(SECOND EDITION.)

AMARANTHUS.

AMARANTHUS, *αμαρανθος*, formed from *α*, *μαρανω* and *αθος*, or from *α* and *μαρανω*, and denoting *incorruptible*, because the flower being cropped does not soon wither, in *Botany*, a genus of the *monoecia pentandria* class and order, of the *triandria trigynia* of Gmelin's Linnæus, of the *miscellanea* of Linn. and *amaranthi* of Juss.; its characters are, that those species which have male flowers on the same plants with the females have a *calyx*, which is a five or three leaved perianthium, upright, coloured, and permanent, the leaflets lanceolate and acute; no *corolla*; the *stamina* have five or three capillary filaments, from upright patulous, of the length of the calyx, the anthers oblong and versatile: of those which have female flowers in the same raceme with the males, the *calyx* is a perianthium the same with the former; no *corolla*; the *pistillum* has an ovate germ, styles three, short and subulate; stigmas simple and permanent; the *pericarpium* is an ovate capsule, somewhat compressed, as is also the calyx on which it is placed, coloured, and of the same size, three-beaked, one-celled, cut open transversely; the *seed* is single, globular, compressed, and large. Martyn reckons 29, and Gmelin 22 species. Those with *three stamens* comprehend, 1. *A. gracizans*, pellitory-leaved amaranth, "with glomerules axillary, and leaves lanceolate, repand and obtuse." The stem is a span high, smooth, grooved, and whitish, except at the base, where it is purplish; leaves smooth, green, and marked with lines; petiole very short; the glomerules in pairs, green, four or five-flowered; and the calyx both of the male and female flowers is composed of three subulate, mucronate leaflets: a native of North America; cultivated in Chelsea-garden in 1723; flowers from July to September. 2. *A. albus*, white A. "with glomerules axillary, leaves roundish ovate, emarginate, and stem four-cornered and simple." The stem is a span high, greenish white, decumbent and smooth; the leaves petioled, green, smooth, marked with lines, ending in an herbaceous, reflex, minute, whitish point;

the petioles winged and channelled, and almost the length of the leaves; glomerules in pairs, sessile, and few-flowered; leaflets of the calyx oblong-lanceolate and whitish, with a green nerve, and at the end a subulate, herbaceous point; nearly related to the first species; a native of Pennsylvania, whence it was brought to Italy, introduced here in 1778 by M. Thouin; flowers in July and August. 3. *A. deflexus*, "with spike very short with few flowers, leaves rhomb-lanceolate, and capsules not gaping;" the stem weak, filiform, decumbent, divided at the base into a few branches, green, except at bottom, where it is brownish, round, slightly flreaked and smooth; leaves green and smooth; petioles channelled and green; spike solitary, composed of only five or six flowers; no lateral glomerules, but a flower or two scattered in the axils of the leaves; the calyx five-leaved; leaflets diaphanous, white, oblong, and edged with green; distinguished from the rest by the capsules not opening transversely, but being entire. Its native place is unknown. 4. *A. polygonoides*, spotted-leaved A. blitum of Brown, Jamaic. and chenopodium of Burm. Zeyl. "with three-leaved glomerules, female flowers funnel-shaped, and leaves rhomb-ovate, emarginate." The stem is red and smooth; the leaves smooth and green; the petioles green and channelled; the glomerules axillary, with from six to eight flowers in each; the calyx of the female flower one-leaved and ventricose; the five segments spreading much, and transparent white; the capsules falling with the calyx when the seed is ripe; the calyx of the male-flower three-leaved, membranaceous and transparent; the leaflets oblong and obtuse, with a green nerve. This species varies in different situations, it resembles the second, but differs from it in having the stem round, and the calyx of the female flowers one-leaved and funnel-shaped: it is found wild by waysides and among rubbish in the tropical countries of Asia, Africa, and America, as in Jamaica, Guiana, Senegal, Gui-

VOL. II.

B

nea,

nea, Ceylon, &c. introduced here in 1778 by M. Thouin; and flowers in August. 5. *A. polygamus*, hermaphrodite A. "with glomerules two-flamened, subspiked and ovate, flowers hermaphrodite and female; leaves lanceolate;" the stem $1\frac{1}{2}$ foot high, green, streaked and smooth, leaves petioled and naked; from the axils proceed a branch and a head, consisting of a many-flowered peduncle, with a branch on each side at the base converging into a green head; spike short, ovate, and small; the hermaphrodite flowers with two lamens and two styles, the female with three styles; a native of Guiana, China, Cochin, and Amboina: the leaves and stalks boiled are eaten with oil and pepper by the inhabitants, and much liked; it was introduced here by Sir Joseph Banks in 1780; and flowers in July and August. 6. *A. mangostanus*, "with glomerules subspiked, axillary and solitary, and leaves rhomb-roundish;" the stem is above a foot high, streaked, green, smooth, and decumbent; the leaves smooth and green, with a small brittle, almost as broad as long; petioles as long as the leaves, smooth and channelled; the flowers in large, roundish glomerules, from the axils, on short peduncles, and forming at the top a close, nodding spike; the calyces five-leaved, the leaflets white-membranaceous, transparent, oblong, with a green nerve, terminating in a brittle of the same colour: a native of the East Indies. 7. *A. inamxenus*, "with glomerules subspiked, three-leaved, axillary, geminate, and leaves rhomb-lanceolate." This species very much resembles the last, but differs in having a three-leaved calyx, the glomerules axillary and in pairs, the spike terminating, erect, and more slender, the leaves rhomb-lanceolate, and the petioles shorter than the leaves: supposed to be a native of Japan. 8. *A. melancholicus*, two-coloured A. "with glomerules axillary, peduncled, roundish, and leaves ovate-lanceolate and coloured." This species varies in the colour of the leaves; being in the open air of a dingy purple on their upper surface, and the younger ones green; in a stove the whole plant is purple-coloured; but it is easily distinguished in all states by its colour, leaves, and the lateness of its flowering after all the others are past: it is joined by La Marck with *A. tricolor*; a native of Guiana and the East Indies, and cultivated in 1731 by Miller. The obscure purple and bright crimson of the leaves are so blended as to set off each other, and, in the vigorous state of the plants, to make a fine appearance. 9. *A. gangeticus*, oval-spiked A. "with glomerules in very short spikes, ovate, and leaves ovate-lanceolate, emarginate." Mr. Martyn suggests, that this may be a variety of the preceding species, but differs from it in having a terminating spike, axillary, sessile glomerules, leaves less waved or wrinkled, and also in its colour: its stem being dark red, leaves green above and red below, petioles red, and glomerules of a reddish green colour; it is a native of Bengal and the Society Isles; was introduced here in 1778 by M. Thouin, and flowers from July to September. 10. *A. oleraceus*, eatable A. "with glomerules axillary, branching, and leaves wrinkled, oblong, very obtuse and emarginate." It resembles the next species, but differs from it in the great bluntness of the leaves, deeply emarginate, in the edge of the leaf being neither red nor waved, in the glomerules being branched and solitary, and in the peduncles and pedicels not being flexuose: a native of Guiana, the East Indies, and Egypt. This, which deserves no place in a garden on account of its beauty, and the next species, are in some parts of India used as esculent herbs; they are gathered young, and dressed like spinach, but much inferior to it: cultivated in 1768, by Mr. Miller; flowers in July. 11. *A. viridis*, green A. "with glomerules axillary, geminate trifid male flowers, ovate, emarginate leaves, and erect stem." This sort is distinct from all the rest in having the bristles

not surrounding the flowers, but scattered along the rachis of the glomerule: a native of Jamaica and Brasil; confounded by European botanists with a variety of *A. blitum*; cultivated in 1768 by Miller; flowers in August and September. 12. *A. tricolor*, three-coloured A. "with glomerules sessile, roundish, stem-clasping, and leaves lanceolate-ovate, coloured." This has been long cultivated, being in the garden of Gerard in 1596, for the beauty of its variegated leaves, in which the colours are elegantly mixed; these, when the plants are vigorous, are large and closely set from the bottom to the top of the stalks, and the branches form a kind of pyramid, and therefore there is not a more handsome plant when in full lustre; a native of Guiana, Persia, Ceylon, China, Japan, the Society Isles, &c. 13. *A. lividus*, livid A. "with glomerules subspiked, rounded, leaves elliptic, retuse, and upright stem." This species is a native of Virginia and Guiana; was cultivated in 1768 by Miller, and flowers from July to September. 14. *A. trifidis*, round-headed A. "with glomerules in loose spikes, leaves subcordate-ovate, emarginate, shorter than the petioles." This species is nearly related to the last, but may be easily distinguished by its upright stalk, more loose and slender spike, rhomboidal leaves, and five-leaved calyx: it is a native of China, Cochin, Amboina and Brasil, and used as we do spinach; cultivated in 1759 by Miller, and flowers from June to August. 15. *A. Blitum*, leaf A. or blite, "with glomerules subspiked, three-leaved flowers, leaves ovate-retuse, and diffused stem." There are three varieties, viz. *blitum album majus*, *bl. majus rubrum*, and *bl. rubrum minus*. This is a native of all Europe, except the very cold parts, Japan, &c. in cultivated grounds, on dunghills, banks, among rubbish, &c. 16. *A. scandens*, climbing A. "with spikes interrupted, compound, spikelets, bent in, leaves ovate, and stem weak." It resembles the foregoing species, and is a native of America.

The species with five stamens are, 17. *A. boëticus*, "with flowers in simple spikes, axillary, and glomerate, and leaves ovate, acute." It is doubtful whether this be a distinct species, or merely hybridous; it connects, in point of outward form, the three-stamened and five-stamened amarantus, varies much, and its native place is not known. 18. *A. hybridus*, clustered A. "with racemes decomposed, heaped, erect, and leaves ovate-lanceolate." Willdenow enumerates four varieties: 1. wholly green; 2. with a red stalk; 3. with the racemes reddish, the rest green; 4. with red racemes. These differ in appearance, but are produced by the same seed. This species is found wild in Virginia and Arabia Felix; was cultivated in 1656 by Mr. J. Tradescant, jun. and flowers from June to September. 19. *A. stricus*, "with racemes compound, erect, strict, and leaves ovate, concave." This differs from the five-stamened species in its upright racemes pressed close to the stalk, and the stiffness of the whole habit. Its native place is not known. 20. *A. latus*, "with racemes compound, erect, and leaves ovate, obtuse, and mucronate." It much resembles *A. hybridus*, but is distinguished from it by having the leaves blunt at the end, and being much smaller in stature, the stem never rising more than a foot high. 21. *A. cruentus*, various-leaved A. "with racemes decomposed, naked, patulous, and leaves lanceolate-ovate." This species varies, of a shining red colour, with a red stalk, with pale leaves, with a green stalk, with variegated leaves, &c. When first cultivated in England in 1728, the stem was wholly red and smooth, the petioles, ribs, and nerves of the leaves underneath purple; the spikes purple, much spreading, and a little nodding. They were very beautiful for the first two years, but the seeds degenerated, and the plants had little beauty. It is a native of the East Indies and of China, and flowers from June to August. 22. *A. hypochondriacus*,

A M A R A N T H U S.

driacus, prince's feather A. "with racemes compound, crowded, erect, and leaves oblong-lanceolate, and mucronate." This approaches very nearly in structure and variableness of colour to A. hybridus, and is distinguished from it, but not without difficulty, by the greater redness of the racemes, and sharpness of the leaves at the end, and by the base of the leaves running far down along the petiole; upon the whole, says Mr. Martyn, it seems to be only a variety of that. It is a native of Virginia, and flowers from July to September; was cultivated by Miller in 1739, but is now become a common weed, frequently growing upon dunghills, and abundantly scattering its seeds. 23. *A. sanguineus*, spreading or bloody A. "with racemes compound, erect, branches spreading and smooth, and leaves oblong and acute." The seeds were sent to Mr. Miller from the Bahama island before 1755, as an esculent plant, bearing fine flowers; and he describes it as growing three feet high, with purple stalks and leaves, the spikes short and swelling out in the middle, and at the extremity of the stalk arises a large cluster of spikes transversely, with one upright stalk in the middle; and these are of a bright purple colour at first, but become darker as the seeds ripen; it flowers from the middle of June to September. 24. *A. paniculatus*, "with racemes compound, branches spreading, pubescent, and leaves ovate-lanceolate." This differs from *A. sanguineus* in its pubescent branches, pointed calyxes, closer glomerules, and the whole habit: it is a native of America. 25. *A. retroflexus*, hairy A. "with racemes super-decompound, erect, branches pubescent, and leaves ovate, waved." It approaches to the last species in the pubescence of the racemes, but differs in having green spikes, setaceous-fimbulate bractes, and leaves waved about the edge: it is a native of Pennsylvania, flowers from July to September, was cultivated by Miller in 1759, and is now become a common weed in many gardens near London. 26. *A. chlorostachys*, "with racemes compound, nodding, and lanceolate leaves." It resembles *A. retroflexus*, but differs from it in its smooth stalk, lanceolate, flat leaves, glomerules in more distant racemes, and in being much more slender: its native place is not known. 27. *A. flavus*, pale A. "with racemes compound, nodding, and leaves ovate-lanceolate." It differs from the last in the form and waving of the leaves, in the red lines on the stalk, in the red rachis of the flowers, and in the greater closeness of the racemes; and from *A. retroflexus*, in having the leaves less waved, ovate-lanceolate, and much less obtuse, the stem at bottom and the petioles smooth, and the colour in the stem, rachis, and veins of the leaves red. The flowers, notwithstanding the epithet *flavus*, are always green, and only turn yellow as the seed ripens: it is a native of the East Indies, and cultivated by Miller in 1768. 28. *A. caudatus*, pendulous A. or love-lies-bleeding; there is a variety, which is *A. maximus*, or tree A. the blitum maximum of many authors. This last is made by Mr. Miller a distinct species; it rises to the height of seven or eight feet; the spikes are seldom half as long as the other, which are $2\frac{1}{2}$ feet, but much thicker. This degenerates gradually into the smaller; and the seeds, which are at first white, become red. It flowers in August and September, and was cultivated in 1683 by Mr. James Sutherland: it is a native of Persia, Ceylon, Guiana, Peru, &c. 29. *A. spinosus*, prickly A. "with racemes terminating, compound, and axilsthorny." This varies, with the spikes and stem reddish: a native of the East and West Indies, Guiana, Guinea, &c.; in the former it is eaten as a green boiled with *basella cordifolia*; it was cultivated in 1683 by Mr. J. Sutherland, and flowers from July to September.

The amaranths are annual, herbaceous plants, and most of the species are used as culinary plants in hot countries.

Culture of Amaranths. Those most worthy of a place in the pleasure-garden are the 8th and 12th; but they are tender and require attention. They are usually disposed in pots, with cocks-combs and other showy plants for adorning court-yards, and the environs of the house. Next to these are the 23d and 28th sorts, for the ornaments of the principal borders in the pleasure garden or parterres. The seeds of these should be sown in a moderate hot-bed, about the end of March; and when the plants come up, they should have much air in mild weather. When they are fit for transplanting, they should be removed to another moderate hot-bed, and placed at six inches distance, watering and shading them till they have taken new root; afterwards they should have free air, and frequent but gentle waterings. In the beginning of June they should be taken up with large balls of earth to their roots, and planted either in pots or the borders of the pleasure-garden, shaded till they have taken root, and afterwards frequently watered in dry weather. The tree Amaranth must be planted in a rich light soil, and if it be allowed room, and well watered in dry weather, it will grow to a large size, and make a fine appearance. The 21st is a tender plant, and should be treated like the 23d and 28th. The other sorts are sufficiently hardy to bear the open air, and may be sown on a bed of light earth, in the Spring, and when the plants are fit to remove, transplanted into any part of the garden, where they will thrive and produce plenty of seeds. The 23d and 28th sorts must be sown on a good hot-bed in February, or at the furthest in the beginning of March; and they will rise in about a fortnight; soon after which another hot bed must be covered with good, rich, light earth, about four inches deep; and the plants carefully raised and pricked out into this bed, at the distance of four inches every way, and gently watered. In the middle of the day let them be secured with mats from the heat of the sun, and raise the glasses to give them air; the glasses should be kept dry, for the moisture exhaled by the fermenting dung and perspiring plants is very injurious. When the plants are firmly rooted give them air every day, more or less, as the weather is cold or hot. In about three weeks or a month these plants will have grown so as to meet, and must be removed into another hot-bed, with the same rich earth, about six inches thick; observing to take as much earth about their roots as possible, and to plant them at the distance of six or seven inches every way, watering them, so as to settle the earth about their roots. In the heat of the day let them be shaded; refresh them often with gentle watering; and give them air according to the heat of the weather, and cover the glasses every night with mats. In three weeks more, the plants will have acquired a considerable size and strength, and should be exposed more and more to the open air, when the weather will permit, and thus they will become sufficiently hardened to bear being removed into the places where they are to continue the whole season; but they should not be placed in the open air till after the first week in July, and this should be done, when the air is perfectly soft, and, if possible, in a gentle shower of rain. These plants, when grown to a good stature, perspire very freely, and should, therefore, be every day refreshed with water, if the weather be hot and dry. By this management fine amaranths may be obtained; and these plants, when properly reared, are the greatest ornament to a good garden, for upwards of two months in the latter part of the summer.

Amaranths are very prolific. Willdenow says, that he saved eight ounces of seed from one plant of *A. caudatus*. The seeds retain their germinating quality for several years, but continue longer in the ground than fresh seeds, which

germinate in eight days. Gmelin's Linn. Martyn's Miller. Willdenow.

AMARANTHUS. See ACHYRANTHES, CELOSIA. ILICEBRUM, IRESINE, and RHYSA.

AMARANTHUS luteus. See GNAPHALIMUM.

AMARANTHUS maritimus, Valent. ind. 3. t. 52. f. C. C. This is also the *inugus lapideus undulatus* of Sloane, Catal. p. 2. Jam. i. p. 59: the mycedium cavatum undulatum of Hill. plant. p. 3, and cerebrites of Knorr. delie. tom. A. xi. f. 1. 2.—Linnæus describes it under the specific name of *areola*, as a mushroom. See AREOLA.

AMARDUS, in *Ancient Geography*, a river of Media, which discharged itself into the Caspian sea.

AMARELLA, in *Botany*. See GENTIANA.

AMARGURA, in *Geography*, an island in the Southern Pacific Ocean, lying in S. lat. 17° 57'. W. long. 175° 16' 54". This was the first island discovered by Maurelle, in approaching the Friendly islands in 1781; he called it *Amargura*, i. e. bitterness, on account of his severe disappointment of obtaining refreshments from it; no landing place being found even for boats, and the island itself having a singular appearance of barrenness. In 1791, Captain Edwards coasted the north-west side of this island, observed much smoke upon it, and called it Gardner's island.

AMARIACÆ, in *Ancient Geography*, a people of Asia, in the interior part of Media, near the Mardi, according to Ptolemy.

AMARISCOGGIN RIVER, in *Geography*. See ANDROSCOGGIN.

AMARISPII, in *Ancient Geography*, a people of Asia, in Bactriana, according to Ptolemy.

AMARNA, or AMARUSA, a town placed by Ptolemy in Hyrcania.

AMARULA, in *Conchology*, a species of HELIX, that inhabits the rivers and fresh waters in India: shell imperforate, or without *umbilicus*, oblong; whorls beset with spinous teeth. Linnæus adds to this concise description, that the shell is black, without spots, the spiral striæ sub-convex, and the number of whorls either five or six, each armed along the upper edge with ten sharp spines: the aperture or mouth widely gaping and white, the exterior lip acute, the interior one thick. This shell is likewise defined by another author, *buccinum testa subovata nigra; anfractibus sursum muricatis*; Mull. Hist. Verm. ii. p. 137, n. 330, and is supposed to be the *voluta fluviatilis* of Rumpf. Mus. tom. xxxiii. f. F. F.—Length from nine to 19 lines.

AMARUMAYE, in *Geography*, a river of America, which rises in the Cordelier mountains, and after a course of 400 leagues, joins the river of the Amazons, in S. lat. 5°.

AMARUS, in *Ichthyology*, a species of the CYPRINUS, that inhabits the clear streams of Germany. Its specific character is taken from the number of bony rays in the pectoral and ventral fins, of which there are seven in each; as a secondary character the dorsal fin is said to contain ten rays, the anal eleven, and the caudal twenty rays. The head is small and cuneate or wedge-shaped, the eyes minute, with the iris red and yellow; the jaws equal, gill covers yellow. The body is pellucid, silvery and finely speckled with black; above the lateral line yellow, back greenish, chalybeate-black near the tail. Upper fins reddish, lower fins greenish.

AMARYLLIS, derived either from the name of a shepherdess, mentioned by Theocritus and Virgil, or from *αμαρυλλις* or *αμαρυνη*, *splendor*, *lilio-narcissus* of Tournefort, in *Botany*, a genus of the *hexandria monogynia* class and order, of the natural order of *lilia* or *liliaceæ*, the *spatheæ* of Linn. and *narcissi* of Juss.; its characters are, that the *calyx* is a *spathe*, oblong, obtuse, compressed, emarginate,

gaping on the flat side and withering; the *corolla* has six petals, lanceolate, the nectary has six very short scales without the base of the filaments; the *stamina* have six awl-shaped filaments, with oblong, incumbent, rising anthers; the *pistillum* has a roundish, furrowed inferior germ, the style filiform, almost of the length and in the situation of the filament, the stigma trifid and slender; the *pericarpium* is a subovate, three-celled, three-valved capsule; and the *seeds* are several. The inflection of the petals, filaments, and pistil is very various in the different species of this genus; and the corolla in most of the species is rather hexapetaloid than six-petalled. Gmelin reckons 27, Mr. Martyn 29, and Willdenow 38 species.

Those with a *one-flowered spathe* are as follow: 1. *A. lutea*, yellow A. or autumnal narcissus, *colchicum luteum-majus* of Baulhin, "with an undivided obtuse spathe, sessile flower, bell-shaped corolla erect, shortly tubular at the base, and erect stamens, alternately shorter;" the flowers seldom rise above three or four inches high; the green leaves come up at the same time, and when the flowers are past, the leaves increase through the winter. This species recedes a little from the genus. It is a native of the south of France, Spain, Italy, and Thrace, was cultivated by Gerard in 1596, and flowers in September. 2. *A. Pumilio*, dwarf A. "with two-leaved, one-flowered spathe, corolla funnel-shaped, equal, segments revolute, and stamens bent in and alternately shorter." This is a native of the Cape of Good Hope, was introduced here in 1774, and flowers in November. 3. *A. Atamafco*, *atamafco lily*, "with spathe bifid, acute, flower pedicelled, corolla bell-shaped, nearly equal, erect, shortly tubular at the base, stamens bent down and equal." The flowers are at first of a fine carnation colour on the outside, but fade till they are almost white; they appear at the end of May or beginning of June, and sometimes in August. This is a native of Virginia and Carolina, where it grows plentifully in the fields and woods, and was cultivated here by Mr. Charles Hutton in 1780. 4. *A. formosissima*, *jacobeæ lily*, so called, because some imagined that they discovered in it a likeness to the badge of the order of the knights of the order of St. James, in Spain, the *lilio-narcissus* and narcissus of others, "with a spathe undivided, flower pedicelled, corolla two lipped, nodding, deeply six-parted, stamens and pistil bent down." The flowers are produced from the sides of the bulbs, are large, of a deep red, and make a beautiful appearance; it is a native of America, first known in Europe in 1593, some roots of it having been found on board a ship, which had returned from South America, by Simon de Tovar, a physician at Seville; he sent a description of the flowers to Clusius, who published a drawing of it in 1601, called by Parkinson, by whom it was figured in 1629, the *Indian daffodil*, with a red flower; cultivated in the Oxford garden in 1658. 5. *A. tubifspathe*, "with spathe one-leaved, tubular, bifid and one-flowered, and peduncle twice as long as the spathe;" found at Buenos Ayres, by Commerson. 6. *A. subiflora*, "with spathe one-flowered, two-leaved, corolla funnel-shaped, with a very long tube;" found in the sandy lands of Lima. 7. *A. maculata*, "with spathe one-flowered, two-leaved, linear, flower peduncled, stamens and style bent down;" found in Chili by Dombey. 8. *A. chilensis*, "with spathe one or two-flowered, one or two-leaved, lanceolate, flowers peduncled, and leaves linear." The flowers, which are those of *A. belladonna* or *reginæ*, are of a purple colour; found in Chili by Dombey. 9. *A. clavata*, "with spathe one-flowered, two-leaved, subulate, and corolla club-shaped:" native of the southern part of Africa.

The species with a *two-flowered spathe* are, 10. *A. reginæ*, Mexican lily, "with spathe, having about two flowers, pedicels divaricating, corollas bell-shaped, shortly tubular, nodding, throat of the tube hirsute, and leaves lanceolate, patulous;"

patulous ;" the bulb is green, corolla scarlet, and at the bottom whitish green, the style red, the flowers large, of a bright copper colour, inclining to red: it flowered in Fairchild's garden, at Hoxton, in 1728; and Dr. Douglas wrote a folio pamphlet upon it, giving it the title of *lilium reginae*, because it was in full beauty on the 1st of March, the queen's birth-day: the roots were brought from Mexico, and therefore Mr. Fairchild called it Mexican lily, the name which it has retained: it flowers in the spring in a very warm stove; is in beauty in February, and in a moderate temperature of air, will flower in March or April. 11. *A. purpurea*, purple flowered *A. crinum speciosum* of Linn. Suppl. "with spathe, having about two flowers, corollas somewhat erect, tubular at the base, throat of the tube smooth, and leaves linear-lanceolate:" nearly allied to the last: the corolla large, and of a blood-red purple colour; a native of the Cape of Good Hope, and introduced here in 1774. 12. *A. linearis*, crinum lineare of Linn. Suppl. "with linear leaves, bell shaped corollas, two and narrower segments;" the flowers are large and white; found at the Cape of Good Hope. 13. *A. equesfris*, Barbadoes lily, *A. dubia* of Linn. Amœn. Acad. "with spathe having about two flowers, pedicels erect, shorter than the spathe, tube filiform and horizontal, border spreading, open obliquely and curved upwards, and throat hairy;" a native of the West Indies; introduced by Dr. W. Pitcairn in 1778. 14. *A. reticulata*, flat-stalked *A.* "with spathe having about two flowers, corollas tubular at the base, and nodding, throat of the tube smooth, scape compressed, leaves oblong and attenuated at the base;" distinguished by the transverse veins of the petals and smoothness of the throat; a native of Brasil; and introduced by Dr. E. W. Gray in 1777. 15. *A. tatarica*, "with spathe having about two flowers, corolla sub-campanulated, and deeply six-parted, segments superior, very narrow, inferior obovate acuminate, and leaves linear, longer than the scape." found in Siberia.

The species with a *many flowered spathe* are, 16. *A. Belladonna*, Belladonna lily, "with corollas somewhat erect, six-petalled, petals flat, scape compressed, leaves sharply channelled, bluntly keeled, and very smooth." This species differs from the *A. reginae*, by having the edges of the petals waved, and not reversed at the tip: was first brought to England about 1712, from Portugal, abounds about Florence, and fold under the name of Narcissus Belladonna; usually flowers in England about the end of September or beginning of October, and the stem rises upwards of two feet in height; in a favourable season, and, when screened from frosts, high winds, and heavy rains, will continue in beauty a month or longer, and is an ornamental plant, when other flowers are scarce; a native of the West Indies, on shady hills, by the side of streams. 17. *A. vittata*, superb or ribband *A.* "with flowers pedicelled, corollas wedge-funnel shaped, the rachis of the outer fastened to the edge of the inner petals, scape round, and stigmas grooved." It is striped with red on a white ground, whence its name vittata or ribband *A.*; in perfect blossom, it deserves the name of superb, given to it by Aiton, its stem rising to the height of three or more feet, and producing from two to five beautiful flowers; usually blossoms in April or May; is probably a native of the Cape: and introduced into England by Mr. W. Malcolm, in 1769. 18. *A. falcata*, sickle-leaved *A.* or crinum, "with corollas peduncled, erect, six-petalled, scape compressed, of the length of the umbel, leaves flat, pressed to the ground, about the edge sickle-shaped, white, cartilaginous and crenate." It is a native of the Cape, and introduced here in 1774, by Mr. F. Masson. 19. *A. ornata*, cape coast lily or *A.* "with flowers sessile, corollas tubular at the base, tubes longer than the spathes, and

border, curved, segments of the border oblong, awned, lowest segment divaricate and concave." It is a native of Guinea, probably cultivated by Lord Petre, in 1740, and flowers with us in June and July. 20. *A. longifolia*, long-leaved *A.* "with flowers pedicelled, 12—20 in a spathe, corollas tubular at the base, tube curved, short, segments of the borders lanceolate, obtuse, leaves broad subulate, channelled, and flaccid at the tip." It is a native of the Cape of Good Hope, introduced in 1773, by Mr. F. Masson, and flowers in July. 21. *A. montana*, "with many-flowered spathe, leaves linear-subulate, petals alternate, mucronate, stamens and style erect;" or, according to Willdenow, "with bell-shaped equal corollas, segments alternate, awned, stamens and style straight, and twice shorter than the corolla, foliose scape and linear leaves." This is a native of the higher parts of Mount Lebanon. 22. *A. zeylanica*, Ceylon lily, Javan tulip of Rumphius, "with many-flowered spathe, corollas reclining, tube filiform, very long, and segment uncinate." This is a native of the East Indies. 23. *A. revoluta*, revolute *A.* "with flowers pedicelled, corollas tubular, at the base, tube filiform, short, curved, leaves linear, narrow, channelled, long, flaccid from their origin." It is a native of the Cape of Good Hope, introduced here in 1774, and flowers in September. 24. *A. latifolia*, crinum latifolium of Linn. Miller, and Rheed, "with many-flowered spathe, flowers pedicelled, somewhat reclining, tubular at the base; and leaves oblong-lanceolate." It is found in the sandy soil of the East Indies. 25. *A. aurea*, golden *A.* "with flowers pedicelled, somewhat erect, corollas funnel-form club-shaped, almost six-petalled, segments linear, lanceolate, stamens and style straight, leaves linear, erect, channelled, with a reflex, smooth margin." It is a native of China, introduced in 1777, by Dr. Fothergill, and flowers in August and September. 26. *A. orientalis*, broad-leaved African *A.* "with many-flowered spathe, flowers pedicelled, six-parted, considerably shorter than the peduncles, irregular, germs wedge shaped and angular." It is a native of the Cape of Good Hope, whence Mr. Miller received the roots which succeeded in the Chelsea garden; in the Kew catalogue, said to be introduced in 1767, by Mr. W. Malcolm. 27. *A. sarniensis*, lilium sarniense of Douglas, who published a description of it in 1725, Narcissus of others, Guernsey lily, so called by Mr. Ray in 1665, "with petals linear, flat, stamens and pistil straightish, longer than the corolla, stigmas parted and revolute." The bulb is an oblong spheroid; the leaves are dark willow green; the number of flowers is commonly from eight to twelve, and circumference of each about seven inches; the corolla, in its prime, has the colour of a fine gold tissue wrought on a rose-coloured ground, and when it begins to fade, it is a pink; in full sunshine, it seems to be studded with diamonds, but by candle-light the specks or spangles appear more like fine gold dust; when the petals begin to wither, they assume a deep crimson colour. The flowers begin to come out at the end of August, and the head is usually three weeks in gradually expanding. This beautiful plant is a native of Japan, and has been long naturalized in Guernsey. It is said to have been brought from Japan to Paris, and cultivated in Morin's garden before 1634. It was cultivated at Wimbledon, in England, by general Lambert, in 1659, and in 1664 became more common: it does not seem to have been in Holland before 1695. The plants are reputed to owe their origin in Guernsey to the shipwreck of a vessel returning from Japan, probably before the middle of the 17th century. The bulbs, it is said, being cast on shore, took root in that sandy soil, and produced beautiful flowers, which engaged the attention of Mr. Hatton, the governor's son, who sent roots to several of his friends. A variety of this

found at the Cape of Good Hope is described by Jacquin, "with a many-flowered spathe, corollas very patent, and reflex at the apex, stamens and pistil somewhat straight, longer than the corolla, and leaves ensiform-linear." 28. *A. marginata*, "with oblong revolute petals, stamens and pistil somewhat straight, longer than the corolla, linguulate leaves pressed to the ground, cartilaginous-marginate;" or, according to Jacquin's description, "with a many-flowered spathe, corollas very broad, and reflex at the apex, erect pedicles, sublinguiform and prostrate leaves, terminated with a margin coloured, and undulated towards the apex." This is a native of the Cape of Good Hope. 29. *A. curvifolia*, "with oblong, waved, revolute petals, stamens and pistil somewhat straight, and longer than the corolla, with leaves stiff, linear-ensiform and canalculated;" or, according to Jacquin, "with many-flowered spathe, revolute, undulated corollas, erect pedicles, and leaves sublinear, widely channelled, and subfoliolate." This is a native of the Cape of Good Hope. 30. *A. undulata*, waved flower African A. "with linear channelled, waved petals, stamens and pistil bent down, shorter than the corolla, and obsolete stigma." The flowers have no scent, and expand from November to the beginning of January: a native of the Cape of Good Hope, introduced about 1767, by John Blackburne, esq. and flowers here from April to June. 31. *A. radiata*, snow-drop leaved A. "with lanceolate, waved petals, stamens and pistil bent down, diverging, twice as long as the corolla, and obsolete stigma." The native place of this species is unknown, cultivated by Miller in 1758, and flowers in June. 32. *A. humilis*, "with three or four-flowered spathe, lanceolate, subringent-patent petals, waved-reflex at the apex, with the lowest divaricated, the stamens and pistil ascending, shorter than the petals, and leaves linear, obtuse, smooth, naked and flat;" or, according to Jacquin, "with few-flowered scapes, patent petals, the lowest divaricated, and leaves linear, obtuse, and flat." It much resembles the next species, but the scape and leaves are twice less; a native of the Cape of Good Hope. 33. *A. flexuosa*, "with many-flowered spathe, petals lanceolate, subringent-patent, waved-reflex at the apex, the lowest divaricated, the stamens and pistil ascending, shorter than the petals, and leaves linear, somewhat obtuse, concave, and pustulate dotted;" or, according to Jacquin, "with many-flowered spathe, patent petals, the lowest divaricated, and linear, pointed leaves." The younger leaves are marked with white pustules; the more adult pointed, and when dry the points vanish; a native of the Cape of Good Hope. 34. *A. radula*, "with many-flowered spathe, petals lanceolate, subringent-patent, flat, the lowest divaricated, the stamens and pistil ascending, of the length of the petals, with leaves elliptic, pressed to the ground, and roughly pustuled;" a native of the Cape of Good Hope. 35. *A. striata*, "with many-flowered spathe, corollas bell-shaped, shortly tubulous, segments flat, reflex at the apex, stamens and pistil ascending, and the leaves elliptic-ovate, erect, and marginated;" or, according to Jacquin, "with many-flowered spathe, corollas bell-shaped, equal, and reflex at the apex, sub-ovated leaves, and striated on the back;" a native of the Cape of Good Hope. 36. *A. crispa*, "with few-flowered spathe, petals very patent, oblong, obtuse, and waved, stamens divaricated and shorter than the corolla, straight style, and leaves linear-filiform, and lax;" or, according to Jacquin, "with few-flowered spathe, petals very patent and crisp, and leaves linear and very narrow." The flowers are very small: a native of the Cape of Good Hope. 37. *A. stellaris*, with many-flowered spathe, corollas patent and flat, a very short tube, stamens unequal, divaricated, shorter than the corolla, straight style, and leaves linear and erect;" or, according to Jacquin, "with many-flowered spathe, very patent petals three, alternate,

and barbated below the middle;" a native of the Cape of Good Hope. 38. *A. cypria*, crinum caspiem of Pallas, "with many-flowered spathe, bell-shaped corollas, very short tube, filaments erect, longer than the corolla, and leaves lanceolate and waved;" found near the Caspian Sea, in the beginning of Spring. 39. *A. spiralis*, "with spathe two-leaved, few-flowered, peduncles filiform, very long, and leaves subulate." L'Heritier. This species was discovered by Bruguere in sandy grounds near the Cape of Good Hope. 40. *A. cinnamomea*, "with many-flowered spathe, corollas sub-hexapetalous, lanceolate, waved, stamens and pistil erect, shorter than the corolla." L'Heritier. This species is allied to *Hæmanthus*: was found by Bruguere at the Cape of Good Hope. 41. *A. alba*, "with flowers declining, and leaves linear-lanceolate." Forst. Fl. Æg. Arab. p. 209. Martyn. Gmelin's Linnæus. Willdenow.

Culture and Propagation. Most of these species have very beautiful flowers, and merit the attention of the botanist and florist. The first, or yellow autumnal A. is very hardy, and increases by offsets. The season for transplanting these roots is from May to the end of July, when the leaves are decayed. They will grow in any soil or situation; but they will thrive best in a fresh, light, dry soil, and open situation, and will keep flowering from the beginning of September to the middle of November, provided that they escape severe frosts; and a succession of flowers will spring from the same root. The third, or Atamasco lily, may be propagated by offsets from the bulbs, and will thrive in the open air on a dry soil, and in a warm situation. The 4th, or Jacobæa lily, is propagated by offsets, which are taken off every year; and the best time for shifting and parting the roots is August. They should be planted in middle-sized pots, and they will produce flowers two or three times in a year, and from March to September, when the roots are vigorous. The 10th, or Mexican lily, is less hardy, and must be placed in a warm stove, or the pots should be plunged into a hot-bed of tanner's bark, and may be increased by offsets. It flowers usually in the beginning of Spring and makes a fine appearance in the stove. The 16th, or Belladonna lily, is cultivated by preparing a border near a wall, with a south-west aspect, about six feet wide; and for this purpose the earth should be removed to the depth of three feet, six inches of rotten dung laid at the bottom, and covered to the depth of about twenty inches, with light garden mould: the roots should then be placed at the distance of six inches every way, and covered over with light sandy earth, so as to bury the upper part of the roots about five or six inches; and in the Winter the border is to be covered with rotten tanners' bark to the depth of three inches, in order to guard against the frosts: and in severe frosts mats or straw should be laid over the leaves, to prevent their being killed. Thus managed, the roots will greatly increase, and produce flowers every year, which make a fine appearance during the month of October. The green leaves will abide till June, and then decay, after which the roots should be transplanted. The 17th species may be easily propagated by seeds. The 20th may be treated in the same manner as the Jacobæa lily; will increase by offsets; and usually flowers in Winter, when the pots are placed in a moderate stove; and as there are few flowers in Winter in the open air, it is on this account the more valued. The 26th must be placed during Winter in a stove of moderate warmth, and less watered than the Jacobæa lily. The 27th, or Guernsey lily, has been cultivated for many years in the gardens of Guernsey and Jersey, whence the roots are sent to most parts of Europe. The bulbs are commonly brought over in June and July, and they should then be planted in pots filled with fresh, light, sandy earth, mixed with a small quantity of very rotten dung, placed in a warm

a warm situation, and occasionally refreshed with water. About the middle of September the stronger roots will shew their red-coloured flower-stem; and then the pots should be removed into a situation where they may have the full benefit of the sun, and be sheltered from strong winds; but not placed under glasses, or too near a wall, which would draw them up, and render them less beautiful. When the flowers begin to open, the pots should be put under shelter, so as to be secure from too much wet, but not kept too close or too warm. The flowers will continue in beauty for a month; and though without scent, their rich colour entitles them to the first rank in the showery tribe. After the flowers are decayed, the leaves will grow through the Winter, and they will be best sheltered in a common hot-bed frame. The roots should be transplanted every fourth or fifth year, toward the latter end of June, and planted into fresh earth. The offsets, planted in separate pots, will in three years time produce flowers; these roots will furnish a stock, which will supply blowing roots without the trouble and expence of obtaining them from Guernsey; and the roots preferred here will flower more strongly than those that are usually brought from thence. In order to preserve a large number of these roots without pots, a bed may be prepared in a well-sheltered part of the garden, by mixing a third part of fresh virgin-earth from a pasture ground with equal parts of sand, of rotten dung, and sifted lime rubbish. Of this, when it has been well incorporated, there should be made a bed about two feet thick, raised in dry ground four or five inches above the surface, and if the ground be moist eight or nine inches higher. In this bed the roots should be planted, about the beginning of July, about six or eight inches asunder each way; and in the Winter, when the frost sets in, covered with mats and straw; but in the Spring the covering may be removed, and during the Summer kept clear from weeds, and the earth occasionally stirred; and every year, when the leaves are decayed, a little fresh earth should be sifted over the beds, in order to encourage the roots. Here the roots may remain till they are strong enough to produce flowers, and then removed to pots, or suffered to remain in the same bed to flower. The roots of these plants often flower twice in the compass of three years; after which the same root will not flower again in several years, but only the offsets from it. The 2d, or Ceylon lily, is tender, and must be treated like the Mexican lily. It flowers usually in June and July, and sometimes the same root will flower again in Autumn; and if the pots are plunged into a bed of tanners' bark, the roots generally flower twice every year; but the flowers are not of long duration. The 2d may be increased by offsets from the roots, or by the bulbs which succeed the flowers; and it must be treated like the *Criminus*. The best time for transplanting the roots is about the beginning of August, when the leaves are quite decayed. Martyn's Miller.

AMARYLLIS *Capensis*. See *HYPOXIS Stellata*.

AMARYLLIS *Ciliaris*. See *HÆMANTHUS Ciliaris*.

AMARYLLIS *difficha*. See *HÆMANTHUS toxicarius*.

AMARYLLIS *umbrella*. See *CYRTANTHUS obliquus*.

AMARYNTHUS, in *Ancient Geography*, a small island of Eubœa, according to Steph. Byz.; but, according to Strabo and Pausanias, a small place in the island, famous for a temple of Diana, where she was worshipped, and hence called *Amarynthia*.

AMAS, a mountain of Peloponnesus in Laconia, according to Pausanias, near Las and Gythium.

AMASENUS, *la Toppia*, a river of Italy. Also another river of Italy, which ran into the Liris.

AMASIUS, *Romulus*, in *Biography*, a professor of

Greek and Latin at Bologna, and secretary to the senate, was born at Udine, in Friuli, in 1489. Paul III. invited him to Rome, made him preceptor to his grandson Alexander Farnese, and employed him on several embassies to the emperor, the princes of the empire, and the king of Poland. He taught rhetoric at Bologna with an annual salary of 300 crowns, and at Rome, where he was much esteemed for his learning, and had a pension of 600 crowns a year. He translated Pausanias, which translation was corrected by Sylburgius, and Xenophon's Expedition of Cyrus the Younger. He also wrote a volume of "Orations," and "Scholæ duas de Ratione Inlittuendi." Two books, in which he shews that the Latin tongue is preferable to the Italian, were never printed. Huætius, "de claris Interpret." represents him as a great admirer of perspicuity and politeness of style, and says of him that he enlarged what was too concise, abridged what was too prolix, and elucidated obscure passages. He died about the year 1552, and left one son, named Pompilius, who taught Greek at Bologna, and translated two fragments of the 6th book of Polybius. Gen. Dict.

AMASIA, in *Entomology*, a species of *PAPILIO* in the *nymphales* section. Wings indented, of a green colour, with a row of black spots along the margin of the posterior pair: underside marked with ocellated spots. Found in Surinam. Fabricius.

AMASIA, a species of *PHALÆNA*, of the *noctua* family. Wings varied with cinereous, and whitish, with a fulvous streak: lower-ones yellow, with two black bands, the outer one interrupted. Abbot Inf. Georgia, by Dr. Smith.

AMASIA, in *Ancient Geography*, a district or division of Anatolia Natolia, or Asia Minor, in Asiatic Turkey, bounded on the north by the Euxine Sea, on the east by Armenia, on the west by Anatolia Proper, and on the south by Caramania and Aladulia. The capital of this country is Amasia, called by the Turks Amnusan and Amasich, which is an ancient town, situate among mountains, three miles distant from the river Iris, or Cassimack, and the residence of the governor of Cagherbag. It has been customary for the eldest son of the Grand Signior to reside here till he is called to the throne. The city was formerly the seat of the kings of Cappadocia, and some remains of its ancient magnificence are still existing. It gave birth to the famous geographer Strabo, and in Christian times it has been the see of an archbishop. Its wine and fruits are excellent. It is 12 leagues south of the Euxine Sea, and 200 miles east of Constantinople. N. lat. 40° 31'. E. long. 36°.

AMASIA, or AMISIA, in *Ancient Geography*, a town of Germany, supposed by some to be the present Embden, and by others Marburg. It was near this town that Drusus vanquished the Bructeri.

AMASIS, in *Biography and History*, king of Egypt, was of plebeian extraction, and by his meritorious services obtained the confidence of Apries, his sovereign, whom he succeeded in the throne, B. C. 569, and soon after put to death. Upon his accession he was assiduous in the exercise of his public duties, devoting his mornings to business, and his evenings to social amusement. Under his reign Egypt was singularly prosperous and happy, and is said to have contained 20,000 populous cities. For the preservation of order and the encouragement of industry, he enacted a law which required every person to inform the governor of the province once a year how he earned his living, and those who were not able to give a satisfactory account of themselves were punished with death. To the Greeks he was a great friend, inviting them into Egypt, and granting them places where they might erect altars and temples to their own

own deities; and it is said that he was visited by Solon; he also married a Greek woman. Such was the liberality of his disposition, that he contributed a thousand talents of alum to the Delphians for their relief when their temple was burnt, and he granted to the Greeks several valuable donations. In his own country he erected several magnificent buildings, and at a very great expence enriched the principal temples with gifts and ornaments. Amasis was the first person who subdued Cyprus, and extorted tribute from its inhabitants. The close of his reign, however, was very different from its commencement and progress. Having by some means or other, probably by refusing to pay the same homage and tribute to Cambyses which he had been accustomed to render to Cyrus, incurred the displeasure of the Persian sovereign, Cambyses prepared to invade Egypt, and derived effectual assistance from Phanes of Halicarnassus, who commanded the Greek auxiliaries in the pay of Amasis, and who, leaving Egypt in disgust, embarked for Persia. Amasis was also deserted by Polycrates of Samos, who, after having been his ally and friend, joined Cambyses against him. Thus deserted by a prudent and valiant general, and by a powerful ally, and apprehending the formidable invasion of Cambyses, Amasis was rescued from the evils that threatened him, and that beclouded the closing scenes of his life, by death, B. C. 525, after a reign of 44 years. His dead body was embalmed, and deposited in a sepulchre which he had built for himself in the temple at Sais. The reign of his son and successor, Psammetichus, was short and calamitous; and the victorious Persians, after his defeat, capture, and death, took the body of his father Amasis from the tomb, mangled it in a shocking manner, and then burnt it. Thus terminated the ancient splendour and liberty of Egypt. Herodotus. Diodorus Siculus. Un. Hist. vol. i. p. 314—323. Rollin's Anc. Hist. vol. i. p. 99—101.

AMASIS, in *Entomology*, a species of PHALÆNA, of the *Bombyx* family. Wings deflected; anterior pair whitish, streaked with black, posterior pair yellow, with black spots. Abdomen black, belted with red. It is further described as having the head and thorax whitish, with black spots. The red or sanguineous marks that encircle the abdomen are five in number, and the three black streaks on the anterior wings are angulated. A native of Surinam. Fabr. Ent. Syst.

AMASIVS, in *Ancient Geography*, a river of Germany, the present *Ems*.

AMASONIA, so called from *Amason*, a traveller into America, in *Botany*, a genus of the *didynamia angiospermia* class and order. Its characters are, that the *calyx* is a perianthium, one-leaved, bell-shaped, semi-quinquefid, acute, equal, and permanent: the *corolla* is one-petalled, tubulous, longer than the *calyx*; border quinquefid, sub-equal, spreading, and small; the *filamina* have four filaments at the upper side of the corolla, and longer than it, bending in at the end, two of them shorter, the anthers oval and incumbent: the *psittillum* has an ovate germ, style in the situation and form of the stamens, stigmas two and sharp, no *pericarpium*. The *seeds* are an ovate, one-celled nut, of the same length with the *calyx*. This agrees with the *Taligalea* of Aublet in every thing except the fruit, which, according to him, is a drupe, longer than the *calyx*, one-celled, and containing two small hemispherical one-celled nuts. There is one species, viz. *A. vera*. It is a native of Surinam, with an herbaceous stem, three feet high, round and simple: the leaves are alternate, petiolate, remote, elliptic-lanceolate, subserrate, and scabrous; the flowers in a simple terminal raceme, a foot long, with about three flowers on a pedicel: the

bracts ovate, sessile, a little longer than the flowers, which are yellow, nodding, and grow all on one side of the stalk. Martyn.

AMASSEIA, in *Ancient Geography*, a town of Peloponnesus, in Achaia.

AMASSI, a people of the Asiatic Sarmatia.

AMASTRA, a town of Sicily, the same with Amestratus.

AMASTRIS, now *Amastro*, a town of Asia Minor, in Paphlagonia, upon a small isthmus which joined the peninsula Selamus to the continent. It was built by Amaltris, the wife of Iyfinachus, who gave it to his wife Arsinoc, and by her the government of it was entrusted with Hierocles. Soon after it became very considerable, and put itself under the protection of Ariobarzanus, the son of Mithridates. When the Romans carried their arms into Asia, Amaltris was taken by Triarius, the lieutenant of Cotta. From the Romans it passed to the Greek emperors: it was afterwards taken by the Venetians: from them it became the possession of the Turks; and, having lost its commerce, it is now almost annihilated.

AMATA, in *Entomology*, a species of PAPILIO, in the section *Danaï Candidi*, with rotund fulvous coloured wings, bordered with black on the upper side; beneath greenish; is found in India. Linn. Syst. Nat.

AMATARIA, a species of the PHALÆNA, of the *Geometra* family, that inhabits Europe. The wings are angulated, of a pale brown, slightly speckled, with an obsolete darker-waved streak, and a straight purple line across the middle. It is produced from a green larva, with yellow rings, that feeds on the leaves of oaks. Linnæus. Don. Brit. Insects, tab. 33. fig. 2.

AMATEUR, in the *Arts*, is a foreign term introduced and now passing current amongst us, to denote a person understanding, and loving, or practising, the polite arts of painting, sculpture, or architecture, without any regard to pecuniary advantage. Such have been found in the revivals of painting, &c. in most countries. Amateurs who practise were never perhaps in greater number or of superior excellence than at present, and those who delight in and encourage the arts have been the means of raising them in this country to that eminence to which they are arrived. It is to be regretted, however, that the great works of former ages, collected by amateurs in this kingdom, are not so accessible to our professors as they are in foreign countries, which would tend to accelerate the progress of the arts, and that the encouragement given by these amateurs is in general upon too limited a scale.

It may occasion some surprize to the next generation, that *Royal Patronage* has not roused to emulation in this particular more of the noble amateurs who surround the throne, and induced them to encourage the greater works, as they do such as are of an inferior nature; for thus our reputation in historic art would be elevated so as to be equal, if not superior, to that of any of the neighbouring nations, and even to rival the justly celebrated pictures produced in the 14th and 15th centuries, and our sculptors might be equally esteemed with those of ancient Greece or Rome.

AMATEUR, in *Music*, is equal, in French, to the term *Dilettante*, Ital. implying a lover and cultivator of music, not professionally, but for his amusement—a gentleman performer. In the *Encyclopedie Methodique* we have a long article on the subject, by M. Guinguerié, in which he divides *les Amateurs* into three classes, which he describes in the following candid and fair manner. "The first is composed of such as are born with delicate organs and much sensibility to the beauties

tics of music, and who, not having had leisure, inclination, or the means of cultivating their natural propensity, continue through life to cherish their passion for the art; eagerly attending all concerts and musical dramas; and, finally, by frequent and impartial parallels, dictated by nice and accurate discrimination, becoming, sometimes, better judges of composition and performance than trained professors, possessed neither of taste nor impartiality.

“The second class comprehends those who have had the means of developing, and confirming by study, the gifts of nature, and who have sublimed their dispositions into talents. Of these the number is at present considerable. Music is become so interesting a part of a good education, and vocal and instrumental music have made so great a progress, and are so generally cultivated, that there are few private concerts in which more talents are not displayed by amateurs of both sexes than the most celebrated professors possessed in France 20 years ago. Concerts entirely composed of gentlemen and lady performers are not uncommon; but persons at all difficult are much dissatisfied if the principal parts at least are not guided by able professors.

“The third class is the most numerous and the most distinguished, though they are less ambitious of shining than the second: it is composed of *amateurs*, who, not content with learning to read and execute music, have tried to penetrate into the secrets of the art, and enable themselves to account for the pleasure they receive, by analysing their sensations and studying the theory of music, to enable themselves to judge more accurately of the practice, and to unite intellectual pleasure with that of sense and the heart. Masters are fortunate who have such for judges, where their knowledge is incorporated with natural sensibility and candour; and still more happy, a thousand times, the true *amateur*, who has neither the rage of decision, of disputation, nor the arrogant pretensions of settling ranks; who, knowing the arcana and refinements of the art, discovers and tallies beauties unknown to vulgar hearers; who, preserving his primitive sensibility, enlightens it by meditation and study: and who finds himself impelled, both by judgment and feeling, to treat with regard the artist to whom he owes his pleasure, without distinction of nation or party.

AMATH, in *Ancient Geography*, a town of Syria, called by the Greeks *Emesa*.—Also, a borough of Palestine, near Gadara, the same with *Amatha*.—Also, a town of Cœloryria, called by the Greeks *Epiphania*.

AMATHA, a country of Arabia.—Also, a town of Phœnicia, probably the same that was founded by the 11th son of Canaan, called *Chamati* in the Book of Genesis, and by the Septuagint *Amathi*. According to Josephus, it was the capital of the Amathæans, and some have supposed it to be the same with *Emesa*.—Also, a place of Judea, in that part of it that was allotted to the half-tribe of Manasseh, on the east of Jordan.

AMATHÆI, a people of Arabia Felix, according to Pliny.—Also, a people who inhabited the Land of Promise before the Israelites, and who occupied part of the tribe of Nephtali, towards Mount Libanus. These people were vanquished by the Israelites, and retired into Phœnicia, where they built Amath, or Emath, on the banks of the river Orontes. According to Josephus, they sent forth a colony, who built the town of Amath, near the Lake of Genesareth.

AMATHEA, in *Entomology*, a species of PAPILO, in the *Nymphales* section, that inhabits South America. The wings are angulated, brown, with white spots; a red band, and undulated black line. Linn. Syst. Nat.

AMATHO. See AMATO.

AMATHUS, or AMATHONTE, in *Ancient Geography*,

a town of the southern part of the island of Cyprus, near Lycus, between Curtum to the west and Citium to the east. It was founded by the Phœnicians, and owed its celebrity partly to the fertility of the adjacent country, and partly to the temple and worship of Venus in this place. Strangers, it is said, were sacrificed on her altars. The goddess was displeased, and punished the inhabitants by changing the men into bulls, and by despoiling the women of their modesty, so that they prostituted themselves without shame. Agreeably to this opinion, Ovid reports that the first courtisans appeared in this town. The statue of Venus in this place was that of an hermaphrodite. The statue was allegorical; and probably the men sacrificed to her in female habits, and the women in those of males. There was another temple in this place, as we are informed by Pausanias, consecrated to Venus and Adonis. Amathus was afterwards called Limassol; but it is now utterly destroyed.

AMATHUS was also a town of Peloponnesus, in Laconia, according to Strabo.—Also, a river of Peloponnesus, in Messenia, called *Pamifus*.—Also, a town of Palestine, beyond Jordan, north-east of Mount Abarim, ruined by Alexander Jannæus.

AMATHUSA, one of the epithets of the isle of Cyprus, and the inhabitants were called *Amathusii*, from Amathus above mentioned.

AMATI, ANTON and HIERONIMO, in *Biography*, two brothers, celebrated instrument makers in Cremona, flourished in 1662. Nicolo Amati, the son of Geronimo, was living in 1682. All these were such admirable fabricators of violins, as to render valuable every instrument that was supposed to come from Cremona. See STRADUARIUS and STEINER.

AMATILLAN, in *Geography*, a town of Mexico, in the province of Guatimala; 10 miles S. E. of Guatimala. N. lat. 14° 26'. W. long. 92° 26'.

AMATIQUES, a sea-port town, at the mouth of Guanacos river, which discharges itself into the Amatique gulf, or gulf of Honduras, in the province of Vera Paz, in Mexico. The inhabitants are chiefly logwood-cutters, and on the south of the gulf is a tract of land, called Amatique land. The gulf is formed by the peninsula of Cape Three Points, and that which lies between it and Dolce gulf, and between these it runs far into the land. N. lat. 15° 23'. W. long. 89°.

AMATISSA, AMESSÉ, in *Ancient Geography*, a small river of Gaul, which runs from the S. E. to the N. E. eastward of Ambacia, and discharges itself into the Loire.

AMATITUE, in *Geography*, a river of North America, in New Spain, which discharges itself into the Pacific Ocean, upon the confines of the province of Guaxaca.

AMATKINAK ISLAND is, with Ulak, the largest of the third group of islands between Asia and America.

AMATO, a town of Naples, in the province of Calabria Citra, on a river of the same name, 7 miles S. E. of Nicastro.

AMATO, or AMATHO, anciently LAMETUS, a river of Naples, which spreads itself over a large flat, in 50 different channels, and would overflow a great extent of country if its devastations were not restrained by high cliffs on each side of its bed. Its waters are of a muddy white colour. It discharges itself into the sea, three miles south of St. Eufemia, on the west coast of Calabria Ultra.

AMATORII, MUSCULI, in *Anatomy*, an appellation given to those muscles of the eye, which give them a cast sideways, and assist in that particular look, by some called ogling. When the abductor and humilis act together, they give to the eye this oblique motion.

AMATORIIUS, in *Ornithology*, a species of the PARUS genus, of a deep blue slate colour, with a longitudinal spot in

the middle of the wings, half rufous, half yellow.—It is the *mesinge amurensis* of Buffon, and *amorus tinazufi* (parus amoralis) of Latham. The length is five inches and a quarter, bill two thirds of an inch, black at the base, tip orange.

This bird inhabits the northern parts of Asia, and is remarkable for the affection each sex shows the other. When paired in cages its carrels are scarcely interrupted; a circumstance that has imposed the emphatic names of *amatorius*, *amarosus*, and *amorous* upon this species, to distinguish it from others of the parus genus.

AMATRICE, in *Geography*, a small town of Naples, in Abruzzo, with the title of a principality.

AMATTA DO BRASIL, a town of South America, in the country of Brasil, and government of Pernambuco.

AMATTA FOA, or TOOFOVAMA, OF KANIA, ISLAND, an island in the Southern Pacific Ocean, discovered by Captain Cook, in 1774, about 11 or 12 leagues distant from ANAMOOKA, N. N. W. $\frac{1}{2}$ west. It is about five leagues in circuit, considerably elevated, and probably has a volcano; it is inhabited, but not very fertile. Between this and another island, called Oghao, is a safe channel, about two miles broad, without any soundings.

AMAUROSIS, in *Surgery*, a privation or obscurity of sight, from *αμαυρος*, more commonly named GUTTA SERENA. This disorder is either complete, when total blindness exists, or incomplete, when vision is not perfectly destroyed. It is distinguished from the GLAUCOMA or CATARACT, in as much as the latter is a disease of the crystalline lens, whereas the former is generally seated in the optic nerve. *Amaurosis* may be produced by various causes, and admits of different modes of treatment; but the consideration of these particulars is referred to the article gutta serena. See ANBLYOPIA and DYSOPIA.

AMAXIA, in *Ancient Geography*, a town of Asia Minor, in Cilicia Trachæa or Cilicia Montana.

AMAXITUS, a borough of Asia Minor, in the Troas, and territory of the Alexandrians. In this place there was a temple of Apollo, in which the priest Chryses, mentioned by Homer, is supposed to have sacrificed.

AMAXOBII, a people who, according to Ptolemy, inhabited the interior parts of Scythia, in Europe. Their name, derived from *Αμαξία*, a chariot, refers to the practice which prevailed amongst these people and other Tartarian nations, of placing their tents on carriages for their more easy removal from one place to another. See HAMAXOBII.

AMAYA, in *Geography*, a town of Spain, at the foot of a rocky mountain, in the county of Leon, four leagues from Aquilar del Campo.

AMAZIAH, in *Scripture History*, the eighth king of Judah, was the son of Joash, and succeeded his father in his 25th year, A. M. 3165, B. C. 839. He adhered to the worship of the true God, but not without a mixture of idolatry; and therefore, he is said (2 Chron. xxv. 2.) to have done "that which was right in the sight of the Lord, but not with a perfect heart." We are further informed (Ch. xxv. 3, 4.) that, after his accession to the throne, he put to death the murderers of his father, and in conformity to the humane restriction of the Mosaic law, (Deut. xxiv. 16.) he preserved their children alive. With a large army, formed of his own subjects, and other hired troops from Israel, he marched against the Edomites, who had revolted from Judah, in the reign of Joram, about 54 years before; but having dismissed the Israelite auxiliaries, he led forth his own people to battle, and defeated the enemy in the valley of Salt, with great slaughter. The auxiliaries on their return ravaged the country, killed 3000 men, and carried off a great booty, as a compensation for the advantage which they expected to have derived from their expedition

against Edom. Amaziah, after his victory, took home the gods of the children of Seir, and paid them divine honours. Presuming on his success, and imagining himself to be invincible, he sent a hostile challenge to Joash, king of Israel, expressed by the words (2 Chron. xxv. 17.) "come, let us look one another in the face." Joash, by the fable of the cedar and thistle, endeavoured to dissuade him from his hostile purpose; but he persisted, and the adverse armies met at Bethshemesh, where that of Amaziah was routed, and he himself taken prisoner. Joash led the captive king with him to Jerusalem; and having made a breach in the wall, he entered the city, plundered the temple and royal palace, and then returned to Samaria. After this disastrous event, the reign of Amaziah was prolonged 15 or 16 years; but a conspiracy having been formed against him at Jerusalem, he fled to Lachish, where his enemies overtook and assassinated him, A. M. 3194, B. C. 810. 2 Kings, ch. xiv. 2 Chron. ch. xxv.

AMAZON, in a *General Sense*, denotes a bold, courageous woman, capable of daring and hardy achievements. See *AMAZONS infra*.

AMAZON, or the river of the AMAZONS, called also *Maragnon*, in *Geography*, a river of South America, is one of the largest rivers in the world. Its source is in Peru, in a lake near Guanuco, about 30 leagues from Lima, where the Maragnon rises, and at the head of the river Napo, near Quito; its first direction in Peru is from south to north; it afterwards runs a course from west to east, of about 3000 miles, across South America, and receives near 200 other rivers, many of which have a course of 5 or 600 leagues, and some of them not inferior to the Danube or the Nile. These rivers rush down with amazing impetuosity from the eastern declivity of the Andes, and uniting in a spacious plain, form this immense river. The chief of these, from the south and south-west, proceeding from the mouth westward, are Araguaya, Paratina, Madeira, Eurus, Yulay, Yulacina and Ucagai rivers. From the north and north-west, advancing from its mouth, are Parma, Negro, Yupura, Issa and Napo, which last rises near the town of Archidano, about 150 miles eastward of Quito. The Amazon is interspersed with a great number of islands, which are too often overflowed to admit of culture. It falls into the Atlantic Ocean, almost under the equator, by several channels, and its breadth at its mouth is 150 miles, and at the distance of 1500 miles from hence it is 30 or 40 fathoms deep. In the rainy season it overflows its banks, watering and fertilizing the adjacent country. M. de la Coudamine, who made a voyage down this river in 1743, found its descent in a straight course of about 1860 miles, to be about 1020 English feet, or 6 $\frac{1}{2}$ inches in a mile. The tides are perceptible at 600 miles from its mouth, but at an elevation only of 90 feet. Phil. Trans. vol. lxxi. p. 93. 109.

Besides Orellana, who made this voyage from motives of ambition, and de la Coudamine, who was prompted to it from a love of science, Madame Godin des Odonais, undertook it in 1769, from conjugal affection. The narrative of the hardships which she suffered, of the dangers to which she was exposed, and of the disasters which befel her, is one of the most singular and affecting stories in any language, and exhibits in her conduct a striking picture of the fortune which distinguishes the one sex, blended with the sensibility and tenderness peculiar to the other. Lettre de M. Godin à M. de la Coudamine.

AMAZONA, in *Ornithology*, a species of ALCEDO, first described by Dr. Latham, in his Syn. Av. Sup. p. 116, under the name of AMAZONIAN KINGFISHER. It inhabits Cayenne, and is about thirteen inches in length. The colour above is glossy green, beneath white, passing backwards in a ring

a ring to the nape; the sides are variegated with green: the wings and tail spotted with white. These particulars constitute the specific character: it may be further added, that the bill is three inches long, narrow, straight, and black; the under mandible yellow at the base; the thighs mottled with green, and the breast clouded with the same; tail feathers green, spotted on each side of the web with white, except the two middle feathers which are paler than the rest; legs black.

AMAZONA, a species of EMBERIZA, described by Linnaeus and Gmelin. The general colour is brown, crown of the head fulvous, vent whitish. It inhabits Surinam, and is about the size of the titmouse. The underside of the wings white at the base.—Buffon calls this L'Amazone, tom. iv. p. 364, and Latham gives it the English name of AMAZON'S BUNTING.

AMAZONE, in *Sculpture*, a very fine antique statue, in Parian marble. It was about two hundred years at the *Villa Mattei*, upon Mount Coelius, at Rome; from whence it was removed to the museum of the Vatican, by pope Clement XIV.; and is now in the gallery of antiques at Paris. There is also a beautiful statue of a queen of the Amazons at Wilton; represented in a warlike action; being on one knee; as under a horse, defending herself in battle. Her shield is in the form of a half moon; behind the lower part of which, the sculptor has executed a horse's foot; in order to illustrate the attitude. This statue was executed by the celebrated Cleomenes.

AMAZONIA, in *Geography*, a large country of South America, 1400 miles long, and 900 miles broad, is situated between the equator and 20° S. lat., and bounded on the north by Terra Firma and Guiana, on the east by the Atlantic Ocean and Brasil, on the south by Paraguay, and on the west by Peru. This country was first discovered by Francisco Orellana, about the year 1541, who, in a bark, manned with 50 soldiers, was borne down by the stream of the river Napo into the channel of the Maragnon; and who, after making frequent descents on both sides of the river, sometimes seizing by force of arms the provisions of the fierce savages, seated on its banks, and sometimes procuring a supply of food by a friendly intercourse with more gentle tribes, reached the ocean. This bold and magnanimous adventurer pretended to have discovered along the banks of this river, nations so rich, that the roofs of their temples were covered with plates of gold; and he described a republic of women so warlike and powerful, as to have extended their dominions over a considerable tract of the fertile plains which he had visited. From this community of warlike women, who, with arms in their hands, opposed his passage, he called the country Amazonia, or the land of the Amazons, and he gave the name of Amazon to the river, which had formerly been denominated Maragnon.

The Spaniards have made several attempts to plant this country, but always met with so many difficulties and disasters, as to render their designs abortive. The Portuguese have some small settlements on that part of the coast which lies betwixt Cape North and the mouth of the river Amazon; but these excepted, the natives are in the sole possession of the whole country. The air in this country is cooler than might be expected, considering its situation in the middle of the torrid zone; which is owing partly to the heavy rains, which cause the inundations of the rivers for one half of the year, and partly to the cloudiness of the weather, so that the sun is obscured, during the greatest part of his stay above the horizon. The fair season is about the time of the

solstices, and the wet or rainy season is about the equinoxes. The soil of Amazonia is very fertile, and produces corn, grain, and all kinds of tropical fruits; besides a variety of timber, as cedar, brasil-wood, oak, ebony, iron-wood, log-wood, and other dying woods; and also cocoa, tobacco, sugar canes, cotton, cassava root, potatoes, yams, sarsaparilla, gums, raisins, balsams of various sorts, pine apples, guavas, bananas, &c. The forests abound with wild honey, and also with tigers, wild boars, buffaloes, deer, parrots, and game of various kinds. The rivers and lakes afford an ample supply of fish, sea-cows, and turtles; but the alligators and water-serpents render fishing a dangerous employment. The trees, fields, and plants, are verdant throughout the year. The natives are of good stature, with agreeable features, long black hair and a copper-coloured complexion, and are very different from the natives of Africa, in the same latitude, on the opposite side of the Atlantic. Condamine says, that they have a taste for the imitative arts, especially sculpture and painting, and that they frequently excel in mechanical professions. They spin and weave cotton cloth. Their houses are built with wood and clay, and thatched with reeds. Their arms, in general, are darts and javelins, bows and arrows, with targets of cane or fish skins. The several nations, on both sides of the river Amazon, which are very numerous, are governed by chiefs or caziques; for it is observable, that the monarchical form of government has prevailed almost universally, in both ancient and modern times, in a rude and unrefined state of society. The regalia, by which the chiefs are distinguished, are a crown of parrot's feathers, a chain of tiger's teeth or claws, which hang round the waist, and a wooden sword. They are all idolaters, and worship the images of their ancient heroes; and in their various expeditions they carry their gods along with them.

As to the Amazonian race, if it ever existed otherwise than in the imagination of the original adventurer Orellana, or in the exaggerated reports of travellers and voyagers, it is now wholly extinct; and probably the notion was at first suggested by the activity and courage which the females of this country exerted, in the defence of their privileges, against the encroachment of foreigners.

AMAZONS, in *Geography and History*, denote an ancient nation of warlike women, who founded an empire in Asia Minor, upon the river Thermodon, along the coasts of the Black Sea; and who are said to have formed a state out of which men were excluded. What commerce they had with that sex, was only with strangers, whom, after occasional intercourse at stated times, they put to death; hence, as Herodotus informs us, they have been called *Æorpata*, or murderers of their husbands. They also killed all their male children, or, as some authors say, broke their legs, or dis-jointed their knees, and thus rendered them incurably lame, by luxations, as Diodorus Siculus, Hippocrates, and Galen assert, that they might be the more easily reduced to a state of dependence and slavery. Moreover, they nursed their females, and trained them up to war; and that they might use their arms more readily, and be more fit for the combat, they cut off, or seared with a plate of hot brass, their right breasts, apprehending that there would be otherwise some impediment in the use of the bow. Hippocrates and Galen allow that this fact was reported; but they allege, that this operation was performed, not on account of any impediment in the use of the bow, but to render the right arms stronger by an addition of aliment, as that which would have gone to the breast would be thus restricted to the arm. In reference to the excision of their breasts, Penthesilea, one

of their queens, is represented by Virgil, *Æn.* lib. i. v. 492.

“*Aurea subnectens exsertæ cingula mamma.*”

From this last circumstance it is, that they are supposed to take their name, *viz.* from the privative α and $\mu\alpha\mu\alpha$, *mamma, breast.*

Others have suggested, that the amputation performed on the breasts of the females was invented by the Greek etymologists, in order to explain the name of the nation. Others again have conjectured, that the name was derived from the Circassian word *maza*, the *moon*, which is said to have been a favourite deity among the mountaineers of Caucasus, in the vicinity of which the Amazons were settled. Dr. Bryant (*ubi infra*) traces the etymology of the appellation to $\alpha\omega\eta$, the *sun*, which was the national object of worship. Some have maintained, that the description of the Amazons, given by the ancient writers, is purely allegorical; the amputation of one of the breasts signifying, that the female only was nourished by the mothers; and the killing of the boys denoting, that they were committed to the care of strangers.

It is, however, a point that has been controverted, even among the ancient writers, as well as the moderns, whether such a nation as the Amazons are described to be, have ever existed. Strabo, Ptolemy, and others, absolutely deny it; whilst, on the contrary, Herodotus, Pausanias, Diodorus Siculus, Trojus Pompeius, Justin, Pliny, Mela, Plutarch, &c. expressly assert it.

Herodotus, in his history of the Scythians (lib. iv. c. 110. p. 330—332. ed. Weffeling.), informs us, that the Greeks, who had obtained a signal victory over the Amazons, near the river Thermodon, were carrying off the residue that had escaped the slaughter in ships into their own country. While they were at sea the Amazons conspired against them, and killed all the men whom they had on board; but being unacquainted with the art of navigation, even with the use of the rudder, sails, and oars, they were driven by the wind and tide to the precipices of the Palus Mæotis, in the territories of the free Scythians. Here they went ashore, and marching up into the country, they seized the first horses they found, and began to plunder the inhabitants. The Scythians unacquainted with their language, sex, and dress, took them at first to be youths; but after a skirmish or two, in which some of them were taken prisoners, they found that they were women. Accordingly all hostilities ceased, and they formed connections with them as their wives. But when the Scythians invited these women to accompany them to their own country, they declined accepting the invitation; alleging, that they had been always used to draw the bow, dart a javelin, mount a horse, and such warlike exercises, to which they supposed the Scythian women were altogether unaccustomed, and that they could not consent to exchange their military mode of living for a life of ease and indolence. They therefore exhorted their husbands, if they still retained the same conjugal affection for them, to visit their parents and friends, and to return with the several portions assigned them. They complied with the advice; and upon their return, were informed by their wives, that since they had deprived them of their parents, and committed several depredations in that country, they thought it much safer to fix their habitation on the other side of the Tanais. This scheme was approved and executed. After three days march to the east of that river, and three more northward from the lake Mæotis, they arrived and settled in the country of Sarmatia, where they continued, says Herodotus, to his time. Hence, continues

the historian, the wives of the Sarmatians pursue their ancient mode of life, hunting on horseback either alone, or in the company of their husbands, marching with their armies, and wearing the same dress with the men. The Sarmatians used the Scythian language, corrupted by the Amazons, who had never learned to speak it correctly. Their marriages were attended with this peculiar circumstance, that no virgin was allowed to marry till she had killed an enemy in the field, and therefore some of them were old before they married, according to the requisition of the law.

From Diodorus Siculus (lib. ii. c. 47. p. 156—158. ed. Weffeling.), we learn, that there was formerly a nation who dwelt near the river Thermodon, in which women governed and conducted all their military expeditions. Among these, one excelled all the rest in strength and valour. By her an army was assembled, and trained up in military discipline, to as to subdue some of the neighbouring nations. Her fame increasing with her success, she styled herself the daughter of Mars, and ordered the men to spin wool, and to perform the domestic services of the women. She promulgated laws, which required the women to engage in warlike exercises, and the men to remain at home in an abject condition, and to be employed in the most servile offices. The male children that were born were debilitated in their legs and arms, so as to be unfit for war; and the females had their right breasts seared, so that they might be no impediment to them in fighting; and hence, says the historian, this nation obtained the name of Amazons. The queen, distinguished by her military skill, built at the mouth of the Thermodon a large city, called Themiscyra, and adorned it with a famous palace. In her warlike expeditions she maintained strict discipline and order; and thus reduced to subjection all the neighbouring nations, as far as the river Tanais. Having finished these exploits, she closed her life in the field like a hero, and fell in a battle, in which she had displayed singular courage. She was succeeded by her daughter, who excelled the valour of her mother, and in some respects surpassed her. She caused the young women to be inured to hunting in early life, and also to military exercises. She instituted feasts and sacrifices to Mars and Diana, which were denominated Tauropoli, carried her arms beyond the Tanais, and subdued the people of all those countries as far as Thrace. Upon her return with rich spoils, she caused temples to be erected to the above-mentioned deities, and gained the love of her subjects by her mild and gentle government. She afterwards reduced a great part of Asia, and extended her conquests as far as Syria. The succeeding queens of the same race acquired renown by their government, and greatly enlarged the dominion of the Amazonian nation. The fame of the Amazons continued for several ages, till at length Hippolyta was vanquished and captured by Hercules, the son of Jupiter and Almena; and by degrees the Amazonian name became totally extinct. The last queen of the Amazons was Penthesilea, who assisted the Trojans, after the death of Hector, and was slain by Achilles. So signal and extraordinary were the character and exploits of this queen, and others of the Amazonians, that Diodorus acknowledges, that in later ages, the relations of them have been regarded as fabulous.

Diodorus elsewhere (*viz.* lib. iii. p. 220.) mentions another race of Amazons, much more ancient than those of Pontus, in the vicinity of Thermodon. These inhabited the western parts of Libya; they were under the government of women; and as long as they continued single, they performed the duty of soldiers in the field; and after a stipulated period they associated with the men, and bore children;

but the magistracy and all public offices were retained by the females, and the men were employed in domestic offices, and were altogether subject to their wives, who would not allow them any participation of authority in the state, or any concern in military affairs. Their females had their breasts seared, that they might not be any hindrance to them as they grew up, and engaged in martial exercises. One of the principal queens of this nation was Myrina, who is supposed to have lived in the time of Orus, the son of Isis, and to have conquered Africa and the greater part of Asia, but was at last slain in Thrace.

Justin (ex Trög. lib. ii. cap. 4.) traces the origin of the Amazonian republic in Scythia. About the time of the first irruptions of the Scythians into Asia, in the reign of Sesostris, king of Egypt, two princes of the royal blood, named Hylinos and Scolopytus, were compelled by an adverse faction to retire into Cappadocia with their wives and families. By the assistance of the youths they brought with them, they obtained possession of Thermoscira, on the river Thermodon, whence they made incursions into the adjacent nations for several years, till at last they were all treacherously murdered. Their wives, partly from revenge and partly from a dread of slavery, put themselves under the conduct of some of their chief heroines, and prepared for a bloody war with the murderers. In order to give full scope to their fury, they renounced all future marriages, and destroyed those of their husbands, who had escaped the slaughter; and then proceeded with such vigour and such success against their enemies, as totally to overthrow them, and to compel them to sue for peace. One of their stipulations was, that they should yearly have a month's intercourse with each other, for the propagation of their species; after which they brought up all their girls in their own way, deprived them of their right breasts, that they might be no obstruction to them in drawing their bow; and as for the boys, they either killed them, as Justin says, or disabled them for martial exercise, or sent them to their fathers, according to Herodotus and others. These surprizing exploits were achieved under the government and conduct of two queens, Lampeto and Marphesia, who pretended to be the daughters of Mars; and who, having extended their conquests into Asia, built cities there. The former of these females was left behind, with an army to secure their conquest, and the latter, on her return home, with her spoils, was surprized and cut off, with the rest of her female warriors, by some bands of barbarians. After a succession of female queens, Penthesilea is said to have come to Troy for the assistance of Priamus, as we have already mentioned. This queen, it is added, was the inventress of the battle-axe, and was killed by Pyrihus, the son of Achilles. Another of their queens, named Tomyris, had a bloody encounter with Cyrus, king of Persia; and the famous queen Thalestris had an amorous intercourse with Alexander the Great. Under this last queen it is said, that the Amazonian kingdom and race were ultimately destroyed.

Quintus Curtius (De Rebus Gestis, A. M. lib. vi. c. 5. tom. i. p. 400. ed. Snakenburg.) has given a particular account of this intercourse between Thalestris and Alexander. He says, that the nation of the Amazons were situated upon the borders of Hyrcania, and that they inhabited the plains of Themiscyra, near the river Thermodon. Thalestris, their queen, who governed the whole country between Mount Caucasus and the river Phasis, being desirous of seeing Alexander, sent messengers to request an interview with him. Having obtained permission to visit him, she advanced with 300 of her female warriors; and when she approached his

presence, she leaped from her horse, with two javelins in her right hand. The apparel of the Amazons, says Curtius, does not cover the whole body; but the left side is naked to the breast, and the skirts of their garments, which are tied up in a knot, reach below the knees. Their left breast is preserved, that they may suckle their female offspring; but the right breast is seared, that they may the more easily bend the bow, and shoot their arrows. Thalestris, after observing Alexander for some time with an undaunted countenance, was disappointed, as his personal appearance did not correspond to the ideas she had previously formed of him, from the report of his signal exploits. When the king asked her, whether she had any thing to desire of him, Thalestris without hesitation replied, that she wished to have children by him, and that she was worthy of the honour of giving heirs to his dominions. The female she would reserve for herself, and the male should be delivered to him. When Alexander interrogated her, whether she would accompany him in his wars, she declined, alleging, that she had left her kingdom without a guardian. Alexander, after renewed solicitations on her part, and a delay of 13 days, complied with her wishes; and Thalestris returned to her kingdom.

Plutarch, in his life of Pompey, (Oper. tom. i. p. 678.) says, that the Amazons inhabit those parts of Mount Caucasus, that lie towards the Hyrcanian sea, that they are separated from the Albanians by the Getulæ and Leges, and that they annually, for two months, accompany these people, and cohabit with them near the river Thermodon. They then retire to their own habitations, and live apart for the rest of the year. In his life of Theseus, (Oper. tom. i. p. 13.) Plutarch, after reciting some particulars relating to the history of the Amazons, acknowledges, that the accounts of them which had been preserved were partly fabulous and partly true. The arms of the Amazons were bows and arrows, javelins, and a kind of battle-axes, denominated the axe of the Amazons, the invention of which is ascribed by the elder Pliny to their queen, Penthesilea. On medals, the bust of the Amazons is usually armed with a small two-edged axe, called *bipennis* or *securis*, borne on the shoulder; and a buckler, in the form of a half moon, by the Latins called *pelta*, on the left arm. Hence Ovid's description. Ex Pont.

“ Non tibia Amazonia est pro me sumenda securis,
Aut excisa lævi pelta gerenda manu.”

And Virgil, speaking of the queen Penthesilea in *Æneid*: lib. i. v. 490, says,

“ Ducit Amazonidum lunatis agmina peltis.”

Beside the Amazons of Africa, which formed the most considerable body of these female warriors, and those of Mount Caucasus, near Colchis and Albania, and likewise near the Palus Mæotis, of whom we have already given an account, Polyænus speaks of Amazons in India, who are also mentioned by Nonnus. They likewise occur in *Æthiopia*. They at one time, says Dr. Bryant, possessed all Ionia; and there were traditions of their being at Samos, and in Italy, where they had a town in Messapia, towards the lower part of the country, called Amazonia. Even the Athenians and Bœotians were of the same family; hence it is said, that Cadmus had an Amazonian wife, when he went to Thebes, and that her name was Sphinx. The Colehians and Iberians, as well as the Cimmerians and Mæotæ, according to this learned writer, were Amazonians; and so were all the Ionians, and the Atlantians of Mauritania. Philostratus,

in his *Heroicis*, mentions Amazonians on the Danube, and in Lucius Florus we read of German Amazons.

Among the ancient writers, who consider the peculiar history of the Amazons as fabulous, we have already mentioned Palæphatus, who was complimented for his distinguished understanding, by the appellation “ὁ τὸ πᾶσι λόγος;” and who gave it no credit. Strabo also, although born at Amalthis, in Cappadocia, an Amazonian region, could obtain no evidence to countenance the history. He says, (lib. ii. tom. ii. p. 770.) that many legendary stories have a mixture of truth, and most accounts admit of some variation. But the history of the Amazons has been uniformly the same; the whole a monstrous and absurd detail, without the least appearance of probability. For who can be persuaded, that a community of women, either as an army, or a city, or a state, could subsist without men? and not only subsist, but make expeditions into other countries, and gain the sovereignty over kingdoms; not merely over the Ionians and those who were in their neighbourhood, but pass the seas and carry their arms into Europe; to accede to this were to suppose, that nature varied from her fixed principles; and that in those days women were men, and men women. It may be added, that if such a people really existed, some traces of them would have been found, either in Iberia and Albania; or in the country upon the Thermodon, where they are supposed chiefly to have resided. But Procopius (*De Bell. Gothic. lib. iv. c. 3. p. 570.*) says, that there was no mark, no tradition to be observed concerning them.

Amongst the moderns, who have maintained the existence of Amazons in ancient times, we may mention M. Petit, a French physician, who published a Latin dissertation, in 1685, in order to establish the fact. This dissertation contains abundance of curious inquiries, relating to their habit, their arms, the cities built by them, &c. Dr. Bryant (*Analysis of Ancient Mythology, vol. iii. p. 457, &c.*) explodes the account of the existence of such a nation as fabulous; and he says, that the whole of this strange history has been owing to a wrong etymology of the appellation Amazon. The Greeks, who were fond of deducing every thing from their own language, imagined, that by the term Amazon was signified a person without a breast. This person they inferred to be a female; and, in consequence of it, as the Amazons were a powerful people, they formed a notion, that they were a community of women, who subsisted by themselves; and every absurdity, with which this history is attended, took its rise from the above-stated misconception. They did not consider, that there were many nations of the Amazons widely separated from each other; nor did they know, that they themselves were of Amazonian race. Dr. Bryant is of opinion, that the Amazons were in general Cuthite colonies from Egypt and Syria; and as they worshipped the sun, they were called Azones, Amazones, and Alazones, which are names of the same import and bear reference to the national object of worship. To this purpose Pausanias (lib. iii. p. 274.) mentions Apollo Amazonius, who was worshipped in Laconia. The most noted of them inhabited the region of Pontus, near the river Thermodon; and they were also called Chalybes, and Alybes, and occupied part both of Cappadocia and Armenia, being situated near Sinope, and extending towards Colchis. They are mentioned by Homer (*Iliad. lib. v. v. 856.*) among the allies of the Trojans. One of the principal cities of these Chalybes, besides Sinope, was Amisoa, or as Pliny expresses it more justly (lib. vi. p. 303.) Amazon, and he mentions a mountain near it of the same name. These people had different titles in the countries where they settled, and often in the same

region; and therefore their history has been confused. They were called not only Amazonians, but Syri, Assyrii, Chaldei, Mauri and Chalybes, and were still further diversified. They were the same as the Ionim, and in consequence of it, they are said to have founded the chief and most ancient cities in Ionia, and its neighbourhood. Accordingly the coin of the cities in Asia Minor, and particularly of those in Phrygia, Ionia, and Mylia, has often an Amazon for its device. The Amazons, according to the learned writer now cited, were Arkites, and one of their chief cities was called Archæopolis, who came from Egypt, and worshipped the sun, and Selene, the chief deities of the country, from whence they came. They are stiled by Herodotus *Æor-pata*, not as he conceives from killing their husbands, because, according to their history, they had not any, but from their worship; and this name was given to their priests. It signifies a priest of Ὀρος or Orus; and these priests used to sacrifice strangers, who accidentally came upon their coast, and hence they were stiled, “*Ἀνδροκτονίαι,*” murderers. The Egyptians, it is alleged, admitted the sistrum among their military instruments of music, and made use of it when they went to war. The same practice prevailed among the Amazonians, who worshipped the Isis of Egypt, and made use of her sistrum, when they engaged in battle. The Amazonians of Colchis and Armenia were not far removed from the Minyæ, near Mount Ararat, and were of the same family. They were Arkites, as we may learn from the people of Pontic Theba, and followed the rites of the ark, under the name of Meen, Baris, and Iona. Hence it is, that they have been represented with lunar shields; not that they were of a lunar shape, but the lunette was a device taken from their worship. It was the national ensign, which was painted upon their shields; whence it is said of them, “*πίστις bellantur Amazones armis.*” The Amazonian shield approached nearly to the shape of a leaf, as did also the shields of the Gothic nations; and upon these shields they had more lunettes than one; and from them the custom was transmitted to the Turks and other Tartar nations. One of the most extraordinary circumstances in the history of the Amazons is their invasion of Attica. They are represented as women, who came from the river Thermodon, in revenge for the insult offered them by Hercules, who had plundered their country. Their attack is described as violent; and the conflict for a long time doubtful. At last, having lost many of their companions, they were obliged to retreat and entirely to leave the country. Of this invasion the Athenians pretended to have had many evidences; they exhibited the tombs of the Amazons, who fell in the contest; the place of engagement was called Amazonium; and near it was an ancient pillar, said to be erected by this people. But the history abounds with inconsistencies, though Plutarch (*ubi supra*) seems to credit it, and adduces several circumstances, with a view of establishing its certainty. Such a people, however, as the Amazonians, had certainly been in Attica; the Athenians, as well as the Bœotians, were in a great measure defended from them. The rites to which Plutarch refers, in proof of hostility between the Amazonians and Athenians, afford no conclusive argument to this purpose; because they consisted originally in offerings made to the deity, from whom the Amazons derived their name. He was called Azon, and Amazon, and was the same as Ares, the sun. They worshipped both Ares and Harmon, changed by the Greeks to a feminine Harmonia; and in consequence of this worship, the Amazons were said to be the offspring of those deities. Hence it is, that the wife of Cadmus was said to be Harmonia; for the Cadmians were undoubtedly

undoubtedly Amazonians. What became of these female warriors after their repulse from Attica, the Grecians have not historically ascertained. Some say that they retreated into Magna Græcia, and founded the city Clœite. Isocrates (in Panegy. p. 93.) acknowledges, that none of them returned into their own country; and Lyfias (Funeb. Orat.) says, that their nation was wholly ruined by this expedition, that they lost their territories, and that they were no more heard of. Upon which Plutarch (*ubi supra*) observes, that we must not wonder, when transactions are of such antiquity, if history should prove contradictory and obscure.

The Amazons are said to have always fought on horseback, (Aristoph. *Lysistrata*, v. 680.); and yet the use of cavalry was not known in Greece, till long after this æra; for, according to Homer, the Asiatic nations at the siege of Troy were equally unacquainted with this advantage. As for the tombs, which have been adduced as evidence of this invasion, they were probably high altars, raised in ancient days. The whole of this history relates to old rites and customs; and not to any warlike expedition. The pillar, called Amazonium, indicates, that the Amazons might have been once in this country, and that they probably erected it; but this was the object to which they paid their adoration, as they lived in an age, when statues were not known. Such a one the Argonauts are said to have found in the temple of Arez, when they landed upon the coast of Pontus, and made their offerings to the deity, thus described by Apollonius, (*Argonaut. lib. ii. v. 1174.*) according to the English translation of the original—

“ Now to the grove of Arez they repair,
And while the victims bleed, they take their stand
Around the glowing altar, full in front
Of a fair temple. Here of ebon hue
Rises in air a lofty antique stone.
Before it all of Amazonian name
Bow low, and make their vows.”

That these supposed tombs were altars, is also inferred from their situation in the middle of the city, and in many different places. Every circumstance of this invasion is attended, says our author, with some absurdity. It is owing, we are told, to the injustice of Hercules, who stole the girdle of Hippolyte, and attacked the nation, of which she was queen, so as quite to ruin it. The Amazons, thus defeated and weakened, and not able to withstand their next neighbours (see *Diod. Sic. lib. iv. p. 229. tom. i. p. 262.*) determined to wage war with the Greeks, and particularly with Theseus of Athens. They began their march, but instead of proceeding directly to Greece, they pursued a contrary route, passing north-east in order to arrive at the south-west, and ranging round the whole Euxine sea, by Mount Caucasus and Colchis, to the Cimmerian Bosphorus, and traversing many hills and rivers, they at last arrived at Athens, pitched their camp in the precincts of the city, close to the Acropolis, fought a severe battle, retired, and not being able to return home, were dispersed and annihilated. And yet so far is this female history from terminating, the Amazons are introduced again by the poets, Homer, Virgil, &c. at the siege of Troy, and are to be met with in the wars of Cyrus. Some ages after, in the time of Alexander, an interview is said to have passed, as we have already related, in which the queen of the Amazons makes proposals to that monarch about sharing, for a night or two, his bed. And even in the time of Pompey the Great, during the Mithridatic war, they are supposed to exist; for

after a victory gained by that general, the Roman soldiers are said to have found many boots and buskins, which Dion Cassius (in *Bell. Mithrid.*) thinks were undoubtedly Amazonian. Such, says Bryant, after a long and learned detail of various particulars, of which the above is merely a concise abstract, was the credulity of the ancients about one of the most improbable stories that was ever feigned: and this learned writer concludes upon the whole, “ that the Amazonians were a manifold people, and denominated from their worship. They were some of the Titanic race, who settled in Colchis, Ionia, Hellas, and upon the Atlantic in Mauritania; they were also to be found in other parts, and their family characteristic may in all places be seen. They were the same as the Cadmians; and the structures which bore their names were not erected to them, but were the work of their own hands.” Eumolpus, says Plato (*Menæxenus, vol. ii. p. 239.*), led the Amazons, when they invaded Attica; and he is supposed to have been the principal person who introduced the rites and mysteries, which were observed by the Athenians. His sons were the priests, who officiated at the temple of Ceres in Eleusis. From all circumstances it is concluded, “ that what has been represented as a warlike expedition, was merely the settling of a colony, and those who had the conduct of it were Amazonians, who had been represented as women. And so far is probable, that there were women among them, who officiated at the religious ceremonies which were instituted.” — Among barbarous nations women have often combated by the side of their husbands; but it is almost impossible, says Mr. Gibbon, (*Hist. vol. xi. p. 46.*) that a society of Amazons should ever have subsisted either in the old or new world.

Later geographers and travellers speak of Mingrelian and Georgian Amazons; Amazons in America, in Monomotapa, in the Philippine islands, in Denmark, &c. John de los Sanctos, a Portuguese capuchin, in his description of Ethiopia, mentions a race of Amazons in Africa; and Æneas Sylvius gives us a very precise account of a republic of real Amazons in Bohemia, which lasted nine years, founded by the valour of a young woman, named Valasca. That there have been females of singular talents and very extraordinary firmness and resolution, in all ages and in all nations, no one can dispute; and if we compare the warlike genius of the Scythian women in general, and more particularly that of the Sarmatians, in whose neighbourhood the Amazons are said to have lived, with the occasion which is reported to have given birth to their strange kind of government, namely, the treacherous murder of their husbands, and their being in danger of becoming a prey to their murderers, and in a strange country; we may incline to give some credit to the brave and masculine method which they took to save themselves from slavery, and to revenge the slaughter of their husbands. The Scythian, as well as the Celtic women, were anciently held in great esteem and veneration, for their skill in divination above the men, insomuch that the latter are upbraided by ancient authors for suffering women to assist at and direct their councils and to have even presided in their courts of judicature, and other assemblies; in which their judgment was reckoned decisive, because they were supposed to be divinely inspired. Being, therefore, inured to council, execution, and warlike exploits, exasperated by the barbarous brutality of their husbands, and rendered, as it were, desperate by the prospect of impending slavery, we need not wonder, that they should adopt effectual means of inflicting vengeance, and of defending themselves; and, with this view, that they should

should select one or two of the strongest and most valiant to lead them in an offensive war against their enemies, and that they should carry it on with courage and constancy, and of course with such astonishing success. And if their warlike temper, their government, customs, valour, conduct, and achievements, have been exaggerated beyond credibility, it may be alleged, that this has been done with respect to other nations, governments, and conquerors, which have attracted unusual attention, and which it would be absurd to reject as altogether fabulous on that account. The same allowance should be made in both cases: and this is much more reasonable than to suppose that the various historians who have given an account of them, have been guilty of forgery or of too great credulity.

The true history of the ancient, and even of the modern Amazons, has, without doubt, been blended with much fable, with many marvellous and improbable, not to say altogether incredible relations; but the testimony upon which it is transmitted to us deserves regard, and it would manifest a degree of scepticism, which, applied to other cases, would be not only unwarrantable, but dangerous and pernicious, altogether to discard it. The empire of the Amazons was certainly of a different kind from that which properly belongs to the female sex. "The empire of the woman," says Rousseau, "is an empire of softness, of address, of complacency. Her commands are caresses; her menaces are tears." "The character of the ancient Amazons," says Dr. Johnson, "was rather terrible than lovely. The hand could not be very delicate: that was only employed in drawing the bow, and brandishing the battle-ax. Their power was maintained by cruelty; their courage was deformed by ferocity; and their example only shews, that men and women live best together."

AMAZON is applied, in a figurative sense, to bees, because among these insects the females alone are commonly supposed to bear sway.

Aristotle, treating of the breeding of bees, professes himself ignorant of their sex; and therefore, willing to keep up the prerogative of the males, calls their governor βασιλεύς, *rex*, in which he has been followed by the generality of authors.

An ingenious writer of our own country, takes the liberty to strain the ordinary signification of the word *rex*, and in such places translates it *queen*, this being an *Amazonian*, or female kingdom.

Mr. Warder has published a work under the title of the True Amazons, or the Commonwealth of BEES.

AMAZONIAN, something relating to, or resembling AMAZONS.

AMAZONIAN kingdom, is particularly used for a feminine one, or that wherein the females alone bear rule.

AMAZONIAN habit, in *Antiquity*, denotes a dress formed in imitation of the Amazons.

Marcia, the famous concubine of the emperor Commodus, had the appellation Amazonian, because she charmed him most in a habit of this kind.—Hence also that prince himself engaged in combat, or at least intended to engage, in the amphitheatre, in an Amazonian habit; and of all titles the Amazonian was one of those he most delighted in. In honour either of the gallant, or his mistress, the month of January was also denominated Amazonian. Some also apply Amazonian habit to the hunting dress worn by many ladies among us.

AMAZONIUS is an appellation given to a kind of pastil, or *troche*, anciently used against risings of the stomach, and vomitings.—The ingredients of which it is com-

posed, are smallage, anise-seed, wormwood, myrrh, pepper, *cyborum*, *opium*, and cinnamon.

AMAZONUS, in *Entomology*, a small species of SCARABÆUS, found in Surinam. It is testaceous, with two black marks on the thorax, and a brown callus on the exterior margin of the wing-cases. Linn. Syst. Nat.

AMBA, in *Botany*, a name by which some authors have called the *magna Indica*, or MANGO-tree, called also *ambalam*, and *ambe*.

AMBACHT, in *Topography*, denotes a kind of jurisdiction, or territory, the possessor whereof has the administration of justice, both in *alto* and *basso*; or of what is called in the Scots law a power of pit and gallows, *i. e.* a power of drowning and hanging.

In some ancient writers *ambacht* is particularly used for the jurisdiction, government, or chief magistracy of a city. The word is very ancient, though used originally in a sense somewhat different. Fennius calls a mercenary, or slave hired for money, *ambactus*; and Cæsar (*De Bell. Gallic. vi. 14.*) gives the same appellation to a kind of dependents among the Gauls, who, without being slaves, were attached to the service of great lords.

AMBAGES, in *Rhetoric*. See CIRCUMLOCUTION.

AMBAIBA, the name of a tree in Brasil, called by the Indians, *tipioca*. Ray's Hist. Plant. See CERKOPIA.

AMBATINGA, the name of a tree, whose leaves are so rough that they may be used to polish hard wood. Ray's Hist. Plant.

AMBAPAYA. See CARICA.

AMBAR seed, in the *Materia Medica*, a name by which some have called musk seed.

AMBARES, in *Geography*, a town of France, in the department of the Gironde, and chief place of a canton, in the district of Bourdeaux, five miles north-east of Bourdeaux.

AMBARVALIA, in *Antiquity*, a feast, or ceremony, among the Romans, celebrated annually, in honour of the goddess Ceres, in order to procure a happy harvest.

At these feasts, they sacrificed a bull, a sow, and a sheep; which, before the sacrifice, were led in procession thrice around the fields; whence the feast is supposed to have taken its name: from the Greek *αμβι*, *about*: or the Latin *ambio*, *I go round*; and *arvum*, *field*.—Though others write it *ambarbalia*, and *ambarbia*, and deduce it from *ambire urbem*, *to go round the city*.

From the beasts offered in sacrifice, the ceremony was also called SUOVETAURILIA.

Some will have the *ambarvalia* to have been held twice a year: the first time towards the end of January, or, as others think, in April; and the second time in July, or as Rosinus imagines, in August; at the time when the harvest was ripe, *maturis frugibus*. Which opinion is the more probable, in that Ovid, who, in his *Fasts*, describes the feasts of the first six months of the year, from January to June inclusive, says nothing of the *ambarvalia*.

The sacrifice offered on this occasion was hence called *ambarvale sacrum*, and *hostia ambarvalis*.

The *ambarvalia* were of two kinds, *public* and *private*.

The *private* were those solemnized by the masters of families, accompanied with their children and servants, in the villages and farms out of Rome.—They walked three times round the grounds, every one being crowned with leaves of oak, and singing hymns in honour of Ceres. After the procession, they went to sacrifice.

The,

The *ambrosale carmen* was a prayer preferred on this occasion; whereof we have the *formula* preserved in Cato. "De re rustica." c. 142.

The *public ambervalia* were those celebrated in the boundaries of the city; and in which the twelve *fratres aruales* officiated pontifically, walking at the head of a procession of the citizens, who had lands and vineyards at Rome.

The prayer, or *formula*, here used, as it is given by Festus, in voc. "pefallas," was *avertas morbum, mortem, tabem, nebulam, impetiginem, pestiflatum*. Virgil has described the ambervalia in the first book of his *Georgics*, v. 343, &c.

Some make a quinquennial as well as an annual ambervalia, the one performed once every *lustrum*, the other once a year.

The priests who chiefly officiated at this solemnity, were called *fratres ARVALES*.

AMBERVALIS *flos*, in *Botany*, a name given, by some authors, to the *polygala*, or milkwort.

AMBASSADOR. See EMBASSADOR.

AMBAZAC, in *Geography*, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Limoges, 10 miles north-east of Limoges. The place contains 2783, and the canton 7342, inhabitants; the territory includes 202½ kilometres, and 7 communes.

AMBE, in *Anatomy*, a superficial jetting out of a bone.

AMBE, or AMBI, in *Surgery*, an instrument employed for the reduction of a dislocated shoulder, especially when the head of the os brachii rests in the axilla. Various improvements have been made in the construction of the ambi since Hippocrates's time; but its use is rarely wanted, as a dexterous surgeon can generally replace the shoulder bone by more simple means. See DISLOCATIONS.

AMBEEZES, AMBOISES, or AMBOZES, in *Geography*, an island of Africa, in the Atlantic Ocean, near the coast of Benin. N. lat. 4° 15'. E. long. 10° 50'.

AMBEL, in *Botany*. See NYMPHÆA.

AMBELANIA. See WILLUGHBEIA.

AMBER, *ἤλεκτρον*, Gr.—*Electrum, succinum*, Lat.—*Succin, carabé, ambre jaune*, Fr.—*Bernstein, agtstein, glas Firnstein, wasch-amber*, Ger.—*Gleffum*, ancient German, according to Pliny.—*Bärnsten, ras, glys*, Swed.—*Bernsteen*, Dan.—*Succino, ambra gialla*, Ital.—*Enyokó, Hung.*—*Jantar*, Russ.—*Sacal*, Egypt.—*Bitumen succinum*, Werner.

The colour of amber is generally some shade of yellow, as wine yellow, wax yellow, honey yellow, hyacinth red, yellowish white; it is also found occasionally green or brown. It occurs amorphous, and in detached pieces. Is shining, or little shining, with a waxen lustre. Its fracture is conchoidal, and when broken it flies into indeterminate not particularly sharp fragments. It is commonly transparent, more rarely semitransparent or translucent. Is brittle, and its sp. grav. varies from 1.065 to 1.1.

By rubbing, it readily becomes electric. When applied to a lighted candle it takes fire, swells considerably, but does not run into drops, and exhales a white smoke of a pungent penetrating odour.

