goats, birds, apes, cloth, cotton, calicoes, silk, stuffs, china, mercury, gold in dust and ingots, &c.

A-PLOMB is a very expressive French term in *music* and dancing, for exactness and precision in time, or measure. To say that a vocal or instrumental performer has an exact *à-plomb* is pronouncing him or her to be a good tunist. So a dancer who falls on his feet precisely at the beginning of a bar, or the end of a period or movement, is said to have a good *à-plomb*—the highest praise that can be given him. A leader on the violin, who in *tempo rubato* (borrows time which he never pays), drags a note beyond its due length, and arrives not at the beginning of a bar at the same instant as the rest of the band, has no *à-plomb*. It seems as if the old refinement of *tempo rubato*, and the new one of *relentando*, could only be safely practised in solos, or solo passages, as great confusion must arise in an orchestra by the *relentandos* and accelerations of an individual performer, if the rest are not apprised of the leader's intention.

APLUDA (the name of the chaff, &c. that lies off from grain), in *Botany*, a plant of the grass kind, Lin. gen. 1147. Schreb. 1571. Gertn. t. 1. 5. Juss. 33. Class, *polygamia monœcia*; natural order of *gramina*.

Generic Character. *Calyx*, involucre-common univalve; valve ovate, concave, terminated by a very short point or leaflet, two-flowered; the inferior flower sessile, short at the base, ovate, truncate, hollow down into the two opposite foot-stalks, which are glutinous, flat, vertical; on one of these is placed the superior flower, on the other a very short rudiment of a flower; inferior flower hermaphrodite, almost wholly concealed between the foot stalks; *calyx* involucre-proper univalve; valvelet lanceolate, compressed, rigid, double-toothed at the tip, smooth, embracing the flower with its margins beneath, opposite to the common involucre; glume one-flowered, two-valved; valvelets membranaceous, transparent, shorter than the involucre; the exterior navicular, gibbous on the back, keeled, contracted towards the tip, acuminate; the interior ventricose somewhat sharp, smaller; *corolla*, glume bivalve, membranaceous, very thin, transparent; valve exterior navicular, compressed, smooth, greenish, gibbous on the back, bifid, acute, awned below the tip, concealed within the exterior valve of the calyx; the interior lanceolate, flat, acute, doubled together at each margin, the exterior rather longer; nectary very small, two-leaved, truncate-rounded, greenish; *stamina*, filaments three, capillary; anthers linear, bifid on each side; *stigma*, germ oblong, small; styles two, capillary, erect; stigmas oblong, villose, protruding on each side of the flower; *perispermium* none; corolla cherishes the seed, which is ovate-oblong, compressed and smooth; flower-superior smaller; *achæna*, glume two-flowered, two-valved; valves lanceolate, broadish, flat, sharp, nervose, nearly equal; one floscule female, the other male or neuter; *corolla* of the female a bivalve glume; valves membranaceous, greenish; the exterior ventricose, conered, pointed; the interior lanceolate, narrower, shorter, obtuse; of the male, glume bivalve; valves lanceolate, membranaceous, greenish; the exterior rather ventricose, sharp; the interior narrower, shorter; nectary in both as in the inferior flower, and also the stamens of the male, and pubes of the female flowers. It has been observed, that sometimes each floscule of the superior flower is male.

Essential generic character. *Calyx*, glume common, bivalve;

female floret sessile, males peduncled; male, *calyx* none; *corolla* bivalve; *stamina* three; female *calyx* none; *corolla* bivalve; style one; seed one, covered.

Species. 1. *A. nutica*, leaves lanceolate, all the flowers awnlets; culms very long, weak, smooth, swelled at the joints; leaves long, flat, narrowed at the sheath into a petiole; panicles small, lateral: a native of India. 2. *A. ariflata*, leaves lanceolate; male flowers awnlets, except one at the end, which is awned and sessile; culms a foot long, insected; leaves rough, petiolate; racemes axillary; flowers in threes: a native of India. 3. *A. zugites*, mountain-reed-grass, leaves ovate, flowers similar to those of the *ariflata*; culms from one to two feet in height, filiform, jointed; leaves subpetioled, acute, nerved, reticulate, smooth; panicle spreading, few-flowered: a native of Jamaica, where it was found by Brown. See his Jan. 341. t. 4. f. 3. 4. *A. digitata*, spikes digitate; flowers all pointing in the same direction: a lofty East-Indian grass, discovered by Thunberg.

APLUSTRE, or AMPLUSTRE, in the *Ancient Naval Architecture*, a carved tablet, somewhat after the manner of a shield, fixed by way of decoration to the extremity of a ship's head. This ornament was in the stern, and sometimes on the prow, and from it was erected a staff or pole, with a ribbon or streamer on the top. It answered to the Greek *aplustum*.

The *rostra*, or beaks of ships, were sometimes also called *aplustria*.

But some think that the aplustre answered to what we call the flag, or ensign.

APNOEA, from α and $\nu\epsilon\omega$, *I breathe*, in *Medicine*, denotes a want of breath, or loss of respiration.

In this sense is the word used among the ancients, not as importing a total privation of breath, which would only be another name for death; but to denote the respiration very small and slow, so as to seem quite gone, as is the case in suffocation of the uterus, apoplexies, syncope, lethargies, &c.

APOBATÆ, in *Antiquity*, the name given to those athletes, who were also denominated PARABATÆ.

APOBATANA, in *Ancient Geography*, the metropolis of Media, more properly and more generally called *Ecbatana*.

APOBATERION, from $\alpha\pi\delta\epsilon\iota\chi\omega$, *I depart*, among the *Antients*, a farewell speech or poem, made by a person on his departure out of his own country, or some other place where he had been kindly received and entertained.

Such is that of *Zæus* to *Helena* and *Andromache*. Æn. lib. iii. The apobaterion stands opposed to the *EPIBATERION*.

APOBATHMOS, in *Ancient Geography*, a place of Peloponnesus, on the coast of the Argolide, well of the gulf, near *Geonium* and *Lania*; where, according to tradition, *Danaus* and his sons landed on the shore of Argos; whence the name.

APOBATHRA, a place in the Thracian Chersonesus, where the troops of *Xerxes* landed in their passage from Asia to Europe.

APOBATHRÆ, in *Antiquity*, a kind of little bridges, or stairs, joining the land to ships, or one ship to another.

APOBEE, in *Botany*, a name given by the natives of Guinea to a species of corn-marygold, called by *Petiver* *chrysanthemum acation* Guinea. *se foliis longis angustis*, from its having long and narrow leaves, and no stalk to support the flower. The people of the place use this in the small-pox, and other eruptive fevers, boiled in water, and the liquor drank warm. Phil. Trans. N^o 232.

APOBOMIOL, from $\alpha\pi\omega$, below, and $\beta\omicron\mu\omicron\varsigma$, altar, in *Antiquity*, sacrifices offered on the bare earth, without altars.

APOCALYPSE, formed of $\alpha\pi\kappa\alpha\lambda\upsilon\psi\iota\varsigma$, *I reveal*; *Revelation*: the name of the last book in the canon of Scripture.

The

A P O C A L Y P S E.

The first question that occurs in our examination of this book relates to its *authenticity*. This is a subject on which many ancient and modern writers have disagreed; and it will be sufficient to give a brief view of the evidence which testimony affords concerning it. It has been alleged, that there are evident allusions to this book in the Shepherd or Pastor of Hermas, a piece that was written towards the close of the first century; and that it was received by Papias, who flourished about the year 116. Justin Martyr, about the year 140, was well acquainted with this book, and received it as the genuine writing of the apostle John. Among the works of Melito, bishop of Sardis, one of the seven churches of Asia, about the year 177, Eusebius mentions one, intitled, "of the Revelation of St. John;" and it is probable, that he ascribed this book to the apostle of that name, and esteemed it of canonical authority. It appears to have been referred to by the Martyrs at Lyons, A. D. 177. Irenæus, bishop of Lyons, about 178, who in his youth was acquainted with Polycarp, often quotes this book as "The Revelation of John the Disciple of the Lord;" and he says concerning it, that it was seen not long ago, but almost in our age, at the end of the reign of Domitian. From the writings of Athenagoras, the Testament of the Twelve Patriarchs, and the Clementine recognitions, Dr. Lardner has produced single allusions to the Apocalypse, which prove, that the authors of these books were acquainted with it, though they do not warrant the conclusion, that they considered it as the genuine work of St. John the apostle. But it was undoubtedly received, and often cited by Theophilus, bishop of Antioch, about A. D. 181, Clement of Alexandria, who flourished about 194, and Tertullian about the year 200. Eusebius informs us, that Apollonius, who wrote against the Montanists about the year 211, quoted the Revelation. It was received by Hippolytus about the year 220, who wrote a commentary upon it; and about 230, by Origen, who has often cited it, and who seems to have had no doubts about its genuineness. Dionysius, a disciple of Origen, and bishop of Alexandria, about the year 247, or somewhat later, wrote a book against the Millenarians, in which he allows the Revelation to have been written by John, a holy and divinely inspired man, who was, as he supposes, not John the apostle, but an elder who also lived at Ephesus. About the year 240, and before, it was received by Nepos, an Egyptian bishop, and by many others in that country, and held in great reputation.

After the age of Dionysius, the number of ecclesiastical writers who quote the Apocalypse, as a divine work, begins to increase.

According to Lardner, it was received and frequently quoted by Cyprian, bishop of Carthage, about 248, and by the church of Rome in his time, by Novatus, A. D. 251, and his followers; by Commodian, A. D. 270; by Victorinus, who wrote a commentary upon it, and by Methodius, A. D. 290; probably by the Manichæans, though this is disputed by Beaufobre; by Arnobius, and Lactantius, A. D. 306; by the Donatists, and by the Arians, in the fourth century. In the time of Eusebius, about the year 315, it was not received by all, and therefore he reckons it among contradicted books, observing that it was rejected by some, but by others referred to the class of books universally received. He seems to have hesitated about it; for he neither pronounced it to a forgery, nor ascribed it to St. John the apostle. He says, however, that the Revelation was seen by John the elder, if not by John the apostle. Dr. Lardner observes, that the critical argument of Dionysius of Alexandria had great weight with him, and with others of that time. The Revelation was received by Athanasius, bi-

shop of Alexandria, A. D. 326; by Epiphanius, bishop of Cyprus, A. D. 368; by Gregory Nazianzen, A. D. 370, as some have inferred from his citing it, but others have disputed his acknowledgment of it; by Jerom, A. D. 392, who admitted it after a more cautious examination than was instituted by most of his predecessors, and who appealed in support of its authenticity to ancient testimonies; by Rufinus, A. D. 397; and by Augustine, A. D. 395. The authority of this father was so great, not only in the African church, but in the Latin church in general, that his reception of the Apocalypse contributed very much to its almost universal admission both in Africa and in the west of Europe. During his time, in the year 397, was held the third council of Carthage; and this was the first council in which this book was pronounced canonical. Innocent I. elected pope in 402, declared likewise, that this book, from which his successors were to be proved the Antichrist, was canonical. It is in the catalogue of Dionysius the Areopagite, and in Greek manuscripts, such as the Codex Reuchlini, Alexandrinus, and Seidelianus. It was received by Sulpicius Severus about 401, and declared to be a genuine and divine work, in the fourth council of Toledo, A. D. 633, for this curious reason, because it had been pronounced such by several councils and several popes, and the decree of this council annuls all doubts of its authenticity in the Latin church. Andrew bishop of Cæsarea in Cappadocia, at the end of the fifth century, and Arethas bishop of the same place in the sixth century, wrote commentaries upon it. In the Syrian church, which comprehended not only all the Christians who resided in Syria, Assyria, and Mesopotamia, but likewise all those who were dispersed in Arabia, Persia, Tartary, and China, as well as in the Greek and Latin churches, the book of Revelation was acknowledged as a divine work. To this purpose Ephrem the Syrian, about A. D. 370, not only quoted it, but received it as a divine book; for he says concerning it, "John saw in revelation a great and wonderful book which God had written, and which was sealed with seven seals." In the seventh century, a new and very literal translation was made of the Apocalypse, and taken into the Philoxenian version, which was chiefly used by the Monophysites, so that they did not reject it. In the latter end of the same century, and the beginning of the next, lived Jacob the Monophysite, bishop of Edessa, who has quoted the Apocalypse in his commentary on Gen. xlix. 17. That the Syrians of the Nestorian party likewise received this book in the eighth century, appears from an ancient monument which was dug up at Sanxuen, in the Chinese province of Xensi, in the year 1625. On this monument, which appears to have been erected A. D. 781, at which period, as well as during some centuries later, there was a very numerous colony of Nestorian Syrians, in China, mention is made of the New Testament as containing 27 books, so that the Apocalypse must have been included; but it is needless to pursue the evidence to a wider extent, or to a later period.

Having cited a great number of very respectable authorities in favour of the genuineness of the Apocalypse, it may not be improper, for assisting the judgment of the reader, to present some of the testimonies that have been urged against it.

The most ancient evidence on this side of the question, is that of Ignatius, A. D. 107, who wrote epistles to the churches of Ephesus, Smyrna, and Philadelphia; three of those that are mentioned in the book of Revelation; and who reminds the Ephesians of the praises bestowed upon them by St. Paul, and yet takes no notice of the praises which, according to Rev. ii. 1—7. 8—11. iii. 7—12. their bishops had received from Christ himself. Hence it has been in-

A P O C A L Y P S E.

ferred, either that the Apocalypse was unknown to Ignatius, or if known, not believed by him to be genuine; and if it was a genuine work of St. John the apostle, it could not have remained unknown to him. The old German translator, who lived in the first century, did not translate the Apocalypse; and hence it is presumed, that he either knew nothing of it, or did not believe it to be genuine. The testimony of Papias in its favour is doubtful; for it is urged, that as he was the founder of the system of the Millennium, he would naturally have recurred to the 20th chapter of this book, if he had been acquainted with it, in support of his opinion. In the second century it was acknowledged and cited by many eminent persons; nevertheless in this century there existed a sect, called the Alogians, who were acquainted with the Apocalypse, and yet denied it to be genuine. One of their principal and most plausible objections against the authority of this book is founded on the circumstance recorded in ch. ii. 18—20, in which the fourth epistle is directed to be addressed to the angel of the church at Thyatira; whereas, they affirm, that there existed no church at Thyatira. This objection of the Alogi Epiphanius has delivered in the following words, “*καὶ ἐπεὶ ἐν οὐκ ἔστιν ἐκκλησία χριστιανῶν;*” but these words are ambiguous, for they may denote either that there was no Christian community at Thyatira in the time of St. John, or there was no such community there when the Alogi made their objections. In the latter sense the argument is of no importance; for though there might be no Christian society at Thyatira in the middle of the second century, there might have been one in the reign of Claudius, to which period Epiphanius refers the Apocalypse. But the fact was not true, as there existed a community of Alogi, who certainly considered themselves as Christians, and another sect who were opposed to the Alogi, and who were called Phrygians. It is, therefore, not necessary to recur with Epiphanius to the prophetic spirit of St. John, who foresaw there would be a church at Thyatira in course of time. Besides the Alogi, there were other adversaries of the Apocalypse, who lived partly at the same time with them, and partly in the beginning of the third century; and who rejected the Apocalypse, not so much as the Alogi did, from their antipathy to the term *λογος*, but principally from their dislike of the doctrine of the Millennium. Among these we may reckon the Roman presbyter Caius, who lived about the year 210. Some, however, have supposed that Caius refers to a different Apocalypse from ours. Dionysius of Alexandria, though he did not reject it as a forgery, did not ascribe it to St. John the apostle, and probably did not believe it to be a divine work: but his reasons for not ascribing it to St. John are not historical but critical; and, therefore, their importance depends not on the antiquity of the writer who assigned them, but merely on their own internal strength. It is well observed by Michaelis, who himself hesitates in allowing the genuineness of this book, but who has fairly stated the evidence on both sides, that if it were not written by St. John, we have reason to wonder, that neither Dionysius nor his predecessors, neither the Alogi nor Caius, should have alleged against a work, supposed to have been first ushered into the world about the year 120, any arguments like the following: “It is not preserved in the archives of the seven churches; the oldest persons in these cities have no knowledge of its having been sent thither; no one ever saw it during the life of John; it was introduced in such and such a year, but was contradicted as soon as it appeared.” Arguments like these would have at once determined the question in dispute; but since we meet with no such arguments in the writings of the ancient adversaries of the Apocalypse, its very adversaries have given it an advantage, which,

if not decisive, merits peculiar consideration. Eusebius, who was in possession of almost all the information that was to be collected before his time, had not been able to discover any thing decisive in respect to the Apocalypse, and consequently remained in doubt. He, therefore, neither pronounced it a forgery, nor ascribed it to St. John the apostle. Michaelis closes his examination of the evidence prior to the time of Eusebius, with the following remarks: “How is it possible that this book, if really written by St. John the apostle, should have either been wholly unknown, or considered as a work of doubtful authority in the very earliest ages of Christianity? The other apostolical epistles are addressed only to single communities or churches; but the Apocalypse, according to its own contents, was expressly ordered by Christ himself, in a command to St. John the apostle, to be sent to seven churches; and not only were these seven churches in that part of Asia Minor where Christianity was in the most flourishing situation, but one of them was at Ephesus, where St. John spent the latter part of his life, and consequently where every work of St. John must have been perfectly well known. If St. John then had actually sent the Apocalypse to these seven churches, and that too not as a private epistle, but as a revelation made to him by Jesus Christ, one should suppose that its authenticity could not have been doubted, especially at a time when there were the best means of obtaining information. We cannot say that the book was kept secret, or was concealed in the archives, lest the prophecies against Rome should draw a persecution on the Christians; for secrecy is contrary to the tenor of the book; and the author of it enjoins (ch. i. 3.) that it should be both read and heard. “Under these circumstances,” adds the author, “the authenticity of the Apocalypse appears to me very doubtful; and I cannot avoid entertaining a suspicion, that it is a spurious production, introduced probably into the world after the death of St. John.”

Since the time of Eusebius, and some centuries later, the doubts that had prevailed concerning the authenticity of the Apocalypse considerably abated, especially among the members of the Latin church, who at last received it almost unanimously. Among the Greek writers, however, there were several who rejected it. It was not received by all in the time of Epiphanius; it was omitted in the catalogue of the council of Laodicea, held A. D. 363; but professor Spittler, says Michaelis, has clearly shewn, that the whole of the sixteenth canon, which contains this catalogue, is a forgery; and if this be true, no evidence can be deduced from it in future against the Apocalypse. It was not acknowledged by Cyril, who was bishop of Jerusalem from the year 350 to the year 386; nor was it admitted into the catalogue of canonical books by Gregory Nazianzen; and by Gregory of Nyssa it was placed among the Apocryphal writings. In fact, says Michaelis, it was almost universally considered as spurious by the members of the Greek church at the end of the fourth century; and Dr. Lardner acknowledges, not only that the two celebrated Greek commentators, Chrysostom in the fourth, and Theophylact in the eleventh century, have not quoted it in a single instance; but that Nicephorus, patriarch of Constantinople, about the year 806, expressly rejected it; and on his testimony, it was placed among the Apocryphal books.

Although the Apocalypse made no part of the old Syriac version, which is the vulgate of the Syrian church in general, it was translated in an early age into that language. Nevertheless, it was not received by Severian, bishop of Gabala in Syria, A. D. 403; nor by Theodoret, bishop of Cyrus, in Syria, A. D. 423; nor by Abulpharagius, who was primate of all the Monophysites of the east in the thirteenth century,

A P O C A L Y P S E.

century, and was by far the most learned of all the Syrian writers; and it was entirely omitted in the catalogue of sacred books formed by Ebedjesu, metropolitan of Armenia, who died in the year 1318. It does not appear to have been received, or at least to have been publicly read at Alexandria in the fifth century, but it was received in general by the Egyptian Christians.

In more modern times, although the opinion of learned men has been very generally and decidedly in favour of the authenticity of the Apocalypse, yet there have been some who have entertained doubts about it, and others who have denied it. Among the latter we may mention Luther, who, in the preface to his edition of 1523, positively rejected it; but in the later editions, he has expressed himself in terms less decisive, and left it to others, who, he says, were better qualified than himself to determine whether it merited a place in the sacred canon or not. Michaelis also, after an elaborate examination of the authenticity of this book, concludes with leaving the decision of this important question to every man's private judgment.

The arguments for or against its divinity, deduced from the completion or non-completion of the prophecies contained in it, have been particularly considered by Michaelis (*ubi infra*), and to this learned writer the reader is referred. Sir Isaac Newton closes his brief account of the ancient testimonies in favour of the genuineness of the Apocalypse with this observation: "I do not, indeed, find any other book of the New Testament so strongly attested, or commented upon so early as this."

As to the *author* of this book, there has been a considerable difference of opinion among both ancient and modern writers. Some have ascribed it to John, a presbyter of Ephesus. Of this number seems to have been Eusebius, who, after having shewn from the writings of Papias, that beside St. John the apostle, there lived at Ephesus a presbyter of the same name: he adds, "This latter John was probably the person who saw the Revelation, unless it be insisted on, that it was the former." Others attributed the Apocalypse to Cerinthus, who is supposed to have lived in the time of St. John: and to this class we may refer the Alogi, and, probably, the Roman presbyter Caius, and other persons in Egypt, of whom Eusebius has given an account. *Eccl. Hist. b. vii. c. 25.* Against this opinion it has been justly alleged, that if the inscription be not false, Cerinthus could not have been the author, unless he also was called John; besides, the Revelation contradicts many of Cerinthus's sentiments, and therefore could not be his work. According to Irenæus, Cerinthus denied that God made the world; whereas, the writer of the Revelation often teaches the contrary. See *Rev. c. iv. 11.* He also maintained, that Christ did not suffer, but Jesus only. But the author of the Revelation calls Jesus, Christ, not Jesus alone, the first begotten of the dead; and adds, that the same Jesus Christ washed us from our sins in his own blood (*Rev. i. 5.*); and, *v. 7.* he says of Jesus Christ, that he was pierced. It is, therefore, improbable to the highest degree, that Cerinthus should have written the Revelation under the name of John; for if he had meditated such a fraud in favour of his Millennium, he would have so contrived it, as not to hurt his other equally favourite opinions. It has been also said, that the Revelation does not establish Cerinthus's notions of the Millennium, but directly contradicts and overthrows them; for the author of the Apocalypse describes his Jerusalem as inhabited by numbers of pure and holy persons (*Rev. xxi. 27. xxii. 14, 15.*); whilst Cerinthus's Jerusalem was to be the residence of the earthly and sensual. His citizens were to serve their passions and their pleasures; whilst the men of John's Jerusalem were to serve God and the Lamb (*Rev.*

xxii. 3.). His millenary state was not the life of saints, as the Apocalypse represents it, but the life of libertines.

The more generally received opinion concerning the author of the Apocalypse is, that it was written by St. John the apostle and evangelist, who was the writer of the Gospel and the Epistles. To this purpose it has been argued, that in *ch. i. v. 1.* John styles himself the "Servant of Christ," in a sense not common to all believers, but peculiar to those who are especially employed by him; and, in *v. 2.* the writer is supposed to refer to the written gospel of St. John, and to say, that he had already borne testimony concerning the word of God and of Jesus Christ. On this particular, Dr. Lardner lays no great stress; and he thinks, that if St. John had intended to manifest himself in this introduction, he would have more plainly characterized himself in several parts of this book than he has done. But the evidence of antiquity, in favour of its having been written by St. John the apostle, is of much greater moment; besides, it has been alleged in proof of its genuineness, and of St. John's being the author of it, that there are many instances of conformity, both of sentiment and expression, between this and the uncontroverted writings of St. John. For such coincidences, learned men have referred to *Rev. xix. 13.* *John, i. 1. 1. Rev. v. 6. 12. John, i. 29. 36.; Rev. iii. 7. xix. 11. John, i. 14. xiv. 6.; 1 John, v. 20. Rev. ii. 17. John, vi. 32.; Rev. i. 7. John, xix. 37.; Rev. iii. 20. John, xiv. 23.; Rev. i. 5. 1 John, i. 7; Rev. iii. 21. John, xvi. 33. 1 John, ii. 13. 14. iv. 4. 5.* These coincidences tend to invalidate the objection of Dionysius of Alexandria, who says that there is no affinity or resemblance between them. This learned writer has also observed, that the Gospel and first epistle of John are written correctly, and not only according to the propriety of the Greek tongue, but with elegance of phrase, argument, and composition; quite free from barbarism and solecism, and even idiotism of language; but the writer of the Revelation discovers no accurate skill in the Greek tongue; on the contrary, he has barbarisms and some solecisms. The Apocalypse, it is observed, abounds with harsh constructions, in which a nominative is placed where another case ought to have been used. Bengelius, in his "Apparatus Criticus," has alleged instances from *ch. i. 5.; ii. 20.; iii. 12.; viii. 9.; ix. 14.; xv. 12.; xviii. 11. 12.; xxi. 10. 12.; xiv. 5.; xvii. 4.*: others might be added. Although constructions of this kind were probably not unusual among the Greek Jews, yet we find no such examples in the gospel and epistles of St. John. Some of these unusual constructions, it has been pleaded, are not found in all manuscripts, and only in a very few printed editions; but they occur too frequently in the Apocalypse to be imputed wholly to transcribers: and they existed in this book long before our most ancient manuscripts were written, as in the third century, when they were noticed by Dionysius. Besides, the Apocalypse abounds with Hebraisms much more than the other writings of St. John; and this circumstance has induced some commentators to suppose, that it was originally written in Hebrew, and that our Greek text is only a translation; but this is wholly unsupported by historical evidence. Moreover, though the figurative language of the Apocalypse, when compared with the simple style of St. John's Gospel, cannot be fairly alleged as an argument that the two books were written by different authors; since the same author, when animated by a spirit of prophecy, will write in a different manner from that in which he had written as an historian; yet there is a certain character, it has been said, in the language of the Apocalypse, which is hardly to be reconciled with the manner that is visible in St. John's Gospel. In the latter, there is a soft and gentle character,

A P O C A L Y P S E.

rafter, fo peculiar to itfelf, as to exhibit no trace of imitation; whereas, in the former, we find the author an imitator of the ancient prophets, from whom he borrows his images, and renders them more beautiful than they were in the originals. And the imagery, which is taken from the theology of the rabbins, acquires in the Apocalypfe a taile and eloquence, of which the rabbinical writings themfelves are wholly deftitute. The beauties of St. John's gofpel are of a different kind; for while the author of the Apocalypfe hurries us away to enchanted ground, and refembles a torrent which carries every thing before it, St. John the evangelift is plainnefs and gentlenefs, and is like a clear rivulet, which flows without rapidity and violence. Is it poffible, therefore, fubjoins Michaelis, that St. John the apoftle, and the author of the Apocalypfe, called St. John the divine, were one and the fame perfon? It is, indeed, an undeniable fact, that the ftyle of the Apocalypfe is very different from that of St. John's gofpel. Mr. Blackwall denies this; but it is allowed by Joachim Camerarius, Beza, Mill, &c. "This, I fuppofe," fays the impartial and candid Lardner, "to be the more general opinion of learned men, that there is a confiderable difference of fentiments and words, and manner, in the Revelation, and the acknowledged pieces of the apoftle John: whatever this difference is owing to, whether it be that thefe writings are not all the compositions of one and the fame author, or that it is entirely owing to the diverfity of fubject and defign, or to fome other caufe. I fhall, however, mention another thing to be confidered: if there were any reafon to think, that there was fome confiderable diftance of time between the compofing of any of thefe books, that might be one good way of accounting for differences of ftyle; for it is not unlikely, that one and the fame perfon, writing upon different arguments, and at a great diftance of time, efpecially if he be one who does not frequently exercife his ftyle, or write in the intermediate fpace, fhould have a very different manner in his feveral performances."

Dionyfius has further remarked, that St. John the apoftle has not mentioned his own name in his gofpel, or in any of his epiftles; but, when he has occafion to fpeak of himfelf, he makes ufe of a circumlocution. On the other hand, St. John the divine mentions his own name, not only in places where it was requifite, as in the addrefs to the feven churches (ch. i. 4.) but likewife in places where the fingle pronoun "I," or the expreffion, "he who faw this," would have been full as proper as the term "I John." The one appears to have an exceffive modefty, and to avoid even the fhadow of egotifm; the other avoids it fo little, that he is lavish in the ufe of his name. And what renders this difference the more remarkable is, that the circumlocution by which St. John the apoftle denotes himfelf, *viz.* "the difciple whom Jefus loved," is not once ufed by St. John the divine. This objection admits of various replies. Although St. John has not exprefsly named himfelf in his gofpel, he has fo defcribed himfelf (John xxi. 24. and other places), that it is impoffible not to know him; the other apoftles have forborne to mention their names as well as John; nor is there any name prefixed to the epiftle to the Hebrews; and the character of the prophet being different from that of an evangelift, required the introduction of his name in conformity to the ancient prophets, who had inferted their names at the beginning, and in other parts of their prophecies. Dr. Lardner does not allow this laft obfervation to be fully fatisfactory, as the apoftle has not fpecified the time of his prophecies and vifions, and other particular, which was done by the ancient prophets, and by Daniel in particular. As for the want of any defcription annexed to the name of John, we may infer from this circumftance, that he was the princi-

pal perfon of that name then living, that is, John the evangelift; and as this was the cafe, his name needed no additions. Befides, he is actually defcribed (ch. i. 2.) under characters which were appropriate to John the apoftle. Upon the whole we may obferve, that he calls himfelf John; that he is defcribed as one who bore record of the word of God; that he had been in the ifle of Patmos for the testimony of Jefus; and we have no account of any John who had been an exile in this ifland about that time, except John the apoftle; and, moreover, he writes to the feven churches of Afia, where the apoftle and evangelift is fuppofed to have prefided; and it is not likely that the fpirit of God fhould admonifh and reprove thefe churches by John the elder, allowing there was fuch a perfon, whilft John the apoftle was living, and prefided in thofe parts. Upon the whole, there feems to be fufficient reafon for concluding, that St. John the apoftle was the author of the Apocalypfe.

Another fubject of inquiry, concerning which the learned have differed, is the *time* in which this book was written. On this point fix different opinions have been advanced. 1. It has been afferted, that the Apocalypfe was written in the reign of the emperor Claudius. Epiphanius is the only evidence in favour of this opinion, and he lived 300 years later than St. John. Although Grotius recommends this opinion by having adopted it, and fuppofes that the vifions of the book were feen at feveral times, and afterwards joined together in one book, two very material objections have been urged againft it: the firft is, that there was no perfecution of the Chriftians in the reign of Claudius, and therefore the banifhment of St. John to the ifle of Patmos cannot be referred to this period. This emperor did indeed iffue an edict for banifhing the Jews from Rome, but it did not affect the Jews in the provinces, much lefs the Chriftians; and the governors had no authority to banifh Jews or Chriftians out of their governments, without an order from the emperor; and moreover, St. John was not in Ephesus during the reign of Claudius. The fecond objection to this date is founded on the circumftance, that the feven churches in Afia, to which the Apocalypfe is addreffed, did not exift at fo early a period as the reign of Claudius; for this fact cannot be reconciled with the hiftory given in the Acts of the Apoftles, of the firft planting of Chriftianity in Afia Minor. 2. It has been maintained that St. John was banifhed to Patmos, and wrote the Apocalypfe there, in the reign of the emperor Nero, before the deftruction of Jerufalem. This opinion has one evidence in its favour, but it is anonymous, and without date; and that is, the fubfcription to the Syriac verfion of the Apocalypfe; but thus feebly fupported, it has been fannetioned by the adoption and arguments of fir Ifaac Newton. Dr. Lardner has examined the arguments of Newton, and does not allow them much weight. 3. According to another opinion, the Apocalypfe was written before the time of Domitian, and before the Jewish war, but it does not determine whether it was in the reign of Claudius or in that of Nero. 4. The moft probable, and the generally received opinion is, that St. John was banifhed into Patmos in the reign of Domitian, and by virtue of his edicts for perfecuting the Chriftians, in the latter part of his reign, and that he had the Revelations contained in the Apocalypfe on that occafion; but the book itfelf could not have been publifhed till after St. John's releafe and return to Ephesus. All antiquity, fays Mr. Lampe, is agreed that St. John's banifhment was by order of Domitian. Irenæus, Origen, Eufebius, and various other ancients, refer the banifhment of St. John to the latter part of the reign of Domitian; and they concur in faying, that he there faw the Revelation. As Domitian died A.D. 96, and his perfecution did not commence till near the end of his reign, the

A P O C A L Y P S E.

Revelation seems to be fitly dated in the year 95 or 96, in the last of which years Mill, Bafnage, and Le Clerc place it. Mr. Lowman fuppofes, that he had his visions in the ifle of Patmos, in the year 95; Dr. Lardner refers the visions recorded in this book, and the publication of them, to the years of Chrift 95 and 96, or 97. There are two other opinions, which fhall be merely mentioned, becaufe they are not fupported by any fufficient authority, that refer the banifhment of St. John to Patmos, the one to the reign of Trajan, and the other to that of Adrian. Mr. Wetflein (N. T. t. ii. p. 746.) favours the opinion of thofe who have agreed that the Revelation was written before the Jewish war; and in this cafe, he fays, it is likely that the events of that time fhould be foretold in it. But upon this fuppofition, Dr. Lardner is of opinion, that it was not neceffary the deftruction of Jerufalem, and the calamities attending it, fhould be foretold in this book; becaufe our bleffed Lord's plain predictions, and fymbolical prefigurations of thefe events, had been recorded by no lefs than three hiftorians and evangelifts before the war in Judæa broke out. "If we confider the Apocalypfe as a divine work," fays Michaelis, "I think we muft confine our choice to thofe dates which precede the commencement of the Jewish war; for thus only fhall we be enabled to fhew, that its firft prophecies were fulfilled in a fhort time. And I grant, that if it is referred to the reign of Claudius, the explanation of it is ftill eafier than when it is referred to the reign of Nero; for the fcarcity predicted (ch. vi. 6.) is defcriptive of that which took place in the time of Claudius. If it be confidered as a mere human invention, it may be either afcribed to Cerinthus, or attributed to fome unknown writer, who lived between the time of Papias and that of Julin Martyr; in the latter cafe, it might have been written in the reign of Hadrian. But if it be really a forgery, if it contain prophecies of the Jewish war, made after the events themfelves had taken place, we have reafon to wonder, that the author did not prophesy more circumftantially, and that he appears fo little acquainted with the events of that war."

The book of the Revelation, notwithstanding the pains which have been taken by men of ability and learning to explain it, feems yet to the generality of Chriftians very obfcure; and many look upon it as a fealed book ftill, never to be explained to any certainty or fatisfaction. A great critic, Scaliger, faid, that Calvin was wife becaufe he did not write upon the Revelation. And another (Dr. Whitby), who has written with great reputation on the other books of the New Teftament, confeffes he did not do it for want of wildom; becaufe, fays he, "I have neither fufficient reading nor judgment to difcern the intendment of the prophecies contained in that book." Michaelis has arranged the expositions of the Apocalypfe, confidered as a divine work, under the following claffes. To the firft clafs may be referred all thofe commentaries which are fafhionable among Proteftants, and according to which, the Apocalypfe contains prophecies againft the pope and the church of Rome; and in the commentaries belonging to this clafs, the prophecies in the Apocalypfe are confidered as ftill fulfilling. To this clafs of commentators we may refer Mede, fir Ifaac Newton, Lowman, bifhop Newton, Hurd, &c. &c. and many other Proteftant writers. To the fecond clafs belong thofe commentaries, which confine the prophecies of the Apocalypfe to the three firft centuries, at leaft fuch as relate to perfecution and punifhment: for the happy Millennium may, according to thefe commentaries, be made to commence with the converfion of Conftantine the Great. Commentators of the third clafs find in the Apocalypfe nothing but the deftruction of Jerufalem, and the

flight of the Chriftians from that city to Pella before the commencement of the fiege. The book of Revelation, according to the interpretation of the beft commentators, comprehends a much longer period than has been affigned to it by thofe who fuppofe that the expreffions "which muft fhortly come to pafs," and "the time is at hand," and the like, point out a very fhort period; fo that the whole prophecy fhould be accomplished in a few years after the vifion. Thefe expreffions will, indeed, fhew that the accomplifhment of the things foretold in this prophecy was foon to begin, but determines nothing concerning the time of their termination, the duration of which is much longer, and reaches from the time of the vifion to the day of judgment. The book itfelf feems alfo to fhew farther very plainly the order of the feveral prophecies, according to their feveral periods, as well as the whole duration, from the time of the origin to the finishing of the whole myftery of God's providence towards the church. The Revelation begins, according to Mr. Lowman, by opening the fealed book, which defcribes the future ftate of the church in feven fucceffive periods.

The *firft* period fhews the ftate of the church under the Heathen Roman emperors, from about the year 95 to about the year 323, and comprehends the opening of feven feals. The firft feal represents a white horfe and the rider with a crown, fignifying the Chriftian religion prevailing againft the oppofition of Jews and Heathens. The fecond feal represents a red horfe with its rider, having power to take peace from the earth, denoting the firft memorable judgment on the perfecutors of Chriftianity, in the deftruction of the Jews under Trajan and Hadrian, from 100 to 138. The third feal represents a black horfe, the rider of which has a balance to meafure corn, denoting great fcarcity, approaching to famine, in the time of the Antonines, from 138 to 193. The fourth feal represents a pale horfe with its rider, called Death, fignifying a great mortality and peftilence, in the reigns of Maximin and Valerian, from 193 to 270. The fifth feal represents the fouls of the martyrs under the altar, denoting the fevere perfecution in the reign of Diocleſian, with an encouragement to conftancy; The fixth represents earthquakes, &c. fignifying great commotions in the empire, from Maximian to Conftantine the Great, who put a period to the perfecution of Heathen Rome. The interval between the firft and fecond periods represents an angel fealing 144,000 with the feal of the living God; fignifying great numbers forfaking the idolatrous worfhip of the Heathen Roman empire, and embracing the profefſion of Chriftianity.

The *fecond* period reveals the ftate of the church and providence in the times following the reign of Conftantine, during the invafion of the empire by the northern nations and the rife and firft progrefs of the Mahometan impoſture, till the ſtop put to it in the weſtern empire; extending from the year 337 to 750, and denoted by feven trumpets. The firft trumpet represents hail and fire mingled with blood, fignifying great ſtorms of war falling upon the empire, and the blood that was ſhed in the reigns of the Conftantine family and their ſucceffors, till things were fettled under Theodoſius, from 337 to 379. The fecond trumpet represents a mountain burning with fire, caſt into the ſea, whereby it became blood; denoting the invafion of Italy by the northern nations, and taking the city of Rome by Alaric, from 379 to 412. The third trumpet represents a burning ſtar falling upon the rivers, which became bitter; fignifying the ravages in Italy, putting an end to the Roman empire, and founding a kingdom of Goths in Italy itfelf, from 412 to 493. The fourth represents a third part of the ſea

and

and moon darkened, signifying the wars in Italy between Julliman's generals and the Goths, whereby the exarchate of Ravenna was erected, and the remaining power and authority of Rome quite suppressed, from 493 to 568. The fifth represents the bottomless pit opened, and evils coming out of it, signifying the rise of the Mahometan religion and empire, and the great progress of both till a stop was put to them by a contest for the succession, from 568 to 675. The sixth trumpet represents four angels loosed, which were bound in the Euphrates, signifying the re-union of the divided Saracen powers in the invasion of Europe by them, and threatening the conquest of it, till defeated by Charles Martel, from 635 to 771.

The *third* period reveals the state of the church and providence, in the times of the last head of Roman government, represented by the beast, for 1260 years to its final overthrow, from about the year 750 to about the year 2010. The sealed book opened by the lamb, and given to St. John to eat, denotes a further revelation of what was to follow, in order of time, to the end of the world. There are three general descriptions of this period in the sixth, seventh, and eighth chapters. The first signifies the corrupt state of the church, and the constancy of some faithful witnesses to the truth, though under severe persecutions, during the whole of this period. The second represents a woman forced to fly into the wilderness for safety, and protected there 1260 days, signifying the persecution and preservation of the church during the same period. The third description represents a monstrous wild beast rising out of the sea, with seven heads, ten horns, as many crowns and titles of blasphemy, who was to continue 42 months, signifying that new Roman power, which should use its authority to promote idolatrous worship, and to persecute all who would not submit to it, and should be supported by another power like to its own form and constitution during the same period. In the sixth chapter, the chorus of the heavenly church celebrates in an hymn the happiness of those who remain faithful and constant; and a nuntius or angel is represented as coming down from heaven to declare the certain and severe punishment of the enemies of truth and pure religion in this period. In the seventh chapter, seven angels are represented as receiving seven cups full of the wrath of God; signifying that the enemies of truth and pure religion in this period shall be severely punished in the course of it, and be utterly destroyed in the end. The seven angels pour out their vials or cups: the first vial poured on the earth, and on the worshippers of the beast, denotes great commotions through the whole empire, under the family of Charles the Great, by which that family becomes extinct, and the empire and crown of France are transferred to other families, from 830 to 988. The second vial poured on the sea, signifies the great bloodshed of the holy war, to recover Jerusalem from the Saracens, from 1040 to 1150. The third vial poured on the rivers and fountains, signifies the bloody civil wars between the Guelfs and Gibellines, the papal and imperial factions, when the popes were driven out of Italy into France, from 1200 to 1371. The fourth vial poured on the sun, denotes the long wars in Italy, Germany, France and Spain, occasioned by a long schism in the papacy; the Turks taking Constantinople, and putting an end to the eastern empire; and pestilential diseases occasioned by intemperate heat, from 1378 to 1530. The fifth vial poured on the seat or throne of the beast, signifies the reformation, and the establishment of it by the principal states of Europe, in opposition to the papal authority, from 1560 to 1650. The sixth vial poured on the river Euphrates, makes way for the kings of the east; this, in

the order of the prophecies, seems to be yet future; but may probably mean some invasion of the pope's dominion from its eastern boundary on the Adriatic, from 1670 to 1850. The seventh vial poured on the air, the seat of Satan's empire, describes the utter ruin of this persecuting, idolatrous government, or mystical Babylon, at the end of this period, from 1850 to 2216.

The *fourth* period is described in the xxth chapter; an angel being sent from heaven to shut up Satan in the bottomless pit, as in a secure prison, for 1000 years, during which time there will be a very happy state of the church in purity, peace, and prosperity.

The *fifth* period terminates the 1000 years of the church's prosperity, when Satan will be loosed again for a little season, and a new attempt will be made to revive the corruptions of the church, and a spirit of persecution, which shall end in the final destruction of Satan's power, and of all the enemies of peace and true religion.

The *sixth* period comprehends the general resurrection and final judgment, and the everlasting destruction of the wicked.

The *seventh* period concludes the whole prophecy, with the vision of new heavens and a new earth, representing in strong images, the extent, security, riches, and grandeur of the heavenly Jerusalem; signifying the consummate happiness of the heavenly state; and the sure reward of all who shall be found faithful and constant in the true religion of Jesus Christ. Such is a specimen of the interpretation of the prophecies of the Apocalypse, given by Mr. Lowman, a judicious and approved writer on this subject; but the meaning ascribed to particular parts and prophecies of this book by different commentators, is very various. On this article the reader may consult Newton's Observations on the Apocalypse of St. John, apud oper. by Horsley, tom. v. p. 439—491. Mede's Works. Lowman's Paraphrase and Notes on the Revelation of St. John, preface passim. Lardner's Works. Michaelis's Introduction to the New Testament, by Marsh, vol. iv. p. 457—544.

There have been several other works published under the title of Apocalypses. Sozomen mentions a book used in the churches of Palestine, called the Apocalypse, or Revelation of St. Peter. He also mentions an Apocalypse of St. Paul, which the Coptæ retain to this day. Eusebius also speaks of both these Apocalypses. St. Epiphanius mentions an Apocalypse of Adam; Nicephorus, an Apocalypse of Efdras; Gratian and Cedrenus, an Apocalypse of Moses, another of St. Thomas, and another of St. Stephen; St. Jerom, an Apocalypse of Elias.

Porphyry, in his life of Plotin, makes mention of the Apocalypses or Revelations of Zoroaster, Zoltriar, Nicothæus, Aliogenes, &c.

APOCARITES, from ἀποκείρω, *I cut off*, in *Ecclesiastical History*, denote those who asserted that the human soul is part of, or derived from the substance of God.

The Apocaritæ are ranked as a branch of the Manichæans.

APOCARPASUM, in *Natural History*, a name given by the ancient Greeks to a poisonous drug, called also sometimes simply *carpasum*; it was the exudation of a tree growing in the country of the Abyssines, and was so like the finest myrrh, that it was often mixed with it, and many lives were lost by administering it as myrrh. The wood of the tree which produced it was also poisonous, though in a less degree, and was called by the same writers *apocarpasum*, as the wood of the balm of Gilead tree is *opobalsamum*.

APOCATASTASIS, from ἀποκαθίστημι, *I restore*, denotes the entire restitution, or reintegration of things.

In this sense, we read of the *apocatastasis* of the world, or of all things.

APOCATASTASIS, among *Astronomers*, denotes the period of a planet, or the time wherein it returns to the same point of the zodiac from which it set out.

APOCATASTASIS is also used in *Medicine*, to denote the subsiding or sinking of a thing.

In this sense, we read of the *apocatastasis* of urine, the *apocatastasis* of tumours, and other diseases.

APOCATHARSIS, in a general sense, denotes the same with *catharsis*, or expurgation.

In this sense, we read of *apocatharses* of bile, a symptom mentioned by Thucydides in the plague of Athens.

Quincy defines *apocatharses*, a purging upwards and downwards, but without sufficient authority. Hence also *apocathartica*, a denomination sometimes given to what we otherwise call simply *CATHARTICS*.

APOCENOSES, in *Medicine*, the fourth order of the fourth class, or *locales*, in the arrangement of diseases, by Dr. Cullen; comprehending those which have a flux of blood or some other humour more abundant than usual, without pyrexia, or an increased impulse of fluids. This order includes the following genera, viz. profusio, or a flux of blood; ephidrosis, or a preternatural evacuation of sweat; epiphora, or a flux of the lacrymal humour; pyalismus, or a flux of saliva; anuresis, or an involuntary flux of urine without pain; and gonorrhœa. See the several articles.

APOCHA, from *απο* and *εχω*, *I have*, in *Civil Law*, denotes an acquittance or receipt given by the creditor to his debtor for money paid: in which sense the word stands contradistinguished from *antapocha*, which is given by the debtor to the creditor. Reusner and Zieglerus have dissertations de *apochis*.

APOCHULISMA, from *απο* and *χυλιζω*, *I extract the juice*, in *Pharmacy*, denotes an inspissated vegetable juice; answering to what is called in the shops a *ROB*.

APOCOPE, compounded of the preposition *απο*, and the verb *κοπω*, *I cut*, a figure in *Grammar*, wherein part of the end of a word is cut off; as in *dic* for *dice*, *fac* for *face*, *nihil* for *nihil*, *hypo* or *hypo* for *hypochondriacal*.

A like retrenchment at the beginning of a word is called *apharefsis*.

When the *apocopation* is marked with a superior comma (called an *apostrophus*), the word is said to be *apostrophated*; as *thro'* for *through*.

APOCOPE, from *αποκοπέω*, *alscindo*, in *Surgery*, is synonymous with *Extirpatio*.

APOCRISIARIUS, formed from *αποκρισις*, *responsum*, *answer*, in *Antiquity*, an officer appointed to carry or deliver the messages, orders, and answers, of a prince or emperor. Hence he is usually called *responsalis*, q. d. *answerer*.

The apocriarius afterwards became the emperor's chancellor, and kept the seal. In the barbarous Latin we sometimes meet with *secretaria*, *secretary*, for apocriarius. Zosimus defines apocriarius, secretary for foreign affairs; being the same with what Vopiscus, in the life of Aurelian, calls *notarius secretorum*.

The title of apocriarius became at length appropriated as it were to the pope's deputy, or agent, who resided at Constantinople to receive the pope's orders, and the emperor's answer.

St. Gregory was apocriarius of pope Pelagius, at the time when he composed his morals on Job. The apocriarius did the office of the modern *NUNCIO*. Sometimes, however, he held the rank and quality of the pope's *LEGATE*.

The institution of apocriarii seems to have been in the time of Constantine, or not long after, when, the emperors

being become Christians, foreign churches had more occasion to promote their suits at court than formerly; at least we find the office established by law in the time of Justinian. In one of the novels, it is ordered, that as no bishop was to be long absent from his church without special command from the emperor, if any one had occasion to negotiate any ecclesiastical cause at court, he should prefer his petition, either by the apocriarius of his church appointed for such purpose, or by the oeconomus, or some of his clergy sent express. In imitation of the apocriarii of churches, almost every monastery had their apocriarii likewise, whose business was not to reside in the royal city, as the former did, but to act as proctors for their monastery or any member of it, when they had occasion to enter any appearance at law before the bishop under whose jurisdiction they were. This appears from another of Justinian's novels, which requires the ascetics in such cases to answer by their apocriarii or responsales. Du-Cange. Bingham. Orig. Eccles. lib. iii. cap. 13. sect. 6.

The heresy of the Monothelites, and afterwards that of the Iconoclasts, broke off the custom of having a papal apocriarius at Constantinople.

APOCRISIS, *αποκρισις*, literally denotes an *answer*. Under this denomination were anciently included, not only the rescripts of the emperors to the petitions of parties, but all kinds of decrees and mandates.

We have several books extant under the title of Apocriphes, and some in opposition to these under the title of Antapocriphes.

APOCRUSTICS, derived from *αποκρουω*, *pulso*, *pello*, *I drive*, in *Medicine*, remedies endued with a repelling and allringent power, whereby they prevent the too great afflux of humours to a part diseased. See *REPELLENTS*.

APOCRYPHAL, something dubious; or that comes from an uncertain author, on which much credit cannot be reposed. We say, an *apocryphal* book, passage, history, &c. meaning such as are of suspected authority.

Vossius observes, that, with regard to the sacred books, none are to be accounted apocryphal, except such as have been admitted neither into the synagogue, nor the church, so as to be added to the canon, and read in public.

For this reason also the books of Sibyls were anciently called apocryphal, as being committed to the trust of the *decemviri* alone; and for the like reason the annals of the Egyptians and Tyrians were called by the same name.

In the original meaning of the word, all the writings deposited in the temple were called apocryphal: because they were kept secret from the people.

When the Jews published their sacred books, they only gave the appellation of *canonical* and *divine* to such as they thus made public; and such as were still retained in their archives they called apocryphal, for no other reason but because they were not public; so that they might be really sacred and divine, though not promulgated as such.

Thus in respect of the Bible, all works were called apocryphal, which were not inserted in the Jewish canon of Scripture; and it is in this sense that St. Epiphanius is to be understood, when he says, that the apocryphal books are not put in the ark among the other inspired writings. By the ark he is supposed to have meant not the ark of the covenant, but the common archives; for, according to Josephus, there was no ark in the second temple. Nevertheless, the sacred writings were locked up in the temple; and the apocryphal books were without doubt deposited in a distinct archive from that in which the canonical books were kept. To this purpose Tertullian, speaking of the book of Enoch, says, that some did not own it, "quia nec in Judaicum ar-

morium admittitur;" and St. Austin (de Civ. Dei, l. 15.) says, that the canonical books of the Old Testament were preserved in the Jewish temple by the carefulness of the priests, who succeeded one another. Hence it is probable that the holy books were lodged in the temple in one archive, and the apocryphal in another place.

The word is derived from ἀποκρύπτω, to hide; because the origin of such books was unknown, or because they contain some mysteries not fit to be known.

The notion expressed by the word Apocrypha is taken, as we have just shewn, from the Jews, and though the word itself is of Greek original, it cannot be explained by a Greek etymology, according to which it would convey a much higher idea, and signify writings preserved in the sacred recesses of the temple. It is merely a translation of the Rabbinical word סתרים, which signifies "laid aside," so as not to be read in the synagogue: e. g. if a copy of the bible had two mistakes in one and the same page, it was allowable to correct them; but if there were three mistakes, the book must be laid aside (שליש סתרים), and they used the same expression for books, which were not supposed to be of divine authority. However the terms סתרים, and ἀποκρυφος, though similar in their original meaning, are very different in their use and application. The word סתרים was applied to books divinely inspired, but we apply the term ἀποκρυφος, apocryphal, to those, whose divine inspiration is denied. It is true that the ancient Jews made a distinction, which varied at various periods, between books that were to be read, and books that were not to be read in the synagogue, which latter the Rabbins called סתרים, but these were included in the sacred canon, whereas we apply the term *apocryphal* to those that are excluded from it; and this term, as applied by modern writers to such books as have relation to the New Testament, signifies in general "spurious or supposititious," and in this sense differs in a still higher degree from סתרים as applied to the books of the Old Testament. Fabricius in his "Codex apocryphus N. T." includes such writings as are supposed to be "a forgery;" whereas those of a similar description, which have relation to the Old Testament, are contained in his "Codex Pseudepigraphus." This term is applied by Jerom to books which by their title or otherwise make some claim to be a part of sacred scripture, but are destitute of a right to be so esteemed; and generally, or oftentimes, they are spurious. It is necessary, however, to distinguish between the terms apocryphal and spurious: a spurious work is that which is ascribed to an author who did not compose it; and apocryphal, whether written by the author to whom it is ascribed or not, is used in much the same sense with uncanonical. Michaelis uses the term apocryphal for authentic, as distinguished from inspired, and merely in opposition to canonical; and he cautions against considering it as a term of contempt, or as depreciating a book to which it is applied. The exclusion, he says, of books called on this account apocryphal, from the canon, by no means derogates from their real worth; and although there are many under this title, which are manifestly spurious, there are others again which are highly deserving our esteem. Apocryphal books, according to the definition of St. Augustine (Contr. Faust. l. xi. c. 2. and De Civ. Dei, l. 15. c. 23. n. 4.), are not such as are of authority (or received by the church,) and are kept secret; but they are books whose original is obscure, and which are destitute of proper testimonials; their authors being unknown, or their character either heretical or suspected. The term apocryphal, which is variously used, is sometimes applied to those books that are not in the canon, (see CANON:) and of these there are two classes, viz. that of useful books,

which may be read for the edification of the faithful, though doubtful and opposed, and that of the spurious pieces which are heretical and full of errors. Origen calls all the books which are out of the canon, apocryphal. Eusebius seems to use it for those wicked books that were composed by heretics, and which he distinguishes from those which are cited by ecclesiastical writers. Gregory Nazianzen, Athanasius, Epiphanius in the 8th Heresy, Rufinus, and most of the modern Greeks, give the name apocryphal to such books only, as are apparently spurious and wicked; and usually denominate those which are good and useful, ecclesiastical, though they were not received by all the churches as canonical. On the other hand, Cyril, Epiphanius in his Treatise of weights and measures, Jerom, the African Fathers, most of the Latins, and Antiochus among the Greeks, attribute the term apocryphal in general to all the books which are not in the canon. St. Austin distinguishes two sorts of canonical books; those which are received by all the churches, and those which are only received by some. Sixtus of Siena likewise distinguishes them into two classes; the proto-canonical, which have been always received and were never questioned; and the deutero-canonical, which were formerly doubted, but have been since admitted into the canon. All the rest, according to this author, are apocryphal, though this term had been sometimes applied only to heretical books. Mr. Jones lays down the following criteria or tests, by which we may determine whether any books are apocryphal or spurious, or not. That book is apocryphal, in which are found any contradictions,—which either contains any histories, or proposes any doctrines contrary to those which are certainly known to be true:—which contains things ludicrous or trifling, fabulous or silly relations;—which mentions facts that were later than the time in which the author, whose name it bears, lived:—the style of which is different from, or contrary to, the style of the author whose name it bears, in his known and undoubted writings:—the idiom or dialect of which are different from the known idiom or dialect of the author whose name it bears, or the country where he lived:—which manifests a disposition in its author, different from the known temper of the author whose name it bears:—and which for the most part is transcribed or stolen out of another.