It is sometimes confounded with COPAL and HONEYSTONE, but may be distinguished from each without much difficulty. Copal is softer than amber, and when inflamed melts into drops. Honey-stone is much weaker in its electrical properties, and when laid on a hot coal becomes white.

The only proper mines of this substance that are as yet known, are in ducal Prussia, near the sea coast. They are worked in the usual way by shafts and galleries to the depth of about a hundred feet. The amber is imbedded

in a stratum of fossil or carbonated wood, and occurs in nodules from a few grains in weight, to three or even five pounds: specimens also are occasionally met with consisting of the wood penetrated by veins of amber. The upper and under strata are sand and sandstone. Amber is also found along the whole shore of the German sea, and on the south coast of the Baltic. The projecting eastern shore of England too, and the coast at the entrance of the channel from the north affords many specimens. Rounded nodules have been occasionally met with in the beds of gravel near London. It is not, however, exclusively, though principally a northern product: the coast of the Adriatic sea and the Sicilian shores furnish a small quantity, and occasionally pieces have been dug up near Sisteron in Provence.

The property of amber, when rubbed, to attract hair, straws, and other light substances, was first observed by Thales one of the Greek philosophers, who on this account attributed a certain kind of life to it; and from the Greek name of amber, *electron*, is derived the modern term electricity, being the science of an important class of facts, the first known of which was the attracting power of amber. On this account, and also from the real beauty of the substance, it was held in high estimation among the Romans, who made it into bracelets, necklaces, and other articles of female ornament. Those pieces that contained insects, &c. then as at present were the most valued, and we meet with many allusions in the Roman poets to this circumstance: thus Martial says,

"Cum Phatonteâ formica vagatur in umbrâ,
Implicuit tenuem fuccina gutta feram."

They also held the idle opinion, which till lately was generally received among us, that a collar of amber tied round an infant's neck, would enable it to cut its teeth with safety.

When amber was more in request than it is now, as an ornament, and an article of *Materia Medica*, great attention was paid to it by the Prussian miners, and many experiments were made by the artists to remove its defects, and improve its beauty. The coarser and smallest pieces were called *standstein* or *fehlug*, those that were a little larger and cleaner had the name of *firnis* or *varnish* amber, and the larger and better pieces were called, from the particular works to which they were applicable. Of the transparent ambers the most valuable was the bright golden yellow, of the opaque varieties the most esteemed were the flaky, or scaly. Methods were discovered, especially by Gottlieb Samuelson of Breslau, of making opaque amber transparent, and of tinging it red, blue, violet, green, and white. Most of these secrets have perished with the inventors, but the two following were the usual methods of rendering amber transparent. First, by surrounding it with sand in an iron pot, and cementing it with a gentle heat for forty hours, some small pieces being occasionally taken out to judge of the progress of the operation. Secondly, which was the most usual method, by digesting and boiling the amber about twenty hours with rapeseed oil, when it became harder and clearer; linseed oil has not the desired effect. Amber, however, thus clarified, is always harder and less electric than in its natural state. The value of amber depending on its size, numerous attempts, but constantly without success, were made to solder together or melt down several small pieces, so as to convert them into one large piece.

The origin of amber has exercised the imagination of poets and chemists from the days of ancient Greece to the present, nor is it worth while to enter into an examination of any of these opinions, except those which are held by modern inquirers. Amber is by some considered as a proper mineral bitumen analogous to petroleum, perhaps originating

nating from this, and slightly altered by the action of the air or an acid. By others it is reckoned as a vegetable resin, which, by being buried in the earth in contact with carbonaceous and pyritical matters, has become hard, and experienced other modifications of its original properties. That whenever it is found in real mines, it is always accompanied with strata of fossil wood and peat, is a strong presumption of its vegetable origin; and the ants and other insects which it is so frequently found to contain, shew that amber must formerly have been fluid, and when in that state have been in places accessible to these animals, and therefore upon, or at least very near the surface of the earth. It might also be mentioned upon the authority of Götanner, if the uncorroborated authority of this chemist was of any value, that pieces of turpentine have been found in the large ants' nests, that abound in pine forests, penetrated by the acid of ants, and thus partly converted into amber, but still of a ductile consistence like wax.

The chemical properties of amber have been as yet but little examined. Few menstrua will dissolve without in some degree altering it. According to Hoffman, one part of powdered amber, and two of oil of almonds, are capable of combining with each other into a clear gelatinous mass, by being moderately heated for about an hour in a Papin's digester. It is also, according to the same author, totally soluble in caustic potash. Alcohol extracts the colouring part with some resin, but is not a complete solvent. It is said also, that sulphuric acid is a menstruum for amber, but probably not without considerably changing its properties. When exposed to dry distillation in a glass retort, it melts and swells greatly, and gives out first a watery acid liquor smelling strongly of amber, then a concrete acid salt which crystallizes in yellowish needles in the neck of the retort, and is the *succinic acid*; after which there passes a light coloured odorous oil, which, as the distillation goes on, becomes of a darker colour and thicker consistence, a small quantity of the acid also rises at the same time. When all the volatile parts are thus separated, there remains in the retort a spongy intensely black shining coal, the basis of the fine black *VARNISH*. The oil is afterwards rectified by distillation with water, when only the light fragrant colourless part comes over. The relative proportions of oil and acid vary according to the purity of the amber used and the care of the operator. From sixteen ounces of the common dark brown amber of the shops Neumann obtained eleven ounces, six drams of oil, four drams and a half of acid, an ounce and a half of acidulous water, and about an ounce of carbonaceous-residue. From thirty-two ounces of the small granular kind, or sandstein, he obtained nine drams of acid, and twenty-four ounces of oil.

The use of amber as a fumigatory is nearly laid aside, as is also the medical employment of its acid. The oil is used as an antispasmodic, both externally and internally, and when combined with ammonia forms *EAU DE LUCE*.

By the change of fashion, amber is little used as an ornament in Europe. Trinkets of this substance are, however, still valued in Turkey, and the East. The finest specimens are in the cabinet of the king of Prussia: as to the column ten feet high in the Florentine museum, an account of which authors have copied from each other for a century past, it is probably artificial.

AMBER, black, *gagates*. See *JET*.

AMBER, liquid, and *balsam of*. See *BALSAM*.

AMBER, in *Geography*, a river of Germany, in Bavaria, which rises two leagues from Faxsen, and joins the Iser, near Landshut.

AMBER Bay, is situated on the peninsula of Yucaten, in the bay of Honduras, and lies north of ASCENSION Bay.

AMBER-SEED, or *myrt seed*, is a seed that is somewhat like the millet, of a bitterish taste, and brought dry to us from Martinico and Egypt. The Egyptians use it internally, as a cordial, to fortify the heart, stomach, and head, and provoke lust.—It gives a grateful scent to the breath, after eating; but it is not proper for those who are inclinable to vapours.

AMBER-TREE, in *Botany*. See *ANTHOSPERMUM*.

AMBERBOI. See *CENTAUREA*.

AMBERG, in *Geography*, a city of Germany, in the circle of Bavaria, and Upper Palatinate, 32 miles north of Ratibon, and 32 east of Nuremberg. It is the capital of the duchy and residence of the elector's governor; it is seated on the river Vils, which runs through it, is well fortified, and is the largest place in the Upper Palatinate. It has an electoral palace, a cathedral, and a college of Jesuits. It is said to have been raised from a village to a town in 1297; and was taken by the Imperialists in 1703. On a mountain near it stands the pilgrimage-church, called *Mary's help*, and in its vicinity is an iron-mine, which furnishes it with a considerable trade. N. lat. 49° 25'. E. long. 11° 55'.

AMBERG, a mountain of Sweden, in East Gothland, about two Swedish miles from Wadstena. Its height is so considerable, that from the summit of it a person may see 50 churches. Upon this mountain is a flat stone, under which one of the ancient kings is said to be interred. Antimony is found in this mountain near the Wetter-lake.

AMBERGER, CHRISTOPHER, in *Biography*, an eminent painter of portrait and history, was born at Nuremberg, and resided at Augsburg, where he died in 1550. He was a disciple of Hans Holbein, whom he imitated so exactly, that his pictures were sometimes taken for those of his master. He principally excelled in portraits, and acquired great reputation by his history of Joseph, in 12 pictures, and by the portrait of Charles V., for which the emperor paid him three times as much as he expected, besides a present of a rich chain of gold and a medal. Amberger was also an engraver, though his works are not specified. Pilkington and Strutt.

AMBERGREESE KEY, in *Geography*, an island in Hanover Bay, on the east side of the peninsula of Yucaten, in the bay of Honduras. It runs along the mouth of the bay, and is seventy miles in length, but very narrow.

AMBERGRIS, from *amber* and *gris*, **AMBERGREASE**, **AMBERGRISEA**, *succinum griseum*, in *Natural History*, a light, inflammable, greyish, variegated substance, fusible and fragrant with a gentle heat, and used as a perfume and a cordial. Its colour is grey, brown, or yellowish brown, spotted with black; its hardness and consistence are those of wax; its specific gravity from .780 to .926, so that it swims both in water and rectified spirit; its fracture is earthy and rugged, and exhibits bones of fish or beaks of birds; it has scarcely any particular taste, and unless heated, or much handled, very little smell; but in such circumstances its odour is very fragrant, resembling that of burning amber, and to most persons agreeable. It softens between the fingers, melts in a small degree of heat like wax; in a stronger inflames, and if pure, leaves no residuum; cold water has no effect upon it, but to boiling water it communicates its smell, and being partially melted, falls to pieces. It is scarcely affected by spirit of wine, which dissolves it sparingly with the assistance

assistance of a boiling heat, or fat oils: but by the essential, as that of turpentine, it is dissolved almost entirely, and by ether most perfectly. It has been found soluble in caustic fixed alkalis, still more so in oil of vitriol, and precipitable by water. Distilled it yields an aqueous phlegm, a brown-coloured acidulous spirit, a deeper coloured oil, at length, a thick balsam, and as some say, a volatile salt, leaving a black shining residuum. The spirit, oil, balsam, and salt, are similar to those obtained from amber; but the oil is of a more grateful smell. Its chemical products resemble those of bitumens, among which some have ranked it.

It is found on the sea-coasts, floating on the surface of the sea, adhering to rocks, or thrown out upon the shores, in several countries; as along the southern and eastern parts of Africa, Madagascar, the Maldives, some parts of the Mediterranean, and in the West Indies, about the islands of Bermudas and Jamaica, and the Bahama islands, also on the coasts of Carolina, and the western coasts of Ireland. It is likewise said to be found on the coasts of Norfolk, and in the islands of Orkney. It has also been found in the stomachs of whales, of various sizes and shapes. We have several instances in authors of large pieces of this matter: one of the largest that has been known in Europe was bought by the Dutch East India Company, of the king of Tidore, for 11000 dollars, in 1693, and sent to Amsterdam in 1694, and kept in their house for some years. It was almost round; measured two feet in diameter, and weighed a hundred and eighty-two pounds. The great duke of Tuscany offered fifty thousand crowns for it. We are told, however, that one was taken up, near the Cape of Good Hope, which weighed three hundred pounds; and another, if we may credit the relation, fifteen thousand pounds. Phil. Trans. N^o 263. N^o 232.

There has been a great variety of opinions among naturalists with regard to the origin and production of this substance: to rehearse them all, would make a volume. Klobius recites eighteen, to which we could add half as many more. The principal may be reduced to these which follow.

1. Some take it for the excrement of a bird, called in the Madagascar language *aschibobuch*, and by the Maldives *Anacangripasqui*; which being melted by the heat of the sun, and washed off the shore by the waves, they say, is swallowed up by whales, who return it back in the condition we find it.

2. Others, and particularly many of the orientals, imagine it springs out of the bottom of the sea, as *naphtha* does out of some fountains.—They add that the only springs of it are in the sea of Ormus, between the Arabian and Persian Gulfs. Edrissi, who is of this opinion, in the first climate of his Geography, mentions pieces of ambergris on those coasts, weighing a full quintal. Paludanus and Linschotten also speak of it as a sort of bitumen, gradually working up from the bottom of the sea and hardening in the sun.

3. Others take it for a sea-mushroom, torn up from the bottom by the violence of tempests; it being observed, that ambergris is never found but during the south-west monsoons, after storms.

4. Others assert, that it is a vegetable production, issuing out of the root of a tree, whose roots always shoot toward the sea, and discharge themselves into the same. This account we have in the Philosophical Transactions, from one of the Dutch factors at Batavia; and the same is confirmed by Mr. Boyle. Others take it for a kind of wax or gum, which distils from trees, and drops into the sea, when it congeals, and becomes ambergris. Mr. Magellan mentions an undoubtedly vegetable ambergris, gathered from the tree

by M. Aublet, and examined by Rouelle. Cronstett's Mineralogy, p. 458.

5. Others suppose it a spongy kind of earth, which the working of the sea washes off the rocks, where, being lighter than water, it floats.

6. Others maintain, that ambergris is made from the honey-combs which fall into the sea from the rocks, where the bees have formed their nests. This opinion seems to have something of experience on its side; several persons having seen pieces that were half ambergris, and half plain honey-comb; and others, again, having found large pieces of ambergris, in the middle of which, when broken, they discovered both honey-comb and honey. But the error of this hypothesis may be detected by chemical experiments; as honey likewise admits of a solution in aqueous *menstrua*, but resists the most highly rectified spirit of wine.

7. Others are of opinion, that it is a bituminous matter; that it is at first liquid, and runs into the sea: and that it is there condensed, and reduced into a mass. To this purpose Mr. Neumann, chemist to the king of Prussia, after an ample recital of all the different opinions advanced by others, gives us his own; which is, that ambergris is a bitumen, issuing out of the earth into the sea; at first of a viscous consistence, but hardening, by its mixture with some liquid *naphtha*, into the form wherein we find it. Phil. Trans. N^o 433, N^o 434. N^o 425. Mr. Cartheuser is of the same opinion.

This opinion has been considered as the best founded, and strengthened by this circumstance, that ambergris is found in the greatest quantities in the sea, about the island of Madagascar, where the subterranean parts are supposed to be impregnated with bituminous matter.

The pieces are frequently seen composed of divers strata, laid one over another, with stones and other bodies inclosed therein, and the strata are sometimes full of little shells, which seem a species of *concha anatifera*; whence it may be conjectured, that the ambergris has originally been in a fluid state, or, at least, that it has been dissolved and in that state has formed itself afresh, and enveloped such bodies as happened to be in its way.

Neumann gives the chemical characters of this bitumen, and its analysis, by distillation. He distinguishes the sophistications of ambergris, and observes, that it is totally soluble in oils and vinous spirits, and that it yields the same product, as AMBER. See the particulars and the proofs of this in Neumann's Works, p. 239. & seq.

8. Dr. Boyleston, and Mr. Dudley, in the Philosophical Transactions, assert, that the ambergris is a true, animal concrete, formed in balls, in the body of the male spermaceti whale, and lodged in a large oval bag, over the testicles, at the root of the penis. Phil. Trans. N^o 385. and 387. vol. xxiii.

It is certain the whale-catchers have divers times found ambergris in their spermaceti whales, and that chiefly in the large and older fort; and it is from the information of Mr. Atkins, and other whale catchers, that Mr. Dudley chiefly drew his account. But it is added, that it is not one spermaceti whale in an hundred that is found to have ambergris, and that it is found only in the male. To this account it has been objected, that ambergris is frequently found in females as well as in males; and that the beaks of the sepia, which are so constantly found in ambergris taken out of the whale, could not have been absorbed from the intestines by the lacteals or lymphatics, and collected with the ambergris in the above mentioned bag.

9. Others have approached nearer to the truth, who represent ambergris as the excrement of a cetaceous fish; because it has been sometimes found in the intestines, and

sometimes in the fæces themselves of such animals. Notwithstanding this suggestion, it was long thought, that ambergris, after having been swallowed, and in some mode or other changed in the stomach and bowels of the whales, from which it was obtained, was afterwards found among its excrements. But the real animal origin of ambergris has been satisfactorily ascertained by Dr. Swedjar, in the Philosophical Transactions, vol. lxxiii. art. 15.

In the accounts given of ambergris by various writers we have been told, that claws and beaks of birds, feathers of birds, parts of vegetables, shells, fish, and bones of fish, have been found blended with it. But Dr. Swedjar, after examining many fragments of this substance, found no such materials mixed with it; and though he allows that such may occasionally occur, yet the black spots which he discovered in the various pieces, found in the sea or in the whale, that were examined by him, appeared upon accurate scrutiny, to be the beaks of the *sepia octopodis*; and he apprehends, that these beaks were mistaken for claws or beaks of birds, or for shells. From the existence of these beaks in ambergris he infers, that this substance in its origin must have been of a very soft or liquid nature. In order to investigate the true nature of this substance, he premises, that ambergris has been found upon the sea and sea-coast, and also in the bowels of whales; but he observes, that it has never been determined, whether the ambergris found in these different situations be of the same kind, and possessed of the same or similar properties. He also suggests as a subject of previous inquiry, whether ambergris is found in all sorts of whales, or only in a particular species; whether it is constantly to be met with in those animals; and if this be the case, in what part of their body it is to be found. In discussing these subjects of examination, Dr. Swedjar consulted the most intelligent persons concerned in the spermaceti whale fishery, or in procuring and selling ambergris; and from their information it appeared, that this substance is sometimes found in the belly of the whale, but only in that species which is called the spermaceti whale, and which seems from its description and delineation to be the *physeter macrocephalus* of Linnæus. The New England fishermen, having been long apprized that ambergris is to be found in the spermaceti whale, conclude, that whales of this species frequent those seas where ambergris is found. They naturally expect to find ambergris in the spermaceti whales which they catch; but they are generally disappointed. Whenever they took a spermaceti whale, they observed, that it constantly not only vomits whatever it has on its stomach, but also generally discharges its fæces at the same time; and if this circumstance occurs, they seldom find ambergris in its belly. But whenever they discover a spermaceti whale, male or female, which seems torpid and sickly, they commonly find ambergris, as the whale in this state seldom voids its fæces upon being hooked. They likewise generally find it in the dead spermaceti whales, which they find floating upon the sea. Besides, those whales which yield ambergris have a morbid protuberance, or a kind of gathering, in the lower part of the belly, in which, when it is opened, they find ambergris. The whales, that yield this substance, are not only torpid and sick, but always leaner than others; and hence it is inferred, that a larger collection of ambergris in the belly of the whale is a source of disease, and probably sometimes the cause of its death. As soon as a whale, that is torpid, sick, or emaciated, or one that does not dung on being hooked, is caught, they immediately cut the protuberance already mentioned, if there be any, or rip open its bowels from the orifice of the anus, and find the amber-

gris, sometimes in one lump, sometimes in different lumps, generally from three to 12 and more inches in diameter, and from one to 20 or 30 lbs. in weight, at the distance of two, but most frequently of about six or seven feet from the anus, and never higher up in the intestinal canal; which, according to their description, is probably the intestinum cœcum, hitherto mistaken for a peculiar bag formed by nature for the secretion and collection of this singular substance. That this is the intestinal canal is certain, because they constantly begin their incision at the anus, and find the cavity every where filled with the fæces of the whale, which, from their colour and smell, it is impossible for them to mistake. The ambergris found in the intestinal canal is not so hard as that which is found on the sea or sea-coast, but soon hardens in the air. When first taken out, it has nearly the same colour, and the same unpleasant smell, though not so strong, as that of the mere liquid dung of the whale; but, on exposing it to the air, it gradually not only becomes greyish, and its surface covered with a greyish dust like old chocolate, but it also loses its disagreeable smell, and when kept for any long time, acquires the peculiar odour which is so agreeable to most people. In considering whether there be any material difference between ambergris found on the sea or sea-coast, and that found in the bowels or among the dung of the whale, Dr. Swedjar refutes the opinion, that ambergris found in whales is of an inferior quality, and therefore of much less value in price. Ambergris, he observes, is valued on account of its purity, lightness, compactness, colour and smell. On the different coasts pieces of ambergris are found of a very inferior quality; and those found in whales are of a superior quality; and different pieces in the same whale, are, according to the above specified test, of greater or less value. When ambergris is first taken out of the intestines of the whale, it has nearly the same smell with that of the liquid excrements, and also the same blackish colour; and it is found of different degrees of compactness, but never so liquid as the natural fæces of that animal. After being taken out and kept in the air, all ambergris becomes harder and whiter, and gradually loses its smell, and assumes such an agreeable one, as that in general has which is found swimming on the sea, and therefore the goodness of ambergris seems rather to depend on its age. By being accumulated after a certain length of time in the intestinal canal, it seems even then to become of a white colour, and less heavy, and to acquire its agreeable smell. The only reason why ambergris floating on the sea generally possesses the above mentioned qualities in a superior degree is, because it is commonly older, and has been longer exposed to the air.

It is more frequently found in males than in females; those pieces that are found in females are generally smaller, and those in males seem constantly to be larger and of a better quality; and therefore the high price in proportion to the size is not merely imaginary on account of its rarity, but in some respect well-founded, because such large pieces appear to be of greater age, and possess the above-mentioned qualities in a higher degree of perfection than smaller pieces.

It is known, continues our author, that the *sepia octopodia*, a little fish, is the constant and natural food of the spermaceti whale, or *physeter macrocephalus*. Of this the fishermen are so well convinced, that whenever they discover any recent relics of it swimming on the sea, they conclude that a whale of this kind is or has been in that part. Besides, the spermaceti whale, on being hooked, generally vomits up some remains of the *sepia*. Hence it is easy to account for the many beaks, or pieces of beak, of the *sepia* that

that are found in ambergris. The beak of the sepia is a black horny substance, and therefore passes undigested through the stomach into the intestinal canal, where it is mixed with the fæces; after which it is either evacuated with them, or, if these latter be preternaturally retained, form concretions with them, which render the animal sick and torpid, and produce an obstipation, that terminates either in an abscess of the abdomen, or becomes fatal to the animal; whence, in both cases, on the bursting of its belly, that hardened substance, called ambergris, is found swimming on the sea, or thrown upon the coast.

From the circumstances above recited, and from having observed the above-mentioned pieces of sepia in all fragments of ambergris of any size, Dr. Swediær concludes with great probability, that all ambergris is generated in the bowels of the physeter macrocephalus, or spermaceti whale, and then mixed with the beaks of the sepia octopodia, which is the principal food of that whale. He therefore defines ambergris to be the preternaturally hardened dung or fæces of the physeter macrocephalus, mixed with some indigestible relics of its food.

Many of the preceding observations, with regard to the production of ambergris, have been confirmed by the examination of Alexander Champion, Esq. a principal merchant concerned in the Southern whale fishery, and of the captain of a ship, employed by him, in the said fishery. This ship brought home about 300 ounces of ambergris, which the captain took out of the body of a female spermaceti whale, on the coast of Guinea. This was observed to proceed from the fundament of this fish, and whilst they were cutting the blubber, a piece of it was seen to swim on the surface of the sea. Some of this substance was observed in the same passage, and the rest was contained in a small bag, a little between the passage, and communicating with it. The whale seemed sickly, was lean and very old. The spermaceti whale, it was observed, feeds almost wholly on a fish called squids; and when the whale is dying, she throws up a quantity of squid, sometimes whole, and sometimes in pieces. The bills of the squid were found, some in the inside, and some on the outside of the ambergris, sticking to it. The spermaceti whale, when struck, voids her excrement; and if she does not, it is conjectured that she has ambergris in her. It was concluded by the intelligent captain, who communicated this information to the council of trade and foreign plantations, that ambergris is most likely to be found in a sickly fish; and that it is the cause or the effect of some disorder. The whole quantity of ambergris found in the whale, of which the above account was given, was 362 ounces troy, and it was sold for 19s. 9d. per ounce; half of it having been bought for exportation to Turkey, Germany, and France, and the other half having been purchased by the druggists in town. Phil. Trans. for 1791. vol. lxxx. art. 2.

Ambergris is of considerable use among perfumers, who melt it over a gentle fire, and make extracts, essences, and tinctures of it. It is one of the most agreeable perfumes, the least apt to disorder weak constitutions, or such as are liable to be offended by substances of that class. It would be of more use in physic too, were not its smell apt to occasion vapours.

There is a preparation, however, recommended by Hoffman, which is said not to be attended with these ill consequences. The preparation is made in the following manner: Let the spirit of roses, perfectly dephlegmated, be, not only once, but twice, at least, drawn off from the salt of tartar, which is burnt, or calcined, in a vehement fire. By this means there is produced a spirit, which, by its penetrating

quality, enters into the inmost substance of the ambergris, and so separates and resolves its oleous texture. This, we are assured, will not excite commotions and agitations in a weak body, as does the common preparation of ambergris, which is made with a mixture of musk or civet. Hoffm. Observ. Phys. Chem. lib. i. c. 18.

Ambergris enters into the composition of many cordial, sudorific, and alexiterial waters. But its chief virtue consists in its antispasmodic and sedative qualities, similar to those of musk and castor, and its power of relieving certain hysterical, convulsive, and other nervous affections. It may be taken inwardly from half a grain to ten or twelve grains, or more; for as to doses, there can be no fixed rules about remedies and diseases of these kinds. Dr. Lewis says, that taken internally, from two or three grains to a scruple, it is accounted a high cordial, corroborant and antispasmodic; and with this view it is prescribed by Riverius, in hypochondriacal affections. Dr. Swediær observes, that we cannot expect any medicinal effects from this substance in doses of two or three grains, but that it should be administered in the quantity of as many scruples for a dose; though even then it could not be expected to produce any great effect, as he himself took 30 grains of pure unadulterated ambergris in powder at once, without any sensible effect. A sailor once took half an ounce, and found it a good purgative. The faculty of Paris directs a tincture to be drawn by digesting two scruples of ambergris in two ounces of a highly rectified spirit, impregnated with roses. They have also a compound tincture made from the same quantity of ambergris, with half as much musk, ten grains of civet, six drops of oil of cinnamon, and four drops of oil of rhodium, digested together in four and one-half ounces of a spirit impregnated with roses, and orange flowers. This compound tincture is a very high perfume; and a few drops of it will give a fine scent to a large proportion of inodorous matter. In preparing these tinctures, the spirit should be made to boil or simmer with it first, that this ingredient may be completely dissolved before the more soluble ones are added. The orientals are said to look upon it as an aphrodisiac, and suppose that the frequent use of it contributes to longevity. In Asia and part of Africa, ambergris is used not only as a perfume and a medicine, but as an article of cookery; in which it is added to dishes in lieu of allspice. A great quantity of it is bought by the Mecca pilgrims, probably to use it for the purpose of fumigation and sacrifice, as the Catholics use frankincense. With us it is used by the perfumers to scent pillars, candles, balls, bottles, gloves, and hair-powder; and it is mixed with pomatums for the face and hands, either alone or compounded with musk, &c.

Ambergris is very commonly counterfeited and adulterated. The first generally consists of musk, civet, storax, laudanum, and aloes wood, mixed together; the latter of a large quantity of bullock's blood, duly flavoured with musk and civet. It is one of the most agreeable perfumes; but must be proportioned so sparingly, as that while it improves the smell of what it is added to, its own may not be perceived.

It may be known to be genuine by its fragrant scent, when a hot needle or pin is thrust into it, and its melting like fat, of an uniform consistence. Whereas the counterfeit will not yield such a smell nor prove of such a fat texture. One thing, however, is very remarkable, that this drug, which is the most sweet of all the perfumes, should be capable of being resembled in smell, by the preparation of one of the most odious of all fœtid substances. Mr. Homberg found that a vessel in which he had made a long digestion of the human fæces, acquired a very strong and perfect smell of ambergris, inasmuch that any one would have thought a great quantity

of essence of ambergris had been made in it. The perfume was so strong and offensive, that the vessel was forced to be removed out of the laboratory. Mem. Acad. Roy. 1700.

AMBERIEUX, in *Geography*, a town of France, in the department of the Ain, and chief place of a canton, in the district of Belley, 8 leagues north-east of Lyons. The place contains 2850, and the canton 7275 inhabitants. The territory comprehends 105 kilometres, and 5 communes. N. lat. $45^{\circ} 58'$. E. long. $5^{\circ} 15'$.

AMBERING is used, by some writers, to denote the giving a scent or perfume of amber to any thing. This is otherwise called *enambering*. Dr. Hooke mentions an extraordinary method of *ambering in infinitum*, i. e. with a small quantity of amber, and other requisites, *enambering* a hundred or a thousand pounds of sugar, or the like, so as the first matter still remains undecayed, to be used again. Hooke's Phil. Collect. N^o 4.

AMBERT, in *Geography*, a town of France, in the department of Puy de Dome, and chief place of a district, situate on the rivere Dore, $10\frac{1}{2}$ leagues south-east of Clermont. It has a manufacture of camblcts and woollen stuffs, and also of excellent paper and playing-cards, &c. The place contains 5926, and the canton 16,376 inhabitants. The territory includes 265 kilometres and 8 communes. N. lat. $45^{\circ} 33'$. E. long. $3^{\circ} 39'$.

AMBETTUWAY, in *Botany*, the local name of a tree, the leaves of which are said, when boiled in wine, to create an appetite, and used by the people of Guinea, for that purpose.

AMBIA, in *Ancient Geography*, an episcopal city of Africa, in Mauritania.

AMBIANI, a people of Gaul, in Belgia Secunda, mentioned by Cæsar, Strabo, Pliny, and Ptolemy. They were situated between the Morini to the north, the Atrebatii and Veromandui to the east, the Bellovaci to the south, and the Caleli to the west, and had the sea on the north-west. Their principal river was Samara, and their capital Samarobriua, which afterwards took the name of the people. These people were distinguished among the ancient Belgians. We learn from Cæsar that they furnished 5000 men for the siege of Alesia, and their cavalry are much commended.

AMBIANUM, now *Amiens*, the capital of the Ambiani.

AMBIBARI, a people of Gaul, supposed to be the Armorica of Cæsar; and since his time the ABRINCATUI. M. D'Anville does not know where to place them.

AMBIDRANI, a people placed by Ptolemy in Norica.

AMBIDEXTER, compounded of *ambo*, both, and *dexter*, right hand; by analogy to the Greek, $\alpha\mu\beta\iota\delta\epsilon\chi\iota\omicron\varsigma$, which signifies the same; one who uses both hands alike, the left as well as right, or in cases where only the use of one is necessary.

Women, according to the observation of Hippocrates, are never ambidextrous. But this is denied by some moderns, who give instances of the contrary; though it is owned, they are but few in comparison of those that are found in the other sex. It may be imputed to education and habit, that men as well as brutes are not all ambidexters, there being no difference of right and left in the nature of things. Nurses are even forced to be at some pains to enure the infants under their care to forego the use of their left hand. How far it may be our advantage to be deprived of half our natural dexterity, may be doubted. It is certain there are infinite occasions in life, when it would be better to have the equal use of both hands. Surgeons and oculists are of necessity obliged to be ambidexters; bleeding, &c. in the left-arm or

left-ankle, and operations on the left-eye, cannot be well performed but with the left-hand. Divers instances occur in history, where the use of the left-hand has been cultivated preferably to the right. But by the laws of the ancient Scythians, people were enjoined to exercise both hands alike, without partiality either for the right or left; and Plato enjoins *ambidexterity* to be observed and encouraged in his republic. In the Grecian armies their more distinguished soldiers, their pikemen and halberdeers, as those who formed the first line of their battalions, were to be able to fight indifferently with the left hand or right. We find it mentioned in Scripture, that, on an extraordinary occasion, the single tribe of Gad produced 700 brave men, who fought with the left hand as well as the right; and the Roman historians assure us, that they had gladiators who were trained up to the same exercise. An ingenious French writer is surprised, that among all the modern refinements in the art of war, none have thought of restoring the ancient practice of forming ambidexters, which, it is certain, might be of considerable service in the way of stratagem. In performing on keyed instruments, the harp, the dulcimer, and such as have a separate part for each hand, ambidexterity is necessary. On the piano forte, organ, harpsichord, or clarichord, *two right hands* are so necessary, that a child rigidly prohibited the use of the left hand in the common offices of life, can never have a powerful left hand in performing on the instruments just mentioned; but in rapid divisions, fugues, and imitations, the clumsiness with which difficult passages are performed with the left hand disgraces the player and injures the composition. In the serious studies and practice of the student on the piano forte intended for the profession, it might be necessary for him perhaps to try to execute all kinds of feeble passages, shakes, beats, and trills with the left hand, till they can be played with so much ease and brilliancy, that a distant hearer, out of sight of the instrument, shall not be certain which hand has been employed.

AMBIDEXTER, in *Law*, denotes a person who takes money from both of the contending parties to aid them in their cause. In this sense the word may be applied to a judge, juror, a solicitor, or the like. The penalty on a juror, in such a case, is to forfeit DECIES TANTUM, ten times as much as he receives.

AMBIGNA, in *Antiquity*, an appellation given to a victim, which was surrounded, or attended at the time of offering it, with other lesser ones. In this sense the word is also written *ambegui*. We read of *ambigna oves*, used in sacrificing to Juno; which were sheep, having brought forth twins, and offered up with two lambs fallen on either side.

ABIENT, formed of *ambire*, to encompass, a term applied to such things as encompass others round about; called also *circumambient* bodies. The whole body of air, because it encompasses all things on the face of the earth, is often by physical writers called, by way of eminence, the *ambient*, or *ambient air*.

AMBIERLE, in *Geography*, a town of France, in the department of the Rhone and Loire, and chief place of a canton, in the district of Roanne, eight miles north-west of Roanne.

AMBIGENAL *hyperbola*, in *Conics*, a name given by Newton in his "Enumeratio Linearum tertii Ordinis," to one of the triple hyperbolas, EGF (Plate I. *Conics*, fig. 1.) of the second order, having one of its infinite legs, as EG, falling within the angle ACD, formed by the asymptotes AC, CD, and the other leg GF falling without that angle. See HYPERBOLA.

AMBIGU denotes a kind of mixed entertainment, where-

in both flesh and fruit are served together; so that it seems doubtful whether to denominate it a mere collation, or a meal.

AMBIGUA, in *Conchology*, a species of BULLA. Shell somewhat tapering, slightly compressed, pale flesh colour, with two remote bands, one broad and brown, the other blue. Gmelin. Country unknown. It is uncertain whether this shell belongs to the Linnæan genus, in which Gmelin places it.

AMBIGUA, in *Entomology*, a species of CICADA, that inhabits China. Its colour is olive. Wing cases clear, anterior margin testaceous. Donovan. *Inf. China*.

AMBIGUA, a species of PHALÆNA, of the *noctua* family. Thorax smooth; wings deflexed, greyish, speckled with black; behind the middle a black streak. Inhabits Austria; and is produced from a larva with a brown head and body, variegated with ferruginous and brown. Lower wings whitish, with a black spot in the middle. Fabricius.

AMBIGUOUS, something dubious, obscure, or which may be taken in different senses. See EQUIVOCAL.

The word is formed of *ambo*, both, and *ago*, I drive; q. d. that which keeps the mind wavering, or in suspense, not knowing which side to choose. The answers of the ancient oracles were always ambiguous. An anonymous writer has published a dictionary of ambiguous words. *Lexicon Philosophicum de Ambiguitate Vocabulorum*. Francoff. 1597, 4to.

Ambiguity is occasioned either by a wrong choice of words and the use of equivocal terms, or by an improper arrangement of them. Ambiguities of the last kind are either where the arrangement leads to a wrong sense, or where the sense is left doubtful. Dr. Campbell expresses the former by the term equivocation, and appropriates that of ambiguity to the latter. See *Elem. of Criticism*, vol. ii. p. 20—54. and *Campbell's Philosophy of Rhetoric*, vol. ii. p. 28—38. See PERSPICUITY.

AMBIL, in *Geography*, one of the smaller Philippine islands, with a volcano, near the island of Luban.

AMBILATRI, in *Ancient Geography*, a people of Gaul, supposed by Martin to be the same with the *Ambiliates*, who are called by Orosius *Ambivarites*. Sampson places them in Brittany, towards Lamballe.

AMBILICI, a people of Norica, according to Ptolemy.

AMBISNA, a town of Spain, assigned by Ptolemy to the Murgobi.

AMBISONTII, or AMBISSUNTES, a people so called by Pliny, and placed by Ptolemy in Norica.

AMBIT of a figure, in *Geometry*, denotes the *perimeter*, or the line or sum of all the lines by which it is bounded.

Isaac Vossius has a particular inquiry concerning the ambit, or circumference of ancient Rome. That of the city he makes to be 60½ miles, or *mille passus*, and that of the city and suburbs together 72 miles; exceeding ancient Babylon, whose ambit was only 60 miles.

AMBIT, *ambitus*, called also *angiportus*, was particularly used, in *Antiquity*, to denote a space of ground to be left vacant betwixt one building and another. By the laws of the Twelve Tables, houses were not to be built contiguous, but an ambit or space of 2½ feet was to be left about each for fear of fire. This was usually a thorough-fare, but sometimes not. For when Rome was crowded with houses, these interstices were only left between some houses. Nero, after the dreadful fire which happened in his time, restored the ancient mode of building houses separate from one another. *Tacit. Annal.* xv. 43.

The *ambitus* of a tomb, or monument, denoted a certain number of feet, in length and breadth, around the same, within which the sanctity assigned to it was limited. The

whole ground wherein a tomb was erected was not to be separated from the common uses: for this reason, it was frequent to inscribe the *ambit* on it, that it might be known how far its sanctity extended: thus, *in fronte pedes tot, in agrum pedes tot*.

AMBITIANUS *Vicus*, in *Ancient Geography*, the place in which Caligula was born, and in which, according to Pliny, there were altars erected in honour of that prince. Clavier makes it the village of Capella, near Coblentz. M. d'Anville places it on the Rhine, between Confluentes on the north-west, and Banderbrica to the south.

AMBITION, in *Ethics*, is the passion which prompts men to value or to seek any kind of eminence or distinction, as well as to avoid degradation and reproach. It is a kind of compound of *admiration* and *desire*, and becomes either a virtue or a vice, honourable or disgraceful, useful or pernicious, according to its direction or degree. The opinions of others concerning us, when expressed by words or actions, are principal sources of happiness or misery. The pleasures of this kind are usually referred to the head of honour; the pains to that of shame; but as it is most convenient to have a single word, to which to refer both pleasure and pain of this class, Dr. Hartley selects ambition for this purpose. He classes the several particulars which persons, under the influence of ambition, wish to have known to others, or concealed from them, in order to obtain praise or dispraise, under four heads; *viz.* external advantages or disadvantages, of which the principal are finclothes, riches, titles, and high birth, with their opposites, rags, poverty, obscurity, and low birth; bodily perfections and imperfections, of which the chief are beauty, strength, and health on the one hand, and on the other, deformity, imbecility unfitting a person for the offices of life, and disease; intellectual accomplishments or defects, such as sagacity, memory, invention, wit, learning, and their opposites, folly, dulness, and ignorance; and moral qualities, *i. e.* virtue or vice. This ingenious writer investigates, in conformity to his proposed theory, the associations by which the pleasures and pains of ambition are produced. *Observations on Man*, § 2. prop. 95. p. 262, &c. Ed. 1791.

The Romans erected a temple to Ambition; and this was the divinity to which they offered the greatest number, or at least a very considerable number of sacrifices. It was represented with wings on its back, and naked feet, to express the extent of its designs, and the promptitude with which they were executed. "A being of the nature of man," says an elegant historian, at the close of his account of the Byzantine princes, "endowed with the same faculties, but with a longer measure of existence, would cast down a smile of pity and contempt on the crimes and follies of human ambition, so eager, in a narrow span, to grasp at a precarious and short-lived enjoyment. In a composition of some days, in a perusal of some hours, 600 years have rolled away, and the duration of a life or reign is contracted to a fleeting moment; the grave is ever beside the throne; the success of a criminal is almost instantly followed by the loss of his prize; and our immortal reason survives the 60 phantoms of beings who have passed before our eyes, and faintly dwell on our remembrance. The observation, that in every age and climate ambition has prevailed with the same commanding energy, may abate the surprise of a philosopher; but while he condemns the vanity, he may search the motive of this universal desire to obtain and hold the sceptre of dominion." *Gibbon's Hist.* vol. ix. p. 10.

AMBITNI, in *Ancient Geography*, a people of Galatia.

AMBITUS, among the *Ancient Romans*, the act of soliciting, or making interest, for offices or honours.

The candidates, in this case, went about the city, and into all publick places and assemblies, to beg votes; which was

was called *ambitus*: from *am*, in the ancient Latin, signifying *circum, about*, and *ire, to go*.

Among the Romans, it differed from *ambition*, as the former lies in the act, the latter in the mind. *Ambitus* was of two kinds, one lawful, and even laudable; the other infamous. The first, called also *ambitus popularis*, was when a person offered his service to the public frankly, leaving it to every body to judge of his pretensions as they found reasonable. This kind was not prohibited by any law, but always approved and practised by the best and greatest men.

The means and instruments here made use of were various: 1. *Amici*, or friends, under divers relations, including *agnati, affines, necessarii, familiares, vicini, tribales, clientes, municipes, sodales, collegæ*. 2. *Nomenclatura*, or the calling and saluting every person by his name; to which purpose the candidates were attended with an officer, under the denomination of *interpres*, or *nomenclator*. 3. *Blanditiæ*, or obliging persons by serving them, or their friends, patrons, or the like, with their vote and interest on any other occasions. 4. *Præsentio*, the shaking every person by the hand, offering him his service, friendship, &c. 5. *Affiduitas*. 6. The *toga candida*, worn loose. 7. *Benignitas*, the distributing largesses, *congiuria*, &c.

The second kind was that wherein force, cajoling, money, or other extraordinary influence was made use of. This was held infamous, and severely punished, as a source of corruption and other mischiefs. This kind of *ambitus* was at one time the great trade of Rome, and demanded a constant supply of great sums of money. Tully assigns this as the cause of the high rate of interest, and tells us it had raised it from 4 to 8 per cent. Bribery was come to the pitch of 80729l. per tribe; and there being no less than 35 tribes, it is obvious how expensive this corruption was grown. It is also well known where it ended. Several laws were made against it; as the *Lex Acilia*, or *Calpurnia*, A. U. 686, *Aufidia*, A. U. 692, *Bebia*, A. U. 571, *Æmilia*, A. U. 675, *Cornelia*, A. U. 672, *Cæcilia Didia*, *Fabia*, *Julia Augylli*, *Julia Cesaris*, *Licina*, A. U. 698, *Maria*, *Patelia*, A. U. 397, *Pompicia*, A. U. 701, *Tullia Vestus*, A. U. 960.

In the year of Rome 321, the use of the *toga candida* was prohibited. In the year 397, the candidates were forbid to go to the markets and meetings in the neighbouring towns. In 571, severe penalties were laid on the givers of largesses. In 594, this was made punishable by banishment. In 692, by the *lex Aufidia*, it was enacted, that if a candidate presented money to a tribe, and did not pay it, he should be exempt, but if he did pay it, he should be obliged to pay to every tribe a yearly fine of 3000 sesterterii as long as he lived. In 697, heavy fines were imposed. By the *Lex Tullia*, made in the consulship of Cicero, the candidates were forbidden to bestow any combats of gladiators on the people, to make any public feasts, or to cause themselves to be followed by a crowd of clients for two years before they offered themselves for any place. A senator, who was guilty of a breach of this law, was punished with ten years banishment; others were fined, and rendered incapable of any dignity for ever.

Ambitus was not only practised at Rome and in the forum, but in the meetings and assemblies of other towns in Italy, where numbers of citizens were usually found, on account of trade and business. The practice ceased in the city from the time of the emperors, because posts were not then to be had by courting the people, but by favour from the prince. Persons who had causes depending practised the same, going about among the judges to implore their favour and mercy. They who practised this were called *ambitiosi*. Hence we also meet with *ambitiosa decreta*, and *ambitiosa*

justa; used for such sentences and decrees as were thus procured from the judges, contrary to reason and equity, either gratuitously or for money.

AMBITUS, in *Music*, a name sometimes appropriated to signify the particular extent of each tone, or modification of grave and acute.

AMBLIVARETI, in *Ancient Geography*, a people of Belgic Gaul, placed by Cæsar beyond the Menfe. Martin places them between the Scaldi to the west, and Mosa to the east; and to the south of the Menapii, near the situation of the present Brabant.

AMBIX, in *Ancient Writers*, denotes a vessel of glass or shell. Hence the origin of the word *alambic*, which we sometimes also find denoted by the word *ambix*.

AMBLADA, in *Ancient Geography*, a town of Asia Minor, in Pisidia, according to Stephan. Byz. but in Caria, according to Strabo, who says, that the wine of Amblada was useful in medicine.

AMBLAU, in *Geography*, one of the Molucca islands, is the smallest of those that are subject to the governor of Amboyna, and distant three leagues from Bouio.

AMBLE, *AMBLING*, in *Horseman's lerp*, a peculiar kind of pace, wherein a horse's two legs, of the same side, move at the same time.

The ambling horse changes sides at each remove; two legs of a side being always in the air, and two on the ground at the same time: an amble is usually the first natural pace of young colts, which, as soon as they have strength enough to trot, they quit. There is no such thing as an amble in the manege; the riding-masters allowing of no other paces beside walk, trot, and gallop; their reason is, that a horse may be put from a trot to a gallop, without stopping him; but not from an amble to a gallop without stopping, which loses time, and interrupts the justness and cadence of the manege. This movement, which is very laborious to the horse, and in which he ought not to be indulged, except on smooth ground, is very easy to the rider; it has not the hardness of a trot, because the hind leg moves along with the fore one, and creates no resistance to the motion. Connoisseurs say that horses which naturally amble never trot, and that they are much weaker than those which have no such movement. Colts, indeed, often assume this mode of moving, when forced to go quick, and when they have not strength enough to trot or to gallop; and even good horses, after being fatigued, or when they begin to decay, are apt, when pushed, to amble spontaneously. The amble may, therefore, be regarded as a motion occasioned by weakness or defect. But there are two other movements assumed spontaneously by weak or decayed horses, which are still more defective than that of the amble, and they are known by the name of *broken ambles*. The one is a motion between walking and ambling, and the other between trotting and gallopping. Both proceed from great fatigue or weakness in the loins, and are conspicuous in many of our hackney and post-horses.

There are various practices and methods of discipline for bringing a young horse to amble; some choose to toil him in his foot-pace through new-ploughed lands, which naturally inures him to the stroke required in the amble. But its inconveniences are, the weakness and lameness that such disorderly toil may bring on a young horse.

Others attempt it by sudden stopping or checking him in the cheeks when in a gallop, and thus putting him into an amazedness, between gallop and trot, so that losing both he necessarily stumbles upon an amble. But this is apt to spoil a good mouth and rein, and exposes the horse to the danger of a hoof-reach, or sinew strain, by over-reaching, &c.

Others

Others prefer ambling by weights as the best way; and to this end some overload the horse with excessive heavy shoes, which is apt to make him interfere or strike short with his hind feet. Others fold leaden weights about the fetlock pasterns, which are not only liable to the mischiefs of the former, but put the horse in danger of incurable strains, crushing of the coronet, and breeding of ring-bones, &c. Others load the horse's back with earth, lead, or the like massy substance; but this may occasion a swaying of the back, over-straining the fillets, &c.

Some endeavour to make him amble in hand before they mount his back, by means of some wall, smooth pail or rail, and by checking him in the mouth with the bridle hand, and correcting him with a rod on the hinder hoofs, and under the belly, when he treads false. But this is apt to drive a horse to a desperate phrensy before he can be made to understand what they would have of him, and to rear, sprawl out his legs, and to make other antic postures, which are not easily quitted again. Others think to effect it by a pair of hind shoes, with long spurs or plates before the toes; and of such length, that if the horse offers to trot the hind-foot beats the fore-foot. But this occasions wounds of the back-sinews, which often bring on an incurable lameness.

Some attempt to procure an amble by folding fine soft lilt strait about his gambels, in the place where he is gartered for a stifle-strain, and turn him thus to grass for two or three weeks, and afterwards take away the lilt. This is a Spanish method, but disapproved; for though a horse cannot then trot but with pain, yet the members must be sufferers; and though the amble be gained it must be slow and unsightly, because attended with a cringing in the hind-part. In effect, ambling by the trammel, as practised by us, appears the nearest to nature, and best and most assured way.

There are divers errors, however, usually practised in this method; as, that the trammel is often made too long, and so gives no stroke, but makes a horse hackle and shuffle his feet confusedly; or too short, which makes him volt and twitch up his hind feet so suddenly, that by custom it brings him to a string-halt, from which he will scarce ever be recovered. Sometimes the trammel is misplaced, and, to prevent falling, put about the knee and the hind-hoof. In which case the beast cannot give any true stroke, nor can the fore-leg compel the hind to follow it; or if, to evade this, the trammel be made short and straight it will press the main sinew of the hind-leg and the fleshy part of the fore-thighs, so that the horse cannot go without halting before and cringing behind.

As to the matter of the trammel some make it all of leather, which is inconvenient, in that it will either stretch or break, and thus confound the certainty of the operation. In a true trammel the side ropes are to be so firm as not to yield to a hair's breadth; the hose soft, and to lie so close as not to move from its first place; and the backband flat, no matter how light, and to descend from the fillet so as not to gall.

When the horse, by being trammelled on one side, has attained to amble perfectly in the hand, it is to be changed to the other side, and that is to be likewise brought to rule.

When by this changing from one side to another with a half-trammel, the horse will run and amble in the hand readily and swiftly, without snappering and stumbling, which is ordinarily done by two or three hours labour; the whole trammel is to be put on, with a broad, flat, backband, and both sides trammelled alike. See TRAMMEL.

This pace is now generally disused, and not admitted in the regular system of the Manege.

AMBLAUW, or BELAUW, in *Geography*, one of the Molucca islands, about four leagues in circumference, two leagues south of Bourro.

AMBLESIDE, an old irregular town of Westmreland, near the lake of Windermere or Winandermere. It is 274½ miles from London, and its weekly market is on Wednesday.

AMBLETEUSE, a sea port town of France, in the department of the Straits of Calais, in the English channel, eight miles north of Boulogne, and twelve south-west from Calais. It is defended with a battery of cannon. King James II. on his departure from England, in 1688, landed in this place. At this port, called *Ambletoniensis portus*, Cæsar embarked his cavalry when he passed over into England. N. lat. 50° 48'. E. long. 1° 37'.

AMBLYGON, or AMBLYGONIUM, formed of *αμβλυ*, *obtusè*, and *γωνία*, *angle*, and denoting *obtusè-angular*; in *Geometry*, denotes a triangle, one of whose angles is obtuse, or consisting of more than ninety degrees.

AMBLYOPIA, AMBLYOPY, in *Surgery*, dulness of sight, from *αμβλυ*, *dull*, and *ὀφθαλμὸς*, *the eye*: *visû debilis* of Ætius; *visû hebitudo* of Boerhave. By this term Paulus and Actuarius denote the GUTTA SERENA, or AMAUROSIS. See DY-SOPIA and GUTTA SERENA.

AMBO, or AMBON, a kind of pulpit or desk in the ancient churches, where the priests and deacons stood to read or sing part of the service, and preach to the people; called also *analogium*.

The term is derived from *ἀναβαίνειν*, *to mount*. The *ambo* was mounted upon two sides, whence some also derive the application from *ambo, both*. The *ambo* was ascended by steps, which occasioned that part of the office performed there to be called the gradual. The Gospel was read at the top of the *ambo*, the Epistle a step lower.

The modern reading desks and pulpits have been generally substituted instead of the ancient *ambos*, though, in some churches, remains of the *ambos* are still seen. In that of St. John de Lateran, at Rome, there are two moveable *ambos*. M. Thiers inveighs against the disuse of the ancient *ambo*. Those by whom this innovation has been effected he calls by a new word *ambonoclastes*. It was in the *ambo* that publication was made of feasts, fasts, processions, &c. Here were read the acts of the martyrs, the *sancta sanctorum*, the diptychs, or commemoration of the dead; the letters of peace and communion, which one church sent to another. Here new converts made their public confession of faith, and bishops their defence against accusations brought against them. Here treaties of peace were sometimes also concluded, and coronations of kings and emperors performed, &c.

Several antiquaries hold that the *ambo* was anciently the place from whence the bishops and presbyters made their sermons; pulpits for that purpose having only been introduced by the mendicants at the beginning of the thirteenth century. A late writer combats this opinion, and shews, that the usual place from whence the ancients preached was the steps of the altar; not but St. Chrysostom and St. Augustine both appear to have preached from the *ambo*, but this was looked on as a thing somewhat extraordinary.

AMBOES, or AMBUS, in *Geography*, a people of Lower Guinea in Africa.

AMBOHITSMENE, or VOHITSANGHOMBE, a province of Madagascar, situate west and north of Antavare, derives its appellation from the red mountains of the same name, lying in 20° of south latitude. The high mountains resemble the Tafelberg of the Cape of Good Hope, and

are seen from a great distance at sea. On one side of this long and lofty ridge of mountains, which extends fifteen leagues inland, is the sea, and on the other a flat country, abounding in ponds and marshes. Here is also a lake fifteen leagues long, and of the same breadth, that contains several small islands. The people that inhabit these mountains are called Ambohitmenes.

AMBOINENSE, in *Conchology*, a species of *CARDIUM*. This shell is rather oblong, white, with blackish spots, and the ribs very convex. It inhabits the shores of Amboyna, is an inch and three quarters in length, and the ribs are usually about twelve in number.

AMBOINENSIS, in *Ornithology*, a species of *CERTHIA* that inhabits Amboyna; it is of a cinereous colour above, beneath green, head and neck yellow, breast red, and wings black. Gmelin's Linn. This bird is remarkably brilliant and glossy, the length is about two inches and three quarters, bill half an inch long, and yellowish, and the edges of the wings and quills yellow.

This is the Thioi, or Kakopit of Seba. Mus. or *Avis Amboinensis*; and *Polytmus Amboinensis* of Brisson. Dr. Latham calls it the Amboina Creeper, observing, that "both Edwards and Buffon say, that *humming-birds* are peculiar to South America, and that none are found on any part of the old continent. It is most probable that the three last-mentioned (*viz.* the Macassar, Indian, and Amboinan creepers) may belong to the creeper genus on our better acquaintance with them; which is the more to be supposed, as the whole description has been taken from Seba, who lived in an age not sufficiently enlightened in these matters.

AMBOINENSIS, a species of *PSITTACUS*, or parrot. It is of a fine scarlet, with a blue back, and a green spot in the wing. Gmel. Linn. This is the *Psittaca Amboinensis coccinea* (red Amboyna parrot) of Brisson, and *Lori Perruche tricolor*, (three-coloured Lory parrot) of Buffon, as well as the *Perruche rouge d'Amboine*, Pl. enl. of the latter author.

The length of this bird is fifteen inches and an half, the bill red, with a black tip; the head, throat, neck, and under parts scarlet; back, rump, upper tail, lesser underwing coverts, and the edge of the wings fine blue; under tail coverts violet in the middle, surrounded with red; the two middle tail feathers nine inches and an half in length, and of a violet brown; the exterior feathers decrease gradually in length, the outer one on each side being only four inches and an half long, and is distinguished from the rest by having the interior margin red. The legs and claws are red. It is a native of Amboyna, as its specific names imply.

AMBOINENSIS, a species of *TURDUS*, rather bigger than a lark; it inhabits Amboyna, and is remarkable for its fine singing, and for stirring up its tail, which reflects on the back in the breeding season.—The colour is ferruginous or reddish-brown, beneath yellow; the secondary quill-feathers from the base to the middle yellowish, tail cuneiform or wedge-shaped, and fulvous beneath. Gmel. Linn. Seba calls this *Avicula Amboinensis cinerea*. It is the *Merula Amboinensis* of Brisson, *Le Merle d'Amboine* of Buffon, and *Amboina thrush* of Latham.

AMBOISE, GEORGE D', in *Biography*, a French cardinal and minister of state, was born of an ancient and noble family in 1460. As he was a younger son he was destined for the church, and at the age of 14 obtained the bishopric of Montauban. He was appointed almoner to Lewis XI. and raised by Lewis XII., to whose interest, whilst he was duke of Orleans, he attached himself, and for whom he suffered imprisonment, to the archbishopric of Narbonne, which

he changed for that of Rouen. In the situation of lieutenant-general, under the duke of Orleans, who was governor of Normandy, he was instrumental in restoring justice and order to that province. Upon the accession of Lewis XII. he was made cardinal and prime minister, and acquired popularity by diminishing the imposts. After the conquest of the Milanese in 1499, he recovered the people who had revolted to their allegiance. As the pope's legate in France he attempted the reformation of the ecclesiastical orders, and promoted it by his own example; for he held only one benefice at a time, and devoted two-thirds of the revenue of his archbishopric to the relief of the poor and the repair of religious edifices. He aspired to the papacy with a view of more effectually accomplishing his schemes of reform, but he was counteracted and outwitted by the Italian cardinals. As a minister of state he contributed so much to the welfare of the nation, that he was honoured with the appellation of "the father of the people." For the purpose of reforming the courts of judicature, and suppressing partiality and bribery in the administration of justice, he caused to be compiled a new code of regulations, and exercised his authority in Normandy, where he was governor, in reducing them to practice. The disappointment of his views with regard to the papacy, induced him to recommend a war with the Venetians, to whom he conceived it was owing. Conscious of some errors and faults into which his ambition had led him, he expressed his concern in the review of his conduct to an infirmity brother, who attended him at the convent of the Cælestines, at Lyons, where he was taken ill, in the prosecution of his journey for the Venetian war.—"Brother John! why have not I been all my life-time brother John." He died in this place, A.D. 1510, in the 50th year of his age. During the whole of his administration he caused the sciences and trade to flourish. He was a munificent patron and encourager of literature; and such was his general conduct in the various stations which he occupied, and especially as prime minister, that he was as much beloved by the people as by his master. Gen. Dict.

AMBOISE, FRANCIS D', was the son of a surgeon to Charles IX. of France, and maintained by his liberality in the college of Navarre, where he studied rhetoric and philosophy. In 1572 he was made solicitor of the French nation, and afterwards applying to the study of the law, became one of the best advocates of the parliament of Paris. From this employment he was advanced to that of counsellor in the parliament of Bretagne, and then to be a master of requests and counsellor of state. He published several pieces chiefly of a poetical kind, and others containing an account of his travels into various countries. He took great pains in collecting the MSS. of Abelard, and he prefixed an apologetical preface to the edition of 1616. His two brothers, Adrian and James, arrived at considerable literary and professional eminence; the former as an ecclesiastic and the latter as a physician. Gen. Dict.

AMBOISE, *Ambasia*, or *Ambacia*, in *Geography*, a town of France in the department of the Indre and Loire, and chief place of a canton, in the district of Tours; situate at the conflux of the Loire and Amasse. The place contains 5100, and the canton 14,415 inhabitants; the territory comprehends 322½ kilometres and 16 communes. It has two parish churches, four convents, and a hospital; and near it is a large castle seated on a high rock, and difficult of access, in which are shewn the statues of Charles VIII. and of his consort Anne. In this place the protestants conspired in 1560, and the civil war commenced in 1561, and here it is said the name of Huguenot had its origin. In the castle of this town Lewis XI. instituted

stituted the order of St. Michael, in 1469; and Charles VIII. was born in 1470, and died in 1498, at Amboise, N. lat. $47^{\circ} 24' 51''$. W. long. $0^{\circ} 59' 7''$.

AMBOISES, see AMBEEZES.

AMBON, a town of France, in the department of the Morbihan, three leagues S.E. of Vannes.

AMBONUM, in *Natural History*, a term used by some old writers, to express the prominent tubercles on certain stones.

AMBORA, in *Botany*. See MITHRIDATEA.

AMBOTÉ, in *Geography*, a town of Poland, in Samogitia, on the river Wardana, 28 miles north north-east of Mednik.

AMBOTEN, a town of the duchy of Courland, eight leagues south of Goldingen.

AMBOULE, *valley of*, a province of Madagascar, is situated somewhat more northward than 23° south latitude, at the mouth of the river Manampani, which waters the whole valley. In this valley stands a large town of the same name. The country produces abundance of plants and fruits, particularly yams, and the sesame herb, whose seeds yield by expression the oil called menachil; the oxen and cows are very fat, and their flesh excellent. It has also iron mines. Near the town of Amboule is a fountain of hot water, within 20 feet of a small river whose sand is almost burning. The water of this fountain is said to boil an egg hard in two hours, and to be a sovereign remedy against the gout. The inhabitants of the country are employed in different preparations of iron and steel, which they obtain from their own mines, and forge darts and various other instruments, with considerable skill. The voadziri, or chief governor of the country is honoured with the title of great lord, or rabertau; and he is the richest and most powerful of the chiefs in this country. He exercises sovereign authority, and absolute power; but in times of public distress his subjects often assemble in great numbers, seize his person, and threaten him with death, unless they are relieved; and this he does, by issuing orders for distributing provisions among them. The people are represented as licentious, dishonest, and indolent. Mod. Un. Hist. vol. xi. p. 404.

AMBOURNAY, or AMBRONAY, a town of France, in the department of the Ain, and chief place of a canton, in the district of St. Rambert. It is situated in the road from Lyons to Geneva; has a parish church, a hospital, and an abbey of Benedictine monks, founded about the year 800; nine leagues north-east of Lyons,* and one mile and an half north-west of St. Rambert. N. lat. $46^{\circ} 1'$. E. long. $5^{\circ} 16'$.

AMABOUTNOSSI, a small island on the coast of Madagascar, near the bay of Galemboule; and also a river of the same name.

AMBOY. See PERTH-AMBOY.

AMBOYNA, one of the Molucca or spice islands, in the Eastern Indian Ocean, lies in S. lat. $4^{\circ} 25'$, and E. long. $127^{\circ} 25'$. This island is about 60 miles in length from north to south, and is divided on the west side, by a large bay into two parts or peninsulas, one of which, being about 12 leagues long, and two and a half broad, is called Hetou; and the other about five leagues in length, and one and a half broad, is called Leytimor. On the eastern side is another bay, with a bad harbour, where the Portuguese erected their chief fortress Victoria. The town of Amboyna, which is the capital of the island, is neatly built, and stands near the south-west extremity. As the island is subject to frequent earthquakes, the houses generally consist only of one story; but the state-house is a more lofty

edifice of two stories. The face of this island is beautiful; as woody mountains and verdant vales are interspersed with hamlets, and enriched by cultivation. The soil is chiefly a reddish clay, but in the vales it is blackish and sandy. The chief produce of the island, in consequence of the restrictions imposed by the monopolizing avarice and despotism of the Dutch, is cloves; and the clove-tree grows to the height of about 40 or 50 feet, with spreading branches, and long pointed leaves. Some of these trees, that are situated in deep sheltered vales, yield annually thirty pounds weight, and the chief crop is from November to February. The Dutch governor, in order the more effectually to secure this monopoly, makes an annual progress through the spice islands, for the purpose of enforcing the observance of existing treaties, and of preventing the culture of cloves beyond the limits to which it is restricted. About eleven years ago, indeed, nutmegs were allowed to be cultivated in Amboyna, because Banda did not supply a sufficient quantity. The growth of indigo is prohibited, lest the natives should become rich and turbulent: but the sugar and coffee are excellent, and among many delicious fruits, which the island produces, is the mangusteen of Hindostan. Cattle, grain, &c. are imported from Java, and they have a variety of curious woods, but these are chiefly brought from Ceram. The plants of the island have been described by Rumphius. The principal animals are deer, and wild hogs, and among their birds is the cassowary. Amboyna, with its dependencies, contained in 1796, when it was taken by the English, 45,252 inhabitants, of whom 17,813 were protestants; the rest were Mahometans, except a few Chinese, and savages. As this is the next settlement to Batavia, with respect to wealth and importance, the Dutch are tolerably polished; but the natives are still rude and uncultivated. They resemble the other Malays, and when intoxicated with opium they will commit any crime. Their dress is a loose shirt or frock of cotton cloth; the men wear large whiskers, and leave a little hair upon the chin; the women tie the hair in knots; wives are bought of their fathers, and if they prove barren, the marriage is dissolved. Their houses are made of bamboo canes and sago-trees; they sleep on mats; and their weapons are bows and arrows, javelins, scymetars, and targets; and their chiefs are called Rajas.

The islands that are immediately subject to the Dutch governor of Amboyna are ten, comprehending an extent of about five degrees of longitude, that of Amboyna being farthest to the south: these islands are Ceram, Ceram-Lavut, Bouro, Amblau, Manipa between Bouro and Ceram, Kelang, two leagues north-east of Manipa, Bonva farther north, Orna two leagues east of Amboyna, Honimoa, a league east of Orna, and Nousla-Laout, a league south-east of Honimoa. The three last islands are denominated Uli-iffers. The culture of cloves is restricted to these three islands, and Amboyna; but they formerly grew in all the islands, more especially in Ceram. Amboyna is the centre of this rich commerce, and the Dutch have taken care to destroy all the clove-trees in the adjacent islands, and it is said that even in Amboyna, when the harvest is very large, part of the produce is burnt. Soon after the fruit is gathered from the tree, the cloves are collected and dried on hurdles before the fire; and thus their natural and beautiful red colour is changed into a deep purple or rather black, to which their being sprinkled with water probably contributes. The reason assigned for this sprinkling is to prevent the worm from getting into the fruit; but it has been generally supposed that the true reason is to add weight to

the cloves. The cloves are carefully gathered by the hand ; and the produce is very different in different seasons ; but at a medium of seven years it has been estimated at a million of pounds.

Amboyna was first discovered by the Portuguese adventurers Diego d'Abreu and Ferdinand Magellan, about the year 1515, and taken possession of in 1564 ; it was conquered by the Dutch about the year 1605 ; but it was some time before they became complete masters of the whole island. The English were at this time in possession of several factories, that were protected by the Dutch castle, but differences having arisen between the English and Dutch colonists, they were terminated, or rather suspended, by a treaty concluded in 1619 between Great Britain and the States General of the United Provinces. In consequence of this treaty, the English lived in security at Amboyna, and enjoyed one-third part of its cloves, whilst the Dutch were in possession of the other two-thirds. In the year 1622, fresh occasions of discord arose ; these were referred to the council of defence established at Jacatra, in the isle of Java ; and the council, not being able to decide to the satisfaction of all parties, the state of the case was transmitted to Europe to be settled by the East India Companies of both nations, or, in the last resort, by the king of England and the States General. During the deliberations in Java and Europe, the dissension at Amboyna increased, and the Dutch contrived, by a feigned plot, to get possession of the whole island. This plot, as it was pretended, was confessed by two soldiers in the Dutch service, one a Japanese, and the other a Portuguese, who, upon a ground of suspicion, trivial and even imaginary, had been put to the torture ; and, by the testimony of these two unhappy wretches, confirmed by that of an English prisoner who was also sentenced to the rack, the English were accused of being confederates in a conspiracy against the Dutch settlement. Upon this extorted confession, the English were seized ; some of them were imprisoned, and others loaded with irons and confined on board the ships in the harbour : and their books and property were seized. By a process of varied torture of the most savage kind, the governor and fiscal constrained some of the wretched sufferers, after protesting their own innocence and total ignorance of the pretended conspiracy, to acknowledge the truth of charges that were altogether unfounded. Some were racked, drenched with water, and scorched with fire ; others were compelled to swallow such quantities of water as caused their bodies to be distended to more than twice their usual dimensions, and then made to disgorge, by violence, the water which they had swallowed ; and others were consumed by burning them gradually from the soles of the feet upwards. But humanity shudders at the recital of such acts of barbarity. Of those who escaped or survived this savage treatment, ten Englishmen, with one Portuguese, and eleven Japanese were executed, though all of them protested their innocence with their expiring breath. The day following that of the execution was spent, by order of the governor, in public rejoicings and thanksgivings for so signal an escape and deliverance from a pretended conspiracy, and for the iniquitous extirpation of their rival traders. That the conspiracy was a mere pretence on the part of the Dutch for gaining the sole possession of the island, is evident from various concurring circumstances. They had, at this time, a garrison of 300 men in the fort, and several other garrisons in the island ; whilst the number of the English did not amount to 20 persons, who were unprovided with arms and ammunition for effecting the pur-

pose with which they were charged. The English had not one vessel in the harbour, whereas the Dutch had eight ships near the town. When the boxes of the factors were opened, and their papers riddled, no trace of any such conspiracy could be discovered ; and, besides, the sufferers on this occasion persisted in avowing their innocence. The English factory was withdrawn from the island ; and the Dutch governor retained the effects that had been seized, amounting, as some say, to the value of 400,000 pounds. When the English council at Jacatra demanded justice, the conduct of the governor was vindicated, and his proceedings were declared to be just and indispensably necessary ; and from all the subsequent proceedings of the Dutch, it sufficiently appears, that the plot was of their own invention, and that their object was to monopolize the whole trade of the spice islands ; for, after the catastrophe at Amboyna, they seized all the English factories in these islands, and dispossessed the English, to their incredible loss and damage.

When the news of this transaction reached England, and sufficient proof was adduced of the treachery and cruelty of the Dutch, it was natural to expect that reparation would be demanded and obtained. If, indeed, king James I. had acted with becoming spirit, and made proper representations to the States General, justice would probably have been done ; for such atrocious villainies could not have been abetted by any civil community. But James submitted to the national injury even without requiring satisfaction, and contented himself with merely telling the Dutch ambassador, " That he never heard nor read a more cruel or impious act, than that of Amboyna." But he adds, " I forgive them, and I hope God will, but my son's son shall revenge this blood, and punish this horrid massacre." Charles I. finding remonstrances, letters of request, and memorials ineffectual, was preparing to increase his shipping, and to call the Dutch to an account ; but he was prevented from accomplishing his design by the civil war which ensued. Cromwell, in this instance, avenged the wrongs of the British nation ; for among the conditions on which he gave peace to the Dutch, in April 1654, it was inserted, " That they should deliver up the island of Polorone in the East Indies," which they had taken from the English in the time of king James, and where they had acted a tragedy similar to that at Amboyna, " into the hands of the English East India Company ; and pay a good sum of money (300,000*l.*) for the old barbarous violence exercised for many years since at Amboyna, for which the two last kings could never obtain satisfaction and reparation." The Dutch, however, have long retained unmolested possession of this island.— But both Amboyna and Banda were taken without resistance in February and March, 1796, by the English admiral Rainier ; however they have been restored to their Batavian masters by the treaty with France in the year 1801. *Mod. Un. Hist.* vol. viii. p. 288—301. vol. ix. p. 70. *Asiatic Register* for 1800. p. 200.

AMBRA, or AMBRO, *Cape*, in *Geography*, sometimes called Cape Natal, is the north point of Madagascar island. S. lat. 12° 15'. E. long. 49° 10'.

AMBRACIA, in *Ancient Geography*, was one of the most considerable cities of Epirus, and situated in the territory of Theprotia, near the mouth of the river Arachthus or Arethon, and the gulf to which it gave its name. It was built, according to Polybius, (lib. iv.) by Ambrax, son of Theprotus ; probably when the territory of his father had been ravaged by the Dryopes, and afterwards by Hercules ; and thus the origin of the Ambracians is traced to an æra about 50 years before the last war of Troy. *Strabo*

(lib. vii.) says, that Ambracia was the work of Tolgus, the son or the brother of Cypselus, who was tyrant of Corinth, and lived about 620 years before the Christian æra. A colony from Corinth under the conduct of Cypselus arrived in Epirus, and delivered the Ambracians from the tyranny of Phalæcus, and reduced them into subjection to himself; and Aristotle informs us, that they drove away Periander the son of Cypselus, and recovered their ancient liberty, for it was originally a free city. It was afterwards reduced by the Æacidæ kings of Epirus, who chose it for the place of their residence. In process of time, the Ætoliæ made themselves masters of it, and held it till the year before Christ 189, when they were subdued by the Romans, who found at Ambracia a great number of pictures and statues belonging to the magnificent palace of Pyrrhus.

At this time it was a place of great strength, defended on one side by the river Arachthus, and on the other by steep and craggy hills; and it was surrounded by a high and thick wall, about three miles in circuit. It was vigorously besieged by the Romans and their allies, the Epirots, under the conduct of the Roman consul Marcus Fulvius, and as bravely defended by the Ætolian garrison. It was at length compelled to capitulate; and Fulvius was presented with a crown of gold, which is said to have weighed 150 pounds. Paulus Æmilius also deprived its inhabitants of their privileges and effects. Livy (lib. xxviii. c. 4.) has given a particular description of Ambracia. It is now reduced to a small place of Turkey in Europe, called *Ambrachia*, on the lower part of the gulf of Larta in the southern Albania.

AMBRACIUS SINUS, the gulf of Ambracia, now the gulf of Larta, was situated between the country of the Molossi in Epirus, to the north, and Acarnania to the south, and communicated with the Ionian Sea, by a strait called that of Astium.

AMBRARIA, in *Botany*. See ANTHOSPERMUM.

AMBRAS, or OMBRAS, in *Geography*, a town of Germany, in the county of Tyrol, four miles east of Innspruck.

AMBRAVETTY, a river of Hindostan, which runs into the Cauvery, eight miles east-north-east of Carroor.

AMBREADA, thus they call the false or factitious amber, which the Europeans use in their trade with the Negroes on the coast of Africa, and particularly on the river Senegal. There are some large and red pieces of it, a thousand of which making twenty ropes of strings weigh three pounds. There are others small, and also red, which weigh but two pounds and a half.

AMBRES, in *Geography*, a small town of France, situate on an eminence, in the department of Tarn and diocese of Castres.

AMBRESBURY, or AMESBURY, a town of England, in the county of Wilts, pleasantly situate in a small valley on the banks of the Upper Avon, and consisting of two streets. The town is indifferently built, and has all the appearance of decay. Whether it derived its name from Ambres' consecrated stone, as Poland suggests—from its neighbouring monument, Stonehenge, being erected by Aurelianus Ambrosius, who is supposed to have been slain near this place—or from Ambri, a British monk, who founded a monastery in this place—it is not easy to determine. In former times it was a place of importance. Some have supposed that, when the Britons resorted to the general *Gorsedd* at Stonehenge, Ambresbury might have been used as a resting-place, or place of Assembly, and that Ambri founded a monastery here for the benefit of future devotees. At this town a nunnery was founded by Elfrida, widow of king Edgar, in expiation, as it has been said, of the atrocious and unpro-

voked murder of her son-in-law, Edward the Martyr, at Corse Castle. Queen Eleanor, widow of Henry III. retired to Ambresbury, took the veil, and died a nun in 1291; and her grand-daughter Mary, the sixth daughter of Edward I. followed her example, and in company with 13 children of the English nobility resorted hither, and took the veil in 1285. The estates belonging to this runnery, after its dissolution, and in process of time, became the property of the Queensbury family. To the west of the river Avon is a camp, occupying the whole summit of a hill, which has been generally attributed to Vespasian; but an ingenious tourist suggests that it is the camp, or town, often mentioned in the old British writings under the name of Caer Caradoc. It is constructed in the shape of an oblong square, with a very deep vallum towards the west; and to the east it overlooks the town. The road passing from Ambresbury to Warminster is cut through the rampart of this fortification. The market of this town is on Friday: and it is distant from London 78 miles.

AMBRI, in *Ancient Geography*, a name given by Justin to a people of India, who lived upon the banks of the river Acesines. The Ambri are, according to M. d'Anville, the same with the Oxydraci.

AMBRIÈRES, in *Geography*, a town of France, in the department of Mayenne, and chief place of a canton in the district of Mayenne, two leagues north of Mayenne. The place contains 2231, and the canton 14,077, inhabitants; the territory includes 162½ kilometres, and 10 communes. N. lat. 48° 24'. W. long. 0° 44'.

AMBRIZ, or AMBRISI, a river of Africa, in the kingdom of Congo, which springs from a lake in the eastern mountains of Tenda, and runs westward into the ocean between the mouths of the Lahunda and Loze. It runs by the town of St. Salvador. Its course is rapid; its channel deep, and large; and its waters muddy. S. lat. 7° 10'. E. long. 13° 25'.

AMBROCHOS, in *Ancient Geography*, a country of Africa, in Marmarica, according to Ptolemy.

AMBRODAX, a town or borough, placed by Ptolemy in Parthia.

AMBROGI, DOMINICO, in *Biography*, an Italian artist, flourished in 1653, and painted history and landscape. He was the disciple of Brizio, and, as an engraver, he is said to have executed some prints on wood in Chiaro-Scuro. One of his engravings is "a woman seated in a triumphal car, holding two flambeaux and a serpent, conducted by Neptune." Strutt.

AMBROMA, in *Botany*. See AEROMA.

AMBRONES, in *Ancient Geography*, a people of Gaul, known in the Cimbric war. They were probably the ancestors of the Ligurians, and had possessions to the north and south of the Po. They invaded the Roman territories, as Plutarch (in Marco) informs us, in conjunction with the Cimbri and Teutones, and were defeated with great slaughter by Marius, about 102 years before Christ. Their wives, who were waiting the issue of the engagement, seeing their husbands flying and the Romans pursuing, armed themselves with axes, and, gnashing their teeth, fell furiously on the pursuers and the pursued, without distinction. Heedless of their own defence, they threw themselves upon the combatants, seized their swords, and endeavoured to snatch away their bucklers; but when their rage was exhausted, they offered to capitulate on this single condition, that their honour should be preserved. When this condition was denied, these unfortunate women, being reduced to despair, first killed their children, and afterwards themselves, not one of so great a multitude remaining alive.

AMBROOK Island, in *Geography*, a small island of the Baltic, under Cēfel, seven leagues south-east from Demefnefs, and eight leagues north-west from Round island. See **ARENSBURG**.

AMBROSA ISLAND, is situated on the coast of Chili, in South America, on the Pacific Ocean. S. lat. 26° 40'. W. long. 82° 35'.

AMBROSE, of Alexandria, in *Biography*, the friend of Origen, flourished about the beginning of the third century. He was descended from a good family, affluent in his circumstances, and distinguished by his intellectual accomplishments and Christian virtues. According to Jerom he was a Marcionite, but Eusebius calls him a Valentinian; and he was convinced of his errors by Origen, about the year 212, in consequence of which he became a deacon of the church, either at Alexandria, or at Casarea, where Proctoetus was presbyter. To both these persons Origen inscribed his book on Martyrdom, and he dedicated to Ambrose many of his other works, which were published at his desire and charge. Origen and Ambrose lived on terms of the most intimate friendship; they were alike indefatigable in their application; and Ambrose assisted Origen by procuring him notaries, and amanuenses, who copied his works, and to whom he occasionally dictated. Origen represents his friend, as a person eminent for his piety and for his diligent study of the Scriptures. Although Jerom reports that Ambrose was blamed by many for making no provision at his death for Origen, who was not only poor but likewise far advanced in years, Tillemont suggests this apology for him, that he knew his friend's mind, and that Origen chose to be poor, and to live in a state of dependence upon Providence. Some say that Ambrose died, with his friend Proctoetus, as a martyr, in the persecution under Maximin, about the year 236; but the dedication of Origen's eight books against Celsus shews, that though he died before Origen, yet he lived to the year 250, or near it. Ambrose had a wife named Marcella, by whom he had several children; and she is commended by Origen as a true Christian and a faithful wife. Lardner's Works, vol. ii. p. 447. Cave's H. L. vol. i. p. 122.

AMBROSE, ST. bishop of Milan, descended from a noble family of Romans, was born in Gaul, as some say, in the year 333, but according to others, in 340. His father, at the time of his birth, was prætorian præfect of Gaul, and resided at Arles, the capital of Gallia Narbonensis. The son, after passing through the studies of a liberal education, attained, by the regular gradation of civil honours, the station of Consular of Liguria, a province which included the imperial residence of Milan. In the exercise of this government, he manifested a degree of wisdom and equity which obtained general esteem. At the age of 34, and before he had received the sacrament of baptism, a circumstance occurred which served suddenly to transform him from a civil magistrate to an ecclesiastical governor. His mother, and his sister Marcellina, both women of distinguished piety, had trained him up not only in habits of virtue, but with an early bias towards the religious system of the Catholic church. Thus previously disposed, he was prepared for availing himself of a dispute concerning the succession in the episcopal see of Milan, that had been produced by the death of Auxentius, who had been the leader of the Arian party in the west. In a tumultuous contest between the Arians and Catholics for supplying the vacancy, Ambrose presented himself to the assembly, and by an eloquent speech recommended a peaceable election. At the close of his address, a child exclaimed—"Ambrose is bishop!" The voice of the infant was regarded by the su-

perstitious multitude as a miraculous suggestion, though others might more naturally have inferred that it was the result of contrivance on the part of Ambrose or his friends. But the expedient, however, was effectual, and Ambrose was immediately elected by acclamation. The civil magistrate expressed great reluctance in complying with the public choice, and resorted to a variety of singular expedients to divert the multitude from persisting in the appointment. The emperor Valentinian was at length solicited to confirm and enforce the election; and as the talents and character of the bishop elect were well known to him, he very readily interposed. Ambrose submitted to his authoritative injunction, and, after baptism, was ordained to the episcopal office. The ecclesiastical historians, acquitting the bishop and his friends of art and intrigue, and considering his opposition as real, represent the choice as "a divine election," and "the peculiar work of God." But the traces of human contrivance were much more discernible in the whole conduct of this business than those of a divine operation; and it will not be easy to exculpate the bishop himself from all concern in the plot.

Unprepared as Ambrose was, by the habits and occupations of his former life, for the new office that was devolved upon him, the active force of his genius soon qualified him to exercise, with zeal and prudence, the duties of his ecclesiastical jurisdiction. With this view, he bestowed his money upon the poor, settled his lands upon the church, with the reserve of a life-interest in favour of his sister, and committed the care of his house and family to his brother. Thus disengaged from secular concerns, he commenced a course of theological study with Simplician, presbyter of Rome, and devoted himself to ecclesiastical business. In 377 he was obliged, by the irruption of the Goths and other northern barbarians, to retire to Illyricum; but the invaders were soon defeated by the Roman emperor, and Ambrose and the other exiles were allowed to return home. The prevalence of the Arian doctrine furnished ample occasions for the zealous exertions of Ambrose. Having written a treatise concerning the Trinity, for the establishment of the faith of Gratian, he was less successful in his attempts for converting the younger Valentinian, Gratian's colleague in the empire. The instructions of his mother Justina, who was an avowed Arian, counteracted the arguments of the orthodox prelate. Ambrose, by his influence with Gratian, prevented the assembling of a general council, which he had agreed to convene; and probably fearing that the sentiments of the whole body of Christian bishops would be favourable to Arianism, he wished the decision of the dispute to be referred to an assembly of the western clergy. Here the two "rotten heretics," as he called the two Arian bishops, Palladius and Secundianus, might be easily silenced. Accordingly a synod, consisting of 32 bishops, was held at Aquileia in 381, and Ambrose presided. Palladius very properly demurred against the decision of such a partial assembly, and it terminated with Ambrose's ejection of the two obnoxious bishops from the episcopal office. The orthodox prelate was no less zealous in his opposition to the followers of the ancient pagan religion than in his efforts for suppressing Arianism. The leader of the pagans was Symmachus, a wealthy and eloquent senator; and in the year 384 he was employed to prepare and present a petition for restoring the Altar of Victory to its ancient place in the hall of the senate; and the public funds for the support of the seven vestal virgins, and their religious ceremonies. To the talents of Symmachus were opposed those of Ambrose, who addressed a letter to Valentinian, in reply to the pleas of this petition; and he concludes with observing, that it

was a debt which Christian princes owed to their faith, not to give countenance to heathen rites. Ambrose prevailed, and the petition of Symmachus was rejected.

The Arians were at this time a more formidable body to the intolerant bishop than the pagans. They were supported by the young emperor Valentinian and his mother Justina; and they concurred in demanding from the bishop the use of two churches, one in the city and the other in the suburbs of Milan. The bishop peremptorily refused; alleging, that though the palaces of the earth might belong to Cæsar, the churches were the houses of God; and that, within the limits of his diocese, he was the lawful successor of the apostles, and was the only minister of God. The privileges of Christianity, temporal as well as spiritual, were confined to the true believers; and Ambrose was satisfied in his own mind that his own theological opinions were the standard of truth and orthodoxy. He therefore declared, that it was his firm purpose to die a martyr rather than to yield to the imperious sacrilege, by delivering up the temple of the Lord into the hands of heretics. Justina resented the refusal as an act of disloyalty and rebellion; and as she desired to perform her public devotions on the approaching festival of Easter (A. D. 385), Ambrose was ordered to appear before the council. He obeyed, accompanied by a tumultuous crowd of people; and the affrighted ministers of Valentinian, instead of pronouncing a sentence of exile on the bishop, humbly requested that he would interpose his authority to protect the person of the emperor, and to restore the tranquillity of the capital. Notwithstanding the tumult and clamours of the people, the bishop persisted in his refusal, and the court proceeded to the exercise of power. Orders were issued to the officers of the household to prepare, first, the Portian church, and afterwards the Basilica, for the immediate reception of the emperor and his mother. But it was found necessary to defend them by a strong guard from the insults of the people. The Arian ecclesiastics, who ventured to shew themselves in the streets, were exposed to the most imminent danger of their lives; and Ambrose had enjoyed the merit and reputation of rescuing his personal enemies from the hands of the enraged multitude; but while he laboured to restrain the effects of their zeal, the pathetic vehemence of his sermons continually inflamed the angry and seditious temper of the people of Milan. The characters of Eve, of the wife of Job, of Jezabel, of Herodias, were indecently applied to the mother of the emperor; and her desire to obtain a church for the Arians was compared to the most cruel persecutions which Christianity had endured under the reign of Paganism. The prelate was supported, not only by the populace, but by the most respectable citizens; and the court, finding violent measures to be ineffectual, had recourse to the milder method of persuasion, and solicited Ambrose to restore peace to his country by a timely compliance with the will of his sovereign. He resolutely replied: "if you demand my patrimony, which is devoted to the poor; take it; if you demand my person, I am ready to submit; carry me to prison, or to death, I will not resist; but I will never betray the church of Christ. I will not call upon the people to succour me; I will die at the foot of the altar rather than desert it. The tumult of the people I will not encourage; but God alone can appease." In his sermons he asserted the exclusive power of the catholic bishops over the churches, and expressly denied the right of the emperor even to the use of a church for himself. Valentinian and his court were not disposed to submit to this ecclesiastical tyranny. An attempt was made for seizing the Basilica; and a body of Goths, urged by their Arian prin-

ciples and ferocious spirit, advanced towards the church. On the threshold they were met by the bishop, who, thundering out a threat of excommunication, asked them, by what authority they presumed to invade the house of God? Superstitious terror held the barbarians in suspense: and the empress was persuaded to leave the catholics in possession of all the churches of Milan, and to dissemble, till a more convenient season, her intentions of revenge. The mother of Valentinian, however, could never forgive the triumph of Ambrose; and the royal youth uttered a passionate exclamation, that his own servants were ready to betray him into the hands of an insolent priest. This temporary triumph of Ambrose was succeeded by an edict of general toleration in favour of those who professed Arianism, and by a sentence of easy and honourable banishment, enjoining the prelate to leave Milan, and to chuse the place of his exile as well as the number of his associates. This sentence was resisted by the bishop, and his refusal to obey it was supported by the unanimous consent of his faithful people, who guarded his person and his palace. He devised various expedients for securing and increasing their attachment. By his bounty to the poor he formed a train of indigent persons; by introducing into Italy from the east the alternate or responsory psalmody, he aided the public devotion; and by alluding to existing characters and circumstances in his discourses and commentaries upon the scriptures, he increased the popularity which was annexed by the superstition of the times to his religious and episcopal character. Pious frauds and pretended miracles served also to augment the esteem and veneration with which he was regarded by the credulous multitude. The contending prelate was fortunately directed by a dream to the discovery of the remains of two martyrs, Gervasius and Protasius, which had been under the pavement of the church for 300 years. Two perfect skeletons were found, with the heads separated from the bodies, and a plentiful effusion of blood. These holy relics were presented with solemn pomp, to the admiration of the people; and many miracles were wrought on possessed and diseased persons who touched them, and one recovered his sight by touching the bier on which the bodies were deposited with his handkerchief. Ambrose appealed to these miracles in his sermons, and the people believed them to be real. The incredulity of the Arians, and the decision of Justina and her court, were reproached and condemned; and the miracles were attested not only by Ambrose himself, but by Augustine, and Paulinus, who were then resident in Milan. Dr. Cave, relying on these testimonies, expresses his firm belief of their reality, and says, "that God suffered them to be wrought, at this time, on purpose to confront the Arian impieties." Such were the talents of Ambrose and the general estimation in which his character was held, that his assistance was repeatedly solicited in times of public exigence and danger; and it ought to be recorded to his honour, that he surrendered his private resentment to the public good, and served his country with fidelity and ardour. After the assassination of Gratian in 383, Ambrose was deputed by Valentinian on an embassy to Maximus, and contributed by his authority and eloquence to check the ambition of the tyrant, to dissuade him from passing the Alps, and thus to protect the peace of Italy. In 387 he undertook the same office; and if the council of Milan had availed themselves of the information given them by Ambrose on his return from an unsuccessful embassy, they might have been guarded against the perfidy of Maximus, and Italy might possibly have escaped the desolation which soon followed. The conqueror, however, entered Milan in triumph; Justina and her son Valentinian fled precipitately

capitately from the country, and put themselves under the protection of Theodosius, the emperor of the east, in the port of Thessalonica; but Ambrose remained resolutely at his post, and during the depredations of a victorious army, humanly ordered the church-plate to be sold, and the money to be distributed among the unfortunate sufferers. After Theodosius had restored Valentinian to the kingdom in 388, he received information that the monks and populace of Callinicum, an obscure town on the frontier of Persia, had tumultuously burnt a Jewish synagogue. The magistrate of the province had ordered the bishop, by whose instigation the synagogue had been burnt, either to rebuild it or to repay the damage; and his order was confirmed by Theodosius. Ambrose remonstrated; representing the toleration of the Jewish, as the persecution of the Christian religion; boldly declaring, that he himself, and every true believer, would eagerly dispute with the bishop of Callinicum the merit of the deed, and the crown of martyrdom; and lamenting, in the most pathetic terms, that the execution of the sentence would be fatal both to the fame and salvation of Theodosius. Besides this private admonition, he publicly addressed the emperor from his pulpit, nor would he consent to offer the oblation of the altar, till he had obtained from Theodosius a solemn and positive declaration, which secured the impunity of the bishop and monks of Callinicum. After an interval of five years, and at a distance from Ambrose, his spiritual guide, Theodosius, tolerated the Jews, and condemned the destruction of their synagogue. How different were the feelings and conduct of Theodosius and Ambrose on another occasion! The tolerant emperor, incensed by the conduct of the populace at Thessalonica, who had murdered Botheric, and several of the principal officers of his army, and irritated by the suggellions of his minister Rufinus, issued a general order for the massacre of the inhabitants. The promiscuous carnage continued three hours, without discrimination of strangers or natives, of age or sex, of innocence or guilt; the most moderate accounts state the number of the slain at 7000; and it is affirmed by some writers, that more than 15000 victims were sacrificed to the manes of Botheric. "A foreign merchant, who had probably no concern in his murder, offered his own life, and all his wealth, to supply the place of one of his two sons; but while the father hesitated with equal tenderness, while he was doubtful to chuse, and unwilling to condemn, the soldiers determined his suspense, by plunging their daggers at the same moment into the breasts of the defenceless youths." Ambrose, on the other hand, though unforbearing and intolerant on occasion of the slightest religious differences, heard the relation of the massacre with horror and anguish; reproached Theodosius with the enormity of his crime; admonished him not to receive the holy eucharist with hands that were still polluted with the blood of an innocent people; and stopped him in his approach to the church of Milan, declaring to his sovereign in the tone and language of an ambassador from heaven, that private contrition was not sufficient to atone for a public fault, or to appease the justice of the offended deity. When Theodosius repented, that David, the man after God's own heart, had been guilty both of murder and adultery, the undaunted Ambrose rejoined, "you have imitated David in his crime; imitate then his repentance." After a delay of eight months, Theodosius was absolved and restored to the privilege of communion; but in the interval he appeared, stripped of the ensigns of royalty, in a mournful and suppliant posture, in the church of Milan, soliciting the pardon of his sins, and he signed an edict enjoining a space of 30 days before any sentence of death or

confiscation, and its execution. After the assassination of Valentinian, A.D. 392, the empire of the West was usurped by the ignoble Eugenius; but Ambrose, with a laudable resolution, refused to enter into alliance with the usurper, and withdrew from Milan; but when the empire was regained by Theodosius, he generously interceded with the emperor for the pardon of the adherents of Eugenius. Ambrose did not long survive Theodosius, whose funeral obsequies he performed; but after a short illness, in which his mind was perfectly composed, and which afforded him an opportunity of declaring to his friends, "that he had not conducted himself so among them as to be either ashamed to live or afraid to die," he departed this life in April, A. D. 397.

Many fabulous particulars are related concerning Ambrose, which are not worth minutely recording, and which the allowable scepticism of the present age will not admit. Such are the stories of the swarm of bees that settled upon his face, when he was an infant in the cradle; of the paralytic woman, who was instantaneously cured, when he was praying by her bed-side; of the two Arians, who having affronted him, were instantly thrown from their horses and killed; of the globe of fire, which covered his head in his last illness, and insinuating itself into his mouth, left his face white as snow; and of the voice, which proclaimed in the hearing of a bishop, just as he was expiring, "arise, and hasten to him, for he is departing." These tales are gravely related by Paulinus, Dr. Cave, and others; but they will claim little credit. Of his general character, it will be sufficient to say, that his most partial advocates cannot acquit him of dishonest artifice, arrogance, and intolerance; and that his most prejudiced enemies cannot deny him the praise of firmness in avowing his sentiments, assiduity in the performance of his ecclesiastical offices, liberality to the poor, generosity in his conduct towards his enemies, and zeal in the cause of humanity. With energy of mind he combined a great degree of tenderness and sympathy, and in his general conduct he was virtuous and amiable, except on occasions when he was misled by professional ambition or religious bigotry. As a writer, many of his sentiments will now be thought absurd, trivial, or ludicrous; his style is concise and affected, and somewhat resembling that of Seneca. "Ambrose," says Mr. Gibbon, "could act better than he could write; his compositions are destitute of taste, or genius; without the spirit of Tertullian, the copious elegance of Lactantius, the lively wit of Jerom, or the grave energy of Augustin." The writings of Ambrose are numerous; but many of them are little more than transcripts from the Greek fathers, particularly Origen. Their chief object is to maintain and establish the faith and discipline of the Catholic church; or recommend perpetual celibacy as the summit of Christian perfection. One of the most valuable is his book "De Officiis," intended to explain the duties of Christian ministers, formed on the model of Cicero's "Offices." In his "Commentaries on the Scriptures," he chiefly follows the absurd method of allegorical interpretation; his "Epistles" throw much light on the history of his life and times. The most accurate and complete edition of his works is that of the Benedictine Monks, in two volumes, folio, in 1682; reprinted in 1690. Ambrose appears to have received all the books of the New Testament, which we receive, without any other. For in his works he does not pay any particular regard to the writings of Barnabas, Clement, or Ignatius, or to the recognitions, or constitutions. Hence we may reasonably conclude, that these writings were not esteemed of authority by himself,

himself, or other Christians at that time. Cave's H. L. vol. i. p. 261. Gibbon's Hist. vol. v. p. 38—78. Lardner's Works, vol. iv. p. 447.

AMBROSE, a monk of Camalduli, was born at Portico, near Florence, studied Greek under Emanuel Chrysoloras, at Venice, and entered into the order of Camalduli at the age of 14 years. He was made general of the order in 1431, after having lived in it 30 years; at the council of Basil, to which he was deputed by Eugenius IV., he defended the authority of the papal see; at the councils of Ferrara and Florence he displayed equal ardour against the Greeks; and at Florence he was employed to draw up the articles of union between the Latin and Greek churches. The Greek oration, which he addressed at Ferrara, in 1437, to John Paleologus, emperor of Constantinople, was much applauded. He was much esteemed by Cosmo de Medicis, who had his letters collected into a volume, that has been kept in the library at Florence; and by Paul Jovius, he is represented as a person who united piety with good humour, and who was so free from envy, and from a spirit of contradiction, that when he endeavoured to reconcile Poggius with Laurentius Valla, he declared to them, that they acted neither as true men of letters nor like Christians, since they disgraced the dignity of the sciences by their satirical writings. Ambrose died, on his return from the council of Florence, in the year 1439, and his remains were deposited in the oratory of Camalduli, without any epitaph or ornament. He collected a very large library in the convent of St. Mary de Angelis, where he lived; and left behind him several translations of Greek authors; such as those of Dionysius Areopagita de Cælesti Hierarchy, Manuel Calecas against the errors of the Greeks, Palladius's Life of Chrysoſtom, Æneas of Gaza's Theophrastus, S. Ephrem's Sermons, Diogenes Laertius's Lives, &c. He also wrote, "Hodæporicon," or a Journey through Italy, in 1431, to visit several monasteries and nunneries of his order, and to correct their abuses; published in 4to. in Florence, in 1681; and "Letters," above-mentioned, which have been inserted in the third volume of Martenne's and Durand's "Veterum Scriptorum et Monumentorum Collectio." Paris, 1724, fol. some of which contain hints concerning the lives and characters of the learned men of his time. Gen. Dict. Cave's H. L. vol. ii. p. 155.

AMBROSE, ISAAC, an English Presbyterian divine, was the son of a clergyman, and descended from the Ambroses, of Ambrose-hall, in Lancashire. In 1621, he was admitted into Brazen-nose college, in Oxford, where he took a degree of bachelor of arts; and he afterwards took holy orders, and officiated in the church of England, but he obtained no preferment. In 1641, he left the established church, joined the Presbyterian party, took the covenant, and preached first at Garitang, and afterwards at Preston, in his native county. His zeal against the established clergy recommended him to the office of assilant to the commissioners for ejecting such as were called scandalous and ignorant ministers and school-masters. It was his custom to retire for a month every year into a hut in the wood for the advantage of solitude and religious meditation. He anticipated his death for some time before it occurred, and took leave of all his friends at their own houses. He then died suddenly, as it is supposed, of an apoplexy, in 1634, at the age of 72. His works, written in the truly puritanical style and spirit, are numerous. They are entitled "Prima, Media, et Ultima; or Regeneration, Sanctification, and Meditations of Man's Misery and God's Mercy, &c." 1682 and 1689, Lond. "Looking upon Jesus," 1658, 4to. Lond. "War

VOL. II.

with devils, ministrations of and communication with angels," printed with the former. Biog. Brit.

AMBROSE, ST. *Gulf or Haven*, in *Geography*, lies on the west coast of Africa, south-south east from Cape Negro, S. lat 20° 25'. E. long. 13°.

AMBROSE.—*St. Ambrose in the Wood*, by the Italians called *al nemo*, is an order of religious, confirmed in 1431, under the rule of St. Augustine.

The monks of *St. Ambrose al nemo* wear the image of the saint engraven on a little plate, and make use of the Ambrosian office.

In the province of Berry, in France, the titled *fathers of St. Ambrose* is also given to the canons regular of St. Augustine, because their abbey at Bourges is dedicated to St. Ambrose de Cahors.

AMBROSIA, in the *Heathen Theology*, &c. a delicious kind of food, on which the gods were supposed to feed.

The word is compounded of the primitive particle *α*, and *βροτος*, *mortal*; because it rendered those who fed on it immortal, or because it was the food of the immortals.

Lucian, rallying the poetical gods, tells us, that *ambrosia* and *nectar*, of which one is the meat, and the other the drink of the gods, were not so excellent as the poets describe them; since these deities would leave them for blood and fat, which they come to suck from the altars like flies.

But though the ambrosia is commonly represented as the solid food of the gods, by way of contradistinction from the fluid, which was called *nectar*; yet the appellations are sometimes inverted, and the name ambrosia given to the drink of the deities, as that of *nectar* to the meat.

Wedelius has a dissertation on ambrosia and nectar, wherein he shews, that the term is sometimes used to denote honey, sometimes wine, sometimes perfumes, and particularly ambergris; sometimes the method and ingredients for embalming and preserving dead bodies from putrefaction, and sometimes also for a state of unchangeableness or immortality.

AMBROSIA is also a splendid kind of title given by some physicians to certain alexipharmic compositions of extraordinary virtue. In this sense *ambrosia*, *αμβροσια*, amounts to much the same with *αθανασια*, *athanasia*, as being supposed to conduce to immortality. This name was particularly given to a famous antidote of Philip of Macedon against all poisons, bites, and stings of venomous creatures, as well as many internal diseases.

AMBROSIA is also used for a pure spirituous kind of medicine, artfully extracted from the gross elementary parts of a body, and which being administered in the smallest dose is of considerable virtue, and may be taken without disgust or inconvenience. In this sense *ambrosia* amounts to much the same with what we otherwise call *QUINTESSENCE*. Nic. Abr. Frambesa has a treatise on the preparation of these *ambrosie*. Ambrosiopa, Ludg. Bat. 1628, 12mo. Francof. 1629, 4to.

AMBROSIA is also used by some of the *Ancient Writers* to express what they judged to be the food of the BEES.

This substance is by some taken to be a gross or solid honey, and is contradistinguished from the liquid or purer sort, which is denominated *nectar*.

The ambrosia will not keep, and, if not speedily spent, corrupts and turns sour, making what is sometimes called *coom*, or *sopping*, or, after the Greeks, *σανδαράκ*; highly offensive and pernicious to the hive. See *PAIN des Abeilles*.

AMBROSIA, in *Antiquity*, denotes a feast celebrated in Ionia, and in almost all the countries of Greece, in honour of Bacchus, at the time of vintage.

The ambrosia were also denominated *εβρα* and *λενα*.

They were held in the month called Lenæon, consecrated to Bacchus.

AMBROSIA, in *Mythology*, the daughter of Atlas, was one of the HYADES.

AMBROSIA, formed of α and $\beta\epsilon\sigma\omega\varsigma$, and denoting *immortal food*, in *Botany*, a genus of the *monoecia pentandria* (*pentandria monogynia*, Gmelin) class and order; of the natural order of *compositæ nucamentaceæ*, and *corymbifera* of Jussieu: its characters are as follow. Male flowers compound: the *calyx* is a common, one-leaved, flat perianthium, of the same length with the stamens; the *corolla* compound, uniform, tubulous, equal, and hemispherical; the proper, one-petalled, tubulous, funnel-shaped, erect, quinquefid (trifid, Linn.); the *stamina* have very small filaments, anthers erect, parallel, and acuminate; the *pyllium* has a filiform style, of the length of the stamens, stigma orbiculate and membranaceous; the *receptacle* common, scarcely any, naked. Female flowers, below the males, doubled; the *calyx* is a one-leaved, acuminate, entire, permanent perianthium, the belly five-toothed, and one-flowered: no *corolla*; the *pyllium* is a germ ovate, in the bottom of the calyx, style filiform, of the same length with the calyx, stigmas two, setaceous, long, and divaricate; the *pericarpium* a subovate nut, formed from the calyx hardened, one-celled, not opening, crowned with the five acuminate teeth of the calyx; the *seed* single and roundish. There are five species, *viz.* 1. *A. trifida*, trifid-leaved A. "with three-lobed, serrate leaves." There is a variety, β . *A. gigantea* inodora, fol. asperis trifidis. Ray. Hist. This species is a common annual weed in North America, growing often eight or ten feet high, and in a rich moist soil, spreading out into many branches; the flowers are not more conspicuous than those of hemp: cultivated in 1609 by Mr. C. Bobart. The fort common in gardens has three-lobed leaves; but the larger variety β . has the lower leaves five-lobed. 2. *A. elatior*, tall A. "with leaves pinnatifid, racemes panicle, terminal, and smooth." This is an annual, herbaceous plant, from two to three feet in height, upright, and branched; male flowers more numerous, approximating and nodding; the female flowers fewer, sessile, from three to six, aggregate: a native of Jamaica, in barren, sandy, rocky situations, by river sides, in the southern part of the island; flowers there from February to June, with us in July and August; cultivated in Kew garden by Mr. S. Doody, in 1696. It has the appearance and taste of wormwood; and the seeds have been imported from Virginia and Carolina, as well as from the West India islands. 3. *A. artemisifolia*, mugwort-leaved A. "with bipinnatifid leaves, the first leaves at the origin of the branches quite entire;" differs from the second in having the spikes of the flowers axillary; the racemes are lateral, and not terminal as in the preceding species; the primary stem about a foot high, is more diffused, and the branches four feet long: a native of North America; cultivated, in 1759, by Mr. Miller. 4. *A. maritima*, sea A. "with multifold leaves, spikes solitary, hairy and subsessile;" rises about two feet high: the leaves, when handled, emit a strong odour; the spikes of the flowers are axillary; the spike does not sit on a long peduncle as in the preceding species: grows naturally in Cappadocia, Tuscany, and the county of Nice, on sandy shores; cultivated in Kew garden in 1570. 5. *A. arborescens*, tree A. "with pinnatifid, hirsute leaves, racemes solitary and terminating, and stem shrubby:" a native of Peru, grows to the height of 10 or 12 feet; the spikes and flowers are produced at the extremities of the branches, and the female flowers grow in small, separate clusters. The fifth species of Gmelin's Linnæus is *A. simplicifolia*, with simple, lanceolated leaves, and axillary, subsolitary leaves. Walt. Flor. Carol. p. 231.

Culture.—The seeds of the first species, sown in Spring, will remain till the following Spring; and when the plants come up, they may be transplanted into a moist, rich soil, at the distance every way of four or five feet. If the seeds ripen, and are suffered to scatter, they will vegetate the following Spring, provided that the ground be not disturbed; or if the seeds be sown in Autumn, the plants will come up in the Spring, and may be treated as above. The second sort will thrive in the open air in England; but in order to obtain the seeds every year, they should be sown on a moderate hot-bed in March; and when the plants are two inches high, they must be transplanted into another moderate hot-bed, allowing to each plant a square distance of three or four inches, watering and shading them till they have taken root, and afterwards exposing them to the air in warm weather, and well watering them: when the plants are pretty strong, they should be taken up with balls of earth to their roots, and planted in large pots filled with light earth: towards the latter end of May they should be placed abroad with other hardy, annual plants; they will flower in July, and their seeds will ripen in September. The third sort may be cultivated in the same manner. The seeds of the fourth sort should be sown in a warm border in Autumn; and when the plants come up in the Spring, they should be transplanted into a warm border of poor ground; the best method for obtaining good seeds, is to plant some of them in lime-rubbish; the plant has not much beauty, and is admitted into gardens merely for variety. The fifth sort may be propagated by cuttings or seeds; if the former are used, they should be planted in a shady border in any of the summer months, and frequently watered; in four or five weeks they will have good roots, and should be taken up and potted; this sort is hardy enough to admit of being exposed to the open air in Summer, and in Winter, if it be sheltered in a common greenhouse, it will live several years; the seeds that are sown in the Spring will seldom come up the same year, but those which fall, or are sown in Autumn, will come up the following Spring. Martyn's Miller.

AMBROSIA. See ARTEMISIA and COCHLEARIA.

AMBROSIACA, in *Ornithology*, a species of HIRUNDO, or swallow, that inhabits Senegal, and smells particularly strong of ambergris. It is of a greyish brown colour, bill blackish, legs brown. Gmel. Linn. Syst. The length is five inches and an half, bill half an inch, the plumage darkest on the head and quills, and the tail very forked. This is the *hirundo riparia Senegalensis* of Brisson. av. ii. p. 508. N^o 13. L'Hirondelle ambrée of Buffon. Ois. vi. p. 612.; and ambergris swallow of Lath. Gen. Syn. iv. p. 568.

AMBROSIACA β . It is uncertain whether this should be considered as a distinct variety of the preceding species, or merely a sexual difference. Dr. Latham describes it as "cinereus subtus cinereo-alba, cauda elongata maxime forficata;" (Ind. Orn. tom. ii. 575.) general colour inclining to grey, beneath cinereous white, tail long, and greatly forked; its length is five inches. This was observed in the collection of Sir Joseph Banks, Bart. after the former had been described, and was published in the supplement of the Gen. Syn. It is supposed to inhabit China.

AMBROSIAN *rite*, or office, denotes a particular office or formula of worship, used in the church of Milan, which is sometimes also called the Ambrosian church.

The denomination takes its rise from St. Ambrose, archbishop of Milan, in the fourth century, who is usually supposed to have been the author of this office. Yet some are of opinion the church of Milan had an office different from that of the Roman and other churches of Italy before the time

time of that father. In effect, till the time of Charlemagne, each church had its several office: and when in after-days the pope took on him to impose the Roman office on all the other churches of the West, that of Milan sheltered itself from the imposition, under the name and authority of St. Ambrose; from which time the phrase Ambrosian rite has obtained, in contradistinction to the Roman rite.

The public library of Milan is also called the *Ambrosian Library*.

We also meet with the *Ambrosian chant*, or song.

AMBROSIAN CHANT. There are few writers on ecclesiastical music who do not speak of the *Ambrosian chant*, and of its being different from the Gregorian; but no satisfactory account has been given of their specific difference; nor was I able (says Dr. Burney) in hearing the service performed at the Duomo in Milan, (where it is said to be preserved in all its purity), or by a perusal of the Missals, or other books on *canto fermo* published in that city, to discover any considerable deviation from the plain song used in the service of other cathedrals in France or Italy, where the Gregorian chant is said to subsist. The truth is, that there are no vestiges of the Ambrosian chant remaining, sufficient to ascertain its peculiar character. The fragments of it that Gafurio has inserted in his *Practica Musica* are very suspicious, not only as they have a much more modern appearance than even the ancient Gregorian chants that are come down to us, but on account of the number of modes in which he gives them, which amount to eight; whereas all writers on these subjects agree in saying that St. Ambrose only used the four authentic modes, and that the four plagal were added afterwards by St. Gregory. Those who pretend to know the difference between the Ambrosian and the Gregorian *canto fermo*, tell us, that it is louder, higher, and of greater compass—*fortior, durior, et magis extensa*; but this conveys nothing to the mind of a musician as to the difference in the melody of the two chants. See GREGORIAN CHANT, CANTO FERMO, and PLAIN SONG.

AMBROSIN, in *Middle Age Writers*, denotes a coin struck by the lords or dukes of Milan, whereon was represented St. Ambrose on horseback, with a whip in his right hand. The occasion of this coinage is said to have been a vision of that saint, who appeared to the Milanese general in 1339, during the time of a battle.

AMBROSINIA, so named in honour of the two brothers Bartolomeo and Hyacinto Ambrosini, for 52 years professors of botany at Bologna, in *Botany*, a genus of the class and order of *gynandria polyandria* of Miller, *monoecia monandria* of Schreber, *polyandria monogynia* of Swartz, and *polyandria polygynia* of Gmelin's Linnæus, of the natural order of *piperrita*, and *aroidæ* of Jussieu: its characters are, that the calyx of the males is a spathe, one-leaved, cowed, convolute at the base, and converging at the tip, partition membranaceous. (Spadix *Basis*), divided into two cells communicating at top; no corolla; the stamens have no filaments; the anthers are very many, solitary, within the hinder cell of the spathe, in the upper part of the partition, digested in a distinct order; the nectaries are two, roundish, concave, at the base of the anthers. The calyx of the female is a spathe common with the males; no perianthium; the pistillum has a germ in the anterior cell of the spathe, and the lower part of the partition, solitary and roundish; the style cylindrical, shorter than the spathe; the stigma obtuse; the pericarpium a roundish one-celled capsule; the seeds are very many, ovate and nestling. There is one species, viz. *A. Bassii*, arisarum of Morison, Ray, and others, a native of Sicily near Palermo, first found, described and figured by Bocconi, requiring the pro-

tection of a green-house, and capable of being increased from the root.

AMBROSIUS, AURELIANUS, or AURELIUS AMBROSIUS, in *Biography and History*, a famous general, and afterwards king, of the ancient Britons, was of Roman extraction, and is supposed to have been the son of one of the kings elected by the Britons after the Romans had left the island. He was educated at the court of Aldroen, king of Armorica, and sent over at the request of the Britons with 10,000 men under his command, to assist them against the Saxons, whom Vortigern their king had invited into Britain.

His success in this expedition was so considerable, that, after the death or abdication of Vortigern, Ambrosius, probably king of the Damnonii, in consequence of the death of his father, was elected to the pendragonship or sovereignty of all England; which supreme office he exercised with great honour to himself and benefit to his subjects. During his reign, and under his direction, the famous Arthur obtained several victories, and was eminently successful in restraining the progress of the Saxons among the Northern Britons. Ambrosius, after distinguishing himself by his valour on several occasions, and by his zeal, as it is said, in regulating the affairs of the church, died at Winchester, according to the report of Geoffrey of Monmouth, of poison, administered by a Saxon disguised as a physician, and hired for the purpose by one of the sons of Vortigern, or, according to the more generally received opinion, was killed in a battle fought in 508, against Cordic, one of the Saxon generals. Geoffrey of Monmouth pretends that Ambrosius built **STONE-HENGE**, near Salisbury, in commemoration of 300 British noblemen, who were massacred by the Saxon general, Hengist. Polydore Virgil says, that this edifice was erected by the Britons as a monument to their general Ambrosius, on the place where he fell in battle, to perpetuate the memory of the illustrious services which he performed for his country. But both these stories are rejected as fabulous by the best antiquarians, though they are by no means agreed as to the true origin of this building. Biog. Brit.

AMBERY, the place where arms, plate, vessels, and every thing belonging to house-keeping, were formerly kept.

Hence, probably, the *ambry* at Westminster was so called, because formerly set apart for that use; or rather, from *ambromery*, a house adjoining to an abbey; in which the charities were laid up and distributed to the poor. The word is still used in Scotland, in the same sense.

AMBRYM, or AMBRIN, island, in *Geography*, one of the New Hebrides in the south Pacific Ocean, S. lat. 16° 9' 30". E. long. 168° 12' 30". It has a volcano, and is about 50 miles in circumference.

AMBRYSUS, or AMBRYSUS, in *Ancient Geography*, a town of Greece in the Phœide. M. d'Anville places it between two chains of mountains, west of Lebadea, and north-west of Anticyra. It is called by Pausanias Amphryssus. This town was separated from Delphi by Mount Parnassus; and it was fortified by the Thebans, in their war with Philip of Macedon. Near it was a temple of Diana Dictynnea, to which the inhabitants paid peculiar homage. Her statue was of black marble. Pausan. lib. x. c. 36.

AMBUBAJÆ, in *Antiquity*, a kind of wanton minstrels about Rome, who lived by playing on the flute, dancing in places of resort, and prostituting their bodies for hire.

Authors speak as if there had been a regular college, or community of ambubajæ, and that these were the same with

what were otherwise called *tibicine*. Thus Horace, sat. i. speaks of

“*Ambubajum collegia, Pharmacopole.*”

Some suggest that the ambubajæ were of the male kind, only dressed in the habit of women.

Antiquaries have been greatly divided about the ambubajæ; some will have them to have come to Rome out of Syria; others suppose them to have been Roman women, though called by a name of Syriac origin.

Torrentius, Turnebus, and Pulmannus, derive the name from *ambu*, or *am*, an old Latin preposition, denoting *circum*, *about*, and *Bajæ*, a delicious place near Naples; and maintain, that the ambubajæ were a kind of courtezans, who frequented the baths of that city. Cruquius is of a different opinion, taking the word ambubajæ to have been used for *ambubeja*, and primarily to denote a seller of *ambubeja*, an herb mentioned by ancient naturalists. These sellers of *ambubeja* being a kind of empirics, their name became afterwards applied to all charletans, and quacks.

Others say, that ambubaia is a Syriac word, and that in the Syriac language, it denotes a flute, or the sound of a flute. From Juvenal it appears, that Syria was famous for furnishing the best players and musicians. Thus he says, sat. iii. 62.

“*Jam pridem Syrus in Tiberim defluxit Orontes,
Et linguam, et mors, et cum tibicine chordas
Obliquas, necnon gentilia tympana secum
Vexit, et ad Circum iussas prostrare puellas.*”

Suetonius exhibits the emperor Nero as attended by these Syrian women, and Roman courtezans at table; thus, “*Cœnitabat non nunquam—inter scortorum totius urbis, et ambubajarumque ministeria.*” The followers of the profession of female flute-players became so numerous and so licentious at Rome, that their occupation was prohibited in the Theodosian code; but with so little success, that in the time of Justinian, as we are informed by Procopius, the sister of the empress Theodora, who was a flute player, or *tibicina*, appeared on the stage without any other dress than a slight scarf thrown loosely over her. These performers even became so common in all private entertainments, as well as at public feasts, where they frequently obtruded themselves, uninvited, that towards the close of this reign their profession was regarded as infamous, and utterly abolished.

Hoffman has a discourse on the ambubajæ.

AMBUBEIA, in *Botany*, a name given, by some authors, to wild succory.

AMBUILLA, or AMBOILLA, in *Geography*, a country of Africa, in the kingdom of Congo, between the lake of Aquebond and St. Salvador.

AMBULANS, in *Entomology*, an insect of the *PODURA* genus, described by Linnæus; it is white, with an extended tail, and lives amongst mosses. This is the “*Podura terrestris nivea,*” of Degeer *Inf. vii. p. 33. n. 6. tom. iii. f. 5.*

AMBULANS, a species of *CRYPTOCEPHALUS*, one of the new genera, adopted by Gmelin in the Linnæan arrangement, from Geoffroy and Fabricius. This insect is a native of Germany, is black, shining, and has the wing-cases punctured. *Fab. et Gmel.* It approaches *Cryptocephalus elongatus*, very nearly, and the antennæ of both species are serrated, but the thorax of the latter is rufous and downy, which in the former is black.

AMBULANT, or AMBULATORY, a name formerly

given in France to those commissioners or clerks of the king's farms, who had no settled office, but visited all the offices within a certain district, to see that nothing was done in them against the king's right, and the interest of the farm.

AMBULANT is also used to denote those brokers at Amsterdam, or exchange agents, who have not been sworn before the magistrates. They transact brokerage business, but their testimony is not received in the courts of justice.

AMBULATION, or walking. See EXERCISE.

AMBULATION, in *Physic*, is used by some for the spreading of a gangrene or mortification.

AMBULATOR, in *Entomology*, a species of *LAMIA*, figured by Petiver, *Gazop. tab. 37. fig. 6.* and described by Fabricius. The anterior part of the thorax is armed on each side with two spines, and the body is clouded with cinereous and chestnut. It is properly a *cerambyx* of Linnæus. See *LAMIA*.

AMBULATORIUS, a species of *ICHNEUMON*, with a yellowish scutellum, and spotted thorax, the second joint of the abdomen ferruginous brown, the margins of the others white. This insect is very rare, it inhabits Great Britain, and was first described by Fabricius in the *Species Insectorum*, from a specimen in the cabinet of Sir Joseph Banks, Bart. The species was known to Linnæus, and his latest editor Gmelin has adopted the above Fabrician specific character. The head of this creature is black, the antennæ yellow beyond the middle, the thorax is black, with a yellowish line in the anterior part, and a spot of the same colour before the base of the wings: the abdomen is black, except the ferruginous or second joint, and the white margins of the third, fourth, and fifth.

AMBULATORY, formed from *ambulare*, to walk, a term anciently applied to such courts, &c. as were not fixed to any certain place; but held sometimes in one place, and sometimes in another.—In opposition to stationary courts.

The court of parliament was anciently ambulatory; so also were the courts of king's bench, &c.

We sometimes also say, in a legal sense, a man's will is ambulatory to the time of his death; meaning, that he has it always in his power to revoke it.

AMBULIA, in *Botany*, a genus of the *didynamia angiospermia* class and order; the essential characters of which are, that the *calyx* is quindentated, the *corolla* tubulose, quadrifid, with unequal segments; and the *capsule* pentagonous, single celled, and single-seeded. There is one species, *viz. A. monosperma* of Gmelin, or *A. aromatica* of La Marck, who represents the capsule as polyspermous. This plant, particularly described by La Marck, (*Encycl. tom. i. p. 128.*) grows in Malabar, in a sandy and watery soil, and appears to be annual. All its parts have a sweet and aromatic smell, resembling that of pepper, when it is green. Its taste is bitterish; and it is administered in a decoction, for allaying fevers, and in four milk in cases of vertigo. La Marck suggests that it is the *manga-nari* of Rheed, and the *terchinthiana* of Rumphius.

AMBULII, in *Mythology*, a name given at Lacedæmon to Jupiter, Minerva, Castor, and Pollux, where they had altars before a large portico, in which the inhabitants were accustomed to walk. They are said to have derived their name from *αμβολη*, delay, because it was thought that those deities had it in their power to retard the instant of death.

AMBULON, in *Botany*, a tree which grows in the island

island of Aruchit, and the fruit of which is white, and resembles that of fugar, and about the size of the coriander seed. La Marek suggests that it is a species of *GALLIUM*, the fruit of which contains a white dust resembling that of fugar, but is a sort of wax of which are made bougies. It is probably the *Myrtus Brabantica similis*, &c. mentioned by Plukenet, in his *Almagest*, p. 260. Ray mentions a tree called Ambulong, which, he says, is a sort of palm, the fruit of which grows in large cones, like the *NIPA*.

AMBURBIUM, or **AMBURBIALE Sacrum**, in *Antiquity*, a religious feast or ceremony, practised among the Romans, in which they made processions around their city. See a description of an amburbiale in Lucan's *Pharsalia*. lib. i. v. 392, &c. Hence also we have *amburbiales victime*, the victims carried along in the procession, and afterwards sacrificed.

The word is compounded of *ambio*, *I go round*; or of *amb*, or *ambu*, an ancient preposition, signifying *around*, and *urbs*, a city.

Scaliger, in his notes on Festus, followed by many others, maintains the amburbia to be the same with amburvalia. Servius, however, expressly distinguishes between the amburbia and amburvalia, and says, the one was performed in the city, and the other in the country.

AMBUSCADE, **AMBUSH**, **AMBUSHMENT**, in *Tactics*, a body of men who lie in a wood, &c. in readiness to rush out upon, or inclose an enemy unawares.—Or, the place wherein such a corps hide themselves.

Ambuscades in battle are certain arrangements or dispositions, in which a general, by drawing back one of his wings, or his centre, or even his whole army, entices the enemy to follow him, and by these means draws him into some snare, which he has prepared for receiving him. No general in ancient times ever manifested a greater talent for stratagems, or used them with better success, than Hannibal. He defeated Sempronius on the banks of the river Trebia, by means of an ambuscade, composed of a thousand horse and a thousand foot, placed in ravines and bushes near this river, by which the two armies were then separated. Minutius, who commanded the Roman army jointly with Fabius, fell into a similar ambuscade at Gerunium. On another occasion Hannibal surprised the consuls Crispinus, and C. Marcellus. Livy.

Amongst the moderns, the eastern nations, though little versed in tactics, are, perhaps, of all people, those who best understand the art of stratagem; thus endeavouring to compensate for the defects of other parts of their military discipline. A singular instance of a well-contrived and successful ambuscade is furnished by the history of Thamas Kuli Khan, the famous usurper of the throne of Persia. Whilst he was besieging Gangea, a city on the confines of Armenia, he received intelligence, that the Ottoman army, consisting of more than 100,000 men, was advancing to succour the place; upon which he immediately raised the siege, joined a body of troops commanded by his son, and encamped on the plains of Erivan: but some mountains, which were on his rear, suggested to him the idea of insuring victory by a stratagem. This stratagem he conducted with so much art and assiduity, that by a feigned retreat he allured the Turks into a pursuit, and at length into the defiles prepared in the mountains; when they suddenly found themselves attacked by the Persian artillery in ambush, and abysses opened under their feet, by the springing of mines, which swallowed up whole battalions

of them. The Turks, on this occasion, lost 50,000 men, their artillery, baggage, and military chest; and among the killed were nine bathaws, with the general in chief, Abdoual Cuperli. Similar instances of successful ambuscades frequently occur among the Asiatics, who have recourse to them on a greater variety of occasions than the Europeans.

AMBUSTA, in *Entomology*, a species of *PHALÆNA* of the *noctua* family. Thorax crested; wings incumbent, greyish-brown, with three yellowish streaks, an annule in the middle, and an undulated streak behind.—This moth is produced from a naked brown larva, with white lines. The antennæ are ferruginous, white at the base; head, and thorax reddish grey. Posterior wings white, tips brown. Inhabits Austria, on Lichen parietinus. Fabricius.

AMBUSTA, or **AMBUSTIO**, in *Surgery*, a solution of continuity, caused by the application of heated substances. See **BURN** and **SCALD**.

AMBUSTUS, in *Ornithology*, a species of *FALCO*. The body is pale tawny, front of the head between the eyes and bill naked, cere large, legs bluish. Gmel. Linn. This is the tawny vulture of Brown and Latham. The bill is dusky, short and thick, cere large, and beset with bristles, the chin bearded with a tuft of long slender feathers: head, neck, breast, belly, and thighs, pale tawny; coverts of the wings intermixed with brown; tail dirty white, with brown bands; legs slender, bluish claws, long and slightly bent. The length of this bird is two feet four inches; it inhabits Falkland islands.

AMBY, in *Geography*, a town of the Austrian Netherlands, in the province of Limburg, opposite to Maestricht, and on the east side of the river Maese.

AMBUTUA. See *PAREIRA Brava*.

AMCHITCHE, one of the Fox islands in the North-Pacific Ocean. N. lat. 53° 22'. E. long. 178° 14'.

AME, fowl, is made a musical term by the French, for feeling and expression. As to its effect in the *airs tendres* of their old music, it degenerated into over-charged tenderness, displeasing to all ears but their own.

AMEA, in *Botany*, a name given, by the natives of Guinea, to a plant which they use in bleeding at the nose, drying and powdering the leaves, and snuffing up the powder. It seems to be of the family of the plant called *pajamirioba*, by Sir Hans Sloane, in his Jamaica Catalogue. Its leaves are large and alated, and of a beautiful green, even when dried. Phil. Trans. N° 232.

AMEDABAD, in *Geography*. See **AMHEDABAD**.

AMEDAN, a town of Persia in the province of Taberistan, 20 leagues S. S.W. of Amol.

AMEDEL, *Amedians*, in *Ecclesiastical History*, formed of the Latin *amans Deum*, q. d. *lover of God*, or rather of *amatus Deo*, *beloved of God*, a congregation of religious in Italy, instituted in 1400.

The Amedei wore a grey habit, and wooden shoes, had no breeches, and girt themselves with a chord. They had twenty-eight convents, and were united by Pope Pius V. partly with the Cistercian order, and partly with that of the Socolanti, or wooden-shoe wearers.

AMEDEUS, in *Biography*, a monk; was bishop of Lausanne about the middle of the 12th century. His "Sermons in praise of the Virgin Mary," printed at Basil in 1537, and at Antwerp in 1600, are included in the *Bibliotheca patrum*. Dupin.

AMEDNAGUR, in *Geography*, a country or Soubah of Hindostan, bounded on the north by Candeish and Malwa,

on the west by the Gatte or Balagat mountains, on the south by Bejapour or Visapour, and Tellingana, and on the east by the province of Berar.

AMEDNAGUR is the capital of the above Soubah, now called Dowlatabad, situate at the foot of the Balagât mountains, 105 miles N. N. W. of Visapour, and 63 N. E. of Poonah. This city has been generally placed 50 miles S. E. of its true position. N. lat. $17^{\circ} 6'$. E. long. $74^{\circ} 52'$. See ARMEDNAGUR.

AMED. See DIARBEKIN.

AMEENABAD, or AMINABAD, a town of Hindostan, in the country of Lahore; 30 miles north of Lahore. N. lat. $31^{\circ} 30'$. E. long. $72^{\circ} 40'$.

AM-EIS, a town of Germany, in Carinthia, on the Drave, five miles W. S. W. of Lavamund.

AMEIVA, in *Zoology*, a species of LACERTA, having a verticillated long tail, thirty abdominal scales, and a kind of collar consisting of a double wrinkle beneath. Linn.

The ameiva inhabits America. Dr. Shaw says it is principally found in South America, but that it is said to occur in some parts of Asia and Africa. "This creature varies considerably in colour, but is commonly blue or bluish green above, with somewhat irregular variegations of black and white, which are sometimes disposed in streaks, and sometimes in spots or patches; and commonly in such a manner as to leave several whitish, or pale blue round spots scattered on different parts of the body and limbs; the under parts are dusky, with more or less of a bluish cast, and often marked here and there with small whitish spots."—Dr. Shaw. Zool.

AMELANCHIER, in *Botany*. See CHIONANTHUS and MESPILUS.

AMEL, see ENAMEL.

AMELANDT, in *Geography*, an island in the German Ocean, about four leagues long, and one wide, situated about two leagues north from the main of Friesland. N. lat. $53^{\circ} 30'$. E. long. $6^{\circ} 12'$.

AMELBUREN, a town of Germany, in the circle of Westphalia and bishopric of Munster, six miles south of Munster.

AMEL CORN, in *Agriculture*, the same with SPFLT-CORN.

AMELIORATING SUBSTANCES, in *Agriculture*, are such, either of the animal or vegetable kind, as, when applied to land, render it more fertile and productive.

AMELIORATING CROPS, are such as are supposed to improve the lands on which they are grown. Most of those plants which have a large stem and shady leaf are thought to render the soils on which they are produced more fertile. Carrots, turnips, artificial grasses, and many other green vegetables, are in general considered as ameliorating crops; but it is probable, that all sorts of vegetables, carried off the land, are in some degree or other exhausters of the soil; and that green crops, such as have been just mentioned, are only less so, than such crops of grain or other vegetables as contain large proportions of gluten, or vegetable matter in their compositions. The improvement of lands, therefore, by what are termed ameliorating crops, in a great measure probably depends either upon the culture, which the ground receives while they are growing, and the returns which they make to it in the way of manure, after decaying, or being consumed by animals, or from their taking up only such sorts of matters as are not necessary to the succeeding crop.

AMELL, in *Botany*, *Kareta-Amelpodi* of Rheed, Malab.

is a tree about seven feet high, with a slight stem, and white wood, covered with brown bark. The leaves are opposite, ovate-lanceolated, pointed at the two ends, thick, entire, soft, smooth, glossy, of a blackish green above, and greenish below. The flowers are white, and grow at the summit of the branches, disposed in short panicles, and corymbiform. Each flower has a corolla with five oval-pointed petals, opening in a star, thick, white above, and striated with red lines below; the stamina are five, a little longer than the petals, white, withered anthers, and an ovary with a purplish style, forked at its summit. The fruit is a roundish capsule, of a brownish green colour, glossy, with three cells; but Rheed does not mention its seeds. This tree grows on the coast of Malabar, in sandy stony soil. It is always green; flowers all the year, and produces mature fruit about the month of August. The decoction of its leaves in water is recommended as a sovereign remedy in colics. Its leaves and roots, boiled in oil, furnish a topic which is said to be efficacious in resolving large tumours. Rheed mentions another species of Amel, which he calls *Kattou-belutta amelpodi*, somewhat smaller than the former, but little differing from it in other respects; it grows in the mountainous and uncultivated parts of Malabar. La Marek, *Encycl. tom. i. p. 129.*

AMELIA, in *Geography*, a county of Virginia, in North America, situate between the Blue ridge and the tide waters, having Cumberland county to the north, Prince George county to the east, and Lunenburg county to the south and west. Amelia, including Nottaway, a new county, contains 18,097 inhabitants, of whom 11,037 are slaves.

AMELIA island, lies on the coast of East Florida, in America, about seven leagues north of St. Augustine, and very near Talbot island on the south, at the mouth of St. John's river. It is thirteen miles long, and two broad, is very fertile, and has an excellent harbour. Its north end lies opposite to Cumberland island, between which and Amelia island is the entrance into St. Mary's river, in N. lat. $30^{\circ} 52'$. W. long. $67^{\circ} 23'$.

AMELIA, anciently AMERIA, a small town of Italy, seated on a mountain in the duchy of Spoleto, and the residence of a bishop, holding immediately of the pope, fourteen miles south of Todi. N. lat. $42^{\circ} 33'$. E. long. $13^{\circ} 20'$.

AMELIUS, GENTILIANUS, in *Biography*, a Platonic philosopher, was born in Tuscan, chiefly resided at Apamea in Syria, and flourished about the year of Christ 263. Having been instructed in philosophy by Lyfimachus, he became the disciple of Plotinus, and continued with him at Rome 24 years, viz. from the year 246 to the beginning of the year 269. His talents and taste were so similar to those of his master, that he was soon admitted into his friendship, and employed by him in resolving questions proposed by his disciples, and refuting the objections and calumnies of his enemies. Here he commenced an intimate acquaintance with Porphyry, who, during the last six years of his residence at Rome, was his fellow disciple and companion, and who represents him as the most studious and laborious of all the disciples of Plotinus. He made large collections from the lectures and disputations of the schools: and in a work of his own, consisting of 40 books, he refuted Zostrianus, a Christian heretic, who confounded the doctrines of the gospel with those of the philosophers. He also vindicated his master from a charge of plagiarism, in a treatise "On the difference between the Doctrine of Numenius and that of Plotinus." His works, amounting,

as it has been said, to 100 volumes, are lost. Longinus speaks of him as a verbose writer, but says, that Amelius and Plotinus were the only philosophers, who, in his time, published works that were worth procuring. Eusebius, Cyril, and Theodoret cite a passage from his writings, in which he refers to the Evangelist John, and quotes the beginning of his gospel in confirmation of Plato's doctrine concerning the divine nature. His proper name, as we learn from Porphyry, was Gentilian; and he chose to have his surname written with an *r*, *Amerius*, as it is in Eunapius, and not *Amelius*; the last in Greek denoting negligence, the former integrity. He survived his master Plotinus some years, and probably died at Apamea. Porphyry. Vit. Plot. apud Fabr. Bib. Græc. tom. iv. p. 104. Suidas. Brucker's Hist. Phil. by Enfield, vol. ii. p. 70. Lardner's Works, vol. viii. p. 160.

AMELLOIDES, in Botany. See CINERARIA.

AMELLUS, a genus of the *syngenesia polygamia superflua* class and order; of the natural order of *compositæ oppositifoliae*, and *corymbiferae* of Jussieu: its characters are, that the common *calyx* is imbricate, roundish, (scales linear, pressed close) the *compound corolla* is radiate, corollets hermaphrodite, very many in the disc, females very many in the ray; *proper* of the hermaphrodite tubulous, five-cleft, female ligulate, lax, two or three-toothed; the *stamina* in the hermaphrodites, have five capillary, short filaments, anther cylindrical and tubulous; the *psyllium* in the hermaphrodites has an obovate germ, style filiform, of the length of the stamens, stigmas two, and filiform; females very like the hermaphrodites; no *pericarpium*; *calyx* unchanged; *seeds* to the hermaphrodites solitary, obovate; down capillary, to the females very like the others; the receptacle chaffy. *Obf.* The teeth in the corollets of the ray are scarcely visible. Martyn reckons two; Gmelin and La Marck three, species. 1. *A. Lycnitis*, trailing *A. verbefina asteroides* of Linn. spec. edit. 1. *chrysanthemum Africanum* of Breynius, "with leaves opposite, lanceolate, obtuse, downy, peduncles one-flowered." This species rises from two or three feet high, sending out branches on every side, terminated by flower-stalks, each supporting one violet-coloured flower, with a yellow disc, shaped like those of the aster, and appearing in July or August. The down is villose with few rays; a native of the Cape of Good Hope; cultivated in Kew Gardens, by Mr. Miller, in 1768. 2. *A. umbellatus*, umbelled *A. solidago villosa*, &c. of Brown Jam. "with leaves opposite, three-nerved, downy underneath, flowers umbelled." This species has herbaceous, upright, simple round hairy stems, two or two and a half feet high; the leaves at first radical, petioled, wedge-shaped at the base, somewhat decurrent and serrate, nerved, smooth, dark green, white and soft beneath; the stem towards the top generally divided into three branches, each of which is subdivided into many small flower branches, forming a sort of umbel; the umbellules have from three to eight flowers, with linear leaflets, the peduncles an inch long, each sustaining one large yellow flower; the scales of the calyx lanceolate, membranaceous, and hoary; the seeds obconical; the down sessile and hairy; the receptacle hirsute. It has the habit of tussilago, and would be of that genus, if the down were stipitate, and the receptacle naked. It is connected with the first species by the bristly chaffs between the florets. It is a native of Jamaica, in the rocks, woods, and mountains, and flowers there in Summer. 3. *A. tenuifolius*, slender-leaved *A. amellus fruticosus*, "with alternate linear leaves, and one-flowered

branches." This species is about fifteen inches high; its stem is woody, and divided at the bottom into cylindrical branches, hairy, leafy, and generally simple; the leaves one line and a half long, and one line and a half broad, are straight, linear, soft, pubescent and alternate, the flowers terminating, the branches are solitary, and resemble those of the first species in their form and colour; the scales of their calyx are straight, very acute, hairy, and almost equal to one another; the receptacle contains small seeds. The account of this plant was communicated by M. Sonnerat to La Marck. It was found at the Cape of Good Hope. Its wood is yellow. 4. *A. carolinianus* of Gmelin, "with opposite, sublanceolate, subserrate leaves, the peduncles double, one-flowered and axillary." Walt. Flor. Carol. p. 213.

The first species is a perennial plant, and may be easily propagated by cuttings, planted in the shade in the Summer months, and well watered. The plant should be taken up with beds of earth, and put in pots, so as to be sheltered in winter, under a common frame or in a green house, with plenty of air in mild weather. The second species may be propagated by seeds sown on a hot-bed in spring; two or three of the plants, when they are fit to be removed, should be planted in pots, and plunged into a hot bed of tan, so as to get ripe seeds in the autumn, otherwise the plants will require a stove in winter. Martyn's Miller.

AMELLUS. See CALEA and ERIGERON.

AMELLUS *Virgii*. See ASTER.

AMELOT DE LA HOUSSAYE, ABRAHAM NICHOLAS, in Biography, was born at Orleans in 1634, and formed under the president of St. André, ambassador at Venice, who employed him as his secretary. His manner and his writings were alike austere; and as he never rose much above indigence, he was often indebted to the liberality of his friends. The events of his life are little known; and he died at Paris in 1706, in the 73d year of his age. His writings are numerous, and attracted notice, as he wrote with freedom on political subjects. The principal of his works, which were written in French, are the following:— "A Translation of Father Paul's History of the Council of Trent," 4to. 1686, well received, and highly commended by the assertors of the liberty of the Gallican church, now greatly superseded by that of Courayer; "A Translation of Machiavel's Prince," 12mo. with notes, vindicating that writer from the charge of having taught assassination and poisoning; "A Translation of Gratian's Courtier," 12mo. with moral and political reflections; "A Translation of the Annals of Tacitus," with valuable notes of a political kind; "The History of the Government of Venice," in 3 vols. 12mo. printed in 1714, with "An Inquiry into the original Liberty of Venice, translated from the Italian," which gave great offence to the Venetian state; "The Morals of Tacitus," extracted from his Annals, 12mo. a work that has been much read; "Memoirs, Historical, Political, Critical, and Literary," a posthumous work, abounding with satirical anecdotes. Amelot was at one period of his life confined in the Bastille; but the cause of his imprisonment is not now known. Probably some of his free political writings might incur displeasure. Gen. Dict.

AMELOTTE, DENNIS, a priest of the Oratory, and a famous writer among the Roman Catholics, was born at Saintes, in 1606, ordained priest in 1632, and maintained a great correspondence with the fathers of the Oratory. He published at Paris, in 1643, a life of Charles de Gendron, second superior of that congregation, which contained reflections

tions on the famous abbot of St. Cyran, that incurred the resentment of the gentlemen of Port Royal, and excited them to write a libel against the author; but it had ample retaliation, so that he did them greater prejudice than the whole body of Jesuits. The work which principally deserves to be mentioned is, "The French Translation of the New Testament, with Annotations," in 4 vols. 8vo. printed in 1660, 1667, and 1678. His chief object in this translation was to find expressions more proper and elegant than those of the former versions, and with this view he obtained the assistance of Mr. Courart, a protestant, well skilled in the French language, but ignorant of Greek and Latin, so that in turning a period he perverted the true sense of the text, or enervated its force, for want of being able to consult the original. In the preface to the first edition he boasted that he had consulted the manuscripts of the Vatican, and many others, but afterwards he confessed that he had never seen any of them. He also wrote "An Abridgment of Divinity;" "A Catechism for the Jubilee;" "A kind of Christian Manual;" (*Journée Chrétienne*) and "A Harmony of the Gospels," in 12mo. published in French, in 1669, and in Latin in 1670. Amelotte entered into the congregation of the Oratory in 1650, and continued with them till his death in 1678. *Gen. Dict.*

AMEN, a scriptural and ecclesiastical term, used as the conclusion of all solemn prayers, &c. and signifying *so be it, or fiat*.

The Hebrews had four kinds of *amen*. That just mentioned they called *amen pass*, which was accompanied with the greatest attention and devotion: in this sense the word has passed into almost all languages, without any alteration.

Some authors are of opinion, that the word *amen* is formed of the initial letters of these words, *Adonai, Melech Neeman, Dominus Rex Fidelis*; an usual expression among the Jews when they would give weight or sanction to any thing they said. In effect it is known that to express the words *אדני מלך נאמן Adonai Melech Neeman*, in the ordinary way of abbreviatures; the rabbins only take the initial letters, which, joined together, are really the letters of the word *אמן amen*.

On the other hand, there are some of their Cabbalists, who according to their usual manner of finding a hidden meaning in words, which they call *notaricon*, out of the letters of the word *amen* form the whole phrase *Adonai Melech Neeman*.

Yet it is certain also that the word *amen* was in the Hebrew tongue before ever there were any such things as cabbala or cabbalists in the world, as appears from Deuteronomy, chap. xxvii. ver. 15.

The primitive of the word *amen* is the verb *aman*, which, in the passive voice, signifies to be true, faithful, constant, &c. Hence came the noun *אמן amen*, which signifies *truth*. And, lastly, of this noun *amen* they made a kind of affirmative adverb, which, when placed at the end of any phrase, or proposition, signifies, *so be it, be it true, I acquiesce in it, &c.* Thus in the passage above cited from Deuteronomy, Moses ordered the Levites to cry aloud to the people, *Curfed is he that makes any graven or molten image, &c. and all the people shall say amen*, i. e. yes, may he be curfed, we desire, we agree to it.—But at the beginning of a phrase, as in several passages of the New Testament, it signifies, truly, verily.—When it is redoubled, or repeated twice together, as is always done by St. John, it has the effect of a superlative; agreeably to the genius of the Hebrew tongue, and her two daughters, the Chaldee, and Syriac.—In this sense we are to understand *amen, amen, dico*

vobis. The Evangelists usually preserve the Hebrew word *amen*, in their Greek *אמן*, though St. Luke sometimes renders it by *αληθως, truly*, or *υα, certainly*.

AMENABLE, or AMAINABLE, from the Fr. *amener, or venir, Land*, is applied in our law-books to a woman, who is supposed to be governable by her husband.

It is likewise used to signify a right or power of bringing persons before a particular jurisdiction: thus, we say, a person is *amenable* before such a court, or magistrate.

AMENANUS, in *Ancient Geography*, a river which passed by Catana.

AMEND, or AMENDE, in the French *Cyffons*, a mulct, or pecuniary punishment, imposed by a sentence of the judge; for any crime, false prosecution, or groundless appeal.

AMENDE HONORABLE, denotes an infamous kind of punishment, used in France, &c. on traitors, parricides, facerious persons, and other heinous criminals.

It consists in this, that the offender is delivered up to the common hangman; who, having stripped him to his shirt, and put a rope about his neck, and a wax taper in his hand, leads him to the court, where he is to beg pardon of God, the king, the court, and his country.

Sometimes the punishment ends here; and sometimes death, or the galleys, are added.

The phrase *amende honorable* is also used by way of allusion, where a person is condemned to come into court, or into the presence of some person injured, and make an open recantation, ask pardon, &c.

AMENDMENT, in a general sense, a change made in a thing for the better.

Amendment amounts to much the same with melioration, reformation, correction, &c.

AMENDMENT, in *Agriculture*, is more particularly used for a MANURE laid on the ground, to fatten or enrich it.

AMENDMENT, in a *literary sense*, is used to denote the corrections and other alterations made in the posterior editions of books. In this sense, amendments are also denominated emendations.

AMENDMENT, in *Law*, the correction of an error committed in a process, and discovered after judgment.

If the error be committed in giving judgment, *viz.* if a wrong judgment be given, there they cannot amend it; but the party aggrieved must bring his writ of error.—However, where the fault appears to be in the clerk who writ the record it may be amended. *Terms de Ley.* 39.

At common law there was little room for amendments; for, says Britton in a treatise, published in the name and by the authority of the king, probably about the 13 Edw. 1., because the last statutes therein referred to are those of Winchelsea and Westminster the second, the judges are to record the parols or pleas, deduced before them in judgment; and king Edw. 1. granted to the justices to make record of pleas pleaded before them, but prohibited their making their own record a warranty for their own wrong, and raising their rolls, amending them, and recording them contrary to their original enrolment. So rigidly was this statute observed, that when justice Hengham, in the same reign, was induced from motives of mere compassion for a poor man, who was fined 13s. 4d. to erase the record and to make it 6s. 8d., he was fined 800 marks. With this fine, it has been said, a clock-house was built at Westminster, and furnished with a clock; but the true æra of the invention and use of clocks in this country, which did not take place till about 100 years afterwards, or about the close of the 14th century, falsifies

falsifies this story. There were, however, some cases, that were amendable at common law. Original writs were not amendable at common law; for if the writ be not good, the party may have another: judicial writs may and often have been amended. 8 Rep. 157. Whatever at common law might be amended in civil cases, was at common law amendable in criminal cases, and so it is at this day: resolved by Holt, Ch. J. Powell, and Powis J. 1 Salk. 51.

Formerly the suitors were much perplexed by writs of error brought upon very slight and trivial grounds, as mispellings and other mistakes of the clerks, all which might be amended at the common law, while all the proceedings were in *paper*; for they were then considered as only *in fieri*, and therefore subject to the controul of the courts. But when once the record was made up, it was formerly held, that by the common law no amendment could be permitted, unless within the very term in which the judicial act so recorded was done; for during the term the record is in the breach of the court; but afterwards it admitted of no alteration. But now the courts are more liberal; and, when justice requires it, it will allow of amendments at any time while the suit is depending, notwithstanding the record be made up, and the term be past. For they at present consider the proceedings as *in fieri*, till judgment is given; and therefore, that, till then, they have power to admit amendments by the common law; but when judgment is once given and enrolled, no amendment is permitted in any subsequent term. Stat. 11 Henry IV. c. 3. Mistakes are also effectually helped by the statutes of amendment and *jeofails*, so called, because when a pleader perceives any slip in the form of his proceedings, and acknowledges such error (*jeo faille* or *j'ai faille*), he is at liberty by those statutes to amend it; which amendment is seldom actually made, but the benefit of the acts is attained by the court's overlooking the exception. Stra. 1011. These statutes are 12 in number; and by these all trifling exceptions are so thoroughly guarded against, that writs of error cannot now be maintained, but for some material mistake assigned. See Com. Dig. tit. *Amendment*.

By stat. 14 Edw. III. c. 6. no process shall be annulled or discontinued by the misprision of the clerk in writing one syllable or one letter too much or too little; but it shall be amended; and by stat. 9 Henry V. c. 4. it is declared, that the judges shall have power to make these amendments, as well *after* as *before* judgment, as long as the record in process is before them. This statute is confirmed by stat. 4 Hen. VI. c. 3. For further enlarging the authority of the courts the stat. 8 Hen. VI. c. 12. gives power to amend what they shall think in their discretion to be the misprision of their clerks in any record, process, and plea, warrant of attorney, writ, pannel, or return. There are only two statutes of amendments, *viz.* 14 Ed. III. stat. 1. c. 6. and 8 Hen. VI. c. 12. and 15.; the rest are reckoned to be statutes of *jeofails*, and not of amendments. As these statutes only extended to what the justices should interpret the misprision of their clerks, and other officers, it was found by experience, that many just cases were overthrown *for want of form*, and other failing, not aided by stat. 8 Hen. VI. c. 15. though they were good in substance; and therefore the statutes of *jeofail* were made. By stat. 32 Hen. VIII. c. 30. it is enacted, that if the jury have once passed upon the issue, though afterwards there be found a *jeofail* in the proceedings, yet judgment shall be given according to the verdict. The stat. 13 Eliz. c. 14. ordains, that after verdict given in any court of record, there shall be no stay of judgment, or reversal,

for want of form in a writ, count, plaint, &c. or for want of any writ original or judicial; or by reason of insufficient returns of sheriffs, &c. By stat. 21 Jac. I. c. 13. if a verdict shall be given in any court of record, the judgment shall not be stayed or reversed for variance in form between the original writ or bill and the declaration, or for want of averment of the party's being living, so as the person is proved to be in life; or for that the *venire facias* is in part mis-awarded; for misnomers of jurors, if proved to be the persons returned; want of returns of writs, so that a pannel of jurors be returned, and annexed to the writs; and for that the return-officer's name is not set to the return, if proof can be made that the writ was returned by such officer, &c.

The stat. 16 and 17 Car. II. c. 8. called in 1 Ventr. 100. an omnipotent act, and made perpetual by stat. 22 and 23 Car. II. c. 4. enacts, that judgment shall not be stayed or reversed after verdict in the courts of record at Westminster, &c. *for default in form*; or because there are not pledges to prosecute upon the return of the original writ, or because the name of the sheriff is not returned upon it, for default of alleging and bringing into court of any bond, bill, or deed, or of alleging or bringing in letters testamentary or of administrations; or for the omission of *vi* and *armis*, or *contra pacem*, mistaking the Christian name or surname of either party, or the sum of money, day, month, or year, &c. in any declaration or pleading, being rightly named in any record, &c. preceding; nor for want of the averment of *hoc paratus est verificare*, or for not alleging *prout patet per recordum*, for that there is no right *venire*, if the cause was tried by a jury of the proper county or place; nor shall any judgment after verdict, by confession, *cognovit actionem*, &c. be reversed for want of *misericordia* or *captiur*, or by reason that either of them be entered, the one for the other, &c.; but all such defects, *not being against the right of the matter of the suit, or whereby the issue or trial is altered*, shall be amended by the judges:—though not in suits of *appeal*, of *felony*, *indictments*, and *informations*, on *penal statutes*, which are excepted out of the act.

By stat. 4 and 5 Ann. c. 16. all the statutes of *jeofails* shall extend to judgments entered by confession, *nil dicit*, or *non sum informatus* in any court of record, and no such judgment shall be reversed, nor any judgment or writ of inquiry of damages thereon shall be stayed for any defect which would have been aided by those statutes, if a verdict had been given, so as there be an original writ filed, &c.—By stat. 9 Ann. c. 20. § 7. this act and all other statutes of *jeofail* are extended to writs of *mandamus* and *informations*, in the nature of a *quo warranto*: the statutes of amendment and *jeofails* not being construed to extend to criminal proceedings, or on penal statutes in general. Bull. N. P. 325. 2 Mod. 144. But a *mandamus* may not be amended after return. 4 Term. Rep. 689. The stat. 5 Geo. I. c. 13. ordains, that, after verdict given, judgment shall not be stayed or reversed for defect in form or substance in any bill or writ, or for variance therein from the declaration, or any other proceedings.

By the foregoing statutes, from 14 Edw. III. c. 6. to 8 Hen. VI. c. 15. the faults and mistakes of clerks are in many cases amendable; the misprision of a clerk in matter of *fact* is amendable, though not in matter of *law*. Palm. 258. If there be a mistake in the legal form of the writ, it is not amendable; the negligence of the clerk shall be amended, but his ignorance in the legal course of original writs is not amendable. 8 Rep. 159. A party's name was mistaken in an original writ; and it appearing to the court

that the curfitor's instructions were right, the writ was amended in court; and they amended all the proceedings after. 2 Vent. 152. Cro. Car. 74. If a thing which the plaintiff ought to have entered himself, being a matter of substance, be totally omitted, this shall not be amended; but otherwise it is, if omitted only in part and misentered. Danv. Abr. 346. By the common law a writ of error, returned and filed, could not be amended; because it would alter the record; but now by stat. 5 Geo. 1. the writs of error, wherein there shall be any variance from the original record, or other defect, may be amended by the court where returnable.

When the award of a writ of inquiry on the roll is good, the writ shall be amended by the roll. The court cannot amend to make a new writ, or to alter a good writ and adapt it to another purpose, &c. only when the writ is *prima facie* bad. Mod. Caf. 263. 316. Annaly 367. A declaration grounded on an original writ may not be amended, if the writ be erroneous; though if it be on a bill of Middlesex or a latitat, it is amendable. 1 Lill. Abr. 67. A plaintiff may amend his declaration in matter of form, after a general issue pleaded, before entry thereof, without payment of costs; if he amend in substance, he is to pay costs, or to give imparlance; and if he amend after a special plea, though he would give imparlance, he must pay costs. 1 Lill. 58. A declaration in ejectment laid the demise before the time; this was not amendable, because it would alter the issue and make a new title in the plaintiff. 1 Salk. 48. A demurrer may be amended after the parties have joined in demurrer, if it is only on paper. Style. 48. For the amendment of a plea, in paper or on record, &c. see stat. 4 Geo. II. c. 26.

As to the amendments of records, &c. an issue entered upon record, with leave of the court may be amended; but not in any thing material, or that shall deface the record. 1 Lill. Abr. 61. A record may be amended by the court in a small matter, after issue joined, so as the plea be not altered. Danv. Abr. 338. If on a writ of error a record is amended in another court in affirmance of the judgment, it must be amended in the court where judgment was given. Hard. 505. Where the record of *nisi prius* does not agree with the original record, it may be amended after verdict, provided it do not change the issue; but a record shall not be amended to attain the jury, or prejudice the authority of the judge. A general or special verdict may be amended by the notes of the clerk of assize in civil causes; but not in criminal actions. 1 Salk. 47. The issue roll shall be amended by the imparlance roll, which is precedent; but a roll may not be amended after verdict, where there is nothing to amend it by; though surplusage may be rejected, and so make it good. Cro. Car. 92. 1 Sid. 135.

A mistake of the clerk in entering a judgment was ordered to be amended. Cro. Jac. 351. Hut. 41. A judgment may be amended by the paper-book, signed by the master. 1 Salk. 50. At common law, the judges may amend their judgment of the same term, and by statute of another term. 8 Rep. 156. 14 Edw. III. If judgments are not well entered, on payment of costs, they will be ordered to be done so. When judgments are entered, it is said that the defects therein being the act of the court, and not the misprison of the clerk, are not amendable. Golb. 104. Mistakes in returns of writs, fines, and recoveries, by mutual assent of parties may be amended. Judgment shall not be stayed after verdict, because an original wants form, or varies from the record in point of form, which are amendable. 5 Rep. 45. After verdict given in any court of record, there shall be

no stay of judgment for want of form in any writ, or insufficient returns of sheriffs, variance in form between the original writ and declaration, &c. Stat. 32 Hen. VIII. 18 Eliz. 5 Geo. 1. c. 13. The *poslea* may be amended by the judge's notes. 1 Wilf. 33. 2 Stra. 1797. For amendments in informations by the attorney general, see 4 Terin. Rep. 457, 8. Amendments are usually made in affirmance of judgments, and seldom or never to destroy them; and where amendments were at common law, the party was to pay a fine for leave to amend. 3 Salk. 29. Jacob's Law Dict. by Tomlins, art. *Amendment*. Blackst. Com. vol. iii. p. 407.

AMENDMENT of *Bills in Parliament*, means some alteration made in the original draught; and we read of *amendments of amendments*, *amendments* of returns of representatives, &c.

In cases of wrong returns, so reported by the committee of privileges and elections, and voted by the house of commons, it is usually ordered, that the returns be *amended* by the returning officer, according to the directions of the house, without issuing a new writ.

Amendments ought always to be in that house from whence the thing to be amended originally proceeded, though the directions for the amendments came from the other house. Hakew. Mann. of Passing Bills, p. 167.

AMENDOLARE, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Citra; fourteen miles north-east of Cassano.

AMENDUS, in *Ancient Geography*, a town of Caria, supposed, by Martiniere, to be Myndus.

AMENEBURG, in *Geography*, a town of Germany, in the circle of the Lower Rhine, five miles east-south-east of Marburg, 48 north-north-east of Mentz.

AMENIA, a town of Asia Minor, belonging to the Chalybes, who inhabited the eastern part of Pontus.

AMENIA, in *Geography*, a thriving township of Duches County, New York, in America, six miles from Sharon, in Connecticut; containing 3078 inhabitants, of whom 383 are electors.

AMENORRHOEA, formed of *a priv.* *μηνες*, the *menfes*, and *ρην*, to *flow*, in *Medicine*, is an absence or deficiency of the *menstrual* excretion in women, between the age of thirteen and forty-seven. See MENSES, OBSTRUCTION, and CHLOROSIS.

AMENTACEOUS, in *Botany*, a term applied to the flowers of certain trees and plants, which are composed of a vast number of *apices*, or *anthers*, hanging down in form of a rope, such as the hazel, &c. See CATKIN.

AMENTACEÆ denote one of the classes of plants in Linnæus's natural method of classification; and they are such as bear catkins.

AMENTIA, in *Medicine*, is that deficiency of memory or reasoning which constitutes an *ἰδιότης*. This lamentable malady is placed, by Dr. Cullen, under *nervous* diseases affecting the *mind*; because the mental deficiency is generally the most prominent symptom. In many instances, however, the bodily defects are equally conspicuous, and we may conclude that the *cause* of the disease is always to be traced to some imperfect organization of the body, particularly the brain and head.

A degree of mental imbecility is sometimes observed to follow violent *fevers* and *apoplexie* attacks; and this is the only kind from which we expect a patient to recover.

In these cases the return of mental power is observed to be proportionable to that of the corporeal functions; and therefore

therefore to be promoted by the means employed in the treatment of these diseases.

AMENTUM, in *Antiquity*, a leathern thong fastened about the middle of a dart, or javelin, whereby, after calling it at the enemy, it might be drawn back again to the owner. The amentum served also to increase the force of the stroke; for which reason, some of their great men refused to use it, as confiding wholly in the natural strength of their own arms. *Amentum* denoted also a leathern string or latchet that bound their sandals.

AMENTUM, in *Botany*, see CATKIN.

AMENY, in *Geography*, one of the Laccadive islands, situate in the Indian Sea. N. lat. 11° 37'. E. long. 72° 30'.

AMER, a river of Germany, which runs into the Neckar, one and one-half mile east of Tübingen.

AMERADE, a kind of officers among the Saracens, answering to the governors of provinces among the Europeans.

The name is originally the same with that of *emir*.

AMERBACH, JOHN, in *Biography*, a learned printer, was born at Reutling, in Swabia, and acquired great reputation in the practice of his art at Brasil. The works of Augustin were very correctly printed, for the first time, at his press, in 1506. He begun an edition of Jerom, but died, in 1515, before it was finished. We are indebted to Amerbach for the introduction of the beautiful and useful Roman type instead of the Gothic and Italian.

AMERCEMENT, or AMERCIAMENT, from Fr. *Merci*, in *Law*, a pecuniary punishment imposed upon the offenders, at the discretion of the court; frequently also called *miseri-cordia*.

In the new Terms of the Law, *amercement* is said to be properly a penalty assessed by the peers or equals of the party *amerced*, for an offence done; for which he puts himself upon the mercy of the lord.

There is this stated difference between fines and amercements; that fines are punishments certain, and determined by some statutes; but amercements are arbitrary impositions, proportioned to the fault, and wholly at the mercy of the court.—Manwood, in his *Forest Law*, makes another difference; as if an amercement were a more easy and merciful penalty, and a fine a more sharp and grievous one. If amercements were too grievous, release might be sued by an ancient writ called *moderata misericordia*.

Fines also are imposed and assessed by the court; amercements by the country: and no court can impose a fine, but a court of record; other courts can only amerce. 8 Rep. 39. 41. A town shall be amerced for the escape of a murderer in the day-time: and if the town be walled, it is said it shall be subject to amercement, whether by day or night. 3 Inst. 53.

By the statute of *Magna Charta*, c. 14. a freeman is not to be amerced for a small fault, but proportionable to the offence, and that by his peers. 9 Hen. III. c. 4.

Before this period amercements were often excessive, and they were imposed on a thousand different occasions, not only for real crimes, but for trivial or imaginary offences, and on the most frivolous pretences; of course they were the sources of infinite vexations to the subjects, as well as of great riches to the sovereigns of England. They fell heavy not only on the common people, but upon the greatest prelates, and most powerful barons of the kingdom. This gave occasion to the above-mentioned article of the great charter, and to the rules founded upon it, which enacted, that no

man should have a larger amercement imposed upon him than his circumstances or personal estate would bear; saving to the landholder his contencment or land, to the trader his merchandize, and to the countryman his wainage, or team and instruments of husbandry. In order to ascertain which, the great charter also directs, that the amercement, which is always inflicted in general terms ("*fit in misericordia*,") shall be set, *ponetur*, or reduced to a certainty, by the oath of good and lawful men of the neighbourhood, which method of liquidating the amercement to a precise sum was usually performed in the superior courts by the assessor or assessor of the coroner, a sworn officer chosen by the neighbourhood, under the equity of the statute Westm. 1. c. 18. and then the judges estreated them into the exchequer. But in the court leet and court baron it is still performed by assessors, or suitors sworn to assere, that is, tax and moderate the general amercement, according to the particular circumstances of the offence and the offender. Amercements imposed by the superior courts on their own officers and ministers were assessed by the judges themselves; but when a pecuniary mulct was inflicted by them on a stranger, (not being party to any suit), it was then denominated a FINE; and the ancient practice was, when any such fine was imposed, to inquire by a jury, *quantum inde regi dare valeat per annum, salva sustentatione sua, et uxoris, et liberorum suorum*. And since the disuse of such inquest, it is never usual to assess a larger fine than a man is able to pay, without touching the implements of his livelihood; but to inflict corporal punishment, or a limited imprisonment, instead of such fine as might amount to imprisonment for life. Hence it happens that fines in the king's court are frequently denominated ransoms, because the penalty otherwise falls upon a man's person, unless it be redeemed or ransomed by a pecuniary fine; according to an ancient maxim, *qui non habet in crumena luat in corpore*. Yet, where any statute speaks both of fine and ransom, it is holden, that the ransom should be treble to the fine at least. Blackst. Com. vol. iv. p. 380.

A court leet can amerce for public nuisances only. 1 Saund. 135. For a fine and all amerciaments in a court leet, a distress is incident of common right: but for amerciament in a court baron, distress may not be taken but by prescription. 11 Rep. 45. When amerciament is agreed on, the lord may have an action of debt, or distrain for it, and impound the distress, or sell it at his pleasure; but he cannot imprison for it. 8 Rep. 41. 45.

There is also amercement in pleas in the courts of record, when a defendant delays to tender the thing demanded by the king's writs, on the first day. Co. Litt. 116. And in all personal actions without force, as in debt, detinue, &c. if the plaintiff be non-suited, barred, or his writ abate for matter of form, he shall be amerced; but if on judicial process, founded on a judgment and record, the plaintiff be non-suited, barred, &c. he shall not be amerced. 1 Nelf. Abr. 206. And an infant, if non-suited, is not to be amerced. Jenk. Cent. 258.

Amerciament royal, is used by some to denote a pecuniary punishment laid upon a sheriff, coroner, or such-like officer of the king, by justices, for some offence or abuse in his office.

AMERI, in *Botany*. See INDIGOFERA.

AMERIA, in *Ancient Geography*, a district of Armenia, mentioned by Strabo (tom. ii. p. 835.) situate in the vicinity of Cabira, in which was a temple of the month Pharnacus, a number of priests or Hieroduli, and a sacred territory, the fruits of which were appropriate to the pontifex. The

month Pharnacus, which was the deity denominated Luvius among the ancients, was held in such veneration, that the oath by the fortune of the king and of the mount Pharnacus, was called the *royal oath*.

AMERIA, now AMELIA, a town of Italy, south-west of Spoleto, founded, according to Cato, 964 years before the Persian war, or 1135 years B. C. Augustus established a colony in it. The celebrated Roscius is said to have been a native of this city. The whole of its territory was assigned by Augustus to the veteran soldiers.

AMERIA, in *Geography*, a town of Asiatic Turkey, in Natolia, 72 miles east of Kutaja. N. lat. 39° 25'. E. long. 32° 14'.

AMERICA, *General History of*. Throughout the history of the world no event more curious, in the eye of the philosopher, has happened than the discovery of the new continent, which, with its surrounding seas, forms a complete hemisphere of our planet, whereof the ancients knew no more than a hundred and eighty degrees of longitude, which might even, by a strict discussion, be reduced to a hundred and thirty; for, such is the error of Ptolemy, that he shoves back a hundred and forty-eight degrees and more the eastern mouth of the Ganges, which, according to astronomical observations, taken by the moderns, is settled at about a hundred and eight: thus manifestly giving an overplus of forty degrees of longitude in the statement of Ptolemy, who seems to have had no notion of any of the parts beyond what we denominate Cochinchina, which consequently forms the eastern boundary of the world, as known to the ancients, as our first meridian is the boundary of the world to the west.

To pretend that the Phœnicians and the Carthaginians made the voyage to America is an opinion truly ridiculous, and no better supported on authentic documents than the stories related in our times of the pretended navigations of the Chinese towards the shores of Mexico. It is well known, from inquiries made at Pekin, that the work wherein some traces of these navigations to the latitudes of Mexico were supposed to be found, is a romance to the full as gross as the fictions related by Ælian, (Hist. Divers. lib. iii.) in regard to an imaginary country, entirely full of gold, and which has seemed to have a complete conformity with Peru, in the eyes of several of the learned, whose judgment was extremely confined. Notwithstanding what Vossius is pleased to say, in his commentaries on Pomponius Mela, and M. Huet, in his dissertation on the commerce of the ancients, where he cites the *Annals of Ormus*, which nobody knows, it is certain that the Chinese never took long voyages; and that in 1430 they had not any notion whatever of the island Formosa, which is at no greater distance than eighteen leagues from their coast. If they had been in the practice of making long voyages, the ignorance in geography would not be so prodigious as it actually is at present, to such a degree that they have never been able to lay down the map of China: accordingly, whenever they wanted a map of China, they have been obliged to employ Europeans, whose performances we are well acquainted with, and know them to fall very far short of what positive geography has a right to demand concerning so vast a region as Asia.

If any people in Europe in reality did frequent some parts of the coast of North America prior to the æra of the navigations of Columbus and Vesputius, it must have been the Icelanders and Norwegians; since it cannot be disputed that both the one and the other of these people had before the fifteenth century formed settlements in Green-

land, which should at present be reckoned as a part of the new continent. But here, we cannot avoid observing, that we should never have been able to discover the centre of America, if no other way had been found for penetrating thither, than that of Greenland, by reason of the huge bodies of ice which at once prevent any great progress within land, and from making any considerable advances towards the pole. Besides, the danger to be encountered in these high latitudes, the excessive severity of the climate, the want of every species of sustenance, and the little hope of meeting with any treasures to counterbalance the arduous enterprise, would have been enough to dishearten the most intrepid navigators. Christopher Columbus, however, in 1492, discovered an easy passage; and, when we perceive him pushing up as far as the 25th degree of north latitude, to fetch that east wind which commonly prevails between the tropics, and afterwards proceeding in nearly a straight line to the island of St. Domingo, we are almost tempted to believe that he had a previous intimation of that track; and therefore, the Spaniards, with a degree of ingratitude altogether monstrous, endeavoured to deprive that great man, because he was not born in Spain, of the credit of his discovery, by publishing on this occasion the most puerile and contradictory fables. The truth of the matter is, that Columbus submitted to be guided by one of his brothers, named Bartholomew, who was a geographer by profession; and in drawing his maps of the world, such as they were able to make them at that time, he was perpetually astonished, that of three hundred and sixty degrees of longitude, only a hundred and eighty at most were known; and, of course, there remained as much of the world to be discovered as had already been found out: and as it seemed by no means probable that the ocean could extend, without any interruption, over one entire hemisphere, he maintained, that by keeping constantly to the west from the Canaries, they must infallibly come either to islands or to a continent. And in fact so it turned out. They first came to islands, and then to a continent, where every thing wore the face of such extreme desolation, that one cannot reflect upon it without amazement. It is by no means our intention here to follow the ancient stories, in which, to the credulity of childhood has been added the dreams of dotage. In these accounts whatever we meet with favours of the marvellous; nothing is examined into: it shall be our business, therefore, to endeavour at communicating to the reader clearer notions and juster ideas.

Among the various populations dispersed throughout the forests and deserts of this newly discovered world, it is not possible to point out above two that had formed any sort of political society, the Mexicans and the Peruvians, and even their history is stuffed with fables. Besides, their population must have been much lower than has been stated, since they had no iron instruments for felling the trees, nor for tilling the ground; they had no animal fit for drawing the plough, and the construction of the plough itself was even unknown to them. It is easily conceived, that when the labour of the field must altogether be done with a wooden shovel, and by the hand, it is impossible to lay out much ground in agriculture: and without a regular agriculture, wherein the labour of animals concurs with that of mankind, no people can become numerous in any part of the world. It is, however, very surprising, that at the time of its discovery America possessed scarcely any animal fitted for tillage: the ox and the horse were unknown, as well as the ass, which was anciently employed in culture by several nations of our continent, as in Bœtica and Lybia, where the lightness of the

the foil, says Columella, (*De Re Rust. lib. vii.*) enabled this animal to supply the place of horses and oxen. It is commonly thought that the American bison might have been serviceable in tillage; but the bison being of a rude untractable nature, it would have required a long series of generations to tame him gradually for the purposes of husbandry. Now this is what no one ever even thought of in America, where the people are both less indoltrous and less inventive than the inhabitants of our hemisphere: their laziness and indolence particularly struck the more attentive and sagacious observers. In short, the stupidity they evince on certain occasions is such, that they seem, according to the expression of M. de la Condamine, to live in eternal infancy. (*Voyage sur le fleuve des Amazones.*)

At the same time no irregularity has been noticed in their outward organs, unless we chuse to except the absolute defect of a beard, and of that down which persons of both sexes should have on the chin, after arriving at the age of puberty. It is in vain to affirm that the germ of this soft down is destroyed or eradicated, since at a very advanced age, here and there some scattered hairs of it grow, which they commonly pluck up with nippers made of shells. Their stature differs not from that of others of our species in the temperate zones: for beyond the arctic circle, the tribe of Esquimaux or Innuits, though of American descent, is composed of only short people; because the action of the extreme cold is hostile to the complete expansion of the members; and the case is nearly the same with the inhabitants of Greenland, which is known to have been originally peopled by hordes of American race, of which the perfect agreement between the language of the Greenlanders and that of the Esquimaux leaves no room to doubt.

Nothing but a blind fondness for the marvellous could have occasioned the propagation of such absurd fictions as those relating to a gigantic race, found on the Magellanic shores, now customarily denominated Patagonia. The most sensible navigators, as Narbrough, (*Voyage to the South Seas*), who have had communication with the Patagonians, describe them to be of the ordinary stature of mankind, living by small troops in those immense regions, where the English, who traversed them from one extremity to the other, from Cape Blanco to Buenos Ayres, saw not an inch of ground cultivated, nor the least trace of tillage; inasmuch that the difficulty of finding the means of subsistence must have been exceedingly great, prior to the time of the discovery, and while there was not a horse in existence, since the flesh of that animal is at present almost the sole nourishment of the Patagonians who occupied the midland countries between the river de la Plata, and the 45th degree of south latitude. Such is the extreme indolence of these savages, that they devour the very animals by means of which they might clear their deserts, and at length put an end to that miserable mode of existence in which they are not a jot above the level of the beasts under the guidance of instinct alone.

We shall not, as has been hitherto done, reckon among the particular and distinct races, those Blasards that are found in numbers by no means considerable at Costa Rica, and the isthmus of Darien, (*Waser's Description of the Isthmus of Darien, and Coreal Voyages, tom. i.*) this being only a disease, or an accidental alteration in the temperament of the parents who produced these discoloured individuals, who are known to bear a great analogy with the white negroes, or the Dondos of Africa, and with the Kakerlakes of Asia. The distemper in which these symp-

toms originate attacks more or less all the black or extremely swarthy people in the hottest climates of the globe. The pygmies, spoken of in an account translated by M. Gomberville of the French academy, the himantopodes, or savages having the inflection of the knee turned backwards, and others that have but one leg, may be ranked in the same class with the Amazons, and the inhabitants of El Dorado, among the absurdities which some travellers have been weak enough to believe, and vain enough to publish. All the monstrous people that have been seen in the New World, were rendered so by artifice; such as those that have the head completely round, and are called bowl-heads, those who have it flatted, and are denominated plagiocephali; in short, such as have it conical, or lengthened out, and are styled macrocephali. Among a naked people, where the garments cannot be affected by fashions, they influence the body itself, and produce those various deformities which have been noticed among the savages, some shortening their neck, others piercing the cartilage of the nose, the lips, the balls of the cheeks, others lengthening their ears, or causing their legs to swell by means of a ligature above the ankle.

It is not known, and it will ever be a matter of difficulty to trace the true source of the venereal disease with which the Americans were afflicted in the West India islands, the Caribbees, at Florida, in Peru, and throughout a great part of Mexico: on this subject several curious conjectures have been thrown out, some of them sufficiently ridiculous. It has been pretended, that the flesh of the fish intoxicated with the cururn-ape, and the flesh of the game killed with arrows poisoned with a species of woodbine, called woorara, produced this contagion among them. But the ancient wild people of our continent poisoned in the same manner their hunting weapons, without any consequences in the least degree prejudicial to their health; and it is a well-known fact, that the fishes killed in the ponds with the *cocula orientalis officinarum*, and that the fowls slain in some districts of the Alps with knives rubbed over with *suc de napel*, afford a very wholesome nutriment. Besides, in the island of St. Domingo, where the venereal disease was extremely rife, the use of poisoned darts was not in practice as among the Caribs and several tribes on the Terra Firma. Neither is it true, that the sting of a serpent or lizard of the iguan tribe, or that the human flesh eaten by these anthropophagi, engendered the venereal virus in the blood of the inhabitants of the New World. The hypothesis of M. Astruc, as stated in the last edition of his great work "*De Morbis Venereis*," borders far more on probability than the fanciful opinions just mentioned; though this hypothesis of that famous physician is by no means generally adopted. We shall content ourselves with observing, that the venereal disease may have been a morbid affection in the temperament of the Americans, like the scurvy in the countries of the north: for, after all, we are not to imagine that this distemper made the same ravages in America as it did in Europe some time after its transplantation.

The almost total want of culture, the vast extent of the forests, the immense tract of country, the waters of the rivers exundated from their beds, the infinite number of swamps and lakes, together with the host of insects which are a natural consequence from all these, rendered the climate of America insalubrious in certain parts, and much colder than it might otherwise be expected, considering the relative latitude of its territory. The difference of temperature in the two hemispheres, under the same parallels, has been estimated at twelve degrees, and by a closer calculation, it might

might even be fixed at some degrees more. Now, these several causes operating conjointly must have had an influence on the constitution of the indigenous people, so as to produce some alteration in their faculties: accordingly, it is only to a want of penetration that we can ascribe the little progress they had made in metallurgy, the first of all arts, as that without which the others fall, as it were, into a lethargy. It is well known that nature has not denied iron mines to America; and yet no nation of America, neither the Peruvians nor the Mexicans, possessed the secret of forging that metal; whereby they were deprived of many conveniences, by rendering it impossible for them to make regular falls of timber in their forests, and to restrain the rivers within their beds. Their hatchets of stone could not enter the trunks of trees, except by the application at the same time of fire to them; so that they were forced to convey away all the parts reduced to coal, in order to prevent the flame from coming at the rest. Their process was nearly the same whenever they wanted to make barks of a single piece, or cauldrons of wood for boiling their victuals, by afterwards casting in red hot stones; for comparatively but few of the savages had the art of making vessels of clay. The farther these methods were from perfection, the more time they required in the practice: therefore, in South America it was often observed, that men were employed for two whole months in felling three trees. To conclude, it will be easily imagined, that the more stationary populations, as the Mexicans and the Peruvians, notwithstanding the want of iron, had acquired a degree of industry greatly superior to the mechanical skill possessed by such as were dispersed by families, like the *Worons*, where they have not sufficient resources, says Dr. Bancroft, for procuring the most necessary part of clothing; and it is only with the reticulation found in the cocoa nut, or with some bark of trees, that they cover the organs of generation. Natural History of Guiana.

Hence we are not to be surpris'd, that the New World contained so few inhabitants at the time of its discovery: for the savage life is repugnant to the multiplication of the species beyond what we should at first sight imagine; since the less the savages cultivate the soil, the more ground they want to live upon. In the northern tracts of America districts of forty leagues have been travelled over in all directions, without meeting with a single hut, or perceiving the smallest vestige of a habitation. After a march of nine or ten days, keeping always the same course, the traveller has perhaps come up to a petty horde, or rather a family, separated from the rest of mankind, not only by mountains and deserts, but also by its language differing from all known tongues. Nothing more strongly proves the little communication then subsisting between the Americans in general, than the incredible number of dialects spoken by the different tribes of savages. Even in Peru, where social life had made some faint advances, a great variety of languages was nevertheless found, reciprocally incomprehensible or unintelligible, and the emperor could not issue his commands to the greater part of his subjects, except by means of interpreters. It naturally occurs on this occasion, that the ancient Germans, though distributed likewise in populations, separated by vast deserts, yet spoke only one mother-tongue; and a person might, before the Augustan age, as well as at present, make himself tolerably well understood by means of the *Tudisque*, from the centre of Belgium, to the banks of the Oder: whereas, in the New World, we need only, says Acolta, to cross a valley for hearing another jargon. *De procur. Indorum salut.*

The depopulation was perhaps still greater in the more southern parts of America than in the north, where the forests had usurped every thing; so that much of the great game might propagate, and sustain themselves in them, and at the same time afford nourishment to the hunters; whereas in the Magellanic countries there are plains upwards of two hundred leagues in extent where no wood is seen, but only bushes, briars, and noxious weeds. (*Beschreib. von Patagonien.*) Whether it be that the quality of the briny or acid waters found there is repugnant to the propagation of forests, or that the ground there secretes depositions of gravelly and stony substances, from which the roots of large trees can derive no aliment. In short, for forming some idea of the desolation of the Magellanic regions, it will suffice to say, that the English, carried into slavery by the Patagonians, have often travelled, in the train of their barbarous masters, for a whole fortnight together, before they came up with a few miserable huts covered in with horie hides. In the village that has been stiled the capital of Patagonia, and where the grand cacic resided, they could reckon in 1741, no more than fourscore persons of both sexes. *Anson's Voyages.* Besides, in the southern degrees of latitude, there are low lands, one part whereof is marshy, and the other annually overflowed, because the rivers and torrents, which have not channels proportionate to their volume of water, deluge the country to immense distances on the access of the rainy season in the torrid zone. From Sierra Itatin to the extremity of the mission of the *Moxes*, about the fifteenth degree of south latitude, through a space extending upwards of three hundred leagues, are found either these swamps or those lands where the inundations frequently drive the inhabitants up the mountains: accordingly there were seen but few, and they spoke thirty-nine languages, not one of which had any affinity with the rest. *Relation de la Mission des Moxes.*

It is thought that the entire population of the New World, at the time of its discovery, might be forty millions; which falls short of the sixteenth part of the total amount of the human species, upon the computation of those who give to our globe eight hundred millions of individuals. Yet it is supposed, that in dimension the new continent is nearly equal to the old one: however, it is of consequence to observe, that the calculations of Templeman, Struyek, and several others, in regard to the surface of America, reduced to square miles, are not entitled to much confidence, as the geographical maps are still too defective for such an operation; and it would scarcely be believed, that all the known maps contain an error of almost a hundred leagues in the longitude alone of some stations of Mexico, as that longitude has been lately determined by an eclipse of the moon. But this is not all, inasmuch as there is a tract of country beyond the *Sioux* and the *Assenipoils*; the commencement whereof towards the west is not known any more than where it terminates towards the north.

M. Buffon had already observed, that some Spanish authors must have been guilty of great exaggerations in what they relate concerning the number of persons who, according to them, were found in Peru. But nothing more completely proves that these writers have exaggerated, than what we have mentioned of the small quantity of ground rendered productive in this country, where Zarate himself agrees, that there existed only one place that had the aspect of a town, and that town, says he, was *Cuseo*. (*Hist. of the Conquest of Peru*, book i. chap. 9.) Nay, so long ago as the year 1510, the court of Spain saw, that, to remedy the depopulation of the conquered provinces in America, no

other means were left than to transport negroes thither, wherein the regular traffic began in 1516, and cost enormous sum: it is even computed that each African brought to the isle of St. Domingo came to upwards of two hundred ducats, or more than two hundred chequins, at the rate that the Genoese merchants charged for them. The Spaniards have, doubtless, contrary to their own interest, destroyed a great number of Americans, both by the labour of the mines and by atrocious depredations; but it is no less certain, that countries whither the Spaniards never penetrated, as the parts adjacent to Hudson's Bay, are still more desert than others that fell under the yoke of the Castilians.

We now conceive how great the difference in the fifteenth century, between the two hemispheres of our globe. In one, civil life was but just commencing; literature was utterly unknown: the very names of the sciences had scarcely been heard: the generality of trades were wanting: tillage was in so rude a state as hardly to deserve the name of agriculture, since neither the plough nor the harrow had been invented, nor any animal trained to draw them: reason, which alone can dictate equitable laws, had not yet caused her voice to be heard: human blood was shed upon the altars; and even the Mexicans were still in some respects anthropophagi; an epithet that may also be extended to the Peruvians, since, by the confession of Garcilasso, who is by no means prone to calumniate them, they shed the blood of children on the *cancu*, or sacred bread, if that name may be assigned to a paste, kneaded, so as for fanatics to eat it in a kind of temples by way of honouring the deity of whom they had no knowledge. In our continent, on the other hand, societies had so long been formed, that their origin is almost lost in the darkness of antiquity, and the discovery of forged iron, so necessary and so unknown to the Americans, has been in use among the inhabitants of our hemisphere from time immemorial. For, though the process employed for obtaining the malleability of a metal so stubborn in its mineral state be very complicated, yet M. de Mairan has clearly proved that the several æras, at which writers have pretended to fix this discovery, are to be regarded as fabulous. *Lettres sur la Chine.*

It is impossible here to enter into a regular analysis of the systems proposed for explaining the causes of this difference between the two parts of the same globe. It is a secret of nature, on which the human mind becomes more and more confused in proportion as it obstinately determines to fathom it. Nevertheless, those physical vicissitudes, the earthquakes, the volcanoes, the inundations, and peculiar catastrophes, whereof we, who live in the calm of the elements, have not a very accurate idea, may have had some influence in its production: and it is well known at present that the most violent shocks of earthquakes, which are sometimes felt throughout the whole extent of the new continent, communicate no succession at all to ours. Had it not been for the private advices received from different parts, we in Europe should never have known that, on the 4th of April, 1768, the whole tract of America was shaken: whence we may infer, that anciently dreadful calamities may have happened, whereof the inhabitants of our hemisphere, so far from feeling them, have not had the slightest intimation. Neither should we, following the example of some of the learned, apply to the New World the prodigies found in the *Timæus* and the *Critias* of Plato, concerning the Atlantis sunk by a torrent of rain that lasted only four and twenty hours. The basis of this tradition was brought from Egypt, but Plato embellished or disfigured it by a number of allegories, some philosophical and others puerile; such as the victory obtained over the Atlantes by

the Athenians, at a period when Athens was not yet in being: these anachronisms occur so frequently in the writings of Plato, that it certainly was not without reason that the Greeks themselves accused him of being unacquainted with the chronology of his country. *Athen. lib. v. cap. 12 & 13.* The great difficulty is to know whether the Egyptians, who were no mariners, and consequently could be but little versed in positive geography, had any accurate knowledge concerning a large island or a continent situate beyond the pillars of Hercules. Now it must be owned that this is not probable; but their priests, while studying cosmography, might surmise that there were more portions of land dispersed in the ocean than they had knowledge of. The less they knew, from the total want of navigation, the more natural it is that they should have fallen on this conjecture; and especially if it could be shewn that prior to the mensuration of the earth performed in Egypt by Eratosthenes, under Euergetes, the priests had already an idea of the actual dimensions of the globe. However this be, their doubts and their surmises concerning the existence of some large tract of country, had no more relation to America in particular than to all other lands with which they were unacquainted; and the limits of the ancient world, precisely as we have fixed them, remain invariably the same.

That the cataclysm, or inundation of the Atlantis, rendered the sea beyond the straits of Gibraltar so muddy as to make it innavigable, as Plato affirms, is flatly contradicted by all experience from the voyage of Hanno to our own times. And yet M. Gesner, whose erudition is universally acknowledged, thought that the isle of Ceres, spoken of in a poem of very high antiquity, attributed to Orpheus under the title of *Αργοναυσιχα*, was a fragment of the Atlantis: but this isle, which is described by its forests of pines, and particularly by the black clouds which surround it, has no where been found; so that it must have been swallowed up in the abyss subsequent to the Argonautic expedition, even supposing, contrary to all probability, or rather contrary to possibility, that these Argonauts could have come from the Euxine into the Atlantic ocean, by conveying the ship *Argo* from the Borysthenes into the Vistula, to enable them afterwards to enter the Mediterranean by the columns of Hercules, as it is mentioned towards the end of that poem ascribed to Orpheus; whence we may conclude, that there has been no sparing of the marvellous, and that M. Gesner might have been less credulous without any impeachment of his prudence.

If we find any where to the west of us some traces of a continent converted into a multitude of isles, it is doubtless in the Pacific ocean; and we shall not here repeat what the President de Brosse has advanced on this subject in his work, in which he treats of the navigations to the southern parts.

As to those who pretend that the human race has only of late found its way to America, by crossing the sea at Kamtschatka, or the straits of Tschutski, either upon the fields of ice or in canoes, they do not consider that this opinion, besides that it is extremely difficult of comprehension, has not the least tendency to diminish the prodigy: for it would be surprising indeed that one-half of our planet should have remained without inhabitants during thousands of years, while the other half was peopled. What renders this opinion less probable is, that America is supposed in it to have had animals, since we cannot bring those species of animals from the Old World which do not exist in it, as those of the tapir, the glama, and the tajaçu. Neither can we admit of a recent organization of matter for the hemisphere opposite to ours: because, independently of the accumulated difficulties in this hypothesis,

hypothesis, and which can by no means be solved, we shall observe, that the fossil bones discovered in so many parts of America, and at such small depths, prove that certain species of animals, so far from having been recently organized, have been annihilated a long while ago. It is an indubitable fact, that when Christopher Columbus arrived there, there existed neither in the islands nor in any province of the new continent quadrupeds of the first magnitude: there was neither the dromedary, the camel, the giraffe, the elephant, the rhinoceros, the horse, nor the hippopotamus. Therefore the large bones that have been dug up have belonged to species extinct or destroyed some centuries anterior to the epocha of the discovery of that country; since the very tradition of them no longer subsisted among the natives who had never so much as heard talk of any quadrupeds of larger size than those found among them in 1492. Yet the molar tooth, in possession of the late Abbé Chappede, who died in California, was eight pounds in weight; as we learn from the extract of the letter addressed to the academy of Paris by M. Alzate, who affirms, that at Mexico is still preserved the bone of a leg, the knob whereof is a foot in diameter. Some of the large species of the hippopotamus, such as are found in Abyssinia and on the shores of the Zaire, produce grinders weighing upwards of eight pounds; and yet it may be doubted whether there be any elephants having legs that contain parts of such prodigious dimensions as those mentioned by M. Alzate, whose account, however, may not be absolutely exempt from exaggeration. The same may be said of the dimensions given by Father Torrubia, in his pretended Gigantology, to some fragments of skeletons dug up in America, and which are at present pretty generally to be seen in the cabinets of Europe. The late Mr. Hunter, who made this subject his particular study, thought that they belonged to carnivorous animals; and it was not till after he had gone through a long course of comparative anatomy, that he delivered this opinion to the Royal Society of London. [Phil. Transact. for the year 1768.] But if this were true, nature must have acted upon a contrary plan in America to what she has followed in our continent, where all the terrestrial quadrupeds of the first magnitude are frugivorous and not carnivorous. It is a mistake in Prosper Alpinus and M. Maillet, to imagine that the hippopotamus is sarcophagous or carnivorous. The reason whereof seems to be the difficulty that carnivorous animals of the first magnitude would have had in finding sustenance, and that at all times; whereas the vegetables immediately spring up, and in such abundance, as to be more than sufficient for the nourishment of frugivorous beasts of the most enormous bulk: accordingly, the opinion of those who attribute these relics to zoophagous genera is scarcely probable. In vain were the savages who dwell on the banks of the Ohio interrogated concerning their notions about the huge bones that were found on the borders of that river in 1738; they threw no more light on the subject than the inhabitants of Siberia do on the discovery of the fossil ivory of their country, which some of them consider as the spoils of giants, and others as the remains of an animal living under ground, which they call *mammut*, a being more worthy of appearing in the mythology of the north than in the nomenclature of natural history. [See Tooke's View of the Russian Empire, vol. i. p. 26.] Nevertheless M. Bertrand, that sagacious observer, who traversed Pennsylvania and a great part of North America, assures us, that some savages, on seeing oyster-shells found in the chain of the Blue Mountains, reaching from Canada to Carolina, said that it was not surprising to find shells about the Blue Mountains, since they knew that in days of yore the sea had surrounded them with its waters.

This relation is founded on the tradition universally disseminated among all the tribes of America, from the straits of Magellan as far as Canada. They affirm, that in former times the low lands of their continent were submerged, which obliged their ancestors to retire to the heights. It is not without some degree of astonishment that we read in Acosta, that in his time traces strongly marked of that inundation were still seen in several places: "Certe in novo orbe ingentis cujusdam exundationis non obscura monumenta a pritis notantur." [De Natura Nov. Orb.]

However this be, we are unable to explain how all the populations of America had so little commerce and connection with each other, as is proved from the multiplicity of languages in use among them, otherwise than by admitting that their manner of living by the chase or by the fishery not only prevented them from uniting, but even obliged them to retreat from each other. Accordingly, it has been seen, that when distinct tribes have come so near as to intercept the game, it kindles national wars, which only terminate in the destruction or the retreat of the weaker or less courageous tribe. Handfuls of men there dispute for the possession of immense deserts; and the enemies are often at the distance of above a hundred leagues asunder: but a hundred leagues are nothing to hunters, who, in the search of game, or in the distant pursuit of it, always meet in some part or other. The difficulty of fixing boundaries, which is very great even among sedentary nations, is much greater among hordes who roam from forests to forests, and yet pretend to be the absolute proprietors of districts which they only run over.

Such nations as were really fishers, or ichtyophagi, existed only in the northernmost regions of the New World: for, though we find between the tropics savages who are much addicted to fishing, they nevertheless plant several feet of manioc around their huts. But throughout America this culture, as well as that of the maize, was the business of women, and the reason of it is very easy to discover; but little of it was cultivated, so that this employment was not regarded as the principal occupation. Many hunters have even been discovered, as well in the south as in the north, who followed no species of cultivation, living solely on game. As it happened that they were more successful at some seasons than at others, they could only preserve their meat by broiling it: for the nations dispersed towards the centre of the continent had not the slightest knowledge of salt; but almost all those who dwelt in the torrid zone, and even at the extremities of the temperate zones towards the equator, made great use of pimento (*capsicum annum*) or other herbs as hot; and this they were taught by nature. We should here observe, that the physicians of Europe have generally been and are still in an error in regard to spices. In burning climes great and continual use of them is necessary to aid digestion, and restore to the bowels the heat which they lose by a too copious transpiration. Thus travellers inform us that those savages of Guiana, who sprinkle so much pepper over their victuals as to excoriate the tongues of persons not accustomed to it, constantly enjoy a more confirmed state of health than the other people of the country, as the Acoquas and the Moroux, who cannot always procure pimento in sufficient quantities. Even in Europe we see how necessary this spice is to the Spaniards, who sow whole fields with it as we sow barley: in short, it is well known that, in proportion as the heat of the climate augments, it has been found all over Asia and Africa that the consumption of spices has augmented in a direct ratio with that heat.

Among the hunting nations of the New World different compositions, to which we commonly give the name of nutritive powders or condensed aliments, have been discovered, which

which they expressly reduce to a small compass, in order that they may be able the more easily to convey them when they are to take a long course through the deserts, where the ground, often covered with snow to the height of two or three feet, affords no resources except what proceed from the game, which are very uncertain, because many animals then keep close to their coverts, which are sometimes in places at a great distance from those in which they are in quest of them. Moreover, we gather, from various accounts, and even from some passages in history, that the generality of ambulatory nations of our continent have had or still have similar practices: the savages of Great Britany composed a kind of these pastes with karemyle, which is supposed to be the tubercules of the magion, called by the country folks wild vetches, though in fact it is a *lathyrus*. By swallowing a ball of this drug the Bretons were enabled to dispense with all other aliment for an entire day. [Dio Cassius, in Sever.] The case is nearly the same with the green powder, in use among the savages dispersed along the river Susquehanna, which falls into Chesapeake Bay: it will suffice here to observe, that this substance is composed of torrefied maize, which forms the principal ingredient, roots of angelica and salt. It may be conjectured, however, that these barbarians, before they had any communication with the colonies of Europe, employed no salt in the composition, as it cannot add much to the alimentary properties.

As to the method of procuring fire, it was the same throughout the whole extent of the New World, from Patagonia to Greenland; that is, by rubbing pieces of hard wood against other very dry pieces, so long and so forcibly till they emitted sparks or kindled into a flame. It is true, that among certain populations to the north of California, they had the method of inserting a kind of pivot in the hole of a very thick plank; and by the circular friction produced the same effect with that above mentioned. [Muller, Reise und Entdeckungen von den Russen.] It should seem as if it were insufficient alone, or, if the expression may be allowed, the innate industry of man, that taught him this practice: so that, on this supposition, what some accounts relate concerning the inhabitants of the Marianes, the Philippines, Los Jordanas, and the Amicuanes, who were ignorant, as they pretend, of the secret of procuring fire, must be entirely without foundation. And if we find similar facts in the geographers of antiquity, as Pomponius Mela, in regard to certain tribes of Africa, it is necessary we should know that this author drew his information from the relations of Eudoxus, whom Strabo describes as an impostor, who, in order to have it believed that he had doubled the Cape of Good Hope, takes the liberty of telling abundance of falsehoods. It appears, from the history of China, and particularly from the custom still subsisting among the Kamtschadales, the Siberians, and even among the Russian peasants, that the method of causing wood to take fire by friction must have been common in our continent prior to the knowledge of steel and of pyrites: the heat felt by savage man in his hands on rubbing them taught him the art.

As there were in America a very great number of petty nations, of which some were more deeply sunk in barbarism than the rest, and in a total ignorance of all that constitutes the rational animal, it is extremely difficult to distinguish accurately the customs adopted only by some particular tribes from the practices generally followed. There are travellers who have thought that none of the savages of the New World had the smallest idea of incest, at least in the collateral line, and that brothers indiscriminately married their sisters, or cohabited with them without marriage; which gave occasion to some persons to imagine that both the physical and moral faculties of those savages must have undergone an alteration,

since it is thought that it is with mankind as with domestic animals, whereof some become stunted by incestuous copulations; a circumstance that has pointed the necessity of mixing or crossing the races, for the purpose of maintaining the vigour and perpetuating the beauty of them. It is evident, from experiments recently made on a single species, that the degeneracy is greater and more rapid by a succession of copulations in the collateral than in the direct line: a result which certainly would not have been expected. However, according to the "Lettres Edifiantes," and the accounts of fathers Lafiteau and Guinilla [Mœurs des Sauvages & Histoire d'Oronoque], it is certain that there existed several tribes in America, among whom marriage was not contracted even in the third degree of parentage; so that it cannot be said that the conjunctions which we term illicit, or incestuous, were in general practice there, as they undoubtedly were among the Caribs and several others. Garcilasso likewise relates [Histoire des Incas] that the grand cacics, or the emperors of Peru, by a curious sort of polygamy, married their sisters and their cousin-germans at the same time. He adds, indeed, p. 68. tom. ii. that this custom extended not to the people; but it is a fact that seems to us almost impossible to explain. However, we ought not to give implicit faith to all that we read in Garcilasso touching the legislation of the Peruvians; besides, he agrees that, among the hordes of this country, where the authority of the grand cacic or emperor was unsettled, as among the Antis, "marriage was unknown; when nature inspired them with desire, chance gave them a mate, taking whatever woman they met; their daughters, their sisters, their mothers, were indifferent to them; these last, however, were more excepted. In another canton," he adds, "the mothers kept their daughters with extreme care, and when they married them, elles les desfloroient en public de leurs propres mains, pour montrer qu'elles les avoient bien gardées," tom. i. p. 14. This last custom, if true, would appear still more astonishing than the incest, which must have really been in vogue among the petty hordes, composed of not above 130 persons, such as are at present seen in the forests of America, than among the more numerous tribes; and especially if we reflect on the multiplicity of languages reciprocally unintelligible, which prevented these petty hordes from procuring wives from their neighbours.

It should here be remarked, that what we have mentioned on the subject of the degeneracy that may arise from incestuous copulations to the human race, as well as to several species of animals, is nothing more than a bare supposition. The truth is, that we are not at present, nor are likely soon to be, sufficiently informed on a subject of such importance, for being able to speak on it with confidence; for it would be to no purpose here to cite the example of some nations of antiquity, particularly that of the Egyptians, whose laws, which are thought to be the best known, are often the least understood. The Greeks, who wrote on the history of Egypt after the death of Alexander, might easily have confounded the sanctions of a foreign code, adopted under the dynasty of the Lagides, with the sanctions of the national code, wherein we, who have made it our particular study, have not been able to find any satisfactory proof of the law that is conjectured to have existed there prior to the time of the conquest of the Macedonians; but a more ample discussion of this matter would here be certainly out of place. What convinces us, however, that we ought not to insist on the necessity of crossing the races in regard to mankind, as we do when speaking of the domestic animals, is, that the Circassians and the Mingrelians constitute a people who never mingle with any other, and with whom the degrees of consanguinity that prevent marriage are extremely con-

tracted; and yet their blood is generally known to be the best in the world, at least in the far west; and it is by no means credible that the men there are as ugly as is pretended by the Chevalier d'Arvien, in his *Voyages au Levant*, whose testimony is in direct opposition to M. Chardin, who had been upon the spot, whereas M. d'Arvien never was. On the other hand, the Samoyedes, who intermix neither with the Laplanders nor with the Russians, compose a people extremely mean and ill-favoured, and absolutely beardless, although we know, beyond all doubt, from the observations of M. Klingkædt, that the Samoyedes never contract incestuous marriages, as has been asserted by some writers who have been very ill informed.

In the climate of America there may exist some particular causes why certain species of animals are smaller than the analogous races of our continent; such as wolves, bears, lynxes, and some others. It is likewise in the qualities of the soil, of the air, of the nourishment that M. Kalm thinks we should seek the origin of that bastardisement that follows among the cattle transplanted from Europe into the English colonies on the main land, from the fortieth degree of latitude to the extremity of Canada. [Hist. Nat. & Civ. de la Pennsylvanie.] And the same thing is observed in the northern parts of Russia. As to savage man, the coarseness of food, and the little inclination he has to labour with his hands, render him less robust than we should be disposed to believe, were we ignorant that it is the habit of work that principally fortifies the muscles and nerves of the arm, as the habit of hunting enables the Americans to sustain long marches: and it was probably this that determined M. Fourmont to give those nations the appellation of running nations, [Reflexions Critiques,] though they neither run nor hunt, except when forced to it by the most pressing necessity. For while they have any provision of flesh preserved by broiling after their manner, they remain day and night lying at length in their huts, which necessity alone ever forces them to leave; and it is well known at present, from repeated observations collected in different regions, that all savages in general have so great a propensity to idleness, that it forms one of the characteristics that most distinguish them from civilized people. To this shameful vice must be added an insatiable thirst for spirituous or fermented liquors, and then we shall have a tolerably just idea of all the excesses whereof these barbarians are capable. Those who imagine that extreme intemperance in drink prevails only among people situated in cold climates are much mistaken, since we learn from all accounts, that in the hottest as well as in the coldest climates, the Americans are as furiously addicted to intoxication, as often as they can find opportunity, and they would find an opportunity if they were less indolent. But, as they cultivate maize and manioc only in very small quantities, the primary substance from which inflammatory liquor is extracted is frequently wanting to them; for we know that the caouin, the pivoré, the chica, and other factitious beverages of that nature are mostly drawn from the flour of maize and cassave. The hordes that absolutely cultivate nothing at all, as the Moxes, the Patagonians, and numberless others, employ roots, blackberries, and other wild fruits, for giving a taste to the water, and communicating to it an inebriating quality; which is very easily done by means of the fermentation which comes on of itself. It is supposed that the cold and phlegmatic temperament of the Americans conducts them more than other men to those excesses, which may be termed, with M. Montesquieu, a national intoxication: the liquors, however, which they brew themselves are not by far so destructive to their health as the brandy sold to them by the Europeans, making as much havoc among them as the

small-pox, which the Europeans likewise carried with them into the New World, where it is particularly fatal to such of the savages as go naked, because their epidermis, and their mucous texture being always exposed to the air become thick, and their pores are still more closed by the greasy and oily colours with which they smear the whole body, to defend it from the stings of the insects, swarming in multitudes, beyond all imagination, in the forests and uncultivated places: and it is the persecution they undergo from the maringuins and musketoes that has also taught them the use of smoking tobacco.

The ancient accounts talk much of the extreme old age to which the Americans attain; but it is now well known that gross exaggerations have slipped into these narratives, and have probably given encouragement to that ridiculous impostor that appeared in Europe under the name of Hultazob, attempting to pass for an American six 500 years old. It has been remarked by us, and Dr. Bancroft made the same observation at Guiana in 1766, that it is impossible to know exactly the age of savages, because some are totally destitute of numerical words, and with others the numerical words are scarcely carried as far as three; they have no registers, nor any thing that can supply the place of them; and, for want of calendars, they are often ignorant not only of the day, but even the year of their nativity. In general they live to the usual term with the rest of the species, at least in the northern countries: for the heat between the tropics, by exciting a continual perspiration in the body, there abridges the course or the dream of life. Nothing is more true, however, than that almost all the American women bring forth without pain and with extreme facility; so that it scarcely ever happens that any die in childbirth, or from the consequences of it: histories relate, that before the arrival of Pizarro and Almagro they had never heard of midwives at Peru. Hence it has been surmised, that this effect was only owing to a particular configuration of the organs, and likewise to that want of sensibility observed among the Americans, of which striking instances are found in the relations of travellers. Almost 200 years had elapsed before the method employed by the female savages for fastening the umbilical cord of their children came to our knowledge: it is a great mistake to pretend that they tie it, and then to add that it is a practice pointed out by nature to all the nations in the world. They do not tie it, but apply a burning coal to it, which carries off one part, and the other shrivels up to such a degree that it can never afterwards open. If nature has taught a method of process in this respect, it must be confessed that it is a difficult matter to distinguish it from those which she has not taught.

Among the Americans very few individuals have been found maimed or deformed from their birth; and the reason is, because, like the Lacedæmonians, they had the barbarity to destroy such children as by a vicious organization, or some natural deformity, were incapable of procuring themselves a livelihood from the fishery or the chase. Besides, as the savages have no arts, so neither have they the diseases incident to artizans, and never dislocate their limbs in raising edifices or managing machines. The long journeys that pregnant women are obliged to take, sometimes occasion them to miscarry, but it seldom happens that the violence of the movement maims the infant in the womb. The absolute deficiency of all kinds of domestic cattle, and of course the total want of all milky diet, is the reason that the American women keep their babes a long time at the breast; and that when they are delivered of twins, they sacrifice that which appears to them the weakest of the two: a monstrous practice, but introduced among petty roving nations, where

the men never take any burden that might encumber them in the chace.

Nothing is more surprizing than the observations that are found in the memoirs of some travellers concerning the stupidity of the American children they have attempted to teach. Marcgrave asserts [Comment. ad Hist. Brasiliæ], that in proportion as they approach the term of adolescence their capacities seem to contract. The miserable state to which we know, that education is reduced in the colonies of South America, that is to say, among the Portuguese and Spaniards, might induce us to suppose that the ignorance of the masters may be sufficient to occasion that of the scholars; but we have not seen that even the professors of the university of Cambridge in New England have yet formed the minds of any young Americans, so far as to enable them to produce them in the literary world. We shall here only remark, that, in order to ascertain how far the intellectual faculties of the native Americans are extensive or confined, we ought to take their children while yet in the cradle, and conduct their education with great gentleness and patience; for after these children have contracted, during a number of years, the barbarous or savage manners of their parents, it is extremely difficult to efface from their minds those impressions that have struck the deeper root from their being the first. Besides, the experiment should not be confined to two or three subjects, but extended to a great number, since even in Europe, out of such multitudes of children as are put to study from their earliest years, such a small number of reasonable men are obtained, and a still smaller of enlightened persons. Is it, however, from a few merchants of America, from a few adventurers, guided in all their actions by the most sordid avarice, that we are to look for these arduous attempts? Alas, we should form no such expectations!