As the number of books in the Jewish canon was equal to the number of Hebrew letters, it amounted to 22; and that this number might not be exceeded, the book of Ruth was joined to that of Judges, and the Lamentations to the prophecy of Jeremiah. The books, therefore, that were not contained in this number, were excluded from the canon, and deemed apocryphal. The ancient catalogues of the canonical books of the Old Testament, which are to be met with in Christian writers, whether Greeks or Latins, are conformable to the canon of the Jews, and contain no other books: such are those of Melito bishop of Sardis, of Origen, of the council of Laodicea, of Jerom, &c. &c. The first catalogue in which the books of Wisdom, Ecclesiasticus, Tobit, Judith, and the two Maccabees were admitted as canonical, and as having the same authority, is that of the 3d council of Carthage, A. D. 397, which confirms the decree of the council of Hippo, A. D. 303, in which these books were received into the canon. St. Augustine, according to the authority of the African church, reckons all these books as canonical. Pope Innocent I. on behalf of the church of Rome, places the same books in the canon of the Old Testament, as did also pope Gelasius in the council held A. D. 494; and moreover the decree of pope Eugenius, and the canon of the council of Trent, agree with the canon of the council of Carthage, and with the decree

of pope Innocent, and rank the above mentioned books among those of the Old Testament. See ECCLESIASTICUS, JUDITH, &c.

Among the books which have been wholly thrown out of the canon of holy scripture, we may mention a part of the book of Daniel, which the Jews rejected, containing the prayer of Azarias, and the song of the three children in the fiery furnace, which begin at the 24th verse of the 3d chapter, and end at the 91st: the history of Susanna, related in the 13th chapter; and of Bel and the Dragon, in the 14th and 15th. These subjects are not in the Hebrew or Chaldee text, nor in the Greek version of the Septuagint, but are taken out of the Greek version of Theodotion, which was then used by the church, in Daniel's prophecy, as St. Jerom has observed. Africanus, Eusebius, and Apollinarius, have rejected these narrations, not only as being uncanonical, but also as fabulous; and St. Jerom seems to be of the same opinion. Theodoret, in his exposition of Daniel, mentions neither the history of Susanna, nor that of Bel and the Dragon. However that which is related in these two chapters is cited under Daniel's name, and as part of his prophecy, by Irenæus, Clement of Alexandria, Tertullian, Origen, Cyprian, Didymus, Hilary, Basil, Gregory Nazianzen, Ambrose, Augustine, the author of a homily erroneously attributed to Chryostom, Fulgentius, Avitus, and Bede. Sulpitius Severus, and the author of the Synopsis of Athanasius, mention these histories as part of the sacred text; though the latter owns, that the history of Susanna is one of the dubious books. Ambrose quotes the words of Daniel, related in the third chapter, as being certainly of divine inspiration; and Rufinus upbraids Jerom for having cut off from Daniel the song of the three children, the history of Susanna, and that of Bel and the Dragon. The council of Trent, sess. 4. declared the following six books to be canonical, viz. Tobit, Judith, Wisdom, Ecclesiasticus, and the first and second of Maccabees; but joined Baruch with Jeremiah, so that the whole number amounts to seven. The apocryphal books enumerated in the 6th article of the church of England, are the 3d and 4th of Esdras, the book of Tobias, that of Judith, the rest of the book of Esther, that of Wisdom, that of Jesus the son of Sirach, Baruch the prophet, the Song of the three children, the story of Susanna, of Bel and the Dragon, the prayer of Manasses, and the first and second books of Maccabees. These books, by the same article, the church doth read for example of life and instruction of manners, but doth not apply them to establish any doctrine. Accordingly in the table prefixed to the Common Prayer, and appointing the lessons, they are directed to be read in the months of September, October and November. It appears, however, that in the Common Prayer of Edward VI. there was for Nov. 22d and 23d, no Bel and Dragon, nor history of Susanna; but the order proceeded from Baruch to Jeremiah. The apocryphal books are prohibited in the other reformed churches. The Puritans, in the reign of queen Elizabeth, disliked and objected to the reading of these books in the church.

The spurious and apocryphal books, composed in the early days of Christianity, published under the names of our Saviour, his apostles, their companions, &c. and mentioned by the writers of the first four centuries, under the titles of gospels, epistles, acts, revelations, &c. are numerous. Most of them have been long lost, and some few are still extant, to which class belong our Saviour's letter to Abgarus; his letter, which fell down from heaven at Jerusalem, directed to a priest named Leopas, in the city Eris; the constitutions of the apostles; the creed of the apostles; the apostolical epistles of Barnabas, Clemens, Ignatius, and Polycarp; the shepherd

of Hermas; the gospel of the infancy of our Saviour; the gospel of the birth of Mary; the prot-evangelion of St. James; the gospel of Nicodemus; the martyrdom of Thecla or acts of Paul; Abdias's history of the twelve apostles, or the acts of Pilate; St. Paul's epistle to the Laodiceans, and St. Paul's six letters to Seneca, &c.; the others, that are not extant, are enumerated by Mr. Jones, *ubi infra*. These books were not much used by the primitive Christians. There are no quotations of them in the apostolical fathers, i. e. Barnabas, Clement of Rome, Hermas, Ignatius, and Polycarp, whose writings reach from about the year of our Lord 70, to the year 108. Some of them are mentioned, but not cited, by Irenæus and Tertullian. Several of them are mentioned and quoted by Clement of Alexandria and Origen, but never as having authority, and sometimes with expressions of disapprobation. Eusebius mentions some of them, and says, that they were of little or no value, and that they were never received by the founder part of Christians. Athanasius, without naming any of them, passes a severe censure upon them in general; and Jerom speaks of them with dislike and censure. We may observe further, that these books, so far from militating against the evangelical history, confirm it; for they are written in the names of such, as our authentic scriptures say, were apostles, and companions of apostles; and they all suppose the dignity of our Lord's person, and a power of working miracles, together with a high degree of authority, to be conveyed by him to his apostles. It ought also to be considered, that few, if any, of these books were composed before the beginning of the second century. As they were not composed before that time, they might well refer to the commonly received books of the New Testament, as most of them certainly do; and therefore, instead of invalidating the credit of our books, they really bear testimony to them. All these books are not properly spurious, that is, ascribed to authors who did not compose them; but as they were not composed by apostles, nor at first ascribed to them, they may be fitly called apocryphal; for they have in their titles the names of apostles, and they make a specious pretence of delivering a true history of their doctrine, discourses, miracles, and travels, though that history is not true and authentic, and was not written by any apostle or apostolical man. Moreover, we may account for the publication of these apocryphal or pseudepigraphal books, as they were unquestionably owing to the fame of Christ and his apostles, and the great success of their ministry. And in this respect the case of the apostles of Christ is not singular: many men of distinguished characters have had discourses made for them which they themselves knew nothing of, and actions imputed to them which they never performed; and eminent writers have often had works ascribed to them, of which they were not the authors. Christians of former ages exercised a laudable caution and circumspection with regard to books of doubtful authority. For a good while, the epistle to the Hebrews, some of the Catholic epistles, and the revelation, were doubted of by many, when other books of the New Testament were universally acknowledged. Upon the whole, the books, now and for a long time called apocryphal, afford no valid argument against either the genuineness or the authority of the books of the New Testament, generally received as written by apostles and evangelists; but they sanction the truth of their genuine writings, and the reputation of their character; they confirm the general account given us in the canonical scriptures, and thus they indirectly establish the truth and divine original of the gospel.

The writing of books under spurious names, and obtruding them for the works of inspired authors, though once reputed laudable, and consecrated under the name of pious

fraud, was condemned very early by an apostolical canon, in the instance of a priest who was deposed for forging the acts of Paul and Thecla. Bing. Orig. Eccl. lib. xvii. cap. 5.

Fabricius has published the fragments and remains of the apocryphal books both of the Old and New Testament. Fabric. Codex Pseudepigraphus Veteris Testamenti, Hamb. 1722 & 1723, 8vo. 2 vol. Codex Apocryphus Novi Testamenti, 2 vol. Hamb. 1719, &c. 8vo.

Wolffius has given the literary history of the apocryphal books, their various editions, translations, commentaries, &c. See also Jones's Canon, vol. i. and vol. ii. Dupin's complete history of the Canon, &c. ch. i. Lardner's works, in various places. Michaelis's Introd. vol. i. p. 170. p. 376.

APOCYMA, from *απο*, and *κυμα*, wave, in the *Materia Medica* of the Ancients, a name given by the Greek authors to a sort of cement, used to daub over the bottoms of their ships, to preserve them from injuries by the water; they called this also by the name of *zopissa*; and Avicenna and Scapian call it *ketran*, *kiran*, or *alkitran*. It was a mixture of bees-wax and pitch melted together, and after it had been soaked some time in the sea-water, it was supposed to have peculiar virtues, and was used in many compositions.

APOCYNUM, (*ἀπό κυνος*, because it is supposed to kill dogs), in *Botany*, Dog's-bane. Lin. gen. 305. Schreb. 426. Juss. 146. Class, *pentandria digynia*; nat. order, *contortie*; *apocinea*. Juss. Gen. Char.; cal. perianth, one-leaved, five-parted, acute, short, permanent; cor. monopetalous, bell-shaped, semiquinquefid; divisions revolute; nectary, five glandular oval corpuscles surrounding the germ; *stam.* filaments very short; anthers oblong, erect, acute, converging, bifid at the base; *piſt.* germs two, ovate; styles, short; stigma, roundish, bifid at the tip, mucicate, glued to the anthers; *per.* follicles two, long, acuminate, one-valved, one-celled; *seeds* very small, numerous, crowned with a long down; receptacle subulate, very long, rough, free.

Essen. gen. char. cor. bell shaped; nectaries five, alternate with the stamens.

Species. 1. *A. androsamifolium*, *tuslan-leaved dog's-bane*; stem straightish, herbaceous, leaves ovate, smooth on both sides; cymes terminating; its stems are erect about three feet high; leaves opposite; flowers white, with purplish nectaries. If flies alight on this plant they are frequently entangled by the glutinous matter and destroyed. Hence this plant has been called *Herbe à la puce*. It is a native of Virginia and Canada, flowering from July till September: a perennial, cultivated by Miller, in 1731. 2. *A. cannabinum*, *hemp dog's-bane*; stem straightish, herbaceous; leaves oblong; cymes lateral, longer than the leaf; stems about two feet high; leaves in pairs, smooth, and like the former abounding with a milky juice; flowers small, of an herbaceous white colour, and not having an handsome appearance. The plant is only cultivated for the sake of variety. It flowers about the same time, and is a native of the same countries as the former species. The Indians of North America use this species for the same purpose as we do hemp. It was cultivated by the duchess of Beaufort, in 1699. 3. *A. hypericifolium*, *St. John's-wort-leaved dog's-bane*; stem straightish, herbaceous; leaves oblong-cordate, smooth; cymes shorter than the leaf. Martyn's Miller's Dict. *A. sibericum*, Lin. syst. Jacq. hort. 3. 37. t. 66. an annual, a foot and a half high, with opposite, sharpish, subsessile leaves, and small inodorous flowers. A native of North America, cultivated in 1756, by Miller. 4. *A. venetum*, *spear-leaved dog's-bane*; stem straightish, herbaceous; leaves ovate-lanceolate: a perennial, about two feet high: leaves opposite, smooth; flowers

in small umbels, purple or white, appearing in July and August. It grows in the islands of the Adriatic. Cultivated here in 1690. 5. *A. minutum*, *pretty dog's-bane*; stems prostrate; leaves hastate; stems filiform, about seven inches long; leaves opposite; peduncles alternate, umbelled with about six flowers. Found at the Cape by Montin. 6. *A. filiforme*, *thread-leaved dog's-bane*; stem prostrate, herbaceous; leaves filiform, flowers umbelled. Found at the Cape by Thunberg. 7. *A. frutescens*, *shrubby dog's-bane*; stem erect, shrubby; leaves lanceolate-oval; corolla acute, villose at the throat; flowers salver-shaped, on axillary peduncles, in loose bunches, and of a purple colour. A native of the East Indies, Ceylon, and the coast of Guinea. 8. *A. reticulatum*, *net-leaved dog's-bane*; stem twining, perennial; leaves ovate veined. This species climbs to a considerable height; its dark green leaves are beautifully reticulated with milky veins. A native of the East Indies and Cochin-China, cultivated by Miller. 9. *A. linear*, *linear-leaved dog's-bane*; stem twining, herbaceous; leaves linear, flat; umbels axillary, compound. Discovered at the Cape of Good Hope by Thunberg. 10. *A. triflorum*, *three flowered dog's-bane*; stem twining, herbaceous; leaves lanceolate; umbels axillary, two or three-flowered. Found at the Cape by Thunberg. 11. *A. juvenas*, *renovating dog's-bane*; stem twining, shrubby, leaves ovate, hairy; racemes dichotomous; the stem is hairy, red, usually procumbent; flowers greenish yellow, small, cut into lanceolate segments, which are three times the length of those of the calyx. A native of Cochin-China. This plant is esteemed by the Chinese for possessing similar properties to those of the ginseng. Lour. Coch. 12. *A. alterniflorum*, *alternate flowered dog's-bane*; stem climbing, shrubby, leaves ovate, acuminate, smooth; axils alternate, umbelliferous; flowers pale, inodorous; nectary composed of ten lobes. It grows in the islands near Canton. 13. *A. africanum*, *african dog's-bane*; stem suberect, shrubby; leaves ovate-oblong; peduncles two or three flowered. Loureiro Coch. A native of the coast of Zangubar in Africa. Mr. Miller enumerates six other species. 14. *A. scandens*, *climbing dog's-bane*; leaves oblong-cordate, stiff; flowers lateral; stem shrubby, twining. It was discovered by Plumier in some of the French islands in America, and by him described to be citron-leaved with maculated pods. Since that time it has been found near Carthagea in New Spain, from whence seeds have been transmitted here, which have succeeded in several gardens. Miller. 15. *A. nervosum*, *nerved-leaved dog's-bane*; leaves ovate, nerved; cymes lateral; flowers yellow, large, with a long tube; stem shrubby, climbing. A native of New Spain, near Carthagea. Miller. 16. *A. cordatum*, *heart-leaved dog's-bane*; leaves oblong-cordate, pointed, sessile; flowers lateral; stem climbing. 17. *A. villosum*, *villose-flowered dog's-bane*; leaves cordate, smooth; flowers villose, lateral, on long peduncles; stem climbing. Both the two last species were discovered at La Vera Cruz, in 1729, by Dr. Houffoun, who sent their seeds to England, where they have risen in stoves to the height of twenty feet, but the last, though more luxuriant than the other, never had any appearance of flowers. The pods of these plants afford a cottony down which is in great esteem in France for stuffing chairs, making quilts, &c. The French call it *Delawad*; and in the southern parts of France there are several plantations of some of these species for the sake of the down.

Propagation and culture. The first, second, and third sorts are propagated by parting their roots in March, before they put out new stems. They are hardy enough to thrive in the open ground; but the soil should be light and dry, other-

wife the roots are apt to rot in winter. The fourth sort will also live in the open air, provided it be planted in a warm situation and dry soil. The spring, before the stems shoot out, is the best time to remove it. The other species are tender, and must be constantly kept in a hot-house, plunged in the tan-bed. They may be propagated by cuttings, during the summer months; but should be laid dry in the stove three or four days before they are planted. When the seeds are obtained from their native places, they should be sown in pots filled with light sandy earth, and plunged into a tan-pit: in a month or five weeks they will appear, and should then be watered sparingly. As they advance, they will require larger pots; and the second year the plants will generally flower, and some of them make a fine appearance. Martyn Miller's Dict.

APOCYNUM. See ASCLEPIAS, CEROEGIA, CYNANCHUM, and ECHITES.

APODA, in *Ornithology*, a species of PARADISEA, called the greater bird of paradise. The side feathers are longer than the body; the two middle tail feathers long and fetaceous. Gmelin. This is called Manucodiata, by Brisson and Marcgrave; Paradisea Avis, by Seba, &c.; Oiseau de Paradis, by Buffon; bird of Paradise, by Willughby; and Greater Bird of Paradise, by Albin and Edwards.

This bird appears from the plumage to be as large as a pigeon, but the body scarcely exceeds in size that of the thrush. The length is twelve inches, the bill greenish yellow, and an inch and an half in length; its eyes are small; head and neck covered with short thick feathers, of which those on the head and hind part of the neck are of a pale gold colour. The base of the bill is surrounded with black; front of the neck green; lower part of the neck, back, wings, and tail are chestnut, deepest on the breast, where it assumes a tint of purple. From under the wings spring a great quantity of feathers, which are loosely webbed, and appear like the herring-bone; some of these are eighteen inches in length, and of different colours; but the prevailing tint is yellowish white. The legs are stout and of a brown colour.

The female is said to be like the male, except that the webs of the two wire-like feathers in the tail are shortest. They inhabit the Molucca islands, and those surrounding New Guinea, and particularly that of Aroo. It is supposed they breed in New Guinea, from whence they emigrate in the westerly or dry monsoon, and return when the easterly or wet monsoon commences. They are seen at these times in flights of thirty or forty, with a leader at their head, which is constantly seen flying higher than the rest. During their flights, it is observed they take the advantage of going against the wind, and have a cry like the starlings; but should the wind shift, they are in great distress, and croak like ravens, for their long scapular feathers then become ruffled, their flight is impeded, and they fall to the ground, from which they cannot rise until they gain an eminence, or into the water, from which they cannot extricate themselves. The natives, who make a trade of their skins with the Dutch, watch this opportunity, and take them in large numbers: the value of each to the people of Aroo is a *spike-nail*; but at Banda they fetch half a rix-dollar apiece, and perhaps of late more, since it is the plume of this species which has become a fashionable ornament to the head-dresses of the ladies in England. The food of these birds is not certain; some say they feed on berries; others, on butterflies; and others again, on small birds; the latter of which is probable, as they are very courageous, and are furnished with claws and beak of strength sufficient for that purpose. They were formerly brought to Europe without legs, and many were persuaded they never had any; but

the truth is, the legs being useless for the purpose of ornament, the only motive for which they are taken, are torn off on the spot, and thrown aside. They were worn in the East Indies by people of distinction; the grandees of Persia and Surat use them as aigrettes, and even adorn their horses with them.

In Forrest's Voyage to New Guinea, &c. a smaller bird of this kind is described as a native of Papua; Gmelin makes it a variety only (β) of this species.

APODACRYTICA, from $\alpha\pi\sigma\sigma$ and $\delta\alpha\kappa\upsilon$, a *tear*, in *Pharmacy*, medicines proper to excite tears. Some also use the term apodacrytica, for remedies proper to suppress tears.

APODECTÆ, from $\alpha\pi\sigma\delta\epsilon\chi\omicron\mu\alpha\iota$, *I receive*, in *Antiquity*, a denomination given to ten general receivers, appointed by the Athenians, to receive the public revenues, taxes, debts, and the like.

The apodectæ had also a power to decide controversies arising in relation to money and taxes, all but those of the most difficult nature and highest concern, which were reserved to the courts of judicature.

APODECTÆI, in the Athenian government, officers appointed to see that the measures of corn were just.

The *apodectai* were nearly related to the *agoranomi*.

APODEMICA, from $\alpha\pi\sigma\delta\eta\mu\epsilon\upsilon$, *I travel*, the doctrine or science of travelling, whether for knowledge or devotion's sake.

Jo. Meraker has published an apodemica. Ranzovius, a *methodus apodemica*.

APODES, in a general sense, from α and $\pi\omicron\upsilon\varsigma$, denotes things without feet. Zoologists apply the name to a fabulous sort of birds said to be found in some of the islands of the New World, which being entirely without feet, support themselves on the branches of trees by their crooked bills.

The Germans and Dutch have also their apodes, a sort of birds somewhat like swallows, whose legs and feet are so very small, that they seem rather formed for creeping than running.

APODES, is one of the four orders of fishes in the Linnean distribution of animals. Their character is that they have no belly fins.

APODICTICAL *argument*, or SYLLOGISM, signifies a clear convincing proof, or demonstration of a thing. The word is formed of $\alpha\pi\sigma\delta\epsilon\mu\omicron\nu\mu\alpha\iota$, *I demonstrate*.

APODICTICAL *method*, is used by some writers, to denote the systematical or scientific method of teaching or writing.

APODIOXIS, from $\alpha\pi\sigma\delta\iota\omicron\chi\iota\varsigma$, *I exclude*, in *Rhetoric*, a figure whereby we either pass over a thing slightly, or refer treating of it to some other time or place.

This is also called by Latin writers, *rejection*, e. g. "Quid ego senatum defendam, judices? Equidem debeo," &c. Again, "Quid ego senatum hoc loco defendam, judices? Fiat id rectius, tum quum," &c.

APODIOXIS, in *Logic*, the rejection of such things as do not necessarily belong to the question to be considered.

APODIPNE, or APODEIPNE, songs which the Greeks sung after supper; either to thank the Gods, or congratulate themselves for their good fare.

APODIXIS, from $\alpha\pi\sigma\delta\epsilon\mu\omicron\nu\mu\alpha\iota$, in *Rhetoric*, denotes an evident proof, or demonstration of a point.

We have several books extant under the names of apodixes; and some by way of answer to these, under that of antapodixes.

APODIXIS, in *Middle-Age Writers*, denotes a receipt for money paid. In which sense it amounts to the same with *apocba*.

APODIXIS is also sometimes used for a specimen or proof of a thing.

APODOSIS, from $\alpha\pi\sigma\delta\omicron\delta\omicron\varsigma\iota\varsigma$, *I apply*, in *Rhetoric*, makes

the third part of a complete exordium, being properly the application, or restriction of the preface.

The apolysis is the same with what is otherwise called *anthesis*, and stands opposed to *prothesis*, *c. p. p. p. p.* "all branches of history are necessary for a complete history; but that without them, it can never make any considerable figure;" *ap. l. f. s.* "but history is of a more special use, which recommends it." *ib. s. p.*

Apodosis is also used in the law of homicide, for that part which makes the acquittal of the murderer.

Apodosis is also used, in a rhetorical period, for the consequent to a preface, or antecedent preface.

Apodosis is also used for a return to something antecedent, or that went before.

This is otherwise called *anthesis*.

APODYTERIUM, *form. d. or. = δωα, to undress, in Antiquity*, a dressing room, or apartment at the entrance of baths, or in the palestra, wherein persons dressed and undressed, either for bathing, or for the gymnastic exercises.

This was otherwise denominated *corricum, gymnasium, and spoliarium*.

Some will have the apodyterium to have been the same with the *coniferium*; but Vossius shows they were two different places.

APOGEE, formed of *απο, from*, and *γη, earth*, in *Astronomy*, that point in the orbit of the sun, or a planet, which is farthest distant from the earth.

The apogee is a point in the heavens at the extreme of the line of the apsides; in which the sun, or a planet, is at the greatest distance that it can be at, from the earth, in its whole revolution, and the opposite point to this is called the **PERIGEE**.

The ancient astronomers, regarding the earth as the centre of the system, chiefly considered the apogee and perigee; the moderns, making the sun the centre, change the apogee and perigee for **APHELION** and **PERIHELION**.

The apogee of the sun is, therefore, the same with the aphelion of the earth, and the perihelion of the sun the same with the perigee of the earth. The manner of determining the place of the apogee of a planet is exactly the same with that for determining the place of the aphelion for the sun and superior planets. See **APHELION** and **PLANETS**. The place of the apogee of the sun, at the beginning of the year 1750, was, according to the tables of La Caille, $3^{\circ} 8' 58'' 4''$.

The quantity of the motion of the apogee may be found by comparing two observations thereof made at a great distance of time; converting the difference into minutes, and dividing it by the number of years elapsed between the two observations: the quotient gives the annual motion of the apogee. Thus, from an observation made by Hipparchus in the year before Christ 140, whereby the sun's apogee was found $5^{\circ} 32'$ of Π ; and another made by Ricciolus, in the year of Christ 1646, wherein it was found $7^{\circ} 26'$ of Θ ; the annual motion of the apogee is found to be $1' 2''$. See **APHELION**.

Its secular motion, with respect to the equinoxes, is, according to the tables of La Caille, $1^{\circ} 49' 10''$. The cause of this motion is the attraction of the planets, particularly of Venus and Jupiter, as M. Euler has shewn in his tract "On the inequalities of the earth," which obtained the prize of the Academy of Sciences, in 1756.

The apogee of the moon, in 1750, was in $5^{\circ} 21' 2' 32''$, and its annual motion is about $1' 10' 39' 50''$; and the resolution of the apogee, according to the tables of Mayer, in relation to the fixed stars, is performed in 8 years, 311 days, or 3231 days, $8^h 34' 57\frac{1}{2}''$.

Besides the progressive motion of the apogee of the moon, astronomers have also considered the orbit of the moon as subject to an equilibrium of its apogee, joined to a variation in its eccentricity. Horrox was the first author of this ingenious hypothesis, which Newton adopted in his "Principia," and upon which are founded Halley's tables of the moon, and those of Flamsteed, which were published by M. le Monnier, in his "Astronomical Institutions." M. Euler was the first who substituted to this hypothesis an equation more convenient, and called *evanescence*, the quantity of which is $1' 26' 34''$. In order to explain the hypothesis of Horrox agreeably to the principles of attraction, it ought to be considered that the motion of the apogee of the moon depends upon the diminution of the central force of the moon towards the earth; so that the motion ought to be the greatest when the line of the syzygies coincides with the line of the apsides, or when the place of the sun corresponds to the apogee or perigee of the moon. When it is in the quadratures, the motion of the apogee is the slowest, because the total diminution of the central force is then the least; when the sun is at 45° from the apsides, the true motion of the apogee is equal to the mean motion; but his true place differs then the most from the mean place, and the equation is the greatest, because it results from all the degrees of velocity which the apogee has acquired to this point. This equation, in the tables of Halley, amounts to $12^{\circ} 18'$. There is also an inequality in the place of the apogee, which proceeds from the distances of the sun with respect to the earth, and which is $23' 12''$ additive, when the sun is at 3 signs of anomaly: this is an annual equation. See **MOON**.

APOGRAPH, a copy or transcript of some book or writing. The word is formed of *απο, ab, from*, and *γραφω, I write*. In this sense apograph stands opposed to *autograph*, as a *copy* to an *original*.

APOGRAPHE, in the *Ancient Law*, was, when a person being sued for money supposed due to the public, pleaded that the charge was unjust, and withal produced all the money he was possessed of, and declared by what means it came to his hands.

Suidas adds, that it is sometimes taken for an action against such as neither paid the fines laid upon them before the ninth *prytanea* following their sentence, nor were able to give sufficient security to the city. Potter, *Arch. Græc.* lib. i. cap. 23.

APOGRAPHE, in the Roman *Law*, denotes a catalogue or inventory of goods.

APOKERA, in *Geography*. See **CAPE BECUR**.

APOKOPA, in *Ancient Geography*, a name given to the **CAPE BAXOS** of the Portuguese, situate upon the coast of Zanguebar.

APOLDA, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Weimar, eight miles N. W. from Weimar, and 40 S. W. from Leipzig. N. lat. $50^{\circ} 56'$. E. long. $11^{\circ} 22'$.

APOLEPSIS, from *απολεπω, I leave*, in the Athenian *Law*, an action of divorce; brought when a woman had fled from her husband.

APOLEPSIS, from *απολαμβάνω, I retain*, in the *Ancient Physic*, denotes a retention of the urine, or any other matter which ought to be evacuated.

APOLEPSIS is also understood of an interception of the blood or spirits, or an extinction of the native heat of the veins.

APOLEPSIS is also a denomination of a species of apoplexy, wherein the speech, sense, motion, &c. suddenly fail.

This seems to coincide with what is otherwise called a *CATALEPSIS*.

APOLIDES, from α and $\pi\omega\lambda\iota\varsigma$, *city*, in *Antiquity*, those condemned for life to the public works, or exiled into some island, and thus divested of the privileges of Roman citizens.

APOLLINARIANS, *APOLLINARISTS*, called also by Epiphanius, *Dimertite*, in *Ecclesiastical History*, ancient heretics, who denied the proper humanity of Christ, and maintained that the body which he assumed was endowed with a sensitive, and not a rational soul, but that the Divine Nature supplied the place of the intellectual principle in man.

This sect derived its name from Apollinaris, bishop of Laodicea in the fourth century.

The *Apollinarians* have been charged with other opinions, such as the *Millenarian* and *Sabellian*, the pre-existence of the body of Christ, and the passion of his Deity; but ecclesiastical writers are not agreed with respect to these and other particulars. Their doctrine was first condemned by a council of Alexandria, in the year 362, and afterwards in a more formal manner by a council at Rome in 375; and by another council in 378, which deposed Apollinaris from his bishopric. Notwithstanding these censures, his doctrine spread through most of the churches of the East; and his followers were subdivided into various sects. The sentence against Apollinaris and his followers was confirmed by a council held at Alexandria in 378, by an oecumenical council, assembled at Constantinople in 381, as well as by the council of Antioch in 379. In 388, the emperor Theodosius enacted a law, forbidding them to hold assemblies, to have any ecclesiastics or bishops, or to dwell in cities. The rigorous execution of this law, in concurrence with the decrees of different councils, reduced them to a very small number, and their doctrine had no long duration. Dupin. Mosheim. Lardner. Bower's *Lives of the Popes*. Gen. Dict.

The doctrine of Apollinaris, viz. that the Logos, a divine person, which descended from heaven, supplied the place of a soul in Christ, says a learned and acute writer, (*Mordecai's Letters*, p. 53.) is plain and intelligible; and answers much better than any other to the texts, which assert that "Christ took on him the seed of Abraham—was made in the likeness of man—God was manifest in the flesh—came in the flesh, in the likeness of sinful flesh—in him dwelleth the fulness of the Godhead; the Word was made flesh—was incarnate." "All these texts of scripture," says Dr. Sykes (*External Peace of the Church*, p. 29, 30.), "are, upon the Apollinarian scheme, natural, plain, and easy; it teaches a most proper unity of person; as making the God-man, Jesus Christ, to be strictly one intelligent agent." It makes the very same person suffer and die, that came down from heaven; which is the fundamental article of the Christian religion. Mr. Whiston also says (see *Account of the Convocation's proceeding against him*, p. 87.), "the scripture and earliest antiquity never affirm that Christ took a human rational soul; they never say he took a whole human nature; never say, he was in that sense a true and perfect man; but that he was made flesh, had a body prepared for him; was the Word, or a God incarnate; was made in the likeness of man; was found in fashion as a man, while he was God the Word. Nay, Ignatius directly affirms, that it was the Word, and not a human soul, which inhabited in that body; and almost all the ancients agree in the same doctrine; even Athanasius himself, before the council of Nice." Notwithstanding the pains that were

taken to discourage this opinion, it appeared again in different forms, in the Christian church, in the doctrine of the Monothelites, who held, that Christ had only one will, which, without doubt, is sufficient for one person.

APOLLINARIAN GAMES, *Apollinares ludi*, in *Antiquity*, games at Rome, instituted A. U. C. 541, celebrated yearly in honour of Apollo, on the fifth day of July, under the direction of the prætor, in the Circus maximus.

The occasion was a kind of oracle delivered by the prætor Marcus, after the fatal battle at Cannæ, declaring that, to expel the enemy, and cure the people of an infectious disease which then prevailed, sacred games were to be annually performed in honour of Apollo. And that the prætor was to have the direction of them; and the *decemviri* were to offer sacrifices after the Grecian rite.

The senate ordered that this oracle should be observed, because another of the same Marcus, wherein he had foretold the overthrow at Cannæ, had been verified; for this reason they gave the prætor twelve thousand *asses* out of the public cash to defray the solemnity. There were sacrificed an ox to Apollo, as also two white goats and a cow to Latona; all with their horns gilt. Apollo had also a collection made for him, besides what the people, who were spectators, gave voluntarily. The first prætor by whom they were held was P. Cornelius Sylla. For some time they were moveable and indictive, but at length were fixed, under the prætorship of P. Licinius Varus, to the fifth of July, and made perpetual. Livy, xxvii. c. 25. tom. iv. p. 75. Ed. Drakenb.

The men who were spectators at these games, wore garlands on their heads; the women performed their devotions in the temples at the same time; and at last they caroused together in the vestibules of their houses, the doors standing open.

The tradition reports, that at the first celebration hereof, the people were suddenly invaded by the enemy, and obliged to take to their arms: upon which occasion a cloud of darts and arrows falling upon their enemies, the Romans soon returned victors to their sports.

The Apollinarian games were only scenical; and at first only observed with singing, piping, and other sorts of music; but afterwards there were also introduced all kinds of mountebank tricks, dances, and the like, yet so as that they still remained scenical, no chariot races, wrestlings, or the like laborious exercises of the body, being ever practised at them. Danet, and others, confound the *ludi Apollinares* with the *Actiæ* or *ACTIAN GAMES*.

APOLLINARES LUDI was also a general name given to all *SCENICAL GAMES*.

These were also called *ludi liberales*, and *scenici*.

They differed from the *ludi theatrales*, in that the former were celebrated with all sorts of plays, farces, poems, recitations, &c. the latter only by dancing and music.

This kind of *Apollinarians* had their share in almost all the solemn games.

APOLLINARIS, *CLAUDIUS SULPITIUS*, in *Biography*, a celebrated grammarian, was born at Carthage, and flourished in the second century under the Antonines. He was succeeded in his profession by his scholar Helvius Pertinax, who afterwards became emperor: to him are ascribed the verses prefixed to the comedies of Terence, and the following epigram written upon the orders which Virgil gave to burn his *Æneid*:

"Infelix alio cecidit prope Pergamon igne,
Et pene est alio Troja cremata rogo."

Julius Cæſar (l. viii. c. 10.) ſpeaks of him in terms of very high commendation; repreſenting him as “the moſt famous man of the age,” and as altogether deſtitute of pedantic arrogance. Gen. Dict.

APOLLINARIUS, SIDONIUS C. SOLLITUS, an eminent biſhop of France, was born at Lyon, of a noble family, in the year 431, and educated under maſters by whoſe iſtruction he profited ſo as to make a great proficiency in the arts and ſciences, and particularly in poetry and polite literature. His firſt profeſſion was military, in the exerciſe of which he was captured by Majorianus, by whom his father-in-law, Avitus, was deprived of the empire; but having been kindly treated by the new emperor, he compoſed in honour of him a panegyric, for which he had a ſtatue erected to him at Rome, and was honoured with the title of Count. In 467, the emperor Anthemius raiſed him to ſeveral poſts of dignity, and erected a ſtatue to him for a ſimilar ſervice. But quitting military and civil employments, he was preferred to the biſhopric of Clermont, the duties of which he is ſaid to have diſcharged with great integrity. Having occupied this ſee 15 years, he died, according to Dupin, in 487; but according to Cave and Olearius, in 482. He has been eſteemed the moſt elegant writer of the age in which he lived, both in proſe and verſe. Beſides his panegyrics on the emperors, there are extant poems addreſſed to his friends upon particular ſubjects, and letters collected in ſix books, containing a variety of particulars relating to polite literature and proſaic hiſtory. His works were printed at Baſil in 1543, 8vo.; at Lyons, in 8vo. in 1552; and at Paris, in 4to. in 1590; and in 8vo. in 1614. They are publiſhed in the ſixth volume of the “*Bibliotheca Patrum.*” Cave, Hiſt. Lit. vol. i. p. 453. Gen. Dict.

APOLLINARIUS, OF APOLLINARIUS, CLAUDIUS, was biſhop of Hierapolis in Phrygia, A. D. 176, and flouriſhed in the time of M. Antoninus, to whom he preſented an apology for the Chriſtian faith. Eusebius and Photius mention other works, none of which are now extant. Eusebius informs us, that Apollinaris had mentioned the extraordinary deliverance and victory obtained by Antoninus in the year 174, when the thundering legion became ſo famous. Theodoret, in mentioning his writings againſt the Montaniſts, ſays, that he was worthy of praife, and that he had added to the knowledge of religion, the ſtudy of polite literature; and Photius commends his ſtyle. Lardner’s works, vol. ii. p. 294.

APOLLINARIUS, or APOLLINARIS, the elder, was a native of Alexandria, and flouriſhed about the middle of the fourth century, or according to Cave, A. D. 362. He was diſtinguiſhed, both as a grammarian and a divine. After having been a teacher of grammar at Berytus in Phœnicia, he became preſbyter at Laodicea in Syria. Under the reign of Julian, when the Chriſtians were forbidden the uſe of the Greek and Roman classics in their ſchools, he compoſed a grammar in a Chriſtian form, and wrote many books in imitation of the ancients. He translated the books of Moſes into Greek heroic verſe, and wrote in the ſame manner the whole hiſtory of the Hebrews to the time of Saul, which he divided, like Homer’s Iliad, into twenty-four parts, to which he prefixed, in regular ſeries, the letters of the alphabet. The remaining hiſtorical books of the Old Teſtament he exhibited partly in hexameters, and partly in a dramatic or lyric form, imitating the tragedies of Euripides, the comedies of Menander, and the odes of Pindar. Sozomen (Eccleſ. Hiſt. l. vi. c. 15.) ſpeaks highly of his talents and performances, and leads us to lament, in proportion to our confidence in his judgment,

“works equal in number and merit to the ancient Greek mod 13.” Suidas. Cave, Hiſt. Lit. vol. i. p. 225.

APOLLINARIUS, or APOLLINARIS, the younger, the ſon of the former, was the diſciple of Epiphanius the loſophiſt, and taught grammar at Laodicea, of which city he was at length ordained biſhop. At the time, viz. A. D. 362, when Julian iſſued the decree mentioned in the preceding article; he concurred with his father in rendering ſervice to the Chriſtians; and he is ſaid to have put the goſpels and the apoſtolic doctrine into dialogues after the manner of Plato. He alſo wrote commentaries on the book of Pſalms, the Eccleſiaſtes, the prophecy of Iſaiah, that of Daniel, (rejeſting the ſtories of Sulanna, and Bel and the Dragon, as not extant in Hebrew.) and that of Hoſea, and likewiſe on ſeveral books of the New Teſtament. His apology for the Chriſtian religion againſt Porphyry, in thirty books, is mentioned with commendation by Jerom and others. Some learned men have been of opinion, that he publiſhed a new Greek tranſlation of the books of the Old Teſtament, compiled from the Greek verſions that had been made before; but this does not ſeem to have been a fact, though Fabricius enumerates this as one of his works. Sozomen (Eccleſ. Hiſt. l. v. c. 18. p. 624.) mentions a valuable work of this author, addreſſed to the emperor himſelf and the Greek philoſophers, intitled, “Of the truth;” in which he ſhewed, by reaſon alone, without alleging the divine ſcriptures, that they did not think rightly of the deity. It is ſaid, that Julian writing to ſome Chriſtian biſhops concerning this book, made this remark; “I have read, underſtood and condemned;” to which he received this answer, “You have read, but you did not underſtand; if you had underſtood, you would not have condemned.” Beſides all theſe, Apollinaris wrote divers books againſt thoſe called heretics; and he employed his poetical talents in compoſing ſhort pſalms and hymns fitted for feſtivals and for all ſeaſons, on a variety of ſubjects; ſome of which were uſed in their religious aſſemblies, and others were ſung by the men at their works and entertainments, and by the women at their ſpindle. For an account of the doctrine of Apollinaris, and of the ſect of which he is ſaid to have been the founder, ſee APOLLINARIANS.

The character of Apollinaris has been very differently appreciated by modern writers. Lord Chancellor King, the reputed author of “The Apoſtle’s Creed,” &c. calls him the great Apollinaris, the ornament and ſplendor of the church of that age, the moſt ſignalized champion for the faith, and an illuſtrious example of piety and virtue; by all eſteemed the greateſt man of his age both for learning and piety; a moſt accurate and nervous defender of the faith againſt all its enemies, whether heathens or heretics. Dupin ſays, he was beloved and eſteemed by St. Athanaſius, St. Baſil, St. Epiphanius, and all the great men of his age, for learning and knowledge. St. Jerom ſays, that he had often ſeen him at Antioch, that he honoured him, and that he learned many things of him. Philoſtorgius, the Arian hiſtoriographer, ſays, that he and Baſil, and Gregory Nazianzen, defended the divinity of Chriſt better than any either before or after them; in compariſon of whom, the great Athanaſius was eſteemed to be but a child; and the moſt conſidered and eſteemed of theſe three was this Apollinaris; and that theſe three were wanting in nothing neceſſary for underſtanding and reading the ſcriptures; and eſpecially this Apollinaris, who underſtood the Hebrew language. He wrote againſt the Arians and other heretics, &c. in many volumes, overthrew heretiſes, and confuted errors oppoſite to the faith; and in thirty large and noble books, moſt convincingly baffled

And the calumnies of Porphyry: and his moral character was as conspicuous as either Gregory's or Basil's. His writings surpassed in beauty and strength every thing that had been written by Eusebius, or any of the ancients. Nevertheless he was excommunicated by George bishop of Laodicea, for taking the part of Athanasius against him. To these testimonies in favour of Apollinarius, we shall subjoin a very different kind of judgment formed concerning him by M. Tillemont. "He maintained to the end his impiety, and died in his heresy: so that we cannot admit the hope of any other lot for him, but the condemnation of hell." Dupin having mentioned Apollinarius's paraphrase of the psalms, adds, "All the other works of this author are lost, except some fragments. His error in all probability occasioned this loss: the catholics had such a dread of the books of heretics, that they have not preserved so much as those which had no relation to their heresy, and which might have been useful to the church."—"If that be so (says the candid and impartial Dr. Lardner), we must acknowledge that the catholics were to blame; it is like rooting up tares and good corn altogether. And we may hence receive this instruction, to be upon our guard that we admit not too great an aversion for men on account of difference of sentiment in things of a speculative nature; lest by violence in opposing error, we should obstruct the progress of knowledge, and the cause of truth which we are desirous to serve." Apollinarius died, according to Jerom, in the reign of Theodosius, and probably not long after the beginning of it, in 382, or soon after; for Epiphanius, in 376 or 377, calls him a venerable old man. Lardner's works, vol. iv. p. 380—397. Mosheim's Eccl. Hist. vol. i. p. 223. &c. Cave, Hist. Lit. vol. i. p. 250, &c.

APOLLINIS URBS, or APOLLINOPOLIS MAGNA according to Ptolemy, or APOLLONOS according to the Itinerary of Antonine, or APOLLONIAS according to Hierocles, in *Ancient Geography*, the capital of the fifty-second nome of the same name in the southern part of Upper Egypt, about twenty-five leagues nearly north of the great cataracts. M. d'Anville, Savary, and Denon, agree in assigning to it the situation of the present village of *Edfou* or *Esfu*, governed by an Arabian sheik.

The site of this ancient city is singularly advantageous, as it commands the river and the whole valley of Egypt: and its magnificent temple, seated on a rising ground, towers over the rest like a large citadel which keeps the adjacent country in awe; and, indeed, it is known to the natives merely by the name of "the fortrefs." The extent, majesty, magnificence, and high preservation of this edifice, says M. Denon, surpassed every thing he had before seen in Egypt, or elsewhere. The building itself is a long suite of pyramidal gates, of courts decorated with galleries, of porticoes, and of covered naves, constructed, not with common stones, but entire rocks. The excellent preservation of this ancient edifice forms a wonderful contrast with the grey ruins of modern habitations built within its vast inclosure; a part of the population of this village being contained in huts built in the courts, and around the fragments of the temple. This temple is the most beautiful in Egypt, and, next to those of Thebes, the largest. As it was built at a period when the arts and sciences had acquired all their splendour, the workmanship of every part is equally beautiful, the hieroglyphics are admirably executed, the figures more varied, and the architecture of a higher order than in the Theban edifices, the building of which must be referred to an earlier age. At the foot of this greater temple, and on a much lower level, is a smaller one, at present almost buried; but in a hollow surrounded with rub-

bish may be seen a little portico of two columns, and as many pilasters, a peristyle, and the sanctuary of the temple inclosed within a pilastered gallery. A single column with its capital rising from the ruins to the height of forty feet above the portico, and the angle of a wall forty feet beyond, shew that there formerly existed a court in front of the temple. The gates, it is observed, are not exactly in the middle of the sides. It seems to have been dedicated to the evil genius; for the figure of Typhon is seen in relief on the four sides of the plinth which surrounds each of the capitals: the whole friezes and all the paintings within appear descriptive of Isis defending herself against the attacks of this monster. M. Denon has illustrated his description of these temples by appropriate drawings. See Denon's *Travels into Upper and Lower Egypt*, &c. vol. ii. p. 107. 277.

APOLLINIS URBS, or *Apollinopolis Parva* or *Minor*, another city of Egypt, called also *Vicus Apollinis* in the Itinerary. According to Ptolemy, it belonged to the forty-eighth nome of Coptos; and was situated between Coptos to the north, and Thebes to the south-west, on the right of the Nile. M. d'Anville refers this to the present situation of *Kous*. Denon found in the middle of the square the summit of a large and well-proportioned gate, sunk into the ground to the cornice. This single fragment, which must have belonged to a great edifice, and which appears larger than all the rest of the city, proves, says this traveller, that *Kous* was built on the site of *Apollinopolis Parva*. The other parts of the edifice are, without doubt, buried under the mountain of rubbish that is occupied by the present town. The inscription, engraved on the listel of the gate, was posterior to the monument, and affords a curious example of ingenious flattery in a prefect of Upper Egypt, at the time of the Ptolemies; who, on account of some repairs twenty or thirty centuries after the building of the temple, ventured to dedicate it to his masters, to inscribe the gate with their names, and thus to transmit them to posterity. Denon's *Travels*, vol. ii. p. 236. 297.

APOLLINIS FANUM, or *Temple of Apollo*, a town of Lydia, according to the periplus of Scylax, which became a bishop's see. This is also the name of a place of Africa propria, according to Ptolemy, situate probably north-east of Tabraca.

APOLLINIS INFULA, an island of Africa, according to Steph. Byz.

APOLLINIS LUCUS, a grove consecrated to Apollo in that part of Cisalpine Gaul called *Transpadana*, among the *Libici*, to the north-west of *Vercelle*.

APOLLINIS OPPIDUM, a small town of Ethiopia, in the country of the *Megabores*, according to Pliny.

APOLLINIS PHESSII PORTUS, a port of Greece, attributed by Pliny to the *Ozole Locrians*.

APOLLINIS PROMONTORIUM, *Ras-Zebib*, was situated to the east of *Utica*, and to the north of *Carthage*. Another promontory of the same name is placed by M. d'Anville after Ptolemy, in *Mauritania Cæsariensis*, north-west of *Cæsarea*.

APOLLINIS REGIO, a name given to the country of Ethiopia.

APOLLINIS TEMPLUM, or *Temple of Apollo*, was situated in *Thrace*, and called *Zerinthium*. Another of this name was situated in *Lycia*, upon the gulf of *Myra*. Another was in *Thessaly*, upon the *Pelægic gulf*, near *Pagasa*.

APOLLINIS URBS, or *city of Apollo*, was a name given to *Delos*, called also *Astena*, in the *isle of Delos*.

APOLLO, in *Entomology*, a species of PAPILO, in the section

fection Parnassus. The wings are white spotted with black : on the upper side of the posterior wings are four eye-shaped spots, and on the under-side six. It inhabits Europe and Siberia : and is the *PAPILIO RHEA* of Poda. Gmelin.

APOLLO, in *Mythology*, a pagan deity worshipped by the Greeks and Romans. Cicero (*De Nat. Deor.* l. iii. c. 23. *Oper.* t. ii. p. 635. ed. Olivet.) distinguishes four deities of this name: the first and the most ancient was the son of Vulcan, and the guardian of Athens; the second was the son of a Corybant, and born in Crete; the third was the son of Jupiter and Latona, who was born in the island of Delos at the same time with his sister Diana, and who was, according to Eusebius, the most ancient of the three, and, in many respects, the most celebrated; the fourth was born in Arcadia, and called by the Arcades, Nomius, or the legislator, because he enacted laws for them. Of these four, the three last were Greeks, and the first an Egyptian, who, according to Herodotus, was the son of Osiris and Isis, and called *Orus* or *Horus*. Pausanias agrees with Herodotus, and ranks Apollo among the Egyptian divinities. Diodorus Siculus also, after saying that Isis had invented the practice of medicine, adds, that she taught this art to her son *Orus*, named Apollo, who was the last of the gods that reigned in Egypt. Indeed, all the Grecian fables and mythologies may be easily traced to Egypt. To this purpose, it is observed, that if the Apollo of the Greeks was said to be the son of Jupiter, it was because Horus, the Apollo of the Egyptians, had for his father Osiris, whom the Greeks confounded with Jupiter. If the Greek Apollo was reckoned the god of eloquence, music, medicine, and poetry, the reason was, that Osiris, the symbol of the sun among the Egyptians, as well as his son Horus, had there taught those liberal arts. If the Greek Apollo was the god and conductor of the muses, it was because Osiris carried with him, in his expedition to India, singing women and musicians. The parallel might be pursued, and sufficient evidence is thus obtained, that the true Apollo was that of Egypt. Cicero says (*De Nat. Deor.* l. ii. c. 27. *Oper.* t. ii. p. 578.), that Apollo is a Greek name, and that he represents the sun; and that the sun is so called, because this luminary is alone so great compared with the other stars, or because this alone appears when it is risen, all the others being obscured. Accordingly the etymology may be deduced from α priv. and $\pi\omicron\lambda\lambda\omicron\varsigma$, many; as the Latins derive *sol* from *solus*, alone. Vossius thinks (*De Idol.* vol. i. l. ii. c. 17. p. 391.), that the Apollo of Greece and Rome was the same as the Abelson of the east; and Abelson was, in the etymological system of Bryant (*Mythol.* vol. i. p. 17), a combination of the terms Ab-El-Eon, denoting "Pater summus Sol", or "Pater Deus Sol." The sun was also worshipped, adds this writer, under the title of Abaddon; which, as we are informed by the Evangelist, was the same as Apollo, or as he terms him (*Rev.* c. ix. v. 11), Απολλων .

Apollo has been peculiarly distinguished by the poets, in preference to the other deities; and many extraordinary discoveries and performances have been ascribed to him. He has been esteemed the inventor of all the fine arts, such as poetry, music, and eloquence, and regarded as the protector of the poets, musicians, and orators. No one has performed like him on the lyre; and he has been thought to possess an intimate acquaintance with all the secret powers of medicine. The muses were under his protection, and he presided on Mount Parnassus at all their concerts. None of the gods was endowed to the same degree with himself, with the knowledge of futurity; and therefore he was the god of divination, and had a greater number of oracles than any other deity. Of these the Delphian claimed the

first rank on account of its antiquity, truth, and the perspicuity of its answers, as well as the magnificence of its structures, the variety and value of its *Anthemata* or presents, and the multitudes that resorted thither. There were others at Cirrha, Delos, among the Milesians, at Abæ, at Claros, at Larissa, in Bœotia at Eutresis, Tegyrae, and Ptoos, at Oropo in Eubœa, at Corycæ in Thessaly, at Hybla, at Ichor in Macedonia, &c. He had also temples through all Greece and Italy; and he was honoured and worshipped, as the representative of the sun, among the Gauls and Britons. It has indeed been doubted whether Apollo was a real personage, or merely a symbolical deity representing the sun. Vossius (*ubi supra*) adopts the latter opinion, and maintains that there was never any other Apollo besides the sun: thus he was styled the son of Jupiter, because that god was reckoned by the ancients, the maker of the world. His mother was called Latona, signifying "hidden," because all things were enveloped in the obscurity of Chaos, before the creation of the sun. He is represented as a beardless youth, because the sun never grows old and decays; and his bow and arrows denote his piercing beams. Besides, according to this writer, all the ceremonies that were performed to his honour bore an obvious relation to the great source of light which he represented. It is in vain then, he concludes, to seek for any other divinity than the sun, which was adored under the name of Apollo. There is reason, however, to imagine, that there might have existed some illustrious personage named Apollo, who after his apotheosis was made the emblem or symbol of the sun; as we know to have been the case with respect to the Egyptian deities, Horus and Osiris.

To the distinguishing qualities above enumerated and ascribed to Apollo, the poets have joined beauty, gracefulness, eternal youth, and the art of charming the ear by the sweetness of his eloquence, and the melodious sounds of his lyre, and of thus captivating both gods and men. Accordingly he is principally distinguished in ancient statues by the beauty of his face, and the gracefulness of his figure: and hence Virgil (*Æn.* iii. v. 119.) calls him "the beautiful;" and Tibullus (*l. ii. el. 3. v. 11.*), "the well-shaped god." We need not wonder then at the amours and love-conquests that have been attributed to him. His musical contests, and some of his other feats, will be related in their proper places, in the course of this work. See *MARSYAS*, *MIDAS*, *PAN*, *PYTHON*, and *THAMYRIS*.

Apollo is usually represented as a beautiful, beardless youth, with long hair (hence called "intonfus and crinitus;" Ovid. *Trist.* iii. 1. 60.), holding a bow and arrows in his right hand, and in his left hand a lyre or harp. He is crowned with laurel, which was sacred to him, and from this circumstance his favourite poets wore the same crown. In the character of the sun, his head is surrounded with rays. He is often represented on the coins of the Syrian princes. The animals consecrated to him were the wolf and hawk, as symbols of his piercing eyes; the crow and raven, from their supposed faculty of predicting the future; the cock, from his announcing the dawn of morning and rising of the sun; the grasshopper, on account of his tuneful powers, recorded and celebrated by Anacreon (*od.* 43); and the swan, partly from his prediction of futurity, and partly from his extraordinary vocal powers. The various appellations which were appropriated to Apollo, were derived either from some of his chief attributes, or from the places where he was worshipped. It would be endless to enumerate them all: we shall therefore content ourselves with some of the principal, and refer for their more particular explanation to the articles under which they occur. He was called *Asian*, in reference

to Actium; *Ἀκτιόκομος*, in his hymn, attributed to Homer; and "Intonus," by Propertius, Ovid, &c. on account of his long hair; *Alexicæcus*, from his power of healing; *Arctæonens* and *Argyrolæoxus*, from his bow and arrows made of silver; *Comæus*, from *κομῶν*, on account of his fine hair, under which appellation he was worshipped at Selencia; *Conseruator*, on a golden medal of Aurelian; *Corybæus*, from *Corybæ*, where he had an oracle; *Cynthius*, from a mountain of this name in Delos; *Delian*, from *Delos*; *Delphian*, from *Delphi*; *Didymæus*; *Ἐκβολῶς*, or *longe ejaculator*, in allusion to his arrows and the rays of the sun; *Latæus* and *Latonian*, from his mother Latona; *Medicus*, from his being the inventor of medicine; *Nauisilis*, from Augustus's having ascribed his victory at Actium to him; *Νομῶς*, or *Nomius*, either from his superintending herds and pasturage, or from the fertility which the earth derives from the influence of the sun; *Pæan*, formed of *παῖν* to strike, because he wounded with his arrows; *Patareus*, from Patara in Lycia, where he had a temple and oracles; *Phæbus*, from Phœbe the mother of Latona, or from his splendour; *Pythian*, from his victory over the serpent Python; *Smintheus*, from *σμινθῶν*, rats, a name given by the Cretes, who, having neglected his worship, were punished by the devastations of these, and rescued by his interposition; *Sortilegus*, from his presiding over lots; *Thuræus*, from *θύρα*, a gate, because he presided at the gates, among the Greeks, who adorned them with his statues; *Thymbreus* (Virgil *Æn.* iii. 85.), from Thymbra, where he had a grove and temple, &c.

APOLLO BELVIDERE, in *Sculpture*, a very celebrated antique statue, esteemed by the majority of artists the most excellent and sublime of all the ancient productions. It was found towards the end of the fifteenth century, at Capo d'Anzo, upon the sea coast, about twelve leagues from Rome, in the ruins of ancient Antium. It was purchased by pope Julius II. when only cardinal, and placed in his palace near the church of Santi Apostoli; but soon after, being made pope, he removed it to the Belvidere of the Vatican; from whence it takes its name, and where it was for three hundred years the admiration of the world; until Rome was taken and plundered by the French, who have transported this divine statue to the museum at Paris.

The marble out of which this statue was worked, is of so peculiar a kind, as to occasion much doubt about the quarry it was taken from. The sculptors of Rome are all of opinion that the marble is Grecian; with the exception of one or two, who call it marble of Luni or Carrara. However positive these opinions may be, it came most probably from a quarry totally unknown at this day.

Some accounts have stated, that this statue was the work of Agathias the Ephesian; but the French artists, who were sent to Rome at the time of the incursion of the French into Italy, to explore the different works of art and their history, state that the author is certainly unknown.

This statue is a standing figure, almost naked, and more than seven feet in height: it has a freedom, grace, and majesty in the whole attitude, and especially in the turn of the head, that surpasses any other antique known. The god is here represented with his quiver hanging behind his right shoulder, and his pallium over his left arm, which is extended, and has in the hand the remains of a bow, out of which he is supposed to have just discharged an arrow at the serpent Python. On this account the statue is called Apollo Pythius. The mind of the god is here so nobly exhibited, that without saying too much, he evidently appears watching the event of his aim; but with such confidence and majesty, as proceed from a certainty of success in the attempt; forming a sublime contrast to the tremulous anxiety of Discobolus, who, in another statue, is represented as having

just thrown the discus. On the stump of a tree, introduced in order to strengthen the figure, is executed a serpent, the symbol of physic, of which Apollo was god. To describe this figure in few words; it is a complete composition of sublimity, elegance, activity, and youthful beauty. The right fore-arm and the left hand, which were wanting, have been restored by Giovanni Angelo da Montorfoli, pupil of Michael Angelo.

In the eighth year of the French Republic, Bonaparte, accompanied by the third consul Lebrun, was present at the inauguration of this statue; and on the occasion, a bronze tablet was presented, in the name of the artists, by Citizen Vien, and placed on the pedestal of the statue, on which was engraved the following inscription:

La statue d'Apollon, qui s'éleva sur ce piédestal trouvée à Antium sur la fin du XV^e siècle, placée au Vatican par Jules II. au commencement du XVI^e, conquise l'an V. de la République par l'armée d'Italie, sous les ordres du général Bonaparte, a été fixée ici le 21 Germinal, an VIII. première année de son consulat.

On the opposite side of the pedestal is engraved:

Bonaparte, I^{er} Consul.
Cambacérés, II^e Consul.
Lebrun, III^e Consul.

Lucien Bonaparte, Ministre de l'intérieur.

Besides the above, there are many other statues of Apollo; some of which possess great merit. In the Villa Mediceis were the following.

One smaller than life, grouped with a figure of the God Pan, who is teaching him to play on the syrinx. (One, the fame as this, was in possession of the Earl of Besborough at Roehampton.)

Another Apollo, leaning his left elbow on the stump of a tree; his right arm rests upon his head. A very elegant and beautiful statue. The left arm and the feet are modern. This is called the Apollo de Medicis.

Another, leaning on the stump of a tree; with his legs crossed. This was originally playing on a lyre; though the lyre is now wanting. Over the tree hangs the pallium of Apollo, and at the bottom is a swan. The air of the head, and the sweep of the body of this figure, are very elegant.

Two others, of the same design; except that their heads are more elevated. These are not quite equal in merit to the first.

Another, is also leaning on the stump of a tree, with his lyre: very fine.

In the palace Farnese, was an Apollo of black marble, leaning on his lyre, with his right hand over his head.

Another in the palace Giustiniani, where he holds the skin of Marsyas: very fine.

A group of Apollo and Marsyas was in the palace Chigi, in which Apollo has one hand on the shoulder of Marsyas, with a knife in the other. They regard each other, in this group, with an expression that is surprizingly well told. The air of Apollo's head is divine.

There are some small beautiful statues of Apollo at Wilton house: several at Paris, and very many in different parts of Europe, besides a great many celebrated bustos and basso-relievos.

APOLLO was also the name of a kind of pantomime dance, which exhibited some actions of this god:

APOLLODORUS, in *Biography*, a grammarian of Athens, was the son of Asclepiades, and a disciple of Aristarchus the grammarian, and of the two stoic philosophers Panætius and Diogenes the Babylonian. He flourished about

the 15th olympiad, or 148 years before Christ, under Ptolemy Philometor. None of his works are extant but three books of his "Bibliotheca," which contain the fabulous history of the Grecian divinities and heroes, from Iachus, who is believed to have founded the kingdom of the Argivi in the time of Abraham, to the time of Theseus, prince of Athens. This history was written in the reign of Pectalus king of Pergamus, who died in the 3d year of the 19th olympiad, or 138 years before Christ. Heinger pronounces this to be a very ingenious and elegant performance, from which we may derive some acquaintance with ancient history, as the fables are founded on historical truth, and as the persons whom it records actually existed, though their actions are exaggerated or disguised. He adds, that we may extract from Apollodorus a more certain and better founded chronology, than from the rhapsodies of Herodotus: and Vossius is of opinion, that by separating the fabulous stories from real events, we may form from his writings a true history. The first edition of this work was published by Spolatinus at Rome, in 1575, 8vo.; but the best edition is that of Gal, among "the five ancient Greek writers of fabulous history;" to which he has annexed notes, and a genealogical table, in 1655. Fabr. *Bibl. Græc.* l. iii. c. 27. t. ii. p. 660, &c.

APOLLODORUS, a famous Athenian painter, flourished about the year before Christ 408. He is said to have possessed the resources, in which his predecessor Polygnotus failed, and to have diversified the tone of his colours, and to have produced a happy mixture of light and shade. Heicybius says, that he was so sensible of his superiority in the exercise of his art, that he wore a sort of regal tiara, as the prince of his profession. Zeuxis improved upon his discovery, and Apollodorus, in a poem written on the occasion, records and exalts that of his rival. "I had discovered," says he, "for the distribution of shades, secrets unknown till our days; they have been wrested from me; the art is in the hands of Zeuxis." Pliny, *Hist. Nat.* l. xxxv. c. 9. Anacharhis's *Travels*, vol. i. p. 448.

APOLLODORUS, a famous architect, was born at Damascus, and flourished under Trajan and Adrian. In the year of Christ 104, he built the stone bridge over the Danube, which was one of the most considerable works of Trajan; and he also constructed the edifices round the Forum Trajanum in Rome, among which were a triumphal arch, and the sculptured column of Trajan, now existing. His offensive reply to Adrian, who seems to have envied his talents and fame, was rewarded with a severity which must be universally condemned. Whilst Apollodorus was conversing with Trajan on some plans of architecture, Adrian interfered, and gave an opinion, which the artist treated with contempt: "Go," says he, "and paint gourds," (an amusement which Adrian was fond of.) "for you are very ignorant of the subject on which we are conversing." When Adrian became emperor, the affront was remembered, and it prevented Apollodorus from being employed: nor was the opinion, which Apollodorus gave with respect to the plans of a sumptuous temple of Venus, which the emperor was building, at all conciliatory. Adrian, meanly jealous, and inexcusably revengeful, banished the architect; and having caused him to be accused of various crimes, put him to death. *Crevier's Rom. Empr.* vol. vii. p. 171. *Gen. Dict.*

APOLLODORUS, born at Lemnos, was physician to Ptolemy Soter, to whom he is said by Pliny to have dedicated a book on the qualities and use of wine. There were two other physicians of that name, both mentioned by Pliny; one of them is supposed to have invented an antidote against the bite of a viper, described by Galen. Haller, *Bibl. Med. Pract.*

APOLLONIA, in *Antiquity*, casts sacred to Apollo at Egalea. It is said, that Apollo, after the defeat of Pytho, having retired to Egalea with his sister Dana, was driven thence by the inhabitants, and obliged to seek a retreat in the island of Crete. In a little while, a plague made great ravages in this place, and upon consulting the oracle, information was received, that seven young women, and as many young men, should be sent to Apollo and Diana to request their return to Egalea. As soon as these deities arrived, the plague ceased; and in commemoration of this event, they annually departed the same number of young women to go, as it were, in search of Apollo and Diana.

APOLLONIA, in *Biography*, a female Christian Martyr of Alexandria, was of an advanced age at the beginning of the Decian persecution, in 248, and yet fell a sacrifice to her profession. Her persecutors struck her upon the cheeks, and beat out all her teeth; then lighting a fire without the city, they threatened to burn her alive, unless the world join with them in pronouncing certain profane words; but she legging a short respite, and being released, threw herself into the fire, and was consumed to ashes. *Euseb. Eccl. Hist. lib. vi. c. 41. p. 257. Gardner's Works.* vol. viii. p. 147.

APOLLONIA, in *Ancient Geography*, the name of several ancient cities; viz. a town of Assyria, situate, according to Steph. Byz. between Babylon and Suza. M. d'Anville places it upon the river Delas, to the north-east of Artemita.—A town of Palestine, between Cæsarea and Joppa, called Apollonias by M. d'Anville, and placed to the north-west of Antipatris. It was re-established by Galinius, president of Syria, after having suffered much in wars of this province.—A town which some authors place in Phisidia, but which M. d'Anville places in Carna, near the Mæander, at some distance to the west of Antiochia Mæandri.—A town of Mysia, according to Steph. Byz.—A town of Asia Minor, in Bithynia, on the north bank of a lake of the same name, and near the Rhynchachus, now Aboullona: this was once a city of great note, and maintained its lustre till the reign of the emperor Alexis Comnenus, when it was taken and pillaged by the Turks. Apollo is represented on the reverse of several medals of this city. There are many Imperial Greek medals that have been struck in this city, in honour of M. Aurelius Verus, Septimius Severus, Caracalla, Gordian, Plautilla, and Getz.—A town of Pontus, according to Pliny.—A town of the small island of Syphnos, one of the Cyclades. A town of Thrace, now Sizeboli, situate on the south side of a small gulf of the Euxine sea: this town was ruined by Lucullus, when he was governor of Macedonia.—A town of Macedonia in Chalcidica, situate upon the Chabrus to the north of Chalcis. Another town in Macedonia, in Mygdonia, south-east of Thessalonica, and south-west of Amphipolis. A town dependent on Macedonia, when it extended to the west as far as the Adriatic sea. It was situate at a small distance north of the Aous, and was an episcopal see.—A town of the Phocide, on mount Parnassus, and formerly called *Erannus*, and also *Cyparissus*.—A town in an island near Acarnania.—A town of Sicily, near the promontory of *Paclinum*, where was a temple of Apollo. The medals of bronze struck in this city, had the legend "Tauromenitan."—A town of Crete, near Gnossus, according to Steph. Byz.—Another town of Crete, formerly called *Eleuthera*. It was, says Steph. Byz. the country of Linus, and of Diogenes the physician.—An island in the vicinity of Lycia, Steph. Byz.—A town of Lybia.—A town of the Cyrenaica, towards the north west, and near the sea. Under the lower empire it took the name of Sozusa, and its modern name is *Marxa-Susa*.—A town of Illyria, on the Ionian sea, near Epidamnus,

Epidamnus, and not far from the port of Oricum, according to Herodotus.

APOLLONIA, *Cape*, in *Geography*, a promontory on the Ivory coast of Africa, in N. lat. $4^{\circ} 50'$, and in the midway between Rio Snero da Costa, and Cape Threepoints, from which it is distant W. by N. 15 leagues. It is remarkable for its height, and the lofty trees with which it is covered. The surf at the Cape is so violent that no boats can land there; and though it has a fort, it is of little or no importance.

APOLLONIAN *Hyperbola* and *Parabola*, in *Mathematics*. See HYPERBOLA, PARABOLA, and CONIC SECTIONS.

APOLLONIATIS, in *Ancient Geography*, a country of Assyria, so called from its metropolis Apollonia, lay east of Adiabene, and is placed by Ptolemy between the rivers Gorgus and Silla.

APOLLONIUS PERGÆUS, in *Biography*, an eminent mathematician of Perga in Phamphyliia, flourished under the reign of Ptolemy Energetes, about 240 years before Christ. He studied under the disciples of Euclid at Alexandria, and there laid the foundation of that celebrity which entitled him to the distinguishing appellation of the "Great Geometrician." Of the various mathematical works which he is said to have composed, the only one now extant is his Treatise on the Conic Sections; and even this has been transmitted to us in an imperfect state. It appears by the author's dedicatory epistle to Eudemus, to have originally consisted of eight books, but of these seven only remain. Heraclius, in a life of Archimedes, charges Apollonius with having appropriated to himself the discoveries and writings of that eminent mathematician; but Eutocius repels the charge, and vindicates him from any dishonest plagiarism. Whilst it might naturally be imagined that he would avail himself of the works of his predecessors, it nevertheless sufficiently appears, that he has made several valuable improvements on Euclid and Archimedes. Eutocius informs us, that before the time of Apollonius, it was usual for mathematicians to deduce the properties of the conic sections from three different sorts of cones; those of the parabola from a right-angled cone; those of the ellipse from an acute cone; and those of the hyperbola from an obtuse cone; because they admitted only one mode of cutting the cone, which was by a plane perpendicular to the side: but Apollonius, by varying the position or inclination of the cutting plane, derived all these sections from any single cone. This valuable improvement, now universally adopted, had been for a considerable time ascribed by Eutocius, Pappus, and others, to Apollonius. Guido Ubalduus, however, in his Commentary on the 2d book of Archimedes's "Equiponderantes," published at Pisa, in 1588, has shewn, that he was acquainted with this method of obtaining the several sections of the cone. Archimedes is said to have appropriated the name of parabola to one of these sections; and the appellations of ellipse and hyperbola are said to have been introduced by Apollonius, in imitation, probably, of the former. However this be, it is universally allowed, that the conic sections of Apollonius rank among the most valuable remains of antiquity. The first four books have been preserved in the original Greek; and the 5th, 6th, and 7th, have been transmitted to us in an Arabic translation. The translation of Apollonius's conics was begun under the caliph Almamon, in the year 830; and Thebit Ben Corah took pains to revise and augment it with that of the three last books, in the course of the same century. Abalpiat made a new translation, under the caliph Abucalighiar, in 924; and this version fortunately fell into the hands of Borelli, in the manner recited in the sequel of this

article. This celebrated work of Apollonius, in its imperfect state of four books, was first known among the western Christians towards the middle of the 15th century, when Regiomontanus projected an edition of it, which he was prevented from completing by his death. In 1537, a Latin translation was made by Memmius, a noble Venetian, and published after his death by his son. This seems to have been the first edition, and its being the first was the only merit that belonged to it. A better translation of the first four books by Commandinus, with the Commentary of Eutocius, and the Lemmas of Pappus, was published at Bologna, in 1566; they were also printed in 12mo. by H. Stephens, at Paris, in 1626; in folio, at Antwerp, in 1655; and in 4to. at London, by Dr. Barrow, in 1675. The loss of the other three books of Apollonius was much regretted by the Europeans; and attempts were made to recover them. Maurolycus, a Sicilian geometrician of the 16th century, sketched out the theory of the 5th and 6th books, and it was published by Borelli, as a Supplement to Apollonius, in 1654. Father Richard, the Jesuit, promised a work of the same nature, but it never appeared; however, his prolix Commentary on the first four books was printed at Antwerp, in 1655, in folio. Whilst Viviani was collecting materials for the restoration of the lost books, Golius returned from the east with a great number of Arabian MSS. among which were the seven first books of Apollonius's Conics. This discovery was speedily announced; and in 1644, it was noticed by Mercennus. Golius delayed the translation that was expected; and in 1658, Borelli, visiting Florence, found in the library of the Medicis, an Arabian MS. the Italian title of which announced the eight books of Apollonius. Ferdinand II. duke of Tuscany, generously entrusted him with this MS. which he carried to Rome; and with the assistance of Abraham Ecchellenfis, an oriental linguist, it was translated into Latin, and published with notes, and a preface, maintaining that these books are not supposititious, in 1661. The 8th book was still wanting; and Golius affirmed, that it was not contained in the Greek copies from which the other books were translated by the Arabians. However, the learned Mercennus, who published Apollonius's Conics, in his "Synopsis of the Mathematics," found an Arabian work of Aben Neden, written about the year 1020, in which the 8th book is mentioned; and it is asserted that all the books were extant in Arabic. A splendid edition of all the eight books has been published at Oxford, in folio, by Dr. Halley, in 1710; together with the Lemmas of Pappus, and the Commentaries of Eutocius; the first four books in Greek and Latin; the rest in Latin only; and the last restored by the editor. An 8vo. edition was also published at Oxford by Dr. Halley.

This excellent work was begun by Dr. Gregory, whose death prevented his proceeding farther than the 44th page; and completed by Dr. Halley, with the assistance derived from an Arabic version in the Bodleian library, made by Thebit Ben Corah; and another Arabic MS. in the same library, made by Abdolmelech Schirazita, a Persian, about 600 years ago, and brought out of the East by Christianus Ravius, and principally the MS. of Golius, purchased of his heirs by Dr. Marsh, archbishop of Armagh, and communicated to him for the public benefit. This MS. contains the first seven books of Apollonius's Conics; was translated by Thebit Ben Corah; and after several amendments, completed, in 1303, at Maraga, a city on the confines of Media and Assyria.

With respect to the conic sections, we shall merely observe, that their properties are derived in the most scientific and

and satisfactory manner from the cone; and this has been done by several moderns, and among others, with peculiar advantage, by Dr. Hamilton. Others have, in a manner more operose, deduced their properties from descriptions of the several curves on a plane; and a late very ingenious attempt, which, in the construction and demonstration, is almost wholly original, has been made to deduce all the properties of the three conic sections, from the 24th proposition of sir Isaac Newton's Universal Arithmetic, in Mr. Walker's Treatise "on the Conic Sections," the first book of which was published in London, in 1794.

The other writings of Apollonius, mentioned by Pappus, are the following: "The Section of a Ratio, or proportional Sections;" "The Section of a Space;" "Determinate Section;" "The Tangencies;" "The Inclinations;" "The Plane Loci;" each of these comprehended in two books. Pappus delivers many Lemmas relating to them; and attempts have been made for restoring them by modern mathematicians. Montucla. Hist. des Math. tom. i. p. 243—253. Voff de Scient. Math. Fabric. Bib. Græc. lib. in. c. 22. § 17. tom. ii. p. 556. Gen. Dict. Halley's Preface.

APOLLONIUS, surnamed *Difcolus*, or the *lean*, on account of the poverty of his condition, a celebrated grammarian of Alexandria, lived in the reigns of Adrian, and Antoninus Pius. Such was his indigence, that having no money to buy paper, he was obliged to write on oyster shells. Priscian prefers Apollonius and his son Herodian to all preceding grammarians, and professes to follow Apollonius as his guide. His treatise "on Syntax," written in Greek, is highly commended by Priscian. A correct edition of this work, with a Latin translation and notes, was published in 4to. at Frankfort, by Sylburgius, in 1590. Another treatise ascribed to this writer, intitled, "Ἱστορίαι θαυμαστίαι, or Wonderful Histories," was published, with other pieces, by Antonius Liberalis, Phlegon and Antigonus, and the works of M. Antoninus, in 8vo. at Basil, in 1568; and a better edition in 4to. at Leyden, in 1620, by Meursius. Suidas. Fabr. Bibl. Græc. lib. v. c. 7.

APOLLONIUS *Rhodus*, so called from his long residence at Rhodes, was a native of Alexandria, and flourished in the 3d century before Christ, under Ptolemy Euergetes. Callimachus was his preceptor, by whom he was severely satirized for his ingratitude; and he succeeded Eratosthenes in the care of the Alexandrian library. Of his works, the most distinguished is a poem, in four books, on the Argonautic expedition. The author, mortified by the censures passed upon it at its first publication, removed to Rhodes, and opened a school of rhetoric; but having afterwards corrected and improved it, the Rhodians applauded it, and conferred on him the freedom of the city. This poem has been differently appreciated both by ancient and modern critics. Quintilian and Longinus give it only the praise of mediocrity, and represent it as having no claim to real genius, and as displaying the rhetorician rather than the poet. By others it has been commended as exhibiting beauties of a sentimental and descriptive kind; and Virgil has borne testimony to its value, by copying several incidents from the relation of the loves of Medea and Jason, into his beautiful story of Dido and Æneas. Rapin, in his "Reflections upon Poetry," (Part ii. Refl. 15.) declares, that his style has no manner of elevation or sublimity, and that the structure of the fable is very injudicious; that the catalogue of the Argonauts is destitute of variety; and that the poem becomes extremely languid from the first book: besides, Apollonius has egregiously erred in making this expedition to continue but four months.

The best editions of the "Argonautics," are Apoll. Rhod.

impress. in literis majusculis, ed. princeps; 4to. Florent. 1406. Apoll. Rhod. Gr. ed. 2d. 8vo. apud Ald. 1513. Apoll. Rhod. Gr. with the Scholia. 4to. H. Stephan. 1574. Apoll. Rhod. Gr. & Lat. by Hoelzlin, Leyden. 8vo. 1641. Gen. Dict.

APOLLONIUS, a famous Rhodian sculptor. The same who, with his contemporary Tauriscus, executed the celebrated groups of Niobe in the Villa Medicis; and of Zethus and Amphion, in the Farnese palace.

APOLLONIUS, a Roman senator and Christian martyr, lived in the time of Commodus, and suffered death at Rome, probably in the year 186 or 187. Being accused before Perennis, præfect of the prætorium, he pronounced an eloquent apology for the faith before the senate; and was then sentenced by their decree, to have his legs broke, and then to be beheaded: according to an ancient law, which enacted, that if any Christian were in a court of justice, he should be punished, unless he denied himself to be a Christian. Eusebius says, that he was celebrated for learning and philosophy; and Jerom mentions him among some of the most eminent Christian writers. Euseb. Eccl. Hist. l. v. c. 21. p. 189. Lardner's works, vol. ii. p. 303. v. viii. p. 339.

APOLLONIUS, a sophist and grammarian, was the preceptor of Apion, and lived in the time of Julius and Augustus Cæsar. He was the author of a Greek lexicon to the Iliad and Odyssey of Homer, which was published for the first time with a Latin translation, after remaining long unknown, in 2 volumes 4to. by J. Baptill de Villouin, at Paris, in 1773, under the title of "Apollonii Sophistæ Lexicon Græcum Iliadis & Odysseæ." Nouv. Dict. Hist.

APOLLONIUS, a stoic philosopher, was a native of Chalcis in Syria, and a preceptor of Marcus Aurelius. When this stoic came to Rome, at the request of Titus Antoninus, instead of hastening to take the charge of his princely scholar, he replied to a message sent to him by the emperor desiring his attendance; "It is not fit for the master to go to his scholar, but for the scholar to come to his master." Antoninus, upon receiving this arrogant and rude reply, mildly and jocosely said, "Apollonius could come from Syria to Rome, but cannot come from his house to the palace." Crevier's Rom. Emp. vol. iii. p. 241.

APOLLONIUS *Tyanaus*, a Pythagorean philosopher and notorious impollor, was born about the commencement of the Christian æra, at Tyana, a city of Cappadocia. At 14 years of age he was sent by his father to Tarsus, to be instructed by Euthydemus a rhetorician; but dissatisfied with the luxury and indolence of the inhabitants, he removed with his preceptor to Ægæ, in which there was a temple of Æsculapius. Here he acquainted himself with the doctrines of the Platonists, Stoics, Peripatetics, and Epicureans: but the Pythagorean tenets and discipline being more consonant to his own views and temper, attached his chief regard; and he made choice of Euxenus for his preceptor in philosophy, and determined to conform in the strictest manner to the Pythagorean discipline. Accordingly he abstained from animal food, and lived wholly upon fruits and herbs; he made no use of the skins of animals for his clothing; he went bare-footed, and suffered his hair to grow to its full length; and he spent the greatest part of his time in the temple of Æsculapius with the priests, by whom he was much admired, and who, without doubt, initiated him by their adulation and inlluertion into the mysteries of impollure. During his abode at Ægæ, he does not seem to have attempted any thing miraculous, but availed himself of the authority of the god, in whose temple he resided, to enforce moral lessons. To an Allyrian youth, who repaired to Æsculapius for the cure of a dropy occasioned by intemperance, he recommended abstinence, and thus cured his disease. A wealthy citizen, who was profuse

in his sacrifices and oblations in the temple, that he might obtain the restoration of an eye that had been lost in punishment of conjugal infidelity, Apollonius dismissed as unworthy of admission into the temple: and he also instructed the people who resorted thither, that when they entered into the temples of the wife, jult, and all-knowing gods, they should pray for obtaining what it is fit for them to receive; and that the wicked, however lavish they might be in the disposal of their wealth, would be rejected; because they made their offerings not to honour the deity, but to purchase exemption from deserved punishment. Upon the death of his father, he attended his funeral at Tyana, and having given the greatest part of his wealth to his brother, and admonished him to reform his vicious conduct, he returned to *Ægæ*, where he erected a temple, and established a school of philosophy. In order to qualify himself for the office of preceptor in the Pythagorean philosophy, he determined to pass through the noviciate of five years' silence, which the Pythagorean system required; and during this period he chiefly resided in Pamphylia and Cilicia, conveying instruction and admonition by his looks and gestures. At *Aspenda* he is said to have quelled a tumult occasioned by famine, and to have relieved the distressed people, by writing on a tablet the following reproof to the covetous engrossers of the grain; "The earth, the common mother of all, is just; but ye, being unjust, would make her a bountiful mother to you alone: desist from your iniquitous proceedings, or ye shall no longer be suffered to live." The terrified corn-merchants opened the granaries, the people were supplied, and the tumult was suppressed. When his term of silence was expired, he visited *Antioch*, *Ephesus*, and other cities, and associated chiefly with the priests. At sun-rising he performed certain religious rites, which he disclosed only to those who had passed through the discipline of silence, the rest of the day was spent in the instruction of his disciples, and in communicating counsel and reproof to the people. His style was neither too florid nor too refined, but truly *Attic*. Avoiding verbose declamation, and ironical railery, he delivered his doctrine with conciseness, and with the authority of a legislator. Being asked why he did not pursue his inquiries, instead of dogmatically asserting his tenets, he replied; "I sought for truth when I was young, it is now my duty to teach what I have found; a wise man ought to speak as a law-giver, and make the doctrines which he embraces, injunctions to the people." Apollonius now resolved to travel through distant nations; and having proposed his design to some of his disciples, they declined accompanying him. He therefore entered upon his expedition attended only by two servants. At *Ninus*, however, he engaged *Damis* as his associate; and to him he boasted, that he was acquainted with all languages, though he had never learned them; and that he even understood the language of beasts and birds: the *Assyrian* youth believed him, honoured him as a god, and accompanied him in his journey. At *Babylon*, Apollonius conversed with the magi; and in an interview with the king, whom he visited in his illness, he discoursed so excellently concerning the soul, that the sick monarch acknowledged to his attendants, that this Greek had taught him not only to despise a kingdom, but even death itself. At the expiration of the term which he had fixed in his prediction, he took his leave of *Babylon*; and furnished with camels and provisions for his journey over *Caucasia*, he pursued his route to *Taxella*, the residence of *Phraotis* the *Indian* king. With *Phraotis* he had many philosophical conferences; and being dismissed with presents, he was recommended to *Jarchas*, the chief of the *Indian* philosophers or *gymnosophists* residing between the *Hyphasis*

and the *Ganges*. After a residence of four months with these *Indian* sages, Apollonius returned to *Babylon*; and from thence passed into *Ionian*, where he visited *Ephesus* and several other places, every where reprovng the people for their misconduct, and enforcing the Pythagorean doctrine and discipline. In his visit to *Pergamus* and the ancient seat of *Troy*, he passed a night by himself near the tomb of *Achilles*; and he afterwards informed his companions, that by the power of an incantation which he had learned in *India*, he raised that hero from his tomb, and held a conversation with him. In the island of *Lesbos* he conversed with the priests of *Lesbos*, and from thence proceeded to *Athens*. He arrived there at the time when they were performing their sacred mysteries, and presented himself for initiation, but was refused because he was an enchanter; at a future period, however, he was admitted. After passing through some other *Grecian* cities, where he pretended to perform miracles and to predict future events, he pursued his course through the island of *Crete* to *Rome*. Just before his arrival, *Nero* had issued an edict, that all those who practised magic should be banished from the city. His friends were alarmed on his account, and though twenty-six out of the thirty-four persons who were his stated associates, deserted him, he persevered in his purpose, and under the protection of the sacred habit obtained admission into the city, and also leave from the consul *Telesinus* to visit the temples and converse with the priests. From *Rome*, Apollonius travelled to *Spain*; and after the death of *Nero*, he returned to *Italy* in his way to *Greece*, whence he proceeded to *Egypt*, where *Vespasian* was trying every expedient to establish his power. This prince engaged the philosopher in his favour; and he in return adapted his measures to the views of the new emperor, and used all his influence among the people in support of *Vespasian's* authority. Whilst he was in *Egypt*, he visited *Æthiopia*; and on his return he was favourably received by *Titus* the successor of *Vespasian*, to whom he wrote the following laconic epistle, on his refusing a crown of victory upon his taking *Jerusalem*: "Apollonius to *Titus* emperor of the Romans sendeth greeting: since you refuse to be applauded for bloodshed and victory in war, I send you the crown of moderation; you know for what kind of merit crowns are due." Upon the accession of *Domitian*, he was concerned in exciting a sedition in *Egypt* against that tyrant, and in favour of *Nerva*. An order was issued for seizing him and bringing him to *Rome*; but as soon as he heard of the order, he repaired thither of his own accord; and was brought to trial before the prætor *Eliau*, who acquitted him. Apollonius now passed over into *Greece*, and visited the temple of *Jupiter* at *Olympia*, the cave of *Trophonius* in *Arcadia*, and other celebrated seats of religion; and wherever he went the number of his followers increased. At length he settled at *Ephesus*, and there established a Pythagorean school, and had many disciples. Of his fate, after he settled at *Ephesus*, nothing certain is related. The time, the place, and the manner of his death, are unknown. It is probable that he lived to an extreme old age, and died in the reign of *Nerva*. After his death, *Damis* became his first memorialist. His memoirs were communicated by a friend, to the empress *Julia*, the wife of *Severus*, and by her to *Philotratus*, with a request that he would transcribe and embellish the narrative. *Philotratus* undertook the task, and so loaded his account of the life of this extraordinary man with marvellous tales, that it is very difficult to ascertain the credit due to his narrative. He relates, for example, that while the mother of Apollonius was pregnant, the *Egyptian* divinity, *Proteus*, appeared

peared to her, and told her that the child she should bring forth was a god; that his birth was attended with a celestial light; that in the Æsculapean temple at Ægæ he predicted future events; that at the tomb of Achilles, he had a conference with the ghost of that hero; and that whilst he was publicly discoursing at Ephesus, he suddenly paused, as if struck with a panic, and then cried out, "Slay the tyrant;" at the very instant when Domitian was cut off at Rome. If to these tales we add the accounts which Philostratus gives of the efficacy of the mere presence of Apollonius, without the utterance of a single word, in quelling popular tumults; of the chains of Prometheus which he saw upon mount Caucasus; of speaking trees, of pignies, plumes, satyrs, and dragons, which he met with in his eastern tour; and of other things equally wonderful; it will be impossible to hesitate in ascribing the marvellous parts at least of Philostratus's narrative to his ingenuity, or his credulity. Nevertheless, the narrative of Philostratus, with all its inconsistencies, was, about a century after its appearance, referred to in preference to other accounts of Apollonius then extant, by Hierocles, who first endeavoured to form a comparison between Christ and this philosopher; and Eusebius, in refuting this attack upon Christianity, admits, in general, the accounts of Philostratus, and shews that, according to his account, Apollonius does not deserve to be compared with Christ.

Dr. Lardner indeed has fully shewn that Philostratus did not write the life of Apollonius with any reference to the life of Christ: and that his design was to exhibit this philosopher as a counterpart to Pythagoras. The narrative of Philostratus may be admitted, in concurrence with other collateral evidence, as a sufficient testimony to the existence of such a man as Apollonius, and to his having been an eminent philosopher of the Pythagorean sect, who travelled through almost every part of the civilized world, exhibiting an example of strict and rigid morality, teaching lessons of moral wisdom, and doctrines of speculative philosophy, and attracting popular attention and reverence by pretending to supernatural powers. After all, very different opinions have been entertained concerning his character. Some have even supposed that the whole series of extraordinary events related concerning him has been the mere invention of Philostratus and others, for the purpose of obstructing the progress of Christianity, and providing a temporary support for the falling edifice of paganism; and it must be acknowledged that several writers on the side of infidelity have availed themselves of his history to cast a shade over the character of Christ, and to perplex and weaken the evidence afforded by his miracles, of his divine origin and mission. Some, allowing that such a person as Apollonius existed, of which there is no sufficient reason to doubt, have apprehended that he was intimately acquainted with nature, and deeply skilled in magical arts; and that he applied his knowledge and skill to the purposes of imposture, that he might thus delude a credulous multitude, and induce them to believe that he was something more than human; whilst others imagine, that he accomplished his fraudulent designs by means of a real intercourse with evil spirits. Perhaps the truth of the case is, that Apollonius was one of those impostors who professed to practise magical arts and perform other wonders for the sake of acquiring fame, influence, and profit among the vulgar. In this light he was regarded by his contemporaries: Lucian, who lived in the time of Trajan, and Apuleius, who flourished under Antoninus Pius, rank him among the most celebrated magicians.

How successfully Apollonius practised the arts of imposture, sufficiently appears from the events which followed.

The dominion over the minds of men which he found means to establish during his life, remained and increased after his death, so that he long continued to be ranked among the divinities. The inhabitants of Tyana dedicated a temple to his name. The Ephesians consecrated a statue to him, in commemoration of his having delivered them from the plague. The emperor Adrian collected his writings, and preserved them in his library. Caracalla dedicated a temple to him, as to a divinity among men. Alexander Severus kept, in his domestic temple, the image of Apollonius with those of Abraham, Orpheus, and Christ. Aurelian shewed the Tyaneans particular favour, from respect to his memory. Eusebius cites Hierocles, as ascribing to Apollonius a divine and hidden wisdom, by which, and not by magical art, he had performed great wonders; and it is added, that in his time there were persons who pretended to perform magical incantations by invoking the name of Apollonius. Ammianus Marcellinus (l. xxi. c. 14.), ranks this philosopher among those eminent men who have been assisted by the supernatural aid of a demon or genius, as Socrates and Numa: and Eusebius, who was indeed a credulous and fantastical Platonist, speaks of him as something between a god and man, and adds, that Philostratus ought to have intitled his history, "The Descent of a God upon Earth." The common people ranked him in the number of deified men, and made use of his name in incantations; and even among the philosophers of the Eclectic sect, he was regarded as a being of a superior order, who partook of a middle nature between gods and men.

Of the writings ascribed to Apollonius, none remain except his "Apology to Domitian," and his "Epistles." The first, in its substance, is genuine, but strongly marked with the sophistical manner of Philostratus: the latter abound with philosophical ideas and sentiments, and are written in a laconic style, which affords a presumption in favour of their authenticity. From these epistles it appears, that Apollonius blended with the Pythagorean system concerning the nature and origin of things, according to which God and nature are primary, independent principles, the notion of the Heraclitean school, viz. that the primary essence of all things is one, endowed with certain properties by which it assumes various forms; and that all the varieties of nature are modifications of the universal essence which is the first cause of all things, or God. Hence Apollonius taught, that all things arise in nature according to one necessary or immutable law; and that a wise man, being acquainted with the order of nature, can predict future events. Thus Apollonius connected superstition with impiety, and made both subservient to imposture. The epistles of Apollonius were edited by Commelin, in 8vo. in 1603; and by Stephens, in 1577. Philostrat. Vit. Apoll. Brucker's Hist. Philos. by Enfield, vol. ii. p. 42—49. Gen. Dict. Lardner's works, vol. viii. p. 256—292.

APOLLOS, a native Jew of Alexandria, and a Christian convert, was celebrated in the time of the apostles for his eloquence and his knowledge of the scriptures; Acts, xvii. 24. In the year 54, he went to Ephesus; and, during the absence of the apostle Paul, preached the gospel in the synagogue, and demonstrated from the scriptures that Jesus was the Christ. Having been more fully instructed by Aquila and Priscilla, he went to Corinth, and preached with such acceptance and success, that he made many converts; and such was his popularity, that they considered him as their leader, in opposition to Peter and Paul; 1 Cor. iii. 7. But this division did not alienate the affections of Paul and Apollos from each other. St. Jerom says, Apollos was so dissatisfied with the division which had happened on his account

at Corinth, that he retired into Crete with Zeno, a doctor of the law; but when the disturbance was appeased by the letter of St. Paul to the Corinthians, Apollos returned to this city, and became bishop there.

APOLLYON, in *Scripture History*, a Greek appellation corresponding to the Hebrew ABADDON, which see; see also APOLLO.

APOLOGETIC, APOLOGETICAL, something said or written by way of excuse or apology for any action or person.

The Apologetic, or Apology of Tertullian, is a work full of strength and spirit. He there vindicates the Christians from all that had been objected to them; particularly from the abominable crimes said to be perpetrated at their meetings, and their want of love and fidelity to their country. The ground of this last accusation was, their refusing to take the accustomed oaths, and swear by the tutelary gods of the empire. Tertullian addresses his Apologetic, written at Carthage about the year 200, to the magistrates of Rome, the emperor Severus being then absent, or rather to the governors of provinces, or perhaps to the proconsul of Africa; and the chief magistrates residing at Carthage. His Apologetic addressed to Scapula, proconsul of Africa, on account of his severe treatment of the Christians, is supposed by Cave (*Hist. Lit. t. i. p. 93.*), to have been written in the year 217.

APOLOGOS, in *Ancient Geography*, *Oboleb*, a town of Asia, upon the bank of the Pafitigris.

APOLOGUE, APOLOGUS, a moral fable, or a feigned relation intended to inform and amend the manners. Jul. Scaliger derives the name *απολογία*, inasmuch as the apologue means something more than what at first sight it expresses. Such are the fables of *Æsop*: whence, moral fables are usually denominated *Æsopic Fables*.

F. de Colonia makes it essential to the apologue, that it contain what passes among brutes; and distinguishes it from the parable by this, that the latter, though feigned, consists of possible circumstances, which the former does not, since brutes cannot speak. There is this farther difference between them, that the latter is a similitude drawn from natural, moral, or any other branches of knowledge; the former only from moral topics. See PARABLE.

Apologue, according to some, differs from fable, as the former is used in speeches and harangues, to persuade; the latter in tragedies, comedies, and other pieces of poetry, to instruct, and correct the manners. See FABLE. Apologue also differs from *enus*, as the latter is only calculated for the use of men, and carries a graver and weightier admonition; whereas apologues are proposed to children. We find many things in authors concerning the origin of apologues, the distinguishing characters of apologues, the use and advantage of the way of teaching by apologues. See Bayle, *Dict. Crit. in voc. & Shaftesb. Charact. tom. iii.*

APOLOGY, formed of *απολογία*, to refuse, defence; a discourse or writing in vindication of a person or performance.

The principal ancient apologies in favour of the Christians are those of Quadratus, written about the year 126, and addressed to the emperor Adrian, which is said by Jerom and Eusebius to have had a good effect on the emperor; of Aristides, written at the same time with the former, and presented to the same emperor; two of Julius Martyr, one of which was written in the year 150, and addressed to Antoninus Pius, Marcus Antoninus, Lucius Verus, and the senate and people of Rome, which is extant entire, and the other in 162, presented to Marcus Antoninus, the beginning of which is wanting; one of Melito, in 177, presented to the same emperor; one of

Athenagoras, written between the years of Christ 177 and 185, and presented to M. Antoninus and Commodus; one of Apollinaris, addressed to M. Antoninus about the year 176 or 177; one of Miltiades, about the year 180, addressed to the princes of this world; three books in defence of the Christian religion, by Theophilus, written a little before his death, in the beginning of the reign of Commodus, A. D. 181, and addressed to Antolycus, a learned heathen; that of Apollonius before the Roman senate, A. D. 186 or 187; the apologetic of Tertullian, and the dialogue of Minucius Felix, called *Octavius*, written in the beginning of the third century.

We have two excellent treatises by the learned and ingenious Dr. Watson, bishop of Landaff, under the title of Apology: one, an "Apology for Christianity," in a series of letters addressed to the well-known historian, Mr. Gibbon, and printed in 1776; and another, "An Apology for the Bible," in a series of letters addressed to Thomas Paine, author of "The Age of Reason," and printed in 1796. The name of the author will sufficiently recommend these tracts in defence of our common faith.

APOLYSIS, from *απολυω*, I release, in a general sense, the solution or resolution of any thing. Thus we read of the apolysis of a disease, the apolysis of a bandage, or the like.

APOLYSIS, in a more particular sense, denotes the exclusion of any thing. Thus we read of the apolysis of the *fœtus*, the secundines, and the like.

APOMELI, in *Medicine*, a kind of decoction prepared of honey, or a honeycomb, mixed with vinegar, and boiled a short time, till the qualities of both be united, and the acrimony of the vinegar allayed.

The *apomeli* is represented as a kind of medium between melle and oxymel. It was anciently of great use among the Greeks, as a detergent, promoter of stool, urine, &c.

APOMYOS DEUS, from *απο*, and *μυια*, fly, in the *Heathen Mythology*, a name under which Jupiter was worshipped at Elis; and Hercules, as well as Jupiter, at the Olympic games. These deities were supplicated under this name, to destroy or drive away the vast number of flies which always attended the great sacrifices; and in those which accompanied the Olympic games, the first was always to the *Apomyos* or *Myiagrus Deus*, that he might drive the flies away from the rest. The usual sacrifice was the bull.

APONEUROSIS, compounded of *απο*, from, and *νευρον*, a nerve, in *Anatomy*, signifies an expanded tendon. See the description of the Aponeurosis of the *musculus obliquus externus abdominis*.

APONEUROTICUS MUSCULUS, a name given by Spigelius, and some others, to a muscle of the thigh, called by Cowper and Winslow, the *musculus lati tendinis*, and *musculus fascie late*. Winslow has called it, with more propriety, the *musculus vaginæ femoris*.

APONIA, from *α*, and *πονος*, labour, among Physicians, a state of indolence, or the absence of pain. In which sense, the word amounts to the same with *anodynia*. Hence also aponia is used by some for medicines which do not excite pain.

APONIANA, in *Ancient Geography*, a name given by Hirtius (*De bell. Afr. c. 2.*), to an island near Sicily, opposite Lilybæum, and supposed by Clavier to be the same with Cēgusa.

APONO, PETER DE, in *Biography*, a celebrated philosopher and physician, born at a village of that name near Padua, about the year 1250, went early to Constantinople to acquire a knowledge of the Greek language, and from thence to Paris, where he was instructed in mathematics and in medicine. He appears also to have visited England

and Scotland. In 1502, he was invited to Padua, to fill the Professor's chair. He afterwards went to Bologna, and so great was his reputation for his skill in medicine, that he is said to have received fifty crowns for every visit he made out of the city. On being sent for to Pope Honorius the fourth, he stipulated to receive four hundred ducats a day while he continued at Rome. As he pretended to a knowledge of astrology, and thence to forecast the termination of the diseases for which he was consulted, he was accused of being a magician, and cited before the tribunal of the inquisition. On this charge, however, he was at that time acquitted, as appears by the following inscription placed over one of the gates of the palace, at the foot of his statue erected there in the year 1420:

" Petrus Aponus Patavians,
Philosophicæ medicinæ quæ scientissimus,
Ob idque Conciliatoris cognomen adeptus:
Astrologiæ vero adeo peritus,
Ut in magicæ suspitionem incidere,
Falsòque de hæresi postulatus, absolutus fuit."

But being again accused of the same crime, he died before the process was finished, aged 66 years. Not appearing, therefore, to answer the charges against him, he was condemned, and his body ordered to be taken up and committed to the flames. The officers not being able to find the body, his friends having removed and privately interred it, they burned him in effigy. Frederic, duke of Urbino, honoured him with a statue, which he placed among those of other illustrious persons in his castle.

While at Paris, he wrote, "Conciliator differentiarum philosophorum, et præcipue medicorum," which was so much esteemed as to acquire for him the title of "Conciliator." This book, which has passed through several editions, was first printed at Mantua, in 1472, in folio; in the same year was printed his book "De Venenis, eorumque remediis;" also in folio, in 1474, "La Fisonomie du Pierre de Apono;" at Padua in 8vo. in 1505, "Textus Mæ sue emendatus," Lugduni, 8vo. For the titles of various other works, and their different editions, see Eloy's Diction. Histor. de la Médecine. Gen. Dict.

APONOGETON, in *Botany*, Lin. supp. 32. Schreb. gen. 835. Thunb. nov. gen. 72. Juss. 19. Class. *dodecandria tetragynia*. Nat. order. *inundata: naiades*, Juss.

Gen. char.: *cal.* none, except a spathaceous scale surrounding the flower, simple, sessile, ovate, obtuse, entire, erect, smooth, coloured; *cor.* none; *stam.* filaments eleven to nineteen, in the upper flowers fewer, inserted between the spathe and the capsules, subulate, smooth, white, many times shorter than the spathe; *pist.* germ usually four; *styles* none; *stigmas* subulate, bent inwards; *per.* capsules four, seldom three or five, ovate, subulate, acute, gibbous on the outside, flat on the inner side, smooth, one-celled; *seeds* three in each capsule, attached to its base, sessile, obovate, very blunt, smooth, sub-compressed.

Ess. gen. char.: *cal.* an amicum; *cor.* none; *caps.* three-seeded.

Species 1. *A. monostachyon*, single-spiked aponogeton: spike simple; leaves cordate-oval; root bulbous; leaves very long, petioled, radical, entire, floating, spike hexangular; bractes instead of a corolla, two below each florèt; stamens six, longer than the bractes. Observed by Koenig to be common in the fields in the East Indies that are flooded for rice. 2. *A. distachyon*, broad-leaved aponogeton: spike bifid; leaves linear oblong, floating; bractes entire; flowers many-stamened. Thunb. nov. gen. 4; root bulbous; spike imbricated within; flowers white, fragrant, alternate, erect,

with an ovate bract: pistils three or four; stamens vary from six to twelve; it flowers almost all the year. Thunberg found it in brooks at the Cape of Good Hope, whence it was introduced here by Mr. F. Masson in 1758. 3. *A. angustifolium*, narrow-leaved aponogeton: spike bifid; leaves linear lanceolate, erect; bractes two-parted; flowers six-stamened. The stamens of this species are in the Supp. Plant. said to vary from six to twelve, whereby it has been confounded with the preceding plant. A native of the Cape of Good Hope, introduced by Mr. F. Masson, in 1788. It flowers during the greater part of the year.

Propagation and culture: these plants are inhabitants of the green house: or cape-flower, and may be increased by offsets from the bulbs. See Miller's Dict. by Martyn.

APONUS, in *Ancient Geography*, an hamlet near Patavium or Padua, and celebrated by Martial as the birth place of Livy, and on account of its baths: now ABANO.

APOPEMPTIC, from ἀποπεμπω, *I dismiss*, in the *Ancient Poetry*, a hymn addressed to a stranger on his departure from a place to his own country.

The ancients had certain holy days, wherein they took leave of the gods with apopemptic songs, as supposing them each returning to his own country.

APOPHASIS, from ἀποφημι, *I declare*, and *I deny*, in the *Civil Law*, an answer or rescript of the prince.

Among *Logicians*, the word is also used for a negation or denial.

APOPHASIS was also used for the account given of estates, at the exchange of them, for avoiding public employments. When any man would excuse himself from any troublesome and chargeable trull, by asking it on another richer than himself, the person produced had power to challenge him to make an exchange of estates, and thereby compel him to undergo the office he had before refused.

APOPHASIS, in *Rhetoric*, a figure whereby we really say or advise a thing, under a feigned show of passing over or dissuading it.

Quintilian makes the apophasis a species of irony. Scalliger holds it the same with what is otherwise called *occupatio*.

APOPHLEGMATIZANTIA, (from ἀποφλεγματίζω, *pituita purgo*), MASTICATORIA, SALIVANTIA.—SIALAGOGUES. This term is applied to those remedies, by which a discharge of saliva is produced, or the evacuation of the saliva promoted. They are, properly speaking, evacuant, stimulating remedies, which, when they are chewed, or made to operate upon the internal parts of the mouth or throat, partly contribute to render the viscid fluid thinner, and partly produce a more copious flow of the saliva and other fluids, and their evacuation from the glands situated within the cavity of the mouth, about the palate, pharynx, larynx, uvula, and tonsils. To this class of remedies belong all those solid substances, which can be moved backwards and forwards in the mouth, without injury; as in consequence of the pressure which they give to the salivary glands, and in mastication, the discharge from those passages is increased: on this account such substances are chosen for this purpose as possess at the same time a degree of acrimony. As a security against the infection of contagious diseases, it has therefore always been recommended to chew cubebs, cardamom, cinnamon bark, juniper berries, wax, marjoram, sage, angelica root, and to spit out the saliva thus secreted. More stimulant remedies of this kind are, tobacco-smoke, the leaves of tobacco, mustard-seed, horse-radish, ginger, pepper, pimpinella, &c.

To the true sialagogues belong those powerfully resolvent medicines, which dissolve the mucous and acrid lymph that

that degree, as to enable it to be separated and discharged by the smallest vessels of the glands:—to these belongs MERCURY.—However the use of sialagogues cannot be recommended without distinction, as they are detrimental to debilitated constitutions, and those that are much inclined to vomiting. They are prejudicial to ulcers within the cavity of the mouth, and are frequently fatal to emaciated and phthisical constitutions.

APOPHORETA, from ἀποφέρειν, *I carry away*, in *Antiquity*, presents made to the guests at a feast or other entertainments, which they carry away with them.

APOPIRADES, from ἀποφραξις, *unfortunate*, derived again from ἀπο, and φραζω, *I speak*, in *Physic*, denote a sort of unhappy days, wherein either no crisis, or an ill one, is to be expected.

APOPTHEGM, from ἀπο and φθεγγμαι, *I speak*, a short, sententious, and instructive saying or maxim, delivered by a person of distinguished character.

Such is that of Cyrus: “He is unworthy to be a magistrate, who is not better than his subjects.” Or this: “He that will not take care of his own business, will be forced to take care of that of others.” Or that of Artaxerxes Mneumon, when reduced to hunger by the loss of his baggage: “How much pleasure have I hitherto lived a stranger to!” Or that of Cato, “Homines nihil agendo discunt male agere.” Or, finally, that of Augustus, “festina lente.” The apophthegms of Plutarch are well known.

APOPHYGE, in *Architecture*, that part of a column where it begins to spring out of its base, and shoot upwards.

The word in its original Greek signifies *flight*; whence the French also call it *escapè, congé*, &c.; and we, sometimes, the *spring* of the column.

The apophyge, in its original, was no more than the ring or ferril heretofore fastened at the extremities of wooden pillars, to keep them from splitting; which afterwards was imitated in stone-work.

It is properly a large concave or arched member, serving either to connect two flat members together, or to join a flat member to another not flat.

In this sense we may distinguish two apophyges, the upper and lower.

APOPHYGE, *upper*, is that part, or sweep, whereby a large flat member of the upper part of an order is connected to the lower.

This is also called by the French *le congé d'enhaut*; and by the Italians, *il cavo di sopra*.

APOPHYGE, *lower, apophygis inferior*, is a concave member, which connects two flat parts in the lower part of an order.

This the French call *le congé d'enbas*; and the Italians, *il cavo di basso*. Sometimes also, *il vivo di basso*.

APOPHYSIS, in *Anatomy*, a protuberance of a bone; or a part eminent, and jutting out beyond the rest. The word literally denotes a production outwards; formed from ἀπο τῆ ἀποφύεσθαι, *to arise from*. It is the same with what we otherwise call process, eminence, protuberance, projection, protuberance, ephyllis, head, and the like. *Apophyses* differ from *epiphyses*, as these latter are only appendages adhering or contiguous to a bone; whereas the former are productions or continuations of the bone itself, shooting out from it like branches from the trunk of a tree. For an account of the kinds of processes or apophyses, which are found in the skeleton, see SKELETON.

APOPHYSIS, or *Processus mammillaris*, a name given to the olfactory nerves, when they lie on the cribriform lamella of the ethmoid bone.

APOPHYSIS *mammillaris*, or *mastoidea*, is a process in the petrous part of the TEMPORAL BONE.

APOPHYSIS *raviana*, denotes a large process of the MALLEUS of the ear, formed to give attachment to muscles.

APOPHYES is also applied by Hippocrates to certain fleshy excrescences found in mules, and female *satufes* of seven months, as appearing rather processes, and origins of members, than distinct members, such as he says may be found in male *satufes*.

APOPHYES, in *Botany*, excrescences from the receptacle of the *musci*.

APOPLANESIS, from ἀποπλανω, *I deceive*, in *Oratory*, a kind of fallacious defence, and flurring over, darkening, and concealing things, in order to blind the judges, or the audience.

APOPLANESIS, in a more particular sense, denotes a sort of confutation, wherein the speaker promises to answer what the adversary objects in another place, but which being too difficult to answer, is afterwards forgot and left to pass unanswered.

APOPLEPTIC, relating to an apoplexy. Thus we say, an apopleptic fit, an apopleptic water, &c.

APOPLECTIC *veins*, a name sometimes given to the *jugulars*.

APOPLECTICA, *apoplectical medicines*, a name used by some for what we more properly call *antapoplectics*.

APOPLECTICAL *balsams* is a name given by some writers, to a sort of sweet scented balsms, prepared of distilled oils, and used by way of perfume.

APOPLEXY, APOPLEXIA, in *Medicine*, a sudden privation of all the senses, and all the sensible motions of the body, excepting those of the heart and lungs, attended with a great depravation or suspension of the principal faculties of the mind.

The word comes from ἀποπλησσειν, *to strike*, or *astonish*; this distemper striking suddenly, and, as it were, like a flash of lightning.