There would be no need to mention the Creoles, as their history is not necessarily connected with that of the natives of the new continent, were it not expedient to observe, that, even granting that Thomas Gage and Corcal, or the traveller who has borrowed this name, have grossly exaggerated in their accounts of the imbecility or rather brutalization of the Spaniards born in the West Indies; [Descript. & Voy. aux Indes occident.] it is nevertheless true, that these Creoles have been generally supposed to have undergone some alteration from the nature of the climate; and that being a misfortune and not a crime, Father Fejoo ought to have been a little more candid in what he has written in their justification, since it should seem that he never would have thought of vindicating them had he not conceived that the glory of the Spanish name was concerned. Such prejudices, however, are unworthy of a philosopher, in whose sight the glory of all the nations in the world should be as nothing, when put in the balance against truth. Readers of any penetration will easily perceive that it was neither to envy nor to any private resentment against the Spaniards that what has been seen of the alteration brought on in the temperament of their Creoles is to be ascribed, since to the full as much has been said of the Europeans, established in the North of America, as any one may convince himself by reading the history of Pennsylvania, which we have already had occasion to cite. If the Creoles had written works capable of immortalizing their name in the republic of letters, they would not have been in want of the pen and the inflated style of Jerome Fejoo to make their apology, which they alone could, and they alone ought to have done. Neither was it from want of time that they neglected it, since Corcal, who has depicted them, as we observed, in such unfavourable colours, failed for America in 1666. In short, the farther

culture proceeds in the interior of the New World, by draining the morasses, by felling the timber, and clearing the woods, the more also will the climate change and soften; which is a necessary consequence, observable from year to year; and that we may here fix exactly the period of the first observation made in this respect, we shall remark, that in the last edition of the Recherches philosophiques sur les Americains, there is a copy of a letter, by which it appears, that so long ago as the year 1677, this change of climate was already perceived, at least in the English colonies, which every one knows to have been the most pertinaciously bent on tilling and ameliorating the ground, on which the savages bestowed hardly any care; they expected all from nature, and nothing from their own industry. It is certainly a grand mistake to suppose that the abundance of game, of fish, and of fruits obtained without culture, retarded the progress of civilized life throughout almost the whole extent of America; to the northern point of Labrador, and all along the coasts of Hudson's bay, from Munk harbour to Churchill river, the sterility is extreme and incredible. Now, the small bands of the human species that have been met there, are as savage, at least, as those that roam at the centre of Brazil, of Guiana, and all along the Maragnon and the Oroonoko, where are found more alimentary plants, more game, more fish, and where the ice never prevents fishing in the rivers. On the contrary, it appears, that the possession of a grain so easily raised and multiplied as the maize, might have induced the Americans, in some provinces, to leave off the ambulatory life, and forego the chace, which renders the heart of man hard and pitiless. It is, however, very certain, that some of those tribes who possessed the seed of the maize, were still anthropophagi, as the Caribs of the main land, who were seen in 1764, to eat the flesh of the Maroons that had revolted against the Dutch, in their settlements on the Berbice. (Naturgeschichte von Guiana, § 161.) Nevertheless it is known to be a fact, that these barbarians, of whom we are now speaking, cultivate not only the manioc, but also the pisang, *musa paradisiaca*; and unhappily they are not the only ones among the Americans, who, without being compelled to it by any species of dearth, have defiled their tables, by serving on them pieces of human flesh, roasted on large wooden spits, or boiled in marabouts.

There is no difficulty in supposing that some travellers may have exaggerated the number of these man-eating hordes; but it is undoubtedly true that they have been found in the south, in the north, and between the tropics. The Atacapas of Louisiana, who, in 1719, ate up a Frenchman, named Charleville, dwell at the distance of more than eight hundred leagues from the district of the Caribs, in huts between the shores of the Essequibo and the Oroonoko; and thence again it is necessary to make an immense journey into the continent to arrive at the Encavellados or long-haired blacks, who likewise roast their prisoners; so that this species of barbarism is common to such nations as cannot have borrowed their manners from one another, nor have been corrupted to such a degree by the force of example.

It is not surprizing that, in the immense quantity of particulars supplied by the accounts concerning the religious practices of the Americans, some falsehoods should have slipped in, whereof some are already perfectly known, and others will be so in proportion as travellers shall become more enlightened than the generality have hitherto been of those who have spoken of the different parts of the New World; monks and people who had no pretensions to philosophy, in any sense that this term can be understood, have taken upon them to write things that sensible persons have repented that

they ever read. We shall only illustrate this observation by one fact which will suffice for enabling the reader to form a judgment on many others. It has been affirmed that several savages of the southern provinces worshipped a gourd or pumpkin; now let us examine how this must be done. Just as the pretended forecers of England make use of a magical drum which they beat in order to drive away the devil whenever they think him lodged in the body of a sick person whom they have not been able to cure by means of their ordinary remedies; so some conjurers in America employ a gourd, which, after extracting the pulp, they fill with pebbles; so that on shaking it a noise is produced that may be heard to a considerable distance during the night. It is natural enough that the savages who are not initiated into the jugglery, should entertain various fancies concerning this mysterious instrument, not unmixed with some degree of dread; accordingly they do not venture to touch or even to approach it; and this is the whole of the affair about the adoration of the gourd. It is to no purpose to interrogate these barbarians on the subject of practices so gross, and many others infinitely more superstitious; the poverty of their language, of which the dictionary might be comprised in a single page, forbids all explanation. We know that even the Peruvians, though united in some sort of political society, had not yet invented terms for expressing either metaphysical beings, or the moral qualities which most distinguish mankind from brutes, as justice, gratitude, and mercy. These qualities were in the number of things that had no name; virtue itself had none in that country on which so many exaggerations have been bestowed. Now, among the petty wandering hordes, the paucity of words is still incomparably greater, to such a degree that every species of elucidation on matters of morality and metaphysics is utterly impossible.

They are certainly mistaken who imagine that among savages religion is extremely simple, extremely pure, and that its corruptions increase in proportion as the people make farther advances in civilization. The truth is, that both savages and civilized people equally plunge into horrid and cruel superstitions, when not under the restraints of sound reason; and, if even the profession of Christianity was unable to prevent the Spaniards from assassinating their brethren to the glory of God, in the grand square of Madrid, it is a plain proof how necessary it is that the reasonable service of Christianity should be well understood. Now, it would be flying in the face of our own judgment to imagine there is much philosophy among savages, who likewise celebrate *auto da fés* in their way, and indeed unhappily to a great excess among the Antis, where were found huge earthen vases filled with the dried carcases of children, who had been sacrificed to statues; and they were sacrificed in this manner, whenever the Antis celebrated an act of faith. As to those who among the savages of America are called *boyés*, *jametyes*, *piays*, *angelottes*, *javas*, *iharangui*, and *outmons*, they should more properly be denominated physicians than priests, as they are generally called; it is true, they are wont to accompany the medicines they administer to the sick, with fantastical practices, which they think adapted to calm or to expel the evil principle, to whom they seem to ascribe all the disorders that attack the human body. Instead of idly reasoning on the theology of these pretended priests, it would be acting far more wisely to engage them by presents and a generous treatment to communicate to us the characters of certain plants whereof they make great use in their medicaments; for we are not acquainted with the fiftieth part of the vegetables that some of these practitioners in

pharmacy carry always about them in little bags, and in which the whole of their medical knowledge consists. But the missionaries, who considered these American jugglers as their rivals, persecuted them with fury; and even whenever they have occasion to mention them in their relations, they still load them with abuse, which disgusts us as much as the barbarous dulness of the style in which these accounts are written, and the prodigies, manifestly false, which they affirm to be true. There has been no want of missionaries in America, but we have rarely seen among them enlightened and charitable men, taking a sincere concern in the miseries of the savages, and employing some means to relieve them. It may safely be advanced, that properly speaking, it is only the Quakers who have settled in the New World, without committing crying acts of injustice and shocking enormities. As to the Spaniards, had we no information from other quarters, we might be tempted to believe that Las Casas was striving to palliate their crimes, by rendering them absolutely incredible. He has the assurance to say, in a treatise entitled, *De la destrucción de las Indias Occidentales per los Castellanos*, and inserted in the collection of his works, printed at Barcelona, that in forty years his countrymen massacred fifty millions of Indians. This, however, is a gross exaggeration; and the reason of his committing it to paper was, that Las Casas wanted to establish in America an order half-military and half-ecclsiastical; his ambition afterwards led him to aspire at being grand master of this order, and so to raise a prodigious tribute in silver from the Americans. To convince the court of the utility of the project, which would have been useful only to himself, he swelled the number of murdered Indians to that extravagant amount.

Nevertheless, it is an undoubted fact, that the Spaniards caused a great number of savages to be torn to pieces by large hounds and a species of mastiffs or bull-dogs, brought into Europe about the time of the Alanes; they likewise occasioned the death of vast numbers more of these poor wretches in the mine, in the pearl-fisheries, and under the weight of burdens that could only be transported on men's shoulders, because throughout the whole extent of the eastern coast of the new continent to beart of burden or of draught was found; and it was only at Peru that any glamas were seen. In short, they exercised innumerable cruelties on the cacics and chiefs of hordes whom they suspected of having concealed any silver or gold; no discipline was observed in their small parties, composed of thieves, and commanded by men who deserved capital punishment for their crimes, and had mostly been taken from the drags of the people. It is an indisputable fact, that both Almagro and Pizarro could neither read nor write. These two adventurers were at the head of a hundred and seventy foot-soldiers, a number of bull-dogs, and a monk named La Valle Viridi, whom Almagro afterwards caused to be beat to death with the but end of muskets, in the island of Puna. Such was the army that marched against the Peruvians; as to that which went to the attack of the Mexicans, under the conduct of Cortez, it consisted of fifteen cavaliers and five hundred infantry at the utmost. Now we may form some idea of the horrors these seven hundred and thirty-nine murderers must have committed at Peru and at Mexico; we may likewise get a notion of the ravages committed in the island of St. Domingo. But it is an insult to common sense to assert that they slaughtered fifty millions of inhabitants. Those who give credit to such extravagant assertions, doubtless, have no proper conception of so great a number of mankind; all Germany, Holland, the Low Countries, with France and Spain taken together, do

do not at the present day contain fifty millions of people. Yet if we except the interior of Spain, the earth there is tolerably well cultivated, and that by the labour of animals, combined with that of the husbandman. In America nothing was cultivated by the labour of animals; accordingly we see from the journals of the Spaniards themselves, that it frequently happened that they marched for five or six days in Peru without coming to a single habitation. In the expedition to Canella, we are told by Juraba, that they made no use of their swords but in hewing the briars and brambles, to clear their passage across the most frightful desert that can be imagined. In the heart of Paraguay and Guiana, whither the little Spanish armies never penetrated, and of course committed none of the ravages that have been imputed to them, at first only forests were discovered, and afterwards forests again or petty tribes were found, often at the distance of a hundred leagues from one another. It is apparent from all that the Jesuits have published concerning the establishment of their missions, how difficult it was to bring together savages in countries more extensive than France, and where the land is better than in Peru, and not inferior to that of Mexico. If we would obtain an idea of the state of the New World at the time of its discovery, we must doubtless study the accounts, but at the same time we should employ a nice discernment and a critical severity for removing the falsehoods and prodigies with which they swarm; compilers without taste or judgment, pick up all they find in the journals of travellers, and thus form disgusting romances, which have but too much increased in our days, because it is much easier to write without reflecting, than with care and meditation.

The thinness of the population of America, and the want of courage in its inhabitants, are the true causes of the rapidity of the conquests made there; one half of the world fell, as it were, in an instant, under the yoke of the other. Those who pretend that fire-arms alone decided the victory, are greatly mistaken; since with those arms it has never yet been practicable to subdue the centre of Africa. The ancient Batavians and the Germans were for the most part naked; they had neither helmet nor cuirass; they had not even iron enough for barbing all their javelins; yet those men, supported by their valour, often fought with advantage against soldiers in coats of mail, helmets, and in short armed with instruments no less murderous than the pilum was of the Roman infantry. If, therefore, America had been peopled by natives as warlike as these Germans and Batavi, seven or eight hundred men would never have conquered from them two empires in a month. Nor can it be said that the band commanded by Pizarro was supported by auxiliary troops, since, at the battle of Caxamalca, the Spaniards alone engaged the army of the emperor Atahualpa, and the event proved that Pizarro had no need of auxiliary forces.

It is not to be denied that by a local disposition extremely remarkable, all the great rivers, namely, La Plata, the Maragnon, the Oroonoko, the river of the north, the Mississippi, the St. Lawrence, have their mouths at the eastern shore, where the Europeans must make their first landing; so that by going up these rivers they penetrated without difficulty into the heart of the continent; whereas the situation, as is well known, is quite different of Peru and Mexico, that is to say, on the western shore; and they cannot otherwise be attacked than by troops already fatigued by the long marches they have made in the interior of the country.

Whatever was the cause of it, the New World was such a desert, that the Europeans might have established themselves

there without destroying any tribe of the natives: and, as they would have given the Americans iron, arts, trades, horses, oxen, and breeds of all the other domestic animals of which they were destitute, that would have been in some sort a compensation for the soil of which they would have taken possession. Some civilians are known to maintain that the hunting tribes of America were not the right owners of the soil; because, according to Grotius and Lauterbach, the property of a country cannot be acquired by hunting in it, by cutting wood or drawing water there; nothing but the precise demarcation of limits, and the intention of cultivating, or culture already begun, can establish the possession. We take the liberty, however, to differ widely from this opinion, and think that the hunting nations of America were well authorized to assert that they were, as has been observed above, the absolute owners of the soil; because, in their method of living, the chase is equivalent to culture; and the construction of their huts is a title against which Grotius, Lauterbach, Titius, and all the civilians of Europe, cannot be appealed to without rendering the appellant ridiculous. It is allowed, that in places where there was already some sort of culture, the right was still more incontrovertibly founded; and it is exceedingly hard to conceive how it could ever come into the head of pope Alexander VI. to grant, by a bull of the year 1493, the whole of the continent, with all the islands of America, to the king of Spain. Yet he did not think he was disposing of uncultivated and uninhabited regions, since he specifies in his donation both towns and castles, *civitates & castra in perpetuum, tenore presentium, donamus*. It may be replied, that this act was only ridiculous: yes, it is precisely, because it was ridiculous that it ought not to have been made, to avoid giving room to weak minds to imagine that the sovereign pontiffs have contributed as much as lay in their power to all the depredations and to all the massacres that the Spaniards have committed in America, where they cited this bull of Alexander VI. whenever they poignarded a cacic and usurped a province. The court of Rome should have solemnly repealed this *act of donation*, at least after the death of Alexander VI.; but unfortunately we cannot find that it ever thought of taking this step in favour of religion.

Another remarkable circumstance is, that some divines maintained, in the 16th century, that the Americans were not men; and it was not merely the want of a beard, and the nudity of the savages, that led them to adopt the sentiment, but the accounts they received concerning the anthropophagi, or the cannibals. This is manifest by a letter still extant of Lullus: the western Indians, says he, have nothing of the reasonable animal except the mask; they scarcely know how to speak, and are not acquainted either with honour, or modesty, or probity; no ferocious animal is so ferocious as they; they devour one another, tear their enemies into morsels, suck their blood, and always have enemies; for wars are eternal among them, and their vengeance knows no bounds. The Spaniards who frequent them, continues he, become insensibly as perverse, as malicious, as atrocious as themselves, whether it be from the force of example, or whether it proceeds from the influence of the climate: *advo corrumpuntur illic mores, sive id accidat exempla incolarum, sive cæli natura*. There is no reason, however, to think that the climate has any influence in this matter; since we have already observed, that in the hottest countries, as under the equator, and in the coldest, as beyond the fiftieth degree, we have alike seen barbarians devour their prisoners, and celebrate in horrible songs the memory of their ancestors, who feasted in like manner at similar banquets.

Lullus,

Tullus, and the divines above mentioned, must have been totally ignorant that the eating of human flesh was likewise extremely common among the ancient savages of our continent: because, when man is not enlightened by the sciences, when neither his hand nor his heart is restrained by law, he every where falls into the same excesses. But, in closing this article, we shall repeat, that it will be for ever a matter of astonishment, that in one entire hemisphere of our globe there was not the least idea of the sciences in the year 1492, so that the human mind was there upwards of 3000 years behind hand. Even at this day there is not, throughout the whole extent of the New World, one American population that is free, and on the point of gaining instruction in literature; for the Indians of the missions have nothing to do with the subject; since all concurs to shew that they are rather converted into fanatical slaves than reduced to a state of humanity.

In regard to the first people of America, and whence they came to recite the various opinions that have been advanced would lead us greatly beyond our purpose. The subject has been copiously and elaborately investigated by the abbé Clavigero and Dr. Robertson, and we may reasonably content ourselves with the result of their inquiries. The latter, after recapitulating and discussing the most plausible opinions on the subject, comes to the following conclusions: 1. That America was not peopled by any nation from the ancient continent, which had made any considerable progress in civilization; because, when America was first discovered, its inhabitants were unacquainted with the necessary arts of life, which are the first essays of the human mind toward improvement; and if they had ever been acquainted with them, for instance, with the plough, the loom, and the forge, their utility would have been so great and obvious, that it is impossible they should have been lost. Therefore the ancestors of the first settlers in America were uncivilized, and unacquainted with the necessary arts of life.

2. America could not have been peopled by any colony from the more southern nations of the ancient continent; because none of the rude tribes of these parts possessed enterprise, ingenuity, or power, sufficient to undertake such a distant voyage; but more especially because that, in all America, there is not an animal, tame or wild, which properly belongs to the warm or temperate countries of the eastern continent.

In short, from these and several other arguments, he thinks it reasonable to conclude, that the progenitors of all the American nations, from Cape Horn to the southern limits of Labrador, from the similarity of their aspect, colour, &c. migrated from the north-east parts of Asia: and that the nations that inhabit Labrador, Esquimaux, and the parts adjacent, from their unlikeness to the American nations, and their resemblance to the northern Europeans, came over from the north-west parts of Europe. Hist. of America, vol. ii. p. 22, &c.

On the other hand, the abbé Clavigero, a native of America, and a later writer than Dr. Robertson, is of opinion, that there remains no other solution to this intricate question than by admitting an ancient union between the equinoctial countries of America and those of Africa, and a connection of the northern countries of America with Europe on the east and Asia on the west; so that there has probably been a period since the flood when there was but one continent. The beasts of cold climates passed over the northern isthmuses which perhaps connected Europe, America, and Asia; and the animals and reptiles peculiar to hot countries passed over the isthmus that connected South America with Africa; for, from various reasons, he is induced

to believe, that there was formerly a tract of land uniting the easternmost part of Brazil to the westernmost part of Africa; and that all the tract of land may be sunk by some violent agitation of nature, leaving only some traces of it in that chain of islands whereof Cape de Verd, Fernandez, De Norona, Ascension, and St. Matthew islands make a part; and also in those numerous sand-banks discovered by different navigators, and particularly by de Buache, who founded that sea with great accuracy. These islands and sand-banks may probably have been the most elevated parts of that immersed isthmus. In like manner it is probable that the north-western part of America was joined to the north-eastern part of Asia by a neck of land which has been sunk or washed away; and the north-eastern parts of America to the north-western parts of Europe, by Greenland, Iceland, &c.

On the whole, we cannot but believe that the quadrupeds and reptiles of the New World passed thither by land, and by different routes, from the old continent. All other suppositions are subject to enormous difficulties; and, though this be not without some, yet they are not altogether unformidable. The most formidable is the supposition of an earthquake, so violent as to submerge a tract of land of more than 1500 miles in length, which, according to our hypothesis, united Africa and South America. We do not, however, ascribe this stupendous revolution to a single shock; it may have been effected by a succession of earthquakes. It is well known that these convulsions are common in the climates where we suppose this isthmus to have been. Neither is it impossible, nor even improbable, that such an effect should be produced by earthquakes; nor is history by any means destitute of examples to our purpose. The earthquake that was felt in Canada, in 1663, overturned a chain of freestone mountains upwards of 300 miles in length, converting the whole of that immense tract into one entire plain. And how prodigious must have been the convulsion occasioned by those extraordinary earthquakes recorded in the histories of America, when the world was thought to be on the verge of dissolution!

It may farther be objected to this system, continues the abbé, that if beasts traversed by land from one continent to the other, it will be no easy matter to assign a cause why some species passed thither without leaving a single individual behind them on the old continent; and, on the contrary, that some entire species should remain in the old continent, and not a single individual of them emigrate to America. But this objection operates with equal force against every other opinion, excepting that which employs angels in transporting beasts. Supposing, however, that it did not, we have a satisfactory answer to it. All the quadrupeds of the earth are not yet known; we cannot, therefore, affirm how many are in the one which are not in the other continent. The knowledge of the best informed zoologists is very imperfect, and they differ among themselves. The count de Buffon enumerates only two hundred species of quadrupeds. Bomare, who wrote a short time after him, makes them amount to 265; but to say how many more there may be, and of what kinds, until we have explored the interior regions of Africa, a great part of Tartary, the country of the Amazons, the vast territory west of the Mississippi, and various other unexplored and extensive countries, which, together constitute a great proportion of the entire globe, would be mere conjecture. No argument, therefore, can be inferred from the difference of the animals in the two continents against our system, till the animals in these unexplored regions shall have been examined. Abbé Clavigero's Hist. of Mexico, vol. ii. diff. 1.

A M E R I C A.

We have dwelt the longer on this article, as it must be highly interesting to every inquisitive mind, and the discussion of it is blended with much useful information.

AMERICA, in *Geography*, or the New World, or the West Indies, is one of the four quarters of the globe, bordered by the ocean, discovered by Christopher Columbus, a Genoese, in 1492, and denominated America, from Americus Vesputius, a Florentine, who landed, in 1497, on that part of the continent, situated to the south of the equator; after which it fell principally under the dominion of the Spaniards, the English, the French, the Portuguese, and the Dutch. It is divided into north and south by the gulf of Mexico and the straits of Panama. North America, as far as it is known, extends from the 11th degree of latitude, or 7° 30', as marked in the map of Lacruz, to the 75th, or, as others state it, to the 72d. Its principal countries are Mexico, California, Louisiana, Virginia, Canada, Newfoundland, the islands of Cuba, St. Domingo, and the Antilles. South America reaches from the 12th degree of north to the 60th degree of south latitude, or, if the strait of Magalhaens be the limit, to the 54th: its countries are, Terra Firma, Peru, Paraguay, Chili, Terra Magellanica, the Brazils, and the country of the Amazons. America, in length from N. lat. 72° to S. lat. 54°, comprehends 126°, or 7560 geographical miles, or in British miles about 8800. The greatest breadth of South America from Cape Blanco west, to that of St. Roque east, is 48°, or 2880 geographical miles; but in the North, from the promontory of Alaska to the most eastern point of Labrador, or even of Greenland, a third part must be added. Supposing the breadth of North America to be 3840 geographical miles, the average breadth will be about 3360 geographical miles, or nearly 4000 British miles. This extensive continent lies between the Pacific ocean on the west, and the Atlantic on the east, and is said to contain upwards of fourteen million of square miles.

SOUTH AMERICA, the population of which is estimated at about 13,000,000, is an extensive peninsula, connected with North America by the isthmus of Darien, and divided between Spain, Portugal, France, Holland, and the Aborigines, as follows:

Spanish Dominions, computed at more than 5000 geographical miles, and containing about 9,000,000 inhabitants.

Chief Towns.

Terra Firma,	Panama and Carthagena.
Peru,	Lima.
Chili,	St. Jago.
Paraguay,	Buenos Ayres.

Portuguese, equal, probably in extent to the Spanish.

Brazil,	St. Salvador.
---------	---------------

French.

Cayenne,	Caen.
----------	-------

Dutch.

Surinam,	Paramaribo.
----------	-------------

Aborigines.

Amazonia.	
Patagonia.	

The climate of TERRA FIRMA, especially in the northern parts, is extremely hot and sultry during the whole year. From the month of May to the end of November, the season, called Winter by the inhabitants, is almost a continual succession of thunder, rain, and tempests; the clouds precipitating the rain with such impetuosity, that the low lands exhibit the appearance of an ocean. Great part of the coun-

try is of consequence almost continually flooded; and this, together with the excessive heat, so impregnates the air with vapours, that in many provinces, particularly about Papayan and Portobello, it is extremely unwholesome. The soil of this country is very different; the inland parts being exceedingly rich and fertile, while the coasts are sandy and barren. It is impossible to view, without admiration, the perpetual verdure of the woods, the luxuriance of the plains, and the towering height of the mountains. This country produces corn, sugar, tobacco, and fruits of all kinds; the most remarkable is that of the manzanillo tree: it bears a fruit resembling an apple, but which, under this appearance, contains the most subtle poison. The bean of Carthagena is the fruit of a species of willow, about the bigness of a bean, and is an excellent remedy for the bite of the most venomous serpents, which are very frequent all over this country. Among the natural merchandize of Terra Firma, the pearls found on the coast, particularly in the bay of Panama, are not the least considerable. An immense number of Negro slaves are employed in fishing for these, and have arrived at a wonderful dexterity in the occupation. They are sometimes, however, devoured by sharks while they dive to the bottom, or are crushed against the shelves of the rocks. This country was called Terra Firma, on account of its being the first part of the continent which was discovered, all the lands found previous to this being islands.

From the situation of PERU, which is within the torrid zone, one would suppose it to be uninhabitable; but the Andes, those lofty mountains, being on one side, and the South sea on the other, it is not so prodigiously hot as tropical countries in general are; and in some parts it is disagreeably cold. In one part are mountains of a stupendous height and magnitude, having their summits covered with snow; on the other, volcanos flaming within, while their tops, chasms, and apertures are involved in ice. The plains are temperate, the beaches and vallies hot; and lastly, according to the disposition of the country, its high or low situation, we find all the various gradations of temperature between the extremes of heat and cold. It is remarkable, that in some places it never rains, a defect supplied by a dew that falls every night, and sufficiently refreshes the vegetable creation; but in Quito they have prodigious rains, attended by dreadful storms of thunder and lightning. In the inland parts of Peru, and by the banks of the rivers, the soil is usually very fertile; but along the sea-coast it is a barren sand.

The climate of CHILI is one of the most delightful in the world, being a medium between the intense heats of the torrid and the piercing colds of the frigid zones. Along the coast of the Pacific ocean, they enjoy a fine temperate air, and a clear, serene sky most part of the year; but sometimes the winds that blow from the mountains in Winter are exceedingly sharp. There are few places in this extensive country where the soil is not exuberantly rich; and were its natural advantages seconded by the industry of the inhabitants, Chili would be the most popular kingdom in America.

Some parts of PARAGUAY, situated as it is, must be extremely hot by reason of the almost vertical influence of the solar rays; while districts must be pleasant and delightful. The heat is in some measure, however, mitigated by the gentle breezes, which generally begin at about nine or ten in the morning, and continue the greatest part of the day. Some tracts of the country are very mountainous; but in many others are found extensive and beautiful plains, where the soil is very rich, producing cotton, tobacco, and the valuable herb called paragua, together with a variety of fruits. Here are also extremely rich pastures, in which are bred such

such herds of cattle, that it is said, the hides are the only part exported, while the flesh is left to be devoured by the ravenous beasts of the wilderness. Not long since a horse might be purchased here for one dollar, and an ox, chosen out of several hundreds, for a still more trifling sum.

The climate of *Brazil*, or **BRASIL**, has been described by two eminent naturalists, Piso and Maregrave, who made their observations with a philosophical accuracy, and describe it as temperate and mild, when compared with that of Africa; imputing this circumstance chiefly to the refreshing wind that blows continually from the sea. The air is not only cool, but chilly through the night, so that the natives kindle a fire every evening in their huts. As the rivers in this country annually overflow their banks, leaving a sort of slime upon the lands; the soil here is therefore amazingly rich. The vegetable productions are Indian corn, sugar-canes, tobacco, indigo, lides, ipecacuanha, balsam, Brazil-wood, which is of a red colour, hard and dry, and is chiefly used in dyeing, though not the red of the best kind. Here is also the fustic, of use in dyeing yellow, and a beautiful speckled wood employed in cabinet work. They have five different sorts of palm trees, some curious ebony, and a great variety of cotton trees. This country abounds in horned cattle, which are hunted for their hides alone, 20,000 being sent annually into Europe. Deer, hares, and other game are likewise in great plenty. Amongst the wild beasts found here, are tigers, porcupines, januvers, and a fierce animal somewhat resembling a greyhound; monkies, sloths, and the torpirassu, a creature between a bull and an ass, but without horns and entirely harmless; the flesh is very good, and has the flavour of beef. The country abounds with a numberless variety of fowl, both wild and tame; and among them turkies, fine white hens and ducks: also plenty of fish, insects, and serpents.

Of **CAYENNE**, the land along the coast is very low, and directly subject to inundations during the rainy season, from the multitude of rivers which rush down from the mountains with great impetuosity. Here the atmosphere is sultry, moist, and unwholesome, especially where the woods are not cleared away; but on the higher parts, where the trees are cut down, and the ground is laid out in plantations, the air is more healthy, and greatly tempered by the sea breezes. The soil in many parts is rich and fertile, producing sugar, tobacco, maize, fruits, and other necessaries of life.

In the months of September, October, and November, the climate of **SURINAM** is unhealthy, particularly to strangers. The common diseases are putrid and other fevers, the dry belly-ach and the dropsy. About a hundred miles within land from the sea, a quite different soil is seen, a hilly country, a pure, dry, wholesome air, where a fire sometimes would not be disagreeable. Along the coast the water is brackish and unwholesome, the air damp and sultry. The thermometer ranges from 75° to 90° throughout the year. A north-east breeze never fails to blow from about nine in the morning through the day, in the hottest seasons. As the days and nights throughout the year are very nearly of equal length, the air can never become extremely heated, nor the inhabitants so greatly incommoded by the heat, as those who live at a greater distance from the equator. The seasons formerly were divided regularly into rainy and dry; of late years, however, so much dependence cannot be placed upon them, owing, probably, to the country being more cleared, by which means a free passage is opened for the air and vapours.

The air in **AMAZONIA** is cooler than might be expected,

considering it as situated in the torrid zone. This is partly owing to the heavy rains which occasion the rivers to overflow for one half of the year, and partly to the haziness of the weather, which obscures the sun great part of the time he is above the horizon. During the rainy season the country is subject to dreadful storms of thunder and lightning. The soil is extremely fertile, producing cocoa-nuts, ananas, plantains, and a great variety of tropical fruits; cedar, redwood, pak, ebony, logwood, and many other sorts of dyeing wood, together with tobacco, sugar-canes, cotton, potatoes, balsam, honey, &c. The woods abound with tigers, wild boars, buffaloes, deer, and game of various kinds. The rivers and lakes teem with fish. Here are also sea-cows and turtles; but the crocodiles and water-serpents render fishing a dangerous employment.

The climate is said to be much colder in **PATAGONIA** than in the north under the same parallels of latitude; a circumstance ascribed to its being in the vicinity of the Andes, which cross it, and are covered with eternal snow. It is almost impossible to say what the soil would produce, it not being at all cultivated by the natives. The northern parts are covered with wood, among which is an inexhaustible fund of large timber: but towards the south it is said not to produce a single tree big enough to be of use to mechanics. There are, however, good pastures which give food to incredible numbers of horned-cattle and horses, first carried thither by the Spaniards, and since increased to an amazing degree.

NORTH AMERICA, bounded on the east by the Atlantic, and on the west by the Pacific ocean, extends on the south to the vicinity of Panama; the province of Veragua being universally considered as part of North America. According to the maps of Lopez, a chain of mountains runs north and south, called Sierras de Caratagua, and terminates in the point of Higuera; which, dividing the provinces of Panama and Veragua, forms a natural boundary between North and South America. Its northern limit is not precisely ascertained; but from 72° N. lat., assumed as the northern limit, to 7° 30', the southern boundary, there will be an interval of 64½°, or 3870 geographical miles, somewhat more than 4500 British. Its breadth is very different in different parts.—Those parts of North America not inhabited by Indians, belong (if we include Greenland) to Denmark, Great Britain, the American States, and Spain. Spain claims East and West Florida, with the whole tract west of the Mississippi, and south of the northern boundaries of Louisiana, New Mexico, and California. Great Britain claims all the country inhabited by Europeans, lying north and east of the United States, except Greenland, which belongs to Denmark. The remaining part forms the territory of the fifteen United States; the particular countries and provinces whereof are exhibited in the following view:

	<i>Inhabitants.</i>	<i>Chief Towns.</i>
To Denmark belongs Greenland, containing -	} 10,000	New Herrnhut.

NORTH AMERICA. *History.* America was originally peopled by uncivilized nations, who lived mostly by hunting and fishing. The Europeans who first visited these shores, treating the natives as wild beasts of the forest, which have no property in the woods where they roam, planted the standard of their respective masters wherever they happened first to land, and in their names claimed the country by *right of discovery*. Prior to any settlement in North America, titles of this kind were set up by the English, French, Spanish, and Dutch navigators, who came hither for the purpose of fishing and trading with the natives. Slight as such titles were, they afterwards became causes of contention between the European nations. The subjects of different princes often laid claim to the same tract of country, because both had discovered the same river or promontory, or because the extent of their respective claims was undetermined.

While the settlements in this vast uncultivated country were inconsiderable and scattered, and the trade of it confined to the bartering of a few trinkets for furs, a trade carried on by a small number of adventurers, the interference of claims produced no important controversy, either among the settlers or the nations of Europe. But in proportion to the progress of population and the growth of the American trade, the jealousies of the nations which had made early discoveries and settlements on this coast were alarmed; ancient claims were revived; and each power took measures to extend and secure its own possessions at the expence of a rival.

By the treaty of Utrecht, in 1713, the English claimed a right of cutting logwood in the bay of Campeachy in South America. In the exercise of this right the English merchants had frequent opportunities of carrying on a contraband trade with the Spanish settlements on the continent. To remedy this evil the Spaniards resolved to annihilate a claim which, though often acknowledged, had never been clearly ascertained. To effect this design they captured the

English vessels which they found along the Spanish main; and many of the British subjects were doomed to work in the mines of Potosi.

Repeated severities of this kind at length, in 1739, occasioned a war between England and Spain, which terminated in 1748 by the treaty of peace signed at Aix-la-Chapelle, in which restitution was made on both sides of all places taken during the war.

Peace however, was of short duration. The French possessed Canada, and had made considerable settlements in Florida, claiming the country on both sides the Mississippi by right of discovery. To secure and extend their claims they constructed a line of forts from Canada to Florida. They had secured the important pass at Niagara, and erected a fort at the junction of Allegany and Monongahela rivers, called Fort du Quesne. They took pains to secure the friendship and assistance of the natives; encroachments were made upon the English possessions, and mutual injuries succeeded. The disputes among the settlers in America, and the measures taken by the French to command all the trade of the river St. Lawrence on the north, and of the Mississippi on the south, excited a jealousy in the English nation, which soon broke forth in open war. This war was carried on with various success, till a decisive blow, which proved fatal to the interests of the French in America, put an end to it in 1762. This was the defeat of the French army, and the capture of Quebec, by the brave general Wolfe. That hero was slain at the beginning of the action on the plains of Abram, and M. Montcalm, the French commander, likewise lost his life. The loss of Quebec was soon followed by the surrender of Montreal to general Amherst, and Canada has remained ever since in possession of the English.

In 1763, a definitive treaty of peace was concluded at Paris between Great Britain, France, and Spain, by which the English ceded to the French several islands which they had taken from them in the West Indies, but were confirmed in the possession of all North America on this side the Mississippi, except the island of Orleans.

No sooner was peace concluded than the British parliament adopted the plan of taxing the colonies; and, to justify their attempts, declared that the money to be raised was to be appropriated to defray the expence of defending them in the late war. The first attempt to raise a revenue in America appeared in the memorable *stamp act*, passed March 22, 1765, whereby it was enacted, that certain instruments in writing, as bills, bonds, &c. should not be valid in law, unless drawn on stamped paper, on which a duty was laid.

Immediately as this act was published in America it raised a general alarm. The people were filled with apprehensions at an act which they supposed to be an attack on their constitutional rights. The colonies therefore petitioned the king and parliament for a redress of the grievance, and at the same time entered into associations for the purpose of preventing the importation and use of British manufactures until the obnoxious act should be repealed. This spirited and unanimous opposition of the Americans produced the desired effect; and on the 18th of March, 1766, the stamp act was repealed. The news of the repeal was received in the colonies with universal joy, and the trade between them and Great Britain was renewed on the most liberal footing.

The parliament, however, by repealing this act, so odious to their American brethren, by no means intended to lay aside the scheme of raising a revenue in the colonies, but merely to alter the mode. Accordingly, the next year they passed an act, imposing a certain duty on glass, tea, paper, and painters' colours; articles which were much wanted, and not manufactured in America. This act, as might reasonably

have been opposed, first, at a bold stroke, to the repeal of the measure, and excited a general opposition to the measure, so that parliament thought it advisable, in 1770, to take off these duties, except three pence a pound on tea. Nevertheless this duty, however trifling, kept alive the jealousy of the colonists, and their opposition to parliamentary taxation continued increasing from day to day.

It will be easily conceived that the inconvenience of paying the duty was not the sole nor even principal cause of the opposition; it was the *principle*, which, once admitted, would have subjected the colonies to unlimited parliamentary taxation, without the privilege of being represented. The *right*, abstractedly considered, was denied; and the slightest attempt to justify the claim by precedent was uniformly resisted. Nor could the Americans be deceived as to the views of parliament; for the repeal of the stamp act had been accompanied with an unequivocal declaration, that "the parliament had a right to make laws of sufficient validity to bind the colonies in all cases whatsoever."

The colonies, therefore, entered into measures for encouraging their own manufactures and home productions, and for retrenching the use of foreign superfluities, while the importation of tea was prohibited. In the royal and proprietary governments, and in Massachusetts, the governors and people were in a state of continual warfare. Assemblies were repeatedly called and suddenly dissolved; employing the time while sitting in stating grievances and framing remonstrances. As if to inflame these discontents an act of parliament was passed, ordaining, that the governors and judges should receive their salaries of the crown; thus rendering them independent on the provincial assemblies, and removeable only at the pleasure of the king. These proceedings, with many others of a similar tendency, could not fail to produce a rupture.

In 1773, the spirit of the Americans broke out into open violence. The *Gaspee*, an armed schooner belonging to his Britannic Majesty, had been stationed at Providence, in Rhode Island, to prevent smuggling. The vigilance of the commander irritated the inhabitants to such a degree, that about 200 armed men boarded the vessel under favour of the night, compelled the officers and crew to go ashore, and set fire to the schooner. A reward of 500*l.* offered by government for apprehending any of the persons concerned in this daring act, produced no effectual discovery.

The resolution of the colonies not to import or consume any tea, having, in a great measure, deprived the English government of a revenue from this quarter, the parliament formed a scheme of introducing tea into America under cover of the East India Company. For this purpose an act was passed, empowering the company to export all sorts of teas, duty free, to any place whatever. The company departed from their usual mode of transacting business, and became their own exporters. Several ships were freighted with teas, and sent to the American colonies, and factors were appointed to receive and to dispose of their cargoes.

The Americans, determined to oppose the revenue system of the English parliament in every possible shape, considered the attempt of the East India Company to evade the resolutions of the colonies, and dispose of teas in America, as an indirect mode of taxation, sanctioned by the authority of parliament. The people assembled in various places, and, in the large commercial towns, took measures to prevent the landing of the teas. In Massachusetts they in like manner viewed the tea as a vehicle of an unconstitutional tax, and as inseparably associated with it. To avoid the one they resolved to destroy the other. About 17 persons, dressed as Indians, repaired to the tea ships, broke open 342 chests of

tea, and, without doing any other damage, discharged their contents into the water.

No sooner did the tidings of this destruction of the tea reach Great Britain than the parliament determined to punish that devoted town. A bill was brought in and passed, to "discontinue the landing and discharging, lading and shipping of goods, wares, and merchandizes at the town of Boston, or within the harbour." This act, passed March 25, 1774, and called the Boston port bill, threw the inhabitants into the greatest consternation. The town of Boston passed a resolution expressing their sense of this oppressive measure, and a desire that all the colonies would concur to stop all importations from Great Britain. Most of them entered into spirited resolutions on this occasion, to unite with Massachusetts in a firm opposition to the unconstitutional measures of parliament.

But the port bill was not the only act that alarmed the apprehensions of the Americans. Determined to compel the province of Massachusetts to submit to their laws, parliament passed an act for "the better regulating the government in the province of Massachusetts Bay." The object of this act was to alter the government as it stood on the charter of King William, and to make the sheriffs and judges dependent on the king, and removeable at his will and pleasure.

This act was soon followed by another, which ordained, that any person indicted for murder, or other capital offence, committed in aiding the magistrates in executing the laws, might be sent by the governor, either to any other colony, or to Great Britain, for his trial.

This was shortly after succeeded by the Quebec bill, which enlarged the bounds of that province, and granted many privileges to the Roman catholics. The view of this act was to secure the attachment of that province to the crown of England, and prevent its joining the colonies in their resistance to the laws of parliament.

All these steps, however, far from intimidating, rather exasperated the Americans, by confirming them in their former apprehensions of the evil designs of government, and served only to unite the colonies in a more determined opposition. A correspondence of opinion, in respect to these acts, produced an uniformity of proceedings in the colonies. The people generally concurred in the proposition for holding a congress, in order to concert measures for the preservation of their rights. Deputies were accordingly appointed, and met at Philadelphia on the 26th of October, 1774.

Preparations now began to be made to oppose by force the execution of these acts of parliament. The militia of the country were trained to the use of arms; great encouragement was given to the manufacture of gun-powder, and measures were taken to obtain all kinds of military stores. At Lexington the first blood was spilt in the war; a war which severed America from the British empire. Here was opened the first scene of the great drama, which, in its progress, exhibited the most illustrious characters and events, and closed with a revolution equally glorious for the actors, and important in its consequences to mankind.

In July, congress published their declaration of independence, which separated America from Great Britain. This grand event took place 284 years after the discovery of America by Columbus; 166 from the first effectual establishment in Virginia, and 156 from the first establishment of Plymouth in Massachusetts, which were the earliest English settlements in America.

On the 30th of November, 1782, the provisional articles of peace and reconciliation, between Great Britain and the American states, were signed at Paris; whereby the former acknowledged the independence and sovereignty of the United

United States of America. These articles were ratified by a definitive treaty, September 3, 1783. Thus ended a long and arduous conflict, in which Great Britain expended near a hundred millions of money, with a hundred thousand lives, and gained nothing. America endured every cruelty and distress from her enemies, lost many lives and much treasure, but delivered herself from a foreign dominion, and established a rank among the nations of the earth. Holland acknowledged the independence of the United States of America on the 19th of April, 1782; Sweden February 5, 1783; Denmark the 25th of February; Spain in March, and Russia in July, of the same year. On the 30th of April, 1789, George Washington was inaugurated president of the United States of America, in the city of New York.

Hitherto the deliberations of the Union have been marked with wisdom, and the measures they have adopted have been productive of great national prosperity.

To conclude, the United States, and indeed all parts of North America, seem to have been formed by nature for the most intimate union; as it may truly be affirmed, that no part of the world is so well watered with springs, rivulets, rivers, and lakes, as the territory of the United States. By means of these various streams and bodies of water, the whole country is chequered into islands and peninsulas. The facilities of navigation render the communication between the ports of Georgia and New Hampshire far more expeditious and practicable than between those of Provence and Picardy in France, Cornwall and Caithness in Great Britain, or Galicia and Catalonia in Spain. The canals opening between Susquehanna and Delaware, between Pasquetank and Elizabeth rivers, in Virginia, and between the Schuylkil and Susquehanna, will form a communication from the Carolinas to the western counties of Pennsylvania and New York. The improvement of the Patomak will give a passage from the southern states to the western parts of Virginia, Maryland, Pennsylvania, and even to the lakes. From Detroit to Alexandria, on the Patomak, 607 miles, are only two carrying places, which together do not exceed the distance of 40 miles. The canals of Delaware and Chesapeake will open the communication from South Carolina to New Jersey, Delaware, the most populous parts of Pennsylvania, and the midland counties of New York. Were these, and the canal between Ashley and Cooper rivers, in South Carolina, the canals in the northern parts of the state of New York, and those of Massachusetts and New Hampshire, all opened, and many of them are in great forwardness, North America would thereby be converted into a cluster of large and fertile islands, communicating easily with each other, at little expence, and in many instances without the uncertainty or danger of the seas.

From the numerous competitions in every branch of business in Europe, success in any pursuit may be looked upon in the same light as a prize in a lottery. But the case is widely different in America. Here is room enough for every human talent and virtue to expand and flourish. This is so invariably true that it is generally believed there is not an instance to be found of an industrious, frugal, prudent European, with sober manners, who has not been successful in business in that country.

AMERICAN Earib Nut, in *Botany*. See ARACHIS.

AMERICAN Grass. See AGROSTIS.

AMERICANA, in *Entomology*, a species of CHRYSOMELA that inhabits America; a variety of it is found in the south of France. The general colour is greenish gold, with five sanguineous red lines upon the wing cases. Fab. & Gmel. Feeds on the lavender. A red spot on the head is a secondary distinction of this species.

AMERICANORUM, a species of APIS, described by Fabricius as a native of North America. It is hairy and

black; anterior part of the thorax yellow; abdomen yellow, black at the end. Fab. Spec. Inf. Oms. Fabricius, in his last work, "Entomologia Systematica," gives the apis americanorum precisely the same specific character as he had previously assigned to apis africana, so that at present they are both described as "hirsuta nigra, thoracis dorso flavo, abdomine virecente: segmento primo flavo." To increase the confusion, the latest editor of the "Linnean Syst. Nat." Gmelin, adopts the same error; apis africana, p. 2780, and apis americanorum, p. 2784, and the description in the Spec. Inf. of Fab. is only added as a synonym to the latter. It is probable they are both the same species.

AMERICIMA, in *Zoology*, a name given by some early naturalists to a small kind of lizard found in Brasil. The precise species is uncertain; it is said to be very small; not above three fingers breadth long, and of the thickness of a swan's quill. Its body appears square; its whole back is covered by deep grey scales; its head, legs, and sides with brown ones; and its tail with blue. It is very glossy, the legs extremely slender, and it is generally esteemed poisonous.

AMERIGO, or AMERICUS VESPUCCIUS. See VESPUCCI.

AMERINNUM, or AMERINNON, in *Botany*, a genus of the *diadelphia decandria* class and order, of the natural order of *papilionaceæ* or *leguminosæ*; the characters of which are, that the *calyx* is a one-leaved perianthium, tube bell-shaped, five-toothed, the teeth sharp; the *corolla* papilionaceous, standard with an oblong claw, roundish heart-shaped, expanding and convex, wings lanceolate, shorter than the standard, and keel short; the stamens have 10 filaments conjoined, anthers roundish; the *pyllium* has a germ pedicelled, oblong, compressed leafy, varicose, with lateral veins, within woody, not gaping; cells disposed longitudinally within; the *seeds* solitary, kidney-shaped, thicker at the base, appendicled at the top. There are two species, viz. 1. A. BROWNEI, "unarmed, with leaves petioled, alternate, subcordate-ovate; racemes compound, axillary, and lateral." This shrub rises commonly to the height of ten feet, and supports itself on other shrubs. It is a native of Carthagen, Jamaica, and Domingo. 2. A. *Ebenus*, prickly A. or Jamaica ebony, *pterocarpus sessilifolius* of Lin. p. *buxifolius* of Murray and Aiton, *aspalathus ebenus* of Lin. Spec. and Reich. and *brya* of Browne Jamaic. *spartium arborescens* of Miller and Sloane; "spiny, with leaves subsessile, aggregate, obovate-oblong, and peduncles two-flowered." This is common in Jamaica and several other parts of the West Indies, where the wood is cut, and sent into England under the name of ebony, though the true ebony is a native of the eastern country, and of a different genus. This wood is of a fine greenish brown colour, and admits of polishing well, so that it is much valued by the instrument makers; and it is of a very hard durable nature. Dr. Browne says, that the trunk seldom exceeds three or four inches in diameter; that the slender branches being very tough and flexible are used for riding switches, and kept at all the wharfs about Kingston to scourge the refractory slaves.

This species may be propagated by seeds procured from its native country. The seeds should be sown in pots filled with light fresh earth early in the spring, and plunged into a hot bed of tanners' bark, or placed in tan under pots. In about six weeks the plants will appear, and being very tender should be carefully treated; air should be admitted to them in warm weather, and they should be often refreshed with water. In five or six weeks more they should be transplanted into separate pots filled with light rich earth, and plunged again into the hot-bed, shading them from the sun till they have taken root; they should then have air every day in warm weather, and water once in two or three days, and in cold nights covered with glass. In this hot-bed they may remain till autumn,

When they should be removed into the stove, and plunged into the bark bed. Those whose roots have filled the pot should be removed into those of a larger size. In winter the plant should be kept warm, and have but little water, especially in cold weather; and their leaves, when they contract tith, should be cleared by washing them with a sponge, otherwise the plants will not thrive. These tender plants will not live in the open air in this country, even in the warmest season; they must therefore be constantly kept in the stove or bark bed, and allowed much air in summer when the weather is warm; and when they have acquired strength, they may be exposed for three months in a warm situation in the summer. Martyn's Miller.

AMERINÆ, in *Entomology*, a species of CYNIPS, that forms unequal galls at the ends of the branches of the sweet willow (*Salix pentandria*). It is black except the legs, which are pale. Linnæus.

AMERIOLA, in *Ancient Geography*, a town of Latium, mentioned by Pliny; but not now existing.

AMERQUE, in *Geography*, a city of Mauritania, three leagues from the river Eguile, in the province of Habat, answering, according to Marmol, to the ancient Tocolosida.

AMERSBURY, in *Geography*. See AMBRESBURY.

AMERSFORT, a town of the Netherlands, in the province of Utrecht, situate in a fertile and pleasant country on the river Ems. The objects most worthy of notice in this town are the town-house, the triangular grand palace, the public walks planted with trees, and the great church dedicated to St. George. In its vicinity is the mountain called Amersfort berg, on which trees are planted in a kind of villa, which reaches to Utrecht. The Ems becomes navigable at this town; and all the goods formerly brought out of Germany by Hessian waggons, and consigned to Amsterdam, were shipped at this port. A manufacture of dimity and bombazine has been established in this place. Its trade in beer, rum, and tobacco is now decayed. It is 11 leagues east-south-east from Amsterdam, and $5\frac{1}{2}$ north-east from Utrecht. N. lat. $52^{\circ} 12'$. E. long. $5^{\circ} 4'$.

AMERSHAM. See AGMONDESHAM.

AMERUTHA, or AMERYTHA, in *Ancient Geography*, a village of Upper Galilee, mentioned by Josephus, who fortified it against the Romans, probably the same as Meroth, which terminates Upper Galilee westward.

AMES, JOSEPH, in *Biography*, an industrious antiquarian, was originally a ship-chandler in Wapping, and acquired reputation at an advanced period of life by his study of antiquities. His "Typographical Antiquities," or Historical Account of Printing in England, with Memoirs of our ancient Printers, and a Register of the Books printed by them from 1471 to 1600, with an Appendix concerning Printing in Scotland and Ireland to the year 1749, 4to. is a book well known and often cited. This work was considerably augmented, both in the memoirs and number of books, by Mr. William Herbert, and printed in three volumes, 4to. in 1785. Mr. Ames also published in 8vo. "A List of English Heads engraved and mezzotinto;" and he drew up the "Parentalia" from Mr. Wren's papers. He was secretary to the society of antiquarians, and died in 1759. Nichols's Anecdotes of Bowyer.

AMES, WILLIAM, an English divine, and a famous controversial writer, was descended from an ancient family in Norfolk, and was born in 1576. He was educated at Christ's college, Cambridge, under Mr. William Perkins, from whom he probably imbibed the calvinistical and puritanical sentiments that distinguished his writings. Whilst he was fellow of his college he preached a sermon about 1610-11, in which he inveighed with great vehemence against cards and dice, as the invention of the devil. By this mode of preaching he gave such

offence, that he withdrew from the university in order to avoid expulsion. In the same year he published his "Puritanismus Anglicanus," in which he contrasts the principles and conduct of the puritans against those of other persons with a spirit and language equally illiberal and offensive. No other alternative remained, according to his statement, but either "to suppress episcopacy, or to bring back the pope from hell." Mr. Ames, soon after leaving Cambridge, removed to Holland, and officiated as minister to the English church at the Hague. In 1613, he began his controversy with Grevinchovius, minister at Rotterdam, on the doctrines of election and reprobation, and it was continued from the press. The reputation he thus acquired induced the states of Friesland to invite him to the theological chair in the university of Franeker; and he continued in this respectable station for twelve years. In 1618, he attended the synod of Dort, and from time to time communicated information to the ambassador of king James of the debates of this assembly. From Franeker he removed to Rotterdam, where he preached to a congregation of his own countrymen; and where, after being for some time afflicted with an asthma, he died in 1633. In the last year of his life he wrote his "Fresh Suit against Ceremonies;" but it was not published till after his death.

He was esteemed a learned divine, an excellent casuist, a rigid Calvinist in doctrine, and a zealous advocate for the independent form of church discipline. His writings were numerous, both in Latin and English; most of them were printed abroad; and the principal of them, besides those already mentioned, are the following: "Disceptatio Scholastica inter N. Grevinchovium and G. Amelium," 8vo.; "Disputatio Altera," 8vo. "Coronis ad Collationem Hagensem," 12mo. written against the Arminians; "Medulla Theologica," 12mo.; "De Incarnatione Verbi," 8vo. against the Socinians; "Bellarmius enervatus," 8vo. against the Papists; "De Conscientia," 12mo. and in English under the title of "A Treatise on Conscience," 4to. "Antisynodalia," 12mo. against the Remonstrants; "Demonstratio Logicæ Veræ," 12mo.; "Disputatio Theologica," against Metaphysics; "Technometria," 8vo. on the purpose and bound of Arts; "Reply to Bishop Morton on Ceremonies," and other tracts in the same controversy; "Christianæ Catecheses Sciographia;" and "Lectiones in Psalmis Davidis," 8vo. a posthumous work, dedicated to the magistracy of Rotterdam by Hugh Peters, the colleague of Ames in the English church of Amsterdam. Neal's Hist. Purit. vol. i. p. 579. Biog. Brit.

AMESA, in *Ancient Geography*, a river of Africa in Numidia.

AMESTRATUS, a city of Sicily, called Mutistratus by Polybius, Mustraton by Diodorus Siculus, and Amastra by Silus Italicus; now Mistretta, in the Val di Demona, on the river Halefus. The inhabitants are called by Cicero (in Verren) Amestratini. It was a strong fort of the Carthaginians, besieged by the Romans for seven months with great loss, and, after another siege, taken and razed.

AMESTRIS, in *Entomology*, a species of PAPILIO, with angular indented wings, above black, with rufous and blue lunated marks; beneath obscure. Fab. & Gmel.—Inhabits India. The anterior wings are black; with two rufous spots, and two blue spots in the middle of each; behind these a streak of reddish lunules, which terminates in two white spots at the anterior margin, and along the exterior margin a streak of blue lunated marks. Under side entirely brown, waved with black streaks, and a row of cinereous points. Fabricius.

AMETHYST, in *Mineralogy*. This stone was well known to the Greeks and Romans, from whom it obtained the

the name *αμβύστος*, amethystus, from *α* and *μβύστος*, *non vinosus*, because, according to Pliny, its colour was similar to, but not so deep as that of wine; hence, by the absurd doctrine of sympathies, it came to be esteemed as an antidote against drunkenness.

There are two kinds of amethysts, the oriental and common.

The oriental amethyst is of a reddish or yellowish violet colour; and in hardness, in the form of its crystals, and in short in every physical and chemical property, except that of colour, is the same as the ruby, the sapphire, and oriental topaz, being a mere variety of CORUNDUM. It is a rare gem, and is very seldom brought to Europe. By being heated it loses its colour, and becomes perfectly transparent, and of great brilliancy, so as to be scarcely distinguished from the diamond; so nearly indeed does it resemble this precious stone, as to be occasionally substituted for it in jewellers work. De Boot, in his *Historia Gemmarum*, mentions an amethyst, thus rendered colourless, estimated at 200 rix-dollars, which being cut to the same pattern, and set in a similar manner as a diamond of the value of 18,000 gold crowns, so nearly equalled it in lustre that he could not tell the difference between them.

The common amethyst is crystallized QUARTZ, or rock crystal, tinged naturally of a full violet colour; its properties and characters will therefore be mentioned under the article QUARTZ. The common amethyst, like the oriental, loses its colour in the fire, but is at the same time spoiled by being rendered of an opaque white, owing to a multitude of minute cracks. The best European amethysts come from the vicinity of Carthage in Spain.

To imitate the amethyst in paste or glass, take ten pounds of clear glass or paste, made without manganese, and fuse it down with one ounce and a half of black manganese, and one dram of zaffer. The process recommended by Porta is one dram of Manganese to one pound of frit. Neri's receipt is totally erroneous as to the proportion of colouring matter. He recommends to each pound of glass an ounce of colour composed of eleven parts manganese and one part zaffer, which would produce a deep black glass. Weidenmann *Handbuch der Mineralogie*. De Boot. *Hist. Gemmarum*, lib. ii. c. 32. Pünii *Hist. Nat.* lib. xxxvii. c. 40. Neri, *Art de la Verrerie*, c. 48. *Handmaid to the Arts*, vol. ii. p. 308.

AMETHYST, in *Heraldry*, signifies the purple colour in the coat of a nobleman, which, in gentlemen's escutcheons below that degree, is called *purple*, and in those of sovereign princes, *Mercu-y*.

AMETHYSTEA, *amethyst*, so called from the amethystine colours of the flowers, in *Botany*, a genus of the *dianthria monogynia* class, of the natural order of *verticillate* and *labiate* of Jussieu; the characters are, that the *calyx* is a perianthium one-leaved, tube bell-shaped, angular, semiquinquesid, subequal, acuminate and permanent; the *corolla* is one-petalled, ringent, little longer than the calyx, border five-parted and subequal; upper lip erect, rounded, concave, two-parted, gaping, lower three-parted, the sides rounded, erect, shorter, the middle quite entire, concave, the length of the upper lip; the *stamina* have filaments filiform, approximating under the upper lip and longer than it, anthers simple and roundish; the *pisillum* is a quadrisid gem, style size of the stamens, stigmas two and acute; no *pericarpium*, but the calyx becomes more bell-shaped and spreading; the *seeds* are four, shorter than the calyx, obtuse, and angular within. There is one species, *viz.* *A. carulea*, mountain upright A, which is a native of the mountains in Siberia, from whence the seeds were sent to the Imperial garden at Petersburg, and in 1759 to Chelsea garden, where the plants annually produce seeds.

It is annual, and hath an upright stalk, which rises about a foot high, and towards the top puts out two or three small

lateral branches; these are garnished with small trifid leaves, sawed on their edges, and of a very dark green colour; at the extremity of the branches the flowers are produced in small umbels; these are of a fine blue colour, as are also the upper part of the branches, and the leaves immediately under the umbel; so that though the flowers are small, yet from their colour with that of the upper part of their stalks, the plants make a pretty appearance during their continuance in flower. If the seeds of this plant are sown in Autumn, or are permitted to scatter, the plants will come up early in the following Spring, and these will flower in the beginning of June; but those sown in the Spring will not flower until July. The best time for sowing is Autumn. The flowers have an agreeable smell.

When the plants come up they will require no other care than to keep them clean from weeds, and where they are too close to thin them, for they do not thrive when transplanted; the seeds, therefore, should be sown where they are to remain.

AMETHYSTINE is applied, in *Antiquity*, to a kind of purple garment dyed of the hue of *amethyst*.

In this sense *amethystine* differed from *Tyrian*, as well as from *hyacinthine* purple, being a kind of medium between both.

AMETHYSTINA, in *Entomology*, a species of CHRYSOMELA. Above blue-violet, beneath green and violet. Shells with scattered hollow dots.—Thorax large, antennæ short and black. Fabricius.

AMETHYSTINUS, in *Conchology*, a species of VENUS, described by Argenville; it is of an ovate shape, and violet colour, with perpendicular striæ: about two inches in length, and nearly the same in breadth.—Native place unknown. Gmelin.

AMETHYSTINUS, in *Entomology*, is likewise the specific name of an insect of the APIS genus: it is nearly naked, black: wings violet. A native of the East Indies. Fabricius.

AMETHYSTINUS, a species of CARABUS, that inhabits Cayenne; the wing-cases and abdomen are blue: the head and thorax shining, bronze.—The antennæ are hairy, ferruginous at the base: wing-cases streaked. Fabricius.

AMETHYSTINUS, in *Ornithology*, a species of TROCHILUS, or humming bird, found in Cayenne; its colours are chiefly green gold variegated beneath with grey and brown; throat amethystine blue: tail forked. Gmelin. Size of the red-throated humming-bird, T. Colubris. Linn.—Trochilus amethystinus is le petit oiseau-mouche à queue fourchue & l'amethyste, of Buffon, and amethystine humming-bird of Latham.

AMETZ, in *Geography*, a town of France, in the department of Moselle, and chief place of a canton in the district of Longwy, three leagues west-north-west of Thionville, and three fourth east of Longwy.

AMEVILLE, a town of Savoy, in the valley of Aosta, near the Doria, two miles west of Aosta.

AMEWELL, a populous town of America, in Hunterdown county, New Jersey, containing 5201 inhabitants, of whom 283 are slaves.

AMGAILA, or ANGAILAM, in the *Materia Medica of the Ancients*, a name given by Avicenna and others to a plant sometimes called ACANTHA Arabica, and Amicantha by the Greeks; the roots of which were called *bunkon*, and much used in medicine by the Arabian physicians.

The amgaila, called also *sucaba*, or *zucabai*, is described as a prickly herb, having roots like those of the cyprus, formed of several joints or knots. They were used in stomachic and cardiac compositions, and were chosen by their lightness and good smell.

AMGINSKAIA, in *Geography*, a town and fortress of Russia, situate on the river Amba, 100 miles south-east of Yakutsk.

AMHARA, a kingdom of Abyssinia, situate between the two rivers Babilo and Gelhen, occupying almost the central part of the country; and having Beg-mder to the north, to the west the Nile and the kingdom of Gojam, to the south Walaka, and to the eastward Angot, about N. lat. 11° and E. long. 39°. The length from east to west is about 120 miles, and its breadth somewhat more than 40. It is a very mountainous country, full of nobility: the men are reckoned the handsomest as well as the bravest in Abyssinia. With the ordinary arms, the lance and the shield, they are thought to be superior to double the number of any other soldiers in the kingdom. The dignity of this province derives accession from the high mountain of Gelhen, or the grassy mountain, on which the king's sons were formerly imprisoned, till they were surpris'd and murdered there in the Adelan war. Ludolf enumerates 36 provinces in this kingdom. The Amharic dialect was substituted for the ancient Ethiopic or Geez, in common use and conversation; after the restoration of the royal family from their long banishment in Shoa. This was denominated the king's or royal language, because it was introduced by the sovereigns of the country, when they were called to the government from their exile in the rocks of Amhara, and extended in the court and camp over the whole kingdom. With the sanction of this origin and authority it obtained an ascendancy over all other dialects, and even over the ancient Ethiopic language itself. It differs from the Ethiopic both in construction and grammar; and seven new characters were added to answer the pronunciation of this new language, which is very difficult both to be written and leared. But no book was ever yet written in any other language but the Geez. Although the Amharic dialect be the court language, the Ethiopic retains its original dignity, not only in their books, but in their worship, and also in the king's letters patent, and commissions which are dispatched in his council. Mr. Bruce says, there is an old law in the country, handed down by tradition only, that if any one should attempt to translate the holy Scripture into Amharic, or any other language, he should have his throat cut after the manner in which they kill sheep, his family should be sent into slavery, and his house razed to the ground: and the awe of this law was a great obstacle to his obtaining those translations of the Song of Solomon, which he propos'd as specimens of the different languages of those distinct nations. The dialects of the neighbouring kingdoms, though they differ from one another, approach the nearest to the Amharic.

Ludolf has written a short essay towards a dictionary and grammar of the Amharic. See Ludolf's *Hist. Æthiop.* p. 78. and Bruce's *Travels*, vol. i. p. 425.

AMHERST, one of the MAGDALEN isles in the gulf of St. Lawrence.

AMHERST, a county of Virginia in North America, lies between the blue ridge and the tide waters, on the north of James river, and contains 13,703 inhabitants, including 5296 slaves.

AMHERST, a township in Cumberland county, Nova Scotia, situate on Chignecto basin, on the south side of La Planche river, and on the rivers Napan and Macon. The town was settled by North Irish, Yorkshire, and New England people.

AMHERST, the shire town of Hillsborough county in New Hampshire, is a town of some note, formerly *Souhegan West*, and was originally granted from Massachusetts. It has 2369 inhabitants, and was incorporated in 1762. The Aurean academy was founded here in 1790. This township was formerly much infested by wolves, but they were driven away with dismal howlings by incessant firing of guns and beating of drums for a whole day, and they have never since

done any mischief in the town. Amherst lies on a northern branch of Souhegan river, which falls into Merrimack river, and is 60 miles west of Portsmouth, and 53 north-west of Boston. N. lat. 42° 54'. W. long. 71° 33'.

AMHURST, NICHOLAS, in *Biography*, an English poet and political writer of the eighteenth century, was born at Marden in Kent, received his grammatical education at Merchant Taylors' School, and removed to St. John's college, Oxford, whence he was expelled for misconduct. He attributes his expulsion to the liberality of his sentiments, and his attachment to the principles of the revolution and of the Hanoverian succession. Hence he took occasion to satirize the learning and discipline of the university of Oxford, and to expose the character of some of its most respectable members, in a poem, entitled "Oculus Britannicæ," and published in 1724; and in his "Terræ Filius," a work blending abuse and severity with a considerable portion of wit. It had been an ancient custom in the university, at public acts, for a person under the denomination of "terræ filius," to mount the rostrum, and divert a crowd of spectators with a merry oration in the *Fescennino* manner, interspersed with secret history, railery, and sarcasm, as the circumstances of the times supplied matter; and on this custom the title of this latter work was founded. It was originally written in 1721, came out twice a week in periodical papers, and contained fifty numbers. When Mr. Amhurst quitted Oxford he settled in London as a writer by profession. He first published a volume of *Miscellanies* on a variety of subjects, both sacred and profane. He afterwards published a poem, entitled, "The Convocation," in five cantos, which is a kind of satire against all the writers who had opposed Bishop Hoadly, in the famous Bangorian controversy. He also translated Mr. Addison's Resurrection, and some other of his Latin poems. But his principal literary undertaking was the political paper called "The Craftsman," which was written against Sir Robert Walpole's ministry, and was carried on for a number of years with great spirit and success. In the execution of this work, and in the effect which it produced, he was assisted by Lord Bolingbroke and Mr. Pulteney, and probably by other leaders of the opposition. In 1737 there appeared in this publication an ironical letter, ridiculing the act that had just passed for licensing plays, in consequence of which Mr. Amhurst was arrested and confined, but the prosecution was dropped. He was at length totally deserted by his party, when they made their terms with the crown: and his death happened soon after, viz. in April, 1742. We shall close this article with Mr. Ralph's reflection on the subject. "Poor Amhurst! after having been the leader of his party for the best part of twenty years together, was as much forgotten in the famous compromise of 1742 as if he had never been born! And when he died of what is called a broken heart, which happened a few months afterwards, became indebted to the charity of a bookseller for a grave, not to be traced now, because then no otherwise to be distinguished than by the freshness of the turf, borrowed from the next common to cover it." This anecdote furnishes an instructive lesson to men of literary talents, and teaches them to form, as the basis of their prospects of reputation and happiness, a character for integrity, discretion, and virtue. *Biog. Brit.*

AMIA, in *Ichthyology*, a species of SCOMBER, briefly characterized by Linnæus, as having the last ray of the dorsal fin longer than the rest, "pinnæ dorsalis posterioris radio ultimo longiore." Linn. — Country unknown.

AMIALE, or AMICABLE numbers, in *Arithmetic*, denote pairs of numbers which are mutually equal to the whole sum of each others aliquot parts. Such are the numbers 284, 220, the aliquot parts of which, with their sums, are as follows, viz.

Of 220, 1, 2, 4, 5, 10, 11, 20, 22, 44, 55, 110, — their sum is 284;

Of 284, 1, 2, 4, 71, 142, — and their sum is 220.

The second pair of amicable numbers are 17296, and 18416, which have the same property.

The third pair of such numbers are 9363584 and 9437056.

Schooten, § 9, of his "Exercitationes Mathematicæ." found out these three pairs, and called them *amicable* numbers; though the properties of such numbers had been before treated of by Rudolphus, Des Cartes, and others. Schooten, after Des Cartes, gives the following rule for investigating these numbers. Assume the number 2, or some power of 2, such that if 1 be subtracted from each of these three following quantities, viz. 3 times the assumed number, 6 times the said number, and 18 times the square of the same number, the three remainders may be all prime numbers; then the last prime number being multiplied by double the assumed number, the product will be one of the amicable numbers sought, and the sum of its aliquot parts will be the other. Thus, let $a=2$, and n be some integer number, such that $3a^n - 1$ and $6a^n - 1$ and $18a^{2n} - 1$ be all 3 prime numbers; then will $18a^{2n} - 1 \times 2a^n$ be one of the amicable numbers: and the sum of its aliquot parts is the other.

AMIANTHINITE of Kirwan, in *Mineralogy*. See STRAHLSTEIN.

AMIANTHUS, or MOUNTAIN FLAX, in *Mineralogy*, *Αμιαθος*, Gr. *Amiantus*. *Byffus montanus*. *Linum montan*. *Lana montan*. *Linum incombuftibile*. *Lapis Cyprinus*, Lat. *Amiantb*. *Bergflachs*. *Federweifs*, Germ. *Berglin*, Sweed. *Bierghor*, Dan. *Amiantb Kôlen*, Hung. *Amiant*, Russ. *Lin fossile*. *Amiantb*. Fr. *Amianto*. *Fior di pietra*. Ital. *Talcum asbestos amianthus*, Werner.

The colour of amianthus is generally greenish or silvery white, approaching to mountain green, more rarely yellowish white, olive, or leek green, ochre yellow, or pale flesh red.

It occurs usually amorphous, but sometimes in small separate bundles. Its lustre varies from glimmering to slightly shining, and is either weak-pearly or silken.

Its fracture is fine, and for the most part also strait, and even fibrous, rarely curved. It flies, when broken, into long splintery fragments.

It is found usually slightly transparent, but often opaque. Is soft enough to be scratched by the nail, and is considerably elastic. It has a soft, somewhat greasy feel.

The specific gravity of amianthus, according to Muschenbroeck, is 2.444. According to Brisson, before it has absorbed water, it varies from 0.9088 to 2.3134; after absorption it is from 1.5662 to 2.3803.

This mineral is principally met with in pot-stone or serpentine rocks, either dispersed through them as a constituent part, or accumulated in their clefts and crevices unmixed with any other substance. The Tarentaise, in Savoy, furnishes the purest and most beautiful. It is also met with in Corfica, the Isle of Elba, and Crete; near Zobnitz in Saxony, Salberg, and Swartwick in Sweden; in Cornwall and the Isle of Anglesea in England, and at Portfoy in Scotland.

A filament of the Tarentaise amianthus, when exposed to the flame of the blow-pipe, melts into an opaque globule, which becomes dark-coloured by the continued action of the flame. It dissolves quietly in borax and microcosmic salt, and effervesces with carbonated soda. If exposed in an earthen crucible to a high heat it melts into a dense scoria, strongly adherent to the bottom of the vessel, of a yellowish grey colour, but almost white where it is in contact with the crucible, which last is in some degree penetrated and corroded. The surface of this scoria is overspread with crystalline

needles crossing each other in all directions, or radiating from a common centre; similar acicular crystals are diffused through the substance of the mass. These needles are a little thicker than a hair, and when viewed by a magnifier, appear perfectly transparent, of a quadrangular, prismatic figure, whose angles and faces are remarkably brilliant and well defined; whereas, the filaments of the amianthus, in its natural state, are much too fine to allow of their form being determined even by a very powerful lens. This scoria, on exposure to a greater heat, changes into a green glass, incapable of crystallizing, and which, in a short time, passes through the crucible. A specimen of greyish white amianthus afforded Mr. Kirwan, at 162°.5 Wedgewood, a greenish black, perfectly compact glass. A specimen of amianthus from Greenland, according to Klaproth's experiments, being inclosed in a charcoal crucible, and exposed to the full heat of a porcelain furnace, fused into a scoria of a dirty pearl grey, covered externally with small grains of iron; its fracture shewed a dull, finely porous texture, inlaid with separate, glossy particles.

The action of the mineral acids on amianthus is very feeble; the nitric and sulphuric take up no more than three or four per cent.; the nitro-muriatic, in the proportion of ten parts to one of the fossil, dissolves about 12 per cent. consisting of lime, magnesia, and a little barytes.

Carbonated potash, even assited by ignition, is equally inefficacious with the acids in decomposing this substance. The Tarentaise amianthus, mixed with four parts of pure salt of tartar, and ignited for two hours, only afforded 12 per cent. of matter soluble in sulphuric acid.

The real solvent of this refractory mineral is caustic potash, as appears from Bergman, who, by mixing equal parts of amianthus, carbonated potash, and charcoal, and igniting them for two hours, obtained a mass perfectly soluble in nitro-muriatic acid. This eminent chemist was not, indeed, aware that the addition of charcoal rendered his alkali caustic, the reason of his using charcoal being to decompose the sulphat of barytes, to which he attributes the extraordinary refractiveness of this substance.

The Tarentaise amianthus, according to Bergman, is composed of

Sulphated barytes	-	6.
Carbonated Lime	-	6.9
Carbonated Magnesia	-	18.6
Alumine	-	3.3
Silex	-	64.
Oxyd of iron	-	1.2
		100.0

That of Swartwick contains—

Carbonated Lime	-	13.9
Carbonated Magnesia	-	17.2
Alumine	-	2.7
Silex	-	64.
Oxyd of iron	-	2.2
		100.0

That of Corias in Austria yields—

Carbonated Lime	-	10.5
Carbonated Magnesia	-	12.9
Alumine	-	3.3
Silex	-	72.
Oxyd of iron	-	1.3
		100.0

It is rather singular that sulphated barytes should have been found in the Tarentaise amianthus, as this earthy salt does not once occur among the analyses of the Swedish or Austrian

Austrian specimens, or among those of asbestos, steatite, and other minerals that have the nearest analogy to the amianthus; it is therefore greatly to be wished that some able chemist, in possession of the modern improved means of analysis, would undertake afresh the examination of this mineral.

Amianthus is often confounded with the more flexible kinds of ASBESTUS, to which it bears a near resemblance in external characters and chemical composition. Its fibres are, however, for the most part, more distinct and flexible than those of asbestos; it is more fusible *per se*, and is considerably less acted upon by acids.

The fibrous texture of amianthus, its incombustibility, and the little alteration that it undergoes even in a strong heat, were early noticed, especially among the eastern nations; and methods were found out of drawing the fibres into thread, and afterwards weaving it into cloth: this, when dirtied with grease or other inflammable matter, was cleaned by throwing it into a bright fire; the stains were burnt out, and the cloth was then removed, but little altered in its properties, and of a dazzling white; hence it obtained from the Greeks the name of *Αμιαθος* (undefiled.) In the rich and luxurious times of the Roman empire, this incombustible cloth was purchased at an enormous price, for the purpose of wrapping up the bodies of the dead previously to their being laid on the funeral pile, that the ashes of the corpse might not be scattered and mixed with those of the wood. This practice was indeed probably confined to a few of the richest families, but of its reality there can be no doubt, especially since a funeral urn was discovered in 1722 at Rome, near the Porta Navia, in which there was a skull and other calcined bones, together with a quantity of ashes inclosed in a cloth of amianthus nine Roman Palms long, and about seven palms wide. This interesting relic of antiquity was deposited, by order of pope Clement XI. in the Vatican library.

The dislike of burning the dead occasioned the manufacture of amianthine cloth to be neglected, and at length entirely forgotten in Europe; but though it has ceased to be an article of necessity or luxury, yet the method of its preparation has occasionally attracted the notice of travellers, and occupied the time of the curious. Marco Polo asserts, that in the east the mineral is gently bruised in a mortar to separate the fibres, and, being washed till the water comes off clear, is dried and then manufactured as flax or wool. Ciampini of Rome, in 1691, and then Mahudel, after many trials, published the following as the best way of preparing the incombustible cloth. Having previously steeped the amianthus in warm water, divide its fibres by gently rubbing them with the fingers, so as to loosen and separate all the extraneous matters, then pour on repeatedly very hot water, as long as it continues to be in the least discoloured. Nothing will now be left but the long fibres, which are to be carefully dried in the sun. The bundles of threads are to be carded by very fine cards, and the long filaments thus obtained are to be steeped in oil to render them more flexible. A small quantity of cotton or wool is to be mixed, and by means of a thin spindle the whole is to be drawn into thread, taking care that the amianthus may in every part be the principal material. The cloth being then woven in the usual manner, is to be placed in a clear charcoal fire to burn off the cotton and oil, when the whole remaining tissue will be pure white amianthus. The shorter fibres that are incapable of being woven have been sometimes made into paper; the process of which is the same as that employed for common paper, except that a greater proportion of paste or size is required: after having been once made red hot, however, the paper becomes bibulous and brittle. For written documents of great importance, it

might be worth while to be at extraordinary expence for incombustible paper and indelible ink; the former of these may be prepared from the longer fibres of amianthus, so as to be much less brittle than when the shorter ones are alone made use of; and for the ink the following receipt will be perfectly efficacious. Take one part of sulphat of iron (green vitriol) and two parts of alum, dissolve them together in warm water, and then add pearl-ash as long as any precipitate takes place; boil the mixture, and throw it on a filter, allow the precipitate to drain after being washed with warm water, and, while yet soft, dissolve it in distilled vinegar; use this moderately concentrated for ink, and the characters, after combustion, will be of a yellowish brown colour, and sufficiently legible.

Amianthus threads are also sometimes used as perpetual wicks for lamps; they, however, occasionally require cleaning from the soot that collects about them; and in the hottest part of the flame the fibres are apt to run together, in a state of sensu fusion, so as to prevent the due supply of oil. Weidenmann, *Handbuch der Mineral.* p. 465. Lenz, *Versuch, &c.* vol. i. p. 371. Ciampini, de *Incombustibili Lino*, Romæ, 1691. Nat.* article *Amiante*.

AMIATUS, in *Entomology*, a species of HESPERIA. Wings entire, black, posterior margin yellow: head and tail red. Inhabits America. The antennæ hooked, black: wings uniformly black, except the yellow margin, body black, head and tail red. Fabricius.

AMIAZ *Island*, in *Geography*, lies on the coast of Brazil, in which the city of Santos is situated, and hence it is called the gulf or bay of Santos. St. Vincent's is in another part of the same island, and before both there is good anchoring.

AMICABLE *benches*, *scamma amicabile*, in *Antiquity*, are generally supposed to denote the seats in the Roman courts, whereon the advocates were placed. Some think that these had but little title to the denomination of *amicable*, and therefore will have the word to be here used for the benches whereon the *assessors*, or those called *judices pedagæ*, were placed.

AMICABLE *compounder*, *amicabilis compositor*, is used by some ancient law-writers for an arbitrator.

AMICABLE, or *amicable compounder*, among the French, is a person who acts the part of a common friend, to reconcile two merchants or traders who have disputes, or are at law together. He differs from the *arbitrator*, in that, in order to make the two disputants agree, he often prevails upon both to give up some part of their right or claim, which an arbitrator, who performs the functions of a judge, is not, it seems, at liberty to do.

AMICABLE *Numbers*. See AMIALE.

AMICABLE *society*. See ASSURANCE.

AMICIA. See ALMUCIUM.

AMICITIA.—*Tenure in AMICITIA*, is applied in *Ancient Writers* to land granted freely, and of mere good will, to be enjoyed at the discretion of the donor.

AMICLÆ, or AD LANTULAS, now *Portella*, in *Ancient Geography*, a town of Italy between Terracina and Fofetti.

AMICONI, JACOPO, in *Biography*, a painter of history and grotesque, is supposed to have been born in the territory belonging to the republic of Venice, to have studied the art of painting for some years at Venice, and to have completed himself in his profession at Rome. The liveliness of his imagination,

imagination, the readines of his invention, and the freedom of his hand, soon recommended him to the public esteem, and he found encouragement and employment in most of the courts of Europe. He is said to have possessed many of the accomplishments of a good painter; but though his merit in many respects must be allowed, and his drawing is generally correct, yet his colouring is much too cold, too pale, and, as it is termed by the artists, too mealy. His compositions are well known in this kingdom, and many of his pictures are admitted into the collections of the first nobility; but nevertheless few particulars of his life have been ascertained. Pilkington.

AMICTUS, in our *Ancient Writers*, the uppermost of the six garments, worn by priests; the others are *alba*, *cingulum*, *stola*, *manipulus*, and *planeta*. It was tied round the neck, *Ne inde ad linguam transfret mendacium*; and covered the breast and heart, *Ne vanitates cogitet*.

This garment is otherwise called *anabologium*; sometimes *ambologium*, *anagologium*, and *humerales*. In ancient English writers it is called *mitte*.

The amict is also worn by deacons, sub-deacons, and *accoliti*, when they officiate at the altar.

The priests and deacons, in some dioceses, wear amicts on their heads from All-saints to Easter; though, by the canons, they be expressly forbid to wear the amict without some considerable occasion.

Mr. Thiers asserts, that the use of amicts was introduced into the Latin church before the twelfth century. Dom. de Vert maintains the contrary, chiefly from a figure of St. Firmin, first bishop of Amiens, supposed to have suffered martyrdom towards the beginning of the seventh century, whereon he is represented in his pontifical habit, with the amict on his head.

AMICTUS, in Roman *Antiquity*, denotes any upper garment worn over the tunica.

AMICU, in *Geography*, a lake in the province of Cumana, South America, whose waters run southerly through Parima river, into the Amazon.

AMICULATUS, in *Conchology*, a species of *CHITON*, that inhabits the Kurile islands. Shells of eight valves, kidney shaped, and very brittle. External covering a scabrous coriaceous membrane.—Length six inches. Gmelin.

AMICULUM, in *Antiquity*, denoted an upper garment worn by the women. The amiculum is said to have differed from the *palla*; but wherein the precise difference lay does not appear. An amiculum was also in use among the men. This seems to have been the same with the *chlamys*, or *paludamentum*.

AMICUS, or AMICONESOS, in *Ancient Geography*, an island of the Red Sea, according to Ptolemy. Amicus was the epithet of Hercules among the ancients, and hence it is said was derived the name of this island. This is probably the same with the *Amicusia* of Steph. Byz.

AMICUS *Curie*, in *Law*. If a judge is doubtful, or mistaken in matter of law, a slander-by may inform the court, as *amicus curiæ*. 2 Co. Init. 178. Any one as *amicus curiæ* may move to quash a vicious indictment; for if there were a trial and verdict, judgment must be arrested. Comberb. 13.

AMID AMID, in *Geography*, a ridge of mountains in Abyssinia, lying behind the two ridges of Litchambara and Aforinasha, commence behind Samseen, in the south-west part of the province of Maitsha, and become high only from the mountain of Adama; resembling in their shape the former ridges, and embracing them in a large curve, like a crescent. Between Amid Amid and the ridge of Litchambara is the deep valley known by the name of St. George,

through the middle of which runs the river Jemma, the sources of which are in the mountains of Amid Amid. This triple ridge of mountains, disposed behind one another in the form of three concentric circles, suggest an idea that they are the *MOUNTAINS of the moon*, or the *montes lunæ* of antiquity, at the foot of which the Nile was said to rise. Amid Amid may perhaps exceed half a mile in height; they certainly are not three quarters of a mile, and fall much short of the fabulous height ascribed to them by Kircher. These mountains have excellent soil, and are every where covered with fine pasture; but as this unfortunate country has been for ages the theatre of war, the inhabitants have only ploughed and sown the top of them, out of the reach of enemies or marching armies. On the middle of the mountain are villages built of a white sort of grass, which makes them conspicuous at a great distance; the bottom is altogether grass, where their cattle feed constantly under their view; and upon any alarm, they are driven up to the top of the mountains, so as to be out of danger. The hail lies often upon the top of Amid Amid for hours, but snow was never seen in this country; nor have they in the Amharic dialect any word by which to express it. The hail, nevertheless, which frequently occurred at Gondar, even when the sun was vertical, happened only when the wind blew directly from Amid Amid. Bruce's Travels, vol. iii. p. 583, &c.

AMID, or AMIDA, in *Ancient Geography*, a famous city of Mesopotamia, was situated in a fertile plain, watered by the natural and artificial channels of the Tigris, one stream of which bent in a semicircular form round the eastern part of the city. It was also called Constantia, in honour of the emperor Constantius, who fortified it with strong walls and lofty towers. It was provided with an arsenal of military engines, and the ordinary garrison had been reinforced to the amount of seven legions, when the place was invested by the arms of Sapor, king of Persia. The operations of this siege are minutely described by Ammianus Marcellinus (xix. 1—9.) who himself acted an honourable part in the defence of it, and escaped with difficulty when the place was stormed by the Persians. After a very obstinate combat between the assailants and the besieged, Amida was betrayed by the treachery of a deserter, who pointed out to the Barbarians a secret and neglected staircase, scooped out of the rock that hangs over the stream of the Tigris. But this stratagem failed, and Sapor was under the necessity of recurring to the slower but more certain operations of a regular siege, in the conduct of which he was instructed by the skill of the Roman deserters. His works, artfully and laboriously constructed, were more than once destroyed by the fire of the Romans; but at length the strength of the garrison, wasted by the sword and by disease, was exhausted and constrained to yield to the fury of the assault. The soldiers, the citizens and their wives, all of them who had not time to escape through the opposite gate, were involved by the conquerors in a promiscuous massacre. The siege, however, lasted 73 days, and 30,000 of the veterans of Sapor fell under the walls of Amida. Constantius, the emperor, is said to have wept over its ruins. When the inhabitants of Nisibis were reduced to the necessity of leaving their own city, in consequence of Jovian's treaty with the Persians, they retired to a new-built quarter of Amida; and this city, with the reinforcement of a very considerable colony, soon recovered its former splendour, and became the capital of Mesopotamia. In the year 501 it again sustained a long and destructive siege; and after three months it was taken by Cabades, Cavades, or Kobad, the Persian king. Most of the inhabitants were put to the sword, and the town was pillaged. It was again in 505, restored to the

Romans, on condition of their paying to the king of Persia 50 talents. Upon the decline of the Roman empire, it reverted to the Persians; from them it was transferred to the Saracens; and it is now possessed by the Turks. Amida assumes in modern times the provincial appellation of DIAR-BEKIR, and is also called by the Turks *Kara-amed*; the epithet *kara* being derived from the blackness of the stone which composes the itony and ancient wall of Amida.

AMIDA, in *Mythology*, a god worshipped by the Japanese, who has many temples erected to him in the island of Japan, of which the principal is at Jeddo. They suppose that he flourished many thousand years ago, and that after a life of voluntary mortification and austerities, and of signal miracles and exemplary virtue, extended to 1000 or 2000 years, he passed by a voluntary death to another state, where he was advanced to the dignity of a god. The Japanese have such a confidence in their idol Amida, that they hope to attain eternal felicity by the frequent invocation of his name. One of the figures of this idol is represented at Rome.

Cano, the son of Amida, is likewise held in great veneration, and has a stately temple near the city of Meaco, in which are 1000 images or statues of him, beautifully carved and regularly arranged.

AMID-SHIPS, a *nautical* term, denoting the middle of a ship, either with regard to her length or breadth.

AMIENS, in *Geography*, a city of France, and capital of the department of the Somme; before the revolution it was the capital of Picardy, and the see of a bishop, the suffragan of the archbishop of Rheims. It is situated in a plain, on the river Somme, which passes through it in three distinct channels, that afterwards unite; and may be seen at a great distance, decorated with a number of lofty towers, among which the cathedral commands peculiar notice. This is an elegant Gothic edifice, beautifully proportioned and delicately wrought; and the nave is particularly admired. It has many other collegiate, parochial, and public buildings, and an academy of arts and sciences founded in 1750. It is defended by a citadel and ramparts, on which are planted trees, which form a pleasant walk. The river Somme is navigable to the town. The houses are well built in the old taste; and the number of inhabitants has been reckoned between 40 and 50,000. Tinseau (Statistical view of France,) estimates them at 40,289. Its 4 cantons contain 45,157; its whole territory includes 100 kilometres and 12 communes. The commerce of Amiens has been very considerable, particularly in woollen stuffs, camlets, and shags. It has also been famous for its soap-manufacture.

AMIENS, in Latin *Ambianum* and *Samarobriua*, is a place of great antiquity. It appears from Cæsar's account in his Commentaries to have been one of the principal cities of Gaul; he held a general assembly of the Gauls in it, and committed it to the guard of a legion. Cicero refers to it in several parts of his epistles as a place of note; and Ammianus Marcellinus (lib. xv. c. 27.) mentions it as "a city eminent among others." It was enlarged by the emperors Antoninus and Marcus Aurelius; and it was the place in which Constantine, Constant, Julian, and other emperors frequently resided. The earldom of Amiens, comprehending a great part of the territory of the Ambiani, and since called Picardy, was formerly conferred by the kings on the bishops of this city. Philip Augustus, in 1193, annexed it to the crown. The states of France were summoned at Amiens by Lewis XI. in 1264, on the appeal made to him by Henry III. and the barons of England; and the appeal was decided in favour of Henry. Charles VII. granted it to Philip the Good, duke of Burgundy, in 1435; and Lewis XI. reunited it to the crown in 1477. Amiens was

taken by the Spaniards in 1597, by the following stratagem. Soldiers, disguised like pealants, conducted a cart, loaded with nuts, and let a bag of them fall jill as the gates were opened. Whilst the men in garrison were busily employed in gathering up the nuts, the Spaniards entered in a body, and made themselves masters of the city. Henry IV. however, retook it in the same year. Amiens is distinguished as the native place of Voiture, Rohault, Du Cange, and Gresset. It has lately, *viz.* in 1802, acquired celebrity by the negociation, which terminated the war between England and France, and other belligerent powers, and by the signature of the definitive treaty, by the plenipotentiaries of the four contracting parties, Spain, Holland, France, and Great Britain, on the 27th of March, which established peace. Amiens is situated in N. lat. 49° 53' 58"; and E. long. 2° 17' 56".

AMIESTES, in *Commerce*, cotton cloths which come from the East-Indies.

AMIGONI, OCTAVIO, in *Biography*, a painter of history and portrait, was born at Breiscia, in 1605, and was a disciple of Antonio Gandino. His expression, and taste of design, were very remarkable and very elegant; and his compositions, executed with a free, firm, and masterly touch, and with figures as large as life, were much applauded in several parts of Italy. Pilkington.

AMILICHUS, in *Ancient Geography*, a river of Greece, in Achaia, situate to the north-west.

AMILICTI, in the Chaldaic *Theology*, denote a kind of intellectual powers, or persons in the divine hierarchy. The amilicti are represented as three in number, and constitute one of the triads, in the third order of the hierarchy.

AMILO, in *Ancient Geography*, a river of Mauritania, mentioned by Pliny.

AMILOS, or AMILUS, a town of Arcadia, to the north-west of Orchomane.

AMILPAS, in *Geography*, two volcanoes in the province of Guatemala, in New Spain, near the mountains of Soconusco.

AMINEL, in *Ancient Geography*, a people of Thessaly, who, according to Aristotle, transported their vines into Italy, whence the expression *amineæ vites*.

AMINEL, in *Geography*, a small town of Africa, in Barbary, situate on the eastern side of the kingdom of Tripoli.

AMINIUS, in *Ancient Geography*, a river in the southern part of Arcadia, which runs from north-east to south-east into the Helissus.

AMIRANTE, a great officer in Spain, answering to the lord high-admiral in England.

AMIRANTE, or CARNIBACO BAY, in *Geography*, a large bay on the north coast of the isthmus of Darien, and near the limits of North and South America. It is in the province of Veragua, on the north-west of the Toro channel and bay of Conception, from which it is separated only by a congeries of rocks, which lie in the ocean, near the coast. N. lat. 9° 5'. W. long. 82° 30'.

AMIRANTE ISLANDS. See ALMIRANTE.

AMISENUS SINUS, *gulf of Amisenus*, in *Ancient Geography*, a gulf or bay of the Euxine sea, situate to the east of the mouth of the Halys, on the coast of the kingdom of Pontus; so called from the town of Amisus.

AMISIA. See EMS.

AMISS *Drawing*. See DRAWING.

AMISSA LEX. See LEX.

AMISSEN or MISSEREN, in *Geography*, a point on the gold coast of Africa, east of Cormantine, between it and Dajou or Tagu, near the rough point. N. lat. 5°. E. long. 1° 10'.

AMISTOWES, a town of Bohemia, in the circle of Koniggratz, 10 miles west-south-west of Biezow.

AMISUS,

AMISUS, in *Ancient Geography*, a considerable city of Asia Minor, in the kingdom of Pontus, was situated on the coast of the Euxine sea, near the mouth of the Halys and Iris, founded by the Milesians, and peopled also by a colony of Athenians. It was at first a free city, like the other Greek cities in Asia, but afterwards subdued by Pharnaces, king of Pontus, and made the metropolis of his kingdom. Pliny says, that it maintained its republican and popular form, till it was conquered by the Persians; but Alexander restored its liberty, of which it was deprived by the king of Pontus. It was in extent the largest city of the kingdom, except Sinope. Mithridates had a palace in this city, and it was adorned with temples and many magnificent buildings, when Lucullus took it. Its inhabitants were massacred by Pharnaces, the son of Mithridates; but it was retaken by Cæsar, and made a free city.

AMITERNUM, a town of Italy, north-east of Rome, in the country of the Sabines, situate, according to Strabo, on the declivity of a mountain, and having, in his time, the remains of a theatre and a temple. It was taken by Sp. Carvilius, in the year of Rome 460, and subsisted to the time of the contest between the Guelphs and Gibellines, when it sunk under the town of Aquila, newly erected by the emperor. It was famous as the native place of the historian Sallust. Some remains of it are still discernible near S. Vittorino and the Springs of the Aternus.

AMITHOSCUA, a country of Arabia Felix, according to Pliny.

AMITIENSES, a people of Etruria, according to Pliny.

AMITTERE *legem terræ*, a law-phrase, signifying the forfeiture of the right of swearing in any court or cause; or the becoming infamous.

This is the punishment of a champion overcome, or yielding in the combat: of jurors found guilty in a writ of attain; and of persons outlawed. Vide Glanvil. lib. ii. and see the stat. 5 Eliz. cap. 9. against *perjury*.

AMIXOCORES, in *Geography*, a people of America, in Brazil, near the country of Rio-Janeiro.

AM-KAS, in *History*, a name given to a spacious saloon in the palace of the great Mogul, where he gives audience to his subjects; and where he appears on solemn festivals with extraordinary magnificence. His throne is supported by six large steps of massy gold, set with rubies, emeralds, and diamonds; and estimated at 60,000,000l.

AMLAH, in *Geography*, one of the Fox islands, at the distance of about 15 versts from ATCHAK, and nearly of the same size. It has a harbour on its south side. It lies in about N. lat. 52° 30'. W. long. 173° 30'.

AMLAMGODE RIVER is on the southwest-coast of the island of Ceylon, between Barberin island on the north-west, and Regama point on the south-east, about eleven leagues distant. It is not navigable: it is known by a garden of cocoa trees.

AMLET. See OMELET.

AMLING, CARL GUSTAV. AB, in *Biography*, a painter and engraver, was born at Nuremberg, in 1651, and learned the art of engraving from Francis de Poilly, whose style he imitated but never equalled. He chiefly excelled in portraits, and failed in historical subjects. He was engraver to the duke of Bavaria, and died in 1702. Among his portraits are "Maximilian Emanuel," elector of Bavaria, a large upright plate, esteemed as one of his best; and among his historical subjects are "the history of the emperor Otho," from the tapestries at Munich, in 13 plates, and "the Four Seasons," from the same tapestries. Strutt.

AMLWCH, in *Geography*, a small village in the island of Anglesea, adjoining to the mines of the Paris mountain, and raised into eminence by the works and wealth which they occasion. The two great proprietors of these mines, Lord Uxbridge and Mr. Hughes, have adorned this village with two elegant houses for their occasional residence, one called the Mona, and the other the Paris Lodge. The little port of Amlwch is placed in a small cove, among the cliffs, about half a mile below the village, and is admirably formed for receiving and arranging the several vessels which are employed in the copper and brimstone trade. It often also affords a safe haven to those ships, which, in their passage from Ireland, are driven to the north-east, round the point of Holyhead, and cannot make that harbour.

AMMA, in *Ancient Geography*, *Lacme*, a river of Switzerland, which runs into the Aar, near Soleure.

AMMA, a town of Asia, in Palestine, belonging to the tribe of Aser; called, by Jerom, Amma.

AMMA, in *Middle Age Writers*, denotes a spiritual mother. In this sense, the word was chiefly understood of an abbess, or superior of a nunnery.

AMMA, or HAMMA, from *αμμα*, *vinculum*, in *Surgery*, a technical term, denoting the bandage employed to sustain RUPTURES OF HERNIÆ. This important instrument will be more properly described under the article HERNIA, which see.

AMMÆA, in *Ancient Geography*, a town of Mesopotamia, near the Euphrates, towards the Persian gulf, according to Ptolemy.

AMMÆDARA, a town of Africa Propria, in that part called by Ptolemy Numidia Nova.

AMMAENSIA JUGA, a name given by Pliny to the mountains of Lusitania.

AMMAITIA, a town of Asia, in Assyria.

AMMAN, or AMANA, a town of Asia, in Arabia; it was the principal town of the Ammonites, and called also Rabbath.

AMMAN, in the German and Belgic *Policy*, denotes a judge who has the cognizance of civil causes.

The word is also written *amant*. Thus it occurs in writers on the French officers, where it stands for a notary, or parochial officer, who draws acts or instruments.

AMMAN, JOHN CONRAD, in *Biography*, was born at Schaffhausen, in Switzerland, graduated at Basl in 1687, and practised physic at Amsterdam, towards the close of the 17th and beginning of the 18th centuries. He applied himself with particular attention to the discovery of a method of teaching persons born deaf and dumb to speak; and from observing the motions of the lips and mouths of persons addressing them, to understand their meaning. In this art he attained great perfection, and many persons born with those defects, were restored to society, through his skill and perseverance. In the year 1692, he published an account of the process by which this was effected, first in Dutch, under the title of "Surdus Loquens;" and in 1702, in Latin, adding to the title, "Seu Dissertatio de Loquela:" Opus, Haller says, *vere aureum*; no material addition having been made to his directions, which are now every where practised, by persons professing that art. The work has always been held in high estimation, has been translated into most of the European languages, and passed through numerous editions. Haller *Bibl. Med. pract. et Chirurg.*

AMMAN, JOHN, son of Conrad, also doctor in medicine, settled in Petersburg, where he gave lectures in botany. He published "Icones et descriptiones stirpium rariorum Ruthenicarum." Petropoli, 1739, 4to.

The figures were principally taken from a collection of dried specimens of plants, preserved at the Imperial academy, Peterburgh. Eloy Dictionaire Histor. de la Med.

AMMAN, PAUL, was born at Breslaw, Augull 1634. After finishing his school education, he travelled for improvement over various parts of Germany, Holland, and England. In October 1662, he was admitted doctor in medicine at Leipzig, and in succession, professor of medicine, botany and physiology in the same university, in which offices he acquired considerable reputation. He died, February 4th. 1691.

Haller gives a long list of dissertations published by him, but his principal works are, "Animauni parensis ad docentes occupata," 1673, 12mo.; "Praxis vulnerum lethaliu sex decadibus Historiarum rariorum, Franco," 1700, 8vo. For the titles of his other works, see Haller's Bib. Med. Pract.

AMMAN, or AMMON, JOST or JONOCUS, a designer and engraver, was born at Zurich, in Switzerland, A. D. 1539, resided at Nuremberg, and died there in 1591. He was an indefatigable artist, and possessed considerable merit as an engraver. The number of his designs and plates is very great. His engravings were chiefly on wood, and are much superior to those on copper. Although he does not manifest much invention, his figures are well proportioned; and his animals are touched with great spirit. His manner of engraving is said to have been neat and decided. Among his performances we may select his "*πανεπισταμια*, omnium liberalium mechanicarum et sedentarium artium genera continens, &c." Francof, 1564, amounting to 115 prints, and exhibiting the different artists and tradesmen in their respective employments. He also engraved in wood some detached pieces, and on copper "The Illustrious Women," beginning with Eve; a set of "Figures of Warriors," 1590; "The Four Seasons and the Four Elements," 1569. Strutt.

AMMAN JOHN, an artist and bookseller, lived at Hanau, in Germany, about the year 1640. A set of small wooden cuts, representing "the Passion of our blessed Saviour," executed very much in the style of the former artist, and published at Amsterdam, with Latin verses, in 1623, is reckoned to possess a considerable share of merit. Strutt.

AMMANATI, BARTHOLOMEO, a celebrated sculptor and architect, was born at Florence, in 1511, and studied sculpture in his native town under Bandinelli, and at Venice under Sanfovino. He designed the porticoes of the Pitti palace, and the bridge Della Trinita, at Florence, which is accounted one of the most beautiful works, since the revival of the arts. At Rome he built the palace Ruspoli, and the noble front of the Roman college. On his return to Florence he expended his wealth in building the church of San Giavanno, belonging to the Jesuits, in which he was interred. Ammanati's large work "La Citta," comprehends the designs of all the public buildings necessary in a capital city. He died either in 1586 or 1592. His wife, Laura Battiferi, was distinguished for her poetical productions, of which a collection was printed at Florence, in 1560. Nouv. Dict. Hist.

AMMANNIA, named by Houtson in honour of J. Amman, in *Botany*, a genus of the *tetrandria monogynia* class and order, of the natural order of *calyncathema* and *salicarie* of Jussieu; its characters are, that the *calyx* is a perianthium bell shaped, oblong, erect, with eight streaks and folds, quadrangular, eight-toothed, teeth alternate bent in, and permanent; *corolla* none, or four-petalled, petals vertically ovate, spreading, inserted into the calyx; the *stamina* have filaments, (four or eight) bristly, the length of the

calyx into which they are inserted, anthers two; the *pyllium* is a germ subovate, large and superior, style simple, very short, and stigma headed; the *pericarpium* is a roundish, four-celled capsule (berry) covered with the calyx; the *seeds* are numerous and small. There are seven species, viz. 1. *A. latifolia*, islandia of Brown. Jamaica. aparines of Sloane Jamaica. *A. purpurea* of La Marek, or broad-leaved *A.* "with leaves half-stem clasping, square stalk, and erect branches." This species grows about a foot and a half high, with leaves long, narrow and triangular, as long as the stem, of a pale green colour; and the flowers proceed in clusters from the joints where the leaves adhere. It is a native of moist places in Jamaica, whence the seeds were sent about 1731 by Dr. Houtson to England, and from Chelsea they have been distributed to most of the botanic gardens in Europe. 2. *A. ramosifera*, ludwigia of Clayt. Virg. branching *A.* "with leaves half-stem-clasping, stalk square, and spreading branches." This is an annual plant, and grows naturally in Virginia and Carolina; rises about a foot high, with red succulent stalks, putting out side branches, opposite, round, and simple, the flowers are produced single from the axils on the lower part of the branches, and toward the top in clusters; they have little beauty; cultivated in 1759, and preserved for variety. 3. *A. baccifera*. *A. verticillata* of La Marek, cornelia verticillata of Ard. Spec. "with leaves sub-petiolate, capsules larger than the calyx and coloured;" it has four-toothed calyxes. This is a native of China, and naturalized in Italy. It has little beauty, and is rarely preserved in gardens. 4. *A. octandra*, eight-stamened *A.* "with sessile linear-lanceolated leaves, and flowers petal-bearing, and eight-stamened;" the petals are blood red; found by Koenig in the East Indies. 5. *A. pinnatifida*, pinnatifid-leaved *A.* "with stalks procumbent, rooting, compressed, and leaves linear, pinnatifid." The flowers are small, corolla red, and capsules four-cornered; found by Sonnerat in the isle of Java. 6. *A. debilis*, cluster-flowered *A.* "with leaves lanceolate, attenuated at the base, stem branching, flowers in bundles from the axils, and capsules two-celled." This species is annual, the calyx angular, petals pale-purple, filaments shorter than the calyx, anthers ovate and yellow, capsule ovate and two celled; a native of the East Indies; introduced in 1778 by Sir Joseph Banks; and flowers in July and August. 7. *A. sanguinolenta*, "with leaves, half-stem-clasping, cordate at the base, flowers sub-peduncled, eight-stamened, petal-bearing;" a native of Jamaica and Domingo.