Hippocrates distinguishes two kinds of apoplexies, the one *strong*, the other *weak*; only differing in the greater or less difficulty of respiration and the circulation: in the former the pulse and breath seem almost entirely stopped; in the latter there are considerable remains of them.

The more modern authors distinguish apoplexies from their *causes* (affecting the brain, or nervous system in general), into *sanguineous, serous, nervous, spasmodic, symptomatic*, &c. Dissections discover the *sanguineous* only; unless HYDROCEPHALUS may be considered as producing cases of *serous* apoplexy. The speedy recovery of the patient, in a considerable number of instances, together with some other considerations, have induced medical writers to admit the other species. Whenever apoplexy is followed by paralysis, it appears from dissections, that it always is of the sanguineous kind. For Dr. Cullen's other species, see HYDROCEPHALUS, CATALEPSIA, ASPHYXIA, &c.

The fit of apoplexy is usually preceded by a violent pain in the head, a dimness and loss of sight or memory; sometimes by an universal indolence. It is attended with a steror and difficulty of breathing; sometimes with a fever, rarely with a foaming at the mouth; frequently with a sweat, hæmorrhoids, or diarrhœa.

With respect to the *proximate* cause, a multitude of the most accurate observations have made it appear, that this disorder arises from any cause that is capable of preventing either totally, or in part, the influx of the nervous fluid, supposed to be secreted in the *cerebrum*, to the organs of sense

and voluntary motion; and the reflux of the same fluid from the above mentioned organs to the common sensorium in the brain; whilst the progress, and perhaps the return of the fluid, supplied by the *cerebellum* to and from the heart and organs of respiration, is preserved in a degree sufficient to support in some measure their functions.

All the remote, predisposing, or occasionally exciting causes, as observed and delivered by authors, may for the greater perspicuity be reduced to classes; in the first of which may be reckoned,

1. The natural make of the body. Thus, when the head is naturally large, the neck short, and as it sometimes happens, consisting only of six *vertebrae*, whereas there ought to be seven; this structure disposes to apoplexy, as it favours the congestion of blood in the head. Thus also, if the body is corpulent, the capillary arteries will in general be subject to compressions, or the circulation in them will be more languid in proportion to that in the larger trunks; hence arise local congestions of blood; and the face and neck in particular are observed to be turgid, florid, or bloated.

2. To the second class belong all those causes which induce such a change in the blood, lymph, and nervous fluid, as to render them incapable of circulating freely through their respective vessels in the brain; till lately, this class of causes was considered as more generally applicable to pathology than any other. At present, the existence of such causes is more generally doubted than believed. So great, indeed, is the instability of Medical Theories at this time, that many physicians of great respectability have seriously recommended our return to professed Empiricism. As this, however, is not likely to take place soon, we shall mention the causes which have been assigned by eminent Pathologists, and leave their adoption or rejection to the judgment of the public. Among these are—polypous or grumous concretions in the carotid or vertebral arteries, whether formed originally about the heart, or within the *cranium*; these are discovered by a palpitation of the heart, an unequal pulse, a vertigo, and temporary loss of sight often recurring, and which are increased by motion or heat: an inflammatory siziness of the blood, which may be known by an acute continual fever, an inflammatory pain in the head, eyes, &c.—a thick, glutinous, and sluggish disposition of the whole mass of blood; whence old people, those who are much subject to catarrhs, whose constitutions are cold and moist, and who are pale and leucophlegmatic, are very subject to apoplexies. It is not difficult to presage an apoplexy from this cause, as it is generally preceded by an universal listlessness and dulness of the senses, unusual slowness of speech, tremors, stertors, *incubi* (night mares), frequent discharges of viscid phlegm by vomit, vertigoes, shortness of breath on the least motion, with a compression of the cartilages of the nose.

3. To the third class belongs whatever *compresses* the arteries themselves, or the nervous fibrillæ of the brain, so as to prevent a free circulation of the fluids through them. People who are plethoric and bloated are much subject to this species of apoplexy; especially if extraordinary motion or heat increase the velocity of the circulation. To such, therefore, high feeding, spirituous liquors, acrid medicines, intense and long-continued thought, are pernicious. All humours extravasated or effused within the *cranium* properly belong to this class; as also a too great velocity of the blood in the vessels of the head, determined thither by some impediment to the circulation in the inferior parts, which may arise from an infinite number of causes. Hither also may be referred all compressions, from whatever cause, of the veins without the head, which convey the reflux blood from the contents

of the *cranium* toward the heart; as also effusions of blood, pus, ichor or lymph, which press externally on the *dura* or *pia mater*.

4. To the fourth class belong all those causes, which by any means so dissolve the texture or wear down the coats of the arteries, veins, or lympheducts, belonging to the internal parts of the *cerebrum*, as to cause an extravasation of their respective fluids, which then press upon and injure the medullary origin of the nerves of the *cerebrum*.

5. Some sorts of poisons, which are suddenly deleterious, may be ranked in the fifth class; but these may either be reduced to the second, third, or fourth, or may be more properly said to act on the nervous system or the blood, than the brain. Among these are the fumes of mineral sulphurs, of charcoal, or that gas which exhales from vegetable juices during fermentation.

The anatomical inspection of bodies which have died of apoplexies, and the historical observation of such circumstances as occur in the treatment of these cases, furnish us with a knowledge of their causes: and a due reflection upon these naturally leads us to a distribution of them into the preceding classes, which are well adapted to the investigation of the best methods of cure. The part affected in a perfect, violent, or what Hippocrates calls a *strong apoplexy*, appears to be the entire sensorium commune, or what has been called the whole *brainular system*; but in a *parapoplexia*, those parts only of the common sensorium which are more compressed than the rest; whilst the *cerebellum*, and its dependencies, remain in the beginning of the disorder unaffected. Boerhaave.

As to the *prevention and cure* of apoplexy, no invariable rules can be laid down; for as the predisposing and exciting causes, together with the parts principally affected, are various, the method of relief must also vary; and must be attempted before the predisposition grows inveterate, otherwise success will be very precarious.

In general, however, to prevent an apoplexy, wine, hard labour, excess in eating, and sleeping after dinner, are to be avoided: exercise is to be kept up, anxiety and chagrin to be restrained. To *cure* an apoplexy, the *indications* must be taken from the appearance and age of the patient; but more particularly from the remote and proximate causes. The person being placed and supported as nearly in the sitting posture as possible; and a free access of fresh air secured; we must, during the fit, in the *sanguineous* kind, employ copious evacuations of blood, serum, and *fæces*.

The jugulars or temporal arteries should be opened as soon as a proper operator can be procured. In default of one, the vein of the arm or leg should be tried; or cupping, or leeches applied to the occiput and back of the neck, so as to take away nearly a pint of blood. The head should be shaved, and as soon as a sinapism has inflamed the skin, an active blister must be applied to the whole occiput and back of the neck. Sinapisms also should be applied to the legs.

When these steps have been taken, the patient should be laid on his side, with his head raised; and a stimulating clyster with aloes and spirit of turpentine injected as soon as possible: if no urine is evacuated with the return of the clyster, the catheter should be introduced.

As soon as swallowing becomes practicable, ten or fifteen grains of calomel should be got down, and repeated if necessary. If these means, duly employed, produce no relief in twenty-four or thirty-six hours; the patient's recovery will be very doubtful, if not impossible.

In the *ferous* kind, that is, where the patient has not signs of fulness of blood, but on the contrary a poverty or defect

defect of that fluid, blisters and evacuations of the bowels constitute the principal means of relief; bleeding, even with leeches, should be admitted with caution.

In the *nervous* or *symptomatic* species, the treatment will vary with the cause. When noxious gasses have been inhaled, or poison swallowed, the offending cause should be removed, and its place supplied by salubrious air, or medicated food.

Dr. Flemming recommends trepanning for the cure of apoplexies. Med. Mus. vol. ii. p. 300, &c.

Termination. The disease sometimes degenerates into a *paralysis*; and sometimes only half the body is affected, in which case it is called simply a *hemiplegia*.

Apoplexy differs from *carus*, *lethargy*, and *coma*, as in those three distempers the stupor is not so profound, nor is all sensation quite destroyed.

It differs from *syncope*, in that there is little or no sensible pulse in this last; whereas in an apoplexy, the pulse is often full, and perceptible almost till death.

It differs from *epilepsy*, because all motion is not abolished in that, as in this; and it differs from the *palsy*, inasmuch as the palsy is not attended with any stupor, nor does it deprive the patient of sense and perception.

APOPLEXY is also reckoned among the diseases of hawks; being a distemper which seizes their heads, occasioned by too much grease and blood, or their having stood too long exposed to the heat of the sun, or having taken too long flights in the heat of the day.

Horses are also said to be subject to apoplexies, occasioned by want of exercise, or too plentiful feeding.

The distemper shews itself by a giddiness, reeling, trembling, and sometimes falling suddenly down without sense or motion. The cure is by taking a large quantity of blood from the neck, and applying volatile spirits to the nostrils.

APOPLISTÆ, from *απο*, and *οπλον*, *arms*, in *Ancient Laws*, a sort of officers in the country, appointed to disarm all private persons, or those not entitled to have arms; for the prevention of mischief and violence.

APOPOMPÆ, in *Antiquity*, certain days in which sacrifices were offered to the gods called *pompai*. Who these deities were, is doubtful.

APOPSYCHIA, from *απόψυχα*, *I expire*, is sometimes understood of effluvia emitted from the sun, moon, and other heavenly bodies; to which their influence on sublunary things was ascribed by astrologers.

APOQUENEMY *Creek*, in *Geography*, a creek of America, which falls into Delaware-bay from Middle-town, in Newcastle-county in Delaware, a mile and a half below Reedy island.

APORIA, from *απορειω*, *I doubt*, in *Rhetoric*, denotes a state of doubt or wavering, wherein the orator appears undetermined whether to say any thing or not: e. gr. "*Eloquar, an sileam? Shall I speak out, or hold my tongue?*"

The uneasiness arising from such a disorder of thought, and the hesitation produced by it, are naturally very moving. Of this kind is that of Cicero for Cluentius (c. i.): "I know not which way to turn myself. Shall I deny the scandal thrown upon him of bribing the judges? Can I say the people were not told of it? that it was not talked of in the court? mentioned in the Senate? Can I remove an opinion so deeply and long rooted in the minds of men? It is not in my power. You, judges, must support his innocence, and rescue him from this calamity." Orators sometimes begin their discourse with this figure; and as it expresses a diffidence of mind, and has an air of modesty, it tends very much to conciliate the affections of the hearers.

Livy gives us a very elegant example of this, in a speech of Scipio Africanus to his soldiers, when he called them together after a sedition: "I never thought I should have been at a loss in what manner to address my army.—I am in doubt what or how to speak to you, not knowing what name to give you. Shall I call you citizens, who have revolted from your country? Soldiers, who have disowned the authority of your general, and violated your military oath? Enemies? I perceive the mien, the aspect, and habit of citizens; but discern the actions, words, designs, and dispositions of enemies." Livy, hb. xxviii. c. 27. tom. iv. p. 228. ed. Drakenb.

APORON, or APORIME, a problem difficult to resolve, though it be not certain that the resolution of it is impossible.

The word is derived from *απορος*, which signifies something very difficult and impracticable; being formed from the privative *α* and *πορος*, *passage*.

Such we conceive the quadrature of the circle; the duplication of the cube; the trisection of an angle, &c.

When a question was proposed to any of the Greek philosophers, especially of the sect of academists; if he could not give a solution, his answer was, *απορειω*, q. d. "I cannot conceive it: I am not able to explain it."

This word is also used by some law-writers for an inexplicable speech or discourse.

APORRHOEA, APORRHOES, in *Philosophy*, sulphureous effluvia, or exhalations, emitted from the earth and subterraneous bodies.

The word is formed from *απορρηνω*, *defluo, to flow from*.

APORRHOEA, in *Physic*, is sometimes particularly used for morbid or contagious *miasmata*, or effluvia from unwholesome bodies. The word is also used to denote a shedding or falling of the hair. See ALOPECIA.

APOSIOPESIS, from *αποσιωπωω*, *I am silent*, in *Rhetoric*, otherwise called *reticency*, and *suppression*; a figure, by which a person really speaks of a thing, at the same time that he makes a show as if he would say nothing of it. See PRETERITION.

It is commonly used to denote the same with ELLIPSIS. Jul. Scaliger distinguishes them. The latter, according to him, being only the suppression of a word; as "me, me: adsum qui feci;" the former, the omitting to relate some part of the action; as,

"Dixerat, atque illam media inter talia ferro
Collapsam adspiciunt——."

Where the poet does not mention how Dido killed herself. This figure is of use to keep up the grandeur and sublimity of a discourse.

This figure denotes different passions; as anger, which, by reason of its heat and vehemence, causes persons to break off abruptly in their discourse. Thus the old man in Terence, when he was jealous that his servant obstructed his designs, uses this imperfect but threatening expression: And. act. i. sc. i. v. 137. "Whom if I find." And also Neptune, when described by Virgil as very angry, that the winds should presume to disturb the sea without his permission, after he has called them to him to know the reason of it, threatens them in this abrupt manner: "Whom I—but first I'll lay the storm." Æn. lib. i. v. 139.

Cicero, in writing to Atticus, applies it to express grief; "I know nothing of Pompey, and believe he must be taken, if he is not got on shipboard: O incredible swiftness! But of our friend.—" Ad Fam. lib. vii. ep. 22. And in a letter to Cassius, he uses it to express his fear: "Brutus could scarcely support himself at Mutina: if he is safe, we have carried the day. But if—heaven avert the omen,"

omen," &c. *Hieroglyphica*, "it should be defeated." *Al. Fam. lib. xii. c. 1.*

APOSKELARISMUS, a species of fracture of the skull or other bone, wherein a piece is taken clearly off, as if cut out with a hatchet; from *σκαλίζω*, *to cut*, or *hatchet*.

APOSPASMA, from *σπασμα*, *I tear off*, in *Surgery*, denotes a solution of continuity in some organized part, as a membrane, ligament, or the like.

APOSPHACELISIS, from *σφραγίζω*, *I stamp*, *signification*, &c. in the *Latent Surgery*, denotes a mortification of a fleshy part, happening in sides of wounds and fractures, from too tight a ligation.

APOSPHRAGISMA, from *σφραγίζω*, *I seal*, in *Antiquity*, the figure or impression of a seal.

It was to bid among the ancients to have the figure or image of God on their rings and seals. To this purpose the precepts of Pythagoras, *Ἐπιπέσει τὸν ἑαυτοῦ ἀνδρῶν δακτύλιον ἐν τῷ θεῷ*! But in process of time, this was little regarded; it was usual enough to have the figures of Egyptian and other deities, as well as of heroes, moulders, friends, ancestors, and even brutes, on their *distyli*, or ring-seals. Thus Cæsar had the image of Venus, Pollio of Alexander, Augustus of the *sphinx*, Pompey of a frog, Lentulus of his grandfather, &c.

APOSTASIS, from *ἀφίστημι*, *I depart*, &c. in *Physic*, usually signifies the same with abscess.

In which sense the word is used by Hippocrates and others, promiscuously with *ἀποσθημα*, *aposthem*.

APOSTASIS, in a more particular sense, denotes a departure or removal of the morbid matter, in the crisis or solution of a disease.

APOSTASIS is also used by Hippocrates for a fracture of a bone, wherein some part is entirely separated or broken off.

APOSTASY, a deserting or abandoning of the true religion.

The word is borrowed from the Latin *apostatare*, or *apostare*, to *despise*, or *violate*, any thing. Hence *apostatare leges* anciently signified to transgress the laws. *Qui leges apostabit terre sue reus sit apud regem*. LL. Edw. Confess. The Latin *apostatare*, again, comes from *ἀπο*, *from*, and *ίστημι*, *I stand*.

Among the Romaniſts, apostasy also signifies the forsaking of a religious order, whereof a man had made profession, without a lawful dispensation.

The ancients distinguished three kinds of apostasy: the first, *à supererogatione*, is committed by a priest, or religious, who abandons his profession, and returns to his lay state; the second, *à mandatis Dei*, by a person of any condition, who abandons the commands of God, though he retains his faith; the third, *à fide*, by him who not only abandons his works, but also the faith.

There is this difference betwixt an *apostate* and a *heretic*; that the latter only abandons a part of the faith, whereas the former renounces the whole.

The primitive Christian church distinguished several kinds of apostasy. The first was that of those who relapsed from Christianity into Judaism: the second, that of those who blended Judaism and Christianity together; the third, that of those who so far complied with the Jews as to communicate with them in many of their unlawful practices, without making a formal profession of their religion: and the fourth, was that of those who, after having been Christians, voluntarily relapsed into Paganism. The perversion of a Christian to Judaism, Paganism, or other false religion, was punished by the emperors Constantius and Julian with confiscation of goods: to which the emperors Theodosius and Valentinian added capital punishment, in case of the

apostat.'s perverting others to the same iniquity: a punishment, says Blackstone, too severe for any temporal laws to inflict upon any spiritual offence, and yet the zeal of our ancestors imported it into this country: for we find by Bracton, that in his time apostats were to be burnt to death. It is also said to have been anciently punishable, in England, by burning, and tearing to pieces by harts. Thus Fleta, lib. 1. c. 37. § 2. "Apostati & facilegi. & iniustum, detractari debent & comburi." And, § 4. "Si inde convincantur, detractantur, & suspendantur." Where Du Cange interprets, *detractantur*, by *tirer à quatre chevaux*.

This punishment has long ago become obsolete, and the offence of apostasy was for a long time the object only of the ecclesiastical courts, which corrected the offender "pro salute animæ." Nevertheless, it was enacted by Statute 9 and 10 Will. III. c. 32., that if any person educated in, or having made profession of, the Christian religion, shall, by writing, printing, teaching, or advised speaking, deny the Christian religion to be true, or the holy scriptures to be of divine authority, he shall, upon the first offence, be rendered incapable to hold any office or place of trust; and, for the second, be rendered incapable of bringing any action, being guardian, executor, legatee, or purchaser of lands, and shall suffer three years imprisonment, without bail. To give room, however, for repentance, if, within four months after the first conviction, the delinquent will, in open court, publicly renounce his error, he is discharged for that once from all disabilities. Such, however, is the spirit of toleration which has prevailed in this country, that penal statutes in the province of religion, though they still exist, have long lain dormant, and find few advocates in modern times.

APOSTATA *capiendo*, a writ which anciently lay against one, who having entered and professed some order of religion, broke out again, and wandered through the country, contrary to the rules of the order.

APOSTATE, in a general sense, signifies a deserter from the true religion.

In which sense *apostate* amounts to much the same with lapsed, perverted, &c.

APOSTERIGMA, from *ἀπο* and *στηρίζω*, *I support*, in the *Ancient Physic*, denotes a rest or support for a diseased part, without binding.

Such are pillows, cushions, and the like.

The word seems also to have been used by Hippocrates for a stoppage, or obstruction of some vascular part.

A POSTERIORI. Demonstration *à posteriori*. See DEMONSTRATION.

APOSTHUME, or APOSTEM, APOSTEMA, in *Surgery*, a preternatural tumor; called also ABSCESS, and IMPOSTHUME.

The word comes from *ἀφίστημι*, *abscedo*, *I depart from one place and fix in another*, alluding to the manner wherein the tumor is usually formed of a translated humour.

APOSTHUME is particularly used for a disease of hawks, which occasions swellings in the head, arising from a redundancy of humours, and a preternatural heat of that part.

The aposthume discovers itself by a swelling of the eyes, a moisture issuing from the ears, and their wings extremely stitful.

APOSTIL, *apostilla*, in *Matters of Literature*, a marginal addition, or note to a book, passage, or the like.

APOSTLE, *ἀποστολος*, one of the twelve disciples of Jesus Christ, commissioned by him to preach his gospel, and propagate it to all the parts of the earth. The word originally signifies a person *delegated* or *sent*; from *ἀποστέλλω*, *mitto*; in which sense it occurs in Herodotus, and other profane authors. Hence, in the New Testament, the term is applied

A P O S T L E.

applied to divers sorts of delegates ; and to the twelve disciples by way of eminence. They were limited to the number twelve, in allusion to the twelve tribes of Israel. (See Mat. xix. 28. Luke, xxii. 30. Rev. xxi. 12. 14. ; and compare Exod. xxiv. 4. Deut. i. 23. and Josh. iv. 2, 3. ;) accordingly care was taken, on the death of Judas, to chuse another, to make up the number, Acts, i. 21, 22. 26. This seems to have been a token of respect to the Jews, previous to the offer of the Gospel to them ; whereas, when they had generally rejected it, two more, Paul and Barnabas, were added, without any regard to the number of twelve. Of the first selection and commission of the twelve apostles, we have an account, Luke vi. 13, &c. Mat. x. 1, &c. Having chosen and constituted twelve persons, under the name of Apostles, our blessed Lord determined that for some time they should be continually with him, not only to attend upon his public ministry, but to enjoy the benefit of his private conversation, that he might furnish them the better for the great work in which they were to be employed ; and that, at length, after suitable preparation, he might, with greater advantage, send them abroad to preach his Gospel, and thus make way for his own visits to some more distant parts, where he had not yet been. And to enable them more effectually to do it, he endowed them with the power of working miracles, of curing diseases, and casting out demons ; well knowing that such endowments would command a regard, notwithstanding the meanness of their origin and appearance. About the commencement of the third year of his ministry, according to the common account of its duration, he sent them out two by two, or in pairs, that they might be agreeable companions and assistants to each other in their work ; and he commanded them to restrict their teaching and services to the people of Israel, and to avoid going to the Gentiles or to the Samaritans ; to declare the approach of the kingdom of heaven, and the establishment of the Gospel dispensation ; to exercise the miraculous powers with which they had been endowed gratuitously, and to depend for their subsistence on the providence of God, and on the donations of those to whom they ministered. Their names were : Simon-Peter ; Andrew, his brother ; James the greater, the son of Zebedee ; and John his brother, who was the beloved disciple ; Philip of Bethsaida ; Bartholomew ; Thomas, called Didymus, as having a twin-brother ; Matthew or Levi, who had been a publican ; James, the son of Alpheus, called James the less ; Lebbeus, surnamed Thaddeus, and who was also called Judas or Jude, the brother of James ; Simon, the Canaanite, so called, as some have thought, because he was a native of Cana, or, as Dr. Hammond thinks, from the Hebrew קנא *kana*, signifying the same with Zelotes, or the Zealot, a name given to him on account of his having before professed a distinguishing zeal for the law ; and Judas Iscariot, or a man of Carioth (Josh. xv. 25.), who afterwards betrayed him, and then laid violent hands on himself. Of these four, *viz.* Simon, Andrew, James the greater, and John, were fishermen ; two, *viz.* Matthew, and James, the son of Alpheus, were publicans ; and the other six were probably fishermen, though their occupation is not distinctly specified.

After the resurrection of our Saviour, and not long before his ascension, the place of Judas the traitor was supplied by Matthias, supposed by some to have been Nathaniel of Galilee, to whom our Lord had given the distinguishing character of an " Israelite indeed, in whom there was no guile : " and the twelve apostles, whose number was now completed, received a new commission, of a more ex-

tensive nature than the first, to preach the Gospel to all nations, and to be witnesses of Christ, not only in Jerusalem, in all Judea, and in Samaria, but unto the uttermost parts of the earth ; and they were qualified for the execution of their office by a plentiful effusion of miraculous powers and spiritual gifts, and particularly the gifts of tongues. In consequence of this commission, they preached first to the Jews, then to the Samaritans, and afterwards to the idolatrous Gentiles. Their signal success at Jerusalem, where they opened their commission, alarmed the Jewish Sanhedrim, before which Peter and John were summoned, and from which they received a strict charge never more to teach, publicly or privately, in the name of Jesus of Nazareth. The noble reply, and subsequent conduct of the apostles, are well known. This court of the Jews was so awed and incensed, as to plot the death of the twelve apostles, as the only effectual measure for preventing the farther spread of Christianity. Gamaliel interposed, by his prudent and moderate counsel ; and his speech had so good an effect upon the Sanhedrim, that instead of putting the apostles to death, they scourged them, renewed their charge and threats, and then dismissed them. The apostles, however, were not discouraged nor restrained ; they counted it an honour to suffer such indignities, in token of their affection to their master, and zeal in his cause ; and they persisted in preaching daily in the courts of the temple, and in other places, that Jesus of Nazareth was the promised and long-expected Messiah. Their doctrine spread, and the number of converts in Jerusalem still increased. During the violent persecution that raged at Jerusalem, soon after the martyrdom of St. Stephen, several of the leading men among the Christians were dispersed ; some of them travelled through the regions of Judea and Samaria, and others to Damascus, Phœnicia, the island of Cyprus, and various parts of Syria ; but the twelve apostles remained, with undaunted firmness, at Jerusalem, avowing their attachment to the persecuted intercessor of Christ, and consulting how they might best provide for the unforeseen emergencies of the church, and its infant and oppressed state.

When the apostles, during their abode at Jerusalem, heard that many of the Samaritans had embraced the Gospel, Peter and John were deputed to confer upon them the gift of the Holy Spirit ; for to the apostles belonged the prerogative of conferring upon others spiritual gifts and miraculous powers. In their return to Jerusalem, from the city of Samaria, they preached the Gospel in many Samaritan villages. The manner of its being sent to Ethiopia, by the conversion of the eunuch who was chief treasurer to Candace, queen of the country, is related in Acts, viii. 26. &c. After the Christian religion had been planted in Jerusalem, Judea, and Samaria, and sent into Ethiopia, one of the uttermost parts of the earth (Acts, i. 8.) ; and after it had been preached about eight years to the Jews only ; God, in his wise and merciful providence, disposed things for the preaching of it among the Gentiles. With this view, about the year 41, the next transition was to the devout Gentiles within the borders of Palestine. As they had cast off idolatry on the one hand, and on the other hand had not submitted to the ceremonial part of the Jewish law, they were better disposed and prepared for receiving the Gospel. Cæsarea was the scene in which the apostle Peter was to open his commission for this purpose ; and Cornelius, one of the devout Gentiles, and a man distinguished by his piety and charity, was a proper person to be selected as the first proselyte to Christianity. After Peter had laid the foundation of a Christian church among the devout Gentiles,

other

other Christians imitated his example, and a great number of persons of this description embraced the Christian faith, more especially at Antioch, where the disciples, whom their enemies had hitherto called *Gilelans*, *Nazarenes*, and by other names of reproach, and who, among themselves, had been called *disciples*, *believers*, *the church*, *the saints*, and *brethren*, were denominated, possibly not without a divine admonition, *Christians*.

When Christianity had been preached, for about eight years, among the Jews only, and for about three years more among the Jews and devout Gentiles, the next gradation of its progress was to the idolatrous Gentiles, in the year of Christ 44, and the 4th year of the emperor Claudius. Barnabas and Saul were selected for this purpose, and constituted in an extraordinary manner apostles of the Gentiles, or uncircumcision. Barnabas was probably an elder of the first rank; he had seen Christ in the flesh, had been an eye-witness of his being alive again after his crucifixion, and had received the Holy Spirit on the day of Pentecost, as being one of the 120. Saul also, since his conversion, had preached as a superior prophet, about seven years to the Jews only, and about two years more to the Jews and devout Gentiles. They had both been born in Gentile countries; and therefore may be supposed to have had more respect and affection for the Gentiles, than most of the Jews who were natives of Judæa. Saul had been converted, and had hitherto preached chiefly on Gentile ground; and he had joined with Barnabas in teaching devout Gentiles for a whole year, at Antioch in Syria; by all which previous steps they were regularly conducted to the last gradation, or the conversion of the idolatrous Gentiles. But it was necessary, in order to the being an apostle, to have seen our Lord Jesus Christ alive after his crucifixion, for the apostles were in a peculiar manner the witnesses of his resurrection. Some have supposed that Saul saw the person of Jesus, when he was converted, near the city of Damascus; but others, who conceive from attention to the history of this event, that this could not have been the case, as he was instantly struck blind, are of opinion that the season, when his apostolic qualification and commission were completed, was that mentioned by himself (Acts, xxii. 17.), when he returned to Jerusalem the second time after his conversion; when he saw the Lord Jesus Christ in person, and received the command to go quickly out of Jerusalem, and was informed that he should be sent unto the Gentiles. See also, Acts, xxvi. 16—20., where he gives an account of the object of his commission. He also received a variety of gifts and powers, which, superadded to his own genius and learning, as well as fortitude and patience, eminently qualified him for the office of an apostle, and for that particular exercise of it which was assigned to him. St. Paul is frequently called the *Apostle*, by way of eminence; and the *Apostle of the Gentiles*, because his ministry was chiefly employed for the conversion of the Gentiles, as that of St. Peter was for Jews, who is therefore styled the *Apostle of the Circumcision*.

The apostles having continued at Jerusalem twelve years after the ascension of Christ, as tradition reports according to his command, determined to disperse themselves in different parts of the world. But what were the particular provinces assigned to each does not certainly appear from any authentic history. Socrates (Hist. Eccl. lib. i. c. 19.) says, that Thomas took Parthia for his lot; Matthew, Ethiopia; and Bartholomew, India. Eusebius (Hist. Eccl. lib. iii. *ad init.*) gives the following account: "Thomas, as we learn by tradition, had Parthia for his lot; Andrew, Scythia; John, Asia; who having lived there a long time, died at Ephesus. Peter,

as it seems, preached to the dispersed Jews in Pontus and Galatia, Bithynia, Cappadocia, and Asia: at length, coming to Rome, he was crucified with his head downward, as he had desired. What need I to speak of Paul, who fully preached the Gospel of Christ, from Jerusalem to Illyricum, and at last died a martyr at Rome, in the time of Nero." From this passage we may conclude, that at the beginning of the 4th century there were not any certain and well attested accounts of the places out of Judæa, in which any of the apostles of Christ preached; for if there had, Eusebius must have been acquainted with them.

The stories that are told concerning their arrival and exploits among the Gauls, the English, the Spaniards, the Germans, the Americans, the Chinese, the Indians, and the Russians, are too romantic in their nature, and of too recent a date, to be received by an impartial inquirer after truth. These fables were for the most part forged after the time of Charlemagne, when most of the Christian churches contended about the antiquity of their origin, with as much vehemence as the Academics, Egyptians, and Greeks, disputed formerly about their feebility and precedence.

It appears, however, that all of them did not die by martyrdom. Heraclion, the Valentinian, cited by Clemens Alexandrinus (Strom. lib. iv. p. 502.), reckons among the apostles, who did not suffer martyrdom, Matthew, Thomas, Philip, and Levi, probably meaning Lebbaeus.

To the apostles belonged the peculiar and exclusive prerogative of writing doctrinal and preceptive books of authority in the Christian church; and it sufficiently appears that no epistles or other doctrinal writings of any person who was of a rank below that of an apostle, were received by Christians as a part of their rule of faith. With respect to the writings of Mark and Luke, they are reckoned historical, not doctrinal or dogmatical; and Augustine says, that Mark and Luke wrote at a time when their writings might be approved not only by the church, but by apostles still living. The credit of men, not apostles, though they were companions of apostles, was admitted no farther than as historians, or reporters of what they had seen, or of what they had heard from apostles, or eye-witnesses, and ministers of the word.

The several apostles are usually represented with their respective badges or attributes: St. Peter with the keys; St. Paul, with a sword; St. Andrew, with a cross or saltire; St. James minor, with a fuller's pole; St. John, with a cup, and a winged serpent flying from it; St. Bartholomew, with a knife; St. Philip, with a long staff, whose upper end is formed into a cross; St. Thomas, with a lance; St. Matthew, with a hatchet; St. Matthias, with a battle-ax; St. James major, with a pilgrim's staff, and a gourd bottle; St. Simon, with a saw; and St. Jude, with a club.

This appellation of Apostles was also given to the ordinary travelling ministers of the church. Thus St. Paul, in the epistle to the Romans, xvi. 7. says, "Salute Andronicus and Junia, my kinsmen and fellow-prisoners, who are of note among the apostles." In this inferior sense the appellation is applied by Clement of Alexandria, to Barnabas; and it is alleged that he was not an apostle in the highest sense of the word, so as the twelve and Paul were apostles. Tertullian calls all the seventy disciples, apostles; and Clement calls Barnabas apostolical only in another place, and says, that he was one of the seventy, and fellow-labourer of Paul. These, says Dr. Lardner, are the highest characters which he really intends to give to Barnabas, and what he means when he styles him apostle; therefore he need not be sup-

posed to ascribe to Barnabas that large measure of inspiration and high authority, which was peculiar to the apostles, strictly and properly so called. In a similar subordinate form St. Clement of Rome is called apostle. Timothy also is called by Salvia, apostle, meaning merely apostolical, or a companion and disciple of apostles.

APOSTLE was likewise a title given to those sent by the churches to carry their alms to the poor of other churches. This usage they borrowed from the synagogues, who called those whom they sent on this message, by the same name; and the function or office itself *αποστολη*, *apostle*, q. d. *mission*. Thus St. Paul, writing to the Philippians, tells them, that Epaphroditus, their *apostle*, had ministered to his wants, ch. ii. 25. It is applied in like manner to those persons who first planted the Christian faith in any place.

Thus Dionysius of Corinth is called the *apostle of France*; Xavier, the *apostle of the Indies*, &c. In the East Indies the Jesuit missionaries are also called *apostles*.

In some ages of the church, the pope was peculiarly denominated the *apostle*.

APOSTLE, is also used among the Jews, for a kind of officer anciently sent into the several parts and provinces in their jurisdiction, by way of visitor, or commissary; to see that the laws were duly observed, and to receive the monies collected for the reparation of the temple, and the tribute payable to the Romans.

The Theodosian code, lib. xiv. *De Judæis*, calls those *apostoli*, qui ad exigendum aurum atque argentum a patriarcha certo tempore diriguntur. Julian the Apostate remitted the Jews the *apostle*, *αποστολη*; that is, as he himself explains it, the tribute they had been accustomed to send him.

These apostles were a degree below the officers of the synagogues called *patriarchs*, and received their commissions from them. Some authors observe, that St. Paul had borne this office; and that it is this he alludes to in the beginning of the Epistle to the Galatians: as if he had said, Paul, no longer an apostle of the synagogue, nor sent thereby to maintain the law of Moses, but now an apostle and envoy of Jesus Christ, &c. St. Jerom, though he does not believe that St. Paul had been an apostle of this kind, yet imagines that he alludes to it in the passage just cited.

APOSTLE, in the Greek *Liturgy*, is particularly used for a book containing the Epistles of St. Paul, printed in the order wherein they are to be read in churches, through the course of the year. Another book of the like kind containing the Gospels, is called *Ευαγγελιον*, *Gospel*.

The apostle, of late days, has also contained the other canonical Epistles, the Acts of the *Apostles*, and the Revelations. Hence it is also called *Acts of the Apostles*, *Πραξι-αποστολος*; that being the first book in it.

APOSTLE is also thought by many to have been the original name for bishops, before the denomination *bishop* was appropriated to their order. Thus Theodoret says expressly, the same persons were anciently called promiscuously both bishops and presbyters, whilst those who are now called bishops were called *apostles*.

In the arsenal of Bremen, there are twelve pieces of canon, called the *Twelve Apostles*; on a supposition that the whole world must be convinced, and acquiesce in the preaching of such *apostles*.

APOSTLES' Creed. See CREED.

APOSTLES, in *Ecclesiastical History*. See APOSTOLICI.

APOSTOLA THADEIA, in *Geography*, a cape on the east coast of Siberia, at the west end of the Anadirskoi gulf in the North Pacific Ocean. N. lat. 63°. E. long. 178° 14'.

APOSTOLÆUM, or APOSTOLIUM, in *Ecclesiastical Writers*, denotes a church dedicated to, and called by the name of an *apostle*.

VOL. II.

Sozomen speaks of the apostolæum of St. Peter at Rome, and the apostolæum of St. Peter and St. Paul a Quercus near Chalcedon.

In this sense apostolæum stands distinguished from *prophetium*, *martyrium*, &c.

APOSTOLARE, APOSTOLICARE, *apostolizing*, in some *Middle Age Writers*, denotes the being preferred to the dignity of POPE.

APOSTOLATE, in a general sense, is used for mission. In this sense, Olearius has a discourse concerning the apostolate of Christ. Lip. 1681. 4to.

APOSTOLATE more properly denotes the dignity or office of an apostle of Christ: but it is also used in ancient writers for the office of a bishop.

In this sense, we meet with several letters, petitions, requests, &c. directed to bishops under the title of your *apostolate*, or *apostolatus vester*.

But as the title *apostolicus* had been appropriated to the pope, so that of *apostolate* became at length restrained to the sole dignity of the popedom.

Every bishop's see was anciently dignified with the title of *sedes apostolica*, an apostolical see, which is now the peculiar denomination of the see of Rome.

APOSTOLI, in *Law*, denotes those letters missive which are demanded in cases of appeal.

APOSTOLIC, APOSTOLICAL, something that relates to the apostles, or descends from them.

Thus we say, the *apostolical age*, *apostolical doctrine*, *apostolical character*, *constitutions*, *traditions*, &c.

APOSTOLIC, in the *Primitive Church*, was an appellation given to all such churches as were founded by the *apostles*; and even to the bishops of those churches, as being the reputed successors of the *apostles*.—These were confined to four, *viz.* Rome, Alexandria, Antioch, and Jerusalem.

In after-times, other churches assumed the same quality, on account, principally, of the conformity of their doctrine with that of the churches which were *apostolical* by foundation, and because all bishops held themselves successors of the apostles, or acted in their dioceses with the authority of apostles.

The first time the term *apostolical* is attributed to bishops, as such, is in the letter of Clovis to the council of Orleans, held in 511; though that king does not there expressly denominate them *apostolical*, but *apostolica sede dignissimi*, highly worthy of the *apostolical see*. In 581, Guntram calls the bishops, met at the council of Mafon, *apostolical pontiffs*, *apostolici pontifices*.

In progress of time, the bishop of Rome growing in power above the rest; and the three patriarchates of Alexandria, Antioch, and Jerusalem, falling into the hands of the Saracens, the title *apostolical* was restrained to the pope, and his church alone. Though some of the popes, and St. Gregory the great, not contented to hold the title by this tenure, began at length to insist that it belonged to them by another and peculiar right, as being the successors of St. Peter. The council of Rheims, in 1049, declared that the pope was the sole *apostolical* primate of the universal church.

And hence a great number of *apostolicals*; *apostolical see*, *apostolical nuncio*, *apostolical notary*, *apostolical brief*, *apostolical chamber*, *apostolical vicar*, &c.

APOSTOLIC clerks, see JESUITES.

APOSTOLICAL canons, and *constitutions*; see CANONS, and CONSTITUTIONS.

APOSTOLICAL traditions, see TRADITION.

APOSTOLICAL Fathers is an appellation usually given to the writers of the first century, who employed their pens in the cause of Christianity, and who had conversed with the apostles, or their disciples. To this class are referred, Cle-

ment, Barnabas, Hermas, Ignatius, and Polycarp. We may observe, in general, that these apostolic fathers, and the other writers in favour of Christianity, during the infancy of the church, were remarkable neither for their learning nor their eloquence. On the contrary, they express the most pious and admirable sentiments in the plainest style. This indeed is honourable rather than reproachful to the Christian cause; since we see, from the conversion of a great part of mankind to the gospel by the ministry of weak and unlearned men, that the progress of Christianity is not to be attributed to human means, but to a divine power. Their testimony to the books of the New Testament is important; for in their writings they take all the notice of them that could be expected. From them succeeding writers received great part of that full and satisfactory evidence, which they appear to have had concerning the several books of the New Testament. Of these writers, Cotelerius, and after him Le Clerc, have published a collection in two volumes, accompanied with both their own annotations, and the remarks of other learned men.

APOSTOLICI, APOSTOLI, or APOSTLES, in *Ecclesiastical History*, was a name assumed by three different sects, on account of their pretending to imitate the manner and practice of the apostles. The first *Apostolici*, otherwise called *Apotactita*, and *Apotactical*, rose out of the Encratitæ, and Cathari, in the third century. They made profession of abstaining from marriage, and the use of wine, flesh, money, &c. See ΑΡΟΤΑΚΤΙΤÆ.

Gerhard Sagarelli was the founder of the second sect; he obliged his followers to go about from place to place as the apostles did, to wander about clothed in white, with long beards, dishevelled hair, and bare heads, accompanied with women, whom they called their spiritual sisters. They likewise renounced all kinds of property and possessions, inveighed against the growing corruption of the church of Rome, predicted its overthrow, and the establishment of a purer church on its ruins. With this practice, they made little or no alteration in the doctrinal part of the public religion; but they principally aimed to introduce among Christians, the simplicity of the primitive times, and more especially the manner of life that was observed by the apostles. Sagarelli was burnt alive at Parma in the year 1300, and was afterwards succeeded by Dulcinus, a native of Novara, who added to the character of an apostle those of a prophet and general, and carried on a bloody and dreadful war for the space of more than two years against Raynerius, bishop of Vercelli; he was at length defeated, and put to death in a barbarous manner, in the year 1307; together with Margaret, whom he had chosen for his spiritual sister, according to the custom of the sect. Nevertheless this sect subsisted in France, Germany, and in other countries, till the beginning of the fifteenth century, when it was totally extirpated under the pontificate of Boniface IX.

The other branch of *Apostolici* were of the twelfth century. These also condemned marriage, preferring celibacy, and calling themselves the chaste brethren and sisters; though each was allowed a spiritual sister, with whom he lived in domestic relation; and on this account they have been charged with concubinage: they held it unlawful to take an oath; they set aside the use of baptism; and in many things imitated the Manichees. Bernard wrote against this sect of *Apostolici*.

APOSTOLICUM is a peculiar name given to a kind of song or hymn, anciently used in churches.

The Apostolicum is mentioned by Greg. Thaumaturgus as used in his time. Vossius understands it as spoken of the apostles' creed. Suicer thinks this impossible, because this creed was then unknown in the churches of the East.

APOSTOLIUS, MICHAEL, in *Biography*, a learned Greek, flourished in the fifteenth century, about the years 1450 and 1460; at the time when the empire of the Greeks founded by Constantine the Great was extinguished under Constantine Palæologus, the last Christian emperor. His distinguished learning appears from many small tracts written by him, and still remaining in manuscript in several libraries. When Constantinople, after a long siege, fell into the hands of the Turks, he wrote a funeral oration upon the emperor Constantine, who lost his life on that occasion. After the destruction of the eastern empire, he left Greece some time after the year 1453, and passed over into Italy; for he appears in 1462 to have lived at Viterbo. Dissatisfied with the neglect he experienced, and with the dependent condition to which he was reduced, he wrote against several persons of distinction amongst the learned men who flourished at that time; and having thus incurred the resentment of Bessarion, to whom he was indebted for support, he was compelled by his poverty to retire to the island of Crete, where he maintained himself, in a very mean manner, by transcribing books and instructing children. His aversion to the Roman church induced him likewise to compose a tract against it, "Concerning the procession of the Holy Ghost." His collection of proverbs, amounting to more than 2000 in Greek and Latin, illustrated with notes, was published in quarto by Pontinus at Leyden in 1619. His son Arsenius published at Rome a collection of Apophthegms, which was probably taken from the "Ιωνία" of Apostolius. Fabr. Bibl. Græc. l. v. c. 41. § 8. t. x. p. 222. Gen. Dict.

APOSTOLORUM UNGUENTUM, the *apostles' ointment*, in *Pharmacy*, is a kind of detergent or cleansing unguent, composed of twelve drugs, the number of the apostles; whence its name.

It was invented by Avicenna, and is otherwise called *unguentum veneris*. The principal ingredients are turpentine, resin, wax, gum ammoniac, birth-wort roots, olibanum, bdellium, myrrh, and galbanum, opoponax, verdegriis, litharge, oil of olives, and vinegar.

APOSTOOLIANS, in *Ecclesiastical History*, a sect of the Mennonites, which first sprung up in the year 1664, and derived its name from Apostool, one of the Mennonite ministers at Amsterdam. They concurred with them in doctrine, and admitted to their communion those only who professed to believe all their sentiments which are contained in their public confession of faith.

APOSTROPHE, or ADDRESS, in *Rhetoric*, a figure whereby the orator, in an extraordinary commotion, turns his discourse from the audience, and directs it to some other person, present or absent, living or dead, or to inanimate nature as endued with sense and reason. The word is formed of *απο*, *ab*, from, and *στρεφω*, *verto*, to turn. By this figure the speaker has an opportunity of using greater freedom than would perhaps be consistent with decency, if he addressed the persons themselves; he can admonish, chide, or censure, without giving offence; nor is there any passion that may not be advantageously expressed by this figure.

Thus Cicero, in his oration for Milo, addresses himself to the great patriots who had shed their blood for the public; and calls them to the defence of his client. So the same orator, in his first *Catilinarian*, directs himself to Jupiter the protector of the city and empire, and beseeches him to repel the parricide, &c.

The apostrophe is also frequently addressed to inanimates, as tombs, monuments, deuncts, &c. Cicero's apostrophe to Tubero, in his oration for Ligarius, is judged one of the finest passages in his works. In his oration for Balbus, he
thus

thus calls upon dumb nature to witness to Pompey's virtues: "I invoke you, remote regions, most distant countries, you seas, havens, islands, and shores! For what coast, what land, what place is there, in which the marks of his courage, humanity, wisdom, and prudence, are not extant?"

That apostrophe of Demosthenes, wherein he addresses himself to the Greeks slain at the battle of Marathon, is also famous: cardinal Perron says, it has procured the orator as much glory as if he had raised them from the dead.

An appeal to heaven, or any part of inanimate nature, has a sublimity and solemnity, which frequently occurs in the sacred writings, "Hear, O heavens!" says Isaiah, ch. i. 2. "and give ear, O earth! for the Lord hath spoken." In like manner, the prophet Jeremiah exclaims (ch. ii. 12), "Be astonished, O ye heavens! at this."

APOSTROPHE, or *Apostrophus*, in *Grammar*, also denotes a note or character placed over a letter in lieu of a vowel, to denote that the vowel is cut off, and not to be pronounced: as *ev'n* for *even*; *th'angelic host* for *the angelic*, &c.

The affectation of frequent *apostrophes*, so usual among some English writers, is a great abuse.

In prose, apostrophes are indefensible, and tend to vitiate the language; their use in poetry is to reduce a line to the proper measure.

APOSTROPHIA, in *Mythology*, a surname of Venus, under which her votaries applied to her to be preserved from irregular desires.

APOSYRMA, from *αποσυρω*, *I take off*, in *Surgery*, denotes a disquamation or scaling of the skin. In which sense the word amounts to much the same with ABRASION.

APOTACTITÆ, or APOTACTICI, formed from *αποτακτω*, or *αποτακτω*, to renounce, in *Ecclesiastical History*, an ancient sect, who, affecting to follow the evangelical counsels of poverty, and the examples of the apostles and primitive Christians, renounced all their effects and possessions.

It does not appear, that they gave into any errors during their first state: some ecclesiastical writers assure us, they had divers holy virgins and martyrs, under the persecution of Dioclesian, in the fourth century; but they afterwards fell into the opinions of the Encratitæ, and taught, that the renouncing of all riches was not only a matter of counsel and advice, but of precept and necessity. And hence the sixth law in the Theodosian code joins the *Apotactitæ* with the Eunomians and Arians.

APOTEICHISMUS, from *αποτειχιζω*, derived from *απο*, and *τειχιζω*, *I raise a wall*, or *τειχος*, in the *Ancient Military Art*, a kind of line or circumvallation drawn round a place, in order to besiege it.

This was also called *periteichismus*.

The first thing the ancients went about, when they designed to lay close siege to a place, was the apoteichismus; which sometimes consisted of a double wall, or rampart, raised of earth; the innermost to prevent sudden sallies from the town; the outermost to keep off foreign enemies from coming to the relief of the besieged. This answered to what we call lines of contravallation and circumvallation among the moderns.

APOTELESMA, from *αποτελειω*, *I perform*, in a general sense, denotes an effect of some cause. It is also used for a prognostic, or natural prediction of an event.

In which sense Scaliger speaks of the apotelesmata of Hippocrates. The answers of astrologers deduced from the consideration of the stars are particularly called apotelesms or apotelesmata; which were the expressions they used to denote the effects of the stars and planets on sublunary bodies; in which sense apotelesmata amount to the same with influences.

APOTELESMATICA, the science of *apotelesms*, or the art of foretelling future events, from the aspects and configuration of the heavenly bodies.

In this sense the word amounts to the same with what we otherwise call *judicial astrology*.

APOTHECARY, a person who professes the practice of pharmacy, or that part of physic, which consists in the preparation and composition of medicines.

The word is derived from *αποθηκη*, *shop*, the place where he makes up and exposes his medicines to sale.

The *apothecaries* in England are obliged to make up their medicines according to the formulas prescribed in the College Dispensatory.

Their shops are subject to the visitation of the censors of the College, who are empowered to destroy such medicines as they think not good.

The company of apothecaries was incorporated by charter from James I. procured at the solicitation of Dr. Mayerne and Dr. Atkins; till that time they only made a part of the grocers' company; plums, sugar, spice, Venicetreacle, mithridate, &c. were sold in the same shop, and by the same person. The reason of separating them was, that medicines might be better prepared, and in opposition to divers persons who imposed unwholesome remedies on the people. Observ. on Case of Will. Rose, sect. 2.

In the year 1712, the 10th of queen Anne, an act passed for reviving and continuing several acts therein mentioned, one whereof was for exempting the apothecaries from serving the offices of constable and scavengers, and other parish and ward offices, and from serving upon juries; which act was made perpetual in the ninth year of George I.

They have a hall in Black-Friars, where there are two fine laboratories, out of which all the surgeons' chests are supplied with medicines for the royal British navy.

To his majesty belong two *apothecaries*: the salary to the first, 320*l.* to the second, 275*l.* To the household belong also two.

The charitable dispensation of medicines by the Chinese is well deserving notice. They have a stone, which is ten cubits high, erected in the public squares of their cities; and on this stone are engraven the name of all sorts of medicines, with the price of each; and when the poor stand in need of any relief from physic, they go to the treasury, where they receive the price each medicine is rated at.

APOTHECARY, *apothecarius*, in *Writers of the Middle Age*, denotes a shop-keeper, or warehouse-keeper.

APOTHECARIUS is also used to denote a store-keeper, or officer appointed to have the direction of a magazine, GRANARY, &c.

In which sense *apothecarii* is sometimes rendered by *horrearii* and *rationarii*.

APOTHEOSIS, derived from *απο* and *θεος*, *God*, in *Antiquity*, a heathen ceremony, whereby their emperors and great men were placed among the gods.

After the apotheosis, which they also called *deification* and *consecration*, temples, altars, and images were erected to the new deity; sacrifices, &c. were offered, and colleges of priests instituted. Dio, 47. 56. 59. Suet. Aug. 5. Tib. 40. Patere. 1. Ovid. Pont. 4.

Images were erected to them, with the attributes of divinity (Lucan 7. Dio, 53. Capitolin. Antonin.); and to demolish them was deemed treason (Venul. lib. vi. D. ad Leg. Jul. Mal.); and even the senate decreed that oaths should be taken in their names (Dio, 44. 59, 60. Tac. Ann. 1.). Vide Kirchm. de Fun. Rom. 4. 14.

The Persians, according to Herodotus (l. i. c. 131. l. viii. c. 143.), never conceived that their gods were deified men; and Jablonski, in the prolegomena to his

"Pantheon Egyptianum," maintains that it was a fundamental principle in the mythology of the Egyptians, not to deify any mortal. The Greeks, it is said, were the first who admitted this practice; and the heroes of the first ages were of this description. Under the Cæsars, the Romans imitated the Greeks: at first they contented themselves with deifying Romulus, their founder; but having lost their liberty under Julius Cæsar, they allowed Augustus, his successor, to acknowledge him as a god, to build temples in honour of him, and to offer sacrifices to him. Augustus, at the age of twenty-eight years, was declared the tutelary god of all the cities of the empire. The example was followed by succeeding emperors: so that they elevated to the rank of gods, not only the most stupid, such as Claudius, but the most wicked and abandoned: and the appellation "Divus" was assumed among their ordinary titles.

It was one of the doctrines of Pythagoras, which he had borrowed from the Chaldees, that virtuous persons, after their death, were raised into the order of gods. And hence the ancients deified all the inventors of things useful to mankind; and those who had done any important service to the commonwealth. Tiberius proposed to the Roman senate the apotheosis of Jesus Christ, as is related by Eusebius, Tertullian, and Chrysostom. Juvenal, rallying the frequent apotheoses, introduces poor Atlas complaining that he was ready to sink under the burden of so many new gods as were every day added to the heavens. Seneca ridicules the apotheosis of Claudius with admirable humour. Herodian, lib. iv. in speaking of the apotheosis of Servius, gives us a very curious description of the ceremonies used in the apotheosis of the Roman emperors. After the body of the deceased emperor (said he) had been burnt, with the usual solemnities, they plac'd an image of wax, perfectly like him, but of a sickly aspect, on a large bed of ivory, covered with cloth of gold, in the vestibule of the palace. The greatest part of the day, the senate sat ranged on the left side of the bed, dressed in robes of mourning; the ladies of the first rank sitting on the right side, in plain white robes, without any ornaments. This lasted for seven days successively, during which the physicians came from time to time to visit the sick, always making their report that he grew worse, till at length they published that he was dead.

This done, the young senators and Roman knights took the bed of state upon their shoulders, carrying it through the Via Sacra, the Old Forum, where the magistrates were used to divest themselves of their offices. There they set it down between two kinds of amphitheatres, in the one whereof were the young men, and in the other the maidens, of the first families of Rome, singing hymns set to solemn airs, in praise of the deceased. The hymns ended, the bed was carried out of the city into the Campus Martius, in the middle of which place was erected a kind of square pavilion, the inside whereof was full of combustible matters, and the outside hung with cloth of gold, and adorned with figures of ivory, and various paintings.

Over this edifice were several others, like the first in form and decoration, but less; always diminishing and growing slenderer towards the top. On the second of these was placed the bed of state; and a great quantity of aromatic perfumes, and odoriferous fruits and herbs were thrown all around; after which the knights made a procession or cavalcade in solemn measures around the pile; several chariots also run round it, those who conducted them being clad in purple robes, and bearing the images of the greatest Roman emperors and generals.

This ceremony ended, the new emperor came to the *catafalca*, or pile, with a torch in his hand; and, at the same

time, fire was set to it on all sides; the spices and other combustibles kindling all at once.

While this was doing, they let fly from the top of the building an eagle, which, mounting into the air with a fire-brand, carried the soul of the dead emperor along with it into heaven, as the Romans believed; and thenceforward he was ranked among the gods. It is for this reason, that the medals, wherein apotheoses are represented, have usually an altar with fire upon it, or else an eagle taking its flight into the air, and sometimes two eagles.