Culture. The three first species must be raised from seeds on a hot-bed in spring, and afterwards removed to another hot-bed in order to bring them forward. When the plants have acquired strength they should be transplanted into pots filled with rich light earth, and placed under a frame, shading them till they have taken fresh root; they should then be placed in a glass case or stove, to ripen their seeds, for the plants are too tender to thrive in the open air in this country, unless the summer be very warm. The second sort, raised in a hot-bed, in the spring, and planted in a warm border, will perfect its seeds in the open air. The other species are stove-plants. Martyn's Miller.

AMMANO, in *Geography*, a town of Japan, in the province of Fida.

AMMATA, or ΑΜΜΑΤΗΑ, in *Ancient Geography*, a town of Asia, in Palestine, belonging to the tribe of Juda.

AMMER, in *Geography*, a powerful but infamous tribe of Arabs, who inhabit the province of Constantina, in Africa, and who, contrary to the practice of their brethren, prostitute their wives and daughters. Shaw's Travels, p. 53.

AMMERCOT, a town of Hindoostan, situate in a sandy desert, 138 miles north-east of Nusserpour, and 256 south of Moultan. Feenhta reckons it about 100 cosses from Tatta. In the Ayin Acbaree it is classed as belonging to the Nusserpour division of the province of Sindy. N. lat. 25° 40'. E. long. 70°.

AMMEREN, a town of Germany, in the circle of Westphalia, and duchy of Juliers, six miles east-north-east from Ruremond.

AMMERSEE, a lake of Germany, in the circle of Bavaria, 12 miles long, and from two to three broad, 80 miles west of Salzburg.

AMMESPACH, a river of Germany, runs into the Erlebach, in the archduchy of Austria, on the borders of Stiria.

AMMI, formed from *αμμοι*: *fund*, in Botany, a genus of the *pentandria digynia* class and order; of the natural order of *umbellata* or *umbelliferae*; its characters are, that the *calyx* has its universal umbel manifold, frequently of 50 rays, the partial short and crowded, the universal involucre of many linear, pinnatifid, acute leaflets, scarcely the length of the umbel, the partial many-leaved, leaflets linear, acute, simple, shorter than its umbellet, the proper perianthium scarcely apparent; the *corolla* universal uniform, with all the floscules fertile, the proper of five inflex, heart-shaped petals, of unequal size in the ray, almost in the middle of the disk; the *filamina* have capillary filaments. anthers roundish; the *pistillum* has a germ inferior, styles reflex, and stigmas obtuse; no *pericarpium*, fruit roundish, smooth, small, streaked, and bipartite; the *seeds* two, convex and streaked on one side, and flat on the other. Martyn reckons three, and Gmelin four species. 1. *A. majus*, common bishop's weed, ammioselinon, "with lower leaves pinnate, lanceolate and serrate, upper ones multifid and linear." This species is annual, and grows in vineyards and fields, in the southern parts of Europe, and in the East. There is a variety reckoned by Bauhin a distinct species, under the title of *A. majus toliis plurimum incisus, et nonnihil crispis*; but Mr. Martyn has raised this variety from the beds of the former. 2. *A. copticum*, "with leaves super-decompound, linear, and seeds muricate." This is of the stature of Dill, green, stem smooth and streaked; leaves tripinnate oblong, smooth, and linear; umbels with ten rays; involucre five-leaved; partial involucre seven-leaved; corollas white, equal and five angled; fruit ovate and muricate on every side, seeds streaked with five swellings, aromatic; found by Forskahl in Egypt; annual, introduced in 1773 by John Earl of Bute. 3. *A. glaucifolium*, *daucus petraeus glaucifolius* of Bauhin, perennial bishop's weed, "with the subdivisions of all the leaves lanceolate." This has the appearance of a variety of the first species; is a native of the south of France; described by Miller as a perennial plant, preserved for variety, but having little beauty. 4. *A. laurifolium*, "with bipinnate leaves, the winged leaflets trifid, the fruit connected in whirls with the common rib." La Marek has referred to this genus, the *DAUCUS visnaga* of Linnaeus, and the *ammi anethifolium*, with oblong pinnated leaves, the leaflets multifid and capillary, and the petioles canaliculated; the *daucus meoides* of Hort. Reg. brought originally from the Levant, and flowering in the beginning of Autumn.

Culture. The 1st species is propagated by seeds sown in Autumn in the place where they are to remain; in the Spring the ground should be hoed and the plants thinned as in the management of carrots, leaving them four or five inches asunder, or in good ground at the distance of six inches; after which they will require no further care, besides being kept free from weeds. They will flower in

June, and the seeds will ripen in August, and should be gathered as they ripen, for they will soon scatter. The 3d species will grow in any open situation, is very hardy, and thrives best in a moist soil. Martyn's Miller's Dict.

AMMI, or *semen ammios veri*, in the *Materia Medica*, a kind of aromatic seed, the produce of the sison *ammi* of Linnaeus, sometimes though now rarely brought from the Levant, and formerly used in medicine. The seed is small, whence, according to Lemery, the name of the plant ammi, from *αμμοι*: *fund*, striated, of a greyish brown colour, somewhat bitterish taste, and fragrant smell, approaching to that of organum. This seems to have been the ammi of Dioscorides and Hippocrates. It is now very rarely prescribed. These seeds, distilled with water, yield a considerable quantity of a yellowish essential oil, containing their whole smell and flavour; the remaining decoction is unpleasantly bitterish. Spirit of wine carries off, in its exhalation, the odorous principle of the ammi. These seeds have been recommended as a stomachic, emmenagogue, diuretic, and an elegant aromatic carminative. Linnaeus gives the denomination of *semen ammios veterum* to that of the *LAGOECIA Caminoides*. The seeds of the *ammi majus* above described, or *ammi vulgare*, are substituted for the former in medical use. They are weaker both in smell and taste; nor does their flavour resemble that of organum. The essential oil and the spirituous extract are both less grateful and less pungent.—Lewis and Murray.

AMMI. See BUNIUM, CICUTA, SESELI, SISON and SIUM

AMMIANUS MARCELLINUS, in *Biography*, a Roman historian of the fourth century, was a native of Antioch, where his family made some figure, and in early life served several years in the army in quality of protector domesticus, which was then an honourable post. In 350 he accompanied Ursicinus, a general of the horse under the emperor Constantius, into the East; and followed him in several expeditions, from 350 to 359, in which he acquired military reputation. He attended Julian in his Persian expedition in 363, and was either at or near Antioch in 371, when the conspiracy of Theodorus was discovered in the reign of Valens, and was a witness of the torments of many persons whom Valens ordered to be put to death on that occasion. It is not certain whether he obtained any higher rank in the army than that of domestic protector. When he quitted the army, he resided at Rome, and employed himself in writing the history of the affairs of the empire, during a period of three centuries. Though he was a Greek, he chose to write in Latin: but his Latin, in the opinion of Vossius, indicates that he was a Greek and a soldier. His history was divided into 31 books, commenced with the reign of Nerva, where Tacitus ends, and terminated with the reign of Valens.—The first 13 books, ending with the reign of Constantius, and containing a superficial epitome of 257 years, are lost; the last 18 books, now extant, begin with the 17th year of Constantius, A. D. 353, and conclude with the year 375; though some particulars of a later date are mentioned, from which we may infer, that the historian lived at least to the year of Rome 1142, or A. D. 390. The style of his history is reckoned harsh and verbose; but this defect is amply compensated by the variety of information which he communicates from his own personal knowledge, and by the fidelity and impartiality of his relation. Mr. Gibbon (Hist. vol. iv. p. 426.) represents him as "an accurate and faithful guide, who has composed the history of his own times, without indulging the prejudices and passions, which usually affect the mind of a contemporary." Some have supposed that he was a Christian; but of this

there is no sufficient evidence. As he wrote under Christian emperors, he might not judge it proper to profess his religion unreasonably, and he might think it most prudent to be cautious in his reflections upon Christianity. Although he was a pagan, as is evident from the respect with which he speaks concerning the pagan divinities, and from his defence and recommendation of heathen auguries, and such methods of investigating futurities, he nevertheless manifests no animosity against the Christian religion; on the contrary, he bears honourable testimony to the plain and simple nature, and the equitable and gentle spirit of Christianity, to the moderation of some Christian bishops, whilst he condemns the severity with which some Christians treated one another, and to the firmness and fidelity of the Christian martyrs. Hence Mosheim concluded that Marcellinus and some other learned men about his time were not; alleging, that they neither rejected the Christian religion, nor forsook the religion of their ancestors. But the instances already cited merely prove, that he was a faithful and candid historian. The remaining works of Ammianus Marcellinus have passed through several editions; all of which have been superseded by that of Valæsius, printed in folio, at Paris, in 1681. This edition was reprinted by Gronovius at Leyden, in 1693, with valuable notes. Valæsi Præf. ad Amm. Marc. Fabric. Bib. Lat. cap. xii. tom. ii. p. 98, &c. Lardner's Works, vol. viii. p. 464, &c.

AMMINEA *uva*, in *Botany*, a name given by the old writers, to the grapes of a wild vine, common in the hedges of Italy, and some other places. They used to make wine of these grapes, which they mixed with other richer wines, and had in common use. Columella says, that this wine was first brought from the country of the Amineans in Thesaly, and that the wine produced from its grapes was the first and the most ancient known among the Romans. According to Macrobius, the Falernian wine was more anciently called Aminean. Some write the word *taminea*, instead of *aminea*.

AMMIRABEA or OMMIRABIH, corruptly Marbea, and Umarbea, in *Geography*, a river of Africa, which has its spring on mount Magrau, one of the heads of the Atlas near the confines of Fez, which runs through the plains of Adachson, where it has a beautiful bridge built by Abu'l Hasehen, the fourth monarch of the Benimerini, and thence winding southwards and watering the spacious plains between Dukala and Temesena, becomes wider in its approach to the ocean, into which it discharges itself, and forms a spacious bay, on the east side of Azamor. This river is fordable neither in Summer nor Winter, so that the inhabitants are forced to ferry their effects over it by the help of baskets, fastened to leathern pontoons, or over rafts. Its fish not only furnishes all that country; but is exported to Spain and Portugal.

AMMIRAGLIO, a small river of Sicily, anciently ORETHUS.

AMMIRALIS, in *Entomology*, a species of CERAMBYX found in Surinam. Thorax rather spinous; fourth joint of the antennæ bearded, second spinous. Gmelin. General colour black; base of the wing cases and sides of the thorax reddish.

AMMIRATO, SCIPIO, in *Biography*, an eminent historian of the 16th century, was born at Lecce in Naples, in 1531, and descended from a considerable family, which was expelled from Florence by the Gibelines. He was originally designed for the profession of the law, and with this view went to study at Naples in 1547; but his taste for polite literature diverted his attention from this kind of

study. His father was much offended, and withheld from him necessary supplies, whilst he visited Venice and Padua, so that he was obliged to return to Lecce, to take orders, and to accept a canonry which was conferred upon him by the bishop of this city. At Venice, whither he afterwards removed, his life was endangered by an intrigue; and at Rome he had a quarrel with the pope's filler, which obliged him to return to Lecce, where he founded the academy of the "Transformati." After many projects and wanderings in Italy, he at last settled at Florence, where in 1570, he was engaged by the Grand Duke Cosmo to write the Florentine history. Though he was of an inconstant and querulous temper, he continued in the possession of a canonry, and in the apartments provided for him by the duke for the remaining 30 years of his life. Here he died in 1601, and appointed the assistant of his studies, Christophoro del Bianco, for his heir, who, in conformity to his will, took the name of "Scipio Ammirato the younger." His "Florentine History," first published in 1600, contains the events of Florence from its foundation to 1574, and is much esteemed for its extent and accuracy. The second part was published by Ammirato the younger in 1641, who gave a new edition of the first part, with many additions.

Ammirato the elder wrote also genealogical accounts of the principal families of Florence and Naples, which were very favourably received; and he published "Discourses on Tacitus," with several essays, historical, moral, and political. He wrote arguments in verse, to all the cantos of "Orlando Furioso," and other pieces of poetry; but in this kind of composition he did not excel. Gen. Dict.

AMMITES, or HAMMITES, in *Minerology*, a species of lime-stone. See ROESTONE.

AMMOCÆTUS, in *Ichthyology*, an obsolete name given by Gesner and some others, to the AMMODYTES TOMIANUS of Linnæus.

AMMOCHOSIA, from *αμμος*, sand, and *χω*, I lay along, in the *Ancient Physic*, a kind of a remedy, or operation for drying the body, by lying along on warm sand, and having the body covered with it. Some prefer salt for this purpose to sand.

AMMOCHOSTOS, in *Ancient Geography*, a promontory of the island of Cyprus south of Salamis; whence, by corruption, is derived the modern name Famagouta.

AMMOCHRYSOS, the same as golden MICA, which see.

AMMOCHYSUS, in *Natural History*, a kind of gem, supposed to be the same with the *aventurine*.

AMMODES, in *Ancient Geography*, a promontory of Cilicia, between Pyramus and Cydnus.

AMMODYTES, in *Zoology*, a species of COLUBER, very nearly allied to the viper. It inhabits many places in the eastern regions, and the mountainous parts of Illyria; and hence it has been called *vipera illyrica*. The Linnæan specific character is taken, as in general throughout the genus, from the abdominal plates and subcaudal scales which are 142—32. Its general description is sometimes brown, sometimes pale bluish, with a black dentated dorsal band; the dentations being turned backwards. Nose terminated by an erect wart.

This species is said to be extremely poisonous, and, according to Matthioli, proves fatal in the space of three hours.

AMMODYTES, in *Ichthyology*, the name of a genus in the Linnæan system, of which only one species has been hitherto discovered. The generic character is, head compressed, narrower than the body; upper lip doubled, lower jaw narrow and pointed: teeth sharp pointed. Gill membrane

brane of seven rays. Body long, square. Tail-fin dilated. This species is *Tobianus*. Linnæus. This species inhabits the sandy shores of the Northern seas, and is known by the name of *tobian*, *tobis*, *faudaal*, *fandibz*, and *fand launce*. It is usually from nine to twelve inches in length, its general colour silvery white, greenish on the back.

The name is formed from *αμμος*, *sand*, and *δυνας*, *a diver*, expressing the quality of this creature, to dive into, or bury itself under the sand.

AMMON, or HAMMON, in *Antiquity*, an epithet given to Jupiter in Lybia, where was a celebrated temple of that deity under the denomination of Jupiter Ammon, which was visited by Alexander the Great.

There has been a great dispute about the origin of this name—Some derive it from *αμμος*, *sand*, because the temple was situated in the burning sands of Lybia; others borrow it from the Egyptian *anam*, *a ram*; as having been first discovered by that animal.—Others will have Ammon to signify the sun, and the horns wherewith he is represented the sun-beams. To this purpose Macrobius observes, (Saturn. i. c. 18.) that the inhabitants of Egypt worshipped the sun as the only divinity and soul of the universe; and they represented him under different forms, according to the various appearances of this luminary; in his infancy at the winter solstice, in his youth at the vernal equinox, or in spring, in his maturity at the summer solstice, and in his old age at the autumnal equinox.

The word Amoun, composed of Am ouein, shining, according to Jablonki (tom. i.) denoted the desired effects produced by the sun on attaining the equator, such as the increase of the days, a more splendid light; and, above all, the fortunate preface of the inundation and abundance.

Ammon is said to have been originally derived from Ham, the son of Noah, who first peopled Egypt and Lybia, after the flood; and when idolatry began to gain ground soon after this period, he was the chief deity of these two countries, in which his descendants continued. A temple, it is said, was built to his honour, in the midst of the sandy deserts of Lybia, upon a spot of good ground, about two leagues broad, which formed a kind of island or oasis in a sea of sand. He was esteemed the Zeus of Greece, and the Jupiter of Latium, as well as the Ammon of the Egyptians. In process of time these two names were joined, and he was called Jupiter Ammon. For this reason the city of Ammon, No-ammon, or the city of Ham, was called by the Greeks Diospolis, or the city of Jupiter. Plutarch says, that of all the Egyptian names which seemed to have any correspondence with the Zeus of Greece, Amon or Ammon was the most peculiar and appropriate. From Egypt his name and worship were brought into Greece; as indeed were almost all the names of all the deities that were there worshipped. Bryant's Mythol. vol. i. p. 5.

However this be, Jupiter Ammon, or the Egyptian Jupiter, was usually represented under the figure of a ram; though in some medals he appears of a human shape, having only two rams horns growing out beneath his ears.

The Egyptians, says Proclus, in Timæus of Plato, had a singular veneration for the ram, because the image of Ammon bore his head, and because this first sign of the zodiac was the preface of the fruits of the earth. Eusebius (Præp. Evang. lib. iii.) adds, that this symbol marked the conjunction of the sun and moon in the sign of the ram. Jupiter Ammon, the object of worship in every part of Egypt, was honoured in a peculiar manner at Thebes; and the Greeks, from this circumstance, denominated it Diospolis. Herodotus, Diodorus Siculus, and Pliny have

given particular descriptions of the magnificent temple of Ammon at Thebes; and although it was despoiled and ruined by Cambyses, there still remain vestiges of its ancient grandeur. In this temple there was a statue of Jupiter Ammon. The Ethiopians came down the Nile once a year to worship this deity at Thebes, and they had a small portable temple of this deity, which they carried with them to their habitations and to those of the Lybians, for the purpose of celebrating prosperous events by feasts and dances. This association for religious exercises of the Egyptians, Ethiopians, and Lybians, continued under the reign of Theodosius the younger. The Greek mythologists represent Bacchus, after his conquest of Asia, passing with his army through Africa, and reduced to distress for want of water; when his father Jupiter, assuming the shape of a ram, led him to a fountain where he and his exhausted troops were refreshed with water; and in gratitude for this seasonable relief they say, that he built a temple to Jupiter, under the name of Ammon, from *αμμος*, *sand*, alluding to the sandy desert where it was built.

AMMON, or BEN-AMMI, in *Scripture Biography*, the son of Lot, was the father of the AMMONITES, and lived about 1900 years before Christ.

AMMON, in *Entomology*, a species of FORMICA, with a double-spined thorax, petioled squama, and the two spines incurved. It is found in New Holland. Fabricius.

AMMON, a species of SCARABÆUS, found in America. Thorax, with three teeth; a recurved horn on the head; wing-cases striated. Linnæus.

AMMON, in *Ancient Geography*, a city of Marmarica, in Africa, which belonged to the Ammonii, according to Ptolemy; but Arrian says, that it was only a spot of ground in which the temple of Ammon was erected. It seems probable from Herodotus, (lib. iii. c. 25, 26.) that the Ammonii were a populous nation, and had a king of their own, though part of their territory could only be considered as a barren, sandy desert. From this ancient historian we learn, that Cambyses, having advanced to Thebes, in his way to Ethiopia, detached from thence a body of 50,000 men to lay waste the country of the Ammonii, and burn the temple of Jupiter Ammon; but that, after several days march over the deserts, a strong and impetuous wind blowing from the south, raised such a torrent of sand, as to overwhelm and destroy the whole army. Alexander the Great, about 200 years after this time, was more successful in his journey to that temple. Pliny places the temple of Ammon at the distance of about 12 days journey from Memphis, and mentions the Ammoniac nome of Egypt. Diodorus Siculus and Quintus Curtius (lib. iv. c. 7.) relate, that though this temple was surrounded by a sandy desert, yet its proper district abounded with trees bearing great plenty of fruit, and was ornamented with fountains. It had also several streets or villages in the neighbourhood of the temple, a castle fortified with a triple wall, and near it a holy fountain, called the Fountain of the Sun, because the qualities of the waters varied wonderfully every 24 hours; being warm in the morning, cool at noon, warm in the evening, and scalding hot at midnight. Strabo (lib. xvii.) informs us, that, under the reign of Augustus, the verses of the Sybils, and the Tuscan divinations, had depreciated the reputation of the oracle of Ammon; and in the 13th century it was forgotten; though the Arabs assert, that the district, in which it was situated, was still inhabited. The Fountain of the Sun, described by Quintus Curtius, was nothing more, according to their account, than a hot spring, which seemed to be warmer in the night than in the day.

AMMON, in *Zoology*, a species of OVIS, or sheep, in Gmelin's

Gmelin's Linnean system; the characters of which are, that the horns are large, unidirectionally arch'd backward, and divergent, wrinkled on their upper surface, and smooth on the under side; and the neck has two pendant hairy wattles. This is the capra ammon of the Syll. Nat. hircus, or capra orientalis of Brisson, muson et ophion of Pliny, muson, or muson of Gesner, muson et tragelaphus Bellonii of Ray, tragelaphus, or muson of Klein, rupicapra cornibus arietinis of J. G. Gmelin nov. com. petrop. ovis ferri Sibirica, vulgo argali dicta of Pallas, mouflon of Buffon, stepule baranni of J. G. Gmelin, It. Sibir. lamoni barani oder musmons of Steller, das wilde schaf, et der weisser der alten of Gesner, thierb. orientalisches schaf of S. G. Gmelin, wild sheep of Pennant, and Siberian chamois of Brisson. It inhabits, in small flocks, the rocky and desert tracts of the Alpine region in the centre of Asia, in Kamtschatka, the Kurde islands, probably on the west side of North America and California, and more certainly on the highest mountains of Parbary, Sardinia, Corsica, Greece, and the deserts of Tartary. It is very wild, swift, and active, and fights violently with its horns, acquires its full growth in two years, and seldom lives more than 14; the female produces one or two lambs in the month of March. The general colour in Summer is a brownish ash, mixed with grey on the upper parts of the body, and a whitish ash on the lower parts; in Winter the former changes to a rusty grey, and the latter to a whitish grey; the tail is very short, of a whitish colour, and brownish at the tip; the hair in Winter is about an inch and a half long, which falls off in Spring, and in Summer the coat is very short; the ears are erect and sharp pointed; the eyes are large, and generally of a brown or blue colour; the horns, which arrive at their full size in three years, are whitish, angular, wrinkled transversely, large, close at their bases, and placed on the top of the head, rising at first nearly upright, reflected backwards, divergent, and turned downwards and outwards at their ends: those of the female are smaller and more hooked, but are sometimes entirely wanting; the horns of the old rams are said to grow to such an enormous size, that each of them weighs between 30 and 40 Russian pounds, and measures, with its curvatures, two Russian ells in length; the hind-legs are rather longer than the fore-legs, by which the animal is better adapted for running up hill than on level ground; the flesh and fat are esteemed great delicacies in Siberia; the Kamtschatkans clothe themselves with the skins of these animals. Mr. Pennant distinguishes between the Corsican argali, or ovis ammon Europea, and that of Siberia; though the difference seems to consist chiefly in colour; the former being of a brown colour tinged with tawny on the upper parts, with a white mark on each side pointing to the belly. A specimen, brought from Corsica to England by Paoli, differed from the above in colour, having a large white spot on the front of the neck, and being black on the shoulders. In Corsica this animal is denominated Musro. It is probable that the argali once inhabited Britain, as Boethius mentions sheep in St. Kilda larger than a he goat, with horns as big as those of an ox. In confirmation of this account, the figure of a muson has been discovered in a piece of Roman sculpture, taken from Antoninus's wall, near Glasgow. Buffon says, that the mouflon seems to be the primitive stock of all the different varieties of sheep.

The Kamtschatkans have not attempted to domesticate the argali; but they spend the Summer in hunting them on the wild and precipitous mountains on which they feed. Sometimes they set bent cross-bows in the paths through which they expect the argali to pass, in such a position, that

when the animal treads on a string leading to the bow, the arrow is discharged and lodged in its bowels. Sometimes they employ dogs in the chase. The dog never overtakes the wild sheep; but while the sheep's attention is engaged by the dog, the hunter, without being observed, approaches near enough to load it with a ball or an arrow. The Mongol and Tungus attack them in a different manner. They take out a great number of houses and dogs, and endeavour to encompass the flocks by surprise; but this is not easily done, as they are so swift, and so cunning, that when they distinguish, either by sight or by smell, the approach of an enemy, they infallibly make their escape.

AMMONIA, in *Agriculture*, a term applied to volatile alkali, a substance which has lately been found useful in vegetation. It is formed from the decomposition of all animal and some vegetable matters during the process of putrefaction. It has been suggested by Dr. Darwin, in his treatise on agriculture and gardening, that in the decomposition of water, which partially takes place after being absorbed by the roots of vegetables, the hydrogen, by its union with azote, produces ammoniac, which may contribute to the nutriment of plants by its mixture with oils, and thus producing soaps which become dissoluble in water, and also by decomposing insoluble saline earths, as gypsum or metallic salts, as vitriol of iron, and by this means producing more soluble or innocuous saline matters in the soils.

AMMONIA, in *Antiquity*, seals celebrated at Athens, mentioned by Hefychius.

AMMONIA, or VOLATILE ALKALI. Alkali volatile, *Ammoniaque*, Fr.—*Alkali fluchtiges*; *Harnsalz*, *urinsalz*, *fluchtiges*, Germ.

Under the article ALKALI we noticed some of the peculiar properties of the volatile alkali whereby it is distinguished from the fixed. We shall, in this place, give a more particular account of ammonia, which requires considerable notice from its high importance as a chemical agent, and from the numerous researches which have been made into all its properties and combinations, with more success than perhaps has fallen to the share of any other substance of equal value to the chemist.

As ammonia is never found native in an uncombined state, and is, in most cases, a *product* of various natural or artificial processes, we shall refer the reader to the articles ANIMAL MATTER, CARBONAT of ammonia, MURIAT of ammonia, and salt of HARTSHORN, for every thing that relates to the natural history of this alkali and its production in the large way as a manufacture, and shall here confine ourselves to the purely chemical description.

The volatile alkali (like so many other chemical agents) when perfectly pure and uncombined, is only known to us in the form of a gas; and, as it is the only one of the alkalies which is capable of assuming this form in any common degree of heat, the term *alkaline air*, used by Dr. Priestley and many other chemists, is synonymous with ammoniacal gas. This gas has the following properties: It possesses a most pungent smell, which, when strongly snuffed up the nostrils, provokes to coughing, and gives a temporary sense of suffocation, owing to the contraction of the fauces which it produces. To the taste it is highly stimulating and acrid, and quickly corrodes the skin of the tongue and lips, so that it cannot be taken into the mouth in the undiluted form with safety. It is speedily fatal to animals that are immersed in it, and it extinguishes a taper; but the flame of this last is first enlarged, and becomes of a pale yellow colour. Ammoniacal gas is, next to hydrogen, the lightest of all the gaseous bodies. Its specific gravity,

gravity may be reckoned about 0.735 (distilled water being 1000.) whereas atmospheric air is 1.23, or nearly twice as heavy as alkaline air. The absolute weight of 100 cubic inches of this gas at 30° bar. and 61° therm. is reckoned by Kirwan to be 18.16 grains. It is highly dilatable by heat, and at a very high temperature is decomposed. It is also very rapidly and copiously absorbed by most liquids, especially by water, and hence it cannot be kept over water; but, for the purposes of experiment, it must be confined in well closed bottles or over mercury.

Ammoniacal gas is given out during the distillation of almost every animal, and some vegetable matters, but it cannot in this method be procured sufficiently pure for chemical experiments. For this purpose the muriate of ammonia (or common crude sal-ammoniac is the most convenient material for yielding the gas. This salt is readily decomposed by quicklime, which last unites with the muriatic acid of the salt, and expels the ammonia in its purest and most caustic form of gas. The decomposition is so speedy, that a very pungent smell of volatile alkali is perceived merely on rubbing together these two substances. If one part of dry sal-ammoniac is mixed with two parts of well burnt lime (or less if the lime is good), put into a dry phial or earthen tube, and heated gently, the ammoniacal gas rises in great abundance, and may be directed by means of a bent tube under a jar full of dry mercury, where it may be preserved in the gaseous form for any length of time. Many of the metallic oxyds, especially minium or litharge, will supply the place of the lime and expel the gas from the muriate of ammonia in very great purity. A still more simple method of obtaining the gas is to apply a gentle heat to the liquid or watery solution of ammonia, which expels from it the alkaline air that the water had previously been made to absorb at a lower temperature. It may be remarked that the discovery of ammonia in a gaseous form, as well as many of the most interesting properties of this alkali, is due to Dr. Priestley.

Ammonia, dissolved in water (forming the *liquid ammonia* of modern chemists, the *fluor volatile alkali* of former times, or the *aqua ammoniæ puræ* of the London Pharmacopœia) is the form in which the caustic ammonia is the most familiar to us, and in which many of the properties of the alkali can be most conveniently examined. This when pure should be perfectly transparent and colourless as water, should have the strong burning taste and pungent smell of ammonia, and should give no effervescence with acids. This latter test deserves attention on account of the variety of volatile alkaline liquors that are prepared, all of which, except the *aqua ammoniæ puræ*, contain more or less carbonic acid, and are much milder in all their sensible properties.

Ammoniacal gas is absorbed by water with great rapidity, and at the same time a considerable quantity of heat is given out from the gas, which is sufficient to raise the temperature of the water, and to be sensible to the hand. The same gas, when put in contact with ice, melts it with apparently as much rapidity as if the ice were put into a fire, and is greedily absorbed, at the same time that considerable cold is produced. At a moderate temperature water may be made to dissolve nearly one third of its weight, or many hundred times its bulk, of this gas. The bulk of the water is so much increased by this process that it becomes specifically lighter than distilled water. Mr. Davy, in his experiments on this subject, (Researches into nitrous Oxid, 1800.) found that at the temperature of 52°, 100 grains of liquid ammonia, holding in solution 9.502 grains of the alkali, gave a specific gravity of .9684. When

perfectly saturated, 100 grains of the liquid alkali contained 25.37 grains of ammonia, which is still one-third of the weight of the water employed, and had the specific gravity of .9054. Other writers, however, make the specific gravity of saturated liquid ammonia as little as .897. The gentle heat of a spirit lamp again expels the alkali in the form of gas, but the last portions require a strong ebullition before they can be made to quit the water. When liquid ammonia is exposed to a very intense cold, sufficient to freeze mercury, as Messrs. Foureroy and Vauquelin have observed, it becomes a grey semi-transparent mass, of the consistence of a very stiff jelly, and with scarcely any odour.

The liquid ammonia is prepared in two methods. That which is the oldest and the most usually practised, is to mix together quick-lime, muriate of ammonia, and water, and to distil the mixture with a gentle heat. The London Pharmacopœia orders for the preparation of the pure liquid ammonia, two pounds of lime slacked in two pints of water, and one pound of sal-ammoniac, which are to be mixed with six pints of hot water, and to be kept in a covered vessel till cold. The liquor is then to be distilled, and the first pint which comes over is the pure liquid ammonia. This liquor, however, is by no means saturated with the alkali, for during the heat, even of a gentle distillation, the solvent power of the water is much lessened. The most elegant and effectual way of preparing this liquor is to disengage the gas from the *dry* materials; and by using the beautiful APPARATUS of Woulfe, to cause the alkaline air to pass into cold water where the absorption is much more speedy; and if necessary, the increase of temperature produced by this absorption may be prevented by surrounding the bottles with ice. The proportions of the ingredients here used, may be two parts of lime slacked in as little water as possible, mixed with one part of dry muriate of ammonia and put into a retort for the production of the gas; and in the condensing bottles, about as much water as the weight of the sal-ammoniac employed. The liquid ammonia is known to be thoroughly saturated with the alkaline gas, when the bubbles pass through the water undiminished, and no further absorption takes place.

Many of the combinations of ammonia with different chemical agents are highly curious and important; but as most of them produce alterations which depend on the decomposition of this alkali, they will be better understood by the reader, if we first relate some of the multitude of facts by which the analysis of ammonia has been ascertained. The constituent parts of the volatile alkali are, hydrogen (or the basis of inflammable air), and azot (the basis of phlogificated air), the proportions of these two substances are, about 29, (in weight) of the former, and 121 of the latter; and it may be remarked that this is the only simple combination of these two substances with which we are certainly acquainted. The proofs of this analysis we shall relate nearly in the order of discovery by the various eminent chemists who have thrown light on the subject.

Dr. Priestley was the first who remarked a very interesting change produced on alkaline air by means of electricity. For this purpose he confined a known portion of this gas in a jar over mercury, and passed a number of successive electric explosions and sparks. He found after every shock that the bulk of the confined air increased, and continued to do so till it had expanded to nearly three times its original bulk. The air was now much altered in its properties, for on letting up some water into the jar, scarcely any of the gas was absorbed, whereas before electrization every particle

ticle of it would have rapidly united with this fluid. The gas was found to be highly inflammable, and exploded when mixed with common air, in the same manner as the inflammable air procured from iron by an acid. The gas likewise after being a short time in contact with water had entirely lost its alkaline smell. The colour of the electric spark taken in the alkaline air was red, but white in the centre, when any considerable explosion had been taken.

The same eminent chemist likewise found alkaline air to be decomposed by passing through a red hot tube, though not so completely as by the electric spark. In performing this experiment he found the tube, through which the alkaline vapour had passed, lined with a black matter, and the liquor collected after this distillation also obscured with the same substance. This is probably owing to some fissure in the tube which admitted carbonaceous matter from the hot coals, as we shall mention hereafter. Another property of alkaline air, highly illustrative of its composition, is the reduction of several metallic oxyds which it effects when they are heated in contact with it. Dr. Priestley confined some litharge, or oxyd of lead, in this gas, and by heating it with a burning lens (a method of applying heat of all others the most accurate), he revived the lead in its metallic form, and a quantity of phlogisticated air remained. The red mercurial oxyd, or *red precipitate*, was heated in the same manner, and the mercury was revived, and at the same time a considerable quantity of *water* was produced so as to run down in drops on the sides of the jar, which before appeared perfectly dry. The red precipitate, however, gave out during this reduction a large quantity of uncombined dephlogisticated air, which appeared in the residual air after the reduction was completed. This, in another experiment with the same materials, united with some of the inflammable air contained in the alkaline gas and caused a considerable explosion. The antiphlogistic theory will readily explain the production of *water* during the experiment from the union of the oxygen of the red precipitate, and the hydrogen of the ammoniacal gas; but this fact more properly belongs to the subjects of WATER and PHLOGISTON.

These experiments were soon repeated by various chemists, and with similar results. Landriani found, that in passing ammoniacal gas through a tube heated white hot, the alkaline properties were entirely lost, inflammable air was produced, and likewise a small portion of carbonic acid sufficient to give a precipitate with lime water.

Van Marum, in his experiments on the effect of electricity on the gases, found the same results with ammoniacal gas that we have just mentioned. Two cubic inches and seven eighths of the alkaline gas were enlarged to four inches, and the air was no longer absorbed by water, and was highly inflammable.

Whilst the properties and composition of the volatile alkali were made the subject of so much ingenious and successful research by Dr. Priestley, they received full elucidation by the labours of one of the most eminent of the French chemists, M. Berthollet.

This excellent experimentalist found, that when the oxygenated marine acid is added to liquid ammonia perfectly caustic, a considerable effervescence takes place, and a quantity of gas is collected from the two liquids, which, when examined by the usual chemical tests, proves to be pure azotic gas. At the same time the oxygenated acid loses its peculiar pungent smell, and becomes converted into simple marine acid. The explanation given of these phenomena is, that the ammonia is decomposed by the oxygenated acid; the hydrogen of the alkali unites with the excess of oxygen contained in the acid, and forms water, which unites with the acid; whilst the azot, the other constituent part of the ammonia, appears uncombined in the form of gas. The gas was found by Berthollet to be azotic, both by the common methods of examination, and by its forming nitrous acid when united with oxygen by means of the electric spark, in the method that Mr. Cavendish had discovered. The same decomposition takes place if the oxy-muriatic acid and the ammonia are used in form of gas. See OXY-MURIATIC ACID.

This theory of the decomposition of ammonia was also beautifully illustrated by the same ingenious chemist, in his accurate and original experiments on the nature and preparation of fulminating gold. These will be given more at length under the article GOLD; but it may be here mentioned that the fulminating compound is formed by precipitating a solution of gold in aqua regia by the volatile alkali. This precipitate consists of the metal, of oxygen which it acquires during solution in the acid, and of a part of the ammonia employed to separate it from its menstruum, which is retained by the metallic oxyd, and which gives it the property of exploding in a very gentle heat. M. Berthollet ventured to explode small and known quantities of this preparation in copper tubes, and found the products to be water and azotic gas, and the oxyd of gold completely reduced. The ammonia therefore is here decomposed, its hydrogen produces water with the oxygen of the gold, and its azot is set at liberty in the form of gas. Some other of the metals which have a weak affinity for oxygen are reduced to a reguline state by means of the volatile alkali, which is also decomposed in the process. M. Berthollet also repeated Dr. Priestley's experiment of the analysis of ammoniacal gas by electricity, taking every possible precaution in order to ensure an accurate result; and the calculations deduced from it have been very generally acquiesced in, and confirmed by subsequent enquirers. For this purpose he passed a succession of electric sparks through 1.7 cubic inches of ammoniacal gas till it acquired its utmost degree of expansion, when it occupied 3.3 cubic inches, a degree intermediate between the results of Dr. Priestley and M. Van Marum. A certain quantity of this enlarged gas was then detonated with a superabundance of oxygen gas in Volta's eudiometer, whereby water was produced and the azotic gas of the ammonia remained unaltered. Then (assuming the quantity of oxygen entering into the composition of water to be to the hydrogen, as 74 to 145, according to the calculations of M. Monge, given in the Memoirs of the French Academy) M. Berthollet estimates the proportions of the constituent parts of ammonia to be 2.9, in *bulk*, of hydrogen, to 1.1 of azot, or, in *weight*, (assuming the hydrogen to be eleven times lighter than the azot) 150 grains of ammoniacal gas will contain 121 grains of azot, and 29 grains of hydrogen.—Journal de Physique for 1786.

The above are the principal facts which have been brought to prove the *decomposition* of ammonia. A number of others, equally important and curious, will throw light on the mode of its *formation* from the union of its constituent parts.

An accidental production of ammonia in circumstances where it had not been expected had frequently been remarked by various chemists. Dr. Priestley, in his numerous experiments on nitrous air, found by accident that when iron filings had been long kept in a jar, and moistened with a diluted solution of copper in the nitrous acid, a thick saline

saline red incrustation was formed, mixed with a green matter, which, when broken, had a strong smell of volatile alkali. Repeating the experiment he found that the same effect would be produced, though more slowly, by simply allowing iron to rust in nitrous air, when, after some weeks, the smell of volatile alkali plainly appeared. The nitrous gas likewise underwent a considerable change, being diminished about one third, and then supporting combustion in a high degree, which last property was, however, lost by washing in water, and a large residuum of phlogisticated air was left.

A production of ammonia, in somewhat similar circumstances, is likewise particularly noticed by Mr. Hauffman of Colmar. (*Journal de Physique* for 1787.) He relates, that on mixing nitrous gas with phlogisticated precipitate of iron, a large quantity of the gas is absorbed, leaving only a small residuum of phlogisticated air; and on adding caustic fixed alkali to the iron precipitate, a smell of volatile alkali is very perceptible, and a straw moistened with nitrous acid and held over the mixture also indicates the presence of ammonia by forming dense white fumes. Mr. Hauffman distinguishes accurately between the phlogisticated and the dephlogisticated solutions of iron, the former being formed by dissolving the metal in acetic acid, or in the vitriolic without previous preparation; and the latter being a solution in vitriolic acid of iron which has been previously precipitated from a nitrous solution, and is therefore fully dephlogisticated, or, as is now said, in the highest state of oxygenation. The same chemist employed the solutions of iron in various states, and found, that wherever nitrous gas was absorbed by the iron, a certain quantity of ammonia is also produced, which, he also observes, probably remains in union with the vitriolic acid till it is displaced by caustic fixed alkali. The properties of this compound of nitrous gas and oxyd of iron will be examined more particularly under the article EUDIOMETRY, as it is intimately connected with this subject.

Still further light was thrown on the curious phenomenon of the production of ammonia, by some interesting experiments of Dr. Austin. (*Philosoph. Transact.* for 1788, vol. lxxviii.) The composition of ammonia having been fully ascertained by the experiments of Priestley, Berthollet, and others, Dr. Austin attempted to produce the alkali by a direct union of its constituent parts. For this purpose he mixed inflammable and phlogisticated airs in different proportions, and added to them some of the acid airs in order to favour their combination, tried the effects of cold, of heat, of electricity; and lastly, he decomposed alkaline air, and endeavoured to reunite the identical parts, but in no instance could he succeed in forming ammonia from the constituent parts of this alkali, *when both were employed in a gaseous form.*

Hydrogen and azot, however, are certainly the constituent parts of ammonia, and their refusal to unite when in the form of gas led Dr. Austin to vary his experiments by mixing these substances together in such a manner that the hydrogen should be involved in an atmosphere of azotic gas just at the time when it was itself beginning to assume the gaseous form. This has with great propriety been termed the *nascent state* of a gas, and this experiment was suggested to Dr. Austin by another very striking production of ammonia from nitrous acid and tin, which we shall presently mention. He therefore inclosed in a glass tube some azotic or phlogisticated air, and along with it some iron filings moistened with water, which last were known to yield inflammable air after standing together for some hours; and this air therefore in its nascent state, or at the

instant of its formation, was in full contact with the azotic gas. To detect the minutest quantity of ammonia he also inclosed in the tube some paper stained with the blue of the rind of the radish, which is turned to green by alkalies. In twenty-four hours he found the colour entirely green. Another test was also used to indicate the presence of ammonia, which was paper stained with a solution of nitrated copper; the green of which was, in a few days, converted to blue, the proper colour of a solution of copper in ammonia. Dr. Austin found nitrous air to effect a much more speedy production of ammonia when used instead of the azotic gas. Atmospheric air will also succeed, but requires a longer time than the azotic air, so that ammonia should always be formed whenever iron in contact with water-rusts in the open air. In this formation of ammonia by the direct combination of its principles, it is necessary, as Dr. Austin observes, that the hydrogen should be only in the nascent state when it comes in contact with the azot, for if it is already in the form of gas it cannot be made to unite with the azot in any form so as to produce ammonia.

We may here remark, that this mode of effecting chemical union between bodies which, when uncombined, are only known in the gaseous form, (such as oxygen, hydrogen, and azot) by presenting one to the other when in the nascent state, should always be kept in mind in experiments of research, as it may be the means of very important discoveries in this difficult part of experimental chemistry. Mr. Kirwan, in his valuable experiments on hepatic air, observed the formation of volatile alkali when this air was mixed with nitrous gas. At the same time sulphur is deposited.

Another very striking experiment on the formation of ammonia, which is easily made and seldom fails of success, is the following. Take some powder, or filings of tin or zinc, pour on them some moderately dilute nitrous acid, which will act on them with great vehemence, and the disengagement of copious red fumes. After a short time stir into the mixture some quicklime or caustic alkali, and a very strong pungent smell of ammonia will be produced. In this case the ammonia is formed by the decomposition of the nitrous acid and the water, this ammonia instantly unites with a portion of the acid, forming nitrated ammonia, and the lime again decomposes this ammoniacal salt by simple affinity, and by displacing the alkali from its union with the acid, causes it to assume the gaseous form and to become evident to the senses.

Before we quit the subject of the composition of ammonia, we shall make a few observations on the decomposition of nitrous gas and nitric acid in the experiments above related, whereby the volatile alkali is produced. In the simpler methods of forming ammonia, such as in Dr. Austin's experiments, the union of the nascent hydrogen with azotic gas, the affinities which operate in forming the alkali, may be supposed to be tolerably simple. But when the nitric acid, or nitrous gas are used, the affinities appear to be extremely complex, and perhaps hardly made out with much certainty. It should be noted, however, that, along with the production of ammonia, there appears constantly a proportionate quantity of that singular gas discovered by Dr. Priestley, and called by him dephlogisticated nitrous air; and of late denominated *nitrous oxyd* by Mr. Davy, to whose highly ingenious "*Researches*" we are indebted for much important addition to this curious and difficult part of chemistry. It is a striking property of the nitrous oxyd to support combustion in a very eminent manner, and very similar to oxygen gas, although it contains a less proportion of oxygen, and more azot than *nitrous gas*,
which

which is unfit for combustion. This resemblance to oxygen gas in the nitrous oxyd has misled some chemists in the nature of the air left after the formation of ammonia from nitrous gas and nascent hydrogen, who have supposed a production of oxygen, and have been obliged to account for it accordingly. To explain the changes that take place with moistened iron filings, confined in an atmosphere of nitrous gas, we must observe, that the new compounds, which we know are formed out of these materials, are ammonia, consisting of azot and hydrogen, and nitrous oxyd, composed of much azot and little oxygen. The iron likewise is rusted or oxygenated. The source of the hydrogen in the new products may be supposed to be some of the water decomposed, from which the metal, in rusting, has abstracted its other constituent part, the oxygen. The only source of the azot (allowed by the antiphlogistic theory) is the nitrous gas, which is composed merely of this principle, and of oxygen. But if merely a portion of the azot of the nitrous gas was abstracted from it, the remainder, by losing azot, would be a substance containing (proportionally) *more* oxygen than nitrous gas; whereas, the nitrous oxyd, which is this remainder, contains less. There must, therefore, be an additional method of getting rid of this excess of oxygen, in order to produce a satisfactory explanation; and the only substance that offers is the hydrogen of the water decomposed by the metal, which may be supposed to unite with enough of the oxygen of the nitrous gas to reduce it to the state of nitrous oxyd. Thus then, according to this hypothesis, the metal decomposes the water, the hydrogen set at liberty by this decomposition unites with a small part of the azot of the nitrous gas to form ammonia, and with a greater part of its oxygen, to form water, and the residue of the nitrous gas is in that proportion and mixture which constitutes nitrous oxyd.

We shall not pursue this subject farther at present, as it will apply to all the cases of the production of ammonia by nitrous acid, and it may, perhaps, be thought too hypothetical to be further insisted on, though there are many similar examples to be met with, of very extensive and complicated affinities being set in motion by a single disturbance of the quiescent attractions of the constituent parts of any of the substances contained in the mixture.

Having now enumerated some of the leading facts by which the composition of the volatile alkali has been established, we shall proceed to mention some of the mixtures of ammonia with various chemical agents. It may be observed that though the uncombined volatile alkali is in the form of gas when pure, all its combinations are either solid or liquid, and hence every substance added to the ammoniacal gas causes an absorption of it where any chemical action takes place. However, the tendency to the aeriform state is so far retained by ammonia in all its combinations as to render them volatile, and to weaken its adhesion for them, whenever the temperature is raised to a certain degree. The force of affinity which ammonia exercises is therefore remarkably weakened by heat, where the substance to which it is united is naturally fixed in the fire, and many of the ammoniacal compounds at a high temperature are totally decomposed, and entirely new products result from the operation.

No union takes place by any simple mixture of ammonia with oxygen, hydrogen, or azotic gases. Under particular circumstances, and by the agency of complicated affinities, these substances may however be mutually decomposed, and new compounds produced. Thus, ammoniacal gas passed over heated oxyd of manganese forms NITROUS ACID, as discovered by the ingenious experiments of Dr. Milner.

Ammonia unites with all the acids with very great ease

and rapidity, forming with them very easily soluble salts. These will be particularly mentioned under the respective acids, but some of their properties may here be mentioned. The union of alkaline air with the acid gases, as discovered by Dr. Prickley, forms some of the most striking and beautiful experiments which chemistry furnishes. If ammoniacal gas is passed up into a jar containing carbonic acid there is a thick white fume immediately produced, the two gases by uniting lose their gaseous form, so that there is a complete vacuum suddenly made in the jar, causing the mercury over which it is confined to rise and fill it entirely, a sensible quantity of heat is given out, and a number of minute crystals of carbonated ammonia lining the inside of the jar, is the product of the mixture.

With the muriatic acid gas the appearances are exactly similar, only the white fume is still more dense and copious, the heat greater, and the union more rapid. Crystalline feathers of MURIATED ammonia are the result, and this furnishes one of the most striking instances of alteration in form, and in sensible properties, which two bodies may undergo by chemical affinity; for each of the ingredients when separate are in the state of an invisible gas with a highly pungent smell, and, when united, a scentless solid salt is the product. In making this beautiful experiment both the gases should be confined over mercury; and, on account of the much superior specific gravity of the acid gas over the alkaline, if the former is thrown into a jar of the latter, the white cloud will form slowly, beginning from the point of contact of the gases; but if the alkali be added to the acid gas, it rises through it immediately, and the combination takes place with great rapidity.

The nitrous acid unites with ammonia with great ease, and with the production of white fumes when the two substances are gaseous. The resulting salt NITRAT of ammonia possesses very interesting properties, which will be mentioned under that article.

It may be of use to know that the presence of ammoniacal gas, where it cannot conveniently be detected by the smell, will be readily shewn by holding a piece of glass rod or any other substance wetted with nitrous or muriatic acid, over the part where ammonia is suspected, when thick white fumes will be seen to form around the acid.

Phosphorus will not unite with ammonia at a low temperature. In a red heat the alkali is decomposed, and phosphorated hydrogen, and azotic gas are produced.

With sulphur, ammonia unites with some difficulty, forming the SULPHURET of ammonia, or *Boyle's fuming liquor*.

Charcoal and the volatile alkali do not unite in a moderate heat, but at high temperatures the alkali is decomposed, and, by particular management, that singular substance, the PRUSSIC acid, may be formed.

The affinity of ammonia for the different acids is much weaker than that of the other alkalies, and several of the earths. In several solutions of earths or metals in acids, where the affinity of ammonia for the acid is only in a small degree greater than of the earth or metal, only a part of the substance dissolved is precipitated by the addition of this alkali, and the solution retains the remainder, united with the ammonia, forming together an ammoniacal triple salt. Thus if to a solution of magnesia ammonia is added, part only of the earth is precipitated, and the remaining solution is an ammoniaco magnesian salt. Also the affinities of ammonia are much weakened by heat, owing to the great tendency to volatilization which the alkali possesses.

Ammonia has a very striking property of reducing to the metallic state (either entirely or partially) the oxyds of the several metals. This is performed, as we have already men-

tioned in the instance of fulminating gold, by a decomposition of the alkali, its hydrogen uniting with the oxygen of the metallic oxyd to form water, and its azot appearing uncombined in the form of gas. Thus, as M. Fomcroy has observed, (*An. Chym. tom. 2 & 6.*) if the black oxyd of manganese is moistened with liquid ammonia, and gentle heat be applied, the oxyd passes to the state of the white oxyd, (which is nearer the metallic state) and an effervescence with disengagement of azotic gas takes place. The red oxyd of mercury, treated in a similar manner, gives the same results, and the metal is left in the state of a black powder, which simple exposure to light and air will convert to globules of running mercury. This affords a ready way of cleaning the surface of mercury that has been tarnished and oxydated by acid vapours.

Some of the most difficultly reducible metals, such as manganese or tungsten, are on this account best prepared for reduction by being previously united with ammonia.

The volatile alkali may be made to unite with oils, so as to form ammoniacal Soaps; but this combination is less perfect than the fixed alkaline soaps, on account of the impossibility of applying heat to promote union without driving off much of the alkali in the form of gas. The volatile oils are equally soluble in ammonia with the fixed, an example of which is that union of oil of amber with ammonia, which forms EAU DE LUCE.

A great variety of vegetable and animal substances are dissolved or decomposed by this alkali, which renders it of the highest importance in the ANALYSIS of animal and vegetable matters.

The uses of the volatile alkali are numerous and important. To the chemist, as a re-agent of very extensive utility, it is an indispensable requisite, as there is hardly a single analysis of mineral, vegetable, or animal matter performed (where at all complicated) in which ammonia is not largely employed.

In medicine this alkali is highly valuable, on account of its strong and diffusibly stimulant properties. When taken internally, its first effect is generally upon the throat and fauces, owing to its partial volatilization by the heat of the mouth. Every one is familiar with its use in relieving faintings and sickness when snuffed up the nostrils, though from the great acrimony of the caustic ammonia, the milder form of the carbonated ammonia, or *sal volatile* is generally preferred. The strong and sudden stimulus which it gives to the system, when applied to the nostrils, renders it also one of the most powerful applications in many of the more serious suspensions of the vital powers. The pure liquid ammonia is much too acrid to be used by itself, even as an external application, but when mixed with oil it forms a very useful liniment for strains, indolent swellings, and any case in which a powerful stimulant is required. Simple agitation with oil will unite the two liquors into an uniform milky saponaceous liquid, in which the sensible properties of the alkali are only blunted and not neutralized. A peculiar use of the liquid ammonia largely diluted with water, and taken internally, is in checking the sudden and dreadful effects produced by the bite of venomous serpents.

Priestley on Air.—*Journal de Physique* for 1785, 6, and 7. —*Philos. Transact.* for 1788.—*Anal. de Chimie, tom. ii. & vi.* —*Davy's Researches, &c. &c.*

AMMONIA, in *Mythology*, an appellation of Juno, to whom the Eleans sacrificed, alluding, perhaps, to Jupiter Ammon.

AMMONIAC, *Gum*, or, as it is sometimes, though improperly, called, ARMONIAC, is a concrete, gummy, resinous juice, which is said to ooze from a plant of the umbelliferous kind, as may be inferred from the seeds and pieces of such a plant with which it is intermixed. Ammoniacum

is very analogous to Galbanum, and the former, as well as the latter, is probably procured from a species of the Bubon. The seeds that are found among the tears resemble those of anethum or dill, except that they are larger.

Dioscorides says, it is the juice of a kind of *ferula*, growing in Barbary, and that the plant which produces it was called *agafyllis*. Pliny calls the plant whence it flows *metopion*, and says the gum took its name from the temple of Jupiter Ammon, in the western part of Egypt, now the kingdom of Barca, near which it grew. At present it is brought here from Turkey, and from the East Indies.

The good ammoniac ought to be in dry drops, white within, yellowish without, easily fusible, resinous, somewhat bitter and nauseous, and of a very sharp taste and smell, somewhat like garlic. The white drops or tears are observed to change to a yellowish or brownish colour, on being exposed for some time to the air. It should not be mixed with any scrapings of wood, stone, or sand; this, by the Greeks, was called *ερασμα*, *fragment*. The other, which is full of stone or sand, was called *ζερασμα*, that is, *mixture*. It is purified from the seeds, small stones, &c. commonly intermixed with it, by softening or dissolving it in a little boiling water, pressing it, while hot, through a strainer, and then inspissating it to its former consistence. For internal use the larger and finer tears, unpurified, are preferable to the common strained gum.

From an ounce of this gum-resin six drams may be dissolved by spirit of wine, or six drams two scruples and a half may be dissolved by water. Neumann.

This gum softens by the heat of the fingers, and adheres to them. It is brittle when cold; it is easily melted in an iron spoon; applied to a candle it burns and fumes. The more milky grains are contained in it, so much the more excellent is its quality. If these only be selected it will require no purification.

Some say it served the ancients for incense in their sacrifices. It enters several medicinal compositions, and its principal virtue is that of resolving obstructions, in which intention it is frequently used in asthmas and difficulty of expectoration, in menstrual suppressions, and cachectic indispositions. In obstructions of the breast it is reckoned the most effectual of the aperient gums. It is most commodiously taken in the form of pills; the dose is a scruple, or half a dram, every night or oftener; in larger doses, as a dram, it generally loosens the belly. In phtisical cases, where no injury is to be apprehended from a stimulus, this gum may be elegantly combined with oxymel of squills, distilled water, and syrup. Applied externally, it is supposed to disperse hard indolent tumours; and for this purpose it enters into the composition of many plasters. Plasters formed with vinegar of squills, and with wine vinegar, have been employed for curing the fungus of the joints or dropsy of the knee, and are said to have proved effectual. Plasters of this kind applied to the head, and allowed to remain for six or eight weeks, have removed the tinea capitis. Dr. Cullen (*Mat. Med. vol. ii. p. 369.*) affirms, that he has seldom found the expectorant power of this gum very remarkable, and that the mischief arising from its heating qualities has more than counterbalanced the benefit obtained by its expectorant powers. He adds, that its efficacy in resolving indurated tumours is very doubtful, and that he has had no clear proof from experience of its having any such power.

Ammoniacum, triturated with water, dissolves into an emulsion, or milky liquor, lac ammoniaci, and in this form acts rather more powerfully than in the solid one of a pill. Simple penny royal water is commonly

monly used for this purpose, in such proportion, that four spoonfuls, that is, two ounces, of the emulsion contain thirty grains of the gum. Some have dissolved it in vinegar of squills, and thus obtained a very powerful but unpalatable expectorant. When these milky solutions are kept for some time they deposit a considerable quantity of resinous matter, and become clear. Impurified they yield an extract of no smell, and of only a weak bitterish taste. In distillation no essential oil is obtained, and the distilled water is but slightly impregnated with the flavour of the ammoniacum. In this respect ammoniacum differs remarkably from most of the other deobstruent gums, as assafœtida, galbanum, and sagapenum, which afford not only a strong distilled water, but an actual oil, containing the concentrated flavour of the gums. Lewis. Murray.

AMMONIAC, *sal*, in *Gemistry* and the *Materia Medica*. SEE MURIATE of Ammonia.

AMMONIACAL *preparations*, in *Pharmacy*. There are several pharmaceutical preparations, into which the volatile alkali, under one form or another, enters as a principal ingredient. Of these the only one in which the alkali is employed in its caustic state is the *aqua ammoniæ puræ*, (Pharm. Lond.) also called *caustic spirit of ammonia*, or *spirit of ammonia with quicklime* (*Spiritus ammoniæ cum calce viva*), the methods of preparing which have been described under *liquid ammonia* in the preceding article. It may be observed, that though it is called a *spirit* it only consists of water, impregnated with pure ammonia through the medium of distillation. The appellation "with quick-lime" is added to distinguish it from the simple *spirit of sal ammoniac*, which is prepared (from the distillation of muriated ammonia in both cases, but) with chalk, and is therefore not caustic, but carbonated, and effervesces with acids.

The several preparations of the CARBONAT of Ammonia, employed in medicine, will be mentioned more particularly under that article and HARTSHORN. The principal are the *prepared ammonia*, *ammonia preparata*, (Pharm. Lond.) *Sal volatile*, *salt of hartshorn*, which is the solid carbonat of ammonia in its pure state, prepared for the most part by sublimation of some of the neutral ammoniacal salts with chalk.

Aqua ammoniæ, (Pharm. Lond.) or *spirit of sal ammoniac*, is prepared by distilling muriate of ammonia, chalk, and water; and is in fact nothing but a solution of carbonat of ammonia in water, effected by the medium of distillation, and perhaps containing a small portion of the caustic ammonia, where the chalk is not perfectly mild. Sometimes this liquor is prepared with pearl-ash, or carbonat of pot-ash instead of chalk. The effect will be the same upon the ammoniacal liquor, only when the pearl-ash is used, as it is always in a semi-caustic state, it will render the volatile alkali somewhat less carbonated.

Spiritus ammoniæ, (Pharm. Lond.) *Spiritus salis ammoniaci dulcis sive vinosus*. This differs from the preceding in being a real distilled spirit, as proof spirit of wine is the menstruum employed for the alkali instead of water. The term *spirit* is therefore, in the present London Pharmacopœia, very properly confined to the ammoniacal preparations where spirit of wine is employed; and the term *water* of ammonia is adopted where this liquid is the solvent for the alkali.

The true spirit of ammonia is made the basis of several powerful compound preparations, in which either an aromatic oil and water, or a fetid gum, is united with the alkaline spirit, according to the intention which it is to answer. Of the former kind is the *Spiritus ammoniæ compositus*, or *volatile aromatic spirit*, prepared by dissolving bergamotte essence and oil of cloves in the alkaline spirit (either with or without the help of distillation); of the latter is the *Spiritus ammoniæ*

fatidus, in which a certain quantity of assafœtida is dissolved in the spirit. The ammoniacal spirit is likewise made the basis of some unctures, instead of simple spirit of wine, where the operation of the volatile alkali properly combines with that of the gum or resin dissolved in the mixture.

For external applications, both the watery and the spirituous solution of ammonia, and both caustic and effervescent, are employed according to the strength of the remedy required. The caustic solution makes by much the most rapid and permanent union with oils, whence it is preferred in that delicate preparation, the *EAU DE LUCE*.

AMMONITE, or SNARESTONE.

Cornu Ammonis—*Ammonita*—*Ophiomorpha*, Lat.
Ammonshörner—*Widderhörner*—*Pöschhörner*—*Belschnecken*—*Drachenslein*—*Schlangen*, Germ.
Corne d'Ammon—*Pierre de serpent*—*Cornette de Peshillon*—*Cornette chambrée*, Fr.

The ammonite is a fossile univalve many chambered shell, of a flattened spiral figure, containing many circumvolutions, which decrease in bulk gradually from the circumference to the centre; all the circumvolutions may be divided by the same horizontal plane, and therefore the whole of the spiral is visible on each of the flattened sides. From its resemblance to a ram's horn, or rather to the compressed spiral horn with which the figures of Jupiter Ammon are generally represented, it has derived its common name. The vulgar consider it as a petrified snake; hence its appellation of *snakestone*, &c. The least reflection, however, ought long ago to have destroyed this error, if men in general were as capable of finding out differences as they are willing to see resemblances. A snake always coils himself up, so as to have his head in the centre of the spiral, and therefore the volume of the spires diminishes as they approach the circumference, whereas in the ammonite precisely the reverse takes place.

Ammonites are found of all intermediate sizes, between those which are scarcely visible to the naked eye, and a specimen in the British Museum, above three feet in diameter, and weighing about one cwt. The number of circumvolutions, however, is by no means according to the size of the shell: there are few perfect specimens which contain less than six, and hardly any that exhibit more than twelve. Of some the external surface is smooth, of others it is rugose, or striated, or tiled, or toothed. In fact there seems to be included, under the term ammonite, a very large natural family of shells, agreeing in certain essential characters, but remarkably differing in others; not fewer than thirty different kinds have been found in the neighbourhood of Bath. Scheuchzer, in his "Natur. historie des Schweizerlandes," enumerates 149 varieties, and Rosinus has swelled the catalogue to nearly 300.

There are three species of fossil shells, which have been occasionally confounded with the ammonite.

The first of these is the nautilus, or fossil nautilus; and although the extremes of the two species are readily discriminated from each other, yet the intermediate varieties of the ammonitiform nautilus, and the nautiliform ammonites may without much impropriety be classed under either species. In general, however, the nautilus has much fewer circumvolutions, and these do not gradually increase in capacity from the centre to the circumference, as is the case in the ammonites, but the exterior volute is rapidly and largely dilated, so as to be of much greater dimensions than that which immediately precedes it.

The spurious ammonite, or umbilicite, in external appearance, has a great resemblance to the real ammonite, but totally differs in its interior structure by not being divided into cells or chambers.

The lituite is another spiral many-chambered shell, but may, without much difficulty, be distinguished from the ammonite, as its volutes are fewer, do not touch each other, and the exterior one approaches nearly to a straight line.

Of all the fossil shells ammonites are perhaps the most numerous and most generally diffused: they are found principally in calcareous strata, and are the only organised remains that have been met with at very great heights: De Luc has discovered them on Mount Grenier, 7800 feet above the level of the sea: they also occur in marl, slate, indurated clay, and argillaceous iron ore. The internal cavities of the shell are usually filled with calcareous spar, at other times the whole substance is penetrated with pyrites, and occasionally is met with completely agatized.

The race of animals, of which these are the remains, has probably been long extinct, no naturalist having met with living ammonites more than a few lines in diameter, and even these have been, for the most part, proved to be only nautilus. In the account of the ill-fated voyage of La Perouse is a memoir by Lamanon, describing a living ammonite, four lines in diameter, found in the stomach of a bonetta, caught in the South Sea, between the tropics; but this supposed ammonite, from the figure and description, is probably a nautilus; the exterior volute is by much the largest, and the number of circumvolutions is only two and a half. It was, indeed, an opinion of Linnæus, that living ammonites, corresponding to all the fossil varieties, were still existing in the depth of the ocean; hence they have obtained the name of Pelagian shells: this, however, cannot be proved, and is rendered improbable for the following reasons: first, the shell of the ammonite is very thin, whereas those of animals that live at great depths is always thick. Secondly, ammonites are almost always found mixed with turbines, baccina, and other common shells, which, while alive, are now known to inhabit shallow seas, and are daily thrown up on every coast; the living ammonite, therefore, if still in existence, would probably be found in similar situations, and be occasionally thrown upon the shore, together with those shells by which, in a fossil state, it is commonly found to be accompanied.

Schroter, vollständige einleitung in die kenntnis der Steine, vol. iv.—Schröter, Lithologisches real, &c. vol. i.—Linn. Systema Naturæ.—De Luc, Lettres a la Reine.—La Perouse's Voyage, vol. iii.

AMMONITES, in *Ancient History*, the descendants of Ammon, took possession of the country called by their name, after having driven out the Zamzumims, who were its ancient inhabitants. The precise period at which this expulsion took place is not ascertained; nor does history inform us to any great degree concerning the manners and customs of these people. They had kings, and were uncircumcised, (Jer. ix. 25, 26.) and seem to have been principally addicted to husbandry. They, as well as the Moabites, were among the nations whose peace or prosperity the Israelites were forbidden to disturb, (Deut. ii. 19, &c.) However, neither the one nor the other were to be admitted into the congregation to the tenth generation, because they did not come out to relieve them in the Wilderness, and were concerned in hiring Balaam to curse them. Their chief and peculiar deity is, in Scripture, called MOLOCH; and CHEMOSH was also a god of the Ammonites. Before the Israelites entered Canaan, the Amorites conquered a great part of the country belonging to the Ammonites and Moabites; but it was retaken by Moses, and divided between the tribes of Gad and Reuben. Before the time of Jephthah, ante Christ. 1188, the Ammonites engaged as principals in a war, under an anonymous king, against the Israelites. This prince, determining to recover the ancient country of the Ammonites,

made a sudden irruption into it, reduced the land, and kept the inhabitants in subjection for 18 years. He afterwards crossed Jordan with a design of falling upon the tribes of Judah, Benjamin, and Ephraim. The Israelites resisted the invader: and assembling at Mizpeh, chose Jephthah for their general, and sent an expostulatory message to the king of the Ammonites (Judges x. and xi.) The king replied, that those lands belonged to the Ammonites, who had been unjustly dispossessed of them by the Israelites when they came out of Egypt, and exhorted Jephthah to restore them peaceably to the lawful owners. Jephthah remonstrated on the injustice of his claim; but finding a war inevitable, he fell upon the Ammonites near Aroer, and defeated them with great slaughter. On this occasion the Ammonites lost 20 cities; and thus an end was put, after 18 years bondage, to the tyranny of Ammon over the Israelites beyond Jordan. In the days of Saul (1 Sam. xi.) ante Christ. 1095, the old claim of the Ammonites was revived by Nahash their king, and they laid siege to the city of Jabelh. The inhabitants were inclined to acknowledge Nahash as their sovereign; but he would accept their submission only on condition that every one of them should consent to lose his right eye, and that thus he might fix a lasting reproach on Israel; but from this humiliating and severe requisition they were delivered by Saul, who vanquished and dispersed the army of Nahash. Upon the death of Nahash, David sent ambassadors to his son and successor Hanun, to congratulate him on his accession; but these ambassadors were treated as spies, and dismissed in a very reproachful manner. 2 Sam. x. This indignity was punished by David with signal rigour. Rabbah, the capital of Hanun, and the other cities of Ammon, which resisted the progress of the conqueror, were destroyed and razed to the ground; and the inhabitants were put to death with circumstances of extreme severity. In the reign of Jehoshaphat the Ammonites united with their brethren the Moabites, and the inhabitants of Mount Seir, against this king of Judah; but their hostile attempts were resisted, and they were completely routed. They were afterwards overthrown by Uzziah, king of Judah, and made tributary. 2 Chron. xxvi. 8. But rebelling in the reign of his son Jotham, they were reduced to the necessity of purchasing peace at a very dear rate. After the tribes of Reuben, Gad, and the half tribe of Manasseh were carried into captivity by Tiglath Pileser, ante Christ. 740, the Ammonites and Moabites took possession of the cities belonging to these tribes, and were reproached for it by Jeremiah. Ch. xlix. 1. Their ambassadors were exhorted to submit to Nebuchadnezzar, in the typical language of the prophet, and threatened, on their refusal, with captivity and slavery. Ch. xxvii. 2, 3, 4. The prophet Ezekiel, ch. xxv. 4.—10, denounces their entire destruction, and informs them, that God would deliver them up to the people of the east, and that the Ammonites should no more be mentioned among nations; and this punishment they were to suffer for insulting the Israelites on account of their calamities, and the destruction of their temple by the Chaldeans. This punishment is supposed to have been inflicted upon them in the fifth year after the taking of Jerusalem, when Nebuchadnezzar made war against all the people around Judea, A. M. 3420 or 3421, ante Christ. 583. It is probable that Cyrus granted to the Ammonites and Moabites liberty to return into their own country, whence they had been removed by Nebuchadnezzar; for they were exposed to the revolutions that were common to the people of Syria and Palestine, and subject, sometimes to the kings of Egypt, and sometimes to the kings of Syria. Polybius (lib. v.) informs us, that Antiochus the Great took Rabbath,

or Philadelphia, the capital of the Ammonites, demolished the walls, and put a garrison into it, A. M. 3166, ante Christ. 108. During the persecutions of Antiochus Epiphanes, the Ammonites manifested their hatred to the Jews, and exercised great cruelties against such of them as lived in their parts. At length their city Jaser, and the neighbouring town fell a prey to the Jews, who smote the men, carried their wives and children into captivity, and plundered and burnt the city. Thus ended their long conflict with the descendants of Israel. About the beginning of the second century of the christian era they were thought worthy of being called a numerous nation. Julia Martyr says (*Dial. cum Tryphone*, p. 272.) that in his time there were still many Ammonites remaining; but about this period their name vanished, and they were blended with the Arabians; for Origen assures us in (*Job lib. i.*), that in his days they were only known under the general name of Arabians. In this respect the prophecy of Ezekiel above cited was literally accomplished. Josephus *Ant. l. v. c. 9. l. vii. c. 6, 7. l. xii. c. 12.* Prideaux *Conn. P. ii. book 4.* Calmet.

AMMONITIS, in *Ancient Geography*, the country of the Ammonites. It was a district of Arabia Deserta, extending from south to north to the east of Palestine. The limits to the west and partly to the north were the river Jabbok, which ran, according to Josephus, between Rabbath-Ammon, or Philadelphia, the capital of Ammonitis, and Gerafa, and fell into the Jordan. They had also the river Arnon on the west, which divided them from the land of Gilead, or the tribe of Gad; on the south they had the Ishmaelites, on the east the deserts of Arabia, and on the north the hills of Gilead and Bashan. The territories of the Ammonites seem, according to the sacred historians, to have been anciently confined by the river Arnon and Jabbok; but their frequent conquests on their neighbours occasioned their boundaries to be in a state of constant fluctuation. *Reland. lib. i. p. 104--113.*

AMMONIUS, in *Biography and History*, was general of Alexander Balas's troops, and accused by Ptolemy Philometer of a design to poison him. In his attempt to escape from Antioch, in the disguise of a female dress, he was apprehended and put to death, A. M. 3859, ante Christ. 145.

AMMONIUS, a Peripatetic, was a native of Egypt, and flourished about 140 years before Christ. He was the preceptor of Plutarch, and is frequently mentioned by him, without either commendation or reproach. He attempted to extend the authority of Aristotle beyond the limits of his own sect, by blending the Platonic and Stoic doctrine with the Peripatetic. He taught and died at Athens. *Suidas. Fabricius. Brueker's Phil. by Enfield, vol. ii. p. 104.*

AMMONIUS, Saccas, so called, as it is supposed, from his early occupation as a porter in the harbour of Alexandria, was an eminent Alexandrian philosopher, and flourished about the beginning of the third century. He was born of Christian parents, and was betimes instructed in the catechetical school established at Alexandria. Under the Christian preceptors, Athenagoras, Pantænus, and Clemens Alexandrinus, by whom this school was conducted, and who united Gentile philosophy with the Christian doctrine, he acquired a strong propensity towards philosophical studies, and became exceedingly desirous of reconciling the different opinions which at that time subsisted among philosophers. To him we must refer the complete constitution of the sect of the ECLECTICS, which had been first projected by Potamo, a Platonist. Porphyry asserts, that Ammonius passed over to the legal establishment, that is, apostatized to the Pagan religion. Eusebius and Jerom, on the contrary, affirm, that Ammonius continued in the Christian faith to the end

of his life. But it is probable, that these Christian fathers refer to another Ammonius, who, in the 13th century, wrote a Harmony of the Gospels, or to some other person of this name; for they refer to the sacred books of Ammonius; whereas, Ammonius Saccas, as his pupil Longinus attests, wrote nothing. Porphyry's testimony is more worthy of reliance than that of Eusebius, because he was nearer Ammonius Saccas than this Christian father, and he must have derived his information from his master Plotinus, who spent 11 years with Ammonius. Besides, it is not easy to account for the particulars related of this philosopher, without supposing that he renounced the Christian faith. It seems improbable that a Christian would have accepted the chair in a Pagan school, or would have been followed by disciples who waged perpetual war against Christianity. However, it sufficiently appears, that he was well acquainted with the Christian doctrine, and endeavoured to incorporate it into his system. According to Hierocles, Ammonius was induced to execute the plan of an Eclectic school, by a desire of terminating the contentions which had long distracted the philosophical world; and he bestows great praise on the institution of philosophy, which he established for this purpose; or with a view of evincing the harmony that subsisted between the doctrines of Plato and Aristotle in all the great and essential points, and introducing a system free from dispute.

Ammonius had many eminent followers, both Pagan and Christian. He taught his select disciples certain sublime doctrines and mystical practices, and was called *ἑρμῆσιος*, the heaven-taught philosopher. These mysteries were communicated to them under a solemn injunction of secrecy. Porphyry relates, that Plotinus, with the rest of the disciples of Ammonius, promised not to divulge certain dogmas which they learned in his school, but to lodge them safely in their pure minds. This circumstance accounts for the fact mentioned by Longinus, that he had left nothing in writing. Ammonius probably died about the year 243. Amongst those disciples who were admitted to the knowledge of his mysteries were Herennius, Origines, Longinus, and Plotinus. The two former violated their promise by divulging the secrets of the school of Ammonius; in consequence of which Plotinus thought himself no longer bound by his promise, and became a public preceptor in Philosophy upon Eclectic principles. *Porphyr. Vit. Plotini. Suidas. Fabric. Bib. Græc. tom. iv. c. 26. p. 154, &c. Lardner's Works, vol. ii. p. 414. Brueker by Enfield, vol. ii. p. 62, &c.*

AMMONIUS, a Christian writer of Alexandria, lived about the year 220, according to Cave, and though his time is uncertain, has been confounded by him and many other learned men with Ammonius Saccas. Eusebius mentions a person of this name, who was a presbyter of Alexandria, and suffered martyrdom in the Diocletian persecution; and we might be apt to think this to have been the writer, if Eusebius had not been of a different mind. St. Jerom speaks of Ammonius as an eloquent and very learned man, who, among many excellent monuments of his genius, composed an elegant work of the consent of Moses and Jesus, and invented the evangelical canons, which Eusebius of Cæsarea afterwards followed. The former is quite lost; of the latter we are informed by Eusebius, that Ammonius of Alexandria has left us a gospel composed out of the four with great labour, subjoining to Matthew's gospel the consonant passages of the other evangelists; and that he had composed, in another method, ten canons, which are there subjoined. The evangelic canons, though they are reckoned among the works of Ammonius, may have been probably Eusebius's invention, whilst the harmony of Ammonius might have suggested the design. Whether this harmony be still extant is a subject

a subject in dispute. Cave and Mill agree in supposing, that it is the larger of the two which we now have in Latin. Mr. Jo. James Wetstein will not allow this work to have been composed by Ammonius, but thinks it the production of some writer since Eusebius. Dr. Lardner supposes this work to have been interpolated since it was first composed, and even the form of it to have been altered.

AMMONIUS, the Grammarian, lived in the fourth century, and, according to Socrates, the ecclesiastical historian, was a pupil of the grammarian Helladius of Egypt. He fled from Alexandria in 389, when the heathen temples were destroyed by order of the emperor Theodosius. Photius speaks of him as a great admirer of the Greek poets, and an industrious critic in the Greek language; and to him we owe a treatise on Greek synonyms, entitled "*περί ομοίων και διαφορών λέξεων*," "On words of similar and different significations," in the form of a dictionary. It was first published in Venice in 1497, and afterwards at the press of Aldus, as an appendix to a Greek and Latin lexicon, published in folio, at Venice in 1524, at Paris in 1521, at Basil in 1532, and annexed to Stephens's Thesaurus in 1572, and to Scapula's Lexicon. Fabricius Bib. Græc. lib. iv. c. 26. tom. iv. p. 173.

AMMONIUS, a Peripatetic philosopher, was the son of Hermeas, flourished at the beginning of the sixth century, and taught at Alexandria under the reign of Anastasius. He was the disciple of Proclus, and the preceptor of Simplicius, Asclepius the Trallian, John Philoponus, and Damascius, by the latter of whom he is represented as superior to the other philosophers of his age, and particularly excelling in mathematical learning. His commentaries upon Aristotle and Porphyry are still extant. His commentary upon Aristotle's book, "De Interpretatione," together with a Commentary on the Categories, was printed by Aldus in folio, at Venice, in 1503. An extract from this work on Providence and the fore-knowledge of God, and free will of man, was published by Grotius, at Paris, in 1648, and at Amsterdam, in the third volume of his theological works, in 1679. His Commentary "In Isagogen Porphyrii de quinque Prædicabilibus," was printed by Aldus, at Venice, in 1500, and has passed through several editions. Fabric. Bib. Græc. vol. iv. lib. iv. cap. 26. p. 161.

AMMONIUS, ALEXANDRINUS, an ancient surgeon of Alexandria, called also Lithotomus, from having invented an instrument, a kind of file or saw, for breaking or dividing stones generated in the bladder, and which are too large to pass through the natural passages in their entire state. With what success this art, (which is obscurely hinted at by Celsus) was practised, we are not acquainted. It has long since been lost, and the title Lithotomist, given to persons cutting into the bladder, and extracting the stones through the wound. But those, Le Clerc observes, should rather be called Cystotomists. Haller, Bib. Chirurg.

AMMONIUS, ANDREW, a native of Lucca, who settled in England in the beginning of the 16th century, and lived for some time in the house of Sir Thomas More, and afterwards in St. Thomas's college, not being in circumstances that allowed his having a house of his own. At length he was appointed secretary to Henry VIII. and honoured by Pope Leo X. with a public character at the court of this prince; but his views of higher and more lucrative advancement were disappointed in middle age by his death, occasioned by the sweating sickness in 1517. He was distinguished by the intimate friendship and frequent correspondence that subsisted between him and Erasmus. Erasmus, in the humorous advice which he gives him as to the most effectual method of advancing his fortune, designed to satirize the usual methods that are adopted for this purpose. "In

the first place," says he, "throw off all sense of shame; thrust yourself into every one's business, and elbow out whomsoever you can; neither love nor hate any one; measure every thing by your own advantage; let this be the scope and drift of all your actions. Give nothing but what is to be returned with usury, and be complaisant to every body. Have always two strings to your bow. Feign that you are solicited by many from abroad, and get every thing ready for your departure. Shew letters inviting you elsewhere, with great promises." Erasmus Epist. xiii. lib. 8. p. 414. Erasmus (Epist. v. lib. 23.) thus laments his death. "How many of my companions have I lost! in the first place, Andriæ Ammonius of Lucca: Good God! what a sprightly genius! of what a faithful memory! how noble was his soul! how free from envy and every meanness! when his own qualifications, and the applause of princes had opened him a way to the greatest affairs, he was suddenly snatched off before he was forty years of age, the loss of whom I cannot but lament, as often as I reflect how delighted I was with his acquaintance!" What he writes to Erasmus in one of his letters, viz. that the burning of so many heretics had raised the price of wood, must be regarded as an hyperbole. Ammonius wrote some Latin poetical pieces. Gen. Dict.

AMMOSCHISTA, in *Natural History*, a genus of stones of a laminated structure, and splitting only horizontally, or into flat plates.

The *ammoschista* are coarse, harsh, and rough stones, of a very loose texture, and appearing something porous. They are considerably heavy, and composed of a large, coarse, and obtusely angular GRIT, surrounded, and in part held together, by a loose earthy spar. They are very soft, and friable in the mass, but much more so when reduced to small pieces. They make a violent effervescence with aqua fortis, and will not easily strike fire with steel.

The species of *ammoschista* are six.

AMMUNITION, in general, signifies all sorts of warlike stores and provisions, more especially powder and ball.

The word is *amentio*, which, according to Du-Cange, was used in the corrupt state of that language for *substance*.

Ammunition for small arms, in the British service, is generally packed in half barrels or kegs, each containing 1000 musket or 1500 carbine cartridges. An ammunition waggon will carry 20 of these kegs or barrels, and an ammunition cart 12 of them. The cartouch boxes of the infantry are made of so many different shapes and sizes, that it is impossible to say exactly what ammunition they will contain; but most of them can carry 60 rounds. See CARTRIDGE. The French pack all their ammunition in waggons without either boxes or barrels, by means of partitions of wood. Their 12-pr. waggons will contain 14000 musket cartridges, and their 4 pr. waggons only 12,000 each.

Ammunition, or gun-powder, may be prohibited to be exported at the king's pleasure, by 12 Car. II. cap. 4. sect. 13.

By 1 Jac. II. cap. 8. sect. 2. *ammunition*, arms, utensils of war, or gun-powder, imported without licence from his Majesty, are to be forfeited with treble the value. Such licence obtained, except for the furnishing of his Majesty's public stores, is to be void, and the offender to incur a prebend, and be disabled to hold any office from the crown.

Whoever is curious to know the quantity of ammunition necessary for the siege of a place, may consult the chevalier de St. Julian's treatise, *De la Forge de Vulcain*; and the quantity requisite for the defence of a place, will be found in Suiresg. de St. Remy's *Memoires d'Artillerie*. See ARTILLERY.

AMMUNITION-bread, shoes, &c. what is provided for, and distributed to, the soldiers of an army or garrison.

Such an officer has so many rations of ammunition-bread, &c.

AMMUNITION Cart, a two-wheel carriage with shafts, the sides of which, as well as the fore and hind parts, are inclosed with boards.

AMMUNITION Waggon, is generally a four wheel-carriage with shafts; the sides are railed in with staves and raves, and lined with wicker work, so as to carry bread, and all sorts of tools.

AMNA, in *Physical Writers*, denotes the water found in limy soils, and which is consequently tinged with a whitish colour, as in many places of England.

In this sense Paracelsus speaks of the medical virtues and uses of *amna*.

AMNESIA, in *Medicine*, loss of memory. It is sometimes a consequence of febrile diseases, generally receding as the patient gains his strength.

When it is the consequence of old age it can hardly be expected to be cured.

AMNESTY, or **AMNISTY**, from *α, not*, and *μνησις, I remember*; a kind of general pardon, which a prince grants to his subjects, by a treaty or edict, wherein he declares, that he forgets and annuls all that is past, and promises not to make any farther enquiry into the same.

The word is *αμνηστια, amnesia*; which was the name of an ancient law of this kind, passed by Thrasybulus upon the expulsion of the thirty tyrants out of Athens. Andocides, an Athenian orator, whose life is written by Plutarch, and of whom we have an edition of the year 1575, gives us, in his Oration upon Mysteries, a *formula* of the amnesty, and the oaths taken thereupon.

Amnesties are usually practised upon reconciliations of the sovereign with his people, after rebellions, general defections, &c.

Amnesty is either general and unlimited, or particular and restrained, though most commonly universal, without condition or exceptions; such as that which passed in Germany, at the peace of Osnaburgh, in the year 1648.

Amnesty, in a more limited sense, denotes a pardon granted by a prince to his rebellious subjects, usually with some exceptions; such was that granted by king Charles II. at his restoration.

Amnesty also, in a military sense, signifies the pardon granted by a sovereign to deserters, on condition of their rejoining their regiments.

AMNIAS, in *Ancient Geography*, a river of Paphlagonia, that rose in the country called Domanitis, north west of Germanicopolis, and discharged itself into the gulf of Amisus.

AMNICA, in *Conchology*, a species of **TELLINA**. Shell somewhat heart-shaped and transversely grooved with an obtuse protuberance. Linnæus. This is an European shell, and inhabits pools and ditches; it is less globose than tellina cornea, but about the same size. Inside blue, shining; out side whitish or yellow brown, with one or two blackish ribs. Young ones entirely white and pellucid.

AMNIMODAR, in *Astrology*, the planet that rectifies a geniture, or rather a method of rectifying a nativity, and finding the precise degree in the horoscope at the time of an infant's birth, from the condition of the planet, which had the rule in the last preceding conjunction, or opposition of the luminaries. *Vital. Lex. Math.*

AMNIOS, or **AMNION**, in *Anatomy*, the innermost membrane of the ovum, which contains the fœtus and the waters.—The word seems to be derived from *αμνος, a lamb*; *q. d. pellis agnina, lamb's skin*. See **GENERATION**.]

AMNIOS, liquor of the, chemical properties of. **Al-**

though the analysis of vegetable and animal substances is as yet less satisfactory than that of inorganic matter, a multitude of improvements have, nevertheless, been introduced of late years into this branch of the science for which we are principally indebted to the French philosophers. Vauquelin, Berthollet, and Fourcroy, by abolishing the old method of analysis by fire, according to which all animal substances afforded the same results, and introducing in its stead the use of the simpler menstrua, have been enabled to discover many peculiar products of animalization. According to the ancient mode, in which Neumann was so long and so fruitlessly employed, of destructive distillation, any animal matter was made to yield first an insipid, faint-smelling phlegm, then an impure ammoniacal oil, after which a portion of concrete salt was sublimed, and there remained in the retort a spongy coal of difficult incineration, which, by burning in an open fire, was reduced into a white ash or caput mortuum. If this had continued to be the way of analysis, we should have contented ourselves with giving an instance of one as a specimen of the whole; but since a better method has been found out, it will be right to particularize, in their proper places, most of the modern analyses and experiments on animal substances, as, if not quite satisfactory, they are at least well deserving of mention, in a work like the present, and have already been applied to explain the *rationale*, and improve the practice of some of the most difficult and important among the arts and manufactures.

The liquor of the amnios is a fluid in which all the young of the mammalia are inclosed previously to their birth; and chemistry is indebted to Vauquelin and Buiva for an examination of this secretion, as afforded by the human female and the cow.

The first of these liquors presented the following properties. It has a mild faint odour, like that of all the white or colourless animal fluids. To the taste it is slightly saline. Its colour is a dilute white, owing to its containing some particles of a caseous matter; by filtration, however, it becomes perfectly transparent. Its specific gravity is = 1.005. By agitation it froths considerably. On being heated it acquires a femiopacity like that of milk with a large proportion of water, at the same time a smell is developed like that of boiled white of egg. It decidedly changes the colour of tincture of violets to green, and yet slightly reddens that of tournesol. Potash occasions a flocculent precipitate, resolvable by a weak acid. The acids appear to have no other effect than that of clarifying it. Alcohol throws down a light precipitate, which, when dry, becomes brittle and transparent like glue. With infusion of gall-nut it yields a very copious brown precipitate. Nitrat of silver causes a white precipitate insoluble in nitric acid.

Hence this fluid appears to contain albuminous matter, similar to that of the blood; a muriatic salt, probably muriated soda; and a small quantity of free or carbonated alkali.

When evaporated to dryness it leaves a residue no greater than 0,012 of the mass. This, by lixiviation and evaporation, affords crystals of common salt and carbonated soda, and the remaining animal matter, on being burnt, exhales a fetid ammoniacal odour like horn, and leaves a few white ashes, composed of carbonated soda, and phosphat, and carbonat of lime.

The amniotic liquor of the cow remarkably differs from the preceding.

It is of a brownish red colour; an acid bitterish taste; an odour approaching to that of vegetable extract; its specific gravity is = 1.028, and it has a viscous consistence, like a solution of gum.

It reddens very decidedly the tincture of tournesol. It gives an abundant precipitate with muriat of barytes; and cep fits a large quantity of reddish matter, by the action of alcohol.

When submitted to evaporation a thick scum rises to the surface, and after being reduced to a quarter of its bulk, a number of long acid needleform crystals are produced as the liquor cools; these being all deposited, and the matter further brought by evaporation to the consistence of honey, a fresh production of crystals takes place; these, however, differ in form from the preceding, and are sulphat of soda.

The extractive matter being separated from the acid crystals, and from the water which held them both in solution, by means of alcohol, assumes the appearance of a compact adhesive cement; in colour reddish brown, and of a peculiar indescribable flavour. It is readily soluble in water, to which it gives a viscosity, and the property of frothing by agitation; in this respect it resembles animal mucilage, but differs from this substance in not forming a jelly, nor combining with TANNIN. When exposed to the fire it swells greatly, and gives out at first an odour of burnt mucilage, then of an empyreumatic ammoniacal oil, and finishes with the disengagement of prussic acid. The coaly matter which it yields is bulky, easily incinerated, and affords a light white ash, composed of phosphated magnesia, with a slight trace of phosphat of lime.

The concrete needle-shaped crystals are brilliant, transparent, slightly acid, reddening the tincture of tournesol. They are scarcely soluble in cold water, but readily so in boiling water, from which by cooling they are deposited in long slender needles. This acid combines without difficulty with the caustic alkalies, forming a very soluble salt, but will not decompose the carbonated alkalies, except assisted by heat. It is separated from its alkaline combinations by the mineral acids, in form of a white crystalline powder. It produces no change in the aqueous solution of the alkaline earths, nor does it alter the nitrats of silver, lead, or mercury. By heat it is destroyed, exhaling an ammoniacal odour, mixed with that of prussic acid, and leaves a spongy coal. It is different in its properties from all the known acids, and may be received into the modern nomenclature by the name of the amniotic acid. *Annales de Chimie*, vol. xxxiii. p. 269.

AMNISUS, in *Ancient Geography*, a small river in the island of Crete, mentioned by Callimachus, Apollonius, and Suidas.

AMNISUS, a port in Crete, probably at the mouth of the above-mentioned river, in which the Cretans pretended, according to Pausanias, that Lucina was born, and where this goddess had a temple and was worshipped. Strabo says, that Amnisus was the port of the town of Cnossus.

AMNITÆ, an ancient people, who seem to have been the same with the SAMNITÆ of Strabo, whom he places in a small island to the west of Gaul, and near the mouth of the river Loire. According to him, the women were a sort of Amazons, who allowed intercourse with men only once a year, and who offered sacrifices to Bacchus.

AMNON, a river of Arabia Felix, according to Ptolemy.

AMODOCI, one of the mountains which encompassed the European Sarmatia, according to Ptolemy.

AMOENUS, in *Entomology*, a species of CURCULIO, described by Fabricius as a native of New Holland; it is black with two snowy-white spots on the thorax, and five on the wing-cases.

AMOEBEUM, in the *Ancient Poetry*, denotes a kind of poem, or composition, wherein two parties speak alternately in the same number of verses, but so as that he who answers, either goes beyond or contradicts the other.

The word is ἀμοιβῶν, signifying *mutual* or *alternate*. Hence also we meet with *epistola amabæa*. Such, e. g. are those of Pliny and Trajan.

AMOGABARI, a kind of ancient Spanish soldiery, in great repute for their bravery.—These are otherwise denominated by some writers, *almugaveiri*.

AMOGLOSSUS, in *Ichthyology*, a name of a peculiar kind of flat fish, somewhat resembling the sole, and called in some parts of England, the *lantern*. It is of a very slender, pellucid, and white body, never exceeds three inches in length, and is very smooth to the touch, being covered only with a number of very thin scales, which fall off on touching it. Its flesh is very finely tasted, and requires very little dressing.

AMOK, a term signifying slaughter, and used as the exclamation of the Bokanese slaves in the island of Batavia. These slaves, who are brought from the island of Celebes, when irritated by ill usage, are exceedingly dangerous; as in this case they intoxicate themselves with opium, sally into the street, and murder every person whom they happen to meet. This is called *running amok*, this word being the cry of these desperate wretches. Some have supposed, that from this practice Steele borrowed the idea of the mohock club, mentioned in the Spectator.

AMOL, or AMU, in *Geography*, a town of Asia, in the country of the Usbecks, in Independent Tartary, seated on the Gilon, 115 miles west of Samarcand. N. lat. 39° 30'. E. long. 64° 35'.

AMOMI, is used, by the Dutch traders, for what we otherwise call Jamaica pepper.

AMOMUM, in *Botany*, a genus of the *monandria monogynia* class and order, of the natural order of *scitominæ* and *cannæ* of Jussieu, the characters of which are that the *calyx* is a perianthium one-leaved, cylindraceous and unequally trifid; the *corolla* is monopetalous and funnel-shaped, tube cylindraceous, border three-parted, parts oblong and spreading; the nectary two-leaved or two-lipped, lower lip inserted under the upper segment of the corolla, spreading, almost erect, entire or three-lobed; the *stamina* have no filament, except the upper lip of the nectary, smaller than the lower, and opposite to it, acuminate or three-lobed the tip; along the middle or at the end of which grows longitudinally a large oblong anther, geminate, or divided by a longitudinal furrow into two which are one-valved; the *pisillum* has an inferior, oblong germ, style filiform, drawn through the future of the anther, stigma turbinate, obtuse and ciliate; the *pericarpium* a fleshy capsule, ovate, three-cornered three-celled, and three-valved; the *seeds* are several, covered with a sort of berried aril. Obs. The inflorescence is in a spike, on a distinct scape. Willdenow enumerates 11, Martyn 12, and Gmelin, in his edition of Linnæus, 20 species. 1. *A. zinziber* or *zingiber*, zingiber majus of Rumph. zingiber of Bauhin, inschi of Rheed, achter ingwer of Willd. narrow-leaved ginger, with a middle-sized (naked, G. and W.) scape, ovate spike, (ovate scales, W.) and leaves linear-lanceolate, (ciliate at the tip, W.) The root is creeping by palmate, compressed, fleshy tubers, which become fibrous with age; the culm annual, two feet high, single, solid, and upright; leaves half a foot long, smooth, alternate, on short, embracing petioles; the scape separate, eight inches high, thick, round, scaly, usually without leaves; the spike composed of large ovate, subacuminate, coloured scales, half closing the flowers; calyx a small double spathe; corolla yellowish green with a long slender tube, the segments of the body conical, and nearly equal; nectary reddish brown, ovate, petal-shaped, winged on each side at the base, and somewhat shorter than the corolla; filament, or upper lip of the nectary

tary filiform, placed on the corolla and shorter; anther ovate, cloven longitudinally, embracing the filiform style; stigma cylindrical, ciliate at the tip; capsule smooth, containing many oblong seeds. This species, cultivated here by Miller, in 1731, and flowering in September, is a native of the East Indies, and other countries of Asia, and is much cultivated there and in the West Indies. The dried roots furnish a considerable article of commerce from our West India islands; they are of great use in the kitchen and in medicine, and preserved green as a sweet-meat, are preferable to every other sort. For the dietetical and medical use of ginger, see GINGER. 2. *A. zerumbet*, zingiber latifolium sylvestre of Herm. lampujum of Rumph. katouinseli-kua of Rheed, block ingwer of W. broad leaved G. or zerumbet, with a naked scape, oblong, obtuse spike, subrotund scales, and leaves ovate and smooth at the margin. According to Murray, the *A. zingiber* is more aptly distinguished from the *A. zerumbet*, by its narrow leaves, called ensiform by Jacquin, than by the ovated spike, and the latter is more jolly distinguished from the former by its broad leaves than by its oblong obtuse spike, for the *A. zerumbet* has equally an ovate spike. This species has the tubers of the root much larger, round, twisted, thick, branched, horizontal, pale-coloured, with little smell and a bitterish taste, but not an ardent flavour like true ginger; culm four feet high, perennial, straight, round and solid like the preceding species; leaves lanceolate, large, smooth, petioled, embracing and ascending obliquely; the scape a foot high, distinct, thick, scaly and red; spike large, with rounded, close, one-flowered, red scales; calyx a single acute spathe; corolla pale, with a long tube; nectary of the same colour, petal-shaped, very blunt, bifid, fastened to the throat of the corolla; filament flat, subulate, bent in, adhering to the hinder segment of the corolla, and nearly equal to it; another oblong, fastened to the middle of the filament; cultivated at Hampton Court, in 1690, and flowering with us from September to November, when the stalks perish like those of the true ginger; a native of the East Indies, Cochinchina, &c. and also in Otaheite, and the other Society isles. This is used externally in the East in cataplasms and fomentations, but not internally, as spice or medicine; though Garcias says, that it makes a better preserve with sugar than the other. 3. *A. zedoaria*, with a naked scape, loose cylindrical truncated spike, and ovated acuminate leaves. This is the *A. latihumile*, with larger ovated acuminate leaves, and scape terminated by an oblong spike of La Marck, zedoaria longa of Bauhin, zedoaria officinarum of Petiv. zedoaria seu Indorum tamog of Cam. luz. kua of Rheed, zerumbet common of Rumph. and zittwer ingwer of W. This species grows in Malabar, and other parts of the East Indies. The flowers have an agreeable smell; the root has an acrid pungent, aromatic, and somewhat bitterish taste; its smell is strong, but pleasant; dried and reduced to powder it loses its acrid taste, and it is formed into bread by the Indians in a time of scarcity. See ZEDOARY. 4. *A. sylvestre*, paco ceroca of Piso, Braz. zingiber sylvestre majus, &c. of Sloane, wald ingwer of W. great wild ginger, with a naked scape, spike elongated, with oblong ventricose bractes, and leaves broad-lanceolate. This does not differ from the second species, except that the stalk rises eight or nine feet high, that it has much larger leaves, and that, instead of the flowers and fruits being on the end of the same stalk, they are on another about three feet high, immediately springing from the root. It is a native of the wood of Jamaica; the root is warm and stimulates gently, and may be properly administered as a stomachic and alexipharmic. 5. *A. mioga*, dsjooka vulgo mioga of Kämpfer, Japanischer ingwer of W. Japanese ginger, with a very short

scape, ovate capsule, and ensiform acute leaves. This approaches very near to the *A. cardamomum* of Java, in having the spike of flowers distinct from the leaves, and ovate capsules, but differs from it in having the scape more fasciated and shorter, not oblong and imbricate, the leaves ensiform, and merely acute, whereas in the other they are obovate-elliptic, with a long bristle at the tip; they are also much shorter, only about a span in length, but in the other they are often four feet long. In the leaves it much resembles *A. zinziber* and *A. zerumbet*; but the spike of flowers is radical, with scarcely any scape. It is a native of Japan, where it flowers in September. 6. *A. angustifolium* of Sonnerat, *A. Madagascariense* major, &c. of La Marck, schmalblattriger ingwer of W. narrow-leaved ginger, with a naked, very short scape, capitated spike, and linear-lanceolate leaves. The stem is eight or ten feet high, the pedal leaves are very narrow and linear-lanceolate, the scape very short, the spike globose, and few-flowered, and the capsules ovate. It is a native of the marshes of the island of Madagascar. The seeds have a pleasant aromatic taste; and their smell is agreeable; and hence, says Geoffroy, some have called them grains of paradise; a denomination that more properly belongs to another species. 7. *A. cardamomum*, cardamom, with a very simple and short scape, and alternate, loose bractes, or with the spike radical, sessile and obovate, and leaves obovate-elliptic and cuspidated, W. This species has thick fleshy roots, resembling those of the large flag iris, which in the Spring send forth many green reed-like stalks, that rise to the height of seven or eight feet, garnished with very long narrow leaves, alternate and embracing; the stalks decay in Autumn, and new ones arise from the roots in Spring; the roots thrive and increase, but it has not yet produced flowers in England. In Malabar cardamom is an object of considerable commerce. The Indians also themselves make great use of it, mixing the seeds with their bread, under a notion that it facilitates digestion. See CARDAMOM. 8. *A. villosum* of Loureiro, globba crispa rubra of Rumphius, rauher ingwer of W. with short reclining scape, linear bractes and villose fruit, or with very short, vaginated scape, roundish spike, and bractes lanceolate and longer than the flower. The smell of the whole plant is aromatic, mild, with a small degree of sharpness, the taste of the fruit, when fresh, sweetish and pleasant. It is a native of the mountains of Cochinchina; the seeds are much valued by the Chinese, and used medicinally in China. 9. *A. medium* of Loureiro, with spike cauline, branched; and fruit oblong, and streaked, without a valve. In Gmelin's Linnæus, *A. medium* is characterized as having an oblong three-cornered pyramidal coriaceous capsule and three valves. This species is a native of China, in the province of Yunan, to the west of Canton. The seeds are used in agues, for culinary purposes, and for increasing the strength of odours in general. 10. *A. minus*, with a subglobose, three-furrowed, coriaceous, valveless capsule. Gmelin. 11. *A. globosum* of Loureiro, with spike cauline, branched, and fruit globose, with an even surface; a native of the mountains of China and Cochinchina, and used in both countries medicinally, in disorders of the bowels, &c. 12. *A. hirsutum* of Loureiro, tsjane-kua of Rheed, paco-coatinga of Margrave and Piso, with spike cauline, simple, reclining, and fruit roundish and hirsute; or with stalks foliose and spiked, under-side of the leaves slightly hirsute, and large flowers of a yellowish white colour; a native of Cochinchina, Malabar, and of Brazil, in woods. La Marck suggests that this species is the *costus arabicus* of Linnæus. 13. *A. echinatum*, amomum 2. of Koenig, globba crispa viridis of Rumphius, flachlicher ingwer of W. with spike radical, sessile and subglobose, and capsules furrowed, echinated and globose;

globose; a native of the thick woods of India. 14. *A. repens* of Sunnerat, elettari 1, of Rheed, enfel of Herrn. kriechender Ingwer of W. with ramose decumbent scape, and lanceolate leaves, W. or procumbent scapes, racemose flowers in the base of the spathe, and leaves lanceolate and acuminate on both sides; a native of the mountains of Malabar. 15. *A. granum paradisi*, grains of paradise, elettari 2. of Rheed. paradis Ingwer of W. with scape branching and very short. This species is little known. It is a native of Guinea, and of the Islands of Ceylon and Madagascar, and was introduced into Kew Garden, in 1783, by Lee and Kennedy. See GRAINS of paradise. 16. *A. galanga*, MARANTA galanga of Linnæus, galanga of Rumphius, galangale, with cauline, erect spike, subtriflorous spathes, and capsule three-cornered-ovate, and smooth. The galangale has an horizontal, creeping root, composed of roundish, twisted, knotty tubers; culm perennial, upright, smooth and six feet high, leaves ovate, lanceolate, nerveless, smooth, upright, large, on embracing petioles; spike oblong; perianthium inferior tubulose, and bluntly trifid; corolla superior, yellowish white, segments oblong-ovate, concave, and nearly equal; nectary petal-shaped, roundish, emarginate, nearly equal to the segments of the corolla; filament linear, thick, grooved longitudinally, longer than the corolla; anther oblong, bifid, embracing a style longer than itself; stigma thickish, emarginate; seeds roundish; the smell of the whole plant is aromatic, and it has a biting taste. Linnæus has made the galangale a species of maranta, but Professor Martyn observes, that the corolla is not ringent, nor five-cleft, nor has two segments spreading, but all the segments, which are three in number, are nearly the same in size and figure. It is properly a species of amomum, as Bergius has made it. It is a native of China and Cochinchina, and is cultivated in both countries. The root and seeds are used there medicinally. See GALANGALE. 17. *A. arboreum* of Loureiro, with stem arboreous and calycine fruit. This is a tree about 10 feet in height, with many twisted, spreading branches. It has scarcely any taste or smell, and its use is unknown; the wood is very light, and not even fit for the fire; a native of the island of Sumatra, in a wood, on the eastern coast. 18. *A. curcuma* of Jacquin, with a scape, having loose spathes from the centre of the leaves. The limb of the corolla is sixfid. Gmelin. See CURCUMA. 19. *A. globba* of Koenig, and Rumphius, with stalks solitary, very short scapes, ovated spathes, and leaves alternate, petiolated, bifary, oblong and acuminate. Gmelin. 20. *A. littorale* of Koenig, with very short squamose scapes, ovated spathes, very numerous stalks, and leaves nodding at the apices. Gmelin. 21. *A. Koenigii*, with short scapes, cordated spathes, and leaves elongated at the apex and twisted. Gmelin. 22. *A. uliginosum* of Koenig, with scapes erect-curved, ovated spathes, single flowers, with double bractes, and sessile leaves. Gmelin. 23. *A. spurium* of Koenig, with solitary scaly scapes, ovated spikes, imbricated bractes, and leaves subpetiolated and oblong. Gmelin. 24. *A. scyphiferum* of Koenig, with spikes sessile, erect and oblong, imbricated bractes and sessile leaves. Gmelin. 25. *A. leonurus* of Koenig, with short scapes, erect and oblong spikes, adpressed bractes, and petiolated leaves. 26. *A. nigrum* of Gaertner, with a berry ovate-globose and single-celled, the base of the corolla funnel-shaped and coronated. Gmelin. Of the several species above-enumerated, the 11th, 2^d, 4th, 7th, 8th, 9th, 11th, 12th, 15th, 16th, 17th, are mentioned and described by Professor Martyn.