There are several curious and celebrated monuments of antiquity under the denomination of apotheoses: the first and principal is the apotheosis of Homer, said to have been the work of Archelaus of Priena, a famous ancient sculptor, and discovered, in 1668, in the Appian way near Albano, in a place formerly call'd *Ad Bovillas*, but now *Frattochia*, belonging to the prince of Colonna, where the emperor Claudius had a house of pleasure. This is now one of the principal ornaments of the palace of those princes at Rome. To decypher the figures upon this monument, has been the labour of several celebrated antiquarians, such as Kircher, Cuper, Spanheim, Heinsius, Gronovius, Wetstein, Schott, and Winkelman. The apotheosis of Homer has also been represented on a silver vase, in the form of a mortar, and found at Herculaneum. The apotheosis of Romulus was published at Florence, in 1716, and by Montfaucon, in the third volume of the Supplement to his Antiquities. This work was executed at the time when the arts declined, and was intended to be presented in the Quirinal feasts, or in some other games celebrated by horse races in honour of Quirinus, and call'd Quirini Circenses. The apotheosis of Julius Cæsar is exhibited on a gem in the museum of Brandenburg. Cæsar is mounted on a celestial globe, and holding in his hand an helm and a large crown of laurel. The apotheosis of Augustus is represented on a beautiful agate, which the emperor Baldwin II., when in 1244, he sought succour of the Christian princes, and particularly of St. Louis, is said to have sold to the pious monarch, who deposited it in the museum of the holy chapel at Paris. See *AGATE*. The apotheosis of Germanicus is the subject of a precious gem; that of Claudius is a basso-relievo; that of Titus is exhibited in the arch of Titus at Rome; and that of the younger Faustina, represented in basso-relievo in the Capitol, is mentioned by Montfaucon in the fifth volume of his Supplement.

APOTHERAPIA, from ἀποθεραπειν, *I cure*, in *Physic*, properly denotes a complete or finished cure.

APOTHERAPIA is also used, in the *Gymnastic Art*. for the last part of all regular exercise, viz. friction or unction with oil, before as well as after bathing.

The design of this was partly to cleanse the skin from any filth or dull it might have contracted during the exercise, and partly to remove weariness.

APOTHERMUM, from ἄπο, and θερμός, *hot*, in *Ancient Writers*, a sharp kind of sauce, like that prepared of mustard, oil, and vinegar, or of vinegar alone.

APOTOME, in *Mathematics*, the difference of two incommensurable quantities: such is the difference between $\sqrt{2}$ and 1: and such is the excess of the diagonal of a square above its side.

The word is derived from ἀποτέμνω, *I cut off*.

Euclid (lib. x.) makes six sorts of *apotomes*.

APOTOME prima, is when the greater number is a rational number, and the difference of the squares of both numbers is a square number, e. g. $3 - \sqrt{5}$.

APOTOME secunda, is where the lesser number is a rational number, and the square root of the difference of the squares of both numbers has a ratio expressible in numbers to the greater

greater number; such is $\sqrt{18-4}$, since the difference of the squares 18 and 16 is 2, and $\sqrt{2}$ is to $\sqrt{18}$ as 1 to 3, because $\sqrt{18}=3\sqrt{2}$.

ΑΡΟΤΟΜΕ *tertia*, is when both the numbers which are subtracted from each other are irrational numbers, and the square root of the difference of their squares has a ratio in numbers to the greater. This holds in $\sqrt{24}-\sqrt{18}$, for the difference of their squares 24 and 18 is 6, and $\sqrt{6}$ is to $\sqrt{24}$ as 1 is to 2, for $\sqrt{24}=2\sqrt{6}$.

ΑΡΟΤΟΜΕ *quarta*, is when the greater number is a rational number, and the square root of the difference of the squares of both numbers has no ratio to it in numbers: such is $4-\sqrt{3}$, for the difference of the squares 16 and 3 is 13, but the square root of 13, *viz.* $\sqrt{13}$, has no numerical ratio to 4.

ΑΡΟΤΟΜΕ *quinta*, is when the lesser number is a rational number, and the square root of the difference of the squares of both numbers has no ratio in numbers to the greater number: such is $\sqrt{6}-2$, for the difference of the squares 6 and 4 is 2, and $\sqrt{2}$ has to $\sqrt{6}$ no ratio in numbers.

ΑΡΟΤΟΜΕ *sexta*, is where both numbers are irrational, and the square root of the difference of their squares has no ratio in numbers to the greater: such is the case in $\sqrt{6}-\sqrt{2}$, for the difference of the squares 6 and 2 is 4, and the root thereof 2 has to the $\sqrt{6}$ no ratio in numbers. Peter Ramus censures Euclid's doctrine of *apotomes*, and even all the rest delivered in the tenth book concerning irrational lines.

ΑΡΟΤΟΜΕ, in *Musick*, is the difference of the tone *major* and *LIMMA*, expressed by $\frac{3}{2}\frac{1}{2}\frac{2}{3}$.

The Greeks thought that the greater tone could not be divided into two equal parts; for which reason they called the first part *αποστομην*, and the other *λιμμα*; in this imitating Pythagoras and Plato.

The *apotome* is by some authors, as Boethius, called *hemitonium majus*; and the *limma*, *hemitonium minus*. He also calls the difference of these two, *comma*. The interval of two sounds expressed by $\frac{1}{2}\frac{2}{3}\frac{3}{4}$, was called by the ancients *apotome major*; and that expressed by $\frac{2}{3}\frac{3}{4}\frac{4}{5}$, *apotome minor*.

ΑΡΟΤΟΦΟΤΟ ΒΑΥ, or *Round bay*, in *Geography*, lies on the S. W. coast of Otahe, one of the Society islands, near the island of Otaheite, in the S. Pacific Ocean.

ΑΡΟΤΡΟΠΕΑ, from *αποτροπω*, *I avert*, in the *Ancient Poetry*, verses composed for averting the wrath of incensed deities: and the deities invoked for averting any threatened misfortune were called *Αποτροπαιους*: they were also called *Alexiaci*, from *αλεξω*, *I drive away*; and *Averrunci*, from *averrunco*, which denotes the same.

ΑΡΟΖΕΜ, derived from *αροζω*, *fervefacio*, *I make hot*, in *Medicine*, a form of remedy, otherwise called a *DECOCI-TION*; which see.

ΑΡΡΑ, in *Ancient Geography*, a town of Arabia Felix, according to Ptolemy.

ΑΡΡΑΚΚ, or ΑΡΡΑΓΓΗ, in *Geography*, a town of Africa, in the country of Aardrah, on the slave coast.

ΑΡΡΑΝΑΓΕ, or ΑΡΡΕΝΑΓΕ. See ΑΡΡΑΝΑΓΕ.

ΑΡΡΑΡΑΤΟΡ. See ΑΡΡΑΡΑΤΟΡ.

ΑΡΡΑΡΑΤΟΣ, from *apparō*, *I prepare*, properly signifies a formal preparation for some public and solemn action.

We say, the *apparatus* of a feast, coronation, &c. The prince made his entry with great apparatus and magnificence.

ΑΡΡΑΡΑΤΟΣ is also used for the utensils and appendages belonging to some more considerable machine; as the furniture or *apparatus* of an air-pump, microscope, &c.

The term *apparatus* is used in *Chemistry*, either generally, to express the whole of the instruments and vessels in which or by whose means any process is performed, or in a more limited sense, it is applied to those complicated instruments,

for the most part of modern invention, in which a number of separate parts are combined into one whole. Thus a retort, according to the former application of the term, is an article of chemical apparatus; a receiver is another article; and these two when combined form the retort and receiver, one of the simplest species of *distillatory apparatus*, according to the latter method of applying the term. Thus also the complicated arrangement of vessels invented by Woulfe, is called Woulfe's apparatus, that executed by Nouth is called Nouth's apparatus. It might seem at first sight that this was the proper place to introduce all that we shall have to say concerning chemical apparatus, but by so doing the article would be extended to an unusual length; we have therefore adopted the method of describing every general article under its proper name; of which the articles ΑΛΕΜΒΙΚ and ΑΛΥΔΕΛ, already printed, are examples; and the apparatus for particular experiments is described where the experiments themselves are mentioned; thus under the article ΑΛΚΟΗΟΛ will be found a description of the apparatus invented by Lavoisier for the combustion of that fluid. Certain kinds of apparatus have also a necessary connection with each other, either in similarity of form, or of the uses to which they are applied; there will be found therefore in the course of the work certain general articles, such as *DISTILLATORY apparatus*, *PNEUMATIC apparatus*, &c. where these topics will be discussed.

ΑΡΡΑΡΑΤΟΣ, in *Surgery*, consists of such outward applications as are usually termed *DRESSINGS*, together with such instrumental means as are requisite for the performance of any surgical operation; e. g. bandages, lint, pledgets, tents, compresses, ointments, and various machines. Previous to the performance of any chirurgical operation, a surgeon should always consider what sort of apparatus will be necessary; and he should never, for the sake of parade or ostentation, bring together any instruments which may as well be dispensed with. Modern surgery has very wisely laid aside a number of uncouth, clumsy, and terrific instruments employed by our ancestors, especially the tools named *cauterizing-irons* (see *CAUTERY*), and the immense levers, &c. for reducing dislocations or fractures. Whatever is indispensably necessary in operations, should be prepared before the time fixed for their performance; and it ought to be an invariable rule among surgeons, to prevent the patient from seeing his formidable apparatus, lest he be thereby intimidated and discouraged at the very moment he most stands in need of resolution: for instances are not wanting of patients actually dying from the effects of terror, without having undergone the intended operation.

The term *apparatus* is sometimes used to distinguish the operation of *LITHOTOMY* or *CYSTOTOMY*; thus we say, the greater apparatus, the lesser apparatus, &c. See *STONE*, *cutting for the*.

ΑΡΡΑΡΑΤΟΣ is also used as a title of several books composed in form of catalogues, bibliothecas, dictionaries, &c. for the ease and conveniency of study.

The apparatus to Cicero, is a kind of concordance or collection of Ciceronian phrases, &c. The *apparatus sacer* of Possevin, is a collection of all kinds of ecclesiastical authors, printed in 1611, in three volumes.—Glossaries, comments, &c. are also frequently called *apparatuses*.

ΑΡΡΑΡΑΤΟΣ, from *apparō*, *I appear*, that which is visible to the eye, or evident to the understanding.

ΑΡΡΑΡΑΤΟΣ, in *Mathematics* and *Astronomy*, is used to signify things as they appear to us in contradistinction from real or true; and in this respect the apparent state of things is often very different from their real state; as in the case of distance, magnitude, &c.

APPARENT *Altitude, Conjunction, Diameter, Distance, Figure, Horizon, Magnitude, Motion, Place, Time, &c.* See the several substantives.

APPARENT, *Heir, in Law.* See HEIR.

APPARENT *Island, in Geography,* lies in Dusky bay, on the coast of New Zealand, and is placed by captain Cook on an arm, which captain Vancouver found to be divided into two branches, leaving that island a peninsula joined to the main land by a very high though narrow ridge of mountains; the perpendicular height and very extraordinary shape of the rocky part fronting the arm, render it a most singular and majestic promontory. As the entrance of these arms was called by Cook "Nobody knows what;" Vancouver, having particularly examined them, called them "Somebody knows what." *Voyage round the World, vol. i. p. 63.*

APPARITION, in *Astronomy,* denotes a star's or other luminary's becoming visible, which before was hid.

In which sense the word stands opposed to OCCULTATION. Thus the heliacal rising is rather an apparition than a proper rising.

APPARITION, *circle of perpetual.* See CIRCLE of perpetual apparition.

APPARITION, in a general sense, is the appearance or semblance of a thing.

APPARITION is also used to denote a spectre, or præternatural appearance of some spirit, or the like.

We read of apparitions of angels, genii, dæmons, fairies, witches, departed souls, &c. apparitions of God, of Christ, the Virgin, saints, prophets, and of the devil himself.

Among the most zealous advocates of the reality of apparitions and witchcraft, we may reckon Dr. Henry More, Baxter, and Glanvil. The latter, in particular, has attempted, in a treatise entitled, "Saducismus triumphatus," to prove the doctrine of apparitions, by arguments deduced from the nature of the soul, the testimony of scripture, and the evidence of fact; and he expressly asserts (Part II, p. 2.) that those who deny and deride the existence of apparitions and witchcraft, are prepared for the denial of spirits, a life to come, and all the other principles of religion. It is a strong presumption against the reality of apparitions, however anciently and generally the belief of them has prevailed, that they have been connected with some causes and circumstances of terror, either real or apprehended; and these have previously disposed the imagination for being imposed upon and deluded. The darkness of the night, the gloom that has overspread particular situations, the horror produced by the record of some disastrous occurrence, such as murder or the like, and a state of mind naturally depressed and melancholy, and of course easily alarmed, have contributed to give rise to many of those stories, that have been credulously received and as obstinately vindicated and sedulously disseminated by the vulgar. The ancients also entertained some notions concerning the state of the soul on its escape from the body, which favoured this opinion; and they were disposed to seek the spirits of their deceased ancestors near the habitations in which their bodies were deposited. Hence they would be easily led into deception; and when they fancied that they actually saw their departed friends, they distinguished the illusions which were merely the creations of their own fancy, by the name of "shades." It ought also to be considered, that the relation and belief of apparitions have prevailed chiefly in times of ignorance, and amongst those who had the fewest opportunities for inquiry and information. In fact, as the night has been the season to which the appearance of ghosts has been referred, the belief of their reality has gradually subsided in proportion to the degree in which knowledge has been diffused. It ought also to be considered, that

apparitions are machines that on particular occasions have been of good service to generals, to ministers of state, to priests, and others; to say nothing of the very injudicious and culpable use that has been made of them by those with whom the care of children, at a period when their imagination is easily impressed, has been entrusted. Upon the whole, it must be allowed, that many of the apparitions that are recorded by writers, or reported by tradition, are mere delusions; others are fictions contrived merely to amuse or to answer some purpose; and others have originated in dreams or deliquiums. There are seasons of slumber when we are not sensible of being asleep. On this principle, Hobbes (Treatise of human nature, part i. c. 2. Works, p. 102.) has endeavoured to account for the spectre that is said to have appeared to Brutus. "We read," says he, "of Marcus Brutus (one that had his life given him by Julius Cæsar, and was also his favourite, and notwithstanding murdered him), how at Philippi, the night before he gave battle to Augustus Cæsar, he saw a fearful apparition, which is commonly related by historians as a vision; but considering the circumstances, one may easily judge to have been a short dream. For sitting in his tent pensive and troubled with the horror of his rash act, it was not hard for him, slumbering in the cold, to dream of that which most affrighted him; which fear, as by degrees it made him awake, so also it must needs make the apparition by degrees to vanish; and having no assurance that he slept, he could have no cause to think it a dream, or any thing but a vision." The well-known story told by Clarendon, of the apparition of the duke of Buckingham's father, has been solved in a similar manner. There was no man in the kingdom so much the subject of conversation as the duke; and his character was so corrupt that he was very likely to be misled by the enthusiasm of the times: Sir George Villiers is said to have appeared to him at midnight; and hence it appears probable that the man was asleep; and as he was terrified by the dream, it must have made a strong impression, and was likely to be repeated.

Mr. Andrew Baxter, in his "Essay on the phænomenon of dreaming," recurs to the principle "that our dreams are prompted by separate immaterial beings," in order to account for apparitions. If the power of such beings be unrestrained, this author maintains, that it will equally possess the fancy with delusive scenes, without waiting for the occasion of sleep to introduce them, and obtrude them forcibly upon the organ, amidst the action of external objects. For it requires but a greater degree of the same power to make delusory impressions upon the sensory, while real external objects are making true impressions upon it, than it would require to make the same impressions, while no other impression from external objects is made upon it at the same time. "If our imaginations," says Dr. Tillotson in one of his sermons, "were let loose upon us, we should be always under the most dreadful terrors, and frightened to distraction with the appearance of our own fancy; and an over-ruling power restrains these effects:" i. e. as Mr. Baxter conceives, by restraining the power of invisible beings, which would otherwise incessantly distress the soul with such displeasing sights. Upon this hypothesis he thinks there is nothing inconsistent in those relations of apparitions which we meet with in history, whether the facts be true or false; for these spirits may, upon some important occasions, be licensed to affect the sensory, according to the exigency of the case, that the whole scene of vision, which is then thought to have an existence from without, may be the effect of impressions made on the brain only. Thus, for instance, that apparition mentioned before which was presented to Brutus before he came

over from Asia, and again the night before the battle of Philippi, the noise as of one entering into his tent which he heard, and the words spoken, "I am, O Brutus, thy evil genius, but thou shalt see me again near Philippi," might all be only inward representations upon the sensory, and any other person present might neither have heard nor seen any thing. This, in our author's opinion, affords a better account of the appearance than that of Hobbes; who makes cold produce dreams and visions of fear, without either reason or experience to support his assertion. He makes Brutus to be sleeping; but Plutarch tells us, that he had slept the former part of the night immediately after eating, and had risen to digest something in his own mind; so that, according to Hobbes's scheme, it was a waking vision, and it occurred without any previous distemper either external or internal. The case of Dion, related by Plutarch, is alleged to the same purpose; for he was sitting in the porch of his own house in a thoughtful and meditating attitude, when the spectre appeared to him; and this happened while the assassins were contriving his death, a little before he was cruelly murdered. No men in antiquity could be less liable to the suspicion of weakness and credulity than Brutus and Dion; and therefore, according to Mr. Baxter, the terror they experienced must have proceeded from the power of some superior being. Upon the whole he thinks that although *δεισιδαιμονια*, or a fear of spirits, hath been much abused by vain or weak people, and carried to an extreme, perhaps by designing and crafty men, the most rigorous philosophy will not justify its being entirely rejected. It is true, he adds, no evil can happen to us in God's world but by our own fault; but that subordinate beings are never permitted, or commissioned to be the ministers of his will, is a hard point to be proved; and that direct atheism is better than this deisidemonia is horrid. See Essay on the phenomenon of dreaming, in the "Inquiry into the nature of the human soul," vol. ii. p. 111, &c.

The abbé de St. Pierre has a discourse expressly on the physical method of solving or accounting for apparitions; he makes them the effect of feverish dreams, disturbed imaginations, &c.

APPARITOR, or APPARATOR, a beadle in an university, who carries the mace before the masters, and the faculties.

APPARITOR is also used in some ancient English laws, for a judge or justice.

APPARITOR *comitatus*. There was formerly an officer called by this name, for which the sheriffs of Buckinghamshire had a considerable yearly allowance; and in the reign of queen Elizabeth there was an order of court for making that allowance. But the custom and reason of it are now altered.

APPARITORS also denote messengers who served the process of the spiritual court. Their duty is to cite the offenders to appear, to arrest them, and to execute the sentence or decree of the judges. See stat. 21 Hen. viii. c. 5.

Among the Romans, apparitors were the same with sergeants or tipstaves among us; or rather apparitor was a general term, and comprised under it all the ministers and attendants of the judges and magistrates, appointed to receive and execute their orders. And hence, they say, the name was derived, viz. from *apparere*, to be present, to be in waiting. Under the name *apparitores* were comprehended the *scribae*, *accensi*, *interpretes*, *praecones*, *viatores*, *lictores*, *statores*, and even the *carnifices* or hangmen.

They were usually chosen out of the freedmen of the magistrates, and their condition was held in so much contempt, that, as a mark of ignominy, the senate appointed a city that had revolted from them to furnish them with apparitors.

There were also a kind of *apparitors of cohorts*, called *cohortales* or *conditionales*, as being attached to a cohort, and doomed to that condition. The apparitors of the praetors, *praetoriani*, were those who attended the praetors, or governors of provinces; and who, on their masters' birth-day, were always changed, and preferred to better posts. Add, that the pontifices had also their apparitors, as appears from an inscription of an ancient marble in the *Via Appia*:

APPARATORI
PONTIFICVM
PARMVLRARIO.

APPAUMEE, in *Heraldry*. See *APAUMEE*.

APPEAL, derived from the French verb neuter *appeller*, of the same signification, in *Law*, signifies the removal of a cause from an inferior court or judge to a superior; or the having recourse to a superior judge to rectify what is amiss in a sentence passed by an inferior.

Appeals to Rome were first introduced into England in the reign of king Stephen; and though they were not strictly regarded in the succeeding reigns, they continued till the time of king Henry the eighth, when they were finally abolished by the 24 Hen. 8. c. 12. and 25 Hen. 8. c. 19. 21.: by which appealing to Rome from any of the king's courts, suing to Rome for any licence or dispensation, and obeying any process from thence, are made liable to the pains of *premunire*.

Appeals lie from the archdeacon or his official to the court of arches, and from the arches to the archbishop, and from the bishop or his commissary to the archbishop; and when the cause concerns the king, appeal may be brought in fifteen days from any of the said courts to the prelates in convocation, st. 24 Hen. 8. c. 12.: and by the 25th Hen. 8. c. 29. for lack of justice in the archbishop's courts, the party may appeal to the king in chancery, where commissioners are named, and by reason of this appointment they are called *delegates*; and after the decision of this court, a commission of review may be granted by the king as supreme head, to review the definitive sentence given in appeal in the court of delegates.

Appeals lie from all the ordinary courts of justice, and also from the court of equity in chancery, to the house of lords, who judge *en dernier ressort*; i. e. no appeal lies from them.

But appeals from a court of equity, and writs of error from a court of law, differ in these two particulars: 1. The former may be brought upon any interlocutory matter; the latter upon nothing but only a definitive judgment. 2. On writs of error the house of lords pronounces the judgment; on appeals it gives direction to the court below to rectify its own decree.

There are appeals from ecclesiastical justice to secular.

The first instance of this is that of Paulus Samosatenus; who being condemned and deposed by the second council of Antioch, refused to surrender the episcopal house to Domnus, who had been elected his successor, and appealed to the emperor.

APPEAL is also used, in *Common Law*, in the same sense with *accusatio* among the *Civilians*. And when thus spoken of as a criminal prosecution, it is derived from the French verb active *appeller*, to call upon, summon, or challenge one, and denotes an accusation by a private subject against another, for some heinous crime; demanding punishment on account of the particular injury suffered, rather than for the offence against the public. This method of prosecution is still in force, but very little in use. This private process, for the punishment of public crimes, had probably

probably its original in those times, when a private pecuniary satisfaction, called a *weregild*, was constantly paid to the party injured, or his relations, to expiate enormous offences. This was a custom derived to us, in common with other northern nations, from our ancestors the ancient Germans: and we find in our Saxon laws, particularly those of king Athelstan, the several *weregilds* for homicide, established in progressive order, from the death of the corl or peasant, up to that of the king himself. And in the laws of king Henry I. we have an account of the other offences that were redeemable by *weregild*, as well as of those that were not so redeemable. As therefore, during the continuance of this custom, a process was certainly given for recovering the *weregild* by the party to whom it was due; it seems that, when these offences by degrees grew no longer redeemable, the private process was still continued, in order to insure the infliction of punishment upon the offender; though the party injured was allowed no pecuniary compensation for the offence. It was also anciently permitted, that any subject might appeal another subject of high-treason, either in the courts of common law, or in parliament; or for treasons committed beyond the seas, in the court of the high-constable and marshal. The cognizance of appeals in the latter still continues in force; and so late as 1631, there was a trial by battle awarded in the court of chivalry, in such an appeal of treason; but that in the first was virtually abolished by the statutes 5 Edw. 3. c. 9. and 25 Edw. 3. c. 4.; and in the second expressly by statute 1 Hen. 4. c. 14. So that the only appeals now in force, for things done within the realm, are those of felony and mayhem. Mr. Kyd, the ingenious editor of Comyns's Digest, observes, "that the appeal of treason does not appear to have been taken away by the stat. 1 Hen. 4. c. 14. or any other. But as no instance occurs of any such appeal, before any court of common law, either since that statute was made, or for many years before, the law relating to such appeals seems to be wholly obsolete at this day."

Criminal appeals are either capital or not capital. Of the latter sort, appeals *de pace, de plagis, de imprisonmento*, and of *mayhem*, are now become obsolete; having been long since converted into actions of trespass. Capital appeals are either of treason or felony. The latter may be subdivided into *appeals of death*, or of *murder*, *appeals of larceny or robbery*, *appeals of rape*, and *appeals of arson*, which last are now entirely obsolete. An *appeal of felony* may be brought for crimes committed either against the parties themselves, or their relations. The crimes against the parties themselves are *larceny, rape, and arson*. And for these, as well as for mayhem, the persons robbed, ravished, maimed, or whose houses are burnt, may institute this private process. The only crime against one's relations, says judge Blackstone, for which an appeal can be brought, is that of killing him; either by murder or manslaughter: but Mr. Tomlins, in his edition of Jacob's Law Dictionary, observes, that this seems to be an unguarded assertion of the learned commentator, as an appeal is given to the husband, next of kin, &c. by stat. in case of rape.

Appeal of death, is a vindictive action which the law gives to the wife for the death of her husband, or to the heir male for the death of his ancestor; which heirship was confined, by an ordinance of king Henry I. to the four nearest degrees of blood. It is given to the wife on account of the loss of her husband; therefore if she marries again, before or pending her appeal, it is lost and gone: or if she marries after judgment, she shall not demand execution. The heir must also be heir male, and such a one as was the next heir by the course of the common law at the time of the

killing of the ancestor. But this rule has three exceptions: 1. If the person killed leaves an innocent wife, the only, and not the heir, shall have the appeal. 2. If there be no wife, and the heir be accused of the murder, the person, who next to him would have been heir male, shall bring the appeal. 3. If the wife kills her husband, the heir may appeal her of the death. And by the statute of Gloucester, 6 Edw. 1. c. 9. all appeals of death must be sued within a year and a day after the completion of the felony by the death of the party, which seems to be only declaratory of the old common law. The court must set forth the fact, and the length and the depth of the wound, the year, day, hour, place where done, and with what weapons; and that the party died in a year and a day; and by the above statute, principal and accessories before and after are to be joined in appeal; and this is to be observed, though the accessory is guilty in another country. 3 Hen. 7. c. 1. The case of other appeals than of murder, as of robbery, rape, &c. are not within this last statute, and therefore *auterfois acquit*, upon an indictment within the year, stands at common law, a good bar to an appeal of robbery, or any offence besides murder or manslaughter; and yet the judges at this day never forbear to proceed upon an indictment of robbery, rape, or other offence, though within the year, because appeals of robbery especially are very rare, and of little use, since the statute of 21 Hen. 8. c. 11. gives restitution to the prosecutor as effectually as upon an appeal.

The several appeals above enumerated may be brought previous to any indictment: and if the appellee be acquitted thereon, he cannot be afterwards indicted for the same offence. But if the appellant does not prosecute his appeal, the appellee may be indicted. If a man be acquitted on an indictment for murder, or found guilty and pardoned by the king, still he ought not (in strictness) to go at large, but be imprisoned, or let to bail till the year and day be past, by virtue of the statute 3 Hen. 7. c. 1. in order to be forthcoming to answer any appeal for the same felony, not having as yet been punished for it; though if he has been found guilty of manslaughter, on an indictment, and hath had the benefit of clergy, and suffered the judgment of the law, he cannot afterwards be appealed, for it is a maxim in law, "that *nemo bis punitur pro eodem delicto*." If the appellee be acquitted, the appellant (by virtue of the statute of Westminster 2. 13 Edw. 1. c. 12.) shall suffer one year's imprisonment, and pay a fine to the king, besides restitution of damages to the party for the imprisonment and infamy which he has sustained: and if the appellee be incapable of making restitution, his abettors shall do it for him, and also be liable to imprisonment. This provision proved a great discouragement to appeals, so that thenceforward they ceased to be in common use. If the appellee be found guilty, he shall suffer the same judgment as if he had been convicted by indictment; but with this remarkable difference, that, on an indictment, the king may pardon and remit the execution; but on an appeal, which is at the suit of a private subject, to make an atonement for the private wrong, the king can no more pardon it, than he can remit the damages recovered on an action of battery. And the ancient usage was, so late as Henry the fourth's time, that all the relations of the slain should drag the appellee to the place of execution. However, the punishment of the offender may be remitted and discharged by the concurrence of all parties interested; and as the king of his pardon may frustrate an indictment, so the appellant by his release may discharge an appeal. A peer in appeal of murder, shall not be tried by his peers, but by a common jury; though he shall upon an indictment for murder. Where appeal of death is brought, the defendant cannot

cannot justify *se defendendo*; but must plead not guilty, and the jury are to find the special matter.

An appeal is prosecuted two ways, either by *writ*, or by *bill*.

APPEAL by *writ* is, when a writ is purchased out of chancery, by one for another, to the intent that he may appeal a third person of some felony committed by him, finding pledges that he shall do it.

APPEAL by *bill*, is where a man of himself gives up his accusation in writing, offering to undergo the burden of appealing the person therein named. The appeal of death may be brought by bill before the justices in the King's Bench; before justices of gaol-delivery, and commissioners of oyer and terminer, &c. or before the sheriff and coroner in the county-court; but the sheriff and coroner have only power to take and enter the appeal and count, for it must be removed by certiorari into B. R.

In appeal by original, principals and accessaries are generally charged alike without distinction, till the plaintiff counts; but it is otherwise in appeals by bill. There is but one appeal against the principal and accessory: if the principal is acquitted, it shall acquit the accessory: and both shall have damages against the appellant on a false appeal, or the accessory may bring a writ of conspiracy. If the defendant in appeal is attaint or acquit, or the plaintiff nonsuit after appearance, which is peremptory, no other appeal lies. If an indictment and an appeal be depending at the same time, against the same person, the appeal shall be tried first, if the appellant be ready; otherwise the king would destroy the suit of the party.

APPEAL of *Mayhem* is the accusation of one that hath maimed another; but this being generally no felony, it is in a manner merely an action of trespass, and nothing is recovered by it but damages. Bracton calls this *appellum de plagis & maibemio*, and has a whole chapter upon it. In this appeal, the defendant pleads that the plaintiff had brought an action of trespass against him for the same wounding, and had recovered, and damages given, &c.; and this was a good plea in bar of the appeal, because in both actions damages only are to be recovered. In king John's time, there is recorded an appeal against a Jew, *qui fecit ementulari quendam nepotem suum*.

APPEAL of *rape* lies where a rape is committed on the body of a woman. A feme covert without her husband may bring appeal of rape; and statute 6 R. 2. c. 6. gives power where a woman is ravished, and afterwards consents to it, for a husband, or a father, or next of kin, there being no husband, to bring this appeal: also the criminal in such case may be attainted at the suit of the king. If a woman be ravished by her next of kin, and consents to him, and has neither husband nor father, the next of kin to him shall have the appeal; for he has disabled himself by the rape, whereby he becomes a felon. If there be no husband nor father, the appeal is given to the heir, whether male or female. The statute of Westm. 1. c. 13. which reduced the crime of rape to a trespass, enacts that appeal of rape shall be brought within forty days; but by statute Westm. 2. c. 34. which makes this offence felony, no time is limited for the prosecution, so that it may be brought in any reasonable time. It is to be commenced in the county where the rape was committed. It is held, that though formerly the defendant might have his clergy, it is taken away by the statute 18 Eliz. c. 17. See further on this subject, 2 Hawk. P. C. c. 23. §. 58—73.

APPEAL of *robbery* or *larceny* is a remedy given by the common law, whereby a person robbed of his goods may obtain restitution of them. If a man robbed make fresh pursuit after, and apprehend and prosecute the felon, he may

bring appeal of robbery at any time afterwards. By statute 21 Hen. 8. c. 11. restitution of stolen goods may be had on indictments after attainder, as on appeals; and appeals of robbery, as well as of mayhem and rape, are now much out of use. By the express provision of statute 4 & 5 W. & M. c. 3. an accomplice convicting two others guilty of robbery, shall have the king's pardon; and this shall be a good bar to an appeal of robbery. Blackst. Com. vol. iv. Jacob's Law Dictionary by Tomlius, tit. *Appeal*.

APPEARANCE, the exterior surface of a thing; or that which first strikes the sense, or the imagination.

The Academics maintain, that the sensible qualities of bodies are only *appearances*; and the like doctrine is held by some later philologists.

Our errors arise chiefly from a too hasty and precipitate assent of the will, which acquiesces too easily in the appearance of truth.

APPEARANCE, in *Law*, is the defendant's engaging to answer a cause or action entered against him in some court of judicature; and it is done by filing common or special bail, when he is served with copy of, or arrested on any process out of the courts at Westminster, and there can be no appearance in the court of B. R. or king's bench, but by special or common bail. There are four ways for defendants to appear to actions; viz. in person, or by attorney, by persons of full age; and by guardians or next friend, by infants. It is now the common course for the plaintiff or defendant, in all kinds of actions where there may be an attorney, to appear by attorney, and put in his warrant without any writ from the king for that purpose, as was formerly the case by common law. And, therefore, generally, in all actions real, personal, and mixt, the demandant or plaintiff, tenant or defendant, may appear by attorney. But in all cases where the party stands in contempt, the court will not admit him to appear by attorney, but oblige him to appear in person. In all cases where process issues forth to take the party's body, if a common appearance only, and not special bail is required, there every such party may appear in court in his proper person, and file common bail. In a capital criminal case, the party must always appear in person, and cannot plead by attorney; also in criminal offences, where an act of parliament requires that the party should appear in person; and likewise in appeal or on attachment. On an indictment, information or action, for any crime whatsoever under the degree of capital, the defendant may, by the favour of the court, appear by attorney; and this he may do as well before plea pleaded, as in the proceeding after, till conviction. Attornies subscribing warrants to appear, are liable to attachment, upon non-appearance: and where an attorney promises to appear for his client, the court will compel him to appear and put in common bail in such time as is usual by the course of the court; and that although the attorney say he hath no warrant for appearance: nor shall repealing a warrant of attorney to delay proceedings excuse the attorney for his not appearing, who may be compelled by the court. The defendant's attorney is to file his warrant the same term he appears, and the plaintiff the term he declares, under penalties by stat. 4 & 5 Ann. c. 16. An attorney is not compellable to appear for any one, unless he take his fee or back the warrant; after which the court will compel him to appear.

In actions by original, appearances must be entered with the filazer of the county; and if by bill, they shall be entered with the prothonotary; and by statute 5 Geo. 2. c. 27. where defendant is served with a copy of the process, appearances and common bail are to be entered and filed by him within eight days after the return of the process; and if defendant

defendant does not appear, plaintiff may, on affidavit of the service of process, enter a common appearance for defendant, and proceed upon it; statute 12 Geo. 1. c. 29. And by stat. 25 Geo. 3. c. 83. § 22. a common appearance may be filed by plaintiff, without entering or filing a record, a memorandum or minute for defendant. Jacob's Law Dict. by Tomlins.

APPEARANCE *Day of Term.* See TERM.

APPEARANCE, in *Perspective*, is the representation or projection of a figure, body, or like object, upon the perspective plane.

The appearance of an objective right line is always a right line. See PERSPECTIVE. The appearance of an opaque body and a luminary being given, to find the appearance of the shadow, see SHADOW.

APPEARANCE of a *star or planet.* See APPARITION.

APPEARANCES, in *Astronomy*, &c. are more usually called *phenomena and phases.*

In *Optics*, we use the term *direct appearance* for the view or sight of any object by direct rays, without either refraction or reflection.

APPEARANCES, *to save*, is to discharge one's duty seemingly, or acquit one's self of the formalities and externals thereof; so as to save the character, and avoid giving scandal or offence.

APPEARANCES, in *Physiology.* See PHASMATA.

APPEASING REMEDIES, in *Medicine*, are those which allay the pain in a disease, and give the patient some rest or respite; and at the same time contribute to the cure. These amount to the same with what we otherwise call PAREGORICS, ANODYNES, &c.

APPELDOORN, in *Geography*, a town of the united Netherlands, in the duchy of Gueldres, $4\frac{1}{2}$ leagues N. W. of Zutphen.

APPELLANT, in *Law*, denotes a person who brings an APPEAL.

APPELLANTS, in *Ecclesiastical History*, is a denomination distinguishing those among the French clergy who refused to subscribe the constitution or bull *unigenitus*, issued by Clement XI. in 1713, and appealed from it, either to the pope better informed, or a general council.

APPELLATION signifies the name by which any thing is known or distinguished. See NAME.

APPELLATIVE, formed of *appellare, to name a thing*, in *Grammar*, denotes a common name which stands for a whole rank of beings, whether general or special, in contradistinction to proper names, which belong only to individuals, e. g. fish, man, horse, tree, &c. are appellatives; and so are trout, eel, lobster; for the, all agree to many individuals, and some to many species: but Peter, Gabriel, Bucephalus, are proper names. See NAME.

APPELLEE, in *Common Law*, signifies the person against whom an appeal is brought. See APPEAL, and IMPROVEMENT.

In the civil law, *appellee, appellatus*, properly belongs only to the judge before whom an appeal is brought.

APPENAGE. See APANAGE.

APPENDANT, from *appendo, I hang by*, in *Law*, is understood of such things as by prescription have belonged, appertained, and been joined, to some other principal thing.

Thus an hospital may be appendant to a manor; a common of fishing, to a freehold; a seat in a church, to a house; or the like. As appendants are ever by prescription, they are thus distinguished from appurtenances, which may be created in some cases at this day. See APPURTENANCE.

APPENDANT, *Advowson.* See ADVOWSON.

APPENDANT, *Common.* See COMMON.

APPENDICULA, or APPENDIX *vermiformis*, in *Ana-*

tomy, an appendage to the intestinum cæcum, or caput coli. See the description of the INTESTINES.

APPENDICULÆ *Asteriarum, wires of asterie*, a name given by the writers on *Natural History* to certain small branches which are placed in a circular order at different distances upon the column of the asterie.

APPENDICULATUS, *Appendage*, in *Botany*, a term mostly used to express an additional small leaf.

APPENDIX, or APPENDAGE, in *Anatomy*, is a part in some measure distinct yet connected to another. Thus, the Fallopian trumpets, ovaries, &c. are called the Appendices Uteri.

APPENDIX is more particularly used in the same sense with EPIPHYSIS.

APPENDIX, or APPENDAGE, a thing necessary to, or dependant on another.

The term is chiefly used in matters of literature, for an additional discourse, placed at the end of any piece, or writing, to explain or prosecute something there left deficient, or to draw conclusions from it. In which sense the word coincides with SUPPLEMENT.

APPENSA, from *ad, and pendere, I hang to*, or APPENDED remedies, such as are outwardly applied, by hanging about the neck.

Such are divers amulets, necklaces, phylacteries, &c.

APPENZELL, in *Geography*, a town of Switzerland, and principal place of a canton to which it gives name. N. lat. $47^{\circ} 17'$. E. long. $9^{\circ} 20'$. It is supposed to have derived its name from the Latin, "Abbatis cella," and to have been originally only a religious house belonging to the abbey of St. Gal.

APPENZELL, the thirteenth canton of Switzerland, surrounded by the Rhinthal and the lands belonging to the abbey of St. Gal, is about ten leagues from east to west, and from six to seven broad. The whole country is hilly and mountainous. It is divided into twelve communities; six of which are Protestants, and six Roman Catholics. The country formerly belonged to the abbé of St. Gal; but the inhabitants, wearied with exactions and oppressions, asserted their liberty against the troops of the abbot and the Austrians sent to succour them, and sealed it with their blood. In the year 1513, it was admitted into the Helvetic league, and constituted the thirteenth canton. The population is estimated at 51,000, 13,000 being catholics, and 38,000 protestants; which is a large number in a country of not more than sixty square leagues, and composed for the most part of glaciers, inaccessible rocks and precipices. It yields, however, good pasturage; and, in some parts of it, the manufactures have of late been much encouraged. This canton is popularly divided into Innerooden, or the interior part; and Aufferooden, which comprehends the tracts situate near the borders. In the former part, pasturage is the principal employment; and whatever respects the feeding the cattle, the management of dairies, and the making of cheese, is carried to a high degree of perfection among these mountaineers. The rich and poor are cow-keepers; but the poor, having little or no grass land, employ agents through the canton to inform them where hay may be obtained; and the *fenn*, or cow-keeper, bargains for it, and drives his cattle, when they return from grass, to the places where the hay is to be had. The person who sells his hay, furnishes the *fenn* not only with stabling for his beasts, but boards and lodges him and his whole family. In return, the *fenn*, besides paying the stipulated price for the hay, allows to his host as much milk, whey, and zieggee (a kind of lean cheese), as may be used in the house, and leaves him also the manure of his cows. In the middle of April,

when nature revives, the fenn again issues forth with his herd to the meadows and fertile Alps, which he rents for the summer: so that the life of these people is a constant migration, and they enjoy with it health, content, and cheerfulness. The original breed of cattle in this canton is of a black and brown cast; but the fenns, preferring a motley herd, compose it of black, brown, and some bay cows: to produce which set a black cow with a white belly and a stripe of the same colour along the back is required. The animals are curried, dressed, and tended with the utmost care; and thus they have an appearance of sleekness, cleanliness, and health, superior perhaps to that of any other cattle in the world. The mountaineer, it is said, lives with his cows in a constant exchange of reciprocal acts of gratitude; the latter affording him almost whatever he wants; and the fenn, in return, providing for and cherishing them, sometimes more than his own children. The fine cattle, which are the pride of the cow-keeper who inhabits the Alps, are adorned with large bells suspended from broad thongs; and every fenn has an harmonious set of at least two or three bells. The whole peal, including the thongs, will sometimes be worth between 140 and 150 guilders; while the whole apparel of the fenn himself, when best attired, does not amount to the price of 20 guilders. These ornaments, however, are only worn on particular occasions; as in the spring, when the cows are driven up the Alps, or removed from one pasture to another; or when, in winter, they travel to the different farms, where the owner has contracted for the hay. The fenn, arrayed in his best garb, leads the procession, singing the *ranz des vaches*, consisting of simple tones mostly formed within the throat, and without articulate sounds or words; three or four fine goats follow, then comes the handsomest cow with the great bells, and then two others with smaller bells; these are succeeded by the rest of the cattle; and in the rear is the bull, with a one-legged milking-stool hanging on his horns; and the procession is closed by a sledge in which are the implements of the dairy. The cows themselves, as well as the keeper, seem to be pleased with their ornaments; and if the leading cow is deprived of her honours, she manifests her grief by lowing incessantly, abstaining from food, and becoming lean; and she pursues her rival, who has obtained the badge of superiority, with vengeance, butting, wounding, and persecuting her in the most furious manner. The cows, when dispersed on the Alps, are brought together by the voice of the fenn, who allures them to him by singing the *ranz des vaches*. Of the urine of the cattle, the farmers of Appenzell make salt-petre by a very simple process. Under their stables, which are built on sloping ground, so that one side of the edifice rests on the hill and the other is elevated by means of two strong polls which support it two or three feet above ground, are pits filled with sandy soil. The animal water continually oozes through the planks of the floor; and, having drenched the soil contained in the pit for two or three years, the pit is emptied, and the salt-petre is collected and refined in the usual manner.

Among the various modes of industry in Innerooden, that of feeding snails is one of the most singular. In the garden grounds along the river Sitter, such numbers of snails are kept during the summer season, that the sound caused by the motion of their denticulated jaws, while they are eating, is distinctly heard at several paces from the spot. Young snails are collected in the adjacent parts, placed in these gardens, and supplied (till, on the approach of winter, they inclose themselves, with leaves of lettuce, colewort, cabbage, and other vegetables, by which they grow and fatten to a surprising degree. Some time before Lent, the

owners pack up the closed snails in casks, and carry them for sale to the convents of Suabia, Bavaria, and Austria, and even as far as Vienna, where they are purchased as delicacies. By this traffic some have acquired a handsome fortune.

The food of the inhabitants is exceedingly simple, consisting chiefly of milk, cheese, whey, oatmeal, and potatoes. Bread is not in common use, except among the rich. Their dress is equally plain: and as there is less disparity of fortunes among them than in almost every other part of Europe, a great uniformity prevails in diet, dress, and manners; and this constitutes the main support of their civil and political equality. Some travellers, who have observed crowds of beggars in this canton, have been led to draw erroneous inferences concerning the prosperity of the people; but the fact is, that hordes of beggars, attracted by the charitable disposition of the Appenzellers, flock thither from Suabia, and other neighbouring provinces of Germany. The mountaineers of Appenzell are undisturbed and content, free from the oppression of arbitrary power and the exactions of taxes, and solely occupied with their cows and the Alps on which they graze. The government of this republic confines itself to merely granting protection, and providing for the security of persons as well as of property. The people have no desire of knowledge; and are so ignorant, that the majority of the inhabitants of Innerooden cannot read and write; and of course they have no schools, or such as are in the most deplorable state. This ignorance is necessarily attended with gross and wretched superstition. Parents, whose children are taken ill, seldom seek medical assistance, but have masses read for the purpose of obtaining from heaven their speedy dissolution. On the loss of a still-born child they are inconsolable, under an apprehension that for want of baptism it is gone to hell; but, on the death of other children, tears are scarcely ever shed; on the contrary, the parents are joyful, and their friends say to them by way of congratulation, "now you have an angel in heaven." The punishment inflicted on incontinence is not very severe; the transgressing parties only paying a fine of five guilders each, provided that both be unmarried; but if any female commits the same fault three times, she is sentenced to be publicly whipped. Yet popular opinion requires, that he who violates a virgin shall make her his lawful wife; and if they are not joined in marriage, both of them, especially the ravisher, are branded with indelible shame. The girl, in such a case, is prohibited from wearing the badge of virginity, which is a metal pin stuck into the braided hair, and is obliged to cover her head with a black or brown hood. The male offender is virtually divested of those privileges which belong in common to all citizens; an humiliation than which there is none more grievous in democratical states; for the man so stigmatized is civilly dead in his own country, having lost what is most dear to him, the advantages of a freeman. The preceding remarks pertain chiefly to Innerooden, the inhabitants of which are Roman Catholics: but in Aufferooden, and the outer parts of the canton of Appenzell, the reformed religion has been established since the middle of the sixteenth century. From that period, the manufacture of linen, muslin, and cotton-cloth has constituted the chief branch of industry among the reformed Appenzellers. The manufacturers of Appenzell have now attained to such a degree of skill, as to be able to spin out of half an ounce of flax, a thread measuring from 9 to 10,000 feet in length; whence their cambrics are in great demand on the continent. The Appenzellers, apprized of the improvements of the manufactories in Ireland and Scotland, and dreading to lose their trade, have lately begun to introduce machines for spinning and carding

wool, invented by an inhabitant of Rehetobel. Pasturage, in this district, has of course decreased; the large pasture grounds being divided into small meadows, each sufficient only for two or three cows. The people of Appenzell are industrious and persevering, in common with other Swiss; but their distinguishing feature is quickness of apprehension. They accordingly manifest particular ingenuity in inventing, imitating, and improving machines, as well as other branches of mechanics, without any assistance from instruction or books. Besides some exceedingly skilful weavers, several among them have acquired reputation by the manufacture of watches, clocks, and fire-engines. The wooden bridges of Ulrick Grubenmann, a native of the village of Teufen, are very generally known on the continent. This ingenious mechanic, it is said, offered to build an arched wooden bridge across the river of Derry in Ireland, which is 600 feet wide; but his plan was rejected.

See Schilderung dn Gebirgsvolker des Schweiz, &c. or A Description of the Tribes which inhabit the mountainous parts of Switzerland, by John Gottfried, M. D. vol. i. containing the canton of Appenzell; Svo. Leipzig, 1798.

APPERCEPTION, or ADPERCEPTION, is used by Leibnitz and his followers, for an attribute of the mind, considered as conscious of, or reflecting on its own perceptions: in which sense the word amounts to the same with what Des Cartes and others call CONSCIOUSNESS.

APPERWACK, or CAPPERWACK RIVER, in *Geography*, lies about E. S. E. from the island and city of Cayenne, on the coast of Guiana, in South America. An island extends across the entrance, which is surrounded by a sand bank, and off the river is a cluster of rocks called the Constables.

APPETITE, APPETITUS, APPETENCY, formed of *ad*, *to*, and *peto*, *I crave*, in *Physiology*, a desire of enjoying something that is apprehended to be necessary or conducive to happiness. When this inclination towards any object considered as good, is guided by reason, and results from reflection on the real value of the object, it is called *rational*; but when it proceeds from the mere impulse of the senses, without any distinct apprehension of the value of the object, it is denominated *sensitive*.

Appetite is restrained, by Hutcheson, to such of our desires as have a previous painful and uneasy situation, antecedently to any opinion of good in the object; nay so as that the object is often chiefly esteemed good only for its allaying this pain or uneasiness, or if it give also a positive pleasure, yet the uneasy sensation is previous to, and independent of this opinion of good in it. By another ingenious writer (see *Elem. Crit.* vol. i. p. 44.), appetites are represented as passions directed to general objects, in contradistinction to passions directed to particular objects, which retain their proper name. Thus we say an *appetite* for fame, for glory, for conquest, for riches; but we say the *passion* of love, of gratitude, of envy, &c. Appetite may be also distinguished from passion, since the latter has no existence till a proper object be presented: whereas the former exists first, and then is directed to an object.

Some have erroneously ascribed the appetites solely to the corporeal system or animal part of man; but this mode of representing them must appear to be a mistake on a close investigation; since, however the generality of moral writers may be inclined to regard the grosser appetites as having their seat in the body, and thence term them sensual and carnal, they never reproach the more refined species of corporeal enjoyments with these degrading epithets; nor do they accute a man of being sensually disposed, if he loves music, or receives delight from the contemplation of the beauties of nature. Dr. Reid (*Essays on the active Powers*

of Man, *Ess.* iii. p. 122, &c.), limits the term *appetite* to a particular class of desires, which belong to the animal principles of action, and which are distinguished by the following properties. Every appetite is accompanied with an uneasy sensation proper to it, which is strong or weak in proportion to the desire we have of the object. Moreover, appetites are not constant, but periodical, being satiated by their objects for a time, and returning after certain periods. He adds, those that are chiefly observable in man, as well as in most other animals, are hunger, thirst, and lust. The ends for which our natural appetites are given, are too evident to escape the observation of any man of the least reflection: two of those above enumerated are intended for the preservation of the individual, and the third for the continuance of the species. To act merely from appetite is neither good nor ill in a moral view: it is neither an object of praise nor of blame; and the person who yields to its impulse, when there is no reason to the contrary, acts agreeably to his nature. Appetites, considered in themselves, are neither social principles nor selfish. They cannot be called social, because they imply no concern for the good of others; nor can they justly be called selfish, though they be commonly referred to that class. To this purpose, Dr. Reid observes, that appetite draws us to a certain object without regard to its being good for us, or ill; nay, in some cases, self-love is sacrificed to appetite. But it may be replied, that the impulse of appetite supposes the previous apprehension of good; though this apprehension, and the appetite that results from it, may be misguided and perverted. Besides the appetites which nature hath given to us for useful and necessary purposes, we may create appetites which nature never gave. As it is therefore best to preserve our appetites in that tone and degree of strength which nature gives them, so we ought to beware of acquiring appetites which nature never gave; these are always useless, and often very hurtful. It should also be considered, that although there be neither virtue nor vice in acting from natural appetite, yet there may be much of either in the management of our appetites; and the power of self-government is necessary for their restraint and regulation.

APPETITE, in *Medicine*, is more particularly used to denote a natural periodical call or desire to eat and drink, occasioned by a certain uneasy and painful sensation, and with a view of repairing what had been wasted by the several excretions of the body. A loss or prostration of appetite is called ANOREXIA. The defect of appetite is of two kinds, and is usually divided, by medical writers, under two names, the *anorexia* and *nausea*.

The anorexia is a too great abstinence from food, which sometimes has its origin from depravation of the stomach, sometimes from other causes more remote.

The nausea is defined to be a plenary abstinence from foods, being a complaint of the same nature and origin with the anorexia, but differing in degree.

The signs are very obvious so far as a distaste to food, which is common to both; but there is this difference, that in an anorexia the patients usually eat something, though without appetite, and are troubled always with a pain and uneasiness of the stomach after it; but in the nausea there is a greater distrelsh of food of all kinds, and frequent straining to vomit. Men of idle lives, and such as drink too freely of strong liquors, are subject to *idiopathic* defects of appetite, from actual injuries in the stomach; others labouring under the different diseases before mentioned, are as often subject to the *symptomatic*. People of a languine habit, when afflicted with a loss of appetite, always find great relief in acids of the milder kind; and those of a leucophlegmatic

leucophlegmatic habit are often cured by taking small doses of *elixir proprietatis* every day before dinner. Some persons are very fond of external applications to the stomach in those cases, but these are rarely to be found of any great service. The best of them is a plaster of *tacamahaca*, with oil of mastic.

A prepossessing propensity of things not proper for food is called *PICA*; and an immoderate appetite is called *BULIMIA*, or *fames canina*. Some, however, distinguish between the *βουλιμία*, and *canine appetite*; making it the distinguishing character of the latter, that it is attended with a henty or other cæliacal flux.

APPETITE excessive. See *OREXIS*.

Dr. Cullen, in his arrangement of diseases, makes two distinct sections of erroneous and deficient appetites under the order of *dysforesia*: to the former he refers *bulimia*, *polydipsia*, *pica*, *satyriasis*, *nymphomania* or *furor uterinus*, and *nostalgia*; to the latter, *anorexia*, *adipsia*, and *anaphrodisia*.

APPIA, or *ΑΡΡΙΑ*, in *Ancient Geography*, a town of Asia, in Phrygia.

APPIADES, in *Mythology*, five divinities so called because their temples were at Rome near the fountains of Appius, viz. Venus, Pallas, Vesta, Concord, and Peace.

APPIAN, in *Biography*, a Greek historian, was a native of Alexandria, and lived under the reigns of Trajan, Adrian, and Antoninus Pius, in the former part of the second century. In the time of Trajan, he settled at Rome, and gained such reputation as an advocate, that he was chosen one of the procurators of the emperor, and had the government of a province assigned to him. In the preface to his history, he informs us, that he wrote about the 50th year of Rome, and therefore this preface must have been written about the year of Christ 147, or 148. His Roman History was comprised in 24 books, and compiled, not in the chronological order of Dionysius Halicarnassensis and of Polybius, nor in the biographical method of Plutarch, nor in a continued series like that of Livy, but in the order of the countries in which the events that are related by him happened, as Italy, Gaul, Sicily, Spain, Africa, Greece, Syria, Parthia, Egypt, and Arabia. He is charged with many errors by Bodin, Sidonius, and Scaliger; though the former allows, that he is the only historian, who gives a just and clear account of the Roman provinces, cities, and armies, and a lively description of the Roman empire. La Mothe le Vayer thinks that the principal ground of complaint against him, is his undue partiality to the Romans, so that he represents the right as well as the advantage to be always on their side, to the prejudice of all other nations, and even of his own country. He is also charged with having borrowed many passages from Polybius, Plutarch, and other authors, without acknowledgment; inasmuch that Scaliger reproachfully calls him "alienorum laborum fucum," a drone who robs the industrious bees of their labour. Photius, however, is of opinion, that he wrote with the utmost regard to truth, and that he has shewn a more accurate and extensive acquaintance with military affairs than any of the historians: while we read him, he says, we cannot but imagine that we see the battles which he describes. But his chief talent, according to this author, is displayed in his orations, in which he moves the passions as he thinks proper, either in animating the resolution of the soldiers, or repressing the impetuosity of those who were too precipitate. His style is plain and simple, without any thing turgid or superfluous. In his preface he has given a general description of the Roman empire. Of the nine first books of his "History," some fragments remain, which are preserved in Ursinus's "Excerpta de legationibus," published in Greek, at Antwerp, with notes, in 1582, 4to.; and some

of them are extant in the "Excerptæ Peirescianaæ," published by Valefius, with a Latin version and notes, at Paris, in 1634, 4to.; of the fourth book on the war with the Gauls, only an epitome remains; the sixth and seventh books, on the affairs of Spain, and the war with Hannibal, were first published, in 8vo. by H. Stephens, at Paris, in 1557; the eighth, on the affairs of Libya; the eleventh and twelfth, on those of Syria and Parthia; five books on the Civil Wars; and fragments of the twenty-third, on the affairs of Illyria; are extant. A Latin version of several parts of Appian, by Petrus Candidus, was printed at Rome, in 1472, and at Venice, in 1477 and 1492, in folio. An edition of Appian was published, in Greek, by Charles Stephens, with various readings, at Paris, in 1551, in folio; another, in Greek and Latin, was published by Henry Stephens, at Geneva, in 1592, in folio; an improved edition, by Tollius, was published at Amsterdam, in 1670, in two volumes, 8vo. Appian, Hist. Præf. Fabr. Bibl. Græc. l. iv. c. 12. § 1—4. t. iii. p. 391—396. Gen. Dict.

APPIAN Aquæduct, was so called from Appius Claudius, who was censor of Rome in the 442d year of that city. This aquæduct began seven miles from Rome, and after having run a great way under ground, discharged part of its waters between the gates Capena and Trigemina, and conveyed the rest quite to the Campus Martius; and thus the whole city was plentifully supplied. It was dug under ground, and laid very deep, says Frontinus (*De Aquæductibus*), either because the art of levelling was not then brought to perfection, or because the Roman territory was too much exposed to the incursion of its enemies, who might have destroyed the stately arches, and intercepted the water. This water was for many ages called "Aqua Appia." The principal fountain under this denomination, was placed in the forum of Cæsar, below the temple of Venus Appiades; and by a verse of Ovid it appears to have formed a jet of water:

"Appias expressis aera pulsat aquis."

APPIAN Way, a great Roman highway, constructed by Appius Claudius, censor of Rome, in the 442d year of that city. It commenced at the gate Capena, now called St. Sebastian's, and passing over the mountain called St. Angeli, crosses the plain of Valdranus, the *Palus Pompina*, and ends at Capua, which was the limit of the Roman empire.

The Appian way, called by Statius (*Sylv. i. 12.*), "the queen of roads," extended about 140 miles, and was wide enough for two chariots to go abreast without inconvenience. The stones which Appius employed in this work, were brought from a great distance, and were as hard as flints. They were previously squared and smoothed by skilful workmen, and then joined together without any cement; so that they appeared for several miles like a single stone. In the beginning of Augustus's reign, this road reached to Brundisium, that is, 238 miles farther; but it is not certain, who was the manager of this additional work. It is generally ascribed to Cæsar. Dr. Burnet, in his Letters, says, that in many places, it is still as entire as when it was first made. On each side of it was a deep ditch for receiving off and conveying away the water.

Caius Gracchus placed the small columns called *termini*, which marked the miles.

The new *Appian way* was constructed by Caracalla, from his baths to the gate Capena, where it joined the other.

APPIANI, GIUSEPPE, in *Biography*, an exquisite Italian singer, with a contralto voice, born at Milan, and always mentioned with rapture by some of our friends who heard him at Rome when he was very young; they likewise spoke of him as an excellent actor. He was in the service

service of the empress queen, when he died at Ceussa, near Bologna, in 1742, at only 23 years of age, extremely regretted. He had studied under Porpora, with the celebrated Salimbene. His style was naturally pathetic and touching, and his *adagio*, consequently, extremely admired.

APPIANO, in *Geography*, a town of Italy in the duchy of Milan, 25 miles N. N. W. from Milan.

APPIARIA, in *Ancient Geography*, a town of Europe, in Lower Masia, on the right bank of the Danube, there called Ister. It was situated between Durostorus on the east, and Nicopolis ad Istrum on the west.

APPIDEMISCHKAN, in *Geography*, a town of Prussia, nine miles south-east from Gumbinnen.

APPII FORUM, in *Ancient Geography*, *Borgo Longo*, a small town of Italy, in Latium, in the country of the Volsci. It was situated upon the Appian way, between Sueffa Pomestia to the north-west, and Terracina at some distance to the south-east. It is mentioned in the *Acts*, ch. xxviii. 15. and by Horace in his account of his journey to Brundisium :

“ —inde forum Appii
Differtum nautis, cauponibus atque malignis.”
“ To Forum Appii thence we steer, a place
Stuff'd with rank boatmen, and with vintners base.”

FRANCIS.

On the ruins of this ancient little town is situated an abbey called Fossa Nuova.

APPLANA, in *Entomology*, a small species of PHALÆNA, of the *Tortrix* family, that inhabits Kiel and other parts of Europe. The wings are depressed, brown, with three white dots in the centre. Gmelin. Obs. This is the Fabrician character in the species *Insectorum*, where it is arranged in the section *Pyralis*, t. 2. 288.; and it is also *Phalæna punctata* of Clerk. Icon.

APPLAUSE, properly signifies an approbation of something, witnessed by clapping of hands; and in this respect it differs from acclamation, which was articulate, and performed with the voice. The word comes from the verb *plaudere*, to clap the hands.

The ancient way of applauding by clapping of hands is scarcely retained any where but in theatres. Among the Romans there were three different species of applause denominated from the different noises made in them, viz. *tomus*, *imbrices*, and *testæ*; the first a confused din, made either by the hands or the mouth; the second and third by beating on a sort of sounding vessels placed in the theatres for this purpose.

Persons were instructed to give applause with skill; and there were even masters who professed to teach the art. The proficient in this way let themselves out for hire to the vain-glorious among the poets, actors, &c. and were properly disposed to support a loud applause. These they called *laudicoeni*.

At the end of the play, a loud peal of applause was expected, and even asked of the audience, either by the chorus or the person who spoke last. The formula was, *spectatores plaudite*, or *valete & plaudite*.

The *plausores*, or applauders, were divided into *chori*, and disposed in theatres opposite to each other, like the choristers in cathedrals; so that there was a kind of concert of applauses.

Seneca (*Nat. Quæst.* ii. 28.) has described the different modes of applauding with the hands: “*Aversæ inter se manus collisæ non plaudunt, sed palma cum palmâ collata, plausum facit. Et plurimum interest utrum cavæ concutiantur, an planæ et extentæ.*” The people stood up to applaud in the theatres: thus Propertius (iii. 16.);

“*Stantiaque in plausum tota theatra juvent.*”

Of the awkward applauses of the uninstructed rustics, who did not understand the art of applauding, and who disturbed the general harmony by their discordant sounds, Tacitus speaks; (*Annal.* xvi. 5.) “*cum manibus nefcis fatulentis, turbarent ignaros.*”

APPLE-TREE, *Malus*, in *Botany*, a general name applied to a cultivated orchard-tree, which produces the fruit known by the name of apple. In the system of Linnæus, it is considered as a species of the genus *pyrus*, of which there are three: the *wild-apple* or *crab*, which has a very four fruit; the *Virginian wild crab*, which produces a sweet-scented flower; and the *dwarf-apple*, frequently known by the name of *Paradise-apple*. See PYRUS MALUS.

Trees of this sort are produced in an artificial manner, by means of ingrafting the scions or shoots of such apple-trees as are valuable for their fruit, on stocks that have been raised from the seeds of crabs. Thus a scion of an apple-tree, inserted into a crab stock, occasions the crab-tree from that time to produce *apples* of nearly the same kind and quality with those from which the scion was taken. Mr. Ray, indeed, thinks, that the fruit of these trees always follows the nature of the scions.

In the nurseries, three sorts of stocks are commonly used to graft apples upon: first, *free stocks*, which are raised indifferently from the kernels of all sorts of apples, and which by some are also termed *crab-stocks*, as all those trees which are produced from the seeds before they are grafted, are termed *crabs*, without any distinction. Such stocks should, however, be preferred, as are raised from the kernels of crabs, where they can be procured. Several old writers are of this opinion. Austen, who wrote more than an hundred years ago, says the stock which he accounts best for *apple-grafts* is the *crab*, which is better than *sweeter apples* to graft on, because it is usually free from canker, and will become a large tree, and, he conceives, last longer than stocks of *sweeter apples*, and make fruits more strong and hardy to endure frosts. It is well known, however, that by frequent grafting some sorts of apples upon free stocks, the fruits have been rendered larger, but less firm, and of shorter duration.

The second sort of stock is the *Dutch creeper*; these stocks are designed to stint the growth of trees, and keep them within compass for dwarfs or espaliers. The third sort is the *Paradise apple*, which is a very low shrub, consequently only proper for trees which are kept in pots by way of curiosity, as they do not continue long. See INGRAFTING OF FRUIT TREES.

Trees of the apple kind are found in general to thrive well when planted on strong deep loamy soils, or such clayey ones as, by having a portion of gravel in their composition, are rendered not retentive of moisture. Mr. Knight, in his treatise on the Culture of the Apple and Pear, remarks, that a preference has been given to soils of opposite kinds, by planters of different ages. Those of the last century uniformly contended, he says, in favour of a light sandy loam, and on that their finest cyder fruits were grown; but at present a soil of a diametrically opposite quality, a strong red clay, is generally preferred. Much of the soil which is called clay, in the district where he resides, is, however, he observes, properly argillaceous marle; and some of it contains a large portion of calcareous earth, and effervesces strongly with acids. He has found this soil to form the substratum of some orchards much celebrated for producing fruit of the first quality. It appears, he thinks, to have the effect of mitigating the harshness of rough austere fruits; and that as the trees grow with great luxuriance in it, it is perhaps, of all soils, the best calculated to answer the wishes of the planter; but that the strongest and most highly flavoured

flavoured liquor, which has hitherto been obtained from the apple, is produced by a soil which differs from any of those that have been mentioned—the shallow loam on a limestone basis, such as is met with in the forest of Dean.

It is added, that in regard to situation, the apple-tree succeeds best in those which are neither high nor remarkably low. In the former, its blossoms are frequently liable to be injured by cold winds, and in the latter by spring-frosts, particularly when the trees are planted in the lowest part of a confined valley. A south or south-east aspect is generally preferred, on account of the turbulence of the west, and the coldness of north winds; but orchards succeed well in all: and where the violence of the west wind is broken by an intervening rise of ground, a south-west aspect will, he thinks, be found equal to any. Apple-trees are generally the most productive of fruit when they are situated near the fold-yard, and the ground, in consequence, much trod and manured by the cattle in the winter season. The soil in which old apple-trees have grown, is, however, esteemed very unfavourable to young ones.

When from contiguity to the house, an orchard is planted in this kind of ground, the pear and apple should be made to succeed each other, as has been judiciously recommended by the author of the Rural Economy of Gloucestershire. The land intended to be planted with apple-trees should be well prepared the year before, by thoroughly digging or ploughing; and if dung, in the form of compost with mould, be laid on, it will be of great utility. In choosing the trees, such as are but of two years growth from the graft, are, in general, to be preferred, and they should have strong straight stems. When the trees are planted, they should also be staked, to prevent their being shaken by the wind. For the manner of planting apple-trees, &c. see ORCHARD.

In directing the choice of fruit-trees, for particular situations, great attention should be paid to select such as are proper for the peculiar views of the planter, and sufficiently early to ripen well in them. The apple-tree being naturally very full of branches, frequently requires the operation of pruning; and when properly executed, great advantages will be found to arise from it. Mr. Knight thinks, in this business, the pruner should confine himself almost entirely to the extremities of the bearing branch, which are always too full of wood, and leave the internal part of the trees nearly as he finds it. Large branches should rarely or never be amputated.

In the garden culture of the apple, where the trees are retained as *dwarfs* or *espaliers*, the more vigorously growing kinds are often rendered unproductive by the excessive, though necessary, use of the pruning knife. The above writer has always succeeded, he says, in making trees of this kind fruitful, by digging them up, and replacing them with some fresh earth in the same situation. The too great luxuriance of growth is, he thinks, thus checked, and a disposition to bear in consequence brought on. See PRUNING OF FRUIT-TREES.

Apple-trees sometimes begin bearing at the age of two or three years; but when they are six or seven, they are for the most part found to produce the most abundantly.

The blossoms of apple-trees are liable to be injured or destroyed by various causes; as severe cold, a hazy state of the atmosphere, frosts, and insects of various kinds. And Mr. Knight has remarked, that they also fail frequently from want of impregnation, when the weather is unusually hot and dry, or when cold winds prevail, as he has often observed the *farina* to wither and die on the *anthera* in such seasons. In these cases, those trees have been found to

escape the best, that were moderately full of wood, and consequently capable of affording the blossoms the most protection.

APPLE, a well-known orchard fruit, cultivated for the purposes of the table as well as for the liquor which is prepared from its juice. The varieties of this valuable fruit are extremely numerous. Mr. Forsyth, in his treatise on the Culture and Management of Fruit-trees, mentions eight different sorts, as having been introduced from France; among which the *French rennet*, the *rennet grise*, and the *violet apple*, are most esteemed in this country; and about thirty-six sorts of our own growth, which may be considered as valuable. But the varieties of this fruit will be treated of more fully under the article *PYRUS MALUS*.

In respect to the method of preserving apples for use during the winter season, it has been recommended to let them remain upon the trees until perfectly ripe, and then to gather them by the hand in dry weather, laying them in heaps for a few weeks, in order that they may undergo a slight degree of sweating. They should then be carefully looked over, and all such as are in any way soft or decayed, be removed, the sound fruit being wiped dry, and packed in any kind of large jars that have been previously made clean and dry; the mouths or openings being closely secured, in order to exclude the air as much as possible from them. In this way apples are said to keep sound a great length of time, the flesh or pulp remaining perfectly firm and plump, which is not the case when they are constantly exposed to the action of the open air. But they may be kept perfectly well without this trouble, by being closely packed in large hampers, baskets, or bins, and placed in close dry situations.

The sort of apples that are in general held in most esteem for the table are the following, which stand in the order of their ripening: the *white juncating*, the *margaret apple*, the *summer pearmain*, the *summer greening*, the *embroidered apple*, the *golden rennet*, the *summer white calville*, the *summer red calville*, the *silver pippin*, the *aromatic pippin*, the *la reinette grise*, the *la haute bonte*, the *royal ruffet*, the *wheeler's ruffet*, the *sharp's ruffet*, the *spine apple*, the *golden pippin*, the *nonpareil*, and *l'api* or *pomme d'api*.

But for kitchen use; the *codling*, the *summer marygold*, the *summer red pearmain*, the *Holland pippin*, the *Kentish pippin*, the *courpendu*, the *Loan's pearmain*, the *French rennet*, the *French pippin*, the *royal ruffet*, the *monstrous rennet*, the *winter pearmain*, the *pomone violette*, the *Spencer's pippin*, the *stone pippin*, and the *oaken pippin*.

And for the purposes of cyder; the *stire apple*, the *bagloe crab*, the *golden pippin*, the *old red streak*, and the *woodcock*, were the favourite old cyder fruits; but most of them are now, according to Mr. Marshall, on the decline. The *muß* and the *cocagee* are, however, still in high estimation, especially the latter. Mr. Crocker, in his tract on the Art of making Cyder, observes, that in the districts of Hereford and Worcester, the following are considered as the best liquor fruits: the *Bennet apple*, *Captain Nurse's kernel*, *Elton's yellow*, *Normandy apple*, and the *yellow or forest flyre*. And that in the county of Somerset; the *Fersey*, the *white sour*, the *margill*, *vallis apple*, *barn's-door*, *crab red-streak*, *Du-ann*, *Jack Every*, *cocagee*, *Clark's primo*, *Buckland*, *Pit crab*, *Slater's pearmain*, *Slater's No. 19*, *Slater's No. 20*, *Slater's No. 21*, *Castle pippin*, *saw-pit*, and the *pomme apis*, are supposed most valuable. But that in Devonshire, the most esteemed fruits are; the *Seaverton red-streak*, the *sweet broady*, the *lemon bitter sweet*, *jossey*, *Orcheton pippin*, *wine-apple*, *marygold spice-apple*, *Ludbrook red-streak*, *green Cornish*, the *butter-box*, *red Cornish*, *broad nosed pippin*,
eat's

cal's head, brandy apple, Pine's red-streak, winter red, sweet pomme roi, and the Bickley red streak.

The best and most proper sorts of apples to be cultivated in a small garden are, according to Mr. Forsyth, the *jenet-ting, golden pippin, nonfach, Ribstone pippin, nonpareil, Queen's apple, skyhouse, golden rennet, aromatic pippin, grey ladington, scarlet pearmain, lemon pippin, pomme gee, and the French crab, with ruffetings and colings* for the purpose of baking.

It has been ingeniously suggested by Mr. Knight, in his treatise on the Apple and Pear, that the juice of these fruits might be used with great advantage in long voyages. He has frequently, he says, reduced it by boiling, to the consistence of a weak jelly; and that in this state it has remained several years without the slightest apparent change, though it has been intentionally exposed to much variation of temperature. A large quantity of the inspissated juice would, he further observes, occupy but a very small space; and the addition of a few pounds of it to a hoghead of water would probably, at any time, form a liquor a good deal similar to cyder or perry: it might also, he thinks, be used to supply the place of *rob of lemons* and *oranges*, and might be obtained at a much lower price.

It has been observed by Dr. Grew, in his Anatomy of Vegetables, that the apple is formed of four distinct parts, consisting of the *cuticle or pill*, the *parenchyma*, the *branchery*, and the *core*; that the *pill* or *skin* is only a dilatation of the outermost skin or rind of the bark of the branch on which it grew; and that the *parenchyma* or *pulp*, though tender and delicious to the taste, is only a dilatation of the *albumum*, or inner part of the bark of the same part. This is evident, he thinks, not only from the visible continuation of the bark, from the one through the pedicle or stalk to the other; but also from the structure common to both. And that the branchery, or vessels, are only ramifications of the woody part of the branch dispersed through all the parts of the *parenchyma*, the greater branches being made to communicate with each other by the medium of the smaller ones; and the *core* proceeds originally, he supposes, from the pith of the branch, the sap of which finding room enough in the *parenchyma*, to diffuse itself, quits the pith, which, in consequence, hardens into core.

APPLE is also a name given to divers fruits, bearing some resemblance in figure, rotundity, and the like, to the orchard apple.

APPLE, *Adam's*. See CITRUS, and *Pomum ADAMI*.

APPLE, *Alligator*. See ANNONA.

APPLE, *bitter*, a name sometimes given to the fruit of the COLOCYNTHIS. See CUCUMIS.

APPLE, *blad*. See CACTUS.

APPLE, *custard*. See ANNONA.

APPLE, *dwarf*. See DWARF-TREES.

APPLE-FLY, in *Natural History*, the name given by authors to a small green fly found sometimes within an apple, and hatched of a worm or maggot, very frequently found infesting that fruit.

APPLE, *love*. See SOLANUM.

APPLE, *mad*. See SOLANUM.

APPLE, *male balsam*. See MOMORDICA.

APPLE, *marcbafite*, so called by Dr. Grew on account of its figure, as being round, except on one side, where it falls in, and has a stalk like a young apple. Mus. Reg. Soc. P. iii. § 2. cap. 3.

Among the ancient ornaments of churches we read of *golden apples, poma aurea*; by which it should seem, we are to understand the globular parts of candlesticks. Du-Cange.

Some ancient customs also speak of apples of wax, *poma de cera*.

APPLE, *May*. See PODOPHYLLUM.

APPLES, *eak*, are a kind of excrecences or exudations of the nutritious juice of that tree, joined with some degree of putrefaction.

The like are sometimes also found on willows.

APPLE of the eye. See PUPIL.

APPLE, *pine*. See BRONELIA.

APPLE, *prickle*, is remarkable for the several tufts or bunches of thorns with which it is armed all round; each bunch consisting of six or eight thorns, some erect, others couched a little, and crooked outwards, of several lengths, from one inch to above two.

APPLE, *purple*. See ANNONA.

APPLE, *sap*. See SAPINDUS.

APPLE, *sour*. See ANNONA.

APPLE, *star*. See CHRYSOPHYLLUM.

APPLE, *sugar and sweet*. See ANNONA.

APPLE, *thorn*. See DATURA.

APPLE, *water*. See ANNONA.

APPLE, *Island*, in *Geography*, a small uninhabited island of north America, in the river St. Lawrence, in Canada, on the south side of the river, between Basque and Green Islands. It is surrounded by rocks, and the navigation is dangerous.

APPLEBY, a corporate and borough town, the county-town of Westmoreland, where the assizes are held, and which sends two members to parliament, is situated on the banks of the river Eden. It was formerly a considerable town, and had many privileges; but it has long ago sunk into decay, and now consists only of mean houses in one broad street, which has an easy ascent from north to south, and at the end of it the castle, almost surrounded by the river. It has two churches, a town-hall, a county gaol, a free grammar school; and an hospital for a governess and twelve widows, founded, in 1651, by a daughter of lord Clifford. It is governed by a mayor, twelve aldermen, a common council, two sergeants at mace, &c. It is distant about 32 miles from Carlisle, and 270 from London. Its market is on Saturday, and it is the best corn-market in these northern parts. N. lat. 54° 38'. W. long. 3° 32'.

APPLECROSS, a village of Scotland, seated on a bay to which it gives name, on the west coast of the county of Ross, 52 miles west of Dingwall.

APPLEDORE, a sea-port town of England, in the county of Devon, in Barnstable bay, where the Danes landed under Hubba, in the time of Alfred. The harbour divides into two branches; that to the east goes up to Barnstable, distant from it 10 miles west, and the other to Biddeford.

APPLEDORE, a town of England, in the county of Kent, on the river Rother, 9 miles W. from New Romney, and 63 E. S. E. from London.

APPLE-TOWN, an Indian village on the east side of Seneca-lake, in New York, between the townships of Ovid on the South, and Romulus on the North.

APPLICATE, APPLICATA, *Ordinate* APPLICATE, in *Geometry*, is a right line drawn across a curve, so as to be bisected by the diameter thereof.

Applicate is the same with what we otherwise and more usually call Ordinate.

APPLICATE number. See CONCRETE.

APPLICATION, the act of *applying* one thing to another by causing them to approach or bringing them nearer together. Thus a longer line or space is measured by the application of a less, as a foot or yard by an inch, &c. : and

and motion is determined by successive application of any thing to different parts of space.

APPLICATION is sometimes also used, both in *Arithmetic* and *Geometry*, for the operation of division, or for that which corresponds to it in *Geometry*. Thus 20 applied to, or divided by 4, i. e. $\frac{20}{4}$, gives 5. And a rectangle ab applied to a line c , gives the fourth proportional $\frac{ab}{c}$, or another line,

as d , which with the given line c will contain a rectangle $cd = ab$.

APPLICATION, in *Geometry*, denotes the act of placing one figure upon another in order to determine their equality or inequality. In this way Euclid, and other geometers, have demonstrated some of the primary and fundamental propositions in elementary *Geometry*. Thus it is proved, that two triangles, having two sides of the one equal respectively to two sides of the other, and the two included angles equal, are equal in all respects; and two triangles having one side and the adjacent angles of the one respectively equal to one side, and the adjacent angles of the other, are also in the same mode of application shewn to be equal. Thus also it is demonstrated, that a diameter divides the circle into two equal parts; and that the diagonal divides a square or parallelogram into two equal parts. The term is also used to signify the adaptation of one quantity to another, in order to their being compared; the areas of which are the same, but their figures different. Thus Euclid shews how, on a right line given, to apply a parallelogram that shall be equal to a right-lined figure given. See also I. vi. pr. 28. &c.

APPLICATION of one science to another, signifies the use that is made of the principles of the one for augmenting and perfecting the other. As there is a connection between all the arts and sciences, one of them may be made subservient to the illustration and improvement of the other: and to this purpose algebra has been applied to geometry, and geometry to algebra, and both to mechanics, astronomy, geography, navigation, &c.

APPLICATION of *Algebra*, or *Analysis*, to *Geometry*. After the discovery of algebra and analysis, it was natural to apply these sciences to geometry, since lines, surfaces and solids, which are the objects of geometry, are commensurable, and capable of being compared with one another, and consequently of having their relations and proportions assigned. The application of algebra to geometry is of two kinds: that which regards the plane or common geometry, and that which respects the higher geometry, or the nature of curve lines.

The first of these is concerned in the algebraical solution of geometrical problems, and the investigations of theorems in geometrical figures, by means of algebraical investigations or demonstrations. Instances of this kind of application occur in the works of the most early writers in algebra, as Diophantus, Lucas de Burgo, Cardan, Tartalea, &c. and may be found in those of authors of more modern date even to our own times. Some of the best precepts and exercises relating to this kind of application may be seen in Sir Isaac Newton's "Universal Arithmetic," and in Mr. Thomas Simpson's "Algebra" and "Select Exercises." This method of resolving geometrical problems is, in many cases, more direct and easy, than that of the geometrical analysis; but the latter method by synthesis, or construction and demonstration, is the most elegant. The algebraical solution succeeds best in such problems as respect the sides and other lines in geometrical figures; and those geometrical problems in which angles are concerned are best resolved by the geometrical analysis. See other remarks on this method of solution in Newton's treatise above mentioned. The solution

of problems in this way depends upon a previous acquaintance with the method of expressing geometrical magnitudes, as well as their mutual positions and relations, by algebraical notation: e. g. a line, whether known or unknown, is represented by a single letter: a rectangle may be denoted by the product of the two letters expressing its sides; and a rectangular parallelepipedon by the product of three letters, two of which represent its rectangular base, and the third its height. The opposite position of straight lines may be expressed by the signs $+$ and $-$; and segments of lines may be denoted by letters with these signs prefixed, as circumstances require. In order to express the positions of geometrical figures, which it will be more difficult to do, because they are infinitely various, it will be necessary to have recourse to proportions or equations, which express certain relations that depend upon their positions: and the positions of figures may again be deduced from the equations that express the relations of their parts. Thus, an angle may be expressed by the ratio of its sine to the radius; a right angle in a triangle, by making the sum of the squares of the two sides equal to the square of the hypotenuse; the position of points may be ascertained by perpendiculars let fall from them on lines given in position; the position of lines by the angles which they make with given lines, or by perpendiculars drawn to them from given points; the similarity of triangles by an equation deduced from the proportionality of their sides, &c. But it is not possible to give general rules for all the particular cases that occur. As the geometrical proposition must first be expressed in the algebraic manner, the result, when the operation is completed, must be expressed geometrically. All theorems, in which the proportions of magnitudes only are employed, and all those that express the relations of the segments of a straight line, of their squares, rectangles, cubes, and parallelepipeds, are easily demonstrated in the algebraical method. From the first proposition of the second book of Euclid, the nine following may be derived with ease in this manner; and they may be considered as appropriate examples of this most obvious application of algebra to geometry. Moreover, the algebraical demonstrations of the 12th and 13th propositions of the second book require only the 47th of the first book; and the 35th and 36th of the third book require only the third of the third book and 47th of the first.

In the solution of problems, the following general observations will be of use. When any geometrical problem is proposed for algebraic resolution, you are, in the first place, to describe a figure that shall represent the parts or conditions of the problem, and regard that figure as the true one; then, having considered the nature of the problem, you are to prepare the figure for a solution, if it be necessary, by producing and drawing such lines, as appear most conducive to that purpose. When this has been done, let the unknown line or lines that seem to be the most easily found, and any of the known ones that are requisite, be denoted by proper symbols; then proceed to the operation, by observing the relation which the several parts have to each other. As no general rule can be given for the drawing of lines and selecting the most proper quantities to substitute for them, so as always to bring out the most simple conclusions, because different problems require different methods of solution; it will be best, in order to gain experience in this matter, to attempt the solution of the same problem by several ways, and then to apply that which succeeds best to other cases of the same kind, when they afterwards occur. The following general directions will be of use.

1. In preparing the figure, by drawing lines, let them be either parallel or perpendicular to other lines in the figure,

or so as to form similar triangles; and if an angle be given, let the perpendicular be opposite to that angle, and also fall from the end of a given line, if possible.

2. In selecting proper quantities for substitution, let those be chosen, whether required or not, which lie nearest the known or given parts of the figure, and by means of which the next adjacent parts may be expressed, without the intervention of surds, by addition and subtraction only. Thus, if the problem were to find the perpendicular of a plane triangle, from the three sides given, it will be much better to substitute for one of the segments of the base than for the perpendicular, though it be the quantity required; because the whole base being given, the other segment will be given, or expressed, by subtraction only, and to the final equation come out a simple one; from whence the segments being known, the perpendicular is easily found by common arithmetic: whereas if the perpendicular were first sought, both the segments would be surd quantities, and the final equation a quadratic one.

3. Where in any problem, there are two lines or quantities alike related to other parts of the figure or problem, the best way is to make use of neither of them, but to substitute for their sum, their rectangle, or the sum of their alternate quotients, or for some line or lines in the figure, to which they have both the same relation.

4. If the area, or the perimeter of a figure be given, or such parts of it as have but a remote relation to the parts required, it will sometimes be of use to assume another figure similar to the proposed one, of which one side is unity, or some other known quantity; from whence the other parts of this figure, by the known proportions of the homologous sides, or parts, may be found, and an equation obtained.

Prob. I. "The base b , and the sum of the hypotenuse and perpendicular a , of a right-angled triangle ABC (*Plate II. Geometry, fig. 28.*) being given, to find the perpendicular." Let the perpendicular BC be denoted by x ; then the hypotenuse will be expressed by $a-x$; but (by *Eucl. 47. 1.*) $AB^2 + BC^2 = AC^2$, i. e. $b^2 + x^2 = a^2 - 2ax + x^2$; whence $x = \frac{a^2 - b^2}{2a}$ = the perpendicular required.

Prob. II. "The diagonal, and the perimeter of a rectangle, ABCD (*fig. 29.*) being given, to find the sides." Put the diagonal $BD = a$, half the perimeter, $DA + AB = b$, and $AB = x$; then will $AD = b - x$: and therefore, $AB^2 + AD^2 = BD^2$, we have $x^2 + b^2 - 2bx + x^2 = a^2$; which solved gives $x = \frac{\sqrt{2a^2 - b^2} + b}{2}$.

Prob. III. "The area of a right-angled triangle ABC (*fig. 30.*), and the sides of a rectangle EBDF inscribed therein, being given; to find the sides of the triangle." Put $DF = a$, $DE = b$, $BC = x$, and the given area $ABC = d$; then, by similar triangles, we shall have $x-b$ (CF): a (DF) :: x (BC): $AB = ax$. Consequently $\frac{ax}{x-b} \times \frac{x}{2} = d$, and therefore $ax^2 = 2dx - 2bd$, or $x^2 - \frac{2dx}{a} = -\frac{2bd}{a}$;

which, solved, gives $x = \frac{d + \sqrt{\frac{d^2 - 2bd}{aa}}}{a}$; whence AB and AC will likewise be known.

Prob. IV. "Having the area of a rectangle DEFG (*fig. 31.*) inscribed in a given triangle ABC, to determine the sides of the rectangle." Let CI be perpendicular to AB, cutting DG in H; and let $CI = a$, $AB = b$, $DG = x$, and the given area $= cc$; then it will be, as $b : x :: a : ax = CH$; which, taken from CI, leaves $a - ax = IH$;

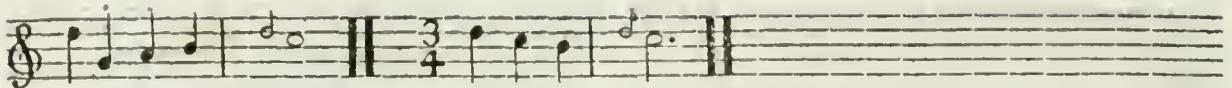

and this, multiplied by x , gives $ax - \frac{ax^2}{b} = cc =$ the area of the rectangle; whence we have $\frac{a^2x - ax^2}{b} = cc$, $x^2 - bx = -\frac{bcc}{a}$, $x - \frac{b}{2} = \pm \sqrt{\frac{b^2 - bcc}{a}}$, and $x = \frac{b \pm \sqrt{b^2 - bcc}}{2}$.

Prob. V. "To inscribe a square in a given triangle." Let ABC (*fig. 32.*) be the given triangle; and suppose DEFG to be the required square; and draw the perpendicular BP of the triangle, which will be given together with the sides. Then, the triangles BAC, BEF, being similar, the notation may be as follows; viz. the base $AC = b$, the perpendicular $BP = p$, and the side of the square DE or EF $= x$. Hence $BQ = BP - ED = p - x$; consequently, by similar triangles, $BP : AC :: BQ : EF$, i. e. $p : b :: p - x : x$; whence $px = bp - bx$; or $bx + px = bp$, and $x = \frac{bp}{b+p}$ the side of the square sought, or a fourth proportional to the base and perpendicular, and the sum of the two, making this sum the first term; or $AC + BP : BP :: AC : EF$.

Prob. VI. "The hypotenuse AC of a right-angled triangle ABC (*fig. 33.*) and the side of the inscribed square BEDF, being given; to determine the other two sides of the triangle." Let DE , or $DF = a$, $AC = b$, $AB = x$, and $BC = y$; then it will be, as $x : y :: x - a$ (AF): a (FD); whence we have $ax = yx - ya$, and consequently $xy = ax + ay$. Moreover, $xx + yy = bb$; to which equation let the double of the former be added, and there arises $x^2 + 2xy + y^2 = b^2 + 2ax + 2ay$; that is, $(x+y)^2 = b^2 + 2a(x+y)$, or $(x+y)^2 - 2a(x+y) = b^2$; whence, by considering $x+y$ as one quantity, and completing the square, we have $(x+y)^2 - 2a(x+y) + a^2 = b^2 + a^2$; whence $x+y - a = \sqrt{b^2 + a^2}$, and $x+y = \sqrt{a^2 + b^2} + a$, which put $= c$, and by substituting $c - x$ instead of its equal y in the equation $xy = ax + ay$, there will arise $cx - x^2 = ac$; whence x will be found $= \frac{1}{2}c + \sqrt{\frac{1}{4}cc - ac}$, and $y = \frac{1}{2}c - \sqrt{\frac{1}{4}cc - ac}$.

Hence it appears that c , or its equal $\sqrt{aa + bb} + a$, cannot be less than $4a$, and therefore b^2 not less than $8a^2$, because the quantity $\frac{1}{4}cc - ac$, under the radical sign, would be negative, and its square root impossible; and all squares, whether their roots be positive or negative, are positive; so that there cannot arise any such quantities as negative squares, unless the conditions of the problem under consideration are inconsistent and impossible. See *Simpson's Algebra, sect. 18, passim.*

The second branch of the application of algebra to geometry, or that which respects the higher geometry, or the nature and properties of curve lines, was introduced by Des Cartes. In this department the nature of the curve is expressed or denoted by an algebraic equation, which is thus formed. A line is conceived to be drawn, as the diameter or some other principal line of the curve, and upon this line, at any indefinite points, are erected perpendiculars, which are called ordinates, and the parts of the first line cut off by them are called abscissas. Calling the absciss x , and its corresponding ordinate y , the known nature of the curve, or the mutual relations of other lines in it, will afford an equation involving in it x and y , and other given quantities. And as x and y are common to every point in the primary line, the equation, derived in this manner, will belong to every position or value of the absciss and ordinate, and may be properly considered as expressing the nature of the curve in all points of it; and is usually called the equation of the curve. Hence

It has been well observed by M. Framery, in the *Encyclopédie Methodique*, that the appoggiatura gives a tender expression to the melody, that would injure marches and movements of spirit, which require energy and strong accents.

Appoggiaturas below the principal note, are more tender and affecting than those above; which are, however, more graceful and interesting. In recitative, though no appoggiaturas are ever written; they are as much understood and expected, as dots to the letter *i*.

Fragment of recitative, from Sacchini's opera of *Creso*.

Eccomi a piedi tu-oi; supplice io chiedo pie-tà da te, ma non rispondi?
al-trove perchè volgi il sembiante? Ah sì; costanza non hai di ri-mirar-mi in questo
sta-to in cui mi tiene an-co-ra.

This piece of *recitative* should be sung as if it were written in the following manner:

Eccomi à piedi tu-oi; supplice io chie-do pie-tà da te, ma non rispondi?
al-trove perchè volgi il sem-biante? Ah sì; cof-tan-za non hai di ri-mirar-mi in questo
sta-to in cui mi tiene an-co-ra.

M. Framery says, that the appoggiatura is the only embellishment in recitative. But Pacchierotti and Marcheli (perhaps since his article was written) have introduced graces in recitative, particularly before a close, which all the Italian singers and their imitators, who can execute them, have followed. See *RECITATIVE*.

The term appoggiatura is derived from appoggiare, to lean on. And as these little notes generally occur on the accented parts of a bar, more force is given to them by good performers, than to the principal note which they precede. In pathetic strains, the soul of the melody may be said to reside in the appoggiaturas.

APPOINTEE, a name formerly given to a foot soldier in the French army, &c. who for his long service and bravery receives pay above private sentinels.

Till the year 1670, they had also captains and lieutenants under the appellation of appointees, who, without residing in the regiment, received their pay. See *ANSPESSADES*.

APPOINTEE, in *Heraldry*, is when two or more things are placed touching each other at the points or ends.

APPOINTMENT, a pension or salary given by great lords and princes to persons of worth and parts, in order to retain them in their service. This term was chiefly used among the French in the time of their monarchy.

Appointments differ from wages, in that the latter are fixed and ordinary, being paid by the ordinary treasurers; whereas appointments are annual gratifications granted by *brevet* for a time uncertain, and are paid out of the privy purse.

APPOINTMENT, in *Law*, is used in contradistinction to a bequest. Thus, by construction of the statute 43 Eliz. c. 4. it is held, that a devise to a corporation for a charitable use is valid, as operating in the nature of an *appointment* rather than of a *bequest*. It is also held, that the statute of Elizabeth, which favours appointments to charities, supercedes and repeals all former statutes, and supplies all defects of assurances; and therefore, not only a devise to a corporation, but a devise by a copyhold tenant without surrendering to the use of his will, and a devise (nay even a settlement) by tenant in tail without either fine or recovery, if made

made to a charitable use, are good by way of appointment. Blackst. Com. b. ii. vol. ii. p. 376.

APPOMATOX, in *Geography*, is the name of a southern branch of James river in Virginia.

APPORTIONMENT, APPORTIONAMENTUM, in *Law*, a dividing of a rent into two or more parts, or portions, according as the land whence it issues is divided among two, or more proprietors.

Thus if a man, having a rent-service issuing out of land, purchase a part of the land; the rent shall be apportioned, according to the value of the land.—So if a man let lands for years, reserving rent, and a stranger afterward recover part of the land; the rent shall be apportioned.

But a rent-charge cannot be apportioned, nor things that are entire; as if one hold land by service, to pay to his lord yearly at such a feast a horse, &c.; there, if the lord purchase a part of the land, this service is totally extinct; because such things cannot be divided without hurt to the whole. But if part of the land, out of which a rent-charge issues, descends to the grantee of the rent, this shall be apportioned.

On partition of lands out of which a rent is issuing, the rent shall be apportioned. The statute 11 Geo. ii. c. 19. § 15. has in certain cases altered the law as to apportioning of rents in point of time; it being thereby enacted, "that if any tenant for life shall happen to die before, or on the day on which any rent was reserved or made payable, upon any demise or lease of any lands, tenements, or hereditaments, which determined on the death of any such tenant for life, the executors or administrators of such tenant for life, shall and may, in an action on the case, recover of and from such under-tenant or under-tenants of such lands, &c. if such tenant for life die on the day on which the same was made payable, the whole; or if before such day, then a proportion of such rent, according to the time such tenant for life lived, of the last year, or quarter of a year, or other time in which the said rent was going due as aforesaid, making all just allowances, or a proportionable part thereof respectively." Before this statute, the rent, by the death of a tenant for life, was lost; but the legislature having thus interposed in favour of tenants for life, the provisions of the statute have, by an equitable construction, been extended to tenants in tail. However, the dividends of money directed to be laid out in lands, and in the mean time to be invested in government securities, and the interest and dividends to be applied as the rents and profits would in case it were laid out in land, were held not to be apportionable, though tenant for life died in the middle of the half year. But where the money is laid out in mortgage, till a purchase could be made, the interest is apportionable. This distinction, however, may be referred to interest on a mortgage, being in fact due from day to day, and so not properly an apportionment; whereas the dividends accruing from the public funds are made payable on certain days, and therefore not apportionable. Upon this principle the Master of the Rolls decreed an apportionment of maintenance-money, it being for the daily subsistence of the infant; and the principle extending to a separate maintenance for a feme covert, such apportionment has, in such cases, been allowed at law.

A man purchases part of the land where he hath common appurtenant, the common shall be apportioned: of common appurtenant it is otherwise; and if by the act of the party, the common is extinct. Common appurtenant and appurtenant may be apportioned on alienation of part of the land to which it is appurtenant or appurtenant. Danv. Abr. 505. 507. Co. Litt. 144. 148, 149. Amb. Rep. 502. 2 P. Wms. 176. 501. 8 Rep. 79. Wood's Inst. 199.

APPOSAL of *sheriffs*, is the charging of them with money received on their account in the exchequer, 22 and 23 Car. II. c. 22.

APPOSER signifies an examiner. In the court of exchequer, there is an officer called the foreign *apposer*.

In the office of confirmation, in the first liturgy of Edw. VI. the rubric directs the bishop, or such as he shall appoint, to appose a child; and a bishop's examining chaplain was anciently called his *poser*.

APPOSITION, from *ad, to*, and *pono, I put*, the act of putting or applying one thing to another.

APPOSITION is used in *Physics*, in speaking of bodies which derive their growth from the adjunction or union of neighbouring bodies.

APPOSITION, in *Grammar*, denotes the putting two or more substantives together in the same case, and without any copulative conjunction between them.

Thus, Flanders, bloody theatre, horrible scene of war; love, enemy of human quiet; peace, parent of riches, source of faction, &c.

APPRAISER, from *ad, to*, and *pretium, value*, one who rates, or sets a value upon goods, &c. He must be a skilful and honest person. It is not a business of itself, but is practised by brokers of household furniture, to which set of men the word is chiefly applied. Yet upholsterers and other brokers are employed, or even any person or persons who are supposed to be skilled in the commodities to be appraised or valued. They are employed in cases of death, executions brought in upon goods, or of stock to be turned over from one person to another, or divided between copartners; and are called *sworn appraisers*, from their taking an oath to do justice between party and party. If they value the goods too high, they shall be obliged to take them at the price appraised, statute 11 Edw. I.

They sometimes appraise on behalf of both sides, each party agreeing to have the same appraiser or appraisers; sometimes in opposition, each part choosing one or more of a side; and sometimes by commission or deputation of trustees, masters in chancery, &c.

APPRECIATION, in *Music*, is the judging accurately of things within the power of our senses and perception. Our organ of hearing is unable to judge of sounds beyond a certain degree of gravity and acuteness. The octave below double C, the lowest note of the additional keys in the base of piano-fortes, is extremely difficult to tune; and the additional high notes seem more the production of wood than wire. However, the great mathematician, Euler, gives the extent of eight octaves to human perception; from the highest appreciable sound to the lowest: but, says Rousseau, these extremes of the scale not being very agreeable, we seldom, in practice, exceed five octaves, which the common compass of keyed-instruments furnishes. There is likewise a degree of force or loudness, which we cannot appreciate. The sound of a great bell, for instance, gives no distinct and certain tone, but a confusion of harmonies, which we cannot distinguish in the belfrey, from the fundamental. We must diminish the force by distance, ere we are sure what the real sound is. It is the same with a wind instrument overblown, and a voice that is forced beyond its natural power; so that those who try to sing loud, with a feeble voice, are always out of tune. With respect to noise, we can never reduce it to any fixed tone; and it is that which constitutes the difference between sound and noise. See BRUIT.

The abbé Feyter, taking up the subject, says, "Euler probably determined the compass of appreciable sounds, from

from the following circumstance: The largest pipe in a 72 feet organ, is an octave below the *bourdon*, or double-bale stop, and two octaves below double C in the open diapason of an organ. Now from the lowest C to the highest, on a piano-forte or harp, there is an interval of four octaves; and if we add two octaves to the bottom, and two to the top, for the low and high stops of an organ, we shall have the eight octaves in question. In order to complete the demonstration, we must have found by experiment, that a pipe less than two inches will not speak: for the most acute C in the 15th has only that length; but though birds, and the seracatto or bird-pipe, do produce more acute sounds, as we are unable to find their unison, we know not what they are.

APPREHENSION, in *Logic*, denotes the simple attention of the mind to an object presented either to our sense, or our imagination, without passing a judgment, or making any inference.

The word literally denotes the action of the hand, whereby it takes hold of, and grasps any thing: being formed of *ad*, and *prehendo*, I catch.

It is by that operation of the understanding, which is called simple apprehension, that we acquire those notions or ideas, which are the materials of all our knowledge. According to Dr. Reid, it is synonymous with conception; and like other simple operations of the mind, it cannot be logically defined. For his account of this operation of the mind, see CONCEPTION.

APPREHENSION is likewise used to express an inadequate and imperfect idea: and thus it is applied to our knowledge of God, in contradistinction to comprehension.

APPREHENSION, in *Law*, signifies the seizing a criminal, in order to bring him to justice. See ARREST.

APPRENDRE, in our *Ancient Law-Books*, a fee or profit to be taken or received. Statute 2 & 3 Edw. VI. c. 8.

APPRENTICE, from *apprendre*, to learn, one who is bound by covenant to serve a tradesman or artificer a certain time, usually seven years, upon condition of the master's instructing him in his art or mystery.

Apprentices may likewise be bound to husbandmen, or even to gentlemen of fortune and clergymen; who, as well as tradesmen, are compellable to take the children of the poor under a penalty of 10*l*. (stat. 8 & 9 Will. III. c. 30. § 5.); and the church-wardens and overseers, with the consent of two justices, may bind them till the age of twenty-one years. stat. 43 Eliz. c. 2. 18 Geo. III. c. 47. And by statute 5 Eliz. c. 4. §. 35. the justices may compel certain persons under age to be bound as apprentices, and on refusal may commit them.

Apprentices may be discharged on reasonable cause, either at their own request or that of their masters, at the quarter sessions, or by one justice, with appeal to the sessions (5 Eliz. c. 4.), who may, by the equity of the statute, if they think it reasonable, direct restitution of a rateable share of the money given with the apprentice; and parish-apprentices may be discharged in the same manner, by two justices, 20 Geo. II. c. 19. But if any, whose premium has been less than ten pounds, run away from their masters, they are compellable to serve out the time of absence, or give satisfaction for it, at any period within seven years after expiration of the original contract, 6 Geo. III. c. 26. Apprentices gain a settlement in that parish where they last served forty days, 15 & 14 Car. II. c. 12. And by the 5th of Elizabeth, c. 4 they have an exclusive right to exercise the trade in which they have been instructed, in any part of England. However, the resolutions of the courts

have in general rather confined than extended the restrictions of this statute.

No trades are held to be within the statute, but such as were in being at the making of it. For trading in a country village, apprenticeships are not requisite; and following the trade seven years, without any effectual prosecution (either as a master or a servant), is sufficient without an actual apprenticeship. See Blackstone's Com. vol. i. p. 426, &c.

By the common law, infants, or persons under the age of 21 years, cannot bind themselves apprentices, in such a manner as to enclose their masters to an action of covenant, or other action against *them* for departing from their service, or other breaches of their indentures; which makes it necessary, according to the usual practice, to get some of their friends to be bound for the faithful discharge of their offices, according to the terms agreed on. If an apprentice misbehaves himself, the master may correct him in his service, or complain to a justice of peace, to have him punished according to the statute 5 Eliz. c. 4. If any one entices an apprentice from his master's service, or harbours him after notice, the master may maintain a special action on the case against the person so doing. By the custom of London, an infant unmarried, and above the age of fourteen, may bind himself apprentice to a freeman of London, by indenture with proper covenants, which covenants, by the said custom, shall be as binding as if he were of full age. By the stat. 5 Eliz. c. 4. § 25. an apprentice must be bound by deed indented; and this must be complied with for all purposes except for obtaining a settlement. Indentures must also be enrolled in all towns corporate. 5 Eliz. c. 5. and 5 Geo. II. c. 46.; and in London, by the custom, in the Chamberlain's office there. In London, if the indentures be not enrolled before the Chamberlain within a year, upon a petition to the Mayor and Aldermen, &c. a *seire facias* shall issue to the master, to shew cause why not enrolled; and if it was through the master's default, the apprentice may sue out his indentures and be discharged: otherwise, if through the fault of the apprentice, as if he would not come to present himself before the Chamberlain, &c. for it cannot be enrolled unless the apprentice be in court and acknowledge it. Indentures are likewise to be stamped, and are chargeable with several duties by act of parliament.

With regard to the assigning of apprentices, it hath been held that an apprentice is not assignable. He cannot be bound nor discharged without deed. But though an apprentice is not assignable, yet such assignment amounts to a contract between the two masters, that the child should serve the latter. By the custom of the city of London, an apprentice may be turned over from one master to another; and if the master refuse to make him free at the end of the term, the Chamberlain may make him free; but, in other corporations, there must be a mandamus to the mayor, &c. to make him free in such case. It seems agreed, that if a man be bound to instruct an apprentice in a trade for seven years, and the master dies, the condition is dispensed with, being a thing personal; but if he be further bound to find him meat, drink, cloathing, and other necessaries; here the death of the master doth not dispense with the condition, but his executors shall be bound to perform it as far as they have assets. But if a person is bound apprentice by a justice of the peace, and the master dies before the expiration of the term, the justices have no power to oblige his executor, by their order, to receive such apprentice and maintain him. It is said, however, that the executor or administrator may bind him to another master for the remaining part of his time. In this case of the master's dying, it is said that by

the custom of London, the executor must put the apprentice to another master of the same trade. By the custom of the city of London, a freeman may turn away his apprentice for gaming: though, if a master turn away an apprentice on account of negligence, &c. equity may decree him to refund part of the money given with him. *Jacob's Law Dict.* by Tomlins, Art. *Apprentice*.

In France, the sons of tradesmen, living in their fathers' house till seventeen years of age, were reputed to have served an apprenticeship. In that country the times of serving are different in the different professions, from three years to eight. After serving out an apprenticeship, the person becomes what they call an *aspirant*, or candidate for mastership, and is to be examined by proper officers as to his skill and proficiency, and also to exhibit a *chef d'œuvre* or masterpiece in the art he has been bred to, before he be suffered to set up to practise for himself. And the custom of France, in regard to apprentices, is not unworthy the imitation of other nations.

Anciently, benchers in the inns of court were called *apprentices of the law*, in Latin *apprenticii juris nobiliores*; as appears by Mr. Selden's note on Fortescue; and so the learned Plowden styles himself. See *BENCHER*.

Sir Henry Finch, in his *Nomotechnia*, writes himself, *apprentice de ley*: Sir Edward Coke, in his *Instit. says apprenticii legis*, in pleading, are called *homines consilarii*, & *in lege periti*; and in another place, apprentices, and other counsellors of law.

APPRENTICESHIP denotes the servitude of an apprentice, or the duration of his indenture. The ingenious Dr. Smith, in his well-known and admirable work on "The Nature and Causes of the Wealth of Nations," has introduced several important and useful observations on this subject. The competition in several employments is restrained to a smaller number, than would otherwise be disposed to enter into them, partly by the limitation of the number of apprentices, which attends the exclusive privilege of incorporated trades, and partly by the long term of apprenticeship, which increases the expence of education. Seven years seem formerly to have been, all over Europe, the usual term established for the duration of apprenticeships in the greater number of incorporated trades. Such incorporations were anciently called universities, which is the proper Latin name for any incorporation whatever. The university of smiths, the university of tailors, &c. are expressions commonly occurring in the old charters of ancient towns. When those particular incorporations, which are now peculiarly called universities, were first established, the term of years during which it was necessary to study, in order to obtain the degree of Master of Arts, appears evidently to have been copied from the term of apprenticeship in common trades, of which the incorporations were much more ancient. As to have wrought seven years under a master properly qualified, was necessary to entitle any person to become a master, and to have himself apprentices, in a common trade; so to have studied seven years under a master properly qualified, was necessary to entitle him to become a master, teacher, or doctor (words anciently synonymous) in the liberal arts, and to have scholars or apprentices (words likewise originally synonymous) to study under him. By the 5th of Elizabeth, commonly called the *statute of apprenticeship*, it was enacted, that no person should for the future exercise any trade, craft, or mystery, at that time exercised in England, unless he had previously served to it an apprenticeship of seven years at least; and thus, what before had been the bye-law of many particular corporations, became in England the general and public law of all trades carried

on in market towns. To country villages the term of seven years' apprenticeship doth not extend; but the limitation of this statute to trades exercised before it was passed has given occasion to several distinctions, which, considered as rules of police, appear as foolish as can well be imagined. A coach-maker, for instance, has no right to make, or employ journeymen for making, coach wheels; but he must buy them of a master wheel-wright, this latter trade having been exercised in England before the 5th of Elizabeth. But a wheel-wright, though he has never served an apprenticeship to a coach-maker, may, by himself or journeymen, make coaches, because this trade, being of a later origin, is not within the statute. Thus also the manufactures of Manchester, Birmingham, and Wolverhampton are, many of them, upon this account, not within the statute, not having been exercised in England before the 5th Elizabeth. The regulations of apprenticeship in Ireland are upon a different footing, and somewhat less illiberal than in England. Prohibitions similar to those of the statute 5 Eliz. obtain in all corporate towns, by authority of bye-laws of the several corporations: but these prohibitions extend only to natives of Ireland; for by a regulation made by the lord lieutenant and privy council, having in this instance, by 17 & 18 Car. II. the force of a law, all foreigners and aliens, as well persons of other religious persuasions as protestants, who are merchants, traders, artificers, &c. shall, upon coming to reside in any city, walled town, or corporation, and paying twenty shillings by way of fine to the chief magistrate and common council, or other persons authorized to admit freemen, be admitted to the freedom of that city, &c. and to the freedom of guilds of their respective trades, with the full enjoyment of all privileges of buying, selling, working, &c.; and any magistrate, refusing to admit foreigners so applying, shall be disfranchised. In Scotland, there is no general law which regulates universally the duration of apprenticeships. The term is different in different corporations: where it is long, a part of it may generally be redeemed by paying a small fine. In most towns too, a very small fine is sufficient to purchase the freedom of any corporation. The weavers of linen and hempen cloth, the principal manufactures of the country, as well as all other artificers subservient to them, wheel-makers, reel-makers, &c. may exercise their trades in any town corporate without paying any fine. In all towns corporate all persons are free to sell butchers' meat upon any lawful day of the week. Three years are, in Scotland, a common term of apprenticeship, in some very nice trades; and, in general, there is no country in Europe in which corporation laws are so little oppressive. In France, the duration of apprenticeships is different in different towns and in different trades. In Paris, five years are the term required in a great number; and before any person can be qualified to exercise the trade, as a master, he must, in many of them, serve five years more as a journeyman. During this latter time, he is called the companion of his master, and the term itself is called his companionship. The institution of long apprenticeships, says Dr. Smith, can give no security that insufficient workmanship shall not frequently be exposed to sale: nor has it any tendency to form young people to industry. Apprenticeships were altogether unknown to the ancients: the Roman law is perfectly silent with regard to them. There is no Greek or Latin word which expresses the idea we now annex to the word Apprentice. Long apprenticeships are altogether unnecessary. The arts, which are much superior to common trades, such as those of making clocks and watches, contain no such mystery as to require a long course of instruction. In the common mechanic trades,

the lessons of a few days might certainly be sufficient. The dexterity of hand, indeed, even in common trades, cannot be acquired without much practice and experience. But a young man would practise with much more diligence and attention, if, from the beginning, he wrought as a journeyman, being paid in proportion to the little work which he could execute, and paying, in his turn, for the materials which he might sometimes spoil through awkwardness and inexperience. His education would generally in this way be more effectual, and always less tedious and expensive. The master, indeed, would be a loser; he would lose all the wages of the apprentice, which he now saves for seven years together. In the end, perhaps, the apprentice himself would be a loser: in a trade so easily learnt he would have more competitors; and his wages, when he came to be a complete workman, would be much less than at present. The same increase of competition would reduce the profits of the masters, as well as the wages of the workmen: the trades, the crafts, the mysteries would all be losers; but the public would be a gainer, the work of all artificers coming in this way much cheaper to market. Smith's *Nature and Causes of the Wealth of Nations*, vol. 1. p. 183—191. Irish Transf. vol. iv. pt. ii. part 59, &c.