As to their propagation and culture, he observes, that they are tender, and require a warm stove to preserve them in this country. They are easily propagated by parting their roots, which should be done in the Spring, before they put

out new shoots. In parting the roots, they must not be divided into small pieces, especially if they are designed to have flowers, nor should they be planted in very large pots. They thrive best in a light rich earth, such as that of the kitchen garden; and with this the pots should be filled within two inches of the top, and the roots should be placed in the middle of the pots, with their crowns upwards, and the pots should then be filled with the same earth; they should then be plunged into a hot-bed of tanner's bark, and sparingly watered, till their stalks appear above ground, when they will admit of more moisture, especially in the Summer months; but in Autumn the waterings must not be frequent nor plentiful, and during Winter very sparing. The pots must constantly remain plunged in the tan-bed; for if they are taken out and placed on shelves in the stove, their fibres often shrink, and thus their roots decay. By this management these plants have greatly multiplied, and the common ginger has produced roots, weighing five or six ounces; but the others have been near a pound weight.

In the West Indies the ginger thrives best in a rich cool soil; in a more clayey soil the root shrinks less in scalding. The land laid out for the culture of it is first well cleared and hoed, and then slightly trenched, and planted in March or April; it flowers about September; and when the stalks are wholly withered, the roots are fit to be taken up, which is generally done in January and February. Browne cited by Martyn.

AMOMUM. See ALPINIA, COSTUS, MYRTUS, and SISON.

AMOMUM *Curcuma*. See CURCUMA.

AMOMUM *Plinii*. See SOLANUM.

AMOMUM, in the *Materia Medica*, a small and rich aromatic fruit, growing in bunches like grapes, valued highly for its medicinal virtues. It is commonly classed among the *seeds*.

The commentators on Pliny and Dioscorides, have never been able to agree upon the ancient amomum; the generality of them seek it in fruits different from our's. Some will have the rose of Jericho pass for it.—F. Camelli is positive he has discovered the real amomum of Dioscorides, and that it is the *tugus* or *birao*, or *caropi*, growing in the Philippine islands; the grains or berries whereof are worn by the natives about their necks; both on account of their agreeable odour, and of their supposed virtue in preserving from infection, curing the sting of the scolopendra, &c. Phil. Trans. N^o 248.

Scaliger is confident, that the amomum of the ancients was not a fruit, but the wood itself, which bore some resemblance to a bunch of grapes, and was particularly used in embalming of bodies, and hence, says he, the term MUMMY was given to the bodies of Egyptians, embalmed with it. On this account, likewise, all medicines and unguents used in the embalming and preserving of dead bodies, were called *amonia*.

The ancient amomum was of divers kinds; but the Armenian was most esteemed. It was a heater, drier, and astringent; used as a narcotic to appease pain, cure poisonous bites, inflammation of the eyes, &c.

The true amomum of the ancients resembles the muscat grape, and grows like it, in clusters; it is about the bigness of a large chich-pea, or middling grape, round, membranous, and divided into three cells, which contain several brown angular seeds; the fruit, on being opened, appears to contain three of them. Ten or 12 of these capsules stand together, without pedicles, upon a woody stalk, about an inch long; each single capsule is surrounded with six leaves, set in form of a star; and the part of the stalk, void of fruit, is clothed with leafy scales; of a very strong aromatic taste and smell; the taste is warm and pungent, approaching to that of camphor, and the smell is quick, penetrating,

and fragrant, resembling that of lavender, but more agreeable. In distillation they yield a large portion of a subtile essential oil; the hulks gave the same kind of flavours in a lower degree. These seeds have long been a stranger to this country.

This fruit was brought from the East Indies; and makes part of the composition of Venice treacle: but the seeds of the *amomum vulgare* have been used instead of it; and cloves have been also employed as a succedaneum to it.

The modern *amomum*, used in the shops, under the denomination of *amomum vulgare*, or *amomum officinarum*, appears to be the seed of the *sison* or *sumum* of the ancients, answering to what in English we call bastard-stone parsley.

It is esteemed a powerful diuretic, and good in nephritic cases. It is also commended as an aperient in general, and prescribed in obstructions of the liver and spleen, and in suppressions of the menses. The people in some parts of England bruise the seeds, and give them in warm ale, in colics; but those of caraway, or anise, are better. Lewis. See *Sison*.

AMONA, in *Geography*, a river on the coast of Guiana, west of Arwacas bay, is deep and navigable far into the country, and capable of containing a large fleet. It falls into the ocean about N. lat. 6°, and W. long. 55° 50'.

AMONA, a river of Italy, which runs into the Adriatic, about three miles south of the Po.

AMONOOSUCK, the Indian name of two rivers of America, in New Hampshire; the one called Upper Amonoosuck, rises near the north end of the White hills, runs northerly about 15 miles to a carrying place of about three miles to Amarisoggin river, thence it pursues the direction of south-west and west nearly 18 miles, and discharges itself into the Connecticut at Northumberland, near the Upper Coos; the other, called Great or Lower Amonoosuck, rises on the west side of the White Mountains, and falls into the Connecticut just above the town of Haverhill, in Lower Coos, by a mouth 100 yards wide. About two miles from its mouth it receives Wild Amonoosuck, 40 yards wide, from Franconia and Lincoln mountains. This last river is subject to very sudden and impetuous floods.

AMONTONS, WILLIAM, in *Biography*, an ingenious experimental philosopher, was the son of a lawyer, who removed from Normandy to Paris, and born in 1663. In very early life he was seized with a deafness, which deprived him in a great degree of the pleasures of social intercourse, and led him, for his relief and amusement, to apply with peculiar attention to the study of geometry and mechanics. From these studies he derived so much satisfaction, that he ceased to regret his defect of hearing as an evil, and declined, it is said, seeking any remedy. He also acquired the arts of designing, land-surveying, and building; and extended his researches to the sublime laws by which the universe is governed. He likewise directed particular attention to the nature and construction of barometers, thermometers, and hygrometers; and in 1687 he presented a new hygroscope to the royal academy of sciences, which was very much approved. In 1695 he published a book, in French, entitled, "Observations and Experiments concerning the Construction of a new Hour-glass, and concerning Barometers, Thermometers, and Hygrometers." To the royal academy, of which he was chosen a member in 1699, he read his "New Theory of Friction," by which he has admirably elucidated an important part of mechanics. He also discovered a method of conveying intelligence to a great distance, in a short interval of time, by means of signals, from one person to another, placed at the greatest intervals from which they could be seen with telescopes; somewhat in the manner of our modern telegraphs. He had

a happy talent in devising and executing experiments; and he communicated a great number of dissertations on the various subjects of air, action of fire, barometers, thermometers, hygrometers, friction, machines, heat, cold, rarefaction, pumps, &c. to the royal academy, which are contained in the volumes of its memoirs, for 1696, 1699, 1702, 1703, 1704, and 1705. His character for integrity, modesty and candour, was no less distinguished than his philosophical genius. His elogy, by M. Fontenelle, is printed in the volume of the Memoirs of the Academy for 1705. In October 1705, an inflammation of the bowels occasioned his death at the age of only 42 years. Gen. Dict.

AMOOD, in *Geography*, a town of Hindoostan, in the country of Guzerat, 51 miles north of Sæurat, and 58 south of Ahmedabad.

AMoor. See AMUR.

AMOPHILA, in *Entomology*, a name proposed by the Rev. Mr. Kirby for a new genus of hymenopterous insects, in the Transactions of the Linnæan Society, vol. iv. The species of this genus are *vulgaris*, *hirsuta*, *affinis*, and *argentea*; the two first are described insects, *vulgaris* being *sphex fabulosa* of Linn. and *Donov. Brit. Inf. and hirsuta*, *sphex arenaria* of Linn. and *Fabr.* The two others belong to the genus *sphexes* in the Linnæan arrangement by Gmelin also. See *Sphex*.

The essential character of Mr. Kirby's new genus *AMOPHILA* is, beak conic, inflexed, concealing a bifid, retractile, tubular tongue. Jaws forcipated, three teeth at the tip; antennæ filiform: either sex, with about fourteen articulations; eyes oval; wings flat; sting pungent, and concealed within the abdomen. The Linnæan character of the *sphex* genus is not strictly applicable to those insects Mr. Kirby has selected for his new genus, nor to many other exotic species; for the mouth of the Linnæan *sphexes* has no tongue. Gmelin has corrected this error by dividing the genus into families, the first has no tongue, and the second is furnished with one.

AMOR, in *Entomology*, a species of *HESPERIA* in the Fabrician system. Wings three-tailed, brown; beneath the disk variegated with white, black and yellow, and a golden marginal streak on the posterior wings. Fabricius. This is truly a *PAPILIO* of the *plebeii rurales* family in the Linnæan arrangement. It is the *papilio triopus* of Cramer, and inhabits the East Indies.

AMORA, in *Geography*, a town of Asia, in the Arabian Irac, situate on the Tigris, 120 miles south-east of Bagdad.

AMORÆANS, from אַמְרַי, *disit*, in *Literary History*, a sect or order of *gemaric* doctors, or commentators on the Jerusalem Talmud.

The word is otherwise written *amorai*, and *amoraitæ*, *amoraim*. The amoræans are also called, by Scaliger, *sophista*; by Alting, *γυμολογοι*, or *speakers of sentences*; by Bartoloccius, *dicentes*, or *disceptantes*, because they conferred and disputed together in a scholastic manner.

The amoræans succeeded the *miscenic* doctors. They subsisted 250 years; and were succeeded by the *seburæans*.

AMORBACH, in *Geography*, a town of Germany, in the circle of the Lower Rhine, 12 miles north-east of Heidelberg.

AMORDI, AMARDI, or AMARBI, in *Ancient Geography*, a people of Scythia, according to Pliny.

AMORE, in *Ichthyology*, the name of a tribe of fishes in Marcgrave's Hist. of Brazil, of which he describes three species. 1. The *amore pizuma*. 2. The *amore guacu*. And, 3. The *amore tinga*.

The *amore pizuma*, or *Gobijs pisonis*, in Gmelin's Linnæan system, has a very broad head, and a very large mouth, but has no teeth. Its body is oblong, and its back and sides are of a dusky iron colour. Its belly,

belly, which is protuberant, is white. Its skin is soft; and it has seven fins, besides the tail, which is rounded, at the end. Its flesh is firm and well-tasted.

The *amore guacu* is like the former, of an oblong figure; but it grows to six inches in length. Its head is thick, its gills large, and its mouth is furnished with small teeth. Its eyes are small, their pupil black, and the iris yellow. It has seven fins, besides the tail, which is long, and rounded at the end. This species is covered with somewhat larger scales, and is of a rusty iron colour, but somewhat paler on the belly than on any other parts.

The *amore tinga* is of the same shape with the former, but is much smaller, and is covered with whitish scales all over, but spotted with brown spots. Its tail is brown, and waved with different degrees of that colour. All the three species are eaten, but the first is esteemed the best. They are caught about the American shores.

AMOREVOLI, ANGELO, in *Biography*, a celebrated tenor singer in the serious opera, was a native of Venice. In 1740 he was the principal tenor in the king of Poland's famous opera at Dresden under the direction of his then maestro di Capella, Haffe. In 1742 he arrived in England with Monticella at the beginning of lord Middlesex's regency, and remained here 2 or 3 seasons. He surpassed in taste and expression all the tenor-singers of his time. He died in 1782.

AMORGO, in *Geography*, an island of the Archipelago north-west of Stampalia, which, in the time of Pliny (see H. N. lib. iv. c. 12.), bore the same name of Amorgos, or Amorgus: more anciently it was called Hypera, and Patage, or Plataga; and, according to Steph. Byz. Paucala, Pŷchia, and Carceŷia, containing three principal towns, viz. Arceŷinos, Minoë, and Ægiale. This island is not quite so large as Stampalia; its shores are less winding, and it has fewer capes and points, and of course fewer retreats to navigators. There are none along its eastern coast, which is very steep, and on its western shore there are not more than two tolerably commodious harbours or havens; the one to the north, is called *Porto Sant' Anna*, and the other to the south, which is the best, is denominated *Porto Vathi*. The inhabitants of Amorgo were formerly friends to the sciences and fine arts; but they are now devoted to ignorance and superstition. In the country, which gave birth to Simonides, the famous Greek poet, are now to be found no others than papas and caloyers, without genius and without knowledge, and distinguished merely by their credulity. They show, in a small chapel, a vase, which they affirm to be a certain oracle, and which the ignorant consult, in order to ascertain the issue of a voyage or enterprise: the vase full of water is a sign of success, but if it be almost empty, it announces ill fortune. The three ancient towns, Arceŷinos, Minoë, and Ægiale, are so completely destroyed, that their site is doubtful; and there remains only a little town, or village, built on an eminence, and monasteries, where miracles are the occupation and the principal revenue of the monks or caloyers, who inhabit them. High mountains, and naked and steep rocks, occupy some parts of the island, and in other parts it presents fertile plains and vallies. The abundance of its wines, oil, corn, and fruits, was renowned; and though it still subsists, in a less considerable degree, it has to surmount the obstacles and difficulties of a bad administration. A few districts are still well cultivated, and yield rich harvests; olive trees furnish a tolerably large quantity of oil, in proportion to the extent of the territory; figs are good and common; and the corn is of an excellent quality. That species of large grape with oval seeds, and a succulent and perfumed pulp, called by the Greeks *ox-eye*, and in France *raisin d' Alexandrie*, here becomes of a considerable size and

very delicious. Agriculture retains, in some degree, its ancient prosperity; but the arts, as well as the sciences that direct them, are extinct. At Amorgos are no longer fabricated those rich silks, which, under the name of *amorgis*, were in great request, both on account of the fineness of their tissue, and of the beauty of the colour with which they were dyed. The inhabitants, nevertheless, still apply themselves to dyeing; and they know how to give to their linen cloths a red colour with archil, a species of lichen which not only clothes the rocks of Amorgos, but also grows on those of several other islands of the Archipelago. Amorgos is distinguished by the mildness and affability of its inhabitants, and by the beauty of its women, who, attached to ancient habits, disguise themselves by the peculiarity of their dresses. In this respect they resemble those of NILO, and ARGENTIERA; with this difference, that the women of Amorgos pass a shawl, or large yellow handkerchief, made of fine wool, over the forehead and the lower part of the face, twill it round the head in the form of a turban, tie it behind, and suffer a long end of it to hang down the back. To this island criminals were formerly banished; and hither Tiberius exiled Vibius Senecus.

South of the island of Amorgos, and at the distance of about three leagues, is seen an uninhabited islet, which is called *Amorgo Poulo*, or *little Amorgo*. Between the same island and that of NAXIA, or to the west of the former, are other islets equally uncultivated and uninhabited, some of which, covered with lentisks (*lentiscus vulgaris* of Tournefort) small cypress-leaved cedars (*cedrus baccifera*, folio cupressi, &c. of Tournefort) and other wild plants, serve for the feeding of the flocks which are kept on them; while the others, which consist of steep masses of rocks, delitute of all verdure, are the abode of a multitude of birds of prey. Sonnini's Travels in Greece, &c. c. xiv. p. 173—180.

AMORIS POMUM, in *Botany*. See SOLANUM.

AMORITES, in *Ancient Geography and History*, were a people descended from Amorrhæus (according to the Septuagint) Hamori (אֲמֹרִי, according to the Hebrew) or the Emorite (in our version), the fourth son of Canaan, (Gen. x. 16.) who first occupied the mountains lying west of the Dead Sea. They also extend themselves to the east of the same sea, between the brooks Jabbok and Arnon, from whence they expelled the Ammonites and Moabites. This conquest of Sihon, king of the Amorites, is celebrated by the most ancient poem extant. Numb. xxi. 27—30. Numb. xiii. 29, 30. Joshua, v. 1. Judges xi. 19, &c.

When Moses sent messengers to Sihon, entreating a free passage through his country, he rejected his request; and marched out against him; but sustained a total overthrow at Jaazer, and lost his whole dominion. Og likewise, king of Bashan, who espoused the cause of Sihon, and attempted to stop the progress of Moses and his people, was vanquished, and fell in battle; and his whole kingdom was transferred to the Israelites. This conquest of the Amorites happened, A. D. 2553, ante Christ. 1451. The prophet Amos (ch. ii. 9.) representing their gigantic stature and valour, compares their height to the cedar, and their strength to the oak. The lands possessed by the Amorites on this side Jordan were given to the tribe of Judah, and those which they had enjoyed beyond Jordan to the tribes of Reuben and Gad. In Scripture, the name Amorite is often used for the Canaanites in general.

AMORIUM, a city of Asia Minor, which some authors place in Phrygia, but it was afterwards comprised in Galatia. It was in the territory of the Tolitobii, on the river Sangarius. After the 6th century it became an episcopal see, and at length the metropolis of the new Galatia. Michael,

Amorium, the father of Theophilus, the emperor of Constantinople, was a native of Amorium; and this original seat of the imperial life was adorned with many privileges and immunities; nor was Constantinople itself of much greater value in the estimation of the sovereign and his court. Amorium gives denomination to a war which subsisted between the emperor Theophilus and the Caliph Motassem, A. D. 838; when the emperor penetrated into Syria, besieged the obscure town of Sozopetra, the birth-place of the Caliph, took it, levelled it with the ground, and marked or mutilated the Syrian prisoners with ignominious cruelty. In revenge of this injury, Motassem prepared to attack Amorium. The name of Amorium was inscribed on the shields of the Saracens, and their three armies were united under the walls of the city. Although the wisest counsellors on this occasion proposed to evacuate the city, to remove the inhabitants, and to abandon the deserted buildings to the resentment of the barbarians, Theophilus determined to defend, in a siege and battle, the country of his ancestors. The Greeks, in a previous engagement, were repulsed and vanquished; and the emperor vainly hoped, after this defeat, to deprecate the fate of Amorium. But the inexorable Caliph rejected with contempt his prayers and promises, and detained the Roman ambassadors to be the witnesses of his great revenge. The vigorous assaults of fifty-five days were encountered by a faithful governor, a veteran garrison, and a desperate people; and the Saracens must have raised the siege, if a domestic traitor had not pointed out the weakest part of the wall, which was decorated with the statues of a lion and a bull. The vow of Motassem was accomplished with unrelenting rigour; nevertheless in the siege of Amorium above 70,000 Moslems had perished, and their loss had been revenged by the slaughter of 30,000 Christians, and the sufferings of an equal number of captives, who were treated as the most atrocious criminals. The Caliph's forces being distressed for want of water, in their return to his new palace of Samaria, in the vicinity of Bagdad, the Christian prisoners rose upon some of them and murdered them; by which action the Caliph was so much exasperated, that he put to death 6000 of the Greeks who had been principally concerned in that commotion. On the bridge of the river Lamus in Cilicia, one day's journey westward of Tarsus, 4460 Moslems, 800 women and children, and 100 confederates, were exchanged for an equal number of Greeks. They passed each other in the middle of the bridge, and when they reached their respective friends, they shouted *Allah acbar* and *Kyrie eleison*. Many of the prisoners of Amorium were probably among them; but in the same year (A. Heg. 231.) the most illustrious of them, the 42 martyrs, were beheaded by the Caliph's orders. Gibbon's Hist. vol. x. p. 67, &c.

The medals of Amorium were bronze, gold, and silver; and Greek medals were struck in this city in honour of Trajan, Caracalla, Geta, and Vespasian.

AMOROSO. in Ital. Mus. implies tenderly; with affection and supplication.

AMORPHA, formed of *a priv.* and *μορφη form*, in Botany, a genus of the *diadelphia decandria* class and order, and of the natural order of *papilionaceæ* or *leguminosæ*; its characters are, that the *calyx* is a perianthium one-leaved, tubulous, cylindrical and turbinate, mouth erect, five-toothed, obtuse, the two upper teeth larger than the others; permanent; the *corolla* composed of one ovate, concave petal, scarcely larger than the calyx, erect, inserted into the calyx, between the two larger and upper teeth, and placed at the upper side of it; the *filamina* have filaments very slightly united at the base, erect, unequal in length, longer than the corolla, anthers simple; the *pisillum*

has a roundish germ, subulate style, of the length of the filament, and simple stigma; the *pericarpium* is a legume, lunulate, reflex, larger than the calyx, compressed, more reflex at the tip, one-celled, and tubercled; the *seeds* are two, oblong kidney-shaped. There is one species, *viz.* *A. frutescens*, bastard indigo. La Murel mentions a variety, *β.* *A. foliis pellucido-punctatis leguminibus glabriscaulis*, which he supposes may be a constant species.

This shrub grows naturally in Carolina, where formerly the inhabitants made a coarse sort of indigo from the young shoots, which occasioned their giving it the title of *bastard indigo*. It rises with many irregular stems to the height of twelve or fourteen feet, with very long winged leaves, in shape like those of the common ACACIA. At the extremity of the same year's shoots, the flowers are produced in long slender spikes, which are very small, and of a deep purple colour; appearing in the beginning of July. After the flowers are past, the germen turns to a sharp pod, having two kidney-shaped seeds; but these do not ripen in England. They were sent to England by Mark Catesby in 1724.

This shrub, which Thunberg observed in the great island of Nipon belonging to Japan, is become very common in all the gardens and nurseries near London, where it is propagated as a flowering shrub, for the ornament of the shrubbery. It is generally propagated by seed, sent annually to England from different parts of America, which arrive in February, and are sown in a light soil; they may be also cultivated by laying down the young branches, which in one year will make good roots, and may then be taken off and planted, either in the nursery, or the places where they are designed to remain.

AMORTIZATION, or AMORTISEMENT, in Law, the act of turning lands into mortmain, *i. e.* of alienating or transferring them to some corporation, guild, or fraternity, and their successors.

The word is formed of the French *amortir*, to *extinguish*. See EXTINGUISHMENT.

The term is also used for the licence or privilege which the king or superior lord grants, to enable such a corporation, &c. thus to receive lands in MORTMAIN; which otherwise they cannot do.—There is always supposed to be some fine or acknowledgment paid to the king, or the lord, in consideration hereof; to make them satisfaction for several incidental dues and profits, which would have fallen to them in the common way, which are hereby cut off.

This practice was borrowed from the ancient *Lex Papiria*, whereby it was forbidden to consecrate any land to religious uses without the consent of the people. Cic. pro Dom. 49.

AMORY, THOMAS, in Biography, a presbyterian divine, was born at Taunton in Somersetshire, A. D. 1700. Having finished his preparatory classical education under Mr. Chadwick, he commenced his academical studies at a respectable seminary for the education of dissenting ministers, under the tuition of Mr. Stephen James and Mr. Henry Grove. In 1722 he began to officiate as an occasional preacher; and removed to London to pursue a course of philosophy under Mr. John Eames, an eminent tutor among the dissenters. In 1725 he became the colleague of his uncle Mr. Grove, in the department of classics and natural philosophy; and at the same time he preached occasionally at Hull Bishops, and some other places in the neighbourhood of Taunton. From the year 1730 to the year 1759 he was pastor of a congregation at Taunton; and in 1738 he succeeded Mr. Grove, and became sole tutor of the academy under his care. As a minister and a tutor he was much respected and esteemed, on account of his

his comprehensive knowledge, unimpeachable integrity, and exemplary moderation. In 1759 he removed to London, to the great regret of his friends at Taunton, but principally with a view of more advantageously settling his family; and accepted an invitation to become colleague with Dr. Chandler, and afternoon preacher to the congregation at the Old Jewry; and at the death of Dr. Chandler in 1766, he was chosen to succeed him as joint-pastor with Mr. White. His real merit entitled him to a greater degree of popularity than he experienced in the metropolis; but though his talents were not of such a nature as to command a numerous audience, he was distinguished by the respectful and cordial attachment of many judicious and liberal friends. In 1768 he received the honour of the degree of doctor in divinity from the university of Edinburgh; an honour to which his talents, learning, and character justly entitled him. He was morning preacher to the congregation at Newington Green, in connection with the celebrated Dr. Price, of whom a particular account will be given in the course of this work; and he was also appointed one of the six preachers at the Merchants' Lecture at Salter's Hall, and a trustee of the charities of the late Dr. Daniel Williams, whose library contains a valuable collection of books, and is, under its present regulations, daily improving both in extent and utility. He retained his faculties, and his capacity of usefulness, to his death, which happened in the year 1774. His funeral sermon was preached by his intimate friend Dr. Flexman; who, after an intercourse of more than 40 years, declared, "that their friendship had never once been interrupted by distaste, or darkened by a frown." Dr. Amory left a widow and six children, one of whom was for many years an eminent banker of the city of London. The subject of this brief memoir, as the writer of it can testify from personal acquaintance, was distinguished by a sound judgment and amiable disposition. His piety and benevolence were eminent features of his character, and were so intimately blended as to command respect and esteem from all who knew him. In the more advanced period of his life, his studies were chiefly directed to subjects of theology and ethics. His sentiments, with respect to some of the principal disputed points, coincided very nearly with those of Dr. Samuel Clarke; his mode of preaching was judicious, practical, and devotional: and though he did not attract the multitude, he approved himself to the sensible and candid. His sermons have been collected in two volumes, *viz.* first, "Eighteen sermons on various Subjects," printed in 1758, 8vo.; the second, "Twenty-two sermons on several Subjects," in 1765, 8vo. Dr. Amory also published "A Dialogue on Devotion, after the manner of Xenophon," with "A Translation of the Conversation of Socrates on the Being and Providence of God," 8vo. 1733 and 1746; "A Family Prayer-Book," 1763; "An Account of the Life and Writings of Mr. Grove," prefixed to his posthumous works, 1740; "Mr. Grove's System of Moral Philosophy, revised and enlarged," 1749; "Memoirs of the Life of Dr. Benson," prefixed to his history of the life of Christ, and "Memoirs of Dr. Samuel Chandler," prefixed to his four volumes of Sermons. He was also the author of "A letter to a Friend," on the study of religion, published in the memoirs of literature, 1731: of "Some poetical pieces, sacred and moral;" and of a volume of posthumous sermons, published after his death. Flexman's funeral Sermon. Biog. Brit.

AMOS, in *Scripture Biography*, the third of the twelve minor prophets, in the order of the Hebrew Scriptures, but the second in the order of time, was the son of a shepherd, and, though probably born in the territories of Israel, re-

tired to Tekoah, a village of the tribe of Judah, about five miles from Jerusalem. Under Uzziah, and Azariah, king of Judah, whose reign commenced in the 27th year of Jeroboam II. king of Israel, B. C. 804, Amos began to prophesy; but the precise year is not ascertained. Archbishop Newcome dates the commencement of his prophetic office in the year 823, B. C.; but Falconer in his "Chronological Tables," assigns it to the year 805, B. C. His first predictions were delivered at Bethel, whence he was driven back to his own country by Amaziah, the high priest of Bethel, who accused him before Jeroboam. These occur in the seventh chapter; and the others were pronounced in Tekoah, whither he retired after his banishment from Bethel. His two first chapters contain his prophecies against Damascus, the Philistines, Tyrians, Edomites, Ammonites, Moabites, Judah, and Israel; and the evils he threatened refer to the invasions of Salmanazer, Tiglath-pileser, Sennacherib, and Nebuchadnezzar. Amos also foretold the calamities that would befall the kingdom of Israel, after the death of Jeroboam II. who was then living; the death of king Zechariah; the invasion of Israel by Phul and Tiglath-pileser, kings of Assyria; the captivity of the ten tribes, and their subsequent restoration. He remonstrates against the prevalent iniquities of Israel, their effeminacy, avarice, and obduracy with regard to the poor, the splendor of their buildings and the delicacy of their tables. He reproves the children of Israel for their pilgrimages to Bethel, Dan, Gilgal, and Beerseba, which were the most famous at that period, and for swearing by the gods of these places. The style of Amos is characterized by its simplicity, and by frequent allusions to pastoral life. Jerom (*Proem. Comment. in Amos.*) referring to the words of St. Paul, calls him rude in speech, but not in knowledge. Succeeding writers, on the authority of this ancient father, have represented him, as if he were quite rude, and destitute of all the beauties of composition. But a very competent judge has given a very different opinion. Let any one, says bishop Lowth, (*Prælectiones de Sacra Poesi. præl. xxi. p. 286.*) who has sufficient discernment and candour for forming a just judgment, from the writings of this prophet and not from the man, turn over the volume of his predictions, and he will pronounce, that our shepherd is "not a whit behind the chief of the prophets." 2 Cor. xi. 5. He will think, that as in sublimity and magnificence he is almost equal to the greatest, so in splendor of diction and elegance of expression, he is scarcely inferior to any. The same celestial spirit indeed, as this excellent prelate adds, actuated Isaiah and Daniel in the court, and Amos in the sheep-folds; selecting always such interpreters of the divine will, as were best adapted to the occasion, and sometimes "from the mouths of babes and sucklings perfecting praise;" occasionally displaying the natural eloquence of some, and occasionally making others eloquent.

The time and manner of the death of Amos are unknown. It appears (2 Chron. xxvi. 22. Is. i. 1.) that Amos was the father of the prophet Isaiah, and of the family of Ashur, (1 Chron. ii. 24.) from whose son Tekoah derived its name. Calmet and many others, however, have thought that Amos the father of Isaiah, was a different person, and of royal rank; but there seems to be no sufficient reason for this opinion.

AMOS, or AMUS, in *Ancient Geography*, a city of Asia Minor, in Caria. Steph. Byz.

AMOTAPE, in *Geography*, a town of South America in Peru, situated near Tumbes, on the coast of the South Sea. The adjacent country, watered by a fine river, is highly improved,

AMOU, a town of France in the department of Landes, and chief place of a canton in the district of St. Sever, five leagues south of Tartas, and four leagues and an half south-west of S. Sever. The town contains 1731 and the canton 11,245 inhabitants; the territory includes 182½ kilometres and 17 communes.

AMOVING, in *Law*, the act of removing or expelling another from his place, office, or the like. We have statutes for removing papists out of London and Westminster, and ten miles round the same. 1 W. and M. cap. 9.

AMOVING a *guardian, a sereno castelo*. See *CUSTODE*.

AMOUR, WILLIAM DE ST. in *Biography*, a French ecclesiastic of the 13th century, was born at St. Amour, in Franche Comte, and became canon of Beauvais, and doctor of the Sorbonne. He distinguished himself in the controversy of 1228 between the Dominicans and the university of Paris. The Dominicans claimed two professorships in the university: but the secular doctors resisted their claim, and passed a law, restricting persons of the regular order to one. The dispute was referred to the court of Rome, and Amour was an able and zealous advocate in favour of the university. In a book "Concerning the perils of the last Times," he attacked the whole mendicant tribe, and attempted to prove, that the prophecy of St. Paul relating to the perilous times (2 Tim. iii. 1.) was fulfilled in the establishment of the friars of this order. The book was condemned by pope Alexander IV. and the author was sentenced to perpetual exile from France. Upon the accession of Clement IV. Amour returned to Paris, and in a collection and enlargement of his works, renewed his attack on the character and conduct of the mendicants. By favour of this pope, who respected his talents and merit, he remained unmolested till his death in 1272. The mendicants reproached him as a heretic; but by the doctors of the Sorbonne he was highly respected. His spirited remonstrances against idleness and hypocrisy, masked by humility and sanctity, justify the panegyric of Mosheim, who represents him as "a man of true genius worthy to have lived in better times, and to have adorned a more enlightened age." His works were published at Paris, in 4to. by Cordeus in 1632; but the editor concealed his name, and the place of publication under the enigmatical inscription, "Constantiæ ad insignem bonæ fidei apud alitophilos." Cave, H. L. tom. ii. p. 302. Mosheim. Eccl. Hist. vol. iii. p. 202.

AMOUSHE, RASEL, in *Geography*, the Battal of Edrisi, a large cape formed by the mountains of the Shenooah, on that part of the sea-coast of Africa, called the Western Province or the province of Tlemsan. At a small distance is the Mers 'el Amoushe, or port of Amoushe, which is very safe in westerly winds. Shaw's Travels, p. 20.

AMOY, an island on the south-west coast of China, where the English East India Company had once a factory, since removed to Canton. It lies west from the nearest part of Formosa island, somewhat more than 3° of longitude, and from the south-east point of China, which is east from Macao, about north north-east. The port of Amoy has been described as one of the most convenient and safe harbours in India, on account of the road which is formed by that island between it and the continent, and it is so deep and large as to be capable of receiving 1000 ships of the greatest size, and of protecting them from every wind. N. lat. 24° 30'. E. long. 118° 45'.

AMPARES, a jurisdiction under the archbishop of Plata, eastward of that city, in the empire of Peru; abounding in grain and cattle.

AMPANA, in *Botany*, a name given in the Hortus Malabaricus to a genus of plants, since described by Linnæus, under the name of BORASSUS.

AMPASA, in *Geography*, a small country and kingdom

of Africa, on the coast of Zanguebar, between the line and Melinda. It has a capital of the same name; the king is a vassal of the Portuguese. S. lat. 1° 30'. E. long. 60° 20'.

AMPATRES, a people of Madagascar, on the southern coast between Carembouli and Careanelli, who live in the middle of forests and subsist by plunder.

AMPELIS, in *Botany*, the *vine*. See *VINE*.

AMPELLIS, in *Ornithology*, a genus of birds in the Linnæan system, belonging to the order *passeres*. The characters of this genus are, bill straight, convex; upper mandible longell, and somewhat incurvated; each mandible notched. Nostrils covered with bristles. Tongue acute, cartilaginous, bifid. Linn. & Gmel. Dr. Latham's generic character of ampelis is somewhat different, viz. bill straight, convex, bending towards the point; near the end of the upper mandible a small notch. Nostrils hid in the bristles. Middle toe connected to the outer at the base.

Gmelin describes eleven species of this genus, *carnifex, carunculata, cyana, coccinea, coinga, cristata, garulus, maynana, pompadora, terfa, and variegata*, which see.

AMPELITES, or candle-coal. See *COAL*.

AMPELLA, or AMPULIA, in *Geography*, a city and seaport in Guatimalagulf, in that of Mexico, 350 miles south-east of the city of Guatimala, which carries on a brisk trade in cochineal, cocoa, hides, indigo, &c.

AMPELONA, in *Ancient Geography*, a colony of Milesians, in Arabia Felix, transported thither by the Persians.

AMPELOS, or AMPELUS, a promontory of the island of Samos, to the west of that island, and opposite to that of Icaria. *Ampelos* was also a promontory of Macedonia, according to Ptolemy, in the country called Parania; probably near the mouth of the Axios. *Ampelos* was also a town of Italy, in Liguria.

AMPELUSIA, called also *Cape Cottes*, is a promontory of Mauritania Tingitana, not far from Tingis, mentioned by Strabo, Ptolemy, and Mela. It is denominated by the moderns *Cape Spartel*. From Mela and Bochart it appears that Cottes and Ampelusia were, in the Phenician and Greek languages, terms of the same meaning, and that they were deduced from the grapes with which that country abounded. *Ampelusia* was also a town and promontory of Crete, now called *Capo Sagro*. It was also a town and promontory of Macedonia, near the gulf of St. Anne, and now called *Capo Canifiro*.

AMPERES, from *αμπερι*, on both sides, in *Antiquity*, a kind of vessels, wherein each mariner wrought two oars at the same time, one with the right hand, and the other with his left, answering to our *scullers*. This is also called *amphericum*.

AMPEZO, in *Geography*, a town of Germany, in the country of Tyrol, ceded to Austria by the Venetians in 1505, 12 miles south of Bruneck.

AMPHANÆ, in *Ancient Geography*, a town of Greece in the Doride. Stephan. Byz.

AMPHANÆ is also a strong place of Thessaly, probably the same as that called by Scylax *Amphineum*.

AMPHAXITIS, a district of Macedonia, in which was situated the city of Thessalonica.

AMPHIA, or AMPHEA, a town of Messenia, mentioned by Steph. Byz. and also by Pausanias, who places it in the vicinity of Laconia.

AMPHIARAUS, in *Mythology*, a famous prophet among the Pagans, was the son of Oicleus, and great grandson of Melampus, to whom part of the kingdom of Argos was assigned, as a recompence for some public service. In consequence of this division of Argos, Adrastus, its king, was overpowered by the party of Amphiarus, and obliged to abandon the kingdom. Amphiarus afterwards married Eriphyle, the filler of Adrastus, and he was restored to the throne. During the preparations for the expedition against Thebes,

Thebes, Amphiarus, who possessed the faculty of divination, was forewarned that he should lose his life in this war, and therefore he concealed himself, in order to avoid engaging in it; but his wife, being prevailed upon by a present of a gold chain, discovered the place where he was hidden, so that he was obliged to accompany the other princes, who marched against Thebes. The expedition was fatal to him; for the chariot being split asunder by a thunder-bolt, both he and his chariot were swallowed up in the gulf. Pindar and Apollodorus mention this circumstance; and they ascribe the event to the kind interposition of Jupiter, who thus prevented the dishonour of his being killed by Periclymenes, by whom he was pursued. After his death he was ranked among the gods, temples were dedicated to him, and his oracle, as well as the sports that were instituted in honour of him, were very famous. He was believed to excel chiefly in divining by dreams, and is said to have been the first who divined by fire. He left in charge with his children to put his wife to death, as soon as they were able to do it. Apollodorus reckons him among the Argonauts.

AMPHIARTHROSIS, in *Anatomy*, a neutral or dubious kind of articulation; distinguished from the *diarthrosis*, in that it has no conspicuous motion; and from the *synarthrosis*, in its not being without sensible motion.

The word is derived from *αμφι*, both, and *αρθρωσις*, articulation, the *amphiarthrosis* being compounded of both the other sorts.

Mr. Winslow cites, as specimens of this kind of articulation, the conjunction of the first rib and sternum by a single cartilage, and the connections of the vertebræ with each other by the intervertebral substance.

AMPHIBALUS, in *Biography*, a monk of Caerleon, who is said by some to have been a Roman by birth, and to have made his escape into Britain in the time of Dioclesian's persecution. Others say, that he was born at Caerleon, the metropolis of Wales, and that he was rector of the university of Cambridge. He was the preceptor of St. Alban, and instrumental in his conversion; and was crowned with martyrdom.

AMPHIBALLUS, **AMPHIBALLUM**, or **AMPHIMALLUM**, among *Middle Age Writers*, denoted a large mantle, such as were the surplices of the monks, which encompassed the body on both sides, (whence it was called *amphibalus*, from *αμφι* and *βαλλων*, and *amphimallum*, from *αμφι* and *μαλλος*, a fleece of wool) and which was not barely thrown over the shoulders, like the toga. See **CARACALLA**.

AMPHIBIA, in *Zoology*, the third class of animals in the Linnæan system, including those which possess, in a certain degree, the power of respiration, and are thereby enabled to live either in water or upon land. The characters assigned by early naturalists to animals of this class are, in many respects, exceptionable; and those of Linnæus are liable to some objections, as the writings of Count de Cuvier, Mr. Schneider, M. Schœpff, and Dr. Shaw have proved in various instances; yet the Linnæan arrangement is still adopted with some amendments, and upon the whole this is most advisable, till this obscure tribe of creatures is more completely ascertained.

The amphibia are either naked, or defended by an external covering; the skins of such as are denominated naked, are in general marked by soft, pulstular warts; the coverings of the others are either horny shields, coriaceous integuments, or scales. The lungs of the amphibia differ materially from those of other animals in the two preceding classes, mammalia and aves, consisting in general of a pair of large bladders or membranaceous receptacles, variously subdivided in different species; and the heart is furnished with one ventricle only. Some late physiologists have, however,

ventured to assert, that the hearts of the amphibia are in reality double, or furnished with two ventricles, with a free or immediate communication between them.

In the Linnæan arrangement, the amphibia were formerly divided into four orders, *viz.* 1. *Reptilia pedata*, reptiles; amphibious animals, which breathe through the mouth by lungs only, and are furnished with four feet. 2. *Serpentes apodes*, serpents; amphibious animals, breathing through the mouth by means of lungs only, and destitute of feet, fins, and ears. 3. *Meantes*, gliders; animals breathing by means of gills and lungs, and furnished with arms and claws; and 4. *Nantes pinnati*, breathing fishes, which respire arbitrarily by means of gills and lungs, and of which the fin-rays are cartilaginous. The amphibia class in the last edition of the *Systema Naturæ*, by Gmelin, consists of two orders, *reptilia pedata*, and *serpentes apodes*, which are sufficiently distinguished, the reptiles being furnished with feet, and the serpents destitute of them. The *Nantes pinnati*, or breathing fishes, being placed in their natural order amongst the **PISCES**, under the title **CHONDROPTERYGII**; that order now includes the genera *Acipenser*, *Chimera*, *Squalus*, *Raja*, and *Petromyzon*: the *Lophius* genus is separated from the others, and arranged amongst the **PISCES BRANCHIOSTEGI**.

The order of reptiles is divided into four genera, *viz.* **TESTUDO**, **DRACO**, **LACERTA**, and **RANA**; and that of serpents into six genera, *viz.* **CROTALUS**, **BOA**, **COLUBER**, **ANGUIS**, **AMPHISBÆNA**, and **CAECILIA**. This is the arrangement of Gmelin, to which must be added the genus **SIREN**; a kind of reptile, whose ambiguity of character induced Linnæus to form the new order **MEANTES**. Linn. *Moen. Acad.* vii. p. 311.—et *Syst. Nat.* vol. i. part ii. Ad-dend. Gmelin has assigned this creature to the first genus of fishes, **MURÆNA**; and Dr. Shaw restores it to the *Siren* genus in the appendix to his *Zoology*, vol. iii. p. 2, **Amp.** It may still be doubted whether this, and two other known kinds of the same family be complete animals, or only the larvæ or first state of some lacertæ, as Dr. Shaw very judiciously suggests.

The new genera of serpents, not noticed by Gmelin, are **ACROCHORDUS**, **HYDRUS**, and **LANGAVA**.

Of the amphibia in general, it has been observed, that their bones are more cartilaginous than those of other animals, and many possess the singular power of reproducing their tails, legs, and other parts when destroyed; in this respect bearing some affinity to many marine insects, as crabs, lobsters, &c. Some are viviparous, or hatch the young ones in the eggs, internally, and bring them forth alive; others deposit their eggs, and hatch them afterwards. The eggs differ also, some are covered with a calcareous shell, others with a tough skin resembling parchment, and many, as in the **RANA** genus, are perfectly gelatinous. Numbers undergo a metamorphosis, or cast their skins; all are extremely tenacious of life, and, from their peculiar internal structure, capable of enduring a longer abstinence than any of the larger tribes of animals. During Winter many remain in a state of torpidity.

Very few of the reptile tribes are venomous; and of the serpents not more than one-fifth are known as such. Those creatures, therefore, which are naked, and without limbs, seem perfectly defenceless, but nature has armed the rest, not only with the means of defence, but the most dreadful means of aggression; and the poisonous serpents, collectively, are undoubtedly the most hideous and formidable tribe of creatures known. The poisonous kinds are furnished with tubular fangs, which are perfectly distinct from the teeth, and situated upon a glandular vesicle on the anterior part of the upper jaw: in this vesicle the fatal fluid is secreted, and when the wound is inflicted, discharges its contents into the fangs, through which it oozes by the linear apertures on one

side, and effects its malignant purpose. The jaws of the serpents are extremely dilatable, and the œsophagus so lax, that they can swallow, without mastication, an animal twice or thrice as large as the neck.

AMPHIBIA, *Anatomy of.* See *CLASSIFICATION of Animals* and *REPTILES in Comparative Anatomy.*

AMPHIBIOUS, in *Natural History*, a term applied to those animals which live both on land and in water. In technical language it is confined to those creatures which conflate the *amphibia* of naturalists; in a general sense it includes the otter, seal, beaver, and various other animals of the mammalia tribe, who live on land, and occasionally go into the water in search of prey; the word being derived from ἀμφί, *utroque, both ways*, and βίωσις, *vita, life*; as living in both places.

Dr. Parsons, in an ingenious paper published in the Transactions of the Royal Society, after considering the economy of amphibious creatures, divides them into two sections; *first*, such as enjoy their chief functions on land, but occasionally go into the water; and *secondly*, such as chiefly inhabit the water, but occasionally go ashore. Of the first kind he considers the phocæ, otters, beavers, and some kinds of rats, frogs, and lizards, the hippopotamus and testudo; all which, he observes, are capable of remaining for an inconsiderable length of time in the water, to collect their prey, but are compelled to rise to the surface to breathe, and return ashore to perform most of the ordinary functions of nature. The last are but of two kinds, eels, or water-serpents, or snakes of every kind.

Most of the amphibious kinds, the castor, or beaver, and otter excepted, have peculiar provisions in their structure to fit them for such a various way of living; particularly in the heart, lungs, foramen ovale, &c.

In some of these animals, as the frog, tortoise, &c. the heart has but one cavity, with an artery to receive the blood coming out of it, and a vein to convey it thither. In others, the foramen ovale appear to be still open for the passage of the blood from the *vena cava* to the *arteria venosa*, without the help of breathing.

In the *castor*, dissected by the academists of Paris, though the foramen was not found actually open, yet the marks of it appeared; and the cause of its closure might be well enough accounted for, from the animal's having been detained a good while from the water, by which the part, having been in disuse, closed up. In the *OTTER* the case is different; there is no appearance of any thing like a *foramen*; and hence the necessity the creature is under of rising, from time to time above water, to take in air. Phil. Trans. N^o 124.

The structure of the feet of the *castor* pronounces it amphibious at first sight, the fore feet being formed like those of terrestrial animals, who hold their food in their feet, *e. gr.* squirrels, while the hind-feet are fashioned after the manner of river fowl, with webs or membranes between the toes, as the goose, duck, &c.

Some kinds of insects, in different stages of life, may be said to be amphibious. The dytiscus, notonecta, and nepa, undergo all their transformations from the egg, larva, and pupa state in the water, and though furnished in the perfect state with wings, and consequently destined to live on land, seldom quit the water except in the evenings, and constantly return to it when their flight is over: these are called water-beetles. Others remain in the water only in the first stages of their transformations, and would perish in their native element from the moment they become winged creatures, as is frequently observed of the libellula, ephemera, and phryganea, and some of the muscæ and culices; amongst the latter the transformation of the species *pipiens*, common gnat, is a

striking instance of this remark. In fact many of those creatures, which are mistaken for aquatic worms, are no other than the larva, or pupas of *amphibious* insects, which their parents deposit in the egg state, on the leaves and stalks of plants, &c. that grow in the water; and those hatching insensibly, remain in the watertill they become winged insects.

Birds are in a much less degree amphibious. Amongst those which are denominated water-fowl, from almost constantly living on that element, the divers and corvorants are capable of remaining a considerable length of time under water; perhaps nearly as long as the otter. Swallows would certainly well deserve the title of amphibious, if, as some have imagined, they passed the whole winter in a state of torpidity under water.

Dr. Hunter observes, that, properly speaking, there are no *amphibious* animals; for that fish cannot live long without air, though much longer than men.

The term *amphibious* has been sometimes also extended to men, who have the faculty of living a long while under water. We have various instances of such amphibious men: the divers employed in the pearl-fisheries possess this faculty in an eminent degree. Credulity itself is staggered at the story of a Calabrian monk, who once offered the king of Spain to continue twice twenty-four hours under water; but it is believed that a Sicilian, named the *Fisch-Colas*, by a long habitude from his youth, had so accustom'd himself to live in water, that his nature seem'd to be quite altered, so that he liv'd rather after the manner of a fish than a man. Kircher.

AMPHICEIDA, in *Entomology*, a species of PAPHILIO. Wings, indented, above brown, with a connected disk of cinereous waved with brown; beneath, tips grey with black lunated marks. Fab. et Gmel.—This species inhabits Africa. Above, the base and margins are entirely brown; cinereous in the middle, with two large undulated waves, the first brown, the second black. Beneath, pale at the base with rufous spots, and undulated lines, apex grey with a row of lunated black marks. Fabricius.

AMPHIBLESTROIDES, in *Anatomy*, a tunic or coat of the eye, more usually call *RETINA*.

The word is compounded of ἀμφί, *σπινθηρον, net*, and εἶδος, *form*; on account of its net-like texture; whence the Latins also call it *retiformis*.

AMPHIBOLOGY, from ἀμφίβολος, *ambiguous*, and λόγος, *discourse*, or **AMPHIBOLIA**, in *Grammar*, a fault in language, whereby it is rendered obscure, and liable to be understood in a double sense.

Amphibology is chiefly used in respect of a phrase, as equivocal is in respect of a word.

Of this kind was that answer which Pyrrhus received, from the oracle, “Aio te, *Æacida, Romanos vincere posse;*” where the amphibology consists in this, that the words “te,” and “Romanos,” may either of them precede, or either of them follow the words “posse vincere,” indifferently. See *ORACLE*.

The English language usually speaks in a more natural manner, and is not capable of any amphibologies of this kind; nor is it so liable to amphibologies in the articles as the French, and most other modern tongues.

AMPHIBRACHYS, the name of a foot in the *Latin* and *Greek poetry*; consisting of three syllables, the first and last whereof are short, and that in the middle long.

The word comes from ἀμφί, *circum*, and βραχυς, *brevis*, *q. d.* a foot short at both ends, and long in the middle.—Among the Ancients it is also called *ianius*, and *scolius*. Diom. iii. p. 475.

Such are the words ἀμάρτ, ἀβίρτ, πατρώνυς, Ομπερς, &c.
AMPHICLEA, in *Ancient Geography*, a city of Phocis in Græcia Propria, mentioned by Steph. Byz. and called by Pausanias

Pausanias and Herodotus, Amphicæa. The Amphictyons, in their decree against the Phocian cities, gave it the name of Ophitea. This city belonged to the Dryopes, and was pleasantly situated to the left of the river Cephissus, and near Mount Oeta. Amphiclea was famous for a temple and oracle of Bacchus, who, under the character of a physician, pretended to cure all diseased persons that applied to him.

AMPHICTYONS, AMPHICTYONES, in *Antiquity*, the deputies of the cities and people of Greece, who represented their respective nations in a general assembly; having a full power to concert, resolve, and appoint what they should think fit for the service of the common cause. They were empowered to employ not only the rigour of the laws, in the execution of their decrees, but even to raise troops, if it were necessary, to compel such as rebelled to submit to them.

The amphictyones very much resemble the states-general of the united Provinces; or rather, what in Germany they call the DIET of the empire.

Some suppose the word ἀμφικτιῶνες, to be formed of ἀμφί, *about*, and κτιῶν, or κτιζῶν, because the inhabitants of the country round about met here in council. Others, with more probability, derived it from *Amphictyon*, son of Deucalion, whom they suppose to have been the founder of this assembly; though others will have Acrisius, king of the Argives, to have been the first who gave a form and laws to this body.

Androtion, in his History of Attica, quoted by Pausanias, (lib. ii. c. 8. p. 815.) informs us, that from the most early period, deputies from the neighbouring states assembled at Delphi, and that these deputies were, *from that circumstance*, called Amphictyons; and that consequently, in process of time, this became the prevailing denomination of that high court. According to this account, whether the author's etymology be right or not, this was an original institution, deriving its establishment from neither Amphictyon nor Acrisius, but existing from the earliest ages of antiquity. Dr. Doig (Edinb. Transf. vol. iii. p. 150, &c.) suggests, that as the Hellenes had founded the oracle of Dodona, they probably established also the oracle of Delphi. This oracle acquired great reputation, and the concourse of the people to the temple of Delphi was immense. Its situation was well chosen for this purpose; and it lay nearly in the centre of those petty tribes that afterwards formed the Amphictyonic association. These states, becoming jealous of the growing power of the oriental colonies, determined to hold their conventions at Delphi, in order to concert measures for their mutual security. Both its sanctity and central situation pointed it out as a place well adapted to this purpose. The Hellenic prefects of the temple, superior to the Barbarians in political sagacity, would strain every nerve to promote a scheme calculated to advance both their honour and their interest. Common sacrifices have, in all ages, been deemed an infallible sign of amity and concord, and also the means of maintaining and promoting them. The confederates would therefore assemble at Delphi to offer sacrifices, and to perform other religious rites on behalf of all the associated tribes. These would serve as an indissoluble bond of their federal union. The confederates, on this occasion, would present liberal donations, and thus greatly enrich the treasury of the temple. It must therefore occur to them, that it would conduce both to their honour and interest to appoint officers for superintending this treasure. Strabo says expressly, (lib. ix. p. 420.) that this was one of the ends of the institution of the Amphictyons. Hence it appears, that the original Amphictyons were a kind of wardens of the temple of Delphi, elected by the suffrage of the confederated tribes. In process of time another class of persons would naturally be added to the former, whose province it should be to watch

over the civil interests of the confederacy. These two classes of superintendents gradually coalesced into one, and both united in discharging the sacred and civil functions annexed to their office. A tribunal, thus formed and established, reflects immortal honour upon Greece, and demonstrates the wisdom and sagacity of the Hellenes, to whom its institution is ascribed by the ingenious writer above cited, and which he connects, in its origin, with the oracular establishment at Delphi. Had its members been always animated by a spirit of peace, of justice, and of good order, it would have rendered itself for ever respectable; and the associated states under its direction would never have become a prey to the despised Macedonians.

This council was principally instituted with a view of uniting in the sacred band of amity the several people of Greece that were admitted into it, and of obliging them, by that union, to undertake the defence of each other, and to be mutually vigilant for the tranquillity and happiness of the country. The Amphictyons were also created to be the protectors of the oracle of Delphos, and the guardians of the wealth of that temple; and also to adjudge the differences that might arise between the Delphians and those who came to consult that oracle.

Authors give different accounts of the number of the Amphictyons, as well as the states who were entitled to have their representatives in this council; according to Strabo, Harpocration, and Suidas, they were twelve, from their first institution, sent by the following cities and states; the Ionians, Dorians, Perrhæbians, Bœotians, Magnesians, Achæans, Phthians, Melians, Dolopians, Ænians, Delphians, and Phocæans. Æschines only reckons eleven, instead of the Achæans, Ænians, Delphians, and Dolopians, he only gives these three, the Thessalians, Cæans, and Locrians. Lastly, Pausanias's list only contains ten Amphictyons; namely, the Ionians, Dolopians, Thessalians, Ænians, Magnesians, Melians, Phthians, Dorians, Phocæans, and Locrians.

In the time of Philip of Macedon, the Phocæans were excluded the alliance, for having plundered the Delphian temple, and the Lacedæmonians were admitted into their place; but the Phocæans, sixty-eight years after, having behaved gallantly against Brennus and his Gauls, were restored to their seat in the amphictyonic council. Under Augustus, the city Nicopolis was admitted into the body; and, to make room for it, the Magnesians, Melians, Phthians, and Ænians, who till then had distinct voices, were ordered to be numbered with the Thessalians, and to have only one common representative. Strabo speaks as if this council were extinct in the times of Augustus and Tiberius; but Pausanias, who lived many years after, under Antoninus Pius, assures us it remained entire in his time, and that the number of amphictyons was then thirty.

When the Lacedæmonians, in order to pass any decrees which they thought proper, were for excluding the Thessalians, Argives, and Thebans, Themistocles (Plut. in Them. p. 122.), in the speech he made to the Amphictyons for preventing that design from taking effect, seems to insinuate that there were at that time 31 cities which had the right of sending deputies to this council.

The members were of two kinds; each city sending two deputies, under different denominations, one called *εξουνημων*, whose business seems to have been more immediately to inspect what related to sacrifices and ceremonies of religion; the other *πυλαγορας*, charged with hearing and deciding causes and differences between private persons. Both had an equal right to deliberate and vote, in all that related to the common interests of Greece. The former was elected by lot; the latter by plurality of voices.

Though

Though the amphictyons were first instituted at Thermopylæ, M. De Valois (Mem. Acad. Belles Lettres, vol. iii.) maintains, that their first place of residence was at Delphi, where, for some ages, the tranquillity of the times found them no other employment than that of being, if we may so call it, church-wardens of the temple of Apollo. In after times the approach of armies frequently drove them to Thermopylæ, were they took their station, to be nearer at hand to oppose the progress of enemies, and to order timely succour to the cities in danger. When they assembled at Thermopylæ, they held their sessions in the temple of Ceres, near the mouth of the river Asopus. Their ordinary residence, however, was at Delphi.

Here they decided all public differences and disputes between any of the cities of Greece; but before they entered on business, they jointly sacrificed an ox, cut into small pieces, as a symbol of their union. Their determinations were received with the greatest veneration, and even held sacred and inviolable.

The Amphictyons, at their admittance, took a solemn oath, the form of which is preserved by Æschines (in Orat. *περι παραπηρηθῆαι*) never to dwell any city of their right of deputation, never to avert its running waters; and if any attempt of this kind were made by others, to make mortal war against him; more particularly, in case of any attempt to rob the temple of any of its ornaments, that they would employ hands, feet, tongue, their whole power, to revenge it. This oath was enforced by terrible imprecations against such as should violate it; *e. gr.* May they meet all the vengeance of Apollo, Diana, Latona, and Minerva, &c. their soil produce no fruit, their wives bring forth nothing but monsters, &c. lose all suits at law, be conquered in war, have their houses demolished, and be themselves and their children put to the sword!

The stated times of their meetings were Spring and Autumn; the Spring meeting was called *Εαρινή Πυθιαία*, that in Autumn *Μετοπηρινή*. On extraordinary occasions, however, they met at any time of the year, or even continued sitting all the year round.

Philip of Macedon usurped the right of presiding in the assembly of the Amphictyons, and of first consulting the oracle, which was called *Προμαντεία*. From this time the authority of the Amphictyons began to decline; for he claimed the right of presiding even by proxy both in this assembly and in the Pythian games, of which games the Amphictyons were judges and agonothetæ in virtue of their office. This Demosthenes reproaches him with in the third Philippic: "When he does not deign," says he, "to honour us with his presence, he sends his *slaves* to preside over us." After the conquest of Greece by the Macedonians, this tribunal was deprived of its lustre. Augustus, too, made some new regulations with respect to the states, which were invested with the privilege of sending deputies to this council. Though it subsisted in the days of Paulanias, as we have already mentioned, it was probably of so little repute in the age of Strabo, that this geographer looked upon it as in a manner annihilated.

The Romans never thought fit to suppress the meeting of the Amphictyons. Potter's Arch. Græc. Mem. Acad. Infer. tom. iv. & vii. Æschin. Orat.

AMPHIDOLI, in *Ancient Geography*, a small town of Triphylia, in the territory of Elis. Steph. Byz.

AMPHIDROMIA, from *αμφί*, and *δρομος*; a *course*, in *Antiquity*, a feast celebrated the fifth day after the birth of a child, called *dies lustricus*, or *LUSTRAL day*.

AMPHIDRYON, in *Ecclesiastical Writers*, a veil or curtain usually drawn before the door of the BEMA in ancient churches.

AMPHIGENIA, in *Ancient Geography*, a town mentioned by Homer, situate in the southern part of Elis, comprehended by the ancients in Messenia. In this town was a temple of Latona; and the inhabitants pretended that their town had given birth to Apollo.

AMPHILOCHI, a town of Spain, in Gallicia, founded by Tencer after his return from the Trojan war; and so called, as Strabo informs us, from the name of Amphilochus, one of his companions, now *Orense*.

AMPHILOCHIA, a country of Acarnania, situate to the east of the Ambracian gulf, and watered by the river Inachus. The inhabitants were called Amphilochi, deriving their name from Amphilochus, the son of Amphiaræus, and their capital was denominated *Argos Amphilochicum*.

AMPHILOCHIS, a place of Peloponnesus, in Elis. Steph. Byz.

AMPHILOCHIUS, in *Biography*, a native of Cappadocia, was appointed bishop of Iconium, the chief city of Lycania, about the year 370 or 374. In his youth he studied rhetoric and practised law; but afterwards devoting himself to a religious life, he retired, with his friends Basil and Gregory Nazianzen, into a solitary part of Cappadocia, called Ozizaia. After he was advanced to the episcopal office, he assisted at the first general council of Constantinople in 381, and also at subsequent councils in 385 and in 394, soon after which he died. His eminence may be inferred from the several letters written to him by Basil, and from the character given of him by Theodoret and others. Jerom joins him with Basil, Gregory, and others, who were equally skilful in secular learning, and in the sacred scriptures. Of his zeal against the Ariæus we have ample testimony from Theodoret Eccl. Hist. (lib. v. c. 16.) and Sozomen (lib. vii. c. 6.) and others. Being very desirous of prohibiting Arian assemblies, and finding the emperor Theodosius remiss in complying with his wishes, he contrived to accomplish his object by the following expedient. Whilst he was in the palace with other bishops, who were paying their respects to Theodosius, he took no notice of his son Arcadius, who had lately been declared Augustus. When the emperor reminded him of this seeming disrespect, and recommended his son to notice, Amphilochius apologized by saying, that he had paid respect to him, and that was sufficient. The emperor was displeas'd, and said, that a slight put upon his son was an indignity to himself. You are angry, replied Amphilochius, with those who slight your son, and cannot endure it: persuade yourself then, that the God of the whole world is offended with those who blaspheme his only begotten Son, and hates them as ungrateful to their Saviour and Benefactor. This mode of reasoning produced the wished-for effect; and Theodosius soon afterwards, A. D. 385. forbade the assemblies of heretics. But this was not the only way in which the bishop manifested his dislike of heretics; and the law procured for this purpose, and dated July 25, A. D. 383, is still extant, which prohibits all heretics, particularly Eunomians, Arians, and Macedonians, to hold any assemblies of worship in public places, or private houses. He wrote a book against the Massalians, and another work, entitled, "Of Pseudepigraphal Books composed by Heretics," both which are lost. "If they had been extant," says Dr. Lardner, "I suppose they would have given me more satisfaction than the law of Theodosius, which affords not any argument:" nor was Amphilochius to be commended, adds this mild and candid writer, for procuring that law. A few fragments are preserved of Amphilochius's book "Concerning the Divinity of the Holy Spirit," and his "Synodic Epistle," edited by Cotelerius. The Iambic poem, addressed to Seleucus, and containing a catalogue of the books of the Old and New Testament, has been ascribed by many to Amphilochius;

philochius; but others are of opinion, that it was written by Gregory Nazianzen; they allege that the style is his, and that we have no information that Amphilocheus ever wrote verse. The poem, however, affords evidence of the care and caution of the ancient Christians concerning books received as a part of sacred scripture, and the rule of their faith. This and other pieces, probably spurious ones, were published by Combefis, at Paris, in 1644. Cave H. L. tom. 1. p. 251. Lardner's Works, vol. iv. p. 411, &c.

AMPHILOCHUS, in *History and Mythology*, the son of Amphiarus, was no less famous as a diviner than his father. He accompanied Alcmeon, his brother, to the second war of Thebes, and assisted in killing his mother, according to his father's injunction. After the war of Thebes, he assisted Mopsus in building the city of Mallus in Cilicia, where he had an oracle; and it is said that he had an altar erected to him at Athens. The answers of the oracle at Mallus were given by dreams; those who came to consult it slept a night in the temple, and that night's dream was the answer required. Dion Cassius mentions a picture done by order of Sextus Condidianus, and representing the answer he received from the oracle in the reign of the emperor Commodus. In the time of Lucian (in *Philopseud.* tom. ii. p. 500.) Amphilocheus was regarded by the superstitious and credulous multitude as a great prophet, and his oracle maintained its reputation. Gen. Dict.

AMPHIMACER, a foot in the *Ancient Poetry*, consisting of three syllables; the first and last whereof are long, and that in the middle short.

The word is derived from the Greek *αμφι*, *circum*, and *μακρος*, *longus*, by reason both extremes are long.

Such are the words *omnium, castitas, γρημύτων*, &c. This foot is also called *creticus*, and sometimes *fescenarius*.

AMPHIMACUS, in *Entomology*, a species of PAPILO. Wings indented, above, black, with a broad bar of shining blue in the middle. Beneath, anterior wings white, posterior wings cinereous. Inhabits India. The body is black. Wings above entirely black except the interrupted bright blue that extends towards the anterior margin. Beneath, from the base to the middle of the wings white, variegated with brown marks: on the posterior pair behind a large white spot, and seven small brown ones, with whitish pupils and circles along the posterior margin. Fabricius.

AMPHIMALIA, or AMPHIMALLIUM, in *Ancient Geography*, was a town of the island of Crete, according to Pliny, situate on the north side, and east of Sydonia. It gave name to a gulf in the same part of the island. Sonnini supposes, that the Amphimale of the ancients is that narrow gulf, which is now formed by Cape Melecca on the west part, and Cape Trepani on the east, and which penetrates nearly two leagues inland. Others place the harbour of Amphimale between Suda and Retimo, where is only a bad haven. Sonnini's Travels in Greece, p. 243. Olivier (Travels, vol. ii. p. 198.) informs us, that the ruins of Amphimale are still visible half a league from the sea to the south of the gulf of Suda. These ruins are now the foundation of a Greek monastery.

AMPHIMALLUM, from *αμφι* and *μαλλος*, a fleece of wool, in *Ecclesiastical Writers*, *amphibalum* and *amphibolum*, from *αμφι* and *βαλλω*. See AMPHIBALLUS.

AMPHIMASCALOS, in *Antiquity*, a tunic or coat worn by the Greeks, with two short sleeves, so as to cover part of the arm to the elbow. In general the tunics of the men and women had not sleeves like these parts of modern dresses. The coats of freemen were *amphimaskaloi*, or had two sleeves; those of slaves only one, and were called

επειρομασκαλοι.

AMPHIMEDON, in *Entomology*, a species of PAPILO,

with wings uniformly brown, the anterior pair radiated with white: five connected red spots in the middle of the posterior pair, with white lunules. The body is large, brown; anterior part of the thorax variegated with three red lines. From Amboyna. Fabricius.

AMPHIMONE, a species of PHALÆNA, of the *Bombyx* family. Wings entire, pale ash-colour, with two black streaks, and a fulvous dot in the middle of the anterior pair. Described by Fabricius from a specimen in the cabinet of Sir Joseph Banks. Inhabits Terra del Fuego. The antennæ are greatly pectinated, body hairy, two yellowish lines on the thorax, abdomen with black belts, a single straight streak on the posterior wings beneath. Fabricius.

AMPHINOME, a species of PAPILO, with indented wings, above black, clouded with numerous blue marks: an oblique white bar across the anterior wings; beneath the lower wings radiated with red. A native of South America. Linnæus.

AMPHINOME, in *Mythology*, one of the 50 Nereide, according to Homer.

AMPHION, in *Entomology*, a species of HESPERIA. Wings entire, blue, margins black: beneath cinereous, with black ocellated spots; posterior wings, with red lunated marks, black points, and golden characters. A native of Germany. Fabricius.

AMPHION, in *Ancient History*, the twin brother of Zethus, was the son of Antiope, the greatest beauty of Greece, by Epopeus, king of Sicyon, or, as Homer says, by Jupiter. Having seized the crown of Thebes, in Bœotia, from Lague, the father of the unfortunate Oedipus, he called the metropolis of the Theban government, or at least the lower city, Thebes, in honour, as it is said, of Thebe, their aunt by the mother's side. Homer says, that to secure the crown which he had usurped, he inclosed the city of Thebes with a wall, fortified with seven gates, and a number of stately towers at a convenient distance from each other. Homer, however, does not say a word of the miraculous powers of Amphion's music, nor of his building the wall, as fable reports, by the sound of his lyre. Pausanias and Pliny concur in relating, that he acquired his musical reputation from his alliance with the family of Tantalus, whose daughter, Niobe, he had married: and both these authors say, that Amphion learned music in Lydia, and, bringing it from thence into Greece, was called the inventor of the Lydian mode. As to the effect of music in building the wall, we may observe, that he might probably captivate the people to carry on the work, by diverting them with the music of his harp, as well as persuade them by his eloquence, which contributed to induce them, though in a state of barbarity, to live sociably and harmoniously together. We learn from Horace (*Ars Poetica*, i. 391.) that Amphion, after the example of Horace, employed the united powers of music and philosophy in civilizing the Thebans.

“Silvestres homines facer interpretesque deorum
Cœdibus et victu sædo deterruit Orpheus;
Dictus ob hoc lenire tigres rabidosque leones.
Dictus et Amphion, Thebanæ conditor arcis,
Saxa movere sono testudinis, et prece blanda
Ducere quo vellet. Fuit hæc sapientia quondam,
Publica privatis fecernere, sacra profanis;
Concubitu prohibere vago; dare jura maritis;
Oppida moliri; leges incidere ligno;
Sic honor et nomen divinis vatibus atque
Carminibus venit.”

“The wood born race of men when Orpheus tam'd,
From acorns and from mutual blood reclaim'd,

'Tis priest divine was fabled to assuage
The tiger's fierceness, and the lion's rage.
'Thus rose the Theban wall; Amphion's lyre,
And soothing voice, the lit'ning stones inspire.
Poetic wisdom marked, with happy mean,
Public and private, sacred and profane;
The wand'ring joys of lawless love suppress'd;
With equal rites the bonds of Hymen blest'd;
Plann'd future towns, and instituted laws;
So verse became divine, and poets gained applause."

FRANCIS.

AMPHIPAGUS, in *Ancient Geography*, a promontory of the island of Coreyra, to the north west.

AMPHIPNEUMA, ἀμφίπνευμα, among *Ancient Physicians*, a great degree or species of difficult respiration.

AMPHIPOLES, from ἀμφί and πόλις, city, in *Antiquity*, archons, or chief magistrates of the city of Syracuse.

They were first established by Timoleon, in the 109th Olympiad, after his expulsion of Dionysius the Tyrant. They governed Syracuse for the space of three hundred years; and Diodorus Siculus assures us they subsisted even in his time.

AMPHIPOLIS, in *Ancient Geography*, a city of Macedonia or Thrace, which was an Athenian colony, on the river Strymon, which separated Macedonia from Thrace; but it is not certain on which side of the river it was situated. Pliny places it in Macedonia, but Scylax in Thrace. Thucydides (lib. iv. p. 320.) reconciles this difference of opinion by observing, that it was washed on two sides by the river Strymon, which was divided from its mouth into two channels, in the middle of which the city stood, whence its name Amphipolis. i. e. ἀμφί and πόλις; and on the side towards the sea there was a wall built from channel to channel. M. d'Anville gives another etymology of the name, and says, that it signifies a town belonging to two countries, viz. Macedonia and Thrace. The ancient name, according to Herodotus, (lib. vii. c. 114.) and Thucydides (ubi supra) was *Ἐνεσσοδοί*, or the *nine ways*; and it was called *Acra*, *Eion*, whence the Turks have formed *Jamboli*, *Myrica*, *Chrademna*, *Chrysofolis*, or *Chrisfolis*. The inhabitants were denominated *Amphipolitani*. Livy. It was founded thirty years after the defeat of the Persians in Greece; and Miltiades conducted a colony into it. Philip, king of Macedon, drove the Athenians from Amphipolis, and permitted the inhabitants to form a republic. The Athenians, however, always considered it as belonging to them; and Brasidas, the Lacedæmonian general, took it from them. Nevertheless, Philip recovered it, and promised to restore it to the Athenians; but when he became master of it, he obtained a surrender of it by a treaty of peace.

AMPHIPOLIS was also a town of Syria, on the Euphrates; its Syrian name was *Turmeda*. It was either founded by Seleucus, or enlarged and adorned by him; and he changed its ancient name. It is the same with the *Thapsacus* of Pliny.

AMPHIPPI, in *Antiquity*, those who practised riding on two horses, by jumping from one to the other.

The word is Greek, ἀμφίπποι; they are sometimes also called ἵππων, ἄγροι, and sometimes by corruption, ἀντπαι. The appellation was given to a sort of cavalry in the Grecian armies, who, for their conveniency, had two horses a piece, on which they rode by turns, leading the other.

AMPHIPRORÆ, from ἀμφί and προρæ, *prova*, were ships which had prows at both ends, that no time might be lost in turning them, and also on account of the rapidity of streams, and narrowness of channels.

AMPHIPROSTYLOS, or AMPHIPROSTYLE, in *An-*

cient Architecture, is characteristic of a particular kind of TEMPLE, which had a PORTICO of four columns, crowned with a PEDIMENT in front, and another of the same form in the back, front, or rear. The portico in front was denominated the PRONAOS, and that in the rear the POSTICIUM. The word is composed of ἀμφί both, *ἔρη before*, and *τυλός column*, and signifies "column in both fronts."

Vitruvius, in the first chapter of his third book, describes seven species of temples differing from each other in the number and arrangement of their columns, of which the amphiprostylos is the third. It is distinguished from the first and second species, by having columns in both its fronts, and from the peripteral and pseudo-peripteral kinds, by having only four columns in each front, and more especially by not having any on the flanks. It is remarked by Saumaïse that the Christians never made entrances in the rear of their temples with PORCHES or porticos, similar to those in the front, and for this reason the French have no word to express the posticum of the Latins, as distinguished from the pronaos, which they denominate the "*Porche*." The same remark is true with regard to the English, and probably to all other Christian nations.

AMPHISA, in *Ancient Geography*, a river of Greece in Messenia, which discharged itself into the Balyra, according to Pausanias, lib. iv. Messen. c. 23.

AMPHISO, in *Mythology*, one of the nymphs called Oceanides.

AMPHISBÆNA, in *Zoology*, the name of a genus of serpents in the Linnæan system, in some respects allied both to that of Anguis and Lacerta; like the Cæcilia it is destitute of scales, but its skin appears completely annulated, or marked with numerous circles that surround the body and tail. This is the Linnæan character of the genus, to which may be added that the body is equally smooth and cylindrical; and the tail obtuse, and scarcely to be distinguished from the head.

Gmelin enumerates five species of this genus, viz. *fuliginosa*, *varia*, *magnifica*, *flava*, and *alba*.

1. *Fuliginosa*. Rings of the body two hundred; of the tail thirty. This species is white, variegated with black or dark brown, and the head is without spots.

2. *Varia*. Variegated with white, black, chestnut and grey.

3. *Magnifica*. Variegated with purple, violet, and yellow; head yellowish, and a purplish streak over the eye.

4. *Flava*. Variegated with white and brown; head yellow.

5. *Alba*. Rings of the body two hundred and twenty-three; of the tail sixteen. The head of this is annulated on the fore-part, and narrowed into an obtuse snout. Found near ant-hills. Gmelin has relied chiefly on Seba in discriminating the characters of these species; yet it may be doubted whether that authority is sufficient. The number of annular rings round the body and tail, and which Linnæus considered as the best specific distinction, is only mentioned in two species, *fuliginosa* and *alba*; the characters of the others, being only taken from the variations in their colours, are not satisfactory. The five kinds mentioned by Gmelin are natives of America.

Dr. Shaw seems to have considered the three species, *varia*, *magnifica*, and *flava*, as varieties of *fuliginosa*; for he observes, that only two species of this genus, *amphisbæna*, have hitherto been discovered, viz. *alba* and *fuliginosa*. *A. alba* is from fifteen to eighteen inches, and sometimes two feet in length; the colour white, but sometimes inclining to pale yellow or brown; the head very short, the eyes very small; the mouth of moderate width, the teeth short, strong, not very sharply pointed, and constituting a single row of about fourteen or sixteen in each jaw; the tongue very large broad, thick, flattish, and bifid only at the tip, the surface of

the base appearing scaly. This is found in woods preying on insects, worms, &c. It is a harmless animal, but it is said, that on handling it for some time the skin becomes affected with a slight itching, accompanied by small pustules, owing to an acrimonious moisture exuding from the animal. *A. fuliginosa* is rarely so large as the preceding species, which it resembles in its manners, and is equally harmless. The Count de Ceppe observes, that above the vent is a row of small perforated papillæ, similar to those in many of the lizard tribe. The skin of the amphibæna is remarkably strong and tenacious, and of a smooth and glossy surface, and it is probable that they are enabled with great facility to perforate the ground somewhat in the manner of earth worms, in order to obtain occasional supplies of food. Dr. Shaw. Zool.

AMPHIBÆNA aquatica, a name given by Bertrutius, Albertus, Gesner, and other authors, to that long, slender worm, called by Aldrovandus and others, the *seta aquatica*, &c. This is the *Gordius aquaticus* of Linnæus. See *GORDIUS*.

AMPHISCII, formed from *αμφι*, *about*, and *σκια*, *shadow*, in *Geography* and *Astronomy*, the people who inhabit the torrid zone.

They are thus denominated, as having their *shadow* turned sometimes one way and sometimes another, *i. e.* at one time of the year to the north, and at another to the south.

AMPHISMILA, or *AMPHISMELA*, an anatomical knife, edged on both sides.

The word is formed from *αμφι*, *utrinque*, *on both sides*, and *σμίλη*, *knife*.

AMPHISSA, called by Herodotus *AMFICEA*, in *Antient Geography*, the chief city of the Ozolean Locrians, about 15 miles to the west of Delphi, situate on the river Evenus, and so called because it was surrounded by mountains, according to Steph. Byz. but Pausanias deduces the origin of the name from Amphissa, who had a monument erected to her honour in this place. On the summit of a hill near the town was a temple of Minerva, with her statue in bronze. The people of the country thought this was one of the spoils of Troy, but Pausanias represents it as an ancient Greek work. Amphissa was taken by the Phocians, and destroyed with the rest of the Phocian cities in the holy war; and when it was rebuilt, Pausanias says that it took the name of *Ophitea*, if the text has not been corrupted by his transcribers. *Amphissa* was also said to have been the name of a town of Magna Græcia, at the mouth of the Sagra, in the Farther Calabria, situate between Locri and Caulona, and now called *Rocella*; but some have doubted the existence of such a city.

AMPHITAPÆ, in *Antiquity*, a kind of carpets, or clothing, having a soft warm nap on each side.

AMPHITHEATRE, in *Architecture*, is an edifice of an elliptical form, consisting externally of two or more stories of open *ARCADES* with a number of interior *GALLERIES* and arched passages, sustaining and serving as communications to several ranges of seats, rising one over another round a spacious area, called the *ARENA*, on which the combats of wild beasts and other spectacles were exhibited.

The word is derived from *αμφι*, *around*, and *θεατρον*, *theatre*, so that amphitheatre signifies a place in which the spectators, ranged circuitously, saw equally well from every side. It was also called *visorium* by the Latins.

The history of amphitheatres, though it occupies no remote or extensive period of time, is interesting from its peculiar connection with the manners of the ancient world, and those which succeeded the establishment of the Christian religion; the rise and splendour of these edifices being occa-

sioned by the ferocious barbarity of the former, and their subsequent diffuse and ruin by the milder character of the latter. They are undoubtedly of Roman invention, in the latter ages of the republic; yet because the combats of *GLADIATORS* were, among other spectacles, exhibited on the *ARENA*, their origin has been ascribed to the *ETRURIANS*, with whom it is said they were sacred edifices set apart for such combats, and with them descended from that people to the Romans. "Religion," we are told, "in *ETRURIA* presided at these games, and elevated amphitheatres." An assertion that is certainly unfounded. Among the Etrurians gladiatory combats were exhibited at feasts as well as at funerals, and probably they were no otherwise religious institutions than as the occasion made them so, like the foot-races and other contests with which the ancients honoured the dead. In the earliest times they were presented before the funeral pile, or at the tomb of the deceased, and afterwards in the squares and open places of cities, as we learn from Vitruvius, who informs us that the Italians made the *INTERCOLUMNS* of their *FORUMS* more spacious than those of the Greeks, "because, by ancient custom, the shows of gladiators were usually given in the forum." This continued to be the practice of the Romans for upwards of 200 years after the introduction of those combats among them, from whence it may be inferred, that neither the Etrurians nor the Romans had any edifice like an amphitheatre till the period we have mentioned; and it is evident that such edifices were not so necessary for the exhibition of gladiatory combats, as to be religiously appropriated to them from time immemorial.

The Romans had an inordinate passion for spectacles of every kind, and especially for such as were sanguinary and terrible; a disposition which their rulers politically encouraged, as tending to preserve that unconquerable spirit which made them masters of the world. In the year of Rome 490, the first gladiatory combats were exhibited in that city not long after the successful termination of the Samnite war had extended the Roman dominion not only over Etruria, but the whole peninsula of Italy. And in the year 502 wild beasts were introduced among the public spectacles of Rome, by Lucius Metellus, who brought into the *CIRCUS* the elephants he had taken from the Carthaginians in Sicily. These two kinds of shows were so consonant to the taste of the Romans, that they were soon converted into engines of political influence, and the candidates for popular favour vied with each other, in exhibiting them with the greatest splendour and expence. Gladiators were trained to fight as to a profession, and hundreds of them were compelled to butcher one another in the forum, while every savage animal that could be procured from the forests of Africa or Asia was brought to parade in chains, or to be hunted in the circus.

In the time of Pompey and Cæsar the combats of beasts were given with a magnificence which we read of with astonishment, though far inferior to those presented by the emperors; and it is to these combats that we owe the invention of amphitheatres, as the name of *theatrum venatorium*, or *the theatre for hunting*, by which they were at first denominated, sufficiently proves. It was found that these spectacles could not be seen equally well from every part of such an extensive place as the circus, interrupted as the prospect was by the *ΜΕΤÆ*, and other buildings on the *ΣΠΙΝΑ*, nor could they be gazed on with the same ease and security as the combats of gladiators; for in the games given by Pompey the elephants made efforts to break down the barriers which confined them in the circus. These circumstances induced Cæsar, when not long after he entertained the people with

similar games, to remove the metes, and to surround the arena of the circus with a ditch, and probably suggested the expediency of constructing edifices, in which the people might enjoy their favourite diversions without interruption or danger. This purpose amphitheatres were peculiarly adapted to answer; and, being equally convenient for gladiatorial shows, they afterwards became the common THEATRE of both.

It is believed that the first building like an amphitheatre was formed of those curious machines constructed by Caius Curio, one of the partizans of Cæsar, for the games he presented at the funeral of his father. Curio caused two capacious theatres to be built of timber, in the usual semicircular form, and placed back to back, in which he amused the people for several days with theatrical diversions till noon; when the scenery was removed, and the two theatres, with an immense crowd of people in each, were wheeled round till they met, and formed an amphitheatre, in which gladiators contended on the area till evening. This information we have from the elder Pliny; who, although he applauds the invention, exclaims against the temerity of the man, who dared to place the governors of the world in such imminent danger. How this was accomplished we are not told, and how much the relation may have been exaggerated by Pliny, it is impossible to know, as the fact is not mentioned by any other writer; nor is it possible to determine whether this ingenious piece of machinery gave the first idea of an amphitheatre, or was itself suggested by some amphitheatre that had been previously constructed. Be this as it may, Julius Cæsar, a few years after, "erected a *hunting theatre* of timber, called indeed an *amphitheatre*, because the seats were placed round it without scenes," in which he exhibited both the combats of wild beasts and of gladiators. This edifice, from the words of Dio, above quoted, has a fair claim to be considered as one of the first fabrics of the kind.

From this time, during the reign of Augustus and the succeeding emperors down to Vespasian, many other amphitheatres of timber were erected in Rome and in the provinces; but not any of stone, except one by Statilius Taurus, in the time of the first-mentioned emperor, which does not appear to have been held in much estimation, as it was seldom used in the splendid spectacles subsequently exhibited; nor could it be entirely of stone, as it was destroyed by fire in the reign of Nero. These timber amphitheatres were sometimes only temporary structures, raised and taken down as occasion required, though some of them were fixed and embellished as permanent buildings. Augustus, whose policy induced him to encourage every public amusement that interested the people, is said to have constructed several. Caligula began one, but did not live to complete it. Nero, who delighted in gladiatorial combats, also erected an amphitheatre of timber, which was near a year in building. This is described by Tacitus as a sumptuous fabric, and capable of containing a great number of persons. In the time of Augustus, Herod of Judea built amphitheatres at Jerusalem and Cæsarea. In the reign of Tiberius a large one was erected at Fidenæ, a town in the vicinity of Rome, which suddenly fell while the games were exhibiting, when, according to Tacitus, upwards of 50,000 persons were either killed or dangerously hurt. There was another at Placentia, celebrated as the largest in Italy, which was burnt in the war between Vitellius and Otho.

Accidents like those at Fidenæ and Placentia, both in theatres and amphitheatres, had undoubtedly been frequent in Rome, as well as in the provinces, and turned the public attention to structures that were secure from conflagration, and of strength sufficient to sustain the multitudes by which

they were crowded. With regard to theatres an example had been given by Pompey, who first constructed a theatre of stone, and drew upon himself the censure of the satirists for thus luxuriously deviating from the simplicity of ancient practice. Statilius Taurus, as already mentioned, had also erected a stone amphitheatre, though it appears to have been of little consideration; and Augustus, who, as it is said, intended to have constructed one of more ample dimensions in the centre of Rome, on the very spot where the coliseum was afterwards erected, did not carry his design into execution. This was reserved for Vespasian and Titus; the former began the Flavian amphitheatre in his eighth consulate, which was completed by his son Titus, and is deservedly celebrated as a prodigy of building among the ancients. Martial is lavish in its praise, and Cassiodorus asserts, that the expence of it would have built a capital city. At the solemn games exhibited when this fabric was dedicated, 5000 wild beasts, according to Eutropius, and 9000, according to Dio, were destroyed on its arena. When the hunting was concluded, the arena was suddenly filled with water, in which aquatic animals were made to contend; and afterwards a sea-fight was exhibited representing a contest between the Corinthians and Coreyrians, whose wars are related by Thucydides. If Martial may be credited, people from every part of the world crowded to Rome to be present at these games. This stupendous pile has been, from time immemorial, called the Coliseum, according to some authors, from a colossal statue of Nero, which stood at a small distance from it; but more probably from its colossal size, when compared with other buildings.

The Flavian amphitheatre became the model of many others that were subsequently erected by the emperors, or by the people of different countries desirous of sharing in the diversions of the imperial city. Of these the most remarkable were at Capua and Verona in Italy, at Nîmes in Languedoc, at Pola in Istria, and Italica in Spain. The vestiges of others are said to be seen at Alba, a small city of Latium, and at Otricoli, a city of Umbria; the remains of one are found near the Garigliano, formerly the river Liris. At Puzzuoli some of the arches and cells of another are still existing. There are vestiges of one at the foot of Mount Cassino, near the house of Varro, and of one at Pœstum in Lucania; of others at Syracuse, Agrigentum, and Catania in Sicily; at Gortina and Gerapitna in Candia, and at Argos and Corinth in Greece. In France there was one at Arles, and one at Autun. The latter, it is said, consisted of four stories, like the coliseum. There are also vestiges of amphitheatres in Britain, near Sandwich in Kent, at Caerleon in Monmouthshire, (the *Ifea Silurum* of the Romans), and in other places.

But it cannot be supposed that all these amphitheatres could deserve to be named as edifices, when compared with the original model, "*the Flavian Amphitheatre*." Some were little more than natural vallies, with benches cut in the declivities of the surrounding hills like the amphitheatre at Corinth. In some places benches of stone were placed on the declivities of two hills, and the ellipsis completed by works of masonry at the extremities, like that of Gortina in Candia. Some were elliptical excavations with benches of turf, like that near Sandwich in Kent, and most of the Cætrelian amphitheatres (for such was the general rage for amphitheatric diversions, that scarcely any camp, or fixed military station, was without its amphitheatre of turf or timber). Some were partly excavated and partly constructed with masonry, like the amphitheatres of Pœstum and Caerleon; some had their exterior circuit constructed of masonry, and the seats and staircases of timber, like that of Pola

AMPHITHEATRE.

in Istria; while others arose on a similar plan, and with nearly the same ornaments of architecture as the Flavian amphitheatre. Such were the amphitheatres of Capua, Verona, Nîmes, and Autun.

In these various structures, the combats of gladiators and the battles of beasts continued to be exhibited for near 250 years, in which time an incredible number of beasts and men were destroyed, and not unfrequently were they sanctified by the blood of the early Christians, who were devoted at a stake, or compelled to fight, for the gratification of the Pagan populace. At length Providence ordained that Christianity should become the religion of the state, and its lenient spirit gradually changed the barbarous amusements of the ancient world for others more congenial to the humanity of its doctrines. In the year of our Lord 325, Constantine the Great prohibited by law the exhibition of gladiatory combats in the east, but they were not finally abolished in Rome till the reign of Honorius, who, in the beginning of the fifth century, banished all professional gladiators out of the country. This was occasioned by the murder of a monk named Telemachus, who, on some solemn day, was destroyed by the people, while he was exhorting them to desist from their sanguinary diversions. The combats of wild beasts, however, continued both in the eastern and western empires for some time after these events, but gradually became less frequent and less magnificent, till in the course of the sixth century, they were every where totally abolished; and amphitheatres being disused for these purposes, were, in a great degree, abandoned to the depredations of men and the injuries of weather. At Verona and other places, during the middle ages, they were sometimes used for judicial combats and for tilts and tournaments; but these customs having also past away, they have since fallen into general neglect, and consequent ruin.

It is not easy by a verbal description to convey an adequate idea of the construction of an amphitheatre, and the means by which such a number of persons crowding to these edifices could have ingress and egress without confusion; but, with the assistance of the sectional diagram in *Plate 11. of Architecture*, and an occasional reference to the plans and sections of such amphitheatres as yet remain, these particulars may be easily understood. We have already observed, that the exterior circuit consisted of two or more stories of arcades; these varied in number according to the extent of the amphitheatre. On the ground floor they opened to an equal number of arched passages, and staircases, tending like radii towards the arena, and were intersected by two or more arched passages, or *CORRIDORS*, that surrounded the whole edifice, and gave an uninterrupted communication to every part. Sometimes in the middle of the fabric there was an intermediate gallery, which, like those on the ground floor, surrounded the whole, and served as a common landing-place to all the staircases that led to the higher galleries, as in the amphitheatre of Nîmes; and sometimes each staircase had its distinct landing, without any gallery of general communication, as in the amphitheatre of Verona. Of the radiating passages the four which were placed on the diameters of the ellipsis were usually made wider than the rest, and were also, by lateral arches, laid open to the adjoining passages on either side of them. Those two which were placed on the shorter diameter were the principal entrances, by which the emperor, the senate, and other distinguished personages were conducted to their seats on the *PODIUM*. The other two led directly into the arena by large arched gateways, and were appropriated to the beasts and gladiators, who probably entered in some processional manner, that required more width and elevation than

the ordinary inlets. These interior gateways still exist at the extremities of the ellipsis, in the amphitheatres of Verona and Pæstum, and in the former interrupt the continuity of the lower benches. Through the other passages the different orders of the people passed to the staircases which led to their respective seats; and as every arch in the exterior circuit was numbered, and also the *CORNER*, which separated the people into classes, in the manner we shall hereafter mention, every one knew the passage which would conduct him to the place assigned by the laws of the amphitheatre to his rank and condition. Those persons whose dignity entitled them to a seat on the podium passed forward to the staircase *A*, and ascended to the doorways that opened upon that distinguished place. Those of the Equestrian order, or of such rank as entitled them to a seat in the division of benches next above the podium, ascended by the staircase *B*; while the other classes made use of the staircase *C*, which arose to the floor of the intermediate landing or corridor *E*; and then either ascended by the staircase *F* to the second division of benches, or by the staircase *D* to the second exterior corridor, and from thence by the staircase *G* to the third division of benches, and higher still by other staircases in a different direction, to the third exterior corridor, which communicated with the uppermost division of benches. Those different staircases were respectively opposite to different arches, and approached by distinct passages, though, for the sake of perspicuity, we have represented them in a single diagram.

The doorways, which opened from the stairs and passages, were denominated *VOMITORIES*. The number of these varied, according to the size of the amphitheatre, and the number of exterior arches. In the amphitheatre of Verona there were 60 of them, placed in four elliptical rows alternately over alternate radii, so that the first and third were on one radius, and the second and fourth on another. In the highest circuit there were 16, in the next to it 16, placed at equal distances, in the next to that 16, but not all at equal distances, as the *BALCONIES* over the great gates of entrance to the arena occupied the places of two at the extremities of the ellipsis; but the number was supplied by two over the shorter diameter, where otherwise there would have been but one. On the lower line there were 12 which opened upon the podium. The number of benches between the several ranges of vomitories was unequal, and probably was not determined by any positive rule. The benches were about two feet four inches broad, and one foot eight inches high. Before every range of vomitories one bench was omitted, which left a platform four feet eight inches broad, (having a wall on the ascending side three feet four inches high) which encompassed the whole, and served as a communication to all the vomitories on the same level. These platforms were called *PRECINCTIONS*, and the fronts of the walls, which bounded them on one side, were denominated *BELTS*. The latter were sometimes embellished with Mosaic work, and surmounted by *BALLUSTRADES*, to protect those from falling, who were seated on the benches immediately above them. The podium was a platform that surrounded the arena, more spacious than the precinctions. Opposite to every vomitory a flight of stairs, two feet six inches wide, descended from one precinction to the belt or ballustrade of the other. In the top of the benches, and close to the edges adjoining to the stairs, small channels were cut, by which the rain-water or urine flowed from bench to bench, till it reached certain pipes or conduits that conveyed it to the drains below. As these stairs radiated from the uppermost bench to the podium, they, with the precinctions, divided the whole interior concavity into wedge,

like portions, in which the spectators were seated according to their rank. These were the *Cunei*, so frequently mentioned by writers, and which do not appear to have been well understood, has the term as been applied to very different parts of the amphitheatre. That the people both in the theatres and amphitheatres were placed in wedge-like divisions, we learn from various passages in ancient authors. Apuleius says, such spectators as could not get places on the marble benches, but stood in the passages or on the stairs, were "unwedged;" and Tacitus informs us, that when Nero placed soldiers in the amphitheatre to applaud his performances, they were distributed through all the "wedged," that every part might ring with applause.

With regard to the laws by which the people were arranged in amphitheatres, our information is very imperfect; but we may presume the same regulations applied to amphitheatres and theatres, as far as the forms of the edifices coincided. We know that persons of the highest dignity had their places on the podium, and in the middle of one side of it was the emperor's PAVILION, called the *SUGGESTUM*. Several of the wedges were assigned to the senatorial order, as the podium was not sufficiently spacious to contain all the senators and other dignified persons. Other *Cunei* were allotted to the Equestrian order, with whom the Tribunes, both civil and military, took their seats, of which the number was very great, as every man who had once filled the office retained the rank. The *Liberti* were cautiously excluded from these orders, and even the *Legati* were prohibited by Augustus from sitting among the senators, because some *Liberti* had been sent in that character. The married men had places distinct from the unmarried. The young men had their appropriate seats, and their tutors sat in other seats near them, that they might observe their behaviour. The attendants and official servants of dignified persons had seats constructed of wood in the higher parts of the building. The places for the vestals were on the podium, and the princesses and ladies of high distinction frequently sat with them; but the front of the gallery, which rose above the gradations of benches, was especially appropriated to the women, where they sat on chairs, and the lowest order of the Plebeians stood behind them. These were the leading distinctions of rank and classes; but for popular accommodation different wedges were, in all probability, allotted to different tribes. The *Cunei* were all numbered as before mentioned; but it is a mistake to imagine that every man had his particular seat numbered and ticketed, for sometimes all the *Cunei* were filled, and the precincts, and stairs so crowded, that many persons who were entitled to places within certain precincts, were obliged to ascend to the gallery, and mingle with the plebeians behind the women. By such arrangements as we have specified, which relate chiefly to the Roman amphitheatre, and which undoubtedly were varied in the provinces, as the ranks and classes of people differed from those of Rome, all confusion and disorder were avoided. The general care of the amphitheatre was given to an officer named the *VILLICUS AMPHITHEATRUM*, and the *Cunei* were under the direction of other officers, called *LOCARII*. The strictest attention was exerted to prevent any one from occupying a place to which he was not entitled; and if a man was wrongfully compelled to quit a seat he had taken, he considered himself as degraded and injured. See *Plate VII. of Architecture*.

The front of the podium, next the arena, was defended by strong netting and rails of iron, armed with spikes, and also with strong rollers of timber which turned vertically, to prevent the hunted animals from leaping over. The emperor's pavilion was lined with silk, and otherwise highly

embellished. The seats of the principal persons were covered with cushions, the marble benches in general with boards, and over all an awning of woollen of different colours, called the *VELUM*, was occasionally stretched to protect the spectators from the sun and rain, which, by means of pulleys and cords, could be let down and drawn up at pleasure. These articles, which may be denominated the furniture, were almost the only combustible parts of the fabric, and in the Flavian amphitheatre they were, at different times, destroyed by lightning, and particularly in the reign of Macrinus, when so much damage was done to that building, that the public games were performed in the circus for several years after.

It has been asserted that amphitheatres had an underground story, consisting of numerous dens and cells, in which the beasts were kept for the games; but whoever considers the space which, on the ground story, was necessary for the ingress and egress of the people, and the difficulty of getting light, however small the quantity requisite, and of gaining convenient entrances to these subterraneous places, to say nothing of the insufferable stench that the food and ordure such numbers of animals would occasion, will at least acknowledge this to be improbable. As the coliseum has not been examined to the foundations, we can say nothing with certainty with regard to the subterraneous parts of that fabric; but the amphitheatre of Verona was cleared in many places by Maffei, and nothing found but drains (see *Plate VIII. of Architecture*), which received the rain and other waters conveyed from above by channels in the staircases. Among the passages, and under the stairs on the ground story, are many cells and rooms that were probably prisons for criminals condemned to fight, or be devoured, in which the beasts might occasionally be stabled; but there is nothing to justify a conjecture that animals were constantly kept there. On the contrary, we learn from a passage in St. Chrysostom, that the beasts intended for the public games were kept in the environs of cities, and Procopius makes particular mention of a spacious place in Rome called the *VIVARIUM*, appropriated to that use. It appears, that Lippus and others were led to conjecture that animals were kept under the amphitheatre, by some passages in ancient authors, which describe them as coming from subterraneous places into the arena. But it was sometimes the practice to give novelty to the games, by erecting pieces of machinery on the arena, representing mountains, on which real trees were planted, and under them hidden caves were formed, from whence the animals rushed out to encounter the combatants, or to devour their victims. It was probably to these caverns that such ancient authors alluded, and not to any permanent caverns constructed under the amphitheatre.

Of the amphitheatres which merit particular notice, the coliseum stands foremost in order of time and in magnitude. It was an ellipsis, whose longest diameter was about 615 English feet six inches, and the shorter 510 feet. The longer diameter of the arena was about 281 feet and the shorter 176 feet, leaving a circuit for the seats and galleries of about 157 feet in breadth. The external circumference, when complete, was about 1770 feet, covering a superficies of about 246,651 feet, or something more than five acres and a half, and could barely be included in a parallelogram of seven acres. These dimensions are taken from Desgodetz, who appears to have examined the remains of this edifice with great care, and to have corrected many mistakes of Serlio and Fontana.

The external elevation of the coliseum consisted of three stories of arcades respectively embellished with columns of the Doric, Ionic, and Corinthian orders; and an inclosed

AMPHITHEATRE.

PILASTRADE of the Corinthian order that ascended to the uppermost cornice. The first story of arcades was raised four steps, or about three feet six inches, above the ground, and the bases of the columns stood on the pavement. In the two superior stories the PIERS and columns were elevated on stylobatae or continued PEDESTALS, which served as PARAPETS to the corridors. The pilastrade was also elevated on a STYLOBATA, in which were the windows of an intermediate gallery, and in every second INTERPILASTER was another window that lighted the highest gallery. The building was crowned by a CANTALIVER CORNICE perforated with square holes, three in each inter-pilaster, through which the upright pieces of timber that supported the awning were passed to a range of CORBELS about the middle of the pilastrade. These several stories of columns and pilasters appear to have been continued, without break or interruption, round the whole external circuit; although on some medals, engraved by Maffei, there is a representation of a PORTICO on one side, as if intended for the principal entrance. Whether this was ever executed, and in what manner, cannot now be determined, as there are no vestiges of such an additional structure, unless the mutilations over the central arch, on the side next the Imperial palace, may be considered in that light. Piranezi says, that in this place there was a bridge which communicated with the portico of Claudius. The height of the first story from the pavement to the top of the cornice is about 33 feet 6 inches, the second about 39 feet, and of the third about 38 feet, of the pilastrade about 46 feet, and the whole height, including the steps and BLOCKING COURSE, about 164 feet. See *Plate IV. of Architecture.*

On the ground plan the exterior circuit of the ellipsis consisted of eighty open arches; the piers of which were about seven English feet, one inch broad, having three-quarter-columns in front of about two feet ten inches diameter; seventy-six of the arches were each about 13 feet 8 inches wide, and the four which answered to the four semi-diameters, about 14 feet two inches. These arches opened into a spacious double corridor, that encompassed the whole, from thence radiated eighty passages and staircases, which either led to two interior corridors and the arena, or ascended to the galleries and vomitories above. This double corridor is a grand and distinguishing feature in the plan of the coliseum. The first interior corridor was lighted by square apertures in the floor of the precinct over it, and the corridor adjoining to the wall of the podium was probably lighted in the same manner. The second story had a double corridor over that on the ground story, connected by passages on the same level, with an interior corridor from whence stairs, on one hand, ascended to the second range of vomitories, and on the other to an intermediate corridor, which formed an ENTRESOL or MEZZANINE-floor, over the interior circuit of the double corridor. In this mezzanine gallery, which was lighted by square apertures in the floor of the gallery over it, the stairs commenced that rose to the next story. The third story consisted of a double corridor, and must have contained the stairs that communicated with the galleries above, but it is too much in ruin to be accurately traced. In the interior wall are some windows, and the doorways or vomitories that opened on the uppermost cunei of benches. The fourth story, in all likelihood, was that appointed for the women, and on the exterior wall there are vestiges of stairs that led to the fifth gallery, which we conjecture was that allotted to servants, and furnished with benches of timber. This gallery contained four staircases that led to a sixth floor, which was,

perhaps, appropriated to those who managed the velum and had no other covering, and from this floor the four staircases continued to the parapet or blocking course, which crowned the exterior wall. These three upper floors were all comprehended externally in the pilastrade, but how their interior fronts were finished we know not: we may, however, presume, that they were so constructed, probably of timber, as to give the least possible obstruction to the prospect, and perhaps nearly in the manner we have represented them in the perspective section, *Plate V. of Architecture*, which with the plans in *Plate III.*, and the sections in *Plate IV.* will sufficiently explain the construction of this edifice.

The exterior circuit of the coliseum is built of Travertine-stone, cramped together with iron without cement. The piers of the double corridor, the VOUSSOIRS of the arches, the heads of the partition walls and some BONDING COURSES are of the same kind of stone. The rest is of brick. The OFFSETS of the front walls are all made on the outside, so that its interior face is nearly perpendicular. Some of the internal walls have remains of ornaments in plaster, and in others they are lined with marble. The floors of the corridors are paved with small flat bricks and covered with a hard incrustation of stucco. The columns in the three stories and the pilasters are all of one diameter. The diminution of the columns commences from the third part of their height. In the first and second orders they are three-quarter columns; in the third order semi-columns. The VOLUTES of the Ionic capitals, and the foliage and other embellishments of the Corinthian capitals, are only rough-hewn or BOSTED. All the mouldings except the IMPOSTS of the arches have the SOFFITS of their projections sloping upwards or higher in front than rear, and in the same degree in the mouldings of the first order as in those at the top of the edifice. This was frequently practised by the architects of antiquity, for the purpose, as many have conjectured, of giving the mouldings a greater apparent projection; but, as Desgodetz justly observes, if the mouldings have in reality their due projection, to make them appear larger is to make them appear false, and as the ancients in all situations gave them the same degree of elevation, he thinks they had some other besides optical reasons for the practice. This edifice is not every where executed with exactness, many of the parts being out of level and larger in some places than others, perhaps the unavoidable consequences of an immense number of persons working upon such an extensive building at the same time, and the unequal settling of so many piers, placed upon a foundation of seventeen hundred feet.

This amphitheatre, according to Justus Lipsius, was capable of containing 87,000 spectators on the benches, to which number Fontana added 22,000 for the galleries, staircases, and passages. But it will be found, that allowing two feet two inches to each seat, and 21 inches for each person, not quite so many as 50 thousand could be contained on the benches, with the addition of one floor of the gallery, and supposing all the precincts and staircases to be filled. If the higher galleries were completely crowded, perhaps about 30,000 more might be added, in all about 80,000; a number sufficiently large without exaggeration.

A structure of such dimensions, and of such contrivance and ingenuity as that we have been describing, throws into obscurity the most magnificent works of the Greeks, and even when compared with the pyramids of Egypt, is more entitled to our praise, though less the object of vulgar admiration.

erations. The pyramids, if they be considered as buildings, are the work of barbarous greatness, performed by ignorant labour, with little invention or ingenuity. The coliseum could not have been constructed till the art of building had arrived at its highest perfection, and probably would never have been constructed if the arch had not been invented, and its powers determined both experimentally and mathematically some short space of time preceding. This, however, is conjecture. When this edifice was complete, its external aspect must have been strikingly grand, from its magnitude, its loftiness, and simplicity of form; and the immensity of its interior concavity, especially when crowded with 50,000 persons, must have been in the highest degree imposing. Even now, when its benches and galleries are in ruins, and the arena filled with the accumulated rubbish of twelve centuries, its remains are contemplated with astonishment. Yet this magnificent edifice, if it was completed by Titus, was erected in two years and nine months, a wonderful example of the energy of the Romans! However, there is a tradition in Rome, that 15,000 men were employed upon it for ten years, which, if true, will place the time of its being completed far in the reign of Domitian, though it was certainly dedicated, and the first games exhibited within it, before the death of his brother. The coliseum has been pillaged greatly at various times, but most by Michael Angelo, who carried away near one-half of the outward wall to build the Palazzo Farnese. Pope Benedict XIV. to stop these depredations, consecrated the ruins, and erected several altars, which on Fridays and Sundays were, before the French revolution, much frequented by devotees. A small building near the centre was furnished with accommodations for a hermit, who constantly resided there to guard the sacred relics from the rude hands of ignorance and impiety, an office which we hope is still continued.

Of the amphitheatre of Verona only four arches of the external circuit were remaining at the beginning of the 18th century. They consist of three stories of *unwrought* RUSTIC arcades, of which the two lower stories were embellished with rusticated pilasters and entablatures, assignable to no legitimate order. In the third story, there were no pilasters, but capitals are executed under the architrave, as if pilasters had been originally intended. On the top of the highest cornice there are two mutilated courses of rustic work, like the rest of the front, and the beginning of two plain pillars which has been supposed the commencement of a fourth story. The height of the three existing stories is about 90 English feet. The whole of the edifice was erected without any cement, the stones being nicely joined and secured by iron cramps, covered with lead. The longer diameter of the ellipsis was 506 English feet. The shorter 405 feet. The arena was about 247 feet by 145. The exterior circuit was 1451 feet. The superficies 204,930 feet, or four acres and nearly one third of an acre.

The exterior circuit was divided into 72 arches, opening into a single corridor, surrounding the whole fabric, from whence radiated 72 passages and staircases, intersected by two other surrounding corridors. The greatest part of these exist, and by consulting the plans and section in *Plates VI. and VII. of Architecture*, a clear idea may be obtained of their construction. The two grand entrances at the ends of the ellipsis were considerably wider than the other passages, and nearly of an uniform width from one end to the other. The GROOVES in the jambs of the remaining external piers shew that the arches have been inclosed by gates; but whether this was the case at Rome and other

places we know not. By the plan of the second story we find that the outward corridor was crossed by eight staircases, which, rising over the circuitous passage-way, conducted the spectators to the third corridor, and the uppermost vomitories. The benches of this amphitheatre, 45 in number, remain, but not in their original places, having been moved and altered according to Maffei in the repairs, which the citizens of Verona, much to their honour, have from time to time made to this edifice. By contriving to make it occasionally useful as a place for public diversions, they have preserved it from entire destruction. As we drew our general description of the precautions and curci, as well as many other particulars, from this amphitheatre, it is unnecessary to repeat them here.

In *Plate VIII. of Architecture*, we have represented the sewers made for the purpose of carrying off the water of the building. In the centre a well is observable that has no connection with the sewers, the use of which it is not easy to conjecture, unless it was intended to receive some mast or pole, erected for the purpose of supporting and working the velum. It is six feet wide and very deep. The time of building this edifice is unknown, some ascribe it to Augustus, and others to the emperor Maximilian, but Maffei supposes it to have been constructed by the citizens of Verona, during the reigns of Domitian and Nerva. The younger Pliny mentions a magnificent exhibition of gladiatory combats at Verona, which gives probability to the conjecture of Maffei. About 30,000 spectators might have been crowded into this amphitheatre if the precautions and staircases, as well as the benches and gallery, were filled.

The elevation of the amphitheatre at Nimes consisted of two stories of open arcades and an ATTIC. The lower story is very lofty, the arches tall and narrow, *EXTRA-DOSSED*, and separated by buttresses of two projections in the Gothic form, crowned by a Tuscan capital. A regular entablature encircles the building, and breaks in projection over every BUTTRESS. The second story is embellished with columns of the Tuscan order, seven diameters in height, over each of which the entablature breaks as in the order below. The arcades on this story were originally defended by a parapet that rose about three feet six inches above the floor of the corridor, formed of one large flat stone, with a sunk PANNEL, on which various designs were carved in bas-relief. On one which remains perfect, there is the representation of a combat between two gladiators. The rest have been removed and their place supplied by others of modern building. On the crown of the attic, directly over every pier, are two CONSOLES, projecting 20 inches before the face of the wall, pierced with a hole about eleven inches diameter. Through this hole the pole which supported the velum was passed to the cornice, where it rested in a socket of the same dimensions and about six inches deep. Other holes are found in the benches at corresponding intervals, in which other poles were fixed, and the *velum* extended by pulleys from one pole to another, as represented in *Plate II. of Architecture*. This method of supporting the velum is more simple than Fontana's, but it shades only the upper ranges of benches, and leaves those where the persons of highest rank were seated, exposed to the weather; yet if we conjecture rightly as to the use of the well in the Veronian arena, the velum might have been further extended by other cords attached to a mast in the centre. See *Plates II. and IX. of Architecture*.

The exterior circuit consists of 60 open arches, of which four at the extremities of the diameters "are ornamented with

AMPHITHEATRE.

with pediments, and formed the grand entrances." The other 56 led to the passages and staircases, intersected by two corridors which encompassed the whole; one in the exterior of the building, and one near the wall of the podium which received light by iron grates from the arena. Another interior corridor or gallery, situated near the middle of the building, and nearly at equal distances of height between the two exterior stories, forms the common landing of the staircases, and communicates both with the exterior gallery on the second story and the benches. The spectators ascended by 20 steps, each nine inches high and twelve broad, into the intermediate gallery, and by 20 more into the exterior one on the second story. There is a fifth gallery in the attic, which was approached by narrow stairs, wrought in the body of the wall, and probably intended for the *velarii* or servants who managed the *velum*. This amphitheatre had no covered gallery surmounting the benches and looking upon the arena, like those of Rome and Verona. All the radiating passages, as well as the four grand entrances, regularly decreased in height and width from the exterior corridor to the wall of the podium. It was the same in the amphitheatre at Arles, as may be seen in the only passage remaining.

The longest diameter of this edifice, extending from east to west, is, according to Beaumont, corrected by another account, about 430 English feet, the shorter diameter 338 feet, and the whole height 76 feet six inches. The superficies 126,273 feet, or something less than three acres. The benches were originally 32 in number, from 18 to 24 inches high and from 18 to 24 in breadth. They were approached by three rows of vomitories, and were capable of containing about 17,000 spectators. The stones with which this fabric is constructed are of very large dimensions; sometimes cemented and sometimes fixed with iron cramps and lead. In several places the impost of the piers is a single stone, nine feet long, seven feet broad, and between two and three feet thick, and many of the stones, which form the benches, are eighteen feet long, two feet broad, and one foot eight inches high.

The vicissitudes of the amphitheatre of Nimes upon record, are so numerous that it is wonderful it should have been preserved so well as it now appears. In the year 472 it fell under the dominion of the Visigoths, who surrounded it with a ditch, built a castle within it, and converted it into a citadel. Part of the towers of the castle still remains; but the ditch was filled up in the 13th century. In 720 it was taken by the Saracens, who were driven from it in 737 by Charles Martel. After that time it was occupied as a fortress by the counts of Provence, who sustained a number of attacks in it, and built a church and a palace on the arena. The steeple of the church is still in existence. In 1226 the knights, who then guarded the citadel, yielded it to Lewis the VIII., and in 1391 it ceased to be a fortress and was evacuated, though the houses continued. In 1533, that polished monarch Francis the First directed it to be cleared, which his subsequent misfortunes prevented from being done, and similar orders were given by the late unfortunate Lewis the XVI., but the work has not yet been completed.

Governor Pownall, who visited Nimes in 1785, says, that the amphitheatre was filled with houses arranged in streets, and looked like a little walled town. The galleries on the ground story and the intermediate gallery were converted into numberless miserable habitations, but the exterior gallery of the second story and that in the attic were perfectly unencumbered as in their original state. The date of

this building is uncertain: but Mons. Menard conjectures it was erected by Antonine, which places it between the years 138 and 161.

What remains of the amphitheatre at Pola, in Istria, is a single elliptical wall of 72 arches, built on the declivity of a hill, having on the western side, which looked towards the sea, two rustic arcade stories with rustic Tuscan pilasters and entablatures, and on the opposite side only one arcade story, the first being gradually lost in the slope of the hill. Above the arcades is an attic story of rustic wall, with 72 windows, which surrounds the whole, and in it are grooves and corbels for the poles that supported the *velum*. At the haunches of the ellipsis are four projecting buildings or towers, of two arches in width, having windows curiously filled with reticulated stone work in the attic, and doors and windows on every story towards the arena. The second story of exterior arches in these projecting buildings are closed up as high as the imposts, and the semicircle is filled with upright *MULLIONS* of stone like the loopholes of an English barn. These towers have been called *COUNTER-FORTS* by Serlio and others, but in all likelihood they were made for another purpose, as will be mentioned hereafter.

The whole of the exterior circuit of this edifice, excepting a very few yards of the parapet, was remaining when it was visited by Maffei, and appeared with extraordinary beauty when viewed from the sea. It was built with stones cramped together without cement. All the benches and other interior parts which were originally constructed of timber had long been destroyed. The longer diameter of the ellipsis is about 416 English feet, the shorter diameter about 337 feet. The circuit about 1182 feet, the superficies 123012 feet, or about two acres and seven-eighths of an acre.

The Marquis Scipio Maffei, whose attachment to Verona made him unwilling to believe that amphitheatres existed in other places, inspected this inclosure, and pronounced it to have been a theatre only, assigning the slope of the hill to the benches for the spectators, and the opposite side which is nearly level, to the orchestra and stage. The two towers on the western side he supposed to have been constructed to represent the houses in the ancient scene, and the other two on the eastern side to have been built for the sake of uniformity only. All this appears highly improbable. The erecting of such an extent of elliptical arcades as half this inclosure, for the actors, would have been a waste of labour and expence to produce a work but ill adapted to its use, and if the towers had been intended to represent the fronts of houses, they would not have had doors and windows on both the upper stories, as well as the arches which gave entrance on the ground story; nor would such appendages have been erected on the opposite side for the sake of uniformity, when, in no point of view, they could be seen together. It is much more likely that the architect took advantage of the slope of the hill to place his benches on one side, and constructed them of timber on the other, and made the staircases to the higher ranges in the four towers, which conjecture renders them useful as well as uniform, on every side. It is said that vestiges of such staircases actually exist, but if they did not, the disposition of the apertures would justify the conclusion. There can be no doubt but the interior of this amphitheatre was filled with benches as high as the second story of arcades, and had a covered gallery on the attic story. If this be not admitted we may ask, why was there a range of windows in the attic story? and for what use was the cornice or coping of the wall formed

formed into a gutter, urets to receive rain water from a roof?

The amphitheatre of Pæstum is one of those which had the arena and part of the benches sunk below the surface of the earth and the excavation, encompassed by other benches and an arched structure of stone. Neither Major's work on the ruins of Pæstum, nor the Italian work on the same subject, published at Rome in 1784, by the Rev. Father Paul Antonio Paoli, enable us to form a clear idea of its construction, or even the exact state of its remains, and it would not have merited particular attention if it had not been made the basis of an hypothesis, respecting the origin and progress of these edifices, which, however simple and pleasing, does not appear to be true. The reverend father conjectures that the first public spectacles were given in small valleys, and that the spectators beheld them from the declivities of surrounding hills. That afterwards, when they were exhibited in cities, excavations were made in the earth, and encompassed with benches of turf, upon which the people enjoyed their diversions without incommoding one another. That the greater the number to be accommodated the more they sunk the arena, and increased the surrounding slope; and finally, that they inclosed it with walls of masonry, and added other benches of stone till it was capacious enough to contain a vast multitude of spectators. This, he thinks, was the first method of forming amphitheatres, which the Romans improved into the magnificent structures we have been describing. The amphitheatre of Pæstum he considers as an example of this ancient method, and supposing the excavated part to be of great antiquity ascends to the time of the Etrurians, and adopts the opinions which we have briefly controverted in the beginning of this article. But, however plausible this theory may be, if it depends on the antiquity of the Pæstum amphitheatre, its probability will decrease in proportion as that antiquity becomes doubtful. The remains of this amphitheatre are indeed situated among temples, which are believed, though perhaps erroneously, to be very ancient; but it is difficult to believe that a city, which could erect such temples, would be content with a simple excavation for the place of its public amusements. As to the part which was built of stone, the arches at either end of the elliptical inclosure, prove it to be the work of a much later period; and if our conjecture be well founded that the invention of the arch and the first construction of stone amphitheatres were nearly coeval, if not reciprocally the causes of each other, the date of that part will be fixed in the reigns of the first emperors, when the fame of the coliseum and the passion for public spectacles spread through all the Roman provinces and tributary nations, and every country endeavoured to imitate in the manner best suited to its population and riches the amphitheatre of Rome. But in whatever age the amphitheatre of Pæstum was made, its form alone is no proof of its antiquity, as the amphitheatre of Caerleon was formed in the same manner, and Britain might with equal reason produce it as an example of the earliest mode of forming amphitheatres, and from such evidence contend with Lucania or Etruria for the honour of the invention. The length of the Pæstum amphitheatre was about 211 feet, its width 151 feet, the superficies 31861 feet, or about three quarters of an acre.

In the five different amphitheatres which we have described, will be found the principal varieties of these edifices in a gradation that may be amusing to those who will take the trouble to compare them. The dimensions have been collected from the best authorities; and the calculations made

and examined with care; but such is the difference among authors in this respect, that the more we have consulted the greater has been our uncertainty. Thus Beaumont gives the dimensions of the amphitheatre of Nimes as 438 by 338 feet, while Governor Pownall states them to be 400 by 300, and the difference between Fontana and Desgodetz, with regard to the coliseum, is not less considerable. Who can wonder that the dimensions of the pyramids should have remained doubtful from the days of Herodotus to the present, when we are uncertain as to the exact sizes of objects in a manner under our eyes.

The writers on amphitheatres, most worthy of regard are the learned Justus Lipsius and the celebrated marquis Scipio Maffei. To the latter we have been greatly indebted, though we have not always adopted his opinions. Serlio, who described the ancient buildings of Italy, about the middle of the 16th century, deserves more attention than he has received. His prints of the coliseum, though rudely executed, and in places, incorrect, preserve some particulars which later authors have omitted. The splendid work of Fontana on the same subject is very ingenious, but inaccurate, and full of improbable conjectures; we have, therefore, followed Desgodetz in preference, who has trodden in the steps of Serlio, corrected his errors, and supplied his deficiencies; but even the plates of Desgodetz are in a few instances incorrect and inconsistent with one another. Governor Pownall's "Antiquities of the Provincia Romana of Gaul," and Augustus Beaumont's "Select Views of Antiquities in the South of France," furnish much information relative to the amphitheatre of Nimes and amphitheatres in general. "The Rovine della Citta di Pesto," by Father Paoli, contains some amusing speculations which are rendered doubtful by the amphitheatre of Caerleon, as described by Giraldus Cambrensis, and that intelligent traveller Mr. Cox, in his "Tour in Monmouthshire." Numberless other notices may be found in writers on local antiquities that illustrate this subject; a subject equally interesting to the architect and the antiquary.

AMPHITHEATRE is used by the French for the seats at the lower end of a theatre which rise above the parterre, opposite to the stage, and occupy the space of the front boxes and a part of the pit of an English theatre. They also give this name to an apartment appropriated to public scientific lectures and discourses, filled with seats, rising one above another, either in a semicircular form, or encompassing the whole room like the seats of an ancient amphitheatre. In the former case the scholars are in front of the lecturer; in the latter, he is placed in the central area, and surrounded by his scholars. Such schools in England are denominated theatres, as the theatre of the University of Oxford, the anatomical theatre at Surgeon's Hall, and the theatre of the Royal Institute, in London.

AMPHITHEATRE, in *Gardening*, is a lofty terrace, ascended by flights of steps either straight or circular, supported by banks and slopes of turf in various forms, and used to terminate the view from an alley or an opening in a thicket. This mode of decoration is also employed to give regularity to the side of a hill, and to gain an easy ascent by means of slopes and platforms of turf to the summit. The banks and slopes are frequently embellished with statues, fountains, vases of flowers, clipped-yews, shrubs, and dwarf-trees, and sometimes behind these are planted trees of nobler size, such as pines and cedars. A taste for gardening more consonant to the beauties of natural landscape, has nearly banished this kind of amphitheatre from England; but it is not uncommon in gardens on the continent.

AMPHITHURA, in *Ecclesiastical Antiquity*, a name given to the veil, or curtain, which divided the chancel from the rest of the church.

The word is *αμφίθυρα*, thus called, on account of its opening in the middle, after the manner of folding doors.

AMPHITRION, in *Entomology*, a species of PAPILIO. Wings indented, above black, with an unequal yellow band; beneath, on the posterior pair, a stripe of yellow dots, and blue lunulated marks. Linnæus. This is the Papilio Cambrifus of Cramer. The body is large, and without spots, general colour black, with an unequal row of yellow spots near the anal angle of the posterior, but not connected with it. Under side of the posterior wings black, with a stripe of seven large orbicular spots, and a streak of blue lunulated marks, terminating at the anal angle in a yellow dot; the margin sinuous with yellow. A native of America. Fabricius.

AMPHITRITE, *Αμφίτριτη*, from *αμφι*, and *τριζυ*, *sono*, in the *Heathen Mythology*, the wife of Neptune, daughter of Oceanus and Thetis, and goddess of the sea, sometimes taken for the sea.

There was a statue of Amphitrite in the temple of Neptune at Corinth, and another in the isle of Tenos. Spanheim says, that she is often represented like a Syren, with the upper part of the body to the waist like a female, and the lower part with the tail of a fish instead of limbs. Amphitrite was the mother of Triton. Two Nereids were also called by this name.

AMPHITRITE, in *Natural History*, a genus of the MOLUSCA order in the class of VERMES. The body is protruded from a tube, and is annulated; peduncle warted; feelers acuminated, approximated and feathered; and it is destitute of eyes. Linnæus. The species of this genus are Reniformis, Pencillus, Ventilabrum, Auricoma, Cristata, Chrysocephala, and Plumosa, which see.

AMPHITRYON, in *Mythological History*, the husband of Alcmena, was the son of Alcæus, and the father of Hercules; but less distinguished by his own exploits than by those of Alcmena, which it is of no great importance to recite.

AMPHODONTA, compounded of *αμφι*, and *οντα*, *tooth*, in *Zoology*, a designation given to animals which have teeth in both jaws, the upper as well as under.

AMPHORA, in *Antiquity*, an earthen vessel, which served as a kind of liquid measure among the ancient Greeks and Romans.

It is called in Homer *αμφιφορευς*, from *αμφι* and *φερω*, and by *syncope*, *αμφορευς*, on account of its two *ansa*, or handles for carriage. It is the same with the *quadrantale*. But we meet with two kinds of *amphoræ* in ancient writers, the Italic and Attic.

AMPHORA, *Italic*, was that used by the Romans, and which is, therefore, sometimes called the Roman amphora. The Italian amphora was also called *quadrantale*, and sometimes *cadus*. It contained 72 pounds of wine or water, 80 of oil, and 180 of honey.

The amphora was equal to 2 *urnæ*, or 3 *modii*, 6 *femodii*, 8 *oenyji*, 48 *sextaries*, 96 *hemina*, 192 *quartarii*, or 570 *cyathi*, amounting to about 7 gallons one pint, English wine measure. Arbuthnot.

The ancient amphoræ were either *sessile*, i. e. such as would stand, or *non sessile*, terminating in a sharp bottom. Of both which kinds, we meet with figures on ancient medals.

The *amphora capitolina* was the standard of this measure, which was kept in the capitol, to adjust others by.

Suetonius tells us of a man, who stood for the *quæstor*.

ship, and who drank an amphora of wine at one meal with the emperor Tiberius. Supposing the amphora to have been a cube of four feet each side, as Politian asserts it to have been, we may venture to say, that ten of the greatest drinkers on earth could not have emptied it. Boddæus's computation is much more reasonable; he makes the amphora of wine amount to about $4\frac{1}{4}$ gallons Paris measure.

AMPHORA, *Attic*, was that used by the Greeks, and therefore sometimes also called the Grecian amphora.

The Attic amphora was one-third part bigger than the Italic; so that as the latter contained 2 *urnæ*, or 48 *sextaries*, the former contained 3 *urnæ*, or 72 *sextaries*, amounting to about ten gallons $5\frac{1}{2}$ pints English wine measure. This was called *αμφορευς*, sometimes also *κεραμιον*, and, by way of distinction from the Roman kind, *μετρητὸν*.

AMPHORA was sometimes also used as a dry measure, containing three bushels; the standard whereof was kept at Rome in the capitol, to prevent false measures.

AMPHORA is also used to denote the largest liquid measure in use among the Venetians. The amphora contains four *bigots*, seventy-six *mustachi*, or two boats, or *muids*.

AMPHORA, in *Astronomy*, a name given to the sign more usually called AQUARIUS.

AMPHORARIUM *vinum*, in *Antiquity*, denotes that which is drawn or poured into *amphoræ* or pitchers, by way of distinction from *vinum doliare*, or cask wine.

The Romans had a method of keeping wine in amphoræ for many years, to ripen, by fastening the lids tight down with pitch or gypsum, and placing them either in a place where the smoke came, or under ground. Colum. Re Rust. lib. i. cap. 6. Plin. Nat. Hist. tom. ii. lib 2.3. cap. 1.

AMPHORITES, a kind of poetical contest, which obtained in the island of Ægina; in which an ox was given to the person who produced the best dithyrambic verses in honour of Bacchus.

AMPHOTEROPLON, among *Civilians*, denotes a kind of naval insurance, where the insurers run the risk both in the going out and return of a vessel.

In this sense the word stands opposed to *heteroplon*, where only the voyage outwards is insured.

AMPHOTIDES, in *Antiquity*, a kind of defence, or armour for the ears, worn by the ancient Pugiles, to prevent giving their adversaries a handle by that part.

Authors have not been well acquainted with the nature and office of the amphotides. Some explain them as a sort of helmet for covering the nose and ears.

Fabretti first ascertained their real use, from the figure of a Pugil, which had amphotides over its ears joined by a piece coming over the forehead, and tied with strings under the chin.

AMPHRYSUS, in *Ancient Geography*, a town of Phocis, called AMBRYSUS.

AMPHRYSUS, or AMPHRYSUS, is also the name of a river of Phthiotis in Thessaly, which ran by the foot of Mount Othrys. Virgil, in speaking of this river, alludes to the time when Apollo, being a shepherd, guarded the herds of king Admetus, whence he is called "pastor ab Amphryso," Georg. lib. iii. v. 2. This river is also mentioned by Callimachus, Apollonius, Ovid, and Lucan. Another Amphrysus in Phrygia is mentioned by Pliny, to which was ascribed the property of rendering women barren.

AMPLA, in *Conchology*, a species of VOLUTA. Shell elongated, aperture large, lip acute, wreaths of the spire scarcely visible. Linnæus.

AMPLEPIUS, in *Geography*, a town of France, in the department of the Rhone and Loire, and chief place of a

ganton, in the district of Ville Franche, four leagues east-south-east of Roaane, and five west of Ville Franche.

AMPLEXICAULE, in *Botany*, denotes embracing the stalk, and is applied to a leaf whose base embraces the stalk sideways. See **LEAF**.

AMPLIATION, in a general sense, is used by some writers for the act of enlarging the compass or extent of a thing.

On a medal of the emperor Antoninus Pius we find the title *ampliator civium* given him, on account of his having extended the *jus civitatis*, or right of citizenship, to many states and people, before excluded from that privilege. In effect, this prince is generally supposed to have made the famous constitution, whereby all the subjects of the empire were made citizens of Rome. M. Spanheim refutes this notion, and makes the emperor Caligula to have been the author of that constitution.

AMPLIATION, in the Roman *Law*, denotes the act of deferring a judicial sentence, either because the cause was not clear, or in favour of him against whom it is to pass.

Ampliation differed from *comperendination*, as the former was granted on the mere motion or pleasure of the judge, the latter at the petition of one or both the parties. Besides, the former was not limited to any certain time, whereas the latter could not be extended beyond the third day. Besides, ampliation might be repealed, which *comperendination* might not.

The first introduction of ampliation was in favour of the *rei*, or persons accused. But it was afterwards used on other occasions; *e. gr.* when certain witnesses were wanting, or the crime or the fact had not been sufficiently proved for a final decision, or the kind or measure of punishment was not agreed on, &c.

In these cases the prætor signified his intention, by pronouncing the word *amplius*, or the letters *N. L.* for *non liquet*, by which he denoted that the cause was not clear, but that the second action must be brought.

The person whose sentence, whether of condemnation or abolution, was thus deferred, was said to be *ampliatius*.

Hence the phrases, *bis ampliatius*, *tertio abfolutus est reus*. Liv. xliii. 2.

AMPLIATION is also used, among *Schoolmen*, to denote the acceptance of a term for a different time from that signified by the verb in the proposition, *e. gr.* *justus peccavit*, *i. e.* *before he sinned he was just*.

AMPLIFICATION, in *Rhetoric*, part of a discourse or speech wherein a crime is aggravated, a phrase or commendation heightened, or a narration enlarged, by an enumeration of circumstances, so as to excite the proper emotions in the souls of the auditors.

Such is the passage in Virgil, where instead of saying merely that Turnus died, he amplifies the circumstances of his death.

— — — *Asi illi solvuntur frigore membra,
Vitaque cum gemitu fugit indignata sub umbras.*

The masters of eloquence make amplification to be the soul of discourse. Longinus speaks of it as one of the principal means which contribute to the sublime: but he censures those who define it a discourse which magnifies things; this equally agreeing to the sublime, the pathetic, &c. The same author distinguishes amplification from the sublime by this, that the latter consists wholly in the elevation of words and sentiments, whereas the former consists also in their multitude: the sublime is sometimes found in a single thought; but amplification cannot subsist, excepting in abundance.

There is likewise a difference between the amplification and the proof; because the one serves to clear the point, and the other to heighten and exaggerate it; and therefore it requires a florid and beautiful style, consisting of strong and emphatical words, flowing periods, harmonious numbers, lively tropes, and bright figures.

There are two general kinds of amplification; the one of *things*, the other of *words*. The first is produced in divers manners; as, 1. By a multitude of definitions: thus it is Cicero amplifies on history: *Historia est testis temporum, lux veritatis, vita memoria, magistra vite, nuntia vetustati*. 2. By a multitude of adjuncts; of which we have a fine instance in Virgil's lamentation for Cæsar's death, by enumerating the many prodigies and monst'rs that either preceded or succeeded it. *Vix quoque per lucos vulgo exaudita silentis ingens, & simulicra modis valentia miris visa sub obscurum noctis; p'cedesque locuta, infandum! sistunt annes terraque desibunt; et mestum illacrymat templis ebur, æraque fudant*. 3. By a detail of causes and effects. 4. By an enumeration of consequences. 5. By comparisons, similitudes, and examples, &c. 6. By the contrast of antithets, and by rational inference.

Amplification by words is effected six ways. 1. By using metaphors. 2. By hyperboles. 3. By *synonima*. 4. By splendid and magnificent terms; as that of Horace, *Scandit eratas vitiosa naves cura, nec turmas equitum relinquit, ocyor cervis, & agente nimbo ocyor euro*. 5. By *periphrases*, or circumlocutions. 6. By repetition. To which may be added, by gradation.

AMPLITUDE of the range of a projectile, in *Gunnery*, denotes the horizontal line subtending the curvilinear path in which it moved. See **PROJECTILE**.

AMPLITUDE, in *Astronomy*, is an arch of the horizon, intercepted between the true east or west point, and the centre of the sun, or a star, at its rising or setting, so that the amplitude is of two kinds; *orientæ*, or eastern, and *occidentis*, or western. These are also called northern or southern, as they fall in the northern and southern quarters of horizon; and the complement of the amplitude, or the distance of the point of rising or setting, from the north or south point of the horizon, is called the **AZIMUTH**.

To find the sun's or star's amplitude, either rising or setting, by the globe, see **GLOBE**.

To find the sun's amplitude trigonometrically; having the latitude and the sun's declination given. Say, as the cosine of the latitude is to the radius, so is the sine of the sun's or star's declination to the sine of the amplitude. Suppose, *e. gr.* the latitude to be that of London, *viz.* $51^{\circ} 32'$, and the declination $23^{\circ} 28'$; then cosine $51^{\circ} 32'$, or 9.7938317: rad. or 10.0000000 :: sine of declination $23^{\circ} 28'$ or 9.6001181: 10.0000000 + 9.6001181 — 9.7938317 = 9.8062864, or sine of the amplitude, or $39^{\circ} 48'$; and this is of the same name with the given declination, *viz.* north, when the declination is north, and south, when the declination is south.

AMPLITUDE, *magnetical*, is an arch of the horizon, contained between the sun or star at its rising or setting, and the magnetical east or west point of the horizon, indicated by the magnetical compass, or the amplitude or azimuth compass; or it is the difference of the rising or setting of the sun, from the east or west points of the compass. For this purpose place the compass on a steady place, from which the horizon may be clearly seen, and looking through the sight-vanes of the compass, turn the instrument round, till the centre of the sun, or other celestial object, may be seen through the narrow slit which is in one of the sight-vanes, exactly in the thread which bisects the aperture in the other sight-

light-vane; and when the centre of the celestial object, whether rising or setting, is just in the horizon, push the stop, in the side of the box, so as to stop the card, and then read the degree of the card which stands just against the fiducial line in the box; and this gives the amplitude required. In this operation allowance must be made for the height of the observer's eye above the level of the sea. The difference between the magnetical amplitude, thus observed, and the true amplitude, obtained by the last article, is the variation of the compass. E. G. If the magnetical amplitude be observed by the compass to be

61° 47', at the time when it is
computed to be - - 39° 47';

then the difference - 22° 0' is the variation west.

AMPLUSTRA, in *Conchology*, a species of BULLA. Shell roundish; spire elevated, obtuse, banded with flesh colour. Inhabits Asia. Linnæus.

AMPOSTA, in *Geography*, a town of Spain in Catalonia, situate on the Ebro, three leagues from its mouth, seven miles south of Tortosa.

AMPOTIS, *αμποτις*, signifies properly the reefs or ebb of the tide. But Hippocrates, who was of Cos, one of the Grecian isles, and must have had many opportunities of observing the tides, very elegantly applies this word to the reefs of humours from the circumference of the body to the internal parts.

AMPRÆ, in *Ancient Geography*, a people whom Pliny places in Arabia Felix.

AMPRELITÆ, a people of Colchis, according to Pliny.

AMPSAGA, a river of Africa, on the eastern part of Mauritania Cæsariensis, separating it from Numidia Propria, rises on Mount Auras, in the confines of the Atlas, and falls into the Mediterranean, ten leagues east of Jijel, or Igiligh. One branch of it, called Rummel, waters Cirta. According to Dr. Shaw, the Ampsaga is now called Wed el Kibbeer, i. e. the Great River, which corresponds with the signification of ampsaga; *ampsaga*, in Arabic, denoting ample, or large.

AMPSALES, a town of Asiatic Sarmatia, according to Ptolemy.

AMPSANCTI Vallis, or Lacus. See MOFFETTA.

AMPSANI, a people of Germany, conquered by Germanicus, according to Strabo.

AMPT, in *Geography*, the name given in Denmark to a lesser jurisdiction or district. The country is divided into several larger districts, called stifts-ampts, of which there are seven; four in Jutland, and three in the islands. Every stifts-ampt is subdivided into lesser districts called ampts. A person of quality is generally chosen stifts-amptman, a post resembling that of lord-lieutenant in England. The amptman, or under-governor of an ampt, is generally a person of inferior rank, who resides in the principal town of his district, and is intrusted with the conduct of all public concerns. The post is generally given for life, as a recompence to those who have faithfully served the court. The salary of the amptman is usually 400 crowns, and that of the stifts-amptman a thousand crowns; besides various exemptions and privileges.

AMPHILL, a town of England, in the county of Bedford, pleasantly situate, near the centre of the county, between two hills. It has been of late years much improved, particularly by the erection of a handsome market-house. The principal streets are neat and regular, crossing each other at right angles. Near the middle of the town is an obelisk of Portland stone in which is a pump, built for the use of the inhabitants by the Earl of Upper Ossory; and west of the

town is Amphill park, his lordship's seat, which is a superb edifice, containing a valuable collection of paintings, by several ancient and modern masters. The town has an almshouse and a charity-school. Its market is on Thursday; and its distance from Dunstable 12 miles, and from London 45 $\frac{3}{4}$.

AMSONIA, in *Botany*. See TABERNÆMONTANA. Gmelin has made Amsonia a distinct genus, including two species, viz, 1. *A. Tabernæmontana*, and 2. *A. Ciliata*. But Mr. Dryander observes, that the *A. Tabernæmontana* of Walter, to which Gmelin refers, is certainly meant for TABERNÆMONTANA *Amsonia* of Linnæus, as the trivial name is printed in Roman character; and he thinks it highly probable that Gmelin's *A. Ciliata* is the same as TABERNÆMONTANA *Angelifolia* of Hort. Kew. Linnæan Transf. vol. ii. p. 228.

AMPTRUARE, in *Antiquity*, denotes a kind of dancing performed by the chief of the *salii*, and answered with a correspondent motion by others in the *chorus*.

This is sometimes also called *ambtruare*; the answer of the *chorus* was particularly called *redamtruare*.

AMPUDIA, in *Geography*, a small place of Spain, in the country of Leon. In the time of the Goths it was a considerable city and bishop's see; 10 miles north of Valladolid.

AMPUGNANI, a town of the department of Golo (island of Corsica) the canton of which contains 4,143 inhabitants.

AMPULLA, in *Antiquity*, an oil-vial or jug, with a large belly, used for unctions at the baths.

The word ampulla was also used for a drinking vessel used at table.

AMPULLA, among *Ecclesiastical Writers*, denotes one of the sacred vessels used at the altars.

The word is sometimes also written in English *ampul*.

Ampullæ were also used for holding the oil used in chrismation, consecration, coronation, &c.

Among the ornaments of the churches we find frequent mention made of ampuls, or vials. In the inventory of the cathedral of Lincoln, we meet with ampuls of crystal, variously enriched with silver feet and covers: one containing a tooth of St. Christopher, another a tooth of St. Cecily, another a bone of the head of St. John Baptist. Dugdale. Mon. tom. iii. p. 272.

AMPULLA, *Knights of St. Ampulla*, belong to an order instituted by Clovis I. king of France; at the coronation they bear up the canopy, under which the ampulla is carried in procession. This ampulla, or sacred vial, with which the kings of France were anointed at their coronation, is said to have been brought from heaven by a dove, for the baptismal unction of Clovis I. the first Christian king of France, A. D. 496, and dropped into the hands of St. Remigius, then bishop of Rheims, where it has been preserved ever since for the purpose of anointing all succeeding kings; and its divine descent is said to be confirmed by this miracle; that as soon as the coronation is over, the oil in the vial begins to waste and vanish, but is constantly renewed of itself, for the service of each new coronation. The Abbé de Vertot vindicates the truth of this miracle, in a dissertation written for this purpose; and Baronius says, that it was a miracle worthy of the apostolical times. Archbishop Hincmar, in the year 869, is the first voucher for the truth of this legendary tale. Jortin's Rem. on Eccl. Hist. vol. v. p. 320. Middleton's Works, vol. i. p. 184.

AMPULLA, in *Conchology*, a species of BULLA. Shell roundish, opaque crown umbilicated. Linnæus.—A most common species in the Indian, Ethiopic, and American seas; about three inches in length; colour white, variegated with cinereous, black, brown, red, and bluish in spots and clouds. There are two, if not more, distinct varieties of this species;

AMPUTATION.

β the first, very oblong, opaque, dark, and scarcely an inch and an half in length; γ the second, transversely streaked, grey and black.

AMPULLA, in *Entomology*, a species of gammarus, having hand claws without fangs; fourteen legs: hind thighs compressed and dilated. Fabricius. This is a CANCER of LINNÆUS. Inhabits the northern ocean. Body almost white; proboscis incurvated and sharp-pointed. Tail of six leaves, last joint bifid.

AMPULLACEÆ CONCHÆ, in *Natural History*, a name by which some authors have called a tribe of shells, which, in the Linnæan arrangement, belong generally to the genus VOLUTA, or BUCCINUM: it is synonymous with *concha* *lobosa*, *dolium*, and *tonnes*. See DOLIUM.

AMPURA, in *Geography*, the name of a province in the kingdom of Peru, before its conquest by the Spaniards. The inhabitants are said to have worshipped two high mountains, because they furnished streams which fertilized the land. It is said to have been conquered by Virachoca, the eighth inca.

AMPURIAS, anciently *Emporia*, a sea-port town of Spain, and the capital of a district called Ampurdan, in Catalonia, situate at the mouth of the Fluvia. It was once considerable, and a bishop's see, but is now a mean place; 15 miles east of Gerona, and 58 north east of Barcelona. N. lat. 42° 10'. E. long. 3°.

AMPURIAS, *Castello d'*, a little town of Catalonia, seated in a bay.

AMPUTATION, in *Surgery*, is that operation by which a member is separated from the body. It differs from EXCISION, in that the latter is cutting out a part of the body; whereas, the former is cutting it off.

Amputation is one of the most formidable and important operations in the whole art of surgery: although it is by no means the most difficult to perform. The skill of a surgeon is often much more clearly evinced, by saving a condemned limb, than by dexterously removing it: so that "the most expert operator," as Mr. O'Halloran observes, "may not always be the best surgeon." Nay, "to do justice to the sick and to ourselves, we must, in many cases, rather avoid than perform capital operations." See Mr. O'Halloran's *Treatise on Gangrene and Sphacelus*; pref. p. 3—7. *et seq.* "As to amputation itself, that its indiscriminate use, or indeed, rather abuse, has been of infinitely greater detriment to mankind than service, must be admitted. We daily hear of sudden accidents that require amputation; and nothing is more common than to be informed, that the patient died in two or three hours after the operation. In sea engagements, where a limb is torn and shattered, death very soon follows mutilation; and after battles the recoveries bear no proportion to the deaths on this account.

"It was this great propensity to lopping off limbs," continues our author, "that caused a complaint to be exhibited to Louis the XIVth, that his surgeons estimated the importance of their service by the number of mutilations only; and they were obliged to defend themselves from this aspersions before a prince, who wisely rated the lives of his subjects too high to suffer characters to be gained at their expence. In fact, it is not enough for a surgeon to know HOW to operate; he must also know WHEN to do it." Mr. O'Halloran computes, that ninety-five patients out of an hundred ought to recover, where amputation is performed at a PROPER TIME, as well as in a proper manner; an acquisition highly honourable to surgery, and acceptable to humanity."

Historical Sketch of Amputation.

Although, from the earliest period of human existence,

there must have been occasion for performing this operation, we have no decisive proofs from history that it was ever done by the father of medicine, Hippocrates. A. C. Celsus, who lived in the reign of Tiberius, and whose book *De Re Medica* should be read by every surgeon, has left us a short description of the mode of amputating gangrenous limbs. It has been often remarked, that Celsus has left no instructions for securing the divided blood vessels; but it has not been commonly noticed, that in his chapter on wounds, he directs us to stop hæmorrhages by taking hold of the vessels, then tying them in two places, and dividing the intermediate portion. If this measure cannot be adopted, he advises the use of a cantherizing iron. Several hints are to be met with in the writings of Celsus, from which it may be inferred, that the ligature of bleeding vessels was sometimes practised in that early age; and this supposition is strengthened by a fragment of Archigenes, preserved by Coelius on the subject of amputation, where he speaks of tying or sewing the blood-vessels. We are not, however, in possession of all the writings of medical authors prior to the time of Galen, and must therefore remain in doubt upon this point.

Celsus recommends amputation to be performed between the sound and corrupted part of the member. The first incision was made with a knife down to the bone, but not over a joint; and some of the sound flesh was to be cut off, rather than leave any of the gangrenous part. The muscles were then to be retracted, and cut close around the bone, to lay it bare: then we were to saw off the projecting bone close to the flesh which still adheres; afterwards the rough edges of the bone were to be made smooth, and the integuments brought over it as much as possible. It is somewhat extraordinary that Galen has neither mentioned this important operation, nor so much as once quoted the name of Celsus, who flourished about a century before him at Rome. "If amputation proved often fatal in the days of Celsus, *sepe in ipso opere*," as he tells us, it was owing to the want of some efficacious method of compressing the blood-vessels during the operation itself; for, although the ligature might, perhaps, be employed, they knew not the use of a tourniquet. See TOURNIQUET, LIGATURE, CAUTERY, and HÆMORRHAGE.

The conciseness of the account left by Celsus renders it uncertain whether the edges of the skin were confined or not, so as to lessen the suppurating surface of the stump; but he evidently intended to preserve a large cushion of skin and muscle, in order to facilitate the cure. And as to the wound, so far as it remains exposed, he directs it to be covered with lint, and then bound over with a sponge dipt in vinegar. From the whole, then, it appears that the ancient Romans had tolerably correct notions of the art of healing. Paulus Ægineta, about eight centuries afterwards, suggests no improvement, except a broad fillet of cloth to retract the divided muscles during the time of sawing the bone: he recommends the application of hot irons, to fear the orifices of the bleeding arteries; and indeed, the early Greek practitioners were more disposed to use the actual cautery than the Romans.

The Arabian surgeons, who chiefly copied from the Greeks, made no material alteration in the mode of amputating; and were strangely inattentive to the advantages of the needle and ligature, which they well knew how to apply on other occasions. Perhaps this last assertion will be controverted; as a surgeon in Edinburgh has presumed to tell the world, in two of his late publications, that the Arabians were ignorant of the needle and ligature for tying blood-vessels, "and never used them otherwise, than by sewing a wound just so much the closer and tighter in proportion to the

AMPUTATION.

the bleeding." He says, "burning irons were used by the ancients, merely because they knew of *no other* means of suppressing the bleeding." Again, "In the times before Paré, not being able to take up an artery," &c.

We shall elsewhere have opportunity to treat of the *LIGATURE* of bleeding vessels; and therefore can only observe, by way of anticipation, that those who (with Mr. John Bell) impute the first discovery of this practice to Ambrose Paré, are greatly mistaken, and not sufficiently familiar with the writings of the old surgeons, whether Greeks, Romans, or Arabians. "It is not only entertaining but useful," says the late Dr. Hunter in his Commentaries, p. 63. "to see by what pursuits and steps an improvement was made; it gives clear ideas of the subject, makes a stronger impression upon the memory, shews the most probable road to improvement in similar inquiries, and raises emulation." But, says he, "if a man writes freely upon any subject, without knowing what has been said by others, he risks being made the object of ridicule or censure." *Ibid.* p. 60.

Guido de Cauliaco, who revived the languishing state of surgery in Europe during the 14th century, agrees with Avicenna and Albucasis, that it is better to cut off a mortified extremity than to let the whole body perish. He advises, when the gangrene is near a joint, to separate the articulation. In other cases he directs us to apply a tight ligature on the edge of the healthy part as well as on the gangrenous part; cutting between them down to the bone, and then sawing through, with a retractor interposed. But sometimes Guido would wrap up a mortified limb, and allow it to fall off of itself; by which means he avoided the odium of amputating members that his patients might have thought capable of preservation. After the example of his predecessors, he had recourse to hot irons, boiling oils, and astringent powders, to stop the hæmorrhage; although he disapproves the practice of Theodoric and others, who gave narcotic remedies to prevent or mitigate the suffering of their patients.

Methods of amputating, somewhat like that of Guido, were used by Bartholomew Maggus, Vesalius, and most surgeons in the 15th and 16th centuries; till Botallus and Regius proposed to lop off the limb by a sort of *GUILLOTINE*, at one stroke, after the manner in which criminals, formerly of Scotland, and lately of France, were decapitated. This summary treatment, however, caused so much contusion and splintering, that it was very soon opposed as unscientific and butcherly. The most important innovations made, about this time in amputating, were introduced by the celebrated Ambrose Paré, a French surgeon; to whose industry, good sense, and skill, we are chiefly indebted for the abolition of cauterising instruments, and the general use of a needle and ligature to suppress the bleeding, after this operation.

Paré recommended to cut off the whole of the gangrenous part, if the limb be mortified; but to encroach as little as possible on the living flesh. At the same time he laid it down as a rule, not to leave a very long stump to an amputated leg; because the patient could more conveniently, he says, make use of a wooden leg, having the stump only five fingers long below the knee, than if much more of the flesh were to be preserved. In the arm, however, he left the whole of the living and healthy portion of the member, only separating the diseased part from the sound.

In preparing for amputation, he directs the skin and muscles to be drawn upwards, and bound tight with a broad bandage, a little above the part where the incision is to be made. This fillet was intended to answer a threefold purpose: 1st, To afford a quantity of flesh for covering the bone and facilitating the cure; 2dly, To close the extremi-

ties of the divided blood-vessels; 3dly, To dull the patient's feelings, by pressure on the subjacent nerves. When this firm ligature has been applied, Paré directs an incision to be made down to the bone, either with a common large scalpel, or a curved knife: then, by a smaller curved knife, we are carefully to divide the muscle or ligament remaining between the bones of the fore-arm or leg; after which we may proceed to saw off the bone, as high as possible, and to remove the asperities occasioned by the saw.

With the assistance of a curved pair of forceps, he drew out the extremities of the bleeding arteries, either by themselves alone, or with some portion of the surrounding flesh, to be firmly tied with a strong double thread. He now loosened his bandage, brought together the lips of the wound over the face of the stump, and kept them as close as he could, without actual stretching, by means of four stitches or sutures. If the larger tied vessels should accidentally become loose, he desires the ligature or bandage to be again passed around the limb; or else, which is better, to let an assistant gripe the limb firm with both hands, and press with his fingers over the course of the bleeding vessel, so as to stop the hæmorrhage; then, with a square-edged needle about four inches long, and a thread four times doubled, the surgeon must secure the artery in the following manner: Thrust the armed needle into the outside of the flesh, half a finger's breadth from the vessel which bleeds, and bring it out at the same distance from the bleeding orifice; then surround the vessel with the ligature, pass it back again to within one finger's breadth of the place where it first entered, and tie a fast knot upon a folded slip of linen rag, to prevent its hurting the flesh. Paré, by this means, says, the orifice of the artery will be agglutinated to the adjoining flesh so firmly, as not to yield one drop of blood: but, if the hæmorrhage were not considerable, he contented himself with the application of astringent powders.

The limb was afterwards treated according to the old plan, with "defensatives, repurcussives, and agglutinatives." The first dressing was not removed for three or four days; but, when a suppuration came on, the "digestive, detensive, and mundificative remedies" were employed, until the ligatures might be safely removed, and exfoliation of the bone took place. As the surgeon saw proper, it was also recommended by Paré to hasten the exfoliation by the actual cautery applied to the extremity of the bone only; and to keep down fungous flesh by the use of burnt alum, blue vitriol, or red nitrated mercury.

Thus did this famous surgeon endeavour, by his single example and precepts, to exclude the barbarous use of hot irons in amputation. He says, he knew not of any such practice among the old surgeons; except that Galen recommended us to tie bleeding vessels, towards their origin, in accidental wounds, and he thought proper to do the same in cases of amputation: but in an apology at the end of his book, Paré has quoted, in his own defence, a dozen authors, who employed or recommended the ligature before him; and he might have cited many more.

From the statement we have here given, it may be seen how far our best writers, of every country almost, have erred in ascribing the original invention of tying arteries to Ambrose Paré. Great merit, indeed, was due to him for the part he took in extending, and even reviving this incomparable practice; nay, it is not certain whether any one before him had ever applied the needle and ligature in similar cases, *i. e.* after amputation: but how very wide of the truth Mr. John Bell's recent account of this matter is, will appear to every person who will enquire into the facts themselves; for not only were needles and ligatures in use among the an-

ients, but likewise the TENACULUM or hook to lay hold of the bleeding vessels when they had buried themselves in the muscles. We refer our inquisitive readers to Avicenna, Aëtius, Albucasis, Brunus, Theodoric, Guido de Cauliaco, John de Vigo, Bertapalia, Tagaultius, Petrus Argillata, Andreas a Cruce, &c. &c. where they will find enough to satisfy them on this head.

From the time of Paré to the commencement of the seventeenth century, a variety of petty reformations and alterations were proposed in amputating; but the surgeons were backward to adopt the needle and ligature in ordinary practice, choosing rather to apply astringent, vegetable, and mineral substances to the bleeding vessels, or to cauterize them with burning irons. One surgeon of note (John Woodall, who was many years surgeon-general to the East India Company, and surgeon of St. Bartholomew's Hospital in London) ventured to deviate from the common rule of dismembering in the sound part of a gangrenous limb. He published a treatise in 1639, chiefly to recommend "the amputating of any member in the mortified part;" and declared that this had been his custom since the year 1617, having amputated in that manner above a hundred limbs, "of which not one died in the cure." He used to wait till either the mortification had ceased, or till a circular line of separation appeared between the gangrenous and the sound part; then he would cut through the limb about one inch below the line, and gently remove the mortified portions of flesh. To facilitate the exfoliation of the bone, it was burnt with the actual cautery, as had formerly been practised by Vesalius and other of his predecessors. The limb was afterwards fomented, and warm dressings applied to encourage the supuration.

Woodall relates, that it was at this time no uncommon thing for criminals, who, in the East Indies, had their feet chopped off at the ancles, to get so well cured as to run on errands for their livelihood, after having put their stumps into large bamboo canes or reeds stuffed with cotton, &c.

Numerous applications, mechanical, chemical, and pharmaceutical, having been thought of to prevent bad and fatal hæmorrhages after bleeding, it occurred to our countryman, James Young, that a more secure way of compressing the artery during amputation would be as follows: He placed a hard wadd or bolster of linen cloth upon the inside of the arm or thigh, exactly in the course of the main artery; then, passing a towel or bandage around the member, he tied the ends together, and twisted them so very tight with a stick or battoon, as to stop the circulation through the blood-vessels. When the limb was amputated, he says, there was scarcely any bleeding, and the pain was greatly diminished by the compress. Before the dressings were applied, he advises to loosen the tourniquet a little, in order to observe where our care and astringents are most wanted. This proposal is described in a curious and scarce book, published at London, A. D. 1679, entitled, "Curtus Triumphalis à Terebinthò:" where may be likewise seen the first hint of the method of amputating with a flap, since claimed as a discovery by two continental surgeons Verduin and Sabourin; but whether or not these writers borrowed the suggestion from Mr. Young, is uncertain. As this mode of amputating is still very frequently practised, and in many cases is unparalleled for its simplicity and advantages, we extract part of the author's original account, where he thus addresses his friend:

"Sir, I find by yours, that you are surprized with the intimation I gave you, of a way of amputating large members, so as to be able to cure them per symphylin in three

weeks, and without soiling and sealing the bone.—I shall now entertain you with an account of the manner of this operation I would recommend to you, after I have told you that it was from a very ingenious brother of ours, Mr. C. Lowdham, of Exeter, that I had the first hints thereof. The ligatures and gripe being made after the common manner, you are with your catling, or some long incision-knife, to raise (suppose it the leg) a flap of the membranous flesh covering the muscles of the calf, beginning below the place where you intend to make excision, and raising it thitherward of length enough to cover the stump: having so done, turn it back under the hand of him that gripes, and as soon as you have severed the member, bring this flap of cutaneous flesh over the stump, and fasten it to the edges thereof by four or five strong stitches: having so done, clap a dossil into the inferior part, that one passage may be open, for any blood or matter that may lodge between; but of that there seldom occurreth any: then lay on a common desensative, *z. bole. sang. dracon. mastich. terræ sigil. cum alb. ovor. & aceto*, and thereto girt it close with your cross bandage, and other compresses, after the usual manner; the former, *viz.* the desensative, not only defends from accidents, as heat, pain, fluxion, &c. but gently constricteth the vessels, thereby contributing to the securing the hæmorrhage, and very considerably assists to the agglutination: the latter, *scil.* the cross bandage, keeps the flesh snug and close to the ends of the divided vessels, confirms the consolidation, keeps the parts from cavity, and the blood from extravasation, and hinders that reflux of humours which would otherwise destroy the intention of cure.

"In this sort of amputation, that manner of compressing the thigh by ligature, or the arm near the shoulder, which I have recommended in the foregoing discourse, is of excellent use; because thereby you may retain the descent of the blood, till by your dress and bandage you have so far secured the part as that it can receive no damage thereby.

"In this way of cure, phlebotomy, juleps, ligature of the extreme parts, if need be, with what else may con-temporate the blood, hinder defluxion and maturation, and promote consolidation, though declaimed against in that discourse, is in this case very useful and necessary.

"In the succeeding dressings, medicines healing per symphylin are to be used, and amongst them, perhaps, there are none better than that already mentioned, adding some powder of the roots of great comfrey thereto; the dossil, if you use any, may be left out the next dressing, or that following it.

"That this method hath cured such a stump in *three weeks*, is a truth I can vouch by sufficient testimony; and I believe you will not much doubt it when you have perused this, and considered how easy and soon such large consolidation hath been made.

"I must not forget to intimate to you that this manner of dismembering, &c. is not to be made use of where the part hath been much inflamed, tumefied from fluxion, or otherwise vexed therewith, nor in members amputated for chronic causes; as cancers, fistulas, &c. or where the body is poeky, or very cachectic, because in such digestion (which would destroy the union) is necessary to rectify and sweeten the mass, which it doth by draining off the mæstra of the disease more than ten fontanels can do. It is also no less unavoidable; for the course of matter that hath that way discharged itself so long (as in a fistula), cannot of a sudden be obstructed, without hazard of a mischievous apostumation: moreover, in such ill habits as those cases either cause or re-

AMPUTATION.

sult from, consolidation is difficult, if not impossible to be so suddenly performed, as this manner of cure requireth: the dyscrasis of the blood having destroyed or weakened its balsam that it cannot expedite the work, which, if not speedily done, cannot be performed securely and firm; and in parts inflamed and tumefied by fluxion, or by congestion, it is easy to imagine there must be a discharge of that concrete matter, which cannot be, and yet the wound cured by sympathy.

“But in most of the amputations made at sea in fight, or on land in battles, or wherefoever acute accidents, such as wounds, recent lacerations require it, it may be done, and that with those advantages of the other way it rivals.”

The author next enumerates eight very singular advantages with which this *new* method is attended, and then concludes his letter as follows:

“These are all the considerable advantages manifestly acquired by this *new way*: without doubt use and trial will discover more, equal to them, and an abundance of lesser conveniences, which at present occur not to my consideration: these are enough to shew the novelty to be considerable and worthy of imitation: let them have with you this accessional manifestation, that I am very ready to obey and serve you.

“*Plymouth, Aug. 3, 1678.*” “JAMES YOUNG.”

We thus have demonstrated, though it is not commonly believed, that what the French call “*OPERATION A LANBEAU*,” claimed as the invention either of Verduin or Sabourin, was put in practice by surgeons of Exeter and Plymouth before the year 1678. The different improvements and suggestions of more modern authors, will be noticed in our account of the amputation of particular members.

Of the Causes which may render Amputation adviseable.

Previous to the time in which the needle and ligature were generally had recourse to, for securing the divided arteries after amputation, this formidable operation was but rarely ventured upon, by even the most enterprizing surgeons; so that, we seldom read among the older authors of a limb having been amputated, from any other cause than a complete mortification. About the middle of the last century, however, the practice of inconsiderately taking off diseased members was so common, that several eminent surgeons attempted to prove it was never, or scarcely ever, absolutely needful. This opinion, although it originated from the best motive, was certainly untenable; since cases daily occur, in which, for want of amputation, patients must either inevitably die, or would only preserve their limbs at the hazard of dragging out a miserable existence, perhaps worse than death itself. Two general causes, at least, will therefore justify the performance of amputation: *First*, when the life of the patient is considerably endangered, by keeping his limb; *secondly*, when its preservation does not secure a more useful member than an artificial one.

The surgeon must know well how to distinguish the circumstances in which the amputation of a limb is necessary, or may even be considered as a benefit; and in which, should it be delayed, or conceived to be unnecessary, the patient would run the risk of losing his limb or his life. To form a determination is no easy matter, and in many cases extremely difficult; especially as, in forming it, we have also to consider whether, by means of the operation, the patient's life or limb can really be saved. For in the cure of limbs that have been materially wounded, the event often depends upon the constitution of the patient, his age, and the air in which he lives;

and it is rarely possible to form a sure prognostic at first, as the symptoms, from which it can be drawn, generally do not make their appearance till during the progress of the cure. Now, though it cannot be denied, that amputation has in many instances been performed when there was no necessity for it, it would be folly to imagine that it may in all cases be avoided. For there certainly are numerous diseases incident to the extremities, in which this operation is the only means of alleviating the sufferings of the patient, and even of saving his life.

1. A *CARIES* OF THE BONES, whatever be its degree and magnitude, is not a sufficient reason for amputation in a young subject, at least not till every possible means have been tried for the preservation of the limb: but when the disease has spread very far, so that no benefit can be expected from the common milder remedies; and when the caries is moreover advancing, and combined with deep spreading ulcers in the surrounding soft part, we have certainly no other remedy left but the operation. However, even in this case, it would be necessary previously to examine, whether benefit were really to be expected from the operation; that is, whether the caries were confined entirely to the part, or, whether it had not spread itself already too far to admit of a cure.

2. When the bones of a limb have been entirely shattered by a *GUN-SHOT WOUND*, and all the muscles, ligaments, vessels, and nerves have been so lacerated by it, as to render the circulation of the blood into the fore-part of the limb altogether impossible, and that its death is altogether inevitable; farther, when a whole limb, or a part of one has been torn off by a cannon-ball, or by any other means, in such a manner that the bones are broken off into uneven splinters, and remain uncovered, and the muscles and tendons likewise are of unequal lengths, and at the same time very much torn and bruised; in both these cases the necessity of the operation is evident.

3. When a large *ANEURISM* of long standing has destroyed the texture of the surrounding parts, and has produced a high degree of suppuration, especially if it be in a joint, amputation is necessary, on account of the diseased state of the surrounding parts; for, on account of the aneurism alone, it would never be adviseable. But it also becomes necessary when, after the operation for an aneurism has been performed, the limb does not acquire again its warmth and sensibility, but dies away. See the article *ANEURISM*.

4. In *COMPOUND FRACTURES*, let them have ever so unfavourable an appearance, amputation is never allowed, provided we are able immediately to procure for the patient all the requisite medicines, rest, attendance, pure and wholesome air, and proper nourishment; for even in the most desperate seeming cases a cure has sometimes been effected. But when, for example, in armies and fleets, every thing requisite for the cure of the wound is wanting, we are obliged to proceed to amputation; which must either be performed very soon after the injury has been inflicted (especially if the bones be shattered near a joint), or delayed until its most immediate effects and consequences, namely, the swelling, inflammation, and fever, have made their appearance.

5. In *LARGE WOUNDS*, combined with much *LACERATION* and contusion, it is extremely difficult to determine the necessity of the operation, which, consequently, ought never to be performed immediately after the wound has been inflicted; but it is at most admissible afterwards, when the wounds suppurate so profusely as to exhaust the strength of the patient, or when they become gangrenous, or when a hæmorrhage

AMPUTATION.

hemorrhage is produced that can be stopped by no other means.

6. In **WHITE SWELLINGS**, when the bones have become carious, the operation is always indicated; but good effects can only be expected from it when the disease is still merely or chiefly local. When it has already become general, or when it is the consequence of a serofulous habit of the body, it is in the first case always, and in the second generally, unsuccessful.

7. In large **SWELLINGS** of the **BONES**, that either endanger the life of the patient, or on account of their size, or from some other cause, become unbearable, the amputation of the limb is the only remedy that remains; provided there be no cause present that renders it inadmissible.

8. **CANCEROUS SORTS**, which, in some rare cases, attack the extremities, may indeed now and then be extirpated without amputating the limb; however, when the disease has already spread itself far among the surrounding parts, and has attacked the bones and ligaments, the amputation of the limb, above the disease itself, may be of some benefit.

9. In other extensive and malignant **ULCERS**, that do not arise from any internal and general cause, and which materially vitiate the whole mass of fluids, injuring the health, and, instead of yielding to the remedies that are employed, spread farther and farther, and become more and more obstinate, we are obliged to advise amputation, as the patient's life is actually in danger.

10. **INCYSTED TUMOURS** are sometimes very deep seated, or are even produced within the bone or upon the periosteum, and increase to a considerable size; so as by the pressure they occasion, to injure the texture of the surrounding parts, and not only to render the bones carious, but entirely to dissolve them. In such cases the operation may, under certain circumstances, be rendered necessary.

11. The extremities, and, according to Dr. Richter, most frequently the feet, are sometimes affected with a singular kind of tumour, the peculiar character of which has not as yet been accurately defined, but for which no remedy has hitherto been discovered, except amputation. The reader will find it described under the head of **OEDEMA**.

12. Sometimes also the **DISTORTION** of a limb may be so considerable, and cause such great inconvenience, on account of its stiffness, that the patient will rather lose the limb than remain longer in that condition. If we are not able to cure or relieve the distortion by any milder means, we may with propriety comply with the desire of the patient.

13. Finally, a **GANGRENE** may render the operation necessary; but that this is advisable in only a few cases, the reader will find maintained under the head of **GANGRENE**.

When, therefore, it appears, upon due consideration of every circumstance, that the diseased limb cannot be preserved, and that the life of the patient can only be saved by immediately amputating it, the operation must be undertaken without farther delay. Considered of itself, it is not so dreadful an operation by far as it formerly was, nor are its consequences so precarious and troublesome; and the cure is effected much more speedily, provided that, in performing it, all the rules prescribed by the present improved state of surgery are observed.

For performing the operation most of the following instruments are requisite:

1. Two straight knives, the blade of one to be from six to seven, and that of the other from five to six inches in length. The first of these is used in amputating the thigh, and the second for the rest of the limbs.

2. A small, narrow, straight knife, or catlin, edged half way down the back, three inches and a half long, half an inch broad. This is used for cutting through the flesh between the two bones, in the fore-arm and leg, and for dividing the periosteum.

3. A fine sharp saw, for sawing through the bone. The blade may either be made of a steel spring, about ten inches long and half an inch broad; or of a wide steel blade, strengthened by a firm back, as represented in the plate of amputating instruments. The handle should be of a size proportioned to that of the blade; it also should be smooth, and without much ornament.

4. A smaller saw, made of a watch-spring, for separating splinters, and dividing the bones of the fingers, &c. The blade of this saw must be provided with a serew, by which it may be turned in either direction.

5. A small straight saw without a frame, for separating splinters in parts where the first saw cannot conveniently be applied.

6. A small pair of scissors, with long handles, for dividing membranes, ligaments, and tendons.

7. A pair of forceps, with a sliding button, for laying hold of the arteries; or, which will answer the purpose better, a tenaculum, with a light handle.

8. A tourniquet. (See the description of this instrument.)

9. A slip of parchment, eighteen inches long, and from four to five broad; it ought to have a slit as far as the middle, terminating in a circular hole. (See **RETRACTOR**.) Its use is to draw back the muscles. We may also use instead of it, a broad leathern strap, or a fillet of linen of the same shape.

10. Two tapes, half an inch broad, for tying round the limb, one above the other, under the place where we intend to make the incision. Still more useful for this purpose, especially when the limb is fat and flabby, are narrow leathern straps with buckles, which hold the flesh firmer than the others. But many surgeons use neither of them.

11. A quantity of adhesive plaister cut into slips.

12. Two single headed bandages, the many tailed bandage, or a woollen cap.

13. A number of pledgets and compresses.

14. Lint, needles, and waxed thread.

General Rules of Practice.

In performing this operation the surgeon must be particularly attentive to the choice of the place where he should amputate; to the prevention of any violent hemorrhage during the operation; in cutting through the skin and muscles, to the saving of as much of these parts as is necessary for entirely covering the stump; in tying up the arteries, he must be careful to spare the neighbouring nerves and other parts as much as possible; he must be attentive to the support of the external integuments, that they may not shrink back again after the operation; and, finally, to the subsequent treatment of the patient, till he is completely cured. In general, a successful event depends upon the surgeon promoting, by every means in his power, a speedy union of the parts, or the healing of the wound without suppuration; the chief method by which this important point may be obtained, is by preventing all exposure of the wounded surface, and retaining the integuments in close contact with the subjacent bone, &c.

Ordinary Steps of the Operation.

Having determined on the propriety of amputating, and fixed the time in which it should be performed, we should prepare and arrange the necessary apparatus. Previously to commencing

AMPUTATION.

commencing the operation, the surgeon will not fail to see every thing in the part which may be wanting, either for his own use or the patient's comfort. When the assistants have been properly instructed, a tourniquet is first to be placed over the main artery of the limb to be amputated, so as to stop the circulation entirely. On some occasions a tourniquet cannot be applied, and in such cases a careful person is to be appointed to the office of preventing the hæmorrhage by other means. The limb being firmly secured, an incision is then to be made through the skin and cellular membrane, down to the muscles, by one circular stroke, except when the *flap operation* has been resolved on. The integuments are next to be raised, and turned back or drawn up from the muscles, more or less, according to the circumstances of the case, for the purpose of afterwards furnishing a covering to the face of the stump: in thus separating the integuments, we must have particular regard to the size of the limb. At the lower edge of the reflected skin and fat, the operator begins his second incision, carrying it through to the bone, in an oblique direction upwards, by holding his knife a little slanting. The retractor, if one be wanting, is now to be applied; and, by means of the double-edged catlin, the flesh, &c. is to be divided between the bones (in the fore-arm and leg). A small line of separation must also be made through the periosteum, but it is not to be scraped, for the entrance of the saw; after which the bone or bones will be divided, by slowly repeated long strokes with the saw, taking care not to make splinters. Having next secured the bleeding vessels, by ligature alone, and wiped away the coagulated blood, after slackening the tourniquet entirely, we finish, by bringing the lips of the wound neatly in contact, retaining them by cross slips of good adhesive plaster, laying soft lint, &c. over the outside, in the direction of the edges of the wound, and bandaging the stump, with the ligatures hanging out at one corner. Thus may we frequently effect a cure in twenty or thirty days, by healing without suppuration, and without danger, after taking off the largest extremities; especially in quiet, airy situations, and with healthy young patients.

Amputation of the Thigh.

In this operation, the patient is to be reclined upon a table of the ordinary height. A common tourniquet must be applied as near as possible to the upper part of the thigh, immediately under Poupart's ligament, in such a manner, that the compress comes to lie straight upon the femoral artery: the fillet laid over it is to be screwed or twiled, by means of a short stick, over a piece of horn or leather placed on the opposite side, so tight, that not only no blood can flow through the large artery, but so as also to squeeze together all the muscular parts as closely as possible. A tourniquet of this kind (see the *PLATE of Surgery*) prevents a hæmorrhage, not only from the principal trunk of the artery, but also from all the lateral branches, and is therefore preferable in such cases to the screw tourniquet. Some surgeons, during the operation, never make use of a tourniquet, but have the artery strongly compressed by an assistant with his fingers and a cushion.

It is a general rule, that we ought never to amputate more of the thigh than the disease absolutely requires; for the more of it we suffer to remain, the more useful the stump will be. Where the injury done to the limb is such, that only the leg is damaged up the knee, we amputate the thigh about a hand's breadth over the knee, in order to gain a quantity of skin sufficient for properly uniting the parts. The incision through the skin must be made at least three fingers breadth lower than the second cut, by which the muscles are divided. In order to hit upon the right mea-

sure, we must principally attend to the thickness of the thigh, for the thicker it is the more skin we must endeavour to gain; but it is in general better to save too much, than too little, of the integuments.

Two assistants, who stand at the head of the patient, hold fast his arms, and a third secures the sound leg. The diseased limb is held by two assistants in a horizontal position, with the knee moderately bent. One of these holds the limb, with both his hands under the knee, firm and immoveable; the other supports the thigh in the middle, holds it fast, and at the same time draws the skin tightly upwards. The operator now applies one of the small fillets to the place where he intends to make the first cut; namely, when the whole thigh is sound close over the patella, and draws it very tight in an exact circle round the limb. With the assistance of this fillet the cut may be made more even and circular; and the fleshy parts, particularly the integuments, are prevented from shrinking and impeding the operation, being held fast and tense at every point. This fillet, therefore, is of great and essential use in the operation, and ought certainly to be retained, though some may be inclined to reject it as superfluous. But to apply a second fillet above the cut, as some do, is unnecessary. The operator, who stands on the outside of the limb, now cuts through the skin and cellular texture, with a straight, strong, and sharp knife, close over the upper margin of the fillet, in an exact circle, without cutting into the muscles. In performing this part of the operation, great attention is necessary, in order that the incision may not be made too superficial, or too deep, or even crooked. When the operator has divided the skin all round, but not the fascia lata, by this first cut, he next divides the fascia cautiously, by repeated cuts, without penetrating into the muscles; after which the skin may be more easily drawn back as far as he thinks proper. The skin is now to be retracted in a uniform manner, in order that the second cut may also be made exactly circular; the first assistant must, therefore, be well acquainted with the method of performing this operation.

When the skin has been drawn back full three fingers breadth (too much is always better than too little), the operator, using the same knife as before, cuts the muscles through down to the bone, close to the margin of the retracted skin, with a perpendicular, even, and circular incision. Some surgeons, however, cut through *obliquely*, by slanting the edge of the knife upwards. If the operator has acquired sufficient dexterity by practice, he will always be able to make this incision without carrying the knife twice round the limb.

"As it frequently happens, in amputating the thigh," says Professor Murinna (*Neue Med. u. Chirurg. Beobachtungen. Berlin, 1796. 8. pag. 515*), "after the circular incision through the muscles, though these are divided three fingers breadths higher than the skin, that the flexor-muscles of the leg contract more than the extensors, and thus, at times, produce a deformity of the stump, which occasions some inconvenience in wearing a wooden leg; this accident might be prevented, by keeping the patient's knee moderately bent, whilst cutting through the extensors, and extended whilst making the incision through the flexors. The incision will, nevertheless, be even and circular; and when performed in the above mentioned positions of the limb, will prevent any deformity of the stump; for the flexors of the leg contract with much more force, after the incision, than the extensors; in order to avoid which, the former must be cut through at their greatest elongation, consequently when extended, and the latter when contracted. By this practice

no time is lost, nor any additional pain given to the patient; and both the cure is more speedily effected, and the stump acquires a better form."

"Generally (says Dr. Richter in *Medicin. u. Chirurg. Bemerk. &c.* B. I. Gottingen, 1793. 8. pag. 232.) the flexor muscles contract with much greater force than the extensors after amputation of the thigh. They do the same during the progress of the cure also, and consequently, even in the most rapid cure, attended with no suppuration, the stump generally grows uneven at the bottom, which causes inconveniences in the application of a wooden leg." He accedes therefore to Prof. Mursinna's opinion, that the extensors should be divided higher and the flexors lower, consequently the first with the knee moderately bent, the second with the knee extended. This practice deserves, therefore, to be generally recommended.

According to Mr. Alanfon's method, the knife ought to be conducted in a slanting direction, with the edge directed upwards, in order to form a hollow cone; but few surgeons have any opportunity of acquiring the dexterity requisite for performing the operation in this manner, by practising it upon dead bodies; and it is not done by some of the most noted surgeons on the continent. Professor Callisen (*Tode Medicin. Journal*, B. I. Copenhagen, 1793, p. 106.) does not make his incision in the form of a cone, but cuts through the skin at the requisite distance from the place where the bone is to be sawed through. He next separates the skin from the muscles, as far as is necessary, in order to turn it back like the cuff of a coat. He next cuts through the flesh, saws off the bone, binds up the vessels; and, lastly, draws down the retracted skin over the stump, and folds it together in such a manner as to make it form an oblong slit from above to below, out of which the ligatures of the vessels hang.

"To hold the knife obliquely (says Prof. Mursinna in *Neue Med. u. chirurg. Beobachtungen*, p. 165.), with the edge turned upwards, in cutting through the muscles, so as to form a conical incision, is a refinement upon the operation, which it is equally difficult and unnecessary to practise."

"I am still of opinion," Dr. Richter remarks (*Med. und Chirurg. Bemerk.* B. I. p. 232), "that the operation by means of which Mr. Alanfon endeavours to make the stump itself hollow, is very difficult, if not entirely impracticable." He performed the amputation in the following manner: The incision was made three fingers breadth above the knee. An assistant laid hold of the limb, with both hands, above the place of the incision, and secured the skin. By the first circular incision, the operator divided not only the skin, but also the cellular texture, as far as the external surface of the muscle; this must necessarily be done, if we wish to be able to draw the skin much upwards. When the cellular texture has not been completely divided, we shall generally find that it becomes tense, whilst we are drawing the skin upwards, and thus prevents its being retracted so far as it otherwise might. Whilst, therefore, the assistant drew up the skin as much as possible, the operator made a second circular incision, close to the margin of the retracted skin, with which he again divided the cellular texture as deep as to the surface of the muscles, whereby the assistant was enabled to draw up the skin still much higher; so that now the upper margin of the skin was at least three full fingers breadths distant from the lower. The separating and turning back of the skin, according to Mr. Alanfon's method, he considers as a very tedious and difficult operation. With the third circular incision he cut into the muscles along the margin of the retracted skin, not so deep as down to the bone, however, but only

about half way through. He now directed this divided external layer of flesh to be drawn upwards, as much as possible, with the slit compress; and with a fourth circular incision along the margin of the retracted skin, he cut through the remaining flesh to the bone. The whole of the flesh was now drawn back with the slit compress so strongly, that the bone was laid bare the length of at least two fingers breadths, and could be sawed off to that height. When the skin and muscles were drawn down, the stump formed a conically excavated surface, at the upper point of which the bone lay so deep within the flesh, that it could not be seen. After the vessels had been tied up, the stump was pressed together on both sides, so that the wound formed a slit in a straight direction from before to behind. The edges of the skin were so close to each other, that the wound resembled a very narrow fissure. The skin was fastened together with adhesive plaster, and the flesh and the stump were pressed together by pads of lint applied to both sides, and then confined by a bandage. The ends of the ligatures hung out at the lowest and posterior angle of the wound. Even on the fifth day, three quarters of the wound, from the top, adhered together, and were quite dry; the lowest quarter, out of which the ligatures hung, was still moist, but discharged only a very few drops of pus during the whole course of the case. On the eleventh day the ligatures were separated, and the remaining small orifice closed in the space of a few days more.

When all the muscles have been cut through to the bone (whether we have recourse to Richter's or Alanfon's mode), the slit compress is applied; by means of which the remaining muscular parts are covered, and these are, at the same time, somewhat drawn back by the hands of the assistant, in order that the operator may be able to use the saw with more freedom, and saw off the bones higher up. When this has been done, the periosteum is divided circularly, as high as possible, with a short, strong knife, and peeled downwards. The saw is now applied horizontally, and the bone sawed through. The operator saws slowly at first, but when the saw has laid proper hold of the bone, he moves it somewhat quicker; and, at the same time, the assistants hold the limb rather high at the superior part, and low at the inferior, so as to bend it somewhat afunder, in order that the saw may not get wedged in during the operation. When the bone is nearly sawed through, the saw is again moved slowly and with short strokes, in order that the stump may become as smooth and even as possible. Should there still remain any small projection on the bone, this must immediately be removed.

As soon as this has been performed, the vessels are to be secured by ligatures. The principal trunk is first tied up, and if it be at the division of the artery, both branches are included in one ligature. For this operation a triple thread is used, which is fastened together with wax, so as to form a flat ligature, in order that the artery may be tied fast with it, without danger of its cutting through. This thread is inserted into a crooked needle; the artery is laid hold of, at its orifice, with a tenaculum, or crooked sharp hook; it is then drawn forwards, and the needle being introduced under the vessel, in such a manner as at the same time to perforate the cellular texture on both sides, it is pulled through. The assistant now holds the hook, whilst the operator takes hold of the ligature inserted under the artery, and ties it fast with a double knot, over which some surgeons make another single one, about two lines above the extremity of the vessel. The ligature is generally left of such a length, that it can be conveniently fastened upon the skin on the outside of the wound. Should we find it difficult to discover the trunk of the artery

AMPUTATION.

tery in proper time, the tourniquet must be loosened, upon which the spouting of the blood immediately discovers its orifice. In order to discover the orifice of the lateral vessels, the tourniquet must always be quite loosened, that they may also be bound up in the manner already described.

As the adhesion of the parts, and the healing of the wound depend upon the blood being entirely stopped, it is necessary that all the lateral vessels which discharge any should be tied up; for which purpose the surgeon, when he has loosened the tourniquet entirely, wipes the stump with a wet sponge, examines whether any of the branches discharge blood, and ties up those which do, be they never so small. When no more blood is discharged, the stump is once more wiped with the sponge, entirely cleansed from the blood, and the lips of the wound are brought together.

The ends of the ligatures, if there be many, ought to be distributed between both angles of the wound, that they may not form a thick bunch, and occasion inconvenience by their pressure. When every part of the operation has been performed in manner above directed, the adhesion will take place easily; but if the directions are not observed, it will sometimes not take place without much difficulty and pain.

The lips of the wound may be brought together in two different ways. Some press them together, on both sides, so that the wound forms a perpendicular slit, which runs in a straight line from the fore to the back part of the thigh, and let the threads of the ligatures hang out of the lowermost and posterior angle of the wound. Others press them together, so as to form a horizontal fissure: in this manner the stump can lie conveniently, and the fluids may still be discharged by the two lateral orifices of the wound, out of which the threads hang. By this method the stump also acquires a better form than when the fold is made perpendicularly.

When the lips of the wound are brought together in either of the abovementioned ways, they must be made to apply neatly to each other, and all the points of the sides of the wound brought into close contact. Whilst the surgeon holds them together in this manner, an assistant applies from four to six slips of adhesive plasters; then lays over the edges of the wound some loose dry lint, and covers this with a quantity of the same substance, spread with a mild, healing ointment. The whole is finally secured with a long bandage, which is applied at the upper part of the thigh, and carried down in spiral folds round the limb to the bottom, where it is doubled round, and carried up again to the upper part; it is then doubled round, and brought over the fore side upon the wound from behind upwards; and these folds are repeated over both sides of the thigh and over the wound, in such a manner, that one fold always half covers the other. The whole thigh is thus surrounded with the bandage. These folds are then secured by circular folds from below upwards, without crossing the bandage over the stump, as that would be an impediment to the adhesion of the wound; but by this method of bandaging, the retraction of the skin is prevented, and the adhesion promoted.

After the bandaging has been completed, the patient is placed in a convenient posture, and the thigh is laid upon a bolster, gently bent; for if laid horizontally, or even lower than the horizontal line, it not only causes pain to the patient, but the flexor muscles of the thigh constantly tend to bend it and bring it to the abovementioned position. If we attempt to counteract this tendency, by applying force to the limb, it becomes convulsed, and the adhesion is frustrated.

If no particular symptoms forbid it, the first dressings are suffered to remain on till the fourth, fifth, or sixth day;

and when all this is still properly united, the adhesive plasters are nevertheless left in their places, the wound is cleansed from the impurities that have been discharged, and the limb is bandaged in the manner above described. If any of the plasters have broken loose, or the lips of the wound have separated at any part, the plaster is cut through over the wound, without pulling it off, and a new one, or if it be necessary, several are applied, in order to bring the separated lips of the wound into proper contact.

Instead of the circular bandage above described, some advise the limb to be rolled with Loder's twenty-seven-tailed bandage, (D. Just. Chr. Loder, Chirurg. Medicin. Beobachtungen, &c. lib. i. Weimar, 1794, p. 14. Tab. I. fig. 4. 5.) in which case a circular bandage is first applied to the upper part of the thigh, and carried down to the bottom in spiral folds, so close to each other, as to prevent the retraction of the skin and muscles, but not to excite pain, or obstruct the circulation. The bandage is fastened with a pin at the lower part of the stump, leaving for future use a piece large enough for folding two or three times round the limb. After the whole of the bandaging has been performed as above described, the remaining part of the fillet is folded twice or thrice round the limb, so that the pressure can be increased or diminished at pleasure, and finally the twenty-seven-tailed bandage is applied.

While we apply the circular bandage, the tourniquet must be removed, but it must be again applied as soon as we have finished the bandaging of the limb, in order that we may be able immediately to stop any hæmorrhage that may come on; for which purpose it must likewise be kept applied for several days after amputation has been performed.

When the patient has been put to bed, and a hooped frame laid over the stump, he should immediately receive an opiate, in order to prevent involuntary spasmodic motions of the stump. During the first days after amputation, an assistant ought frequently to examine the thigh with great care, in order that if he should find blood to flow from any of the vessels, he may draw the tourniquet as tight as is necessary to prevent any material hæmorrhage, till proper assistance can be obtained. If there exude only a small quantity of blood from the surface of the stump, it is unnecessary, on that account, to remove the bandages; but when the hæmorrhage is considerable, it can only be stopped by the application of ligatures; for were it even possible to stop it by compression, this would frustrate our principal aim, namely, the speedy union of the parts without suppuration. After we have stopped the bleeding, we must apply the bandages as before directed.

When every thing goes on according to our wish, the bandages are only renewed every two or three days, in order that we may not impede the uniting of the parts; but oftener, if the suppuration becomes more copious, or a new pain is perceived in the wound. Commonly about the 10th or 11th day, sometimes later, the threads of the ligatures may be drawn out by gently pulling them; frequently they grow loose and fall out of themselves. When the threads have been detached, the open angles of the wound are to be united nearly in the same manner as before; after which the complete cicatrization of the wound takes place in a longer or shorter time, but commonly in a week or a fortnight more.

To prevent inflammation, the patient should be strictly treated during the first days after the operation, according to the antiphlogistic regimen; though this must be used with great caution in exhausted and debilitated constitutions, lest by too strict a regimen we might impair the strength of the body. When the pyrexia has abated, and the patient is in a

AMPUTATION.

state of debility, we give him Peruvian bark, prescribe proper diet, and, at the same time, take care to keep his bowels open. As soon as the patient feels himself well, it is best to give him no medicines at all, but merely to enjoin attention to a proper diet.

It sometimes happens, that in applying the dressings we find the parts red, tense, and painful to the touch, and the degrees of the skin at a little distance from each other. As long as these circumstances continue, we must omit the application of the adhesive plasters, and cover the surface of the stump with a pledget of soft lint spread with cerate, as in the first dressing; over this we are to apply a cushion of lint, which is to be secured with slips of adhesive plaster, or cross pieces of lichen; and the whole of these dressings are to be confined with the circular bandage, the pressure of which ought to be not stronger than is necessary for securing the dressings. When the bandage is soiled, with the pus collected upon it, it should be changed for another; otherwise it may be left in its situation. In general, we ought not entirely to lay aside the bandages till the third or fourth week after the operation; but at that period we should do it lest the stump grow thinner than the other thigh. As soon as the wound is perfectly clean, and the pain and sense of tension removed, the edges of the wound may again be drawn closely together with adhesive plaster.

The amputation of the thigh has been performed only at its lower part, namely, at the adopted distance of three or four fingers breadths from the knee, for fear of a too copious hæmorrhage; but experience has shewn, that in cases of necessity the operation may be safely performed very high upon the limb. Only in such cases the tourniquet must be secured with great care, that it may not slip off in consequence of the retraction of the muscles. For this purpose we may, according to Mr. Schmucker's method, (*Vermischte Chirurgische Schriften*, lib. i. Berlin a Stettin, 1776, c. 8. p. 43.) lay under the tourniquet four pieces of tape about an inch broad, and two feet in length; directing two assistants to lay hold of these like handles, and draw them tight, two of them on the inner, and two on the outer side of the limb, whereby all such disagreeable consequences will be prevented.

Amputation of the Leg.

It is adopted by many as a general rule, that the amputation of the leg should never be performed just above the ankle, even though the disease be seated near the bottom of the limb; but always three or four finger-breadths under the knee: repeated experiments, however, have shewn, that amputation may be successfully performed just above the ankles, and as near to them as the disease permits. The advantage of being able to use the knee-joint in walking is so great, that the surgeon should not deprive the patient of it. (See our account of the *Flap Operation*.) The objection, that a long stump is an incumbrance, may be removed by the use of an artificial foot. In order to promote the cure of those wounds, the projecting tendinous parts must be separated with the scissars. Mr. B. Bell conceives it to be better in every instance, where the circumstances admit of it, to amputate a little above the ankle than at the upper part of the leg: amputation immediately under the knee he rejects entirely, as the cure of the stump is always tedious in this situation, the bones thick, and the soft parts deficient. In such cases he prefers amputating above the knee, though his opinion cannot be unconditionally adopted.

When we are to amputate immediately below the knee, the patient is placed upon a table, and secured in the same manner as in the amputation of the thigh. Some are of

opinion that the tourniquet should be applied a little above the knee, with the cushion upon the artery in the ham; but others apply it also in this operation immediately under Poupert's ligament, or in the middle of the thigh, which is the preferable method. The foot and leg are secured by an assistant, who sits before the patient. A second assistant draws up the integuments towards the knee. The surgeon stands on the inside of the limb, and with his knife makes first a circular cut through the skin and cellular substance down to the muscles; so that after as much of the integuments as will afterwards be necessary for covering the stump, has been separated in this manner from the parts beneath, the muscles and bones may be divided immediately below the part where the tendons and flexor muscles of the leg are inserted. When this has been done, the soft parts between the two bones must be divided with a two-edged knife (named a *CARLIN*), and the periosteum separated downwards. The skin and other soft parts must then be held fast to protect them against the saw, which is to be applied so as to cut through both of the bones together. When this has been done, and the vessels tied, the external integuments are drawn over the stump, and retained with adhesive plasters. During the course of the cure the practice is the same as after amputation of the thigh.

In separating the skin we must be very careful to separate it from the subjacent parts in such a manner as to have as much as possible, if not the whole, of the cellular substance attached to it. The more we deprive the skin of its cellular texture, the more lifeless it becomes, and the less fit for adhering speedily to the stump. As the skin also on the fore part of the leg cannot be retracted with near the same facility as in other parts, for example, the thigh, where it lies upon muscles, whilst on the fore part of the leg; on the contrary, it is connected by a very dense cellular substance immediately to the periosteum, the assistant is always obliged to fold back as much of it as has been separated, before the division of the muscles can be attempted, in order that the surgeon may be able to separate them from the bone, and save as much of them as is requisite for covering the stump.

The reason why the surgeon is directed to stand on the inside of the leg in this operation is, that when the knee and foot are turned inwards, and the fibula raised, he may be able to saw through both bones of the leg together, which he cannot do when he stands on the outside. Finally, he must take care not to suffer the bone to break off, or should such an accident happen, he must remove the inequalities that may be produced by it. Many have advised, in amputating the leg, after the muscles have been cut through, to apply a ligature round both bones, in order to hold them fast, and the same has also been advised in the amputation of the fore-arm; but this can be of no advantage, for it will be better to hold both the bones fast with the hand, and insert the forefinger between them, nearly under the spot where the saw is to go through, in order to prevent their coming into contact with each other.

When the leg is amputated immediately above the ankle, an artificial foot cannot easily be applied and secured upon the stump; the machine must be made heavier and thicker at the ankle, nor can the leg be made so equal in length and thickness as the other, as would otherwise be possible. When the stump is about nine inches in length from the knee, its dimensions are reckoned to be in every respect the most convenient.

Of amputating with a Flap.

In the old method of performing amputation, the cures were very tedious, and the health of the patients much impaired;

AMPUTATION.

paired; and as the stumps became so pyramidal and scantily covered with soft parts, an attempt was made to perform the operation in such a manner as to save a quantity of flesh and skin for the purpose of covering the stump. This operation we have shewn to have been first invented by Mr. Lowdham, of Exeter, and afterwards practised by Mr. Young, of Plymouth; though since their time Verduin, of Amsterdam, and still later, Sabourin, of Geneva, have claimed the merit of this invention. In France this method met with many advocates, but it was never approved of in Germany. In England it had been wholly neglected for a long time, when it was anew proposed by O'Halloran, with some alterations and supposed improvements of his own. (See his *Treatise on Gangrene*, 8vo. London, 1765.)

As it is very difficult to restrain the hæmorrhagy which may accidentally happen to supervene, after the flap has been applied in Mr. Young's manner, it being necessary for that purpose to undo the whole of the bandages, and separate the flap from the surface of the wound; moreover, as the flap does not always adhere uniformly over the whole surface of the stump, and the pain, inflammation, and tension which supervene, are sometimes much more violent than after the ordinary method of amputating, Mr. O'Halloran proposed to dress the stump and flap as two separate wounds for the first twelve or fourteen days; but afterwards, when the danger of a bleeding is over, the symptoms subsided, and suppuration established, to turn the flap back over the surface of the stump, and secure it by adhesive plasters, compresses, and bandages, till a complete adhesion has taken place. It seems that one grand cause of failure in the success of the flap operation, as it was performed in France about a century ago, was "the monstrous hæmorrhagy," as Mr. O'Halloran expresses himself; and, according to *their* unaccountable mode of conducting the operation, we almost agree with the last named writer, that "it was absolutely impossible for it to succeed." But we are surprised that Mr. Benjamin Bell, of Edinburgh, even in the new edition of his *Surgery*, should misrepresent the success of the *present mode*, so much as to deny its having cured "before the fourth week." *System of Surgery*, vol. vii. p. 330. 7th edition; this is certainly an unfair and imperfect statement of Mr. B. Bell.

By Mr. O'Halloran's improvement the flap operation was rendered more safe and certain, but has not come into general use, as that which Mr. Alanson invented in the mean time deserves, in most cases, the preference. The flap may, under various circumstances, be employed with advantage. Where it is impracticable in the common way to cover the divided parts sufficiently, we ought always to cut out a flap of muscle or skin for that purpose: it is best, for example, when we amputate the arm at the shoulder joint, or a finger, or toe. It has also been preferred by some surgeons when the leg is to be amputated immediately under the knee, as the integuments are very thin at that part, and there is reason to suppose that the stump cannot be sufficiently covered by any other means.

It has not been the common practice to make a double flap, although this is at present done with very great advantage by the surgeons of the Liverpool Infirmary. Their method is (excepting for diseases of the feet) to take the flap from each side of the limb, in preference to above and below, as it affords a better outlet for any pus that may collect in the stump. Upon an average, we find, on making recent inquiry, the stumps are healed in about "eighteen days;" which is more than can be said in favour of any other mode of amputating. The double flap likewise is free from the puckered appearance which remains after the single flap; and in a few weeks, we are informed, "the cicatrix can hardly be per-

ceived." Our own experience with the flap operation, even in the metropolis, is much in its favour; so that whatever objections have been raised against it (when properly performed), we are strongly inclined to think they have been chiefly theoretical, and not founded on actual observation.

Amputation with a Flap immediately above the Knee.

This operation may be performed either with one or two flaps; but if it be done with only one, it succeeds best on the fore part of the thigh, as there is here a sufficiency of soft parts for forming the flap and covering the bone; and as the matter thus passes off more readily when the flap is applied, and the patient laid down upon his back.

The patient being placed upon a table, and the tourniquet applied to the femoral artery below Poupert's ligament, an assistant draws the skin firmly up, and retains it in that situation. Whilst this is doing, we ought to mark, with ink upon the skin, the circumference of the intended flap. The extreme angle of the flap should reach to the bottom of the thigh unless the skin be much diseased, in which case the flap must terminate where the disease of the integuments commences. The base of the flap must be at the place where we intend to saw through the bone. Its breadth must be proportionate to the dimensions of the limb. If, for example, the diameter of a stump be twelve inches, a flap four inches and a quarter in length will be fully sufficient to cover it. But as some allowance must also be made for the quantity of skin and muscle that may be saved on the opposite side of the limb, by drawing them up before sawing the bone, a thigh twelve inches thick will not require a flap more than three inches and a quarter long, and so in proportion to the size of the limb. The flap should be as broad at the base as the breadth of the limb will permit; and it should be continued nearly, though not entirely of the same breadth, till within a little of its termination, where it should be cut circular, so as to correspond, as accurately as may be, with the back part of the circumference of the wound.

When now the surgeon has marked out the circumference of the flap, he must place himself on the outside of the thigh, apply the point of a straight double-edged knife to the outer side of the base of the intended flap, and push it in to the depth of the bone; then, carrying the point close to the bone, push it through the integuments on the opposite side of the mark. He must now carry the edge of the knife downwards in such a direction as to cut out the flap according to the figure marked out; but towards the end he should raise the edge somewhat from the bone, so as to make the lower part of the flap somewhat thinner than the base, whereby it will apply more accurately to the surface of the fore. The flap must be held by an assistant, but the skin and muscles on the back part of the limb must, with one stroke of the knife, be cut down to the bone, about an inch lower down than where the bone is to be sawed. The muscles are then to be separated to this height from the bone, with the point of the knife, and all the soft parts must be drawn back with the slit compress, till the bone is sawed. Any splinters that may have been left are then to be separated, the arteries tied up, and the ligatures left hanging out at the edge of the flap.

The muscles and integuments must now be drawn down, and secured with a roller, as has been directed above, in treating of the amputation of the thigh with the circular incision. The flap may now be laid down over the surface of the wound, the coagulated blood having first been carefully wiped off with a sponge, and the flap may then be moderately secured to the stump with adhesive plasters and sutures. The under part of the stump should be covered with
a large

a large pledgit spread with cerate, and a cushion of lint or tow laid over it. The whole should then be secured with cross straps of linen, and several turns of the circular roller. After the space of three or four days, or even longer, the dressings may be renewed. As soon as all the ligatures are removed, and the tension and pain have abated, the skin may be drawn over every part of the wound which before was not covered, and secured with adhesive plasters.

The method now described is generally to be preferred; but if, instead of effecting the cure by promoting a speedy adhesion of the parts, the surgeon deems it advisable, he will treat the flap as a separate wound according to O'Halloran's method; in which case, his easiest mode of proceeding is as follows: The muscles and skin being brought down and secured with the roller, the whole surface of the stump is covered with a soft pledgit spread on both sides with an emollient ointment. Upon this the flap is laid down, and another pledgit of the same kind being laid over the flap, a cushion of lint or soft tow, and a compress of soft linen are applied, and the whole is secured with cross straps of linen and a circular roller; but with no more pressure than is requisite for the security of the dressings. At the end of three or four days the dressings may be renewed in the same manner; and about the tenth or twelfth day, or whenever the tension and inflammation are removed, the ligatures may be taken out.

When now a proper suppuration is established, the flap may be applied to the stump. But previously, the matter must be wiped off from the surfaces of both sores, with soft sponge, and these being brought into contact with the greatest exactness possible, they may be secured either with adhesive plasters or two or three sutures.

Mr. Benjamin Bell, who prefers the latter method, assures us, that when, with a view to immediate adhesion, the flap is laid down directly after the operation, the pain, tension, and inflammation, which ensue, run often so high as to compel the surgeon to remove the dressings: whereas, when O'Halloran's method is adopted, the inflammation which ensues is very trifling, and the cure is accomplished even more quickly, than when the operation has been done according to the former method. We are, however, very much disposed to think the inflammation, &c. is too often produced by tight bandaging or sutures, in the cases where it fails of success.

The operation with *two flaps*, according to Ravaton's method, is performed in the following manner: When the tourniquet has been applied, an assistant draws up the skin tight, and makes a circular incision through the skin and muscles at the lowermost part of the limb, with the edge of the knife turned obliquely upwards. A sharp-pointed knife is now pushed in on one side of the limb down to the bone, at the part where the bone is to be sawed, and the under edge of the knife being turned obliquely outwards, the muscles are divided down to the circular incision. The skin and muscles on the opposite side of the limb are now divided by a similar incision, and with these the intermediate soft parts that may have been left are likewise cut through. When now the bone has been sawed, and the vessels tied up, the surgeon must either lay both flaps together immediately (as we recommend), or keep them separate for the first twelve or fourteen days, after which he may treat them in the manner above directed.

Of the Flap-Operation below the Knee.

This operation is performed nearly in the same manner as that above the knee; and the flap may be applied either immediately, or after the pain, tension, and inflammation are

gone. Only we cannot here, as on the thigh, so commodiously cut out the flap on the fore part of the limb, as the leg has no muscles there. On that account all writers direct the flap to be cut out at the back part: though this is attended with a very considerable inconvenience. For when the flap has been cut out of the calf of the leg, it is scarcely possible, after it has been applied to the stump, to prevent the accumulation and retention of the pus, as it does not find a free vent below, and we dare not apply more than a very moderate degree of pressure to the stump.

Instead therefore of cutting the flap out of the back part of the leg, Mr. B. Bell advises us to do it from the outside of the limb, where there is a sufficient quantity of muscles for the purpose, and where the flap can be no impediment to the discharge of the pus. He therefore performs the operation according to the following method: Let the point of the knife be entered on the outside of the ridge of the tibia, at the place where the bone is to be sawn, and after carrying it backward, in a direct line, to the opposite side of the base of the flap, let the edge be carried down the line previously marked with ink as a direction for the form and length of it.

When we amputate immediately above the ankle, we must cut out the flap behind, as there is not a sufficient quantity of soft parts behind; but it is here to be repeated, what has already been observed, that the leg ought never to be amputated so immediately above the ankle, as to have the stump too long for an artificial leg and foot being conveniently adapted to it. In an adult we ought therefore to form the flap about nine inches under the knee, if we wish to perform the operation in this manner.

Amputation of the Foot, Toes, and Fingers.