APPRISING, in *Scots Law*, the name of the action by which a creditor formerly carried off the estate of his debtor for payment. It was thus called, because the sheriff, when no purchaser of the heritable rights could be found, *apprised*, or taxed the value of the lands by an inquest, so as to make over to the creditor lands to the value of the debt. By the act 1672, apprisings were superseded, and adjudications were substituted in their place. See ADJUDICATION.

APPROACH, *curve of equable, accessus equabilis*, was first proposed by M. Leibnitz, and has given the analysts some trouble. The curve is of such a nature, that a body descending in it by the sole power of gravity approaches the horizon equally in equal times.—This curve has been found by Bernouilli, Varignon, Maupertuis, and others, to be the second cubical parabola so placed as that its point of regression or vertex is uppermost, and the descending body must commence its motion in it with a certain determinate velocity. M. Varignon rendered the question general, by investigating the curve which a body might describe in vacuo, so as to approach towards a given point through equal spaces in equal times, according to any law of gravity. Maupertuis also resolved the same problem, in the case of a body descending in a medium, the resistance of which is proportioned to the square of the velocity. Vide Hist. Acad. R. Sciences, an. 1699. p. 82. Idem, an. 1730. p. 129. Mem. p. 333.

APPROACH, in *Gardening*, is used in speaking of the method of inarching or INOCULATING, which is called GRAFTING by *approach*.

Some physicians also speak of a method of curing diseases by touching or *approach*. See APPROXIMATION.

APPROACHES, in *Fortification*, the several works made by the besiegers for advancing or getting nearer to a fortress, or place besieged. Such are trenches, mines, saps, lodgements, batteries, galleries, epaulements, &c.

APPROACHES, or *Lines of Approach*, are particularly used for trenches dug in the ground, and their earth thrown up on the side next the place besieged; under shelter or defence whereof the besiegers may approach, without loss, to the parapet of the covered way, and plant guns, &c. wherewith to cannonade the place.

The lines of approach are to be connected by PARALLELS, or lines of communication.

The besieged frequently make *COUNTER-approaches*, to interrupt and defeat the enemies' approaches.

The ancients made their approaches towards the place besieged much after the same manner as the moderns. M. de Folard shews, that they had their trenches, their saps, parallels, &c. which, though usually held of modern invention, appear to have been practised long before by the Greeks, Romans, Asiatics, &c. Vide Polyb. t. ii. p. 161.

APPROACHES, *Method of*, in *Mathematics*, a name given by Dr. Wallis, in his *Algebra*, to a method of resolving certain problems relating to square numbers, &c., by first assigning certain limits to the quantities required, and then approaching nearer and nearer till a coincidence is obtained. In this sense, the double rule of false position may be considered as a method of approaches. See APPROXIMATION.

APPROACH, in *Fowling*, expresses the devices made use of to get within shot of shy birds. There are many contrivances practised for this purpose: a very common one is by means of circular pieces of wood or hoops surrounded with boughs, not unlike a chimney-sweeper's or milkmaid's garland, within which the fowler conceals himself with his gun, and steals on the birds, who are completely deceived, imagining the machine a tree, and its approach effected by their own motion towards it: it is therefore necessary that the fowler's approach should be very slow, and his motions very uniform; for any ruffle or shake would alarm the birds, and put them to flight. This mode is successfully practised on water-fowl when they are feeding on marshy grounds or basking on the sides of the water. But when these birds confine themselves principally to the middle of wide rivers, or in moors and lakes, this leafy covering must be placed in a boat; or a tall screen made of straw is sometimes set upright in it, behind which the sportsman remains concealed, and either gently paddles himself near the birds, or permits the boat to drift towards them.

In moonlight nights when water-fowls come on shore to feed, they are approached by the fowler, concealing himself behind a horse, who is made to move gently towards the birds, and this practice has given rise to an artificial figure called a stalking-horse, behind which the sportsman endeavours to gain on the fowls; but this is a less certain method, as they are fearful even of horses, cows, and sheep, as well as of man.

In deep snows, birds are approached by concealing every part of the person in a white dress; and even the gun must be clothed likewise. By this means hares, partridges, and moor-game are killed in abundance: but this device is not held fair in sporting language, because these are less wary animals, and, moreover, because there are regular methods in constant practice to entrap them. When bustards were plentiful on Salisbury plain, it was usual to hunt and approach them in a kind of covered cart with loopholes through which the fowler could see and take aim at them; but cultivation and increased population have nearly destroyed these birds in England.

APPROBATION, a state or disposition of the mind wherein we put a value upon, or become pleased with, some person or thing. Moralists are divided on the principle of approbation, or the motive which determines us to approve and disapprove. The Epicureans will have it to be only *self-interest*; according to them, that which determines any agent to approve his own action, is its apparent tendency to his private happiness; and even the approbation of another's action flows from no other cause but an opinion of its tendency to the happiness of the approver, either immediately or remotely. Those, who incline to this system,

reason thus: having experienced, in some instances, a particular conduct to be beneficial to ourselves, or observed that it would be so, a sentiment of approbation rises up in our minds, which sentiment afterwards accompanies the idea, or the mention of the same conduct, although the private advantage which first excited it no longer exist. Others resolve approbation into a moral sense, or a principle of benevolence, by which we are determined to approve every kind affection, either in ourselves or others, and all publicly useful actions, which we imagine to flow from such affection, without any view to our own private happiness.

Dr. Adam Smith thinks it needless to introduce any new power of perception, in order to account for the principle of approbation; and apprehends that sympathy is sufficient to account for all the effects ascribed to this peculiar faculty. This system places virtue in utility; and accounts for the pleasure with which the spectator surveys the utility of any quality from sympathy with the happiness of those who are affected by it. This sympathy, he observes, is different both from that by which we enter into the motives of the agent, and from that by which we go along with the gratitude of the persons who are benefited by his actions; and he says, it is the same principle with that by which we approve of a well-contrived machine.

Dr. Smith does not reject entirely from his system that principle of utility, the perception of which in any action or character constitutes, according to Mr. Hume, the sentiment of moral approbation. That no qualities of the mind are approved of as virtuous, but such as are useful or agreeable, either to the person himself or to others, he admits to be a proposition that holds universally; and he also admits, that the sentiment of approbation with which we regard virtue, is enlivened by the perception of this utility, or, as he explains the fact, by our sympathy with the happiness of those to whom the utility extends. Nevertheless he insists, that it is not the view of this utility which is either the first or principal source of moral approbation. To sum up the whole of his doctrine in a few words: when we approve of any character or action, the sentiments which we feel are derived from four different sources. First, we sympathize with the motives of the agent; secondly, we enter into the gratitude of those who receive the benefit of his actions; thirdly, we observe that his conduct has been agreeable to the general rules by which these two sympathies generally act; and, lastly, when we consider such actions as making a part of a system of behaviour which tends to promote the happiness either of the individual or of society, they appear to derive a beauty from this utility, not unlike that which we ascribe to a well-contrived machine. These different sentiments, he thinks, exhaust completely, in every instance that can be supposed, the compounded sentiment of moral approbation. "After deducting," says he, "in any one particular case, all that must be acknowledged to proceed from some one or other of these four principles, I should be glad to know what remains; and I shall freely allow this overplus to be ascribed to a moral sense, or to any other peculiar faculty, provided any body will ascertain precisely what this overplus is."

When we approve of good actions, and disapprove of bad, this approbation and disapprobation, when we analyse it, says Dr. Reid, "Essays on the active Powers of Man," (ch. vii. p. 244.) appears to include not only a moral judgment of the action, but some affection, favourable or unfavourable, towards the agent, and some feeling in ourselves. Dr. Ferguson, in "Principles of Moral and Political Science," agrees in the main with Lord Shaftesbury, Dr. Hutcheson, Dr. Reid, and Buffier, in regarding moral ap-

probation as a specific sentiment, incapable of resolution into any other sentiment or principle.

According to Dr. Clarke and others, reason or the understanding, the same faculty by which we distinguish between truth and falsehood, enables us to distinguish between what is fit and unfit, amiable and odious, both in actions and affections; and they argue, that such are the natures of certain actions, that when perceived as they are by a reasonable being, there must result in him certain emotions and affections. An excellent writer adds, that in contemplating the actions and affections of moral agents, we have both a perception of the understanding and a feeling of the heart; and the latter, or the effects in us accompanying our moral perceptions, are deducible from two springs. They partly depend on the positive constitution of our natures; but the most steady and universal ground of them is the essential congruity between the object and the faculty. Hutcheson's Inquiry, &c. tract iv. sect. vi. and Ess. on Pass. p. 207. Smith's Theory of Mor. Sent. Parts iv. and vi. Cudworth's Immut. Mor. b. i. Price's Review, &c. ch. ii. Paley's Philosophy, vol. i. p. 14.

APPROBATION, in *Civil Law*. It is a maxim among civilians, *approbare dicitur qui non improbat. He is judged to approve who does not disapprove.*

By the civil law, a mere approbation of a crime after commission does not make a person guilty; but an approbation attended with fact is equivalent to a command.

APPROBATION is more particularly used in speaking of recommendations of books given by persons qualified or authorized to judge of them.

Those appointed to grant licences and imprimaturs, frequently express their approbation of books.

Books were formerly subjected to a licenfer in England, see 13th Car. II. c. 33. which act is long since expired; and being incompatible with the noble principles of the revolution, has never since, and we hope never will be revived.

APPROPRIARE *ad honorem*, in *Law*, signifies to bring a manor within the extent and liberty of such an honour.

APPROPRIARE *communam*, signifies to discommon, i. e. to separate and inclose any parcel of land, which before was open common.

APPROPRIATE, APPROPRIATED, in *Philosophy*, is understood of something which is indeed common to several; yet, in some respects, is peculiarly attributed to one.

APPROPRIATION, in *Law*, denotes the annexing of an ecclesiastical benefice to the proper and perpetual use of some religious house, bishopric, college, or spiritual person, to enjoy for ever; in the same way as *impropriation* is the annexing of a benefice to the use of a lay person or corporation; that which is an appropriation in the hands of religious persons being usually called an *impropriation* in the hands of the laity. It is computed, that there are in England 3845 impropriations.

This contrivance seems to have sprung from the interested policy of the monastic orders, who begged and bought, for masses and obits, and sometimes even for money, all the advowsons within their reach, and then appropriated the benefices to their own corporation. But, in order to complete such appropriation effectually, the king's licence and the bishop's consent must first be obtained; because both the king and the bishop might some time or other have an interest, by lapse, in the presentation to the benefice, which can never happen if it be appropriated to the use of a corporation, which never dies. The consent of the patron is also necessarily implied, because the appropriation can be originally made to none but to such spiritual corporation as

is also the patron of the church; the whole being, indeed, nothing else but an allowance for the patrons to retain the tithes and glebe in their own hands, without presenting any clerk, they themselves undertaking to provide for the service of the church. When the appropriation is thus made, the appropriators and their successors are perpetual parsons of the church, and must sue and be sued, in all matters concerning the rights of the church, by the name of parsons. This appropriation may be severed, and the church become disappropriate, two ways: as first, if the patron or appropriator present a clerk who is instituted and inducted to the parsonage; for the incumbent so instituted and inducted is, to all intents and purposes, complete parson; and the appropriation, being once severed, can never be re-united again, unless by a repetition of the same solemnities. And when the clerk so presented is dillined from the vicar, the rectory then vested in him becomes what is called a *sine-cure*; because he hath no cure of souls, having under him a vicar to whom that cure is committed. Also, if the corporation which has the appropriation is dissolved, the parsonage becomes disappropriate at common law; because the perpetuity of person is gone, which is necessary to support the appropriation.

In this manner may appropriations be made at this day; and thus were most, if not all, of the appropriations at present existing originally made; being annexed to bishoprics, prebends, religious houses, nay even to nunneries, and certain military orders, all of which were spiritual corporations. At the dissolution of the monasteries by statutes 27 Henry VIII. c. 28. and 31 Henry VIII. c. 13. the appropriations of the several parsonages, which belonged to those religious houses, amounting to more than one-third of all the parishes in England, would have been, by the rules of the common law, disappropriated; if a clause in those statutes had not intervened, by which they were given to the king in as ample a manner as they were before held by the abbots, &c. The alien priories had, in former reigns, been dissolved and given to the crown. From these two sources have sprung all the lay appropriations or secular parsonages in the kingdom; they having been afterwards granted out from time to time by the crown. Blackstone's Com. vol. i. p. 384, &c.

APPROUAGE, or APPROUAK, in *Geography*, a river of South America, in the country of Guiana, which discharges itself into the sea; N. lat. $4^{\circ} 20'$. W. long. $52^{\circ} 46'$.

APPROUAGE, or Approouak, a town of South America, in Guiana, situate at the mouth of the river of the same name.

APPROVEMENT, APPROVEAMENTUM, or APPROVIAMENTUM, is sometimes used in *Ancient Law Writers*, for an improvement, or rise of the value and worth of a thing.

Thus to *approve, approbare*, is to make the best benefit of a thing, by increasing the rent, &c. *Cum omnibus approviamentis, et aliis pertinentiis suis, &c.*

Hence, in some ancient statutes, bailiffs of lords in their franchises are called their approvers. A bailiff is not to think it below him to *approve, approbare*, his master's goods; but of his barley to make malt, of his wool to make cloth, &c.

APPROVEMENT is more particularly used where a man hath common in the lord's waste, and the lord incloseth part of the waste for himself, leaving sufficient common, with egress and regress, for the commoner. Reg. Jud. 8, 9. This inclosure, when justifiable, is called in law *approvalment*, an ancient expression signifying the same as *improvement*. Accordingly, it is provided by the statute of

Merton, 20 Hen. III. c. 4. that the lord may approve, or inclose, and convert to the uses of husbandry, which is a melioration or improvement, any waste grounds, woods, or pastures, in which his tenants have common appendant to their estates, provided he leaves sufficient common to his tenants, according to the proportion of their land.

APPROVER, in our *Laws*, one who, being indicted for treason or felony, and arraigned for the same, doth confess the fact before plea pleaded, and appeals or accuses others his accomplices of the same crime, in order to obtain his pardon; and this confession is called *approvement*.

He is called an approver, or prover, *probator*, because he must prove what he hath alleged in his appeal. This proof was anciently either by battle, or by the country, at the choice of the appellee; and the form of this accusation may be found in Ciomp. Just. 250. See also Bracton, lib. iii. Staundf. Pl. Cor. 52.

If the appellee were vanquished, or found guilty, he must suffer the judgment of the law, and the approver have his pardon *ex debito justitiæ*. On the other hand, if the appellee were conqueror, or acquitted by the jury, the approver must receive judgment to be hanged, upon his own confession of the indictment; for the condition of his pardon has failed, viz. the conviction of some other person, and therefore his conviction remains absolute. It is purely in the discretion of the court to permit the approver thus to appeal, or not; and, in fact, this course of admitting approvements hath been long disused. But we have, in cases of burglary and robbery on the highway, what seems to amount to the same by statute; it being ordained, that where persons charged with such crimes out of prison, discover two others concerned in the crime, they shall have a pardon, &c. stat. 5 Anne, c. 31. Blackst. Com. vol. iv. p. 329.

APPROVERS of the king, are those who have the letting of the king's demesnes in small manors, &c. stat. 51 Hen. III. ff. 5.

In the statute of the 1st of Ed. III. c. 8. sheriffs are called the king's approvers.

APPROVER is particularly used, in *Ancient Law Writers*, for a bailiff or land-steward, appointed to have the care of a manor, franchise, or the like, and improve and make the most of it for the benefit of his master.

In this sense, the word is also written *approvare*.

APPROXIMATION, from *ad*, and *proximus*, near to, in *Arithmetic* and *Algebra*, a continual approach still nearer and nearer to a root or quantity sought, without a possibility of ever arriving at it exactly.

Methods of continual approximation for the square roots and cube roots of numbers have been employed by Algebraists and Arithmeticians, from Lucas de Burgo, and perhaps a much earlier period, to the present time. For the roots of higher powers, and of all simple equations, and also for the roots of all compound equations whatever, we have various approximations by Wallis, Raphson, Halley, and later writers, especially Newton, De Lagny, &c. all of them forming serieses infinitely converging, or approaching still nearer to the quantity required, according to the nature of the series.

It is evident, that if a number proposed be not a true square, it is in vain to hope for a just quadratic root thereof, explicable by rational numbers, whether integers or fractions; whence, in such cases, we must content ourselves with approximations, somewhat near the truth, without pretending to accuracy: and so for the cubic root, of what is not a perfect cube, and the like for superior powers.

This the ancients were aware of, and accordingly they had their methods of approximation; which, though scarcely applied by them beyond the quadratic, or perhaps the cubic

APPROXIMATION.

and thus he proceeded from one correction to another, employing always the first proposed equation to find them, instead of the successive near equations used by Newton.

E. G. Let it be required to find the root of the equation $x^3 - 5x = 31$ or $x^3 - 5x - 31 = 0$: here the root x is evidently equal to 8 nearly: and therefore for x take $8 + z$, and substitute $8 + z$ for x in the given equation, and the terms will be as follow:

$$\begin{aligned} x^3 &= 64 + 16z + z^3 \\ -5x &= -40 - 5z \\ -31 &= -31 \end{aligned}$$

the sum is $-7 + 11z + z^3 = 0$. Then, rejecting z^3 , we have $-7 + 11z = 0$, and $z = \frac{7}{11} = .6363$, &c. or $.6$ nearly. Next assume $z = .6 + y$, then

$$\begin{aligned} z^3 &= .36 + 1.2y + y^3 \\ 11z &= 6.6 + 11y \\ -7 &= -7 \end{aligned}$$

the sum $-.04 + 12.2y + y^3 = 0$, and rejecting y^3 , $12.2y = .04$, and $y = \frac{.04}{12.2} = .003278$ nearly. Assume $y = .003278 - v$, then

$$\begin{aligned} y^3 &= .000010745284 - .006556v + v^3 \\ 12.2y &= .0399910 - 12.2v \\ -.04 &= -.04 \end{aligned}$$

the sum $.000002345284 - 12.206556v + v^3 = 0$, and $v = \frac{.000002345284}{12.206556} = .000000192133$.

Hence, collecting all the assumed differences, with their appropriate signs, we shall have $x = 8 + z + y - v = 8.6 + .003278 - .000000192133 = 8.600327807867$ the required root of the equation proposed, according to the method of Newton.

Raphson's process is as follows: assume $x = 8 + z$, then

$$\begin{aligned} x^3 &= 64 + 16z + z^3 \\ -5x &= -40 - 5z \\ -31 &= -31 \end{aligned}$$

the sum $-7 + 11z + z^3 = 0$; hence $z = \frac{7}{11} = .6$ nearly. Assume $x = 8.6 + y$; then

$$\begin{aligned} x^3 &= 73.96 + 17.2y + y^3 \\ -5x &= -43 - 5y \\ -31 &= -31 \end{aligned}$$

the sum $-.04 + 12.2y + y^3 = 0$; hence $y = \frac{.04}{12.2} = .003278$ nearly; and $x = 8.6 + y = 8.603278$ nearly.

Assume $x = 8.603278 - v$; then

$$\begin{aligned} x^3 &= 74.016392345284 - 17.206556v + v^3 \\ -5x &= -43.016390 + 5v \\ -31 &= -31 \end{aligned}$$

the sum $.000002345284 - 12.206556v + v^3 = 0$; hence $v = \frac{.000000192133}{12.206556}$; consequently $x = 8.600327807867$ as before.

For the cubic equation e. g. $y^3 - 2y - 5 = 0$, Newton proceeds thus:

y is nearly 2 ; assume therefore $y = 2 + p$; then,

$$\begin{aligned} y^3 &= 8 + 12p + 6p^2 + p^3 \\ -2y &= -4 - 2p \\ -5 &= -5 \end{aligned}$$

the sum $-1 + 10p + 6p^2 + p^3 = 0$; hence $p = \frac{1}{10} = .1$ nearly.

Assume $p = .1 + q$; then,

$$\begin{aligned} p^3 &= .001 + 0.03q + 0.3q^2 + q^3 \\ +6p^2 &= 0.06 + 1.2q + 6q^2 \\ +10p &= 1 + 10q \\ -1 &= -1 \end{aligned}$$

the sum $0.061 + 11.23q + 6.3q^2 + q^3 = 0$; hence $q = -.0054$ nearly.

Assume $q = -.0054 + r$; then,

$$\begin{aligned} q^3 &= -.000000157464 + 0.00008748r, \text{ \&c.} \\ +6.3q^2 &= +0.000183708 - 0.06804r, \text{ \&c.} \\ +11.23q &= -0.060642 + 11.23r \\ +0.061 &= +0.061 \end{aligned}$$

the sum will be $+0.000541550530 + 11.16204748r$; hence $r = -.000048517$, &c. Consequently,

$$\begin{aligned} y &= 2 + p + q + r \\ &= 2 + 0.1 - 0.0054 - 0.000048517 \\ &= 2.094551483, \text{ the root of the equation, } y^3 - 2y = 5. \end{aligned}$$

In the same manner Newton performs the approximation for the roots of literal equations, that is, equations having literal coefficients; thus, the root of this equation,

$$\begin{aligned} y^3 + axy + a^2y - x^3 - 2a^3 &= 0, \text{ is} \\ y &= a - \frac{x}{4} + \frac{x^2}{64a} + \frac{131x^3}{512a^2} + \frac{509x^4}{16384a^3}, \text{ \&c.} \end{aligned}$$

Vid. De Analysis per AEquationum infinitas, cap. iv. § 1 and 2. apud Oper. Newton, t. i. p. 270, &c. Geometria Analytica, cap. n. ibid. t. i. p. 374, &c. Ed. Horsley. Raphsoni Analysis AEquationum Universalis. Phil. Trans. Abr. v. i. p. 81, &c. Saunderson's Algebra, vol. i. p. 722, &c. See a memoir on this method of the resolution of equations by the marquis de Courtivron, in the Mem. de l'Academie for 1744. For M. de la Grange's method of approximation for all the roots of a determinate numeral equation, see Mem. of Berlin, tom. xxiii. and xxiv.

Other particular methods of approximation, applicable to various purposes, have been given by many other persons: as for instance, methods of approximating, by series, to the roots of cubic equations belonging to the irreducible case, by Nicole, in the Memoires de l'Academie above cited; by M. Clairaut, in his "Algebra"; and by Dr. Hutton, in vol. i. of his "Tracts." Besides, the methods of infinite series by Wallis, Newton, Gregory, Mercator, Maclaurin, &c. may be considered as approximations in quadratures, and other branches of the mathematics, many instances of which may be seen in Wallis's Algebra, the Philosophical Transactions, and other books on the subject. To this head may be also referred the methods of exhaustions of the ancients, by which Archimedes and others have approximated to the quadrature and rectification of the circle, &c. which was performed by continually bisecting the sides of polygons, both inscribed in a circle, and circumscribed about it; by which means the sums of the sides of the similar polygons approach continually nearer and nearer to each other, and the circumference of the circle is nearly a mean between the two sums. See EQUATION.

APPROXIMATION, in *Medicine*, denotes a magnetical kind of cure or method of transplanting a disease into some other subject, whether animate or vegetable, by bringing it in immediate contact with the patient.

APPROXIMATION, in *Surgery*, APPROPINQUATIO, ENGY-SOMA, ENGISOMA OSSIUM CRANII. Fr. *Approximation des os du crane*; Germ. *Die Uebereinander schiebung der Hirnschalknochen*. This term is applied to those wounds of the head, in which, the scull being fractured, one or more of the splinters are forced under the sound part of the bone, so as to occasion a compression of the dura mater. In the delivery of a child, this occurrence with the bones of the cranium, one lapping over the other, is a natural circumstance.

APPUI, in the *Manege*, q. d. rest or stay upon the hand, is the reciprocal effort between the horse's mouth and the bridle-hand; or the sense of the action of the bridle on the hand of the horseman.

A just appui of the hand, is the nice bearing up or stay of the bridle; so that the horse, being awed by the sensibility and tenderness of his mouth, dares not rest too much upon

upon the bit-mouth, nor check or beat upon the hand to withstand it.

A dull appui, is when a horse has a good mouth, but his tongue is so thick that the bit cannot work, or bear upon the bars; the tongue not being so sensible as the bars: though the like effect is sometimes owing to the thickness of his lips. A horse is said to have no appui, when he dreads the bit-mouth, is too apprehensive of the hand, and cannot bear the bit. He is said to have too much appui, when he rests, or throws himself too much, or too hardly, upon the bit. Horses designed for the army ought to have a full appui upon the hand. See HAND.

APPULSE, from *ad*, and *pulso*, *I ad on*, in a general sense, a thing's being brought to, or in contact with another.

Articulation is either by appulse, i. e. when one of the moveable organs touches and rests on some of those which are immoveable; or without appulse, only by inclination of the moveable organ to the immoveable.

APPULSE of cattle, *appulsus pecoris*, in the *Civil Law*, the right of driving them to water.

APPULSE, in *Astronomy*, the approach of any planet to a conjunction with the sun, or a star; so that they may be seen within the same field of the telescope: or, as some authors have defined it, the actual contact of two luminaries.

The appulses of the planets to the fixed stars have always been of great use to astronomers, in order to fix the places of the former. The ancients wanting an easy method of comparing the planets with the ecliptic, which is not visible, had scarce any other way of fixing their situations, but by observing their track among the fixed stars, and remarking their appulses to some of those visible points. *Hist. Acad. Scienc. an. 1710, p. 417.*

Dr. Halley has published a method of determining the places of the planets, by observing their near appulses to the fixed stars. *Phil. Transf. N^o 369.* See also *Phil. Transf. N^o 76. p. 361.* and *Mem. Acad. Scienc. for 1708*, where Flamsteed and de la Hire have given observations of the moon's appulses to the Pleiades.

For discovering the longitude at sea, observations of the appulses of the moon to the fixed stars afford an excellent method. See LONGITUDE.

Of all the celestial observations hitherto made, none are capable of so perfect an exactness, as the near appulses of the moon and planets to the fixed stars; for though the places of the stars have not as yet attained their ultimate precision, yet such observations are ever good, the places of the planets being thereby ascertained in proportion to the correctness of any catalogues that may be made hereafter. But the ordinary number of stars, with which the planets may be thus compared, being small, the opportunities of observing are consequently rare; whence appears the great use of a full catalogue of all the telescopic stars within the zodiac, viz. that thereby opportunities of observing appulses may be more frequent. Since the royal observatory at Greenwich was put under Dr. Halley's care, he endeavoured to put himself in a condition to supply the many and great vacancies to be met with in the present zodiac; and for the service of astronomy, published a map or planisphere of the starry zodiac; wherein are accurately laid down all the stars to which the moon's appulse has ever been observed in any part of the world. *Phil. Transf. Abr. vol. vi. p. 170.*

His successors in that department, and particularly the present astronomer royal, Dr. Maskelyne, have contributed, in a very high degree, to the facility and use of such observations. See *Nautical ALMANAC*, and LONGITUDE.

APPURTENANCES, or APPERTINANCES, in *Common Law*, signify things belonging to some other as their principal.

The word is formed of *ad*, to, and *pertinere*, to belong. Appurtenances may either be things corporeal, as houses belonging to a chief manor, and common of pasture, &c.; or incorporeal, as liberties and services of tenants. See APPENDANT, and COMMON.

APREMONT, in *Geography*, a town of France, in the department of Vendée, and chief place of a canton, in the district of Sables d'Olonne, 5 leagues N. of Sables d'Olonne, and $2\frac{1}{2}$ S. E. of Challans.

APRES, a fictitious or heraldic animal, drawn as a bull with a short tail, like that of a bear; it is borne as the sinister supporter to the arms of the company of Muscovy merchants.

APRES-LÈS-VEYNE, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton in the district of Gap. The place contains 897, and the canton 5,300 inhabitants: the territory includes 245 kilometres and 9 communes.

APREY, a town of France, in the department of the Upper Marne, and chief place of a canton in the district of Langres, 8 miles S. W. of Langres.

APRI, in *Natural History*, a species of TAENIA that infests the liver of the boar. *Goeze Eingezw.—Gmelin.*

APRI, is also the specific name of another kind of *vermes* that inhabits the intestines of the boar; it is of the TRICHOCEPHALUS genus, and is thus described. Tail furnished on each side with crooked scales. *Goeze Eingezw.* This is of the same size as *T. hominis*, which infests the human body.

APRI, a third kind of *vermes*, also belonging to the ASCARIS genus. It is found in the lungs of the boar; is viviparous, brittle, tapering to a point at each end; slender as a fine thread, and an inch in length.

APRICARIUS, in *Ornithology*, a species of CHARADRIUS, about the size of the golden plover, that inhabits the northern parts of Europe; as Sweden, Denmark, Iceland, and Greenland; and feeds on worms, and the buds of the black-berried heath in the latter. The flesh is delicious.

The specific character is, the chin and abdomen black; body brown, dotted with white and yellow; legs cinereous. Linn. To which may be added, the length of the bill is one inch, its colour black; the eyes large, irides brown, eyelids black; at the base of the upper mandible, the feathers black; forehead, between the eyes, white, a line of which is continued over each eye, down the sides of the neck, and unites on the breast in the form of a transverse bar. The vent is spotted with white; secondaries, quills, and tail, barred with black and brown; legs black.—The male is distinguished by having a black patch on the temples.

This is *pluvialis aurca freti Hudsonis* of Brisson; *pluvier doré à gorge noire* of Buffon; spotted plover of Edwards; and alwargrim plover, *Arct. Zool. & Lath. Gen. Syn.*

APRICOT, in *Botany*. See PRUNUS.

APRICOT, in *Gardening*, a general name applied to a fruit-tree of the plum kind. This tree, we are told by different writers on gardening, came originally from Armenia, whence it takes the name of *Armeniaca*. It was introduced into this country, according to Mr. Forsyth, in 1562. The same writer also remarks, that though the apricot will not take upon the cherry-stock, it will succeed upon all sorts of plums, except the Brussels. The following selection of apricots is recommended as the most suitable for a small garden. *The Masculine*, the *Roman*, the *Orange*, the *Breda*, and the *Moor Park*. The most proper time for planting trees of this sort, the above author observes, is in autumn, as soon as the leaf begins to fall; such trees being chosen for this purpose as have the strongest and cleanest stems, and if such as have been headed down, and are of two

two or three years growth, they will bear and fill the walls much sooner than those which have not been so treated. He thinks they should only have one stem; or if they have two, one of them should be cut off; for by planting those with two stems, the middle of the tree is apt to be left naked, and of course one-third of the wall remains uncovered by the branches. The writer, however, seems fully aware, that it is the practice of many to make choice of trees with the smallest stems; but these, he thinks, always produce weaker shoots than such as he has recommended. The *Breda* is supposed the best and the richest flavoured for a standard, although the *Brussels* is frequently preferred; but Mr. Forsyth would by no means recommend planting more than three trees of each sort in a garden, as standards; as it is not one year in ten, he says, that a tolerable crop is produced from them. He thinks the *Breda*, the *Brussels*, and the *Moor Park*, should always be planted on an east or west aspect. A few trees for an early supply may be planted on a south aspect, according to the size of the garden, and the demand there may be for the supply of the family; but a west aspect is far preferable for the general crop. Those who wish for a late supply, may also have some trees planted on an east aspect.

In planting the trees, it is recommended, where the borders are new, that they should be made two feet and a half or three feet deep of good, light fresh loam; and that in old borders, where the earth has been injured by the roots of the former trees, it will be necessary to take out the old mould at least three feet deep and four feet wide, filling up the hole with fresh loam, taking care to plant the trees about eight inches higher than the level of the old border, to allow for the sinking of the earth, and that they may not afterwards be too deep in the ground. But the propagation, culture, and management of apricot trees, will be more fully treated of under the article PRUNUS.

The produce of the apricot tree is highly valuable as a summer fruit, for different purposes; while green and young, for tarts, pies, &c.; when ripe, it is a fine table fruit, provided it be gathered before it become soft and mealy; and when preserved in sugar, is an excellent sweetmeat.

APRIES, in *Biography* and *Ancient History*, succeeded his father Psammis or Psammutis, as king of Egypt, in the year before Christ 594, and is supposed to have been the Pharaoh-Hophra of Jeremiah, ch. xxxvii. 5.; and Ezekiel, xvii. 15. Herodotus (l. iv. c. 161.) and Diodorus (l. i. p. 62.) give him the character of a martial prince; and speak of successful wars which he carried on against the Tyrians, Sidonians, and Cypriots. Having taken Sidon by storm, and made himself master of the isle of Cyprus, he returned with immense spoil into Egypt. In the first year of his reign, he entered into a league with Zedekiah king of Judah, against the king of Babylon; and about two years after, attempted to relieve Jerusalem, which was closely besieged by Nebuchadnezzar; but as the Babylonians approached, he and his Egyptian army fled, and left the Jews to the merciless rage of their enemies. Towards the latter end of his reign, the Libyans applied to him for succour against the Cyrenzans, a Greek colony of Africa, by whom they were invaded; but the powerful army which he sent to their relief, being defeated with great slaughter, a discontent, which terminated in a civil war, took place among his own subjects. Amasis, who was employed to quell the tumult, betrayed Apries, and was proclaimed king. In a battle near Memphis, Apries was vanquished and made prisoner, and after some time was strangled; having reigned, according to Herodotus, 25 years, but 22 according to Diodorus. *Anc. Un. Hist.* v. i. p. 312.

APRIGLIANO, in *Geography*, a town of Italy, in the

kingdom of Naples, and province of Calabria Citra, 7 miles S. E. of Cosenza.

APRIL, the fourth month of the YEAR, according to the common computation; but the second, reckoning from the vernal equinox.

The word is derived from *Aprilis*, of *aperio*, *I open*; because the earth, in this month, begins to open her bosom for the production of vegetables; or, as others say, from *Αφροδιτη*, the Greek appellation of Venus.

In this month the sun travels through parts of the signs Aries and Taurus.

APRILE GUISEPPE, in *Biography*. See TENDUCCI, and CANTARE.

APRILINA, in *Entomology*, a species of PHALÆNA, in the *Noctua* family, described by Linnæus, and Fabricius. Both authors, it must indeed be remarked, have made great confusion between this and another species of the same family; viz. RUNICA: and Entomologists have been under considerable doubts respecting the identity of either. These are natives of Great Britain, and as such fully noticed by Mr. Donovan, in his "Natural History of British Insects;" from which it appears that the Linnæan species named *Aprilina*, is the same as Fabricius calls *Runica*; and, on the contrary, the *Runica* of Linnæus is the *Aprilina* of Fabricius: to reconcile the difficulties arising from this confusion, the two insects are thus defined.

Phalena Aprilina: thorax crested; wings deflexed, green; a black mark and transverse band; and a single row of black triangular dots near the apex. Vol. x. p. 57.

Phalena Runica: thorax crested; first wings greenish, with black marks; and a row of triangular dots behind. Vol. x. p. 75.

And it is further observed, that the two black femicircles on the thorax, and double row of triangular spots at the ends of the posterior wings, are mentioned as peculiarities of the species *Runica*, by some writers; the latter is, however, liable to considerable variations, the spots being in general crowded in a confused series, and forming an irregularly interrupted line. It may be easily distinguished from the *Phalena Aprilina*, by its superior size; the colours are less vivid, and it is destitute of the broad transverse bar, which is conspicuous on the upper wings of *Phalena Aprilina*. Vide Don. Brit. Inf.

APRILIS, or PRILIS Lacus, in *Ancient Geography*, *Lago de Castiglione*, a lake of Italy, belonging to Etruria, to the west of Rusellæ.

APRIO, in *Geography*, a town of European Turkey, in the province of Romania, the see of a Greek archbishop; situate on the Larissa, between Trajanapolis and Rhodolto. It was anciently called *Theodosiopolis*, from its being a favourite residence of Theodosius the great; and afterwards *Apris* or *Apro*.

A PRIORI *Demonstration*. See DEMONSTRATION.

APRON, in *Naval Architecture*, is a piece of curved timber fixed behind the lower part of the stern, immediately above the foremost end of the keel.

APRON is also a name given to a platform or flooring of plank, raised at the entrance of a dock, against which the dock gates are shut.

APRON, in *Gunnery*, a piece of lead which caps or covers the vent or touch-hole of a cannon.

APROS, in *Ancient Geography*, a river of Gaul, in the country of the Oxybiaus; supposed by M. D'Anville to be the present *Loup*.

APROSIO, ANGELICO, in *Biography*, a learned Augustine monk, was born at Ventimiglia in Genoa, in 1607. In Genoa he taught philosophy for five years, and he afterwards settled at Venice, where he lectured on polite literature.

ature. Of the library of the Augustines, founded by him in his native place, he published a catalogue, under the title of "Bibliotheca Aprobiana," printed at Bologna, in 1673, 12mo.; which contains an account of his own life, and of various authors. He wrote many satirical or humorous pieces under fictitious names. He died about the year 1682. Gen. Dict. Nouv. Dict. Histor.

APRUSA, in *Ancient Geography*, a river of Italy, placed by Pliny in Umbria, and supposed by Hardouin to be the present *Avafa*.

APRUSTUM, APRIGLIANO, a town of Italy, in Bruttium, south-east of Consentia; and supposed by Hardouin to be the *Abufteron* of Ptolemy.

APRUTIUM, a town of Italy, now *Teramo*.

APSALUS, a town placed by Ptolemy in Macedonia.

APSINES, in *Biography*, a sophist and rhetorician of Athens, was born at Gadara of Phœnicia, and flourished about the year 236. Philostratus was his friend, and celebrates his accuracy as a writer, in the last book of his sophists. His remains are to be found in Manutius's Collection of Rhetoricians, published at Venice in 1608. fol. Fabr. Bib. Græc. l. iv. c. 31. § 16.

APSINTHII, in *Ancient Geography*, people who inhabited the southern part of Thrace, towards the coasts, east of the river Melas, and west of the Hebrus. They took their name from the river Apſinthus, which traversed their country.

AP SIS, or APSIS, signifies the bowed or arched roof of a house, room, or oven, &c. as also the ring or compass of a wheel.

AP SIS, in *Ecclesiastical Writers*, denotes an inner part in the ancient churches, wherein the clergy sat, and where the altar was placed. It is supposed to have been thus called, because covered with an arch or vault of its own, by the Greeks called *απισ*, and by the Latins *apsis*. Isidore, with less probability, imagines it so called, as being the most luminous part; from *απτω*, to give light.

Apsis, in this sense, amounts to the same with what is otherwise called *choir*, *concha*, *camera*, and *presbyterium*; and stands opposite to the *nave* or body of the church.

AP SIS is more particularly used for the bishop's seat, or throne, in ancient churches. This was more peculiarly called *apsis gradata*, because raised on steps above the ordinary stalls. It was also denominated *exedra*, and in later times *tribune*.

AP SIS is also used for the reliquary, or case, wherein the relics of saints were anciently kept. It took the name *apsis* from its being round, or arched at the top; or perhaps from the place where it was kept. The *apsis* was commonly placed on the altar; it was usually of wood, sometimes also of gold and silver, with sculptures, &c.

AP SIS, in *Astronomy*, is applied to either of the two points in the orbits of planets, wherein they are at the greatest, and the least distance from the sun, or earth. The *apsis* at the greatest distance is called the *higher* or *summa apsis*; that at the least distance, the *lower*, *apsis ima*, or *infima*. The two *apsides* are also called *auges*. The higher *apsis* is more particularly denominated the *aphelion*, or *apogee*; the lower, the *perihelion* or *perigee*. The diameter which joins these two points is called the *line of the apsides*, and this passes through the centre of the orbit of the planet, and the centre of the earth or sun. In the modern astronomy, this line makes the longer or transverse axis of the elliptical orbit of the planet. Such is the line AQ (*Plate I. Astron. fig. 9.*) drawn from the *aphelion* A to the *perihelion* Q. The eccentricity is reckoned in the line of the *apsides*; being the distance between the centre of the orbit of the planet C, and the centre of the sun or earth, S, according as the Copernican or the Ptolemaic system is followed.

These definitions suppose that the lines of the greatest and least distances form one and the same right line; but this is not always precisely the case; as they sometimes make an angle with each other, which is greater or less than 180 degrees; and the difference from 180° measures the motion of the line of the *apsides*. When this angle is less than 180°, the motion of the *apsides* is said to be contrary to the order of the signs; and when it exceeds 180°, the motion is according to the order of the signs. Astronomers have proposed various methods for estimating the motion of the *apsides*, several of which are recited and explained in the "Astronomy" of Keil and that of Monnier. Newton, in his "Principia," has given an excellent method for determining the motion of the *apsides* of a planet, occasioned by the attraction of another, on the supposition that the planetary orbit is little different from a circle. He shews, that, if the sun be immovable, and all the planets gravitate towards him, in the inverse ratio of the squares of their distances, the motion of the *apsides* will be nothing; or the lines above mentioned will make an angle with each other of 180°, or form one straight line. But, on account of the mutual gravitation of the planets towards one another, their gravitation towards the sun is not precisely in that ratio, and consequently their *apsides* are not always exactly in a right line with the sun: and Newton has given a very elegant method of determining the motion of the *apsides*, on the supposition that we know the force which is thus added to the gravitation of the planet towards the sun, and that this additional force is always directed towards the sun, which is not precisely the case. For the motion of the *apsides*, see APHELION, APOGEE, and PLANET.

Kepler discovered, from observation, that the velocities of the planets in their *apsides*, are inversely as their distances from the sun; whence it follows, that they describe, in these points, equal areas about the sun in equal times. And although he could not prove, from observation, that the same was true in every point of the orbit, yet he had no doubt that this was the case. He therefore applied this principle to find the equation of the orbit, and, finding that his calculations agreed with observations, he concluded it was true in general, "that the planets describe about the sun equal areas in equal times." This discovery was, perhaps, the foundation of the "Principia," as it probably might suggest to sir Isaac Newton the idea that the proposition was true in general, which he afterwards proved it to be.

APSORRUS, or APSARUS, in *Ancient Geography*, a river in the district of Colchis, which fell into the Euxine sea, to the east of Athenæ.

APSORRUS was also the name of a town in Asia, on the coast of the Euxine sea.

APSUS, now *Crevasfa*, a river of Europe, in Macedonia, which rose in mount Tomarus, and ran into the Adriatic sea, at some distance to the south of Dyrrachium. This river watered a valley, which the ancients compared to that of Tempé. The Roman and Macedonian armies encamped on the banks of this river, in the war against Philip.

APSYCHIA, from *α*, privative, and *ψυχη*, soul, in *Medicine*, a swooning or fainting away, called also *hypopsychia* and *apopsychia*.

APSYCTOS, from *α*, and *ψυχω*, I cool, a word used by the ancients, as the name of a stone found in Arcadia, and of the colour of iron, the quality of which they say was, that when once heated red-hot, it would never grow cold again.

We have some stones indeed in England, that when once heated, will retain a warmth for a long time, but all the other accounts seem groundless; our warming-stone, used in Cornwall and Yorkshire to lay at the feet of people's beds, will retain warmth eight or ten hours; and there is a sort of red
stones.

stone cut out of the salt mountains near Cordova, and formed into broad tiles called *ruggiols* by the Italians, which being once well heated, will retain a sensible warmth twenty-four hours; but these do not all come up to the qualities of this imaginary stone of the ancients, the accounts of which must be fabulous.

APSYNTHIUS, in *Ancient Geography*, a town of Thrace, the same, according to Stephan. Byz. with *Ænus*, situate at the mouth of the Hebrus.

APSYRTIDES, the name of four islands of the Adriatic sea, at the entrance of the gulf of Flano.

APSYRTUS, in the *Materia Medica* of the ancients, a name given to the common *marrubium*, or horehound; a plant at that time, as well as now, esteemed very good in coughs, and other complaints of the breast.

APT, in *Geography*, a town of France, and principal place of a district in the department of Vaucluse; the see of a bishop, suffragan of Aix, before the revolution; the cathedral is said to be the oldest in France, and a council was held here in 1365. It is situated on the river Calavon, 9 leagues E. of Avignon, and 7 N. of Aix. N. lat. 43° 52'. E. long. 5° 56'.

APTA JULIA, in *Ancient Geography*, called also *Civitas Aptensium*, a town of Gallia Narbonensis; now APT.

APTENODYTES, in *Ornithology*, a genus of the order ANSERES. The bill is straight, rather compressed, and sharp along the edges; the upper mandible is obliquely sulcated lengthwise; feet palmated, shackled; wings sin-shaped, and without quill feathers.—Gmelin, &c. This is the genus PINGVIN of Dr. Latham's synopsis; his character of it is more copious, and is as follows: bill strong, straight, more or less bending towards the point, furrowed on the sides; nostrils linear, placed in furrows; tongue covered with strong spines, pointing backwards; wings small, more like fins, covered with no longer feathers than the rest of the body, useless in flight; body clothed with thick short feathers, having broad shafts, and placed as compactly as scales; legs short and thick, placed very near the vent; toes four, all placed forwards, the interior loose, the rest webbed; tail very stiff, consisting of broad shafts scarcely webbed.

"This genus of birds," adds Dr. Latham, "seems to hold the same place in the southern parts of the world as the awks do in the northern, and are by no means to be confounded the one with the other, however authors may differ in opinion in respect to this matter. The penguin is seen only in the temperate and frigid zones, on that side of the equator which it frequents; and the same is observed of the awk in opposite latitudes; and neither of the genera has yet been observed within the tropics. The awk has true wings and quills, though small; the penguin, mere fins only, instead of wings. This last has four toes on each foot; but the former only three. The penguin, while swimming, sinks quite above the breast, the head and neck appearing only out of the water; rowing itself along with its finny wings, as with oars; while the awk, in common with most other birds, swims on the surface. Several other circumstances, peculiar to each, might be mentioned, if these were insufficient to characterize this genus.

"The bodies of the penguin tribe are commonly so well and closely covered with feathers, that no wet can penetrate; and as they are in general excessively fat, these circumstances united secure them from cold. They have often been found above seven hundred leagues from land; and frequently on the mountains of ice, on which they seem to ascend without difficulty, as the soles of their feet are very rough, and suited to the purpose." Gen. Syn. vol. iii. p. 2.

The birds called by Buffon and some others penguin or pinguin, belong to the ALCA genus of Gmelin.—The last

author describes the following species of the APTENODYTES genus; chrysoconic, parachonica, papua, antarctica, magellanica, demersa, cataractes, torquata, minor, chilensis, and chilensis.

APTERA, from α and $\pi\tau\epsilon\rho\omega\nu$, wing, in *Entomology*, the seventh and last order of insects in the Linnæan system. The definition of the order is simply this: aptera, wings none; and the genera are divided into the three following sections:

* Legs six; head distinct from the thorax: comprehending the LEPTURA, PODURA, TERMES, PEDICULUS, and PULEX, genera.

** Legs from eight to fourteen, inclusive; head and thorax united: comprehending the ACARUS, HYDRACHNE, ARANEA, PHALANGIUM, SCORPIO, MONOCULUS, and ONISCUS, genera.

*** Legs numerous; head distinct from the thorax: comprehending the two last genera, SCOLOPENDRA, and JULUS.

It must, however, be observed, that this arrangement, though preferable to that of Fabricius in some respects, is not entirely free from objection; for there are abundant instances of apterous insects that can only be referred to the other classes, unless we separate the two sexes of many individual species, as we shall have occasion to notice in the articles FORMICA, MUTILLA, and others hereafter. Brunniche, in his system of entomology, has arranged every insect wanting wings, under his apterous order, without regarding those in which one sex has wings, and the other is destitute of them. Thus, for example, the apterous aphid, the female coccus, the neuters of ants, and the apterous mutillæ, are separate from their own species, and arranged amongst insects that have no affinity with them; and, to complete the disorder and confusion, the pupa of the grylli, creatures in a state yet imperfect, is included with the apterous order also.

No insect can be referred to the apterous order in the Linnæan system, unless both sexes, when arrived at their last state of being, are destitute of wings: although the term *apterous* is used in a general manner, by entomologists, to signify any insect without wings, when complete, whether it be the females of those winged males that belong to the other orders, or not; and even for coleopterous and hemipterous insects that have a hard shelly covering or elytra, and have no wings under them. It is often used, by Linnæus himself, in this manner, as the following examples fully prove.

APTERA, a species of BLATTA; it is apterous, brown, and punctured; posterior margins of the abdominal segments, and legs livid; wings (wing-cases) ferruginous; shanks spinous. Linn. and Gmel.

APTERA, a species of CICADA; apterous and black; wing-cases abbreviated; shanks and antennæ pale. Linn. & Gmel.

APTERA, in *Ancient Geography*, a town of Lycia.

APTERA, or *Apteria*, was also a town of the isle of Crete, situate in the western part to the north-west of Cydonia, and having for its port Cissamos or Kissamos. Near this town, according to Stephan. Byz., the Sirens challenged the Muses to a musical contest, but having been vanquished, they plucked off their wings, and leaped into the sea, whence fable reports its name; but Eusebius, in his Chronicon, says, that it was so called from one Apteras, king of Crete, the supposed founder of it. Here was also a temple or chapel dedicated to Venus Urania. This town is now called *Apteria* or *Paleocastro*.

APTERUS, in *Entomology*, the specific name of an insect in the PTINUS genus, described by Linnæus. The head is brown, and emarginated in front; wing-cases, legs, and antennæ rufous; thighs clavated; shank ciliated. Lesc. p. 7. n. 130.

APTERUS, is likewise the name of a species of **HISTER**, of a fulvous colour, and without wings. It is a native of Italy, and described by Scopoli (ent. carn.). Gmelin.

APTERUS, is a name also given to one of the curculiones, **CURCULIO APTERUS**: thorax spinous, impressed with a cruciform mark; wing-cases dotted with ferruginous brown. Fabr. Obs. The beak is short, legs unarmed, body black, and punctured on the belly. It is the **CURCULIO CRUCIATUS** of Degeer, is of a large size, and inhabits the Cape of Good Hope.

APTERUS is, lastly, a species of **CIMEX** found in Europe. It is variegated with red and black; elytra red with two black spots: no wings. Fab. and Gmel.

AP-THANES, an ancient term for the higher nobility in Scotland. See **THANE**.

APTITUDE, from *aptus, fit*, the natural disposition any thing hath to serve for such or such a purpose. Thus oil hath an *aptitude* to burn, and water to extinguish fire.

APTITUDE, or **APTESS**, is often used in speaking of the talents of the mind, for a promptitude or disposition to learn things with ease and expedition.

In which sense aptness amounts to the same with what the Greeks call *επιβολη*, and the Latins *bona incholes*, and we sometimes *docility*.

Charlton divides aptness into three parts, viz. *acuteness*, *facility*, and *memory*.

APTOTE, derived from *α priv.* and *απτωσις, casus*, in *Grammar*, a noun indeclinable, or which is without any variation or case.—Such are the words *fas*, *nefas*, &c.

APULEIUS, **LUCIUS**, in *Biography*, a Platonic philosopher, was born of a respectable family at Madaura in Africa, and lived in the 2d century, under the Antonines. He prosecuted his studies at Carthage, Athens, and Rome; at which latter place he acquired the knowledge of the Latin tongue without a master: and of these studies he gives the following curious account. “Our first cup of knowledge, which we receive from the hand of the teacher of letters, removes entire ignorance; the second furnishes us with the learning of the grammarian; the third arms us with the eloquence of the rhetorician; and as much as this is drunk by most persons: but at Athens I drank other cups from the deceitful fountain of poetry, from the clear stream of geometry, from the sweet waters of music, from the rough current of dialectics, and from the nectareous but inexhaustible deep of universal philosophy.” In the early period of life he spent his patrimony, which was considerable, in acts of liberality to his instructors and to the indigent, and in his travels, which he undertook for the acquisition of knowledge, and chiefly for gaining information concerning the religious opinions and ceremonies of different countries. With this view he obtained admission into their several mysteries; being initiated, in Greece, into several solemn rites; and devoting himself, at Carthage, to the worship of Æsculapius, their tutelary divinity, and performing the honourable office of Antistes, or chief conductor of the ceremonies, in the college of his priests. Upon his return to Rome, his patrimony was so completely exhausted, that he is said to have pawned his clothes in order to defray the expence of the inaugural ceremonies of his introduction into the fraternity of Osiris. In order to gain a subsistence, he assumed the profession of a pleader, from the exercise of which he derived considerable profit; but with a view of more speedily repairing his fortune, he married Pudentilla, a rich widow of Oea, whose principal attraction was her wealth. This connection involved him in a law-suit with the brother of her former husband, who charged him with employing magical incantations to gain her affection: but

he found no difficulty in proving to the satisfaction of his judges, that the only witchcraft by which he accomplished his purpose were the attractions of his person. The apology which he delivered on this occasion is still extant, and is much admired. In consequence of this unfounded accusation, and without any other evidence, Apuleius was ranked among the professors of magic; and after his death miracles were ascribed to him, which were placed in competition with those of Jesus Christ. Accordingly Lactantius, in the beginning of the 4th century, expresses his surprize that the author whom he confutes, had omitted Apuleius, of whom many wonderful things were reported: and Augustine, in the fifth century, was requested by Marcellinus to exert his utmost efforts in refuting those who falsely asserted that Christ did nothing more than was done by other men, and who produced their Apollonius, Apuleius, and other masters of the magical art, whose miracles they maintained to have been greater than his. Apuleius seems, indeed, to have been no mean proficient in those arts of imposture, which he had learned from priests of different countries; but the idle report above-mentioned was the only ground of the opinion circulated after his decease, that he possessed or exercised miraculous powers. This opinion, probably, originated in an absurd misapprehension of his fable of the “Golden Ass,” for true history. The work is a satirical romance, in which a Milesian fable, on the metamorphosis of Lucius into an ass, invented by Lucius of Patras, and abridged from him by Lucian, is enlarged and embellished. Although there be no sufficient evidence that Apuleius pretended to work miracles, and for instituting any comparison between him and Jesus Christ, yet it is not improbable that in some passages of the fable of the golden ass, he intended to ridicule the Christians; and bishop Warburton was, perhaps, right in his conjecture, founded on a passage in Apuleius’s Apology, that Æmilianus, the brother of Pudentilla’s first husband, who prosecuted him for magic, was a Christian. But there seems to be no sufficient ground for the supposition of this learned writer (see Div. Leg. b. iv. § 4.), that the design of the fable of the golden ass was “to recommend the Pagan religion as the only cure for all vice in general.” The author himself calls it a Milesian tale, and a Greek fable; and the ancients always so understood it. Mosheim and Lardner have examined the hypothesis of Dr. Warburton, and urged against it objections that are unanswerable. The true character of this work seems to be that which Barthius and Bayle have given it, viz. “that it is a perpetual satire on magical delusions, the tricks of priests, and the crimes of adulterers, thieves and robbers, committed with impunity.” This work was published with large notes by Beraldus, at Venice, in 1504, folio; reprinted at Paris, in 1510, folio, and in 1536, 8vo. The beautiful Epitome to it, intitled, “The Loves of Cupid and Psyche,” has been repeatedly translated into various languages. The Apology, or “Oratio de Magia,” was published separately by Casaubon, in 1594, 4to.; and at Leyden, in 1608, 8vo.; and by Pricæus with notes, &c. at Paris, in 1635, 4to. In philosophy, Apuleius wrote a treatise, “De habitudine doctrinarum et nativitate Platonis Philosophi,” in 3 books: the first on the speculative doctrines of Plato; the second on his morals; and the third on his logic. He also wrote a Latin translation of Aristotle’s treatise, “De Mundo;” an oration “De Deo Socratis,” discussing the question concerning his dæmon; and a work intitled, “Florida,” which, though rather rhetorical than philosophical, serves in many particulars to illustrate the history of philosophy. Another botanical work, intitled, “De Herbis, sive de nominibus ac virtutibus Herbarum,” has been ascribed to Apuleius;

but Johnson, the translator of Gerard, supposed it to be a translation of a Greek writer of the 8th century. Fabricius, however, thinks that this is an improbable conjecture. The first edition of the works of Apuleius was printed at Rome under the care of Cardinal Bessarion, in 1469, folio; they have since passed through various other editions, as those of H. Stephens, in 1585, 8vo.; of Elmenhorst, at Frankfort, in 1621, 8vo.; of Scriverius, at Leyden, in 1624, 12mo.; "Variorum" edition, at Gouda in Holland, in 1650, 8vo.; and another, "In Usum Delphini," 2 vols. 4to. at Paris, in 1688. Apuleius by his writings ought to be classed among the wits rather than the philosophers of his age. His writings, the view of Plato's doctrines excepted, are too florid and sportive, and in many parts too loose and wanton, to comport with the gravity of philosophy. Fabr. Bib. Latin. lib. iii. c. 2. tom. ii. p. 17. Gen. Diet. Lardner's Works, vol. vii. p. 459—465. Brucker's Hist. Phil. by Enfield, vol. ii. p. 53.

APULIA, now PUGLIA, in *Ancient Geography*, denoted that large district of Magna Græcia in Italy, which extended along the Adriatic sea from the river Frento or Fronto to the north-west, as far as the cape Japygium to the south-east, and comprehended Daunia, Peucetia, and Messapia. Its boundaries were, on the north and east, the Adriatic sea; on the south, Sinus Tarentinus, or the gulf of Tarentum, and part of Lucania; and on the west, Samnium. The principal mountains were, Garganus to the north, and Vultur to the south: its chief rivers were, Fronto, Aufidus, Cerbalus, and Bradanus; and its principal cities were, Teanum, Apulum, Sipontum, Arpi, Luceria, Aculum, Venusia, Acherontia, Canusium, Butuntum, and Barium; and Messapia, eastwards, Brundisium, and Hydruntum; and in the gulf, Tarentum and Callipolis. M. Freret supposes that the Apulians were a party of the Liburni, of Illyrian origin, who penetrated into Italy about the 6th century before Christ, and established themselves between the Alps and the river Athesis, whence they proceeded to that part which the Romans called Apulia and Japygia.

APULO-BAMA, in *Geography*, a jurisdiction of South America, consisting of missions belonging to the Franciscans, subject to the bishop of Cusco, 60 leagues from that city, in the empire of Peru, and comprehending seven towns of converted Indians.

APULUS, in *Entomology*, a species of SPHINX that inhabits Surinam. The wings are indented; anterior pair fulvous, with two golden-coloured spots; posterior wings white. antennæ feathered. Fabricius and Gmelin.

APURIMA, or APURIMAC, in *Geography*, a very rapid river of South America, rising near the town of Arequipa in Peru, on the west of the Great Lake Titicaca, S. lat. 16° 30', and running into the Ucaial. The Apurimac, in the map of La Cruz, appears to be the original and proper river of the Amazonas, and forms the remotest branch of the Ucaial, which must be regarded as the ancient or genuine Maranon.

APURWACA, or PIRAGUE, a river of South America, in Guiana, which is one of the most considerable rivers in the country.

APUS, *Ævis Indica*, in *Astronomy*, a constellation of the southern hemisphere, placed near the pole, between the Triangulum Australe and the Chameleon, supposed to represent the bird of paradise.

The apus is supposed to be one of those birds called *apodes*, as having no feet.

The stars contained in this constellation, according to Sharp's catalogue, annexed to the British, are eleven; in

Bayer's charts, twelve; but more numerous in La Caille's catalogue. The principal star is of the 5th magnitude; and in 1750, its right ascension was 214° 32' 45", and its southern declination 77° 57' 6".

APUS, in *Entomology* a species of MONOCULUS. The antennæ trifid, and the tail bifid. F. b. Spec. Inf. The shell is rather compressed, retuse in front, truncated behind, and tail terminating in two bristles. Linn. Syst. Nat. Found in stagnant waters.

The synonymous terms for this creature are numerous. It is the binoculus cauda bifida of Geoffroy; binoculus (palustris) oculus superis, testa postice truncata, cauda bifida of Mull. Zool. Dan.; limulus palustris, Mull. Entom.; & apus caneriformis, Scæff.

APUS, in *Ornithology*, the species of HIRUNDO, well known by the name of swift or black martin. The colour is black; throat white; all the toes placed forwards, Linn. This is *hirundo apus* of Aldrovandus, &c.; martinet noir of Bessou; and also grand martinet of the same author.

The length of this bird is eight inches; the wings remarkably long, and measuring from tip to tip, when expanded, no less than eighteen inches; the legs and claws black. The female is rather smaller than the male; the plumage inclines more to brown; and the white on the throat is less distinct.

This bird arrives in England later and departs sooner than either of the other swallows, from whence it is supposed to take a longer journey than the others. It has only one brood in the year; so that the young ones have time to gain strength enough to accompany the parent birds in their distant excursions. They inhabit the whole of the European continent, and have been also noticed at the Cape of Good Hope, and Carolina in North America. Swifts are almost constantly on the wing; they fly higher and with more rapidity than the swallows, and never associate with them. They seldom alight, and if by accident they should fall upon the ground, raise themselves up again with great difficulty. They are said to avoid heat as well as cold, and therefore remain in their holes in the daytime, and fly chiefly in the morning and evening in search of prey; their nests are built in elevated places, such as lofty steeples and high towers; the nest is composed of a variety of materials, as dry grass, moss, hemp, shreds of silk, linen, gauze, feathers, and other light substances. They lay five white eggs, which are rather of a longish form; the young are hatched about the latter end of May, begin to fly about the middle of June, and shortly after the nests are abandoned. Swifts begin to assemble, previously to their departure, early in July; their numbers daily increase, and large bodies of them appear together, they soar higher in the air, with shriller cries, and continue at times to assemble together in greater numbers till the beginning or middle of August, when they leave the island of Britain altogether.

APUTASY, in *Botany*, a name given by the people of Guinea to a tree, a decoction of which is in great use among them for washing the mouth to cure the leucopy in the gums, and preserve the teeth. Phil. Trans. N° 237.

APYCNI, in the *Ancient Music*, was used for such chords or sounds of the scale, as could never enter the spissum. They were fixed, or itables.

APYCNON, from α and $\pi\upsilon\kappa\upsilon\sigma$, *non spissimum, rarum*, in the *Ancient Music*, was applied to those two conjunct intervals of a tetrachord, which taken together were greater than the third.

This happened only in the two diatonic genera.

APYRENOS, in *Botany*, properly signifies without kernels.

APYREXY, formed of the privative α , and $\pi\upsilon\rho$, *ignis*, heat, in *Medicine*, the intermission of a fever, or ague.

APYROI, in *Antiquity*, a denomination given to **ALTARS** whereon sacrifice was offered without fire.

In which sense, the word stands contradistinguished from *empyroi*.

APYROMETALLUM, in *Metallurgy*, a name by which some authors have called gold, from its resisting the force of fire.

APYROUS, in *Chemistry*, is a word applied to denote that property in some bodies, by which they resist the most violent fire, without any sensible alteration.

AQUA, in *Natural History*, *Physics*, *Chemistry*, *Medicine*, **WATER**, &c. which see.

The word is Latin, and supposed to be compounded of *a* and *qua*, q. d. *from which*; alluding to the opinion that water is the basis, or matter of all bodies.

AQUA fortis. The workers in metals, &c. distinguish two kinds of aqua fortis, the double and single, or prima and secunda: the former of these is common **NITROUS acid**, the latter is nitrous acid diluted with an equal bulk of water.

AQUA marina, **AQUA marine**, in *Mineralogy*. See **BERYL**.

AQUA regia, or **AQUA regalis**. This is a combination in various proportions of nitric and muriatic acids. It was formerly known by the name aqua regia, from its being at that time the only acid capable of dissolving gold. In the new nomenclature it has attained the appellation of **NITRO-MURIATIC acid**.

AQUA secunda. This is nothing else but aqua fortis diluted with much pure water. It is employed in several arts, to clean the surface of metals and of certain stones, and for various other purposes.

AQUA sulphurata, *sulphur water*, formerly called *gas sulphuris* by Van Helmont, is at present known by the name of liquid **SULPHUREOUS acid**.

AQUA vite, water of life, *eau de vie* of the French, *usquebaugh* of the Irish, *whisky* of the Scotch, is a name familiarly applied to native distilled spirits. Hence grape wine being the material from which the common spirits are mostly procured on the continent, the French *eau de vie*, the Italian *acqua vite*, the German *brandwein*, are strictly synonymous, and correspond to the English word *brandy*. But fermented barley, rye, &c. being the material made use of in Scotland, Ireland, Holland and England, the terms *usquebaugh*, *whisky*, and *Hollands*, are more properly synonymous with the English **MALT spirits**.

AQUA, in *Pharmacy*, is a term prefixed to a variety of liquid preparations, in which water is the principal liquid vehicle. These are of two kinds, one the *distilled waters*, consisting of water impregnated with the medicinal virtue of various vegetables, through the medium of distillation; and the other kind is simply a solution of various saline substances, in known proportions of water, to ensure a greater accuracy in prescription.

We shall briefly notice the several aqueous preparations which are either actually in use, or have acquired a certain celebrity.

Aqua distillata, Pharm. Lond. **Aqua destillata**, Ph. Edin. Simple distilled water. To prepare this, any quantity of spring water is to be distilled in clean vessels. The first portions are to be rejected, and the process continued, till about two thirds are distilled off, which are to be kept for use in clean glass vessels.

No other water but distilled is allowed by the college to be used in the aqueous preparations. It is particularly requisite in some of the saline solutions, as, for instance, in

that of sugar of lead, which is perfectly clear with distilled water, but milky with pump or river water.

Aqua distillata, P. Lond. **Aqua stillatiæ**, P. Edin. *The distilled waters of Pharmacy*.

The general rule for preparing these waters is to put the plants, or parts of plants employed, into a tinned copper still, to cover them with water, and to distil it off with a gentle heat, as long as the liquor retains sufficient flavour of the plant. The process must be stopped before all the water is evaporated, otherwise the plant would be burned, and would give a disagreeable burnt taste to the liquor. See the articles **DISTILLATION**, **SPIRITS DISTILLED**, and **OILS ESSENTIAL**.

The number of plants submitted to distillation by former pharmaceutical chemists, is almost endless; and in the older pharmacopœias, we find numerous compound waters made of ingredients, many of which are either inert in themselves, or whose virtue is not capable of uniting with water through the medium of distillation. Of this kind are the daisy, bugloss, water-cress, &c. which have been prescribed for distillation; but in the present pharmacopœias, all these useless materials are omitted, and those only are retained that will give some sensible flavour or smell to water distilled of them.

The following are retained at present. **Aqua anethi**, (distilled water of dill)—**cinnamoni**, (of true cinnamon)—**faniculi**, (of fennel)—**mentha piperitides**, (of peppermint)—**mentha sativæ**, (of spearmint)—**pimento**, (of allspice)—**pulegii**, (of pennyroyal)—**rosæ**, (of rose leaves)—**corticis limonium**, (of lemon peel)—**corticis aurantiorum hispalensium**, (of Seville orange peel)—**castia lignæ**, (of cassia cinnamon.)

About a pound of the dry barks and seeds, and a pound and a half of the fresh plants, are sufficient for a gallon of the distilled waters; but three or four pints of water more must be employed to prevent burning, and to allow of that quantity to be distilled off.

It should be remembered that the term *distilled water* is now strictly confined to those preparations in which no other liquid than water is employed to extract the virtue of the plant; but formerly it was extended to those that were prepared with a mixture of ardent spirit and water, or even with pure spirit. Thus the *aqua lavenderæ*, (lavender water) is a *spirituous water*, prepared by distilling a mixture of spirits of wine and water from the lavender.

A few of the most celebrated distilled waters or spirituous waters, may be mentioned.

Aqua epidemica, *plague water*, is prepared by distilling the roots of masterwort (*imperatoria*), the seeds of angelica and elder flowers, in French brandy.

Aqua Regine Hungaria, *Hungary Water*.

The genuine Hungary water is a pure spirit distilled from the rosemary, and strongly scented with the rich perfume of this aromatic plant. The French is reckoned the best.

Aqua odorifera, *honey water*, *eau de miel*.

This is a compound aromatic spirit, prepared by distilling spirit of wine with honey, coriander seeds, vanilloes, cloves, nutmegs, lemon-peel, storax, benzoin, to which are added spirituous rose-water, and orange-flower water.

Aqua Vulneraria, *Arquebuse Water*, is a distilled spirit prepared from a great variety of aromatic plants, such as thyme, origanum, balm, lavender, rosemary, &c.

The reader will find the recipes for the above-mentioned waters, and a great number of others (many of which are now obsolete) in *Beaumé's Elements de Pharmacie*.

The medicinal virtues of the distilled aromatic waters and spirits have, perhaps, been much over-rated, and numerous distinctions between them with regard to their effects, have been made, without much foundation.

All of them are cordial and stimulating, and as such have

considerable efficacy in sudden faintings, sickness, and languor; but the difference of effect between the simple aromatic waters and the spirituous waters is so great, that much of the virtue of the latter is to be ascribed to the ardent spirit. They are largely used in medicine; and from their agreeable flavour and fragrantcy, they will conceal the nauseous taste and smell of many of the most unpalatable drugs. The consumption of the fragrant aromatic spirits is perhaps still greater, as perfumes for the toilet; and the flavoured spirits, more than all, as drams and cordials.

The other kinds of *waters* in pharmacy are simple solutions of various salts, as we have already mentioned. The following are retained in the London and Edinburgh pharmacopœias.

Aqua aluminis composita (formerly *Aqua aluminis Bateana*), is a solution of half an ounce of alum, and half an ounce of vitriolated zinc, in two pints of water.

Aqua cupri ammoniati (formerly *Aqua sapphirina*, or *aqua caelestis*), is prepared by mixing one dram of muriated ammonia with a pint of lime water, and suffering them to stand in a copper vessel till the solution has acquired that beautiful blue colour by which it is distinguished. The same effect takes place in glass vessels, if some thin pieces of copper are added. This preparation is a very weak solution of copper in the caustic ammonia, which is separated from the sal ammoniac by means of the lime water. It is used as a gentle escharotic in surgery, and it also forms a conspicuous ornament to the druggist's shop. See COPPER.

Aqua lithargyri acetati composita, is a mixture of two drams of the aqua lithargyri (or Goulard's extract), with two pints of distilled water, and two drams of proof spirit of wine.

Aqua zinci vitriolati cum camphora, is a solution of half an ounce of vitriolated zinc, in two pints of distilled water, to which half an ounce of camphorated spirit is added, and the whole filtered, to separate most of the camphor which is precipitated by the mixture. Enough of the camphor remains to give its strong smell to the solution.

Aqua ammoniac et aqua ammoniac puræ. See AMMONIACAL preparations.

Aqua ammoniac acetate. See ACETITE of Ammoniac.

Aqua kali preparati (formerly *lixivium tartari*), is a saturated solution of carbonate of potash in water, made by the spontaneous deliquescence of this alkaline salt, when kept for some time in a moist place.

Aqua kali puri (formerly *lixivium saponarium*), is a solution of potash made caustic by means of lime. See POTASH.

Aqua calcis, lime water. See LIME.

Aqua phagedænicæ, a preparation often used in surgery, is a solution of half a dram of corrosive sublimate of mercury, in one pint of lime water. The lime water here decomposes the mercurial salt, and makes a turbid brick-coloured liquor, of great efficacy as an escharotic in foul wounds or obstinate ulcers.

Aque Minerales. See WATERS MINERAL.

AQUA, or *Agua*, in *Geography*, a province of Africa in Guinea, on the Gold Coast, bounded on the south by Fantin, on the north-east by Dinkira, and on the west by the river of Chama, or St. John.

AQUA Augusta, in *Ancient Geography*, called likewise *Alfaina*, from the lake of that name, about 14 miles from Rome, near the Claudian way, was a stream of water brought to the city, and entering it at the porta Esquilina, now the gate of St. Laurence. It was not fit to drink, and served merely to water gardens, and to supply the Naumachie.

AQUA crabra, in *Ancient Geography*, a river which passed by the villa of Cicero at Tusculum, supposed by Cluvier and

M. D'Anville to be that which is now called Maranna: but the abbé Chauppy is of opinion that these were different rivers.

AQUA Julia, a river about 12 miles from Rome, in the Via Latina, brought by Agrippa to Rome during his exile, A. U. C. 721. Its source was called *Caput Julæ*, and it is now known by the name of *Capo d'Aqua*. It enters the city near the Esquiline gate, and had its name, according to Frontinus, from one Julius, who discovered the spring that supplies it.

AQUA Marcia, a stream of water which was conveyed through a considerable distance under ground, near the Tiber. This was also called *Aufalia*, and is said to have been first brought to Rome by the prætor Q. Marcius, from a spring near the Valerian way, upwards of 30 miles distant from the city, which it enters near the Esquiline gate. This was, and still is, reckoned the best water for drinking in Rome.

AQUA Paulina. See AQUEDUCT.

AQUA Tepula, a river formed by the union of several streams, which had its source about ten miles from Rome, in the Via Latina, and was conveyed thither by Agrippa; now known by the name of *Pesori*, near Frascati.

AQUA Virginica, a stream of water; so called, from a country girl's shewing the spring to some soldiers who were ready to perish with thirst; which enters Rome at the gate Pinciana, and was brought thither by Agrippa, A. U. C. 735. At present it issues from the fountain in the Piazza di Spagna, which represents a slip, and from that of Trevi, so called from the Trivium, where three streets meet.

AQUA VIVA, a place in Etruria, north of Rome.

AQUÆ, a small place in Brutium, near the sea; north-east of Scylla.

AQUÆ, baths of mineral waters in Mauritania Cæsariensis; mentioned by Ptolemy, and placed by Antonin in his Itinerary, 25 Roman miles from Cæsarea. The city was once a Roman colony and episcopal see.

AQUÆ Caralægas, a small ancient town situate in Hispania Tarragonensis.

AQUÆ, a small place of Italy, in Picenum, south-west of Alculum.

AQUÆ Albenfes, a town of Africa in Bizacium; also a town of Africa, in Mauritania Setifensis, which had been an episcopal see.

AQUÆ Angitia, a small place of Italy, in Brutium, upon the western coast.

AQUÆ Apollinares, a place of Italy, in Etruria, between Tarquinii on the north-west, and Cære to the south-east.

AQUÆ Augule, or *Tarbellicæ*, a city of Gaul, in Novempopulana, and capital of the Tarbelli. It is now *Acs*, or *Dax*. See ACS.

AQUÆ Billicus, *Vasserbilich*, a town of Gaul, belonging to the Sunuci; and placed by Martin south-east of Orolaunum, and west of Augusta Treverorum.

AQUÆ Bilibitanorum, *Banosse Athama*, a famous place of Hispania Tarragonensis, between Bilbilis to the east, and Anacum to the west.

AQUÆ Borvonis, *Bourbon-l'Archambaut*, a place of Gaul, belonging to the Bituriges Cubi, in Aquitania prima, between Tinconciun to the north-west, and Sitillia, belonging to the Boii, to the east.

AQUÆ Borvonis, *Bourbonne les Bains*, a place of Gaul, belonging to the Sequani, between Andometurum, or Lingones, to the west, and Dittatium to the east.

AQUÆ Calentes, a place of Gaul, belonging to the Averni, situate southwards.

AQUÆ Calide, *Bagni di Ballicano*, baths of Italy, three miles from Plaiscon.—Also, a town of Africa, in Numidia Propria,

Propria, wholly destroyed:—also, *Aigue-Perse*, a place of Gaul:—also, Bath in Somersethire:—also, *Calide Cilinorum*, a town of Hispania Tarragonensis, north of Barcino, belonging to the Laetani:—also, *Calide* or *Tibilitana*, in Africa, about ten leagues south-west of Hippo Regius, now called *Hamam*, or the baths, lying to the east of the Hamam-Meskouteen, on the north side of the river Sci-boufe, in the district of the Bookalwan, of the province of Constantina:—also, *Calide Colonia*, now the *Hamam* or the baths of Mereega, in the African province of Tlemsan, eight miles east-north-east of Maliana, between the river Sheliff and the sea; the largest and most frequented of these (says Shaw, *Travels*, &c. p. 30), is a basin of 12 feet square, and four deep; and the water, which bubbles up with a degree of heat scarce tolerable, after it has filled this cistern, passes on to a much smaller one, which is made use of by the Jews, who are not permitted to bathe in company, or in the same place, with the Mahometans; resorted to by a great concourse of people in the spring, the season of these waters, which are accounted very efficacious for curing the jaundice, rheumatic pains, and some of the most inveterate distempers: near this bath are the ruins of an old Roman town, and tombs and coffins of stone, said to be of an unusual size.—*Calide, Vichi*, a place of Gaul, south of Vorogium, and north-east of Angulstometum, or Averni.

AQUÆ CERETANÆ, a place of Etruria, north-west of Cære.

AQUÆ CILENORUM, a place of Spain, south-east of the river Iria Flavia.

AQUÆ CONVENARUM, *Capbern* according to M. D'Anville, south-east of Turba and north-west of Lugdunum, or Convenæ. Some authors have assigned its situation to that of the present Bagneres; but this does not correspond to the measures given in the Itineraries.—*Convenarum*, or *Onesiorum*, *Cominge*, a town of Gallia Narbonnensis.

AQUÆ CUMANÆ, baths near Cumas in Italy.

AQUÆ CUTILIAE, *Pozzo Ratinano*, a lake of Italy, in the country of the Sabines. Pliny, Seneca, and Varro report, that in this lake there was a moving island, and the latter says, that it was the centre of Italy. Vespasian used these waters every summer, and died in this place. By some they are called *Aquæ Sabine*; and by Strabo, *Aquæ Cutiliæ*.

AQUÆ DURÆ, *Alcala del Rio*, a place of Spain, in Bætica.

AQUÆ FLAVIÆ, *Cbiaves*, a town of Hispania citerior, belonging to the Callaici, and situate to the north-east, in the interior part of the country. Trajan built a bridge on the river now called Tamaga, the ruins of which indicate its former grandeur.

AQUÆ HELVETIÆ, *Baden*, a town of Gaul, belonging to the northern Helvetii, between Vindonissa to the west and Vitodurum to the east.

AQUÆ LATINATÆ, *Sardara*, a town in the island of Sardinia.

AQUÆ LÆÆ, a town of Spain, at the mouth of the Mincius.

AQUÆ MEROM, supposed to be the lake called by Josephus Samachonitis, in Upper Galilee, into which the river Jordan falls before it arrives at the sea of Genesareth. Here Jabin, king of Hazor, encamped, when he was defeated by Joshua. See Josh. ch. xi. 5.

AQUÆ NEAPOLIANÆ, a town of the island of Sardinia.

AQUÆ NERÆ, or *Neri*, *Neris*, a place of Gaul, belonging to the Bituriges Cubi, and situate between Mediolanum to the north-east, and Cantilia to the south-east.

AQUÆ NISIVÆ, or *Nilinei*, *Bouron-Lamy*, a place of Gaul, belonging to the Ædui, south-east of Decetia, and west of Telonnum.

AQUÆ ONOSÆ. See *AQUENSIS VIENS*.

AQUÆ ORIGINES, a place of Spain in the country of the Callaici, upon the Mincius, north-east of Tyde.

AQUÆ PANNONIÆ, baths of Aultria, now called *Baden*.

AQUÆ PASSARIÆ, a place of Italy, in Etruria.

AQUÆ PATAVIÆ, baths in the territory of Venice, near Padua, called *Fontes Aponi* by Livy and Martial, now *Bagni d'Abano*.

AQUÆ PISANÆ, a small place of Etruria, north-east of Pisa.

AQUÆ POPULONIÆ, a small place of Etruria, between Salebro to the south-east, and Manliana to the north-west.

AQUÆ QUERQUERNÆ, a place of Spain, belonging to the Callaici, between Aquæ Origines and Nometobriga.

AQUÆ QUINTIANÆ, a place of Spain, in the country of the Callaici, south-east of Lucus Augusti.

AQUÆ REGIÆ, a town of Africa, situate some miles south of Turzo; the ruins of which still remain.

AQUÆ REGIÆ, baths of Epirus, near Aeroceraunia.

AQUÆ SALVIÆ, a famous place in Italy, three miles from Rome. It was the see of a bishop, suffragan to the archbishop of Carthage.

AQUÆ SEGESIÆ, *Ferrières*, a place belonging to the Senonenses, between Genabum to the south-west and Agedincum to the north-east:—also *Segesle*, *Aissumin*, a place of Gaul belonging to the Seguliani; placed by M. D'Anville near Liger, and south of Forum Segulianorum.

AQUÆ SEXTIÆ, *Aix*, a town in Gaul, in Narbonnensis Secunda, to the north of Massilia. See *AIX*.

AQUÆ SICCÆ, probably *Seiches*, a place of Gaul, situate, according to M. D'Anville, south-west of Tolosa, and near it, and north-east of Vernosol.

AQUÆ STIACIÆ, or *Statiellorum*, a town of Italy in Liguria, now Acqui, in Montserrat.

AQUÆ TACAPITANÆ, a place of Africa in Bizacium, now called *El-Hammah* of Gabs, i. e. the baths of Gabs, or Tacape. These baths are sheltered from the weather by low thatched hovels; and their basons are about the size of those at Mereega. See *AQUÆ CALIDÆ*. One of these baths is called the bath of the lepers, and below it the water stagnates and forms a pool; the same, perhaps, with the lake of lepers, mentioned by Leo.

AQUÆ TAURI, hot baths of Etruria in Italy, three miles from the sea, said to be discovered by a bull, whence their name; now *Aquapendente* in Orvieto.

AQUÆ VACONIS, a place of Spain, south-east of Gerunda.

AQUÆ VOLATERRANÆ, a place of Italy in Etruria, south of Volaterræ, and on the other side of Cecina.

AQUÆ ET IGNI INTERDICTIO. See *INTERDICTION*.

AQUÆ BAJULUS, an ancient name for the clerk officiating under the chief minister, whose business was to assist him in carrying the holy water. The office corresponding to it at present is that of the *PARISH CLERK*.

AQUÆ HÆUSUS, in the *Civil Law*, a right of drawing water, and carrying it through another's ground.

AQUÆ PAVOR, is used by some to denote the *HYDROPHOBIA*. Phil. Trans. N° 147.

AQUÆDUCTUS, *AQUÆDUCTUS*, q. d. *ductus aquæ*, a conduit of water, in *Architecture* and *Hydraulics*, is a construction of stone or timber, built on an uneven ground, to preserve the level of water, and convey it by a canal, from one place to another. Some of these aquæducts are visible, and others subterraneous. Those of the former sort are constructed at a great height across vallies and marshes, and supported by piers and ranges of arches. The latter are formed by piercing the mountains, and conducting them below the surface of the earth. They are built of stone, brick,

brick, &c. and covered above with vaulted roofs or flat stones, serving to shelter the water from the sun and rain. Of these aqueducts, some are double, and others triple; that is, supported on two or three ranges of arches. Of the latter kind are the *pont-du-gard* in Languedoc, supposed to have been built by the Romans to carry water to the city of Nîmes; that of Constantinople; and that which, according to Procopius, was constructed by Cosires king of Parthia, near Petra in Mingrelia, and which had three conduits in the same direction, each elevated above the other. Some of these aqueducts were paved, and others conveyed the water through a natural channel of clay; and it was frequently conducted by pipes of lead into reservoirs of the same metal, or into troughs of hewn stone.

Aqueducts of every kind were reckoned among the wonders of ancient Rome; their great number, and the immense expence of bringing water, 30, 40, or 60, and even 100 miles, either upon continued arches, or by means of other works, when it was necessary to penetrate mountains and rocks, may well astonish us. He, says Pliny (Hist. Nat. l. 36. c. 15.), we consider the incredible quantity of water brought to Rome for the uses of the public, for fountains, baths, fish-ponds, private-houses, garden and country-seats; if we represent to ourselves the arches constructed at a great expence, and carried on through a long distance, mountains levelled, rocks cut through, and vallies filled up, it must be acknowledged that there is nothing in the whole world more wonderful. For 440 years the Romans contented themselves with the waters of the Tiber, and of the wells and fountains in the city and its neighbourhood. But when the number of houses and inhabitants was considerably augmented, they were obliged to bring water from remote places by means of aqueducts. Appius commenced this scheme of improvement. See *APPIAN aqueduct*. About 39 years after him, M. Curius Dentatus, who was censor with Papirius Cursor, brought water from the neighbourhood of the city of Tibur; and applied towards defraying the expence, part of the sums taken in the spoils of Pyrrhus. After them Lucius Papirius, Caius Servilius Cepion, Lucius Longinus Craffus, Quintus Marcius (who brought water to Rome from a spring at the distance of sixty-one miles), Marcus Agrippa, Augustus, and others, signalized themselves by their noble aqueducts. Even Tiberius, Claudius, Caligula, and Caracalla, though in other respects not of the best character, took care of the city in this useful article. There are still to be seen in the country about Rome wonderful remains of the ancient aqueducts, some elevated above the ground by arches continued and raised one above the other, and others subterraneous passing through rocks; such is that seen at Vicovaro beyond Tivoli, in which a canal pierces a rock to the extent of more than a mile, and about five feet deep and four broad. With what attention these immense works were constructed, will appear by inspection of the 128th plate in the 4th volume of Montfaucon's Antiquities. At certain distances vents were provided, so that the water which was accidentally obstructed in its passage, might be discharged, till its ordinary passage was cleared; and in the canal of the aqueduct itself there were cavities into which the water was precipitated, and where it remained till its mud was deposited, and ponds in which it might purify itself. In the construction of these aqueducts, there was a considerable variety: that called the *Aqua Marcia* had an arch of sixteen feet in diameter; it was constructed of three kinds of stone, and was formed with two canals one above the other: the most elevated was supplied by the waters of the Tiverone, *Anio novus*, and the lowest by the *Claudian* water. The entire edifice was 70 Roman feet high. The arch of the aquæ-

duct which brought to Rome the *Claudian* water was constructed of beautiful hewn stone. This is represented by Pliny (Hist. Nat. l. 36. c. 15.), as the most beautiful of all that had been built for the use of Rome. It conveyed the water through a vaulted canal, through the distance of 40 miles, and was so high that it supplied all the hills of the city. According to him, and the computation of Budæus, the charge of this work amounted to 1,85,500 crowns. This aqueduct was begun by Caligula, and finished by Claudius, who brought its waters from two springs called *Cæruleus* and *Curtius*. Vespasian, Titus, Marcus Aurelius, and Antoninus Pius, repaired and extended it: it is now called *Aqua Felice*. The aqueduct that conveyed the *Aqua Neroniana* to Rome, was built of brick; this, as well as the former, was 62 Roman feet high. The aqueduct that brought the *Aqua Marcia* into the city was repaired by Agrippa, who laid pipes from it to several parts of the city. The *Aqua Marcia*, *Aqua Julia*, and *Aqua Tepula* (see *AQUA*), entered Rome in one and the same aqueduct divided into three ranges or stories; in the uppermost of which flowed the *Aqua Tepula*, in the second the *Aqua Julia*, and in the lowest the *Aqua Marcia*. This accounts for the extraordinary height of this aqueduct, which far surpassed that of any other in Rome. From the ruins of this fabric, which still subsist, and are called "Il castel del *Aqua Marcia*," it appears to have been a very superb structure. The aqueducts were under the care and direction, first of the censors and ædiles, and afterwards, of particular magistrates called "Curatores Aquarum," instituted by Agrippa, to whom the aqueducts of Rome were objects of particular attention. Messala was one of these curatores in the reign of Augustus, and Frontinus held the same office in that of Nerva. Augustus caused all of them to be repaired. Procopius reckons only fourteen aqueducts in ancient Rome; but Victor has enlarged the number to twenty. Frontinus, a man of consular dignity, and who had the direction of the aqueducts under the emperor Nerva, mentions nine that emptied themselves through 13,594 pipes, of an inch diameter. Vigenere has observed, that in the space of twenty-four hours, Rome received from these aqueducts no less than five hundred thousand hogheads of water. The three chief aqueducts now in being are those of the *Aqua Virginea*, *Aqua Felice*, and *Aqua Paulina*. The first was repaired by Pope Paul IV. The second was constructed by Pope Sixtus V. and is called from the name which he assumed before he was exalted to the papal throne. It proceeds from Palæstrina at the distance of twenty-two miles, and discharges itself at the Fontana di Termini, which was also built at his expence, and consists of three arches, supported by four Corinthian pillars, and the water gushes out through three large apertures. Over the middle arch stands a beautiful statue of Moses striking the rock with his rod; over another arch is a basso-relievo of Aaron leading the people to the miraculous springs in the wilderness; and the third exhibits Gideon trying his soldiers by their drinking water. Round it are four lions, two of marble, and the other two of oriental granite, said to be brought thither from a temple of Serapis. All the four lions eject water; and on the front is an inscription, importing that this aqueduct was begun in the first and completed in the third year of the pontificate of Sixtus V. 1588. The third was repaired by Pope Paul V. in the year 1612. This divides itself into two principal channels, one of which supplies Mount Janiculus, and the other the Vatican and its neighbourhood. It is conveyed through the distance of thirty miles, from the district of Bracciano, and three of its five streams are not inferior to small rivers, and sufficient to turn a mill.

After recounting the ancient and modern aquæducts of Rome, we might mention those constructed by the Romans in other countries: one of the principal of these is the aquæduct of Metz, of which a great number of the arcades still remain. These arcades crossed the Moselle, which is broad and deep; and the copious waters of Gorze furnished water sufficient for the representation of a sea-fight. The water was collected in a reservoir, whence it was conducted by a subterraneous canal formed of hewn stone, and so lofty that a man might walk in it erect; and it then traversed the Moselle, at the distance of two leagues from Metz. This aquæduct was so accurately wrought and firmly cemented, that its parts have in a great degree resisted the floods of the most severe seasons. From the arcades that crossed the river, other aquæducts conveyed the water to the baths of Metz, and also to the place where the naumachia was exhibited. Of the aquæduct of Segovia, there still remain 159 arcades, consisting of stones of an enormous size, and joined without mortar. These arcades are 102 feet high, and are disposed in two ranges, one above the other. The aquæduct traverses the city, and passes under a considerable number of houses. The famous aquæducts of Constantinople, about six miles from the village of Belgrade, were built by Valentinian the first, Clearchus being præfect, and afterwards repaired by Solyman the magnificent, who emptied twelve adjacent Greek villages from the customary tribute of the empire, in consideration of their keeping these aquæducts in repair. Of these the most remarkable are three large and lofty fabrics, built over so many valleys betwixt the adjoining hills, of which the longest has many but less arches, and may possibly (says Chishull, Travels, &c. p. 43.), be the entire work of Solyman. The other two have the appearance of a more ancient and regular architecture, consisting of two rows of arches one over the other; and those of the second were inclosed by pillars cut through the middle, so as to render the fabric both passable like a bridge, and useful for the conveyance of water. The more considerable of these two consists of only four large arches, each twenty yards long, and somewhat above twenty high, supported by octangular pillars of about fifty-six yards in circumference towards the bottom. For an inquiry into the nature and construction of the aquæducts of the Romans, see Governor Pownall's Notices and Descriptions of Antiquities of the Provincia Romana, of Gaul, 4to. 1788. The aquæduct built by Lewis XIV. near Maintenon, for carrying the river Eure to Versailles, is perhaps the greatest now in the world. It is 7000 fathoms long, and its elevation 2560 fathoms; containing 242 arcades. Vide Phil. Trans. ap. Lowth. Abr. vol. i. p. 594.

AQUÆDUCTUS Fallopii, a name improperly given by Fallopius to the bony canal through which the firm portion of the auditory nerve passes out of the cranium.

AQUÆDUCTUS Cottennii, are real aquæducts serving to carry off redundant water from the labyrinth of the ear. For a more full account of each of these articles, see the description of the EAR.

AQUÆDUCTUS Sylvii, the iter a tertio ad quartum ventriculum, or canalis medius. See BRAIN.

AQUÆMANILIS, from *aqua*, water, and *manus*, hand, is particularly used, in Ecclesiastical Writers, for a kind of basin or laver, anciently placed in the vestibules of churches, serving to wash the hands in.

Aquæmanilis stood contradistinguished from *urceolus*, as the former was placed under the hands, the latter above them, from whence the water trickled down by a cock. The priest also, after celebrating mass, washed his fingers in an *aquæmanilis*.

In the inventories of church plate, we frequently find

mention of *aquæmanilis*, *aquaminilia*, *aquiminalia*, of silver gilt, wrought, &c. Du-Cange.

AQUAFFO, in Geography, a town of Africa on the Gold coast, where is held a slave market, to the west of Cape-coast-castle.

AQUAFORT, a settlement on the east side of the south-eastern extremity of Newfoundland island. N. lat. 47° 10'.

AQUAGE, a water-course.

AQUALICULUS, in Anatomy, a name given by some to the region of the body wherein the trunk terminates, and the thighs commence, and in which also the privities are placed.

The *aqualiculus* is the same with what others call *pubes*, others the *hypogastrium*, *fumen*, *imus venter*, &c.

AQUALLA, in Geography, a town of Africa, in the country of Soko, on the Gold-coast.

AQUAMBOE, a kingdom of Africa on the Gold-coast, bounded on the east by the river Volta, and on the west by Agonna. That part of Aquamboe which lies on the coast is called Acra, and might formerly have been an independent state; but it is now dependent and tributary. Aquamboe is one of the most extensive and powerful monarchies on the coast of Guinea; its maritime dominions extending twenty miles along the coast, and ten times as far into the inland parts. The territory towards the coast is said to be divided into a number of petty royalties, but all of them subject to the king of Aquamboe, who exercises an unlimited and indiscriminate authority over them as his meanest subjects; whence it has become a proverb, that in Aquamboe there are only two ranks of men, the royal family and the slaves. The natives of this country are haughty, turbulent and warlike; and their power is formidable to all the neighbouring kingdoms, except Achem. All the tributary nations are grievously infested by the incursions of the Aquamboans. It has been thought that the king and his nobility are richer in gold and slaves, and possess greater treasures than all the kingdoms on the coast of Guinea, at least on the Gold coast; and the extensive commerce of the maritime part of Acra would be much enlarged, if it were not obstructed by perpetual quarrels between the natives of Aquamboe and Achem. The sovereign of the former claims an annual tribute from the latter, the refusal of which excites frequent dissensions; but the former, sensible of the superiority of the latter, diverts the storm by creating discord in the councils of Achem, and thus he artfully contrives to preserve the tranquillity and trade of his realm. The chief business of the people is trade, agriculture, and war; and war in this country promotes trade and husbandry, by increasing the number of slaves and prisoners, who are obliged to labour for the Aquamboans, while they are maintained by them. Of course, they are by interest and inclination much addicted to war. Though the soil is fertile, yet before the expiration of the year, they are under a necessity of seeking supplies from other countries. The Aquamboans, disdain the employments of fishing and making of salt, leave them to the maritime negroes, who are very numerous, and carry on a great trade with the European shipping. The number of slaves sold here is at least equal to what is disposed of on the whole coast beside, not excepting Anamaboa. In time of war, every man fit to bear arms enters the field; and a certain number is detached to cultivate the ground and sell the prisoners, while the rest are engaged in opposing the enemy. Among the fishermen on the coast there are few warriors; for as they live under the protection of the Europeans, and are defended on the north by their more warlike countrymen, they are seldom attacked, or compelled to change the hook and net for the sword and buckler.

bykler. The countries of Labadde, Ningo, and Soko, all of which have parts on the sea coast, are merely divisions of the great kingdom of Aquamboe.

AQUA-NEGRA. See ACQUA-NEGRA.

AQUANILE, a river of Calabria, supposed by Swinburne (*Travels in the two Sicilies*, vol. ii. p. 175.), both on account of its name and position, to be the Hyllas, anciently the limit between Sybaris and Croton. On its banks the Crotoniates gained the victory which made them masters of the Sybaritan territory.

AQUAPENDENTE. See ACQUAPENDENTE.

AQUAPULCO. See ACAPULCO.

AQUARIA. See ACQUARIA.

AQUARIANS, in *Ecclesiastical History*, a sect, toward the close of the second century, who, instead of wine, used nothing but water in the sacrament.

It is said the occasion of the abuse was owing to the persecution which prevailed in those times: for the Christians, being then obliged to celebrate the sacrament in the night, found it necessary to make use of water, lest the smell of the wine should betray them to the heathens. But they afterwards went farther, and actually forbid the use of wine in the eucharist, even when it might be used with safety.

Epiphanius tells us, the Aquarians were the followers of Tatian; and were so called from the word *aqua*, *water*, because they abstained wholly from wine, and did not use it even in the eucharist.

AQUARIUS, in *Astronomy*, the eleventh sign in the zodiac, reckoning from Aries; from which also the eleventh part of the ecliptic takes its name.

The sun moves through Aquarius in part of the months of January and February: it is marked thus, ♒.

The poets feign that Aquarius was Ganymede, whom Jupiter ravished under the shape of an eagle, and carried away into heaven, to serve as a cup-bearer in the room of Hebe and Vulcan; whence the name.—Others hold, that the sign was thus called, because, when it appears in the horizon, the weather usually proves rainy.

The stars in the constellation Aquarius, in Ptolemy's catalogue, are 45; in Tycho's, 41; in Hevelius's, 47; in Flamsteed's *Britannic Catalogue*, 108.

AQUARTIA, in *Botany*, a plant so named by Jacquin, in honour of his friend B. Aquart, merchant in Martinico, who assisted him in his botanical researches. Linn. Gen. 136. Schrebt. g. 176. Jacq. Amer. 15. Juss. 126. Class, *tetrandria monogynia*. Nat. Order, *Solanee* Juss. Gen. Char. *Cal.* perianth monophyllous, permanent; tube, bell-shaped; limb, subquadricid, expanding; two opposite divisions obsolete. *Cor.* monopetalous, rotate; tube, very short; limb, quadricid; divisions linear, spreading. *Stam.* filaments short; anthers erect, very large, linear. *Pist.* germ. ovate; style, filiform, bending, the length of the corolla; stigma simple. *Per.* a berry, globular, one-celled. *Seeds*, very many, compressed.

Ess. gen. char. *Cal.* bell-shaped; *corolla*, wheel-shaped, with linear divisions; *berry*, many-seeded.

Species, 1. *Aquartia aculeata*. This is a perennial spinous plant, with alternate, ovate, obtuse, petioled leaves. Jacquin observes that it rises with a shrubby branched stem, to the height of four feet, producing white flowers, and yellow shining fruit, about the size of a pea. It has the appearance of a solanum, and Swartz thinks that it ought to be considered as one of that genus, with four stamens. A native of the West-Indies, and of South America. Jacq. ed. 2. Am. pict. t. 15.

AQUA-SPARTA, in *Geography*. See ACQUA-SPARTA.

AQUATANIO, or AQUA D'ACIO; a small river of Italy, which runs into the Tiber about a mile from Rome.

AQUATIA, in *Middle Age Writers*, a right of fishing three days in the year. Du-Cange.

In ancient deeds we find divers grants of this privilege of *aquatia*, or *aquatura*; sometimes also called *aquaria*.

In some writings *aquatia* seems also to have signified a fee, or other service, paid for the privilege of fishing.

AQUATIC, something which lives, breeds, or grows on or about the water. Thus we have aquatic plants, and aquatic animals. Trees which grow peculiarly on the banks of rivers, or in marshes, &c. are also called *aquatics*.

The ancient Romans had also their *aquatic* or *aquatile* gods, *di aquatiles*, called by Catullus, *di horales*; concerning whom we have an inscription in Reinsius, SEPTUO ET DIIS AQUATILIBVS.

To this class belonged the Tritons, the ministers of Neptune.

AQUATIC MANURE, in *Agriculture*, a term applied to such manure as is formed in consequence of the dissolution or decay of various aquatic vegetables, and deposited at the bottoms of ponds, ditches and other similar places. It has been observed by Mr. Marshall, in the *Rural Economy of the Midland Counties*, that he dressed two lands with the aquatic manure (raised two or three years before out of a fish-pool, and afterwards turned up into a heap of digests), the rest of the piece being manured with yard dung, the quantity of each about eight loads an acre, the two lands dressed with the aquatic manure were obviously the better crop of turnips; the plants were, he says, not more numerous but larger and cleaner-skinned, and what was remarkable, while the crop of the piece in general was full of cellock and chick-weed, which arose after the hoeing, the two lands where this sort of manure was applied, were in a manner entirely free from these weeds.

AQUATINTA, in the *History of the Arts*, a method of producing engravings very much resembling drawings in Indian ink.

The principle of this process consists in corroding the copper with aquafortis, in such a manner, that an impression from it has the appearance of a tint laid on the paper. This is effected by covering the copper with a powder or some substance which takes a granulated form, so as to prevent the aquafortis from acting where the particles adhere, and by this means cause it to corrode the copper partially and in the interstices only. When these particles are extremely minute, and near to each other, the impression from the plate appears to the naked eye exactly like a wash of Indian ink. But when they are larger, the granulation is more distinct: and as this may be varied at pleasure, it is capable of being adapted with great success to a variety of purposes and subjects.

This powder or granulation is called the aquatinta grain, and there are two general modes of producing it.

We shall first describe what is called the powder grain, because it was the first that was used. Having etched the outline on a copper plate prepared in the usual way by the copper-smith, (for which see the article ETCHING) some substance must be finely powdered and sifted which will melt with heat, and when cold adhere to the plate, and resist the action of aquafortis. The substances which have been used for this purpose, either separately or mixed, are, asphaltum, Burgundy pitch, rosin, gum copal, and gum mastic; and in a greater or less degree all the resins and gum resins will answer the purpose. Common resin has been most generally used, and answers tolerably well; though gum copal makes a grain that resists the aquafortis better. The substance intended to be used for the grain must now be distributed over the plate, as equally as possible; and different methods of performing this essential part of the operation have been used

by different engravers, and at different times. The most usual way is to tie up some of the powder in a piece of muslin, and to strike it against a piece of stick held at a considerable height above the plate. By this, the powder that issues falls gently, and settles equally over the plate. Every one must have observed how uniformly hair powder settles upon the furniture after the operations of the hair dresser: this may afford a hint towards the best mode of performing this part of the process. The powder must fall upon it from a considerable height, and there must be a sufficiently large cloud of dust formed. The plate being covered equally over with the dust or powder, the operator is next to proceed to fix it upon the plate, by heating it gently, so as to melt the particles. This may be effected by holding under the plate lighted pieces of brown paper rolled up, and moving them about till every part of the powder is melted. This will be known by its change of colour, which will turn brownish. It must now be suffered to cool, when it may be examined with a magnifier; and if the grains or particles appear to be uniformly distributed, it is ready for the next part of the process.

The design or drawing to be engraved must now be examined, and such parts of it as are perfectly white, are to be remarked. Those corresponding parts of the plate must be covered, or stopped out, as it is called, with turpentine, or what is better, mastic varnish, diluted with turpentine to a proper consistence to work freely with the pencil, and mixed with lamp-black to give it colour; for, if transparent, the touches of the pencil would not be so distinctly seen. The margin of the plate must also be covered with varnish. When the stopping out is sufficiently dry, a border of wax must be raised round the plate in the same manner as in etching, and the aquafortis, properly diluted with water, poured on. This is called biting in; and it is that part of the process which is most uncertain, and which requires the greatest degree of experience. When the aquafortis has lain on so long that the plate, when printed, would produce the lightest tint in the drawing, it is poured off, and the plate washed with water, and dried. When it is quite dry, the lightest tints are stopped out, and the aquafortis poured on as before; and this is repeated as often as there are tints to be produced in the plate.

Although many plates are etched entirely by this method of stopping out and biting in alternately, yet it may be easily conceived that in general it would be very difficult to stop round and leave out all the finishing touches, as also the leaves of trees, and many other objects, which it would be impossible to execute with the necessary degree of freedom in this manner.

To overcome this difficulty, another very ingenious process has been invented, by which the touches are laid on the plate with the same ease and expedition as they are in a drawing in Indian ink. Fine washed whiting is mixed with a little treacle or sugar, and diluted with water in the pencil so as to work freely, and this is laid on the plate covered with the aquatint ground, in the same manner and on the same parts as ink on the drawing. When this is dry, the whole plate is varnished over with a weak and thin varnish of turpentine, asphaltum, or mastic, and then suffered to dry, when the aquafortis is poured on. The varnish will immediately break up in the parts where the treacle mixture was laid, and expose all those places to the action of the acid, while the rest of the plate remains secure. The effect of this will be, that all the touches, or places where the treacle was used, will be bit in deeper than the rest, and will have all the precision of touches in Indian ink.

After the plate is completely bit in, the bordering wax is taken off by heating the plate a little with a lighted piece of

paper; and it is then cleared from the ground and varnish by oil of turpentine, and wiped clean with a rag and a little fine whiting, and then it is ready for the printer.

The principal disadvantages of this method of aquatinting are, that it is extremely difficult to produce the required degree of coarseness or fineness in the grain, and that plates so engraved do not print many impressions without wearing out. It is therefore now very seldom used, though it is occasionally of service.

We next proceed to describe the second method of producing the aquatint ground, which is generally adopted. Some resinous substance is dissolved in spirits of wine, as for instance common resin, Burgundy pitch, or mastic, and this solution is poured all over the plate, which is then held in a slanting direction till all the superfluous fluid drains off, and it is then laid down to dry, which it does in a few minutes. If the plate be then examined with a magnifier, it will be found that the spirit in evaporating has left the resin in a granulated state, or rather that the latter has cracked in every possible direction, still adhering firmly to the copper. A grain is thus produced with the greatest ease, which is extremely regular and beautiful, and much superior for most purposes to that produced by the other method. After the grain is formed, every part of the process is conducted in the same manner as above described.

Having thus given a general idea of the art, we shall mention some particulars necessary to be attended to, in order to ensure success in the operation. The spirits of wine must be rectified, and of the best quality: what is sold in the shops contains camphor, which would entirely spoil the grain.

Resin, Burgundy pitch, and gum mastic, when dissolved in spirits of wine, produce grains of a different appearance and figure, and are sometimes used separately, and sometimes mixed in different proportions, according to the taste of the artist, some using one substance and some another.

In order to produce a coarse or fine grain, it is necessary to use a greater or smaller quantity of resin; and to ascertain the proper proportions, several spare pieces of copper must be provided, on which the liquid may be poured, and the grain examined before it is applied to the plate to be engraved.

After the solution is made, it must stand still and undisturbed for a day or two, till all the impurities of the resin have settled to the bottom, and the fluid is perfectly pellucid. No other method of freeing it from those impurities has been found to answer. Straining it through linen or muslin fills it with hairs, which are ruinous to the grain.

The room in which the liquid is poured on the plate must be perfectly still, and free from dust, which, whenever it falls on the plate while wet, causes the grain to form a white spot, which it is impossible to remove without laying the grain afresh.

The plate must be previously cleaned with the greatest possible care, with a rag and whiting, as the smallest stain or particle of grease produces a streak or blemish in the grain.

All these attentions are absolutely necessary to produce a tolerably regular grain; and after every thing that can be done by the most experienced artists, still there is much uncertainty in the process. They are sometimes obliged to lay on the grain several times before they procure one sufficiently regular. The same proportions of materials do not always produce the same effect, as it depends in some degree upon their qualities, and it is even materially affected by the weather. These difficulties are not to be surmounted but by a great deal of experience: and those who are daily in the habit of practising the art are frequently liable to the most unaccountable accidents. Indeed it is much to

be lamented, that so elegant and useful a process should be so delicate and uncertain.

It being necessary to hold the plate in a slanting direction in order to drain off the superfluous fluid, there will naturally be a greater body of the liquid at the bottom than at the top of the plate. On this account, a grain laid in this way is always coarser at that side of the plate that was held lowermost. The most usual way is, to keep the coarsest side for the foreground, being generally the part that has the deepest shadows. In large landscapes, sometimes various parts are laid with different grains, according to the nature of the subject.

The finer the grain is, the more nearly does the impression resemble Indian ink, and the sifter it is for imitating drawings. But very fine grains have several disadvantages. For they are apt to come off before the aqua fortis has lain on long enough to produce the desired depth; and as the plate is not corroded so deep, it sooner wears out in printing. Whereas coarser grains are firmer, the acid goes deeper, and the plate will throw off a great many more impressions. The reason of all this is evident, when it is considered, that in the fine grains the particles are small and near to each other, and consequently the aqua fortis, which acts laterally as well as downwards, soon undermines the particles, and causes them to come off. If left too long on the plate, the acid would eat away the grain entirely.

On these accounts, therefore, the moderately coarse grains are more sought after, and answer better the purpose of the publisher, than the fine grains which were formerly in use.

Although there are considerable difficulties in laying properly the aquatint grain, yet the corroding of the copper, or biting in, so as to produce exactly the tint required, is still more precarious and uncertain. All engravers allow, that no positive rules can be laid down, by which the success of the process can be secured: nothing but a great deal of experience and attentive observation can enable the artist to do it with any degree of certainty.

There are some hints, however, which may be of considerable importance to the person who wishes to attain the practice of this art.

It is evident, that the longer the acid remains on the copper, the deeper it bites, and consequently the darker will be the shade in the impression. It may be of some use, therefore, to have several bits of copper laid with aquatint ground of the same kind that is to be used in the plate, and to let the aqua fortis remain for different lengths of time on each; and then to examine the tints produced in one, two, three, four minutes, or longer. Observations of this kind frequently repeated, and with different degrees of strength of the acid, will at length assist the judgment in guessing at the tint which is produced in the plate. A magnifier is also useful to examine the grain and to observe the depth to which it is bit. It must be observed, that no proof of the plate can be obtained till the whole process is finished.