When the whole foot is diseased, we must perform the amputation in the manner above mentioned, above the ankle. This should also be done even where the joint itself is sound, but all the rest of the foot diseased. Some, indeed, have advised to take off the foot at the ankle joint; but as, when this is done, an artificial foot cannot well be applied, nor the stump covered with fleshy substance, the amputation above the ankle is evidently to be preferred.

But when a considerable part of the foot is still sound, we ought to endeavour to preserve it, and merely to remove what is diseased; and this should be our practice even where two of the metatarsal bones only remain sound; for the patient may still make great use even of a small part of the foot in walking, provided he wears a shoe well made, properly stuffed out, and with a strong unyielding sole. This may be done, especially when the bones on the inside of the foot, or those corresponding to the great toe, and those next it, are left. Very remarkable, therefore, is the case of Mr. Turner's amputating the foot at the middle. The operation was performed on account of a painful tumour, which extended as far as the middle of the metatarsus; and it was thought unnecessary to amputate above the ankle. A double incision was therefore made, and in order to preserve as much as possible of the integuments, a small part of them situated above the tumour, was included in the first incision. As the integuments could not be drawn back to any considerable length, it was impossible to preserve so much of them as might have been wished. The foot was sawed through at the upper part of the metatarsus, the hæmorrhage was easily stopped, and in the course of ten weeks it was completely healed, without any violent symptom having supervened.

When only single bones of the tarsus are diseased, these bones alone are to be taken out. When only one part of a bone

AMPUTATION.

bone is diseased, this must be removed with the saw, chisel, or trephine, but not the whole bone taken away.

In every amputation as much skin as is sufficient for covering the wound must be saved; but this is particularly necessary in amputating any part of the foot, where bad effects are to be apprehended from friction in walking. As the skin of the sole of the foot is commonly very thick, the flap which is to cover the fore ought, if possible, to be taken from that part; for this will prevent the bad effects of friction upon the part, much more than could be done by the skin of the upper part of the foot which is thinner, and unaccustomed to friction or pressure.

In performing this operation, the patient is placed on a table, and the tourniquet applied either below Poupart's ligament, near the upper part of the thigh, or over the knee, with a compress in the ham. The limb is secured by an assistant, and in sawing through the diseased bone, a piece of pasteboard, or a thin splint of wood, should be inserted between it and the contiguous sound bone, in order to protect the latter from the saw. When the diseased bone has thus been removed, and the arteries tied, the flap that has been saved is laid, with as much exactness as possible, on the fore, and secured with slips of adhesive plaster, and a roller. If futures are employed, they ought to be inserted in such a manner as not to injure the tendons of the flexor and extensor muscles of the foot and toes.

In amputating the fingers and toes, we proceed in the same manner as with the larger extremities, and the stump must here also be covered with a flap. The skin is drawn back as much as possible, after which the skin and flesh are cut through with a straight bistoury, between the contiguous sound fingers and the diseased one, in a straight line backwards, till somewhat above the joint, on both sides; the skin and flesh are also cut through above, round the joint; the finger is then bent towards the palm of the hand, and cut off from the out to the inside; the incision terminating at the fore part in such a manner, that still some part of the flesh is preserved for the purpose of being afterwards applied over the wound to facilitate the cure. When we only leave a single flap of integument on the finger, it has been recommended to let it be taken from below in labouring people, to afford a suitable stump for pressure; but, where beauty is more an object than use, we may take the flap of skin from above, as it will then scarcely occasion a visible scar after the cure.

In as much as we here speak of the case, in which the whole finger or toe is amputated from the contiguous metacarpus or metatarsus, we must also proceed in a similar manner when amputating only one or two joints; and if we find it necessary to tie an artery, we should do it by means of the tenaculum. The flap must be laid over the wound, and secured as accurately as possible with adhesive plasters, and moderate pressure with a roller. The objection which has been made that the union of the soft parts with the cartilage is precarious, is not founded in truth; for the skin unites with the cartilage, which covers the bone at the joint almost as readily as with other parts. It is therefore unnecessary that we should separate the cartilaginous surface of the joint with a small saw, as was formerly the general practice.

Amputation of the Arm and Fore-Arm.

This is performed in every respect in the same manner as has formerly been directed for the amputation of the thigh and leg. It should be remembered, however, that a long stump will be more useful in the arm than a short one. When we are to amputate at any other part than the joint, we may

do it without cutting out a flap to cover the wound; for in these parts there is a sufficient quantity of muscles, cellular texture and skin, for covering the stump, if we draw back the skin, according to the directions formerly given, and first divide that, and afterwards the muscles. Should this not be practicable in certain cases, it would then undoubtedly be better to perform the operation with a flap.

Amputations in the Joint.

These operations have been recommended on the authority of a number of cases in which they have been performed. In such an operation we are directed to cut first through the skin, nearly over the joint, with a straight knife upon the upper or foremost side, making a semicircular incision; we then open the capsule of the joint on both sides, and in doing this, we bend the limb (suppose it be the hand) in order to obtain room for cutting through the capsule all round, that we may the better be able to spare the cartilage of the sound member. The rest of the operation and cure is conducted in the usual manner.

But though amputation at the joint is preferable to amputation above the joint, with the fingers and toes, and perhaps also with the hand, the application of the same practice to other joints, such as the elbow, knee, and ankle joint, must be attended with very great difficulties. For, in the first place, this method of amputating is in fact more tedious than the operation above the joint. It is also equally painful, and the hæmorrhage equally dangerous; and as the soft parts in these joints are mostly aponeurotic and tendinous, a favourable inflammation and suppuration are not so likely to ensue. Besides it is very difficult at the elbow and ankle-joint to save so much muscular substance and skin as are requisite for covering the bone at the surface of the articulation, on which account a tedious suppuration and exfoliation generally take place; and there is reason to apprehend, that we may afterwards be still compelled to amputate again above the joint, and saw through the bone.

We shall describe the operation, as it has been done at the hip and shoulder-joint by eminent surgeons.

Amputation of the Arm at the Shoulder Joint.

Though this operation ought never to be performed when we can accomplish our purpose by amputating below the shoulder-joint, it being always a hazardous operation, yet we ought not to hesitate to undertake it, when abscesses in the joint, caries of the humerus extending to the shoulder, complicated fractures reaching as far as the head of the bone, bad gun-shot wounds, or a sphacelus render it necessary. Mr. Bromfield has given the following directions for performing it; and he did it several times with success. See his *Chirurgical Observations*, vol. i. p. 247, *et seq.*

When the apparatus is ready, place the patient upon his sound side upon a table, and in a somewhat oblique posture, that the surgeon may have room to move freely. Let an assistant then compress the subclavian artery at the place where it passes through the scalenus muscle, in such a manner that, by the resistance of the first rib, the passage of the blood through the artery may be entirely prevented. In order to know whether the pressure be sufficient for this purpose, we have only to examine the pulse at the wrist.

The patient being properly secured by the assistants, and pressure made firmly on the artery, the surgeon begins his incision on the inner side of the arm, at the edge of the deltoid muscle, namely, at the place where the great pectoral muscle passes over the axilla, to be inserted into the os humeri. He cuts through the skin and muscles, carrying his incision downwards, and rather obliquely outwards, till he arrives at a little

little below the termination of the deltoid. He then continues his incision across to the outer side of the arm, but so as to make this cross incision semicircular, and continues it on the outer side of the arm as far as the fold of integuments in the axilla. By means of this semicircular incision, we obtain, provided the skin and muscles have been drawn upwards from the bone, a flap of the form of a crescent, with which we may fill up the axilla after the operation.

A second incision must now be made, commencing at the process acromion, to be continued quite through the deltoid muscle in a longitudinal direction, and as far as the place where this muscle is inserted into the os humeri, terminating in the first semicircular incision. This incision, however, must not divide the flap into two equal parts, but it must be carried somewhat more inwards, so as to make the outer division of the flap the largest. The operator then passes his knife under the outer edge of the inner division of this flap, and separates it from the bone as high up as he is able. By these means, the tendon of the pectoralis major is laid bare. He now introduces under the tendon the fore-finger of his left hand, which serves as a conductor to a crooked knife provided with a guard at the point, with which he cuts through this tendon, near to the place where it is attached to the os humeri. If by these means the vessels have not yet been laid sufficiently bare to be easily taken up, he divides also the outermost head of the biceps muscle.

The vessels being now sufficiently in view, the surgeon first ties the artery with a strong ligature about eight inches in length. For this purpose he makes use of a peculiar kind of instrument, which is fixed to a flat handle, like a scalpel, and towards the point resembles a blunt crooked needle, having a transverse eye at its anterior extremity. When he has introduced the ligature under the artery, by means of this instrument, he directs his assistant to lay hold of the ligature, with a small tenaculum, on the other side, near to the eye of the needle; which being done, he draws back the needle. He now cuts through the ligature, at the tenaculum, by which means he obtains two ligatures. The one of these he lays hold of, and draws it a little forwards, in order to find its other end; after which he ties the artery with a surgeon's knot, about two inches below the head of the os humeri. The other ligature is applied about half an inch lower down, and the artery is then divided a little below the second ligature. The great brachial vein must also be tied with the same care, without, however, inclosing the nerve, and then cut through in the same manner as the artery. He then delivers the ends of the ligatures to an assistant, who holds them up with one hand, towards the upper part of the thorax, and with the fingers of the other compresses the vessels at the axilla.

The surgeon then divides the nerve as high as possible, and much higher than the artery. He now separates the outer part of the flap also, as high up as sufficiently to expose the capsule of the joint; he then cuts through the muscles and the capsule at the superior and lateral part, and presses the arm a little backwards, upon which the head of the bone is immediately dislodged from the socket of the joint, after which the remaining part of the capsule is easily divided. He now completes the operation with the third grand incision, which he commences at the inside of the shoulder, where the vessels must be protected by the fingers of the assistant from the knife; and continues it in a semicircular direction through the fleshy parts, which cover the inner side of the joint, till this incision terminates in the first incision on the outside of the arm. Should any of the vessels still throw out much blood, it must be drawn out with the tenaculum and tied, taking care not to include the nerve in the ligature.

The ends of the ligatures are then drawn to the outside of the arm, and the inner part of the flap let fall down in such a manner, as to fit into the semicircular incision. The surgeon then passes a large crooked needle with a thread through the inner flap, about an inch and a half under the upper and inner part of the wound, and carries the point of it through the skin of the wound in the same line, forming the interrupted suture in the usual manner, in order to promote the speedy union of the parts. The same operation he repeats twice with the outer flap, then draws out the ends of the threads through the middle incision in the deltoid muscle, and lets them hang out till they come away spontaneously, which may be in about eight or ten days.

When the socket of the joint is not carious, the operator, before drawing out the ends of the vessels, is recommended (but, we think, very improperly) to separate the cartilaginous substance which lines its socket with a scalpel, and to cover the bone with dry lint, which is to remain there till it comes away of itself. He also makes use of dry lint when the socket of the joint and the adjacent bones are carious. Every long sinus that does not proceed perpendicularly upwards must likewise be laid open by an incision.

After the operation he covers the stump with a double piece of flannel, which he draws together with a needle and thread, in such a manner as to make it lie close upon the upper part of the shoulder, so that it cannot fall down. This he further secures with other stripes of flannel, from three to four fingers-breadth broad, and from six to nine feet in length, according as the strength of the patient requires, sewing such a stripe of flannel on each side to the upper edge of the bandage; the foremost of which he carries behind over the back of the patient, and the hindmost forwards over his breast, so that they cross each other over the shoulder, and again on the opposite side at the axilla, after which their ends are brought back to the stump, and there secured with pins. Two other stripes of flannel are fixed on the inner and outer side, to the inferior margin of the flannel bandage on the stump, one of which is carried across the back, and the other across the breast at the lower part of the sternum; they are then made to cross each other at the axilla of the sound arm, then brought round to the shoulder, and crossed again; after which the end that was brought out under the axilla, and carried to the shoulder, is now passed along the lower part of the neck to the bottom of the stump. The other end is brought forwards, and secured to the bottom of the stump with pins.

Mr. Benjamin Bell advises us to perform this operation, after a method somewhat different from that of Bromfield; although he seems not to have done it himself. He directs us to place the patient upon a table of a convenient height, covered with a mattress and a blanket. Let him be laid upon his back, as near as possible to the edge of the table, and properly secured by assistants. Hæmorrhagy is guarded against by an assistant compressing firmly with his finger and a cushion on the subclavian artery, as it passes over the first rib directly above the clavicle. The diseased shoulder is then made to project somewhat over the side of the table, and the arm is stretched out at nearly a right angle with the body, and supported by an assistant.

The incision is made exactly at the insertion of the deltoid muscle into the humerus, in a circular form through the skin and cellular substance; the integuments are retracted about half an inch, and along their margin all the muscles are divided with a perpendicular cut down to the bone. All this is performed with the common amputating knife; the rest of the operation is performed with a strong round-edged scalpel. With this instrument a perpendicular incision is made

AMPUTATION.

made down to the bone, commencing at the acromion, and terminating in the former circular incision, so as to pass straight between the centre of the deltoid muscle and its outer edge, and end about an inch above, or rather on the outside of the brachial artery. A similar incision is made on the back part of the arm, commencing also at the acromion, and terminating in the circular incision. This should be at such a distance from the first perpendicular incision, that the two flaps formed between them may be both nearly of equal breadth. The brachial artery must be tied, as soon as it has been divided by the circular incision through the muscles; and any other anastomosing branches of arteries that may have been cut must likewise be tied in a similar manner. The two flaps must now be separated from the bone, care being taken not to injure the great brachial artery, in separating that part of the flap near which it lies. An assistant must then press both the flaps asunder, so as to bring the capsular ligament of the joint into view. Into this ligament an opening is now made, and the bone dislocated, by dressing the arm backward. The operation is then finished by dividing the remaining part of the ligament.

Any arteries that may have been cut about the joint must be tied, and the ligature suffered to hang out at the most depending part of the wound. When the parts have been cleared of all the coagulated blood, the two flaps are laid together, in such a manner as to cover the joint as exactly as possible, and retained in this situation by one or two more sutures. A pledget spread with emollient ointment is laid upon the joint, and over this a cushion of lint with a soft compress of linen. All this is secured by a flannel roller, applied so as to make only a moderate pressure, by which the flaps will be kept in contact with the parts beneath. The patient must, in other respects, be treated according to the directions formerly given. In the course of eight or ten days, Mr. Bell says, the ligatures will easily come away; but to avoid any risk from sudden hæmorrhage, he advises an assistant to watch the patient for the first few days after the operation.

This method is undoubtedly more easy and simple than that of Bromfeild: for the muscles are divided at once, down to the bone, with a circular incision; and not, as in Mr. Bromfeild's method, first one muscle cut and then another. As the attachments of all the muscles to the humerus are removed by the arm being taken away, it is not necessary we should divide them with such slowness and caution; one ligature also upon the brachial artery is sufficient, if applied with the requisite care and attention by means of the tenaculum. Neither is it necessary to scrape off the cartilage from the acetabulum of the joint; for, as has been already observed, the soft parts will adhere to cartilage as readily as to bone.

Another method of amputating the arm at the joint was employed by Mr. Default, of Paris, which seems not only to be far more expeditious, but also less painful to the patient, and easier to execute than any other. The manner in which it is performed is as follows:

The patient being placed upon a chair, and the subclavian artery compressed by the finger of an assistant at the place where it passes through the scalenus muscle, the arm is raised in such a manner as to form nearly a right angle with the trunk of the body. A two-edged scalpel, having a straight blade six inches in length, and half an inch in breadth, is thrust into the joint at the place where the long head of the biceps muscle enters it, and brought out again an inch below the axilla; in this manner the capsule of the joint is cut through forwards; and, at the same time, the knife is carried round the head of the os humeri on the same side of the arm, care

being taken to keep it always quite close to the bone. By cutting downwards in this manner, all the fleshy substance is at once separated three finger-breadths below the joint, so as to form a triangular flap, in which the axillary artery and vein are contained. This flap is immediately laid hold of by an assistant, who holds it off from the bone, and compresses the vessels with his fingers. The arm is then bent a little backwards, the knife introduced again into the joint, the remainder of the capsule and ligaments cut through, and, by carrying the instrument downwards from the back part next the bone, and at the same distance from the joint as before, another triangular flap is formed similar to the former in shape and size. The arm being entirely cut out in this manner, the axillary artery and vein are tied as high up as possible.

When the acetabulum of the joint is quite free from disease, the cure is endeavoured to be effected by reunion, for which purpose Mr. Default also conceived it to be unnecessary to scrape away the cartilage. The two flaps are now laid together, so as to fill up the socket of the joint, and the lips united by means of the interrupted suture. Over the fleshy parts dry lint is applied, and over that a compress, in the form of a cross of Malta, spread with ointment; then again a round compress and two languettes, which are all finally secured with a flannel roller. Under the axilla an oval piece of linen is applied, partly in order to resist the impetus of the blood in the axillary artery, and partly to press the fleshy parts more closely to the hollow of the scapula, with a view to facilitate the healing of the wound. The whole of these dressings are likewise secured with a roller.

The knife used in this operation must be sharp, and somewhat ground off on both sides, like a pair of scissors. The blade should not be made of too hard steel, lest it break during the operation; on the contrary it should be rather flexible, but at the same time tough, in order that when it is carried round under the head of the os humeri, it may apply the more aptly to the bone.

Amputation of the Thigh at the Hip Joint.

The proposal of this operation must at first strike a feeling mind with horror; and, indeed, it is so terrible as well as difficult to perform, that many eminent men have thought it impracticable to be done with success. This opinion has even been advanced by Schmucker, in his *Vermischte Chirurgische Schriften*, &c. B. i. p. 48. Berlin, 1776; where the author says, "he is persuaded that no patient on whom it may be performed can ever survive." He very properly dissuades us from relying on experiments which have been made on dogs, and from thence inferring, that similar trials will succeed equally well on the human subject; but Schmucker ought certainly to have spoken with some degree of diffidence, after the publication of facts which seem to establish an opposite opinion to his own. That a person may actually survive this dreadful operation, will appear from what we shall presently state for the reader's information.

The possibility of performing amputation at the hip-joint with success, was discussed so early as the year 1739; and was maintained in a public thesis, at one of the medical schools at Paris, A. D. 1748. The members of the Royal Academy of Surgery at Paris, likewise believing that it was practicable, gave out the following prize question in 1756: "*Dans le cas où l'Amputation de la Cuisse dans l'Article parotroû l'unique Ressource pour sauver la vie à un Malade, déterminer si Pon doit pratiquer cette Opération, et quelle seroit la Methode la plus avantageuse de la faire;*" but not being satisfied with the answer it met with, they again proposed the same subject for the year 1759. On the former occasion, twelve memoirs were received by the Royal Academy; on

the latter, thirty-four. *Disput. Chirurg. Halleri, tom. v.—Opuscules de Chirurgie par M. Morand.—Prix de l'Académie, tom. iv.—Journal de Médecine en 1759.*

Who would have imagined, a priori, that a patient could survive the complete dilaceration of an arm, with the scapula, and all the muscles attached to it? Yet this is a fact that cannot be controverted. The thigh of a young lad, at the Hotel Dieu d'Orleans, was spontaneously separated at the hip-joint, except the round ligament and sciatic nerve: the other thigh, which was much sphacelated likewise, was presently afterwards cut off by his surgeon; and the fore on both sides went on well till the fifteenth day from the first operation, when a fever supervened and destroyed the patient. Another instance of an amputation of the limb at the hip-joint is recorded by M. Sabatier, (*De la Méd. Opér. tom. iii. p. 330.*) which had been performed in consequence of a violent contusion, followed by gangrene: the cure was effected in eighteen months, and remained permanent; so that this man was afterwards married, and had a fine child. Lastly, we beg leave to copy an interesting account of a case published by Mr. William Kerr, of Northampton, in vol. vi. p. 577, of Dr. Duncan's Medical Commentaries; from which we may farther presume on the reasonableness of this operation, under certain circumstances of extreme danger.

"A girl, between eleven and twelve years of age, was brought into the hospital, from Kettering, in December last. She had a tumour on the outside of her right thigh, extending from the middle to near the great trochanter; she was very much emaciated, had a constant cough, night sweats, and many more hectic symptoms. She told us that she had been ailing upwards of two years, during which period she had frequently had fevers, and that her lameness had been gradually increasing from her first illness. That at first she had little pain, but a few months before she came into the house, it became very acute from the groin all round the hip, and till then she never observed the tumour before mentioned.

"She suffered great pain upon the least motion of the joint, and upon every such attempt there was a very perceptible grating to be felt. Being engaged myself," says the author, "I directed Mr. Warden, house-surgeon, to open the tumour the day after she came into the hospital; there was discharged about half a pint of ill-conditioned matter, and we had the same kind of discharge, in a very great quantity, at every dressing, from that time till the operation, which was performed the Saturday following.

"Flattering myself that the hectic symptoms might be the effects of absorption, convinced that the joint was diseased, and concluding, therefore, that there was no other method of cure but by amputating the limb at the articulation, I set about it in the following manner:

"Having laid the patient upon the sound side, upon a table of a common height, and putting the diseased thigh at right angles with the trunk, I began my incision immediately behind the top of the great trochanter, carrying it obliquely, backwards and downwards, to the inside of the thigh, and from thence obliquely upwards to within two inches of the crural artery.

"I then began a second incision at the same place with the former, carrying it in an opposite direction over the upper extremity of the trochanter, and from thence obliquely forwards and downwards to within the same distance of the vessel as in the former.

"These incisions were made only through the skin and fat, which being well drawn back by my two assistants, I cut down into the joint, and from thence carried two other incisions through the muscles in the same order and direction,

and to the same extent as those which were made through the outer teguments.

"I then turned the head of the femur out of the acetabulum, that I might with more ease and security accomplish the most important part of the operation, namely, the taking up the artery. From the foregoing description you will easily conceive that a flap about four inches in breadth, consisting of all the integuments with the artery included, was still undivided. This flap I grasped firmly betwixt the fingers and thumb of my left hand, (my fingers on the skin side of it, and my thumb on the muscular) and cut it through immediately below my hand, and between three and four inches from the passage of the artery under the ligamentum fallopii.

"The incision here was made from above downwards, first through the muscular part of the flap, and then through the fat, vessels, and skin. It was done in this manner that the skin might correspond with that which was divided by the first incisions, and that the edges of the wound, we cannot say slump, might thereby be kept neat and uniform.

"The next step was to secure the artery, which I effected by passing a strong ligature round it with a needle, and getting one of my assistants to tie it up; such a compression being all the while made upon it by my left hand in the manner related above, as to prevent the loss of a single drop of blood, and the hæmorrhage from the other arteries was full as inconsiderable as in any other amputation of the thigh. By saving a good portion of skin the wound was much more decent and seemly than you can well imagine; but, to my great mortification, I found not only the acetabulum carious, but also the adjacent parts of the *ossa innominata*, to a very considerable extent. From her almost constant cough, I was under the greatest apprehension that the artery would be forced open; yet no mischief ensued, and the ligature fell off at the fourth or fifth dressing: the aspect of the fore, in the mean while, giving us the most sanguine hopes of her recovery. But about the tenth or eleventh day her respiration became more difficult, expectoration ceased; her mouth and tongue were covered with aphthæ, and she died on the 18th day from the operation. The appearance of the fore, even to the last, was such as to afford good reason to suppose that the immediate cause of death was the daily increase of the hectic symptoms, and that without these the operation would have succeeded; I therefore had her opened, and our supposition was, I think, pretty strongly confirmed by the following phenomena. The lungs were almost totally reduced to matter, especially on the right side, in which there was scarcely a vestige of pulmonary substance remaining. The left lobe also was full of abscesses, and reduced to less than half the natural size. An abscess (commonly called the psoas abscess) was likewise found on the right side, in the abdomen, which communicated, by a corroded opening with the acetabulum, with the joint.

"I have given you an exact narrative of the circumstances of the case, the operation, and the event of it; at least, I do not recollect any other of consequence. I shall not comment farther upon it than just to observe, that the total destruction of the ligamentum rotundum by the supuration within the joint, contributed greatly to the facility with which the operation was accomplished; for I imagine, if that ligament had been entire, the division of it would have been attended with perhaps considerable embarrassment; I think, however, it might be effected in a sound joint.

"With regard to the expediency of the operation, I am so much convinced of it in certain cases, that in such I shall not, for the future, hesitate to perform it when they occur."

Concluding Observations.

It still remains for us to notice two proposals, one of which is directed to the prevention, the other to the improvement, of the operation of amputation. In cases of ferofulous tumours, or, as they are termed, white swellings of the joints; of collections of matter in the cavities of joints, which often supervene upon simple inflammation; of gunshot wounds and compound fractures of the joints; or often also of the most simple, but, at the same time, penetrating wounds, a variety of morbid symptoms take place, which render timely amputation of the limb the only means by which the unfortunate patient's life can be saved. In these diseases, when they affect the knee and elbow-joint, Mr. Park has proposed, instead of amputating the whole limb, as is generally practised, another remedy, which consists in the complete extirpation of the joint, or rather, in the amputation of the extremities of the bones which form the joint, together with the whole, or at least the greater part of the capsular ligament, the cure is afterwards effected by means of callus, which occupies the place of the bones that have been sawn off, or the femur is attached to the tibia by a synostosis. But in the elbow, the humerus synostoses with the radius and ulna, without the joint retaining any perceptible power of motion. With this view he made the following experiment:

Two inches above the upper end of the patella he made an incision, and carried it down to its lower extremity; he then placed the leg in an extended posture, and made a cross incision immediately above the patella, through the tendons of the extensor muscles, down to the bone, and nearly half round the limb, so as to form a right angle with the former incision. The lower angles which were formed by this incision, he widened so as to lay bare the capsular ligament, and took out the patella. The upper angles he likewise widened, so as to lay bare the head of the femur, and to enable him to pass a small knife across the posterior flat part of the bone immediately above the condyles, taking care to keep one of the flat sides of the point of the instrument close to the bone all the way. He then withdrew the knife, and introduced an elastic spatula in its place, to guard the soft parts during the sawing through of the femur. He then carefully dissected out the head of the femur that had been sawn off. The head of the tibia was then easily turned out; this he sawed off, and cut away as much as possible of the capsular ligament, leaving only the posterior part to cover the vessels, which he found, upon examination, to be not only unhurt, but also that they were sufficiently covered with the remaining part of the ligament, and that, during the whole of the operation, they had been sufficiently far from the course of the knife. Although the wound had a formidable appearance, he saw no reason to doubt that nature would be able to repair the breach; as the limb below would not be deprived of its nourishment, and every healthy fresh-incised surface, both of bone and of soft parts, has a natural tendency to granulate.

The next operation he performed upon the elbow-joint. He made an incision, commencing two inches above the tip of the olecranon, and terminating at the same distance below it; he then raised the integuments, and endeavoured to separate the lateral ligaments from each other, in order that he might be enabled to draw the bones asunder. But as he found this to be difficult, he first sawed off the olecranon, whereby he loosened the joint to that degree, that he could very easily draw it asunder, without being under the necessity of making a cross incision. He then turned out the lower end of the humerus, and sawed it off, and afterwards the heads of the radius and ulna. He does not, however,

flatter himself that this method will prove equally successful in all cases; as, in some, amputation is indispensably necessary; for example, when the disease has spread too far, when the soft parts are too much injured, and the caries too extensive. In general, he thinks the operation is more to be recommended in cases of external injury than in serofulous affections.

The other proposal, which has Mr. Wrabetz for its author, refers to the amputating of limbs without the knife, by means of ligatures. Mr. Ploucquet (*Von der unblutigen Abnehmung der Glieder. Tuebingen, 1786, 8vo.*) describes it as follows: Take a fluxen, or rather a cotton cord, of thickness and strength proportionate to the size of the limb; lay it in spirit of turpentine, mixed with fine powder of tobacco-leaves, the seeds of the ruta, cantharides, and camphor; and after it has lain in this liquid for the space of twelve hours, apply it to the limb in the following manner. Draw back the skin as much as possible towards the sound part of the limb, and apply it above the diseased part round some perfectly sound part of the limb; draw it tight with a turn-screw, and secure the latter. About two inches above the cord rub a quantity of the above-mentioned mixture, till small blisters are raised, which must be opened and dressed with a drawing plaster. By this application and by poultices the requisite degree of inflammation is promoted. As long as the cantharides are employed, the use of which is very beneficial to debilitated habits, the patient must drink mucilaginous liquids, with which cordials are to be combined, such as camphor, Peruvian bark, arnica, &c. and, at the same time, blood-letting and refrigerant remedies, especially nitre, are to be administered. As the cord sinks into the flesh, and grows looser, it must be tightened; and the crevice which it leaves above it must be filled up with a fine powder of Peruvian bark, camphor, and alum, in equal parts. This powder may also be made into a liniment with oil of hypericon, and rubbed into the above-mentioned crevice. That part of the limb which we wish to separate should be swathed in a cloth soaked in a mixture of a solution of alum, lime-water, and some aromatic spirit. Mr. Wrabetz has in one case succeeded in amputating the humerus according to this method, and assures us, that he has often separated small limbs by means of ligatures: it is, however, a practice that cannot be recommended for imitation, although Mr. Manguet has endeavoured to demonstrate the advantages of this operation; for, on the one hand, his observations are too defective to prove any thing, and on the other, the operation should only be attempted in a perfectly similar case.

For an account of the means of supplying defective members, see LIMBS, *artificial*.

AMPUZITZA, in *Geography*, a town of Beffarabia, 26 miles west-north-west of Ismael.

AMPYX, in *Antiquity*, a kind of golden chain, which served to bind the hair of the horses on the forehead. Homer describes by this ornament the steeds of the god of war, calling them χρυσάμπυξες. The term was afterwards used more generally to denote a band or fillet, which formed a part of the dress, and which encompassed the hair. It was sometimes encircled with gold and precious stones.

AMRAM, in *Scripture Biography*, was the son of Koath, of the tribe of Levi, and married Jochebed, by whom he had Aaron, Miriam, and Moses. He died in Egypt, aged 137. Exod. vi. 20.

AMRAN, in *Geography*, a town of Arabia, 20 miles north-west of Sana.

AMRAPHEL, in *Scripture History*, was king of Shinar, and confederate with Chedorlaomer, king of Elam, and two

other kings, in making war against the kings of Sodom, Gomorrah, and the three neighbouring cities. The kings, who were in league with him, plundered these cities, and carried off many captives, among whom was Lot, Abraham's nephew; but Abraham pursued them, retook Lot, and recovered the spoil. A. M. 2092, B. C. 1912.

AMRAS, in *Geography*, a castle or palace of Germany, in the county of Tyrol, called by some writers *Arx Ambrosiana*, and also *Ombrafi*, and situate at the foot of a mountain, two miles south east of Inspruck. In the heat of Summer it is a place of retirement for the archdukes. It is famous for its collection of antiquities, gold medals, cameos and intaglios, most of which were sent to it by Charles V. On the walls and ceilings are many curious paintings, and one, in particular, of Noah's ark by Bassano, for which the grand duke of Tuscany is said to have offered 100,000 crowns. Here are also a library, a gallery full of busts, and many pictures of great value. N. lat. 47°. E. long. 11° 40'.

AMRU, or AMROU, EBN-AL-AS, in *Biography* and *History*, a famous Saracen commander, was the dubious progeny of Aasi, of the tribe of Koreith, by a notorious prostitute. In his youth he was impelled by the passions and prejudices of his kindred: his poetic genius was exercised in satirical verses against the person and doctrine of Mahomet; and his dexterity was employed by the reigning faction, to pursue the religious exiles who had taken refuge in the court of the Ethiopian king. From this embassy he returned a secret proselyte, having renounced the worship of idols; and making his escape from Mecca with his friend Caled, he joined the fugitive prophet at Medina. His impatience to lead the armies of the faithful was checked by the reproof of Omar, who advised him "not to seek power and dominion, since he who is a subject to-day may be a prince to-morrow." Amru, having acquired a high degree of military reputation, was the chief in Irak, when Caled summoned all the Arabian generals to his assistance, in the siege of Damascus. In Palestine, he served during the Caliphate of Omar, under Abu Obeidah, who was the commander in chief. On his arrival in this country he was informed, that Constantine, the son of the emperor Heraclius, lay encamped with a body of troops near Cæsarea. As he was advancing towards the siege of this city, this prince deputed some Christian Arabs to reconnoitre the Moslem camp; when one of them was discovered, and cut to pieces. Amru was much offended, and issued orders that all spies should be brought to him for examination, before they were thus punished; alleging, that such spies might probably, in case of conviction, rather embrace Islamism than suffer death. About this time Constantine expressed a desire to have a conference with Amru. When the Arabian chief was introduced to the prince, he declined making use of a seat that was offered him, and took his place cross-legged on the ground, after the Arabian manner, with his sword upon his thigh, and his lance laid across before him. Constantine made overtures for a pacification, but they were rejected with great insolence by Amru, who insisted upon his paying tribute or embracing the religion of Mahomet. This conference closed with a declaration on the part of Amru, "that the Arabians were tired of living in their scorching deserts, and were resolved to re-enter into the possession of the delightful country, which was the inheritance of their progenitors." Accordingly both parties prepared for action; which terminated in the capture of Cæsarea by Amru, and the subjugation of all the maritime towns of Syria, A. D. 638. Upon the death of Obeidah,

Amru assumed the chief command in Syria, in which, notwithstanding the opposition of Othman, he was confirmed by Omar. Determining to proceed to Egypt, he left his station at Gaza, and advanced forward at the head of only 4000 Arabs; but in his progress he was overtaken by a messenger from Omar, with instructions contained in a letter which he did not open, because he entertained some suspicion of its contents, till his tents were pitched within the territory of Egypt. "If you are still in Syria," said the ambiguous mandate, "retreat without delay; but if, at the receipt of this epistle, you have already reached the frontiers of Egypt, advance with confidence, and depend on the succour of God and of your brethren." After perusing this letter in the presence of his officers, he declared his ready obedience to the commands of the Caliph. After a siege of 30 days, he took possession of Parnax or Pelusium, and this key of Egypt, as it has been justly called, unlocked the entrance of the country, as far as the ruins of Heliopolis, and the neighbourhood of the modern Cairo. From Pelusium, he marched to the ancient Memphis, or Misrah, the siege of which was protracted to seven months; and as the invaders were, by this delay, threatened with the inundation of the Nile, they stormed the place and drove the remnant of the Greeks to their boats and the isle of Rouda. On this spot, the eastern bank of the Nile, recommended to the conqueror by its easy communication with the gulf and the peninsula of Arabia, he built a city called Fostat; and the contiguous quarters of Babylon and Fostat are confounded in their present decay, by the appellation of old Misrah or Cairo, of which they form an extensive suburb. After this conquest, the Coptic Christians, or Jacobites, negotiated, by means of their governor, Mokawkas, a treaty of peace and amity with Amru; agreed to pay a stipulated tribute; swore allegiance to the Caliph, and promised an hospitable entertainment of three days to every Mussulman, who should travel through their country. Their patriarch Benjamin, at the earnest request of Amru, emerged from his desert; and, after the first interview, the courteous Arab affected to declare, that he had never conversed with a Christian priest of more innocent manners and a more venerable aspect. In the march from Memphis to Alexandria, the lieutenant of Omar entrusted his safety to the zeal and gratitude of the Egyptians; and in every step of his progress, he could depend on a constant supply of provisions and intelligence. The fugitive Greeks were pursued to Alexandria, and the road thither was laboriously cleared by the victorious Saracens, in 22 days of general or partial combat. After a siege of 14 months, and the loss of 25,000 men, the city was taken A. D. 640. See ALEXANDRIA. During the progress of this memorable siege, Amru "was betrayed by his imprudent valour; his followers, who had entered the citadel, were driven back; and the general, with a friend and a slave, remained a prisoner in the hands of the Christians. When Amru was conducted before the præfect, he remembered his dignity and forgot his situation; a lofty demeanour, and resolute language, revealed the lieutenant of the Caliph, and the battle-axe of a soldier was already raised to strike off the head of the audacious captive. His life was saved by the readiness of his slave, who instantly gave his master a blow on the face, and commanded him, with an angry tone, to be silent in the presence of his superiors. The credulous Greek was deceived; he listened to the offer of a treaty, and his prisoners were dismissed in the hope of a more respectable embassy, till the joyful acclamations of the camp announced the return of their general, and insulted the folly

of the infidels." After the capture of Alexandria, the whole of Egypt soon submitted to the arms of the conqueror; and in the administration of it he balanced the demands of justice and policy. In the management of the revenue he disapproved the simple, but oppressive mode of a capitation, and preferred with reason a proportion of taxes, deducted on every branch, from the clear profits of agriculture and commerce. A third part of the tribute was appropriated to the annual repairs of the dykes and canals so essential to the public welfare. Under his administration the fertility of Egypt supplied the dearth of Arabia; and a string of camels, laden with corn and provisions, covered almost without an interval the long road from Memphis to Medina. The genius of Amru opened the maritime communication which had been attempted or achieved by the Pharaohs, the Ptolemies, or the Cæsars; and a canal, at least 80 miles in length, was opened from the Nile to the Red Sea. From Egypt, Amru extended his conquests to the neighbouring parts of Africa; but on the accession of Othman, he was superseded in his government of Egypt by Abdallah-ebn-Said. The dismissal of Amru was considered as a public loss, and even disposed the Egyptians to revolt. This change in the sentiments of the people induced Constantine, the Greek emperor, to meditate the reduction of Alexandria, and he easily effected his purpose. Upon this loss Amru was restored to his former dignity; and employed in the recapture of the city. After a vigorous resistance, on the part of the besieged, and great slaughter, he took it by storm; and though by his authoritative interposition he restrained the massacre of the inhabitants, he dismantled it, and utterly demolished all the walls and fortifications. After this exploit, he was again displaced by Abdallah, and recalled to Medina; but Othman found it necessary to avail himself of his influence in quelling a sedition, which he was unable to effect.

Upon the accession of Ali, Amru joined the malcontents, and quitting his command in Palestine, arrived at Damascus, which was then the residence of Moawiyah, the competitor of Ali, and swore allegiance to him. When it was proposed to decide the difference between these two rivals, by single combat, Amru persuaded Moawiyah to accept the challenge; but he declined it, and ascribed Amru's recommendation of it to selfish motives, and to his desire of obtaining the caliphate for himself. Notwithstanding this unjust suspicion, Amru maintained his attachment to Moawiyah, and served him in the business of the arbitration between these two competitors. See ALI. He also took possession of Egypt in Moawiyah's name, after having defeated Mahomet-ebn-Abubeker, Ali's governor, whom he took prisoner, and put to death in a barbarous manner. Amru was now considered of such importance, that he was one of the three conspirators, whom the sect of the Kharijites determined to assassinate, with a view of restoring peace to the Saracen empire. Amru fortunately escaped; being prevented, by a fit of the colic, from attending in the mosque on the day when one of the conspirators went to kill him, but Kharijah, a friend whom he appointed to perform the office of Imam, as his substitute, was struck by the conspirator, who mistook him for Amru, and fell down dead with the blow. In the year of the Hegira 43, A.D. 663, during the caliphate of Moawiyah, Amru ended his days in the palace and city, which he had founded on the banks of the Nile. Of him Mahomet is reported to have said, that there was not a Moslem more sincere and steadfast in the faith than Amru. He was justly esteemed one of the greatest men amongst the Arabs of the age in which he lived; distinguished by his

quick apprehension, solid judgment, undaunted courage, and singular resolution, as well as his profound sagacity and penetration; always excellent in his advice, firm in his purpose and speedy in its execution. The two first successors of Mahomet were not insensible of his merit. To his arms they were indebted for the conquest of Palestine; and in all the battles and sieges of Syria, he united with the temper of a chief, the valour of an adventurous soldier. In a visit to Medina, the caliph wished to survey the sword which had cut down so many Christian warriors; Amru unheathed a short and ordinary scymetar; and as he perceived the surprise of Omar, "Alas!" said the modest Saracen, "the sword itself, without the arm of its master, is neither sharper nor more weighty than the sword of Pharezdak the poet." This saying is preserved by Pocock, and justly applauded by Mr. Harris, in his Philosophical Arrangements, p. 350. After the conquest of Egypt, Amru was recalled by the jealousy of the caliph Othman; but in the subsequent troubles, the ambition of a soldier, a statesman, and an orator, emerged from a private station. His powerful support, both in council and in the field, established the throne of the Omniades; the administration and revenue of Egypt were restored by the gratitude of Moawiyah to a faithful friend, who had raised himself above the rank of a subject; and in the possession of this lucrative dignity his life terminated. His dying speech to his children, in which he deplored the errors of his youth, and particularly his offence in satirizing Mahomet, is celebrated by the Arabians as a model of eloquence and wisdom. Ockley's Hist. of the Saracens, vol. i. and ii. Mod. Un. Hist. vol. i. p. 315, &c. Gibbon's Hist. vol. ix. p. 425, &c.

AMSBEG, in *Geography*, a town of Swisserland, in the canton of Uri, seven miles south of Altorff.

AMSDORF, NICHOLAS, in *Biography*, a Lutheran divine, was born at Meissen, in 1483. After studying at Wittenberg, he became a disciple of Luthier, who appointed him minister of Magdeburg, and afterwards of Naumberg. He was distinguished by his opposition to the Roman Catholics, and by his controversy with Melancthon and his adherents, on the subject of good works; in the heat of which he extravagantly maintained, "that good works were an impediment to salvation." From this imprudent and unwarrantable expression, the flame of controversy received new fuel, and broke forth with redoubled fury. The sentiments of Melancthon in opposition to those of Luther and his partizans, were ably defended by George Major, an eminent teacher of theology at Wittenberg; who, in 1552, maintained the "necessity of good works," against the extravagant assertions of Amsdorff; who died at Magdeburg in 1541.

AMSDORFIANS, in *Church History*, a sect of Protestants, in the 16th century; were so denominated from their leader *Amsdorf*. They maintained, that good works were not only unprofitable, but even opposite and pernicious to salvation. Mosheim's Eccl. Hist. vol. iv. p. 328.

AMSEGETES, in *Antiquity*, those whose grounds abuted on the highway. Vide Fest. de Verb. Signif. in voc.

The laws of the Twelve Tables decree, *amsegetes viam muniant*.

AMSMOE, in *Geography*, an island in the German Ocean, near the west coast of Denmark. N. lat. 54° 40'. E. long. 8° 25'.

AMSTEL, a river of Holland, which passes by Amsterdam, and joins the Y or Wye.

AMSTELLAND, a small district of South Holland, takes

takes its name from the river Amstel, which runs through it. Those parts of this district, which are not healthy, afford good pasturage. It contains several villages; such as Ouderkerk, or Guderkerk, called also Altenkerken, which is the burial-place of the Portuguese Jews of Amsterdam; Diemen situate between this city and Muiden, Amstelveen belonging to Amsterdam, &c. The lakes of Diemer and Beilmer are drained and made arable.

AMSTERDAM, or AMSTELDAM, formerly called *Amstelredam*, i. e. the dam or dyke of the Amstel, the capital of Holland and of the United Provinces, is situated at the influx of the river Amstel, from which it derives its name, into the arm of the sea, called Y or Wye, and which forms a port, capable of receiving a thousand large vessels, about two leagues from the Zuyder sea. Although the Pamphus, which is the only channel leading to it from the sea, is shallow, and ships of considerable burden are lightened before they can pass through it; and they are afterwards under a necessity of waiting for an easterly or north-east wind, in order to proceed through the Marsdiep into the North sea; yet upon the whole its commercial situation is advantageous, on account of its easy connection with the other towns of the province, and its small distance from all the ports of North-Holland, Friesland, Overijssel, and Guelderland. The soil, on which this city is seated, is marshy, and therefore its buildings are founded on oaken piles, which gave occasion to the witticism of Erasmus, "that in his country vast multitudes of people lived on the tops of trees." This circumstance restricted the use of coaches to great men and physicians, who paid a tax for this privilege; and goods are conveyed from one part of the town to another on sledges. In the beginning of the 13th century Amsterdam was a very inconsiderable fishing town, containing a few huts that were the residence of persons engaged in this occupation; but its inhabitants were gradually multiplied, and the earls of Holland gave it the title and privileges of a city; nevertheless, till the year 1490, it was surrounded merely by a weak palisado. At this time it was encompassed by a wall of brick, constructed by order of Mary of Burgundy, in order to defend it from the incursions of the inhabitants of Utrecht, who were frequently quarrelling with the Hollanders; but it was soon afterwards reduced to ashes. The people of Guelderland besieged it in 1512; but not succeeding in their attempts to take it, they set fire to the ships in the harbour. In 1525, the town-house of Amsterdam was attacked by a party of wild enthusiasts, under an anabaptist leader; but they were defeated by the citizens, and most of them were cut to pieces. Tumults of a similar kind were renewed by persons of the same description in 1535, (see ANABAPTISTS,) and these were followed by a regular and deep-laid conspiracy against the magistrates of Amsterdam, with a design to wrest the government of the city out of their hands. Van Geelen, the head of these insurgents, marched his fanatical troop to the town-house, on the day appointed, with drums beating and colours flying, and fixed there his head-quarters. He was attacked by the burghers, assisted by regular troops, and headed by several of the burgomasters of the city; and after an obstinate resistance, he was surrounded, with his whole troop, and they were put to death, in the severest and most dreadful manner. In 1578, Amsterdam was besieged by the Hollanders, and after a resistance of ten months, capitulated; on this condition, among others, that the Roman Catholics should be allowed the free exercise of their religion. The condition, however, was not observed by the Protestants; for they drove the ecclesiastics, monks, and nuns, out of

the city, broke the images, and demolished the altars. From this time Amsterdam became the general rendezvous of persons of all sects and nations; and by them it was raised to that degree of opulence and splendour to which it afterwards attained, and which it long continued to enjoy. The city has been frequently enlarged to accommodate its new accession of inhabitants; particularly in 1555, 1593, 1612, and 1673; and in 1675 it was extended to its present size, surrounded by a wall and a large ditch, 80 feet wide, and full of running water, and fortified on the land side with ramparts and 26 bastions, on each of which was afterwards placed a windmill. It has also eight gates towards the land, and one towards the water. The land side of the town may be easily inundated. Amsterdam is intersected by several navigable canals, which divide the town into a number of islands, joined to each other by wooden and stone bridges, and which are connected with the Wye and the Amstel. These canals, on the side of which are generally planted rows of trees, serve the convenience of trade, and contribute to render the streets through which they pass clean and pleasant; though in hot and calm weather they occasionally emit foetid effluvia. Of these canals the principal is that called the Ammarack, formed by the waters of the Amstel, which admits the influx of the tide, and it has on its side two large quays. It has also several bridges; the chief of which, next the sea, is called Pont Neuf, or the New Bridge; it is 600 feet long and 70 broad, with iron balustrades on each side; it has 36 arches, 11 of which are very lofty, and eight are shut up to enclose the yachts. This bridge affords a fine prospect of the city, port, and sea. The port is a mile and a half in length, and above 1000 paces in breadth; and it is filled with a multitude of vessels, the masts of which appear like a forest, and forming a kind of floating city. Towards the side of the Wye, or of the haven, the city is inclosed by double rows of piles, driven into the ground, and connected by large horizontal beams. Between these piles are openings, through which the ships pass in and out, and which are shut every evening at the ringing of a bell. The streets are generally narrow, but well paved, and the houses, which are built of brick or stone, have the air of neatness, peculiar to those of the Dutch. In the interior of the city there are agreeable walks, but the communication with the environs is chiefly by water; though there is a pleasant road to Oudekerk, through gardens and groves. The population of Amsterdam is estimated at 212,000 persons; and its commercial connections supply a very considerable, but fluctuating, accession of foreigners, who resort to this city from all nations, and are tolerated in their religious worship; though the government is restricted to persons of the reformed or Calvinistic profession. For persons of this profession, which is the established religion of the country, there are eleven churches, whose ministers are maintained by the state, and which are allowed the use of bells. The English have also had three churches; one for the Presbyterians, whose ministers have been paid by the magistracy; a second for the church of England, provided for by his Britannic majesty; and a third for the Brownists, who maintain their own ministers. These churches or congregations were formerly estimated to comprehend about a third part of the inhabitants. The Roman Catholics, who had about 27 places of worship appropriated to their use, amounted to another third part of the population; and the other third part included Jews, Lutherans, Arminians, Anabaptists, &c. The Jews had two synagogues, one of which, *viz.* the Portuguese, is the largest in Europe; and annexed to it are several

several school-rooms, in which children are taught the Hebrew language, and instructed in the Jewish religion. The most remarkable of the churches at Amsterdam is that called the New Church, and dedicated to St. Catherine. It is said to have been begun in 1408, or 1414, and not to have been finished for 100 years. The steeple, intended to be constructed before this church, and standing upon a great number of piles, is not yet completed. The pulpit is a curious structure, and is adorned with various kinds of sculpture, particularly that of the four evangelists. The paintings in the glass windows exhibit, amongst other figures, the emperor Maximilian presenting an imperial crown to the burgomasters of Amsterdam, for the crest of the arms of the city. The organ has been much admired and extolled, on account of its size, and its powers of execution. It has a set of pipes that counterfeit a chorus of voices, and has 52 whole stops, besides half stops, with two rows of keys for the feet, and three rows for the hands. Its sound, when it plays, seems to resemble that of the human voice. The grate, by which the chancel is separated from the body of the church, is constructed of Corinthian brass. The branches of the candlesticks are the richest in the seven provinces. In the church is also a marble monument, erected to admiral Ruyter, who was killed at Messina.

The largest and most stately edifice, not only of Amsterdam, but of all the United Provinces, is the Stadthouse, founded in 1648 on 13,659 piles, and comprehending in breadth 282 feet, in depth 235, and in height 116 feet. On the front is a marble pediment, on which is a female figure in relieve, holding the arms of the city, seated in a chair, which is supported by two lions, and bearing an olive branch in the right hand: on each side are four Naiads, presenting her with a crown of palm and laurel, and two other marine goddesses, offering her different sorts of fruit; there is also Neptune with his trident, accompanied with Tritons, a sea-unicorn and a sea-horse. Above are placed three statues in bronze, representing justice, strength, and plenty; and on the top of the structure is a round tower, 50 feet above the roof, adorned with statues, and an harmonious chime of bells, the biggest of which weighs about 7000 pounds; and they are made to play different tunes every month. The entrance into this edifice is by seven doors, intended to represent the seven Provinces. In the great hall are two globes, celestial and terrestrial, made of black and white marble, and inlaid with jasper and copper, 22 feet in diameter, and 69 in circumference. All the chambers are enriched with paintings, carvings, and gildings. Under the stadthouse is the treasury of the bank of Amsterdam, which is strongly secured, and entrusted to the care and inspection of the burgomasters, and opened only in the presence of one of them. In other vaults are the prisons for debtors and criminals, and also the guard-room for the citizens, in which the keys of the city are deposited every night. At the end of the great hall is the chamber of the schoppen or aldermen, where civil causes are tried; and there are also other apartments and offices of various kinds. In the second story is a large magazine of arms; and in the top of the building are six large cisterns of water, as a supply in case of fire, for the prevention of which the chimnies are lined with copper.

Another public building that deserves notice is the bourse or exchange, constructed of free-stone, and standing upon 2000 wooden piles. Its length is about 250 feet, and its breadth 140. The galleries are supported by 26 marble columns, upon each of which are the names of the people that are to meet there. They are all numbered; and there is a place fixed for every merchandise, under some one of

these numbers. A superb staircase on the right hand of the gate leads to the galleries; on one side are several shops, and on the other a place in which cloths are sold. This exchange resembles that of London. The admiralty-office is in a house which formerly belonged to the princes of Orange. The arsenal for their men of war, 200 feet long and 22 feet broad, is in the harbour; and contains, on the ground floor, bullets, on the second the arms and cordage, and on the third, sails, pulleys, flags, &c. and many curiosities. The conservatory of water on the top of the building holds 1600 tons of water, which, in case of fire, may be distributed into 16 different parts, by leaden pipes. Near this edifice is the dock or yard, in which the men of war are built, and which is 508 feet long. The East India company occupy a large building, divided into several offices or apartments, which serve as magazines or warehouses for goods of various kinds. They have also a kind of arsenal, of considerable extent. The academy, called "the illustrious school," is also a good building; it was formerly a convent belonging to the nuns of St. Agnes; it is now devoted to instruction in Latin, the oriental languages, theology, philosophy, history, &c. The lawyers and physicians have likewise their schools. Besides these, there are several hospitals, or houses for the accommodation and relief of the aged, of orphans, of sick persons, of persons infected with the plague, and of lunatics, &c. The principal houses of correction are the rasp-house and spin-house. In the former offenders are employed in sawing and rasping Brazil wood; and those who will not perform their task are placed in a cellar, into which the water runs, so that if they neglect to work the pump, they are exposed to the danger of being drowned. The spin-house is appropriated to debauched women; in this they are employed in spinning wool, flax and hemp, and other work. The hospitals are maintained partly by voluntary contributions, for receiving which the poor's boxes are fixed in different parts of the city, and partly by taxing all public diversions. Those who have the management of these public charities, are called, "deacons." The governors are selected from the most considerable persons in the city, and are nominated by the magistrates. The places of diversion appropriated to the lower classes are called, "spiel houses," in which the amusements are music and dancing. To this city belong two suburbs, one at the gate of the regulars, and the other extending as far as Overtoon, a village at a small distance, where boats that come from Leyden are forwarded over land upon wooden rollers.

Amsterdam is governed by a senate or council, called Vroedschap, and composed of 36 persons, who represent the whole body of the people, and are invested with the supreme power. Their office is for life, and the survivors supply vacancies occasioned by death. This senate elects deputies to be sent to the states of Holland, and appoints the chief magistrates, called "burgomasters," or "echevins," resembling our aldermen. Their number is 12, and four of these are annually chosen to execute the office, and are denominated "burgomasters regent." Three are discharged every year, and three new ones supply their places. During the term of the office of each, which is three months, they may be compared to the lord mayor of the city of London. To them it belongs to dispose of all offices, that become vacant during their regency. They have likewise the direction of all public works, which concern the safety, peace, and embellishment of the city. The keys of the bank of the city are in the custody of these magistrates.

The college consists of new burgomasters, who are judges
in

in all criminal affairs, without appeal; but in civil causes they may appeal to the council of the province. There are two treasurers, a bailiff, and a pensionary. The bailiff continues in office three years, and it is his business to search after criminals, to take care of their prosecution, and to superintend the execution of sentence. The pensionary is the minister of the magistracy, and is supposed to be well versed in the laws; and it is his province to defend the interests of the city. Amsterdam has in former times contributed to the public income tax above 50,000 livres per day, besides the excise of beer, flesh, and corn, which amounts to above 1,600,000. a year; and this sum is more than the amount of the payments of all the other provinces; and yet Amsterdam bears only the fifth rank in the assembly of the states of Holland, with this distinction, that as the other cities send two members, this sends four.

The militia of Amsterdam is considerable, and has usually consisted of 60 companies, each of which has from 200 to 300 men. From this service the Jews and Anabaptists are excluded, as they are not allowed to bear arms; but they are obliged to contribute to the maintenance of the city-guard, which is composed of 1400 soldiers, and to the night-watch, who patrol about the streets, and proclaim the hour. Besides these, there are trumpeters on every church steeple, who sound every half hour; and if a fire happens, they ring the fire bells, and announce where it is. The trade of Amsterdam, before the late war, and the revolutions and changes that have attended it, was very great; and it was justly regarded as the magazine or store-house of Europe. What alterations may take place in its internal government or foreign relations, in consequence of the peace that has been lately established, cannot now be ascertained. Amsterdam is distant 44 leagues from Brussels, 49 from Liege, and 112 from Paris. N. lat. 52° 22' 45". E. long. 4° 45' 30".

AMSTERDAM, now called TONGATABOO, an island in the South Pacific ocean, said to have been discovered by Tasman, a Dutch navigator, in 1643. It was visited by Captain Cook, and other later navigators. Its extent is about 16 miles in length, and its greatest breadth about eight. It is about six leagues west of Middleburgh. S. lat. 21° 9'. W. long. 174° 46'.

The shore of this island is surrounded by a coral rock, and its most elevated parts are not above six or eight yards above the level of the sea. Its interior parts are highly and universally cultivated, the whole island consisting of inclosures, with reed fences, about six feet high, intersected with innumerable roads; and its plantations supply some of the richest productions of nature. It abounds with bread-fruit, cocoa-nut trees, plantains, bananas, shaddock, yams, sugarcanes, and a fruit like a nectarine, called by the natives "fig-hega." Casuarinas, pandangs, and wild sago palms appear here with their various tints of green, and barringtonia of the size of the largest oaks. As the coral rock, which forms the basis of this spot, is but thinly covered with mould, the bread-fruit does not thrive with the same luxuriance as at the Society islands; neither does this island afford an equal supply of water, though the ships were furnished with as much as they wanted from a pool to which they were directed by the chief.

The men and women are of the common European size; their colour is that of light copper; and they are well shaped, have regular features, and are lively and active. They have fine eyes, and in general good teeth even to advanced age. The women are merry and talkative; many of them are modest, and others of a different character. They swarm about the ships, without any covering, like

amphibious creatures; and were easily persuaded to come on board; though they would not stay after sun-set, but returned to pass the night on shore with the other inhabitants, under the shade of the wood that lined the coast, where they had large fires, and were heard conversing together almost during the whole night. Their hair is black, and worn short, excepting a lock on the top of the head, and a small quantity on each side. The men shave their beards close by means of two shells; and the hair of many was observed to be burnt at the ends, and strewed with white powder, which was found to be lime made of shell or coral, which had singed the hair; some used blue powder, and others an orange-coloured powder, made of turmeric. The dress of both sexes consisted of a piece of cloth or matting, wrapped round the waist, and hanging below the knees. From the waist upwards they were generally naked; and it seemed to be a custom with them to anoint those parts of the body every morning. The practice of tattowing, or puncturing the skin, prevailed amongst them; the men performed this operation from the middle of the thigh to the part above the hips; the women performed it slightly and only on their arms and fingers. The ornaments worn by men as well as women, were amulets, necklaces, and bracelets, the bone, shells, and beads of mother-of-pearl, tortoise-shell, &c. The women also wear on their fingers neat rings, made of tortoise-shell, and occasionally pieces in their ears, about the size of a small quill. They have also a curious apron, made of the cocoa-nut shell, and composed of a number of small pieces, so disposed as to form stars, half-moons, little squares, &c. and studded with beads and shells, and covered with red feathers, so as to produce an agreeable effect. They have cloth similar to that of Otaheite, but not so fine; and they have a method of glazing it, which renders it more durable, and capable, for some time, of resisting rain. Their colours, which they procure from vegetables, are black, brown, yellow, purple, and red. Of matting they have different sorts, used for cloathing, for bedding, and for sails to their canoes; they have also several kinds of baskets made of the same materials with their mats, or of the twisted fibres of the cocoa-nut, which they form of different colours, and stud with beads made of shell or bones. They appear to be ingenious in designing and executing various articles of this kind. Their fishing implements are much the same with those of the other islands; their nets are formed of strong though slender threads. Although their disposition is friendly, they possess very formidable weapons; some of their spears being furnished with many barbs. This island is often stained with the blood of human victims; nor do the ideas of property, which prevail among the inhabitants, prevent their stealing from strangers. The Missionaries, in their voyage, some of whom were left on this island, imparted useful arts to the natives; but the rats were found very destructive to the European plants. These, with hogs, dogs, and guanos, were the only quadrupeds in the islands, till cats were left there in 1797. The morais are here called fiatookas; and are constructed in the form of terraces, with high steps, and the material of which they are formed is coral. In the missionary voyage of 1797 there is an interesting map of this island.

AMSTERDAM, an uninhabited island in the Frozen Sea, near the west coast of Spitzbergen. This is also the name of an island in the Indian Sea. S. lat. 38° 42'. E. long. 76° 54'. (for an account of which, see ST. PAUL); and of another in the Chinese Sea, between Japan and the island of Formosa.

AMSTERDAM, NEW, a name originally given by the Dutch to the city of New York, in America. Amsterdam

is also the name of a new township in Montgomery county, New York; containing 235 inhabitants, who are electors.

AMSTOTTEN, a town of Germany, in the arch-duchy of Aultria, eight miles south-west of Ips.

AMTITZ, a feignory of the circle of Guben, in Lufatia, containing the market town of Amtitz, with a citadel, and several villages.

AMTRUSTIO, in *Ancient Charters*, denotes a sworn or liege tenant, or vassal, of the ancient French or German kings.

The word is also written *antruffio*. Spelman derives it from the German *ampt*, *office*, *business*, and the English *trustee*.

AMTSZELL, in *Geography*, a town of Germany, in the circle of Swabia, eight miles east of Ravensburg.

AMU, or AMOL, or AMU-DARIA, called also GIRON, and said to be the *Oxus* and *Badrus* of the ancients, a river of Independent Tartary, in Bucharía, which formerly discharged itself by two channels or mouths into the Caspian sea; but these are become dry, and the stream has been diverted by art into the sea or lake of Aral. In the reign of Cyrus it was the boundary of the Persian monarchy, and some authors have supposed it to be the Araxis of the ancients. Its source is in the mountains of Paropamisus.

AMU. See AMOL.

AMUDA, in *Ancient Geography*, a town of Syria, distinguished in the *Notitia Imperii* from *Anida*; but its situation is not known.

AMUDARSA, a town of Africa Propria, in the territory of Bizacium, mentioned by Antonine, and placed by M. d'Anville north of Septimunia. It was an episcopal see.

AMULET, AMULETUM, formed from *amoliri*, to remove, a kind of external medicament, to be worn about the neck, or other part of the body, for preventing or removing diseases. Such are quills of quicksilver, or arsenic, which some hang on the neck, or wear under the shirt, against the plague, and other contagious diseases; as also the bloodstones worn by others against hæmorrhages; and that worn by the women of the East Indies to bring the *menfes*.

Amulets are also frequently no other than a sort of spells, or charms; consisting of quaint words and characters, supposed to have the virtue of warding off mischief, witchcraft, and disease, and to which credulity and superstition have annexed wonderful properties. Pliny makes frequent mention of them.

Persons of all ages and nations have used them. The materials of which they were formed, the characters inscribed upon them, and the superstitious ceremonies with which they were prepared, were very various. Amongst the ancient Egyptians they were very common, and those denominated abraxas were peculiarly distinguished. The Persians, having observed in Egypt the practice of suspending to the neck small cylinders, adorned with figures and hieroglyphics, adopted a similar custom, and instead of the Egyptian deities, they substituted representations of subjects deduced from their history and theology, and annexed to them hieroglyphical characters, disposed in the form of a prayer, which, in their opinion, gave a secret virtue to these amulets. A similar practice prevailed also among the Etruscans. The Jews confided in their efficacy for driving away diseases, and they are prohibited by the *Mischna*, unless they had been effectual in the cure of at least of three persons. Christians also in former ages had recourse to amulets, made of the wood of the cross, or ribbands with texts of scripture written on them, as preservatives against diseases.

VOL. II.

The Greeks called this kind of remedies *φιλакτηρια*, *phylacteries*; *πειρακτηα*, *periakta*, *αποτελεσματικα*, *περισματικα*, *βεβησια*, and *εγκολπια*. The Latins call them *amulata*, *apprusa*, *pentacula*, &c.

Some think this word derived from *amula*, a small vessel with lustral water in it, anciently carried in the pocket by the Romans, for the sake of purification and expiation. This last opinion appears the more probable, in that some amulets were made in the shape of little vessels, as appears from the testimony of Pliny, who observes, that pieces of amber, cut in form of little vessels, were hung about children's necks for amulets.

Amulets are by some considered as a natural species of *talismanians*. Others rather make talismanians a species of amulets. The *bullæ*, worn by the ancients; the *abraxas* of the Basilidians, &c. were also amulets. See ABRAXAS, ABRACADABRA, and TALISMAN.

The ancients made great use of gems for amulets; the whole East, according to Chifflet, wore a kind of jasper for this purpose.

That species of amulets compounded of poisons, used as preservatives from the plague, are more particularly denominated *zencucha*.

Under amulets, some also include medical or other substances fixed to brutes, or even plants, to preserve them from certain diseases and dangers.

Charms, words, scrolls, magic figures and numbers, make a large class of amulets, to which the Turks are still greatly devoted. Their amulets, called *chaimaili*, are little bits of paper of two or three fingers breadth, rolled up in pieces of silk, containing short prayers or sentences cut out of the Alcoran, with circles and other figures, in which they inscribe the name of Jesus, the figure of the cross, &c. They hang them about their necks, or place them under their arms-pits, or in their bosom near their hearts, and especially when they go to war, as a preservative against the dangers of it.

The pope is supposed to have the virtue of making amulets, which he exercises in the consecration of *Agnus Dei's*.

Amulets are now much fallen from the repute they were anciently in; yet the great Mr. Boyle alleges them as an instance of the ingress of external effluvia into the habit; in order to shew the great porosity of the human body.—He adds, that he is persuaded some of these external medicines do answer: for that he himself, having once been subject to bleed at the nose, and reduced to use several remedies to check it, found the moss of a dead man's skull, though only applied so as to touch the skin till the moss was warm thereby, the most effectual of any. The same Mr. Boyle shews how the effluvia, even of cold amulets, may, in tract of time, pervade the pores of a living animal; by supposing an agreement between the pores of the skin, and the figure of the corpuscles. Bellini has demonstrated the possibility of the thing in his last propositions, *De Febribus*; and the like is done by Dr. Wainwright, Dr. Keill, &c. However, these are principally used at present by empirics, women, and credulous superstitious persons.

AMULET, in a more particular sense, is restrained to such medicines as do not operate by any physical virtue, or to those wherein there is no proportion between the cause and effect.

In this sense medicines, which operate by effluvia, odours, and the like, do not belong to the class of amulets.

In this sense also those essence-vessels worn by hysterical women on their breasts, called by the Greeks *καρδιοφυλακια*,

and by the Latins *domus pectoris*, were not properly amulets.

AMULET is sometimes also applied, in a more extensive sense, to all medicines, whether internal or external, whose virtue or manner of operation is *occult*.

AMULET, in *Cookery*. See OMILET.

AI-ULETICS, in *Medicine*, is used by some writers for what is more frequently called an *amulet*.

Amuletics amount to the same with what are otherwise called *sympathetics*, and have been chiefly used in late times to stop bleeding; such are the *perforaria*, *lapis hematites*, dried toads, &c. also against warts, *farcomae*, &c.

Sir Kenelm Digby's sympathetic powder is one of the principal amuletics in cases of hemorrhages; and with many the *ancora sacra*.

AMUNCLA, in *Ancient Geography*, a town of Africa Propria, situate between the two Syrtis.

AMUND, in *Ancient Writers*, denotes a person free or discharged from tuition or wardship. The word is also written *amund*, *amod*, and *amont*; and is compounded of the privative *a*, and the Saxon *mund*, *defence*, *tuition*.

AMUR, or AMOOR, in *Geography*, a river of Asiatic Russia, or rather of Chinese Tartary, is formed of two rivers, Argoon and Shilka, and first takes this name on their conjunction in the Chinese territory, E. long. 121° 14', and discharges itself into the Pacific ocean, opposite to the island of Sakhalen, E. long. 142° 14'. N. lat. 53°. The Shilka rises in the Yablonnoy mountains, E. long. 109° 14'. N. lat. 49°, being formed of the tributary streams, called Ingoda, Onona, and Nertcha, passes by Nertchinsk, through the Nertchinskoi district, and joins the Argoon. The Argoon has its source in a lake upon the frontier that parts Russia from China, and forms the border all the way to its exit, in the Shilka. By the treaty of 1727 the Amoor belongs entirely to China; otherwise, the ship-building on the sea of Okhotsk would be much facilitated to the Russians, as great part of their materials might then be brought by water, which are now conveyed by land at a great expence.

AMULO, in *Biography*, was born in France, and after having been deacon of the church of Lyons, under Agobard, was on his death raised to the archbishoprick of that see in 841. He condemned the veneration that was paid to relics as an occasion of error and superstition; he also wrote a letter against Goteschaleus, and some other pieces upon Grace, Predestination, and Free-will; and "a book against the Jews," addressed to king Charles, the brother of the emperor Lotharius. Amulo, considering the time in which he lived, and his high rank in the church, was a man of distinguished liberality and moderation; he was much esteemed on account of his talents and eloquence; and shared in an eminent degree the favour of Charles the Bald. He presided in the council of Lyons in 845. His book against the Jews was published in 1656 by Father Chifflet, under the name of Rabanus Maurus. All his works, except this, were published by Baluze, with notes, at the end of his edition of Agobard, whence they were transferred to the Bibliotheca Patrum. Trithemius says, that Amulo was well skilled in the scriptures and ancient writers, very conversant in secular learning, famous for his knowledge of the Hebrew as well as Latin tongue, and of a quick and lively genius. Cave, H. L. tom. ii. p. 29. Mosheim, vol. ii. p. 332.

AMURACORY, in some *Writers of the Middle Age*, denotes a kind of Turkish soldiery belonging to the corps or order of janizaries.

They seem to be the same with those otherwise called *Scraparii* and *Paciliatores*.

AMURATH, or MORAD, I., in *Biography* and *History*, Sultan of the Turks, was the son of Orchan, and the brother of Solyman, and succeeded his father, A. D. 1360. In pursuing the conquests of the Greek empire, he subdued without resistance the whole province of Romania or Thrace, from the Hellespont to mount Hemus, and the verge of the capital, and made choice of Adrianople for the royal seat of his government and religion in Europe. He afterwards marched against the Sclavonian nations, between the Danube and the Adriatic, *viz.* the Bulgarians, Servians, Bosnians, and Albanians, and having vanquished these hardy and warlike tribes, he converted them by a prudent institution into the firmest and most faithful supporters of the Ottoman greatness. Being reminded by his vizir, that, according to the Mahometan law, he was intitled to a fifth part of the spoil and captives, and that the duty might be easily levied, by stationing vigilant officers at Gallipoli to watch the passage, he selected for his use the stoutest and most beautiful of the Christian youth, and educated many thousands of the European captives in religion and arms. This new militia was consecrated and named by a celebrated dervish, who, standing in the front of their ranks, stretched the sleeve of his gown over the head of the foremost soldier, and pronounced his blessing in these words: "Let them be called Janizaries, (*yenghi cheri*, or new soldiers); may their countenance be ever bright! their hand victorious! their sword keen! may their spear always hang over the heads of their enemies! and wherefoever they go, may they return with a white face!" Such was the origin of the JANIZARIES. By the assistance of these troops, Amurath extended his conquests in Europe and Asia; and he succoured the emperor, John Palaeologus, against the Bulgarians. When a rebellion was concerted by the eldest sons of these two sovereigns against their fathers, Amurath punished his own son by depriving him of his sight, and insisted on the same penalty being inflicted on the son of the emperor. After a prolonged course of success, Amurath was opposed by a formidable league of the Walachians, Hungarians, Dalmatians, Triballians, and Arnauts, under the command of Lazarus, prince of Servia. By the battle of Cossova, Lazarus was defeated and taken prisoner, and the league and independence of the Sclavonian tribes were finally crushed. But as the victor walked over the field, viewing the slain, and triumphing in his success, a Servian foldier started from the crowd of dead bodies, and pierced Amurath, at the moment of his exultation, in the belly with a mortal wound. Others have attributed his death to a Croat, who is said to have stabbed him in his tent; and this accident was alleged as an excuse for the unworthy precaution of piioning, as it were between two attendants, an ambassador's arms, when he was introduced to the royal presence. Amurath died in the 71st year of his age, and 30th of his reign, A. D. 1389. His character has been highly extolled by the Turks, and he has been represented as mild in his temper, modest in his apparel, temperate in his mode of living, and a lover of learning and virtue; he was reproached, however, by the Moslems for his absence from public worship, and he was corrected for his negligence by the firmness of the musti, who refused to admit his testimony in a civil cause. The sultan, it is said, proscribed by the reproof, and atoned for his fault by erecting a magnificent mosque at Adrianople. Gen. Dict. Gibbon's Hist. vol. xi. p. 444. &c.

AMURATH, or MORAD, II., succeeded his father Mahomet I., in 1422, at the age of 18 years. His reign commenced

meaced with the capture and death of an impostor, who pretended to be Multapha, the son of Bajazet, and who was supported by the Greek emperor. He then invested Constantinople; but his attention was diverted by the rebellion of Multapha, his younger brother, who was imprisoned and strangled in his presence. In 1424 he restored the discipline of the Janizaries, and reformed the abuses of the Spahis; and in 1426 he laid waste the isle of Zante, belonging to the Venetians. In the next year he invaded and subdued the Morea, and obliged the Grecian emperor to pay him tribute; and having taken Thessalonica, or Saloniki, he compelled the Venetians to make peace. In 1434 he suppressed the rebellion of Karaman-Ogli; and when a war broke out between the Ottoman empire and the king of Hungary, in which the famous Hungarian general, John Huniades, gained several victories, Amurath crossed the Danube, and laid siege to Belgrade, but Huniades obliged him to raise it. He also invaded and subdued Servia, which was restored in the peace between Hungary and Poland; and on this occasion it was stipulated, that neither party should cross the Danube in a hostile manner into the dominions of the other. Amurath, having awed Karaman-Ogli, who was renewing his attacks, into submission, and granted him peace in compliance with the intreaties of his wife, found his dominions in a state of tranquillity; and formed a resolution of abdicating the Turkish throne. Accordingly, in 1445, at the age of 40 years, perceiving the vanity of human greatness, he resigned the empire to his son, Mahomet, and retired to Magnesia, where he joined the society of dervises and hermits, and adopted all their austerities and fanatic rites. If his motives in this extraordinary proceeding had not been debased by an alloy of superstition, we might have extolled his magnanimity. From this dream of enthusiasm, as it may be justly called, he was soon roused by the Hungarian invasion. Ladislaus, the king of Hungary, and his auxiliaries, instigated by Karaman-Ogli, the inveterate foe of the Turkish empire, penetrated into the Mussulman territories, and Amurath, urged by the earnest intreaty of his son, and the wishes of the people, consented to take the command of the army. Advancing by hasty marches from Adrianople, at the head of 60,000 men, he met the Christians at Warna; and on the first onset the Turkish wings were broken; and Amurath perceiving the flight of his squadrons, despaired of his fortune, and that of the empire. During the heat of the engagement, a copy of the treaty of peace between himself and the Hungarian king, was displayed in the front of the ranks, and it is said, that the sultan in his distress, lifting his eyes and hands to heaven, implored the protection of the God of truth, and called on the prophet Jesus himself to avenge the impious mockery of his name and religion. Whilst the battle was in suspense, the young king of Hungary rushed forward in the confidence of victory, till his career was stopped by the impenetrable phalanx of the Janizaries. If we may credit the Ottoman annals, his horse was pierced by the javelin of Amurath; he fell among the spears of the infantry; and a Turkish soldier proclaimed, with a loud voice, "Hungarians, behold the head of your king!" The death of Ladislaus was the signal of a total defeat. Ten thousand Christians were slain in the disastrous battle of Warna; and of the number was cardinal Julian Cæsarini, distinguished by his talents and learning, and by a volatile genius, equally adapted to the school, the camp, and the court. The circumstances of his death are variously related; but it is believed, that a weighty incumbrance of gold impeded his flight, and tempted the cruel avarice of some

Christian fugitives. However, it is allowed, that he fell a just victim to that pernicious casuistry by which he quieted the mind of Ladislaus in the violation of his oath, and absolved him in the pope's name from the guilt of perjury. The loss of the Turks, more considerable in numbers than that of the Christians, bore a smaller proportion to their total strength, and yet Amurath himself was not ashamed to confess, that his ruin must be the consequence of a second and similar victory. This battle happened on the 10th of November, A. D. 1444; and was followed by the retirement of Amurath a second time to the stillness and devotion of private life. In 1445 he was again called forth to public service by an insurrection of the Janizaries, who filled Adrianople with rapine and slaughter. Having quelled this tumult, he turned his arms against the famous Scanderbeg, prince of Epirus, who had revolted; and followed him to Albania, at the head of 60,000 horse and 40,000 Janizaries. The conquests of the sultan were confined to the petty fortrefs of Sfetigrade; and he retired with shame and loss from the walls of Croya, the castle and residence of the Castriots. Amurath, by the alternative of death or the Koran, converted all the Epirots to his own faith. The Hungarians renewed their invasion of the territories near the Danube; and Amurath fell in with them near Cossova, the place where Amurath I. had been victorious. The result of many partial but bloody actions was the route of the Christian forces, and the capture and imprisonment of Huniades, the supreme captain and governor of Hungary, in his retreat. Amurath returned to Adrianople; and having given up all thoughts of resignation, he married his son Mahomet to the daughter of the prince of Elbistan, and appointed him to the government of Asia Minor. By his disappointment at Croya, and the fatigues of his retreat, his last days were not only embittered, but probably shortened; for on his arrival at Adrianople he was seized with a disorder in his head, which terminated his life in the 47th year of his age, and the 29th of his reign. According to Cantemir, the historian of the Othman empire, he lived 49, and reigned 30 years, six months, and eight days. According to this historian, "he was a just and valiant prince, of a great soul, patient of labours, learned, merciful, religious and charitable; a lover and encourager of the studious, and of all who excelled in any art or science; a good emperor, and a great general. No man obtained more or greater victories than Amurath: Belgrade alone withstood his attacks. Under his reign, the soldier was ever victorious; the citizen rich and secure. If he subdued any country, his first care was to build mosques and caravanferas, hospitals, and colleges. Every year he gave a thousand pieces of gold to the sons of the prophet, and sent 2500 to the religious persons of Mecca, Medina, and Jerusalem." It should be considered, however, that cruelty and violence have been sanctioned by zeal in propagating the Mahometan faith; and that, in the hands of the Turks, the scymetar was the only instrument of conversion; after all the abatements that ought to be made in the preceding panegyric, it is generally allowed that the moderation and justice of Amurath have been attested by his conduct. In the vigour of his age and military power, he seldom engaged in war till he was justified by a previous and adequate provocation; when victorious, he was disarmed by submission; and in the observance of treaties, his word was sacred and inviolate. Mod. Univ. Hist. Gibbon's Hist. vol. xii. p. 150, &c.

AMURCA, in *Pharmacy*, a medicine made of the refuse or recement of expressed OLIVES.

Amurca, being boiled in a copper vessel to the consistence

of honey, becomes a drug of some use in medicine, being reputed an astringent and drier; and as such sometimes prescribed in ulcers, as well as against diseases of the teeth, eyes, &c.

Hippocrates applies the term amurea to a crude, immature, putrid state of the liver.

Some authors have also given the name amurea to the juice of fluid found in the *RENES fucenturiati*.

AMUSKEAG FALLS, in *Geography*, are on Merrimack river, in New Hampshire, America, 16 miles below Concord, and seven below Hookset falls. There are three of them, one below the other, so that the water falls about 80 feet in the course of half a mile. In the middle of the upper part of the second fall is a rocky island, in which are found several excavations or pits, by the circular motion of small stones, impelled by the force of the descending water, which are capable of holding several tons of water. A little below the falls is a bridge 556 feet in length, and 20 in breadth, consisting of 2000 tons of timber. N. lat. 42° 59'.

AMUTRIUM, in *Ancient Geography*, a town of Dacia, according to Ptolemy.

AMUY, in *Geography*, a town of India, beyond the Ganges, near the western bank of the lake Chamai, on the confines of the kingdom of Kanduana.

AMWELL, a village of England in the county of Herts, 21 miles north of London, and one south-west of Ware, in which is the spring of the New River, that supplies a considerable part of London with water. This river or canal was projected by Sir Hugh Middleton, in 1606.

AMY, N. in *Biography*, advocate in the parliament of Aix, in France, died in 1760, and is known by some valuable works, in natural science, viz. "Experimental Observations on the Waters of the Seine, Marne, &c." 12mo. 1749; "New Filtrating Fountains." 12mo. 1757. "Reflections on Copper, Lead, and Tin Vessels," 12mo. 1757.

AMY, in *Law*, the person next of kin to an orphan, or infant, who is to be intrusted for him; properly called *PROCHEIN amy*.

The word in French literally signifies *friend*.

AMY, *alien*, is a foreigner here, subject to some prince, in friendship with us.

AMYBUS, in *Ancient Geography*, an island of the Red Sea, supposed to be the same with AMICUS, or *Amici Insula*.

AMYCI CAMPUS, a name given by Polybius to a plain in the midst of which runs the river Orontes, between Libanus and Antilibanus.

AMYCI PORTUS, was situated on the Thracian Bosphorus, north of Nicopolis, and south of Fanum Jovis. It derived its name from Amycus, an ancient king of the Rebrices, who was killed in a combat with Pollux, and on whose tomb was planted a laurel, Gr. *Daphne*, whence the port was called *Daphnis portus*.

AMYCLÆ, a city of Peloponnesus, in Laconia, situate south-west of Sparta, and near it. Although small, it was famous for its fruit-trees, so that it was called by Statius (Theb. ix. v. 769.) "virides Amyclæ." According to Polybius, the temple of Apollo in this place was the most celebrated in Laconia, whence it was denominated by Statius, "Apollinæ Amyclæ;" and it was pretended that Leda, the mother of Castor and Pollux, resided in this place, whence Silius Italicus, (lib. xi. v. 434.), describes it thus:

"Lædis veniens victor Xanthippus Amyclis.

Venus had also a statue in this place, executed by Gitiades. When this part of Laconia was attacked by the Romans, Q. Flaminius encamped near Amyclæ, and ravaged its territory; and the city was afterwards destroyed. In the time of Pausanias, there were some remains of its ancient magnificence.

AMYCLÆ was also a town of Italy, in Upper Calabria, said to have been peopled by a colony from Amyclæ, in Laconia, but its situation has not been ascertained; though it is supposed to have been between Cajeta to the south-east, and Terracina to the north-west. Pliny and Solinus say, that the inhabitants were so infested with serpents, as to be under a necessity of abandoning their dwellings. The Amyclæ were distinguished among the ancient poets by the epithet, "taciti," or silent, as some say, because it was built by the Lacedæmonians, who, having adopted the system of Pythagoras, recommended silence; or, according to others, because a law was enacted in this place, for the purpose of preventing false rumours, by which the people were alarmed, which prohibited any person from reporting the approach of an enemy; but this law was in the end the cause of the ruin of the city; for the Dorians arrived unexpectedly at the walls, and took the city. To this circumstance Silius refers, lib. viii. v. 530:

"—Quaque evertere silentia, Amyclæ.*"

AMYCLÆI, a people of Africa, who, according to Dionysius Periegetes, inhabited Cyrenaica.

AMYCLÆUM, a town and port of the island of Crete, according to Eustathius.

AMYDON, a town of Macedonia, upon the Axius, in Pæonia, mentioned by Steph. Byz.

AMYGDALA, in *Natural History*, a species of ECHINUS, in the class mollusca of worms, so called, because in shape it resembles an almond.

AMYGDALÆ, in *Surgery*, denotes superfluous flesh growing at the root of the tongue.

AMYGDALÆ, in *Anatomy*. See ALMONDS.

AMYGDALATE, an artificial milk, or emulsion, made of blanched almonds, &c.

AMYGDALÆ. See ALMOND.

AMYGDALIS SIMILIS,* in *Botany*. See THEOBROMA.

AMYGDALOID, in *Natural History*. See TOADSTONE.

AMYGDALUS, in *Botany*, a genus of the *icosandria monogynia* (*polyandria monogynia*, Gmelin,) class and order, of the natural order of *pomaceæ* and *rosaceæ* of Jussieu; its characters are, that the *calyx* is a perianthium, one-leaved, tubulous, inferior, quinquefid, deciduous, divisions spreading and obtuse; the *corolla* of five petals, oblong-ovate, obtuse, concave, inserted into the calyx; the *filamina* have filaments about 30, filiform erect, shorter by half than the corolla, inserted into the calyx, anthers simple; the *pyllium* has a roundish, villose germ, simple style, of the length of the stamens, and headed stigma; the *pericarpium* is a roundish, villose, large drupe, with a longitudinal furrow; the *seed* is a nut, ovate, compressed, acute, with prominent sutures on each side, reticulated with furrows, and dotted with small holes. Obs. the nut of the almond is covered with a dry skin; that of the peach with a small pulp. There are seven species. 1. *A. persica*, with all the serratures of the leaves acute, and the flowers sessile and solitary. There are two varieties, viz. the *peach-tree*, with downy fruit, and the

nectarine,

AMYGDALUS.

nectarine, with smooth fruit. For a particular account of both these, their varieties, and different qualities, and the method of their culture and propagation, See *AMYGDALUS*, in *Gardening, infra*. 2. *A. communis*, the almond tree, with the lower serratures of the leaves glandulous, and the flowers sessile and in couplets. Some reckon three varieties, *viz.* *α.* *A. sylvestris*, the common or wild almond; *β.* *fativa*, sweet or Jordan almond; and *γ.* *A. amara*, bitter almond. Miller makes three species of the almond, *viz.* 1. *A. communis*, or common *A.* cultivated more for the beauty of its flowers, than for its fruit; of which there are two varieties, one with sweet, the other with bitter kernels, which often arise from the fruit of the same tree. 2. *A. dulcis* or Jordan *A.* the nuts of which are frequently brought to England; these have a tender shell, and a large sweet kernel. The leaves are broader, shorter, and grow much closer than those of the common sort, and their edges are crenate. The flowers are very small and of a pale colour, inclining to white. These trees have been often raised from the almonds which came from abroad, and the plants have been found to maintain their difference from the common almond. 3. *A. fativa*, with narrow sharp pointed leaves, flowers much smaller than those of the common almond, and white; the shoots of the tree smaller and joints closer than those of the common sort; and the tree is less hardy, and should therefore have the advantage of a warm situation, otherwise it will not thrive. This sort flowers in the Spring, and rarely produces fruit in England. From an old tree, placed against a wall, with a south aspect, the fruits have some years been ripe, and well flavoured, but their kernels have been small.

Duhamel gives seven species and varieties of the almonds, *viz.* 1. Common *A.* with a small fruit. 2. Sweet *A.* with a tender shell. 3. Bitter *A.* with a tender shell; a variety of the preceding. 4. *A.* with a small fruit, and a tender kernel: *Amande-sultane*,—and, with a still smaller fruit, *amande-pistache*. 5. Sweet *A.* with a large fruit. 6. Bitter *A.* with a large fruit, a variety of the preceding. 7. Bitter *A.* probably a variety of the first. He also mentions another, which he calls *amandier-pecher*, and supposes to have been produced from the impregnation of the almond, by the farina of the peach.

The common almond has leaves which resemble those of the peach, but the lower serratures are glandular; they proceed from buds both above and below the flowers, and not as in the peach, from the ends of the shoots above and not below the flowers. The form of the flowers is not very different, but they usually come out in pairs, and vary more in their colour from the fine blush of the apple-blossom to a snowy whiteness. The chief obvious distinction is in the fruit, which is flatter, with a coriaceous covering, instead of the rich pulp of the peach and nectarine, opening spontaneously when the kernel is ripe. The shell is not so hard as in the first species, and is sometimes tender and very brittle; it is flatter, smoother, and the furrows or holes are more superficial. This tree is a great object in some parts of Italy, and in the south of France, and there are large plantations of it in Provence and Dauphiné. It is common in China, and most of the Eastern countries; and also in Barbary, where it is a native. In the time of Cato it seems not to have been cultivated in Italy; for he calls the fruit *nuces graeca*, or Greek nuts. With us it is valuable as an ornamental tree in clumps, shrubberies, &c. within view of the mansion; for it displays its delicate red-purple bloom in the month of March, when few other trees have either leaves or flowers. An almond-tree, covered with its beautiful

blossoms, is one of the most elegant objects in nature. In a forward Spring, they often appear in February; but in this case, the frost generally destroys them, and they bear little or no fruit; but when they flower in March, they seldom fail to bear plenty of fruit, very sweet, and fit for the table when green, but they will not keep long.

3. *A. pumila*, *perfica africana nana*, &c. of Herm. lugdb. *A. perfica nana*, &c. of Pluk. phyt. *perfica amygdalus* of Miller, double-flowered dwarf-almond, with leaves veined-wrinkled, or leaves lanceolated and double serrated, Willd. The branches are smooth, two or three feet high, and dark-purple; the flowers are generally two in a bud and sessile; the calyx reddish; the petals emarginate (acuminate, Reichard), red, longer than the tube of the calyx; filaments paler; germ and style pubescent at bottom; stipules linear and very deeply serrate; varies with double flowers; and its native country is Africa. These shrubs make an agreeable variety amongst low flowering trees, in small wilderness quarters; the single sort flowering in the beginning of April, and the double commonly three weeks later. It was cultivated by Miller in 1731. 4. *A. nana*, *A. indica nana* of Pluk. and Miller, *prunus inermis*. &c. of Gmelin, *Sibir, armeniaca perficæ solis*, &c. of Amm. Ruth. common dwarf almond, with leaves attenuated at the base. The leaves are lanceolated, subpetiolated, scattered, somewhat rigid, smooth, the serratures very sharp and somewhat spinose; the stipules linear, long and deciduous; the flowers very abundant on the twigs, appearing with the first leaves from all the buds; the calyx subsessile and reddish; segments acute, green, and very finely serrulate; petals of a fine rose-colour: stamens about 20, the inner ones gradually shorter; pistil very villose; fruit usually solitary, sessile, somewhat compressed, very hirsute, with a harsh yellowish wool, the size of a hazel nut, which is of a sharp ovate form, yellowish-grey colour, and grooved at the sutures; the kernel resembles that of the peach and colour in taste; but the trunk seldom an inch in thickness. It varies much in size; on the banks of the Volga, it is annually set on fire, and never rises to any height, but is low and shrubby, creeping very much at the root, and obstructing the plough. In Cherson it scarcely attains a span in height, but in the Ukraine it grows a fathom high, as it does in gardens, where the leaves are broader, and sometimes five inches long. It blooms in April, when all the young shoots are covered with flowers of a peach-blossom colour, and makes a fine appearance among shrubs of the same growth. It is a native of the northern parts of Asia, abounds in Calmuc Tartary, and is very common on the banks of the Volga; cultivated in Kew garden by Mr. Sutherland, in 1683. See *AMYGDALUS infra*. 5. *A. incana*, hoary dwarf *A.* with leaves lanceolate, serrate, wrinkled, subsessile, white tomentose beneath. It may be doubted whether this be not a variety of the preceding species. 6. *A. orientalis*, *A. argentea* of La Marck, silvery-leaved *A.* with leaves lanceolate, quite entire, silvery, perennial, and petiole shorter. The flowers are small, and are not succeeded by fruit in England. It was found growing near Aleppo, whence the fruit was sent to the duke d'Ayen, in France, who raised several plants in his garden at St. Germain's, and sent some to Mr. Miller, who cultivated them at Chelsea, in 1759. It is a native of the Levant. 7. *A. cochinchinensis*, with leaves ovate, quite entire, and racemes, small, and subterminal. This is a large tree, with spreading branches, acuminate, waved, shining, and alternate leaves, white corolla, drupe about half an inch in diameter, and kernel like the common almond, in form.

AMYGDALUS.

form and fruct; a native of the vast woods of Cochinchina. In the culture and propagation of almonds, see *AMYGDALUS* in *Gardening, infra*.

For the diætic and medicinal properties and uses of Almonds, see *ALMONDS*.

AMYGDALUS Æthiopia. See *BRABEUM*.

AMYGDALUS Indica. See *TERMINALIA*.

AMYGDALUS, in *Gardening*, is applied to the *almond, peach, and nectarine trees*; the class, order, and genuine characters, as well as the different species of which, have been given above. In order to render their culture and modes of propagation as clear and intelligible as possible, it may be proper to consider each of them separately.

1st. *Amygdalus, almond-tree.* This sort of tree is cultivated both for the advantage of the fruit, and as being highly ornamental in shrubberies, plantations, and other descriptions of pleasure ground, from its coming into bloom early in the Spring. It is, however, less important in the former than the latter point of view, as the fruit is often liable to miscarry in this climate. All the species and varieties of this tree are deciduous, and of a hardy nature, thriving well in most common garden soils. Those of the tree kind frequently rise to fifteen or twenty feet in height, dividing in many spreading branches, which ultimately form beautiful heads, that are generally well adorned in the beginning of March with innumerable flowers, which continue in full bloom for a fortnight or three weeks, and are followed by the leaves, which are long and narrow, and the fruit takes its growth. This is downy, rather large, and of an oval form, consisting of a thick, tough, leathery substance that embraces an oblong nut or stone, in which the kernel or almond is inclosed, which is the only part of the fruit that is capable of being made use of.

The dwarf shrubby sorts of this tree do not, however, in general, exceed three or four feet in height, having slender stems, which send forth a great number of small branches near to the ground; and in the single-flowered kind various suckers are frequently sent up from the root. And in both the double and single flowered almond tree, all the young branches are thickly beset with flowers in the Spring, which, from their having a fine pale red colour, and continuing some time in blow, are highly ornamental. The single sort have their flowers coming out about the end of March, and the double kind in the beginning of April, each remaining about a fortnight in blow.

The sorts chiefly cultivated for use in this country, are, according to Mr. Forsyth, the *tender-shelled almond*, the *sweet almond*, the *common or bitter almond*, the *sweet Jordan almond*, and the *hard shelled almond*. Those propagated only for ornament are the *dwarf* and the *double-flowering almonds*.

Methods of Propagation, &c.—These are either by budding them upon plum, almond, or peach stocks, or by sowing the stones of the fruit. It is observed in the “*Universal Gardener*,” that in the first way they much sooner form full and regular heads, and attain the state of flowering and producing fruit; and that if it be intended to continue the *sweet-kernelled*, or any other particular sort, it can only be effected with certainty by inoculation, as when raised from seed they are apt to vary, all the varieties often proceeding from the fruit of the same tree. This operation is generally performed about July or August, and may be done either for dwarfs, half, or full standards. Mr. Forsyth remarks, that the Spring after being budded they may be trained for standards, or let grow for half-standards; but that the most common method is to bud them at such a height as the stem is designed to be; and the second year afterwards to plant

them out for good. If they are to be transplanted into a dry soil, it is recommended to be done in October, when the leaves begin to decay; but if into wet ground, in the month of February. Such as are budded on plum stocks are found to grow the best in wet soils, and those on almond and peach stocks in dry ones.

In raising trees of this kind from the stones, it is best to plant them in the early Autumn or Spring months, as October and November, or February and March, being careful to chuse those of the last Summer's growth, drilling them in, in a bed of good light ground, two or three inches in depth. The plants appear in the Spring, and in the Autumn or Spring following, may be transplanted into the nursery, and put in rows for the purpose of being trained for standards, half-standards, or dwarfs, according to the intention of the planter.

When it is intended to bud any of them with peaches or almonds, they will some of them be in a proper state for the operation; for dwarfs the first, and all of them the second Summer after transplanting; but for standards, in order to be trained with proper stems, they should constantly have three years growth.

The dwarf sorts, besides being propagated by budding upon plum or almond stocks, may be easily raised by suckers from the roots, and by layers. The common method in pruning trees of this sort is, in the Spring, to shorten the first shoot from the bud to four or five eyes, in order that the trees may put forth lateral shoots in proper quantity, so as to form regular full heads. But it is advised by Mr. Forsyth, that when the young trees are brought from the nursery, they should never be cut till the young shoots begin to break. And, that, as after wet Autumns, when the wood is not well ripened, hard Winters are apt to kill the shoots, they should in such cases be cut down to the sound wood, care being taken to prune out all such cross shoots as rub against others, leaving the tree open in the middle, cutting the shoots about the same length as for apricots, and in proportion to their strength. The canker parts and decayed wood must always be wholly cut out and removed.

Whether made use of as standards or half-standards, it is recommended that they be planted in sheltered situations, which have a southern aspect. In some cases it may be necessary to protect them by some sort of light covering, against the injury that may be expected from the frosts in February and March. Trees of this sort are also sometimes planted against walls and on espaliers.

The fruit of the almond-tree, after being properly dried, may be preserved in either bran or sand.

2d. *Amygdalus-Perfica*, or *peach-tree*. Its native country is not known. It came to the Romans from Persia, as its Latin name, *Malus Perfica*, indicates; and it has been cultivated from time immemorial in most parts of Asia; it has been adopted by almost every nation of Europe, and now flourishes abundantly in America, where it has been introduced by the Europeans. Of this tree we have only one distinct species, but there are a great many varieties, and by producing them from the seed or kernel, they may be almost indefinitely increased. But though they are capable of being greatly augmented in this manner, it is probable that but very few possess the necessary qualities, as nurserymen seldom cultivate more than twenty or thirty sorts. As in the cultivation of this sort of tree much expence is constantly required in walls or other suitable buildings, none but such as produce fine fruit should be attended to.

This sort of trees will grow to a considerable height as standards, but in order to produce and ripen fruit, requires the shelter of warm walls. They flower early in the Spring

in common, the flowers appearing before the leaves, mostly on the shoots of the preceding year, and either singly or in pairs along their sides. They are formed each of five small petals, with many stamina in the middle, and a small round germen that becomes the peach.

The fruit is distinguished into two sorts, the *peach* and *prive*, from the circumstances of the flesh or pulp quitting or adhering to the stone, as in the former it easily separates, while in the latter it adheres firmly.

There are various sorts of peaches that may be cultivated, but for small gardens Mr. Forsyth recommends the following as the most suitable; the *early avant*, *small mignonne*, the *Anne peach*, *royal George*, *royal Kensington*, *nobleffe*, *early Newington*, *Gallant*, *early purple*, *chancellor*, *nivette*, the *Catharine*, the *late Newington*.

Against north and east walls he thinks the *early avant*, *early Anne*, *early Mignonne*, *royal George*, *red Magdalen*, *royal Kensington*, *nobleffe*, *gros mignonne*, and *Millet's mignonne* are by much the best. In this method a regular succession of fine peaches, may, it is conceived, be procured until the late sorts against the south and west walls come in. But late sorts should never be planted on a north or east wall.

Methods of Culture and Propagation.—It is observed by Mr. Forsyth, that peaches require a lighter soil than either pears or plums, and that a light, mellow loam is the most proper for them. Where the natural soil is a strong brick mould, inclining to clay, it will be necessary to take some of it away in first preparing the borders for the trees, in order to be mixed with some light mould, sand, or old lime rubbish. And in making them up, where the trees are to be planted, the earth should be taken out to the depth of three feet, and the breadth of four, and the rest worked well together with rotten leaves or street dung, and the above mixture, throwing them up as soon as convenient into rough ridges, to be exposed to the action of the frost, and the influence of the atmosphere.

The borders, when it is intended to plant these trees against walls, should never be narrower than three or four feet, and when made six or seven feet, they are more proper. The most advantageous aspects for trees of this description, are those which have the most command of the south sun, but on an eastern or western aspect, they sometimes answer tolerably well.

Where the soil is wet, drains laid deep are recommended by Mr. Forsyth to be made across the borders, to draw the water from the roots of the trees. These may be filled with old bricks or stones at bottom, and above with gravel, having the depth of two feet of good mould upon the latter. And when water is retained after rains from the stiffness of the ground, the borders should be formed with suitable slopes for the same purpose.

If the soil be a four, moist clay, he advises brick-bats to be thrown into the bottoms of the borders, and to be covered with lime rubbish, or the core from the screenings of lime; which should be then watered, and, when nearly dry, well rammed to form a solid surface, and prevent the roots of the trees from penetrating the wet earth below, as well as to assist in taking off the water.

When water is permitted to stagnate near the roots of tender trees, in strong land, it is remarked, that it is certain to bring on the mildew, and thereby totally spoil them. They may, however, in some instances, be recovered by moving them to another aspect. All the French peaches, it is observed, are extremely liable to this disease on lands of the strong adhesive kind.

The propagation of peach-trees is accomplished either by

setting the seed, or by budding upon plum-stocks. The fine varieties of this fruit have been mostly obtained in the first method, though it is tedious, and often attended with but little success, from the great tendency to deviate from the nature of the variety from which the seed was taken.

The manner of proceeding in this way is to sow or set the seeds, in beds of good mould, in small drills two or three inches deep, about October or November; or where this cannot be done, to preserve them in sand till February. They will be up in the Spring following; and after one or two Summers' growth, according to circumstances, they will be fit to be transplanted into the nursery, which should be done in rows, either in the Autumn or Spring months. After having remained about twelve months in this situation, some of them may be taken out, and planted against a paling or other proper fence, in order to be trained.

But the most certain method of propagation for preserving the variety, according to the authors of the "Universal Gardener," is that of budding, as by this means peach-trees are produced that afford fruit in size, colour, and taste, exactly similar to that of the tree from which the bud was taken. Beside, in this way, the trees become much sooner in a bearing state. Though peaches may be budded on different sorts of stocks as those of their own kind, the almond, the apricot, and the plum, yet the plum is always to be preferred for the purpose, as being more hardy and suitable for continuing the trees in a prosperous and full bearing condition. It is also more adapted to grow well in different kinds of soil. The muscle plum-stock is by much the best, where it can be procured.

Stocks for this use may be raised from the different varieties of plums, as well as from peaches, almonds, and apricots, by sowing the seed or stones in the manner that has been already described. The true muscle-plum cannot, however, be produced with certainty in this way, as it is liable to great variety when raised by seed. The only mode of procuring it with certainty is by layers in the Autumn, or suckers from peach or other trees that are known to have been worked upon that sort of plum-stock. These are to be collected in October or November, or in the early Spring months, such being chosen as are about the size of the little finger; the knots of old wood adhering to the roots, and the side branches being then trimmed off, they are to be planted in rows two feet and a half distant, and the following Summer some of them will be ready to bud for dwarfs. For forming dwarfs, the most proper sized stocks for budding upon are those from half an inch to an inch in thickness; but for half or full standards the stocks should be allowed to stand till the stems are an inch thick at the bottom, and four or five feet in height. See STOCK.

The best season for budding them is August, though some gardeners perform the operation in June or July; but when budded too early the buds are liable to shoot weakly the same season, and to be so greatly injured by the Winter, as to make but little progress. See BUDDING and INOCULATION.

As it is mostly necessary that trees of this kind are trained against some sort of fence, they should be principally budded so as to form dwarfs, that their branches may come out low. Where the fences are high, they may, however, be budded for half or full-standards, and trained accordingly. In performing this business, care should constantly be taken that only one bud be inserted into each stock, the head of which should remain perfect until the Spring; when about March the whole of the heads should be cut over, in a sloping direction, just above the places where the buds were inserted. Shortly after this the buds mostly shoot out, producing each a strong

ereft shoot, which by Autumn has generally attained a confiderable height, and the tree, have obtained their firft ftate of formation. They fhould, therefore, in the early Autumn or Spring months, as October and November, or February and March, be tranfplanted either againft fuitable walls, where they may remain, or againft fome fence, merely with the view of being properly trained before they are finally planted out into their intended fituations; but in either cafe, in the Spring, they muft have the firft fhoot from budding head'd down to a few buds or eyes, in order that a proper fupply of lateral fhoots may be produced below. In two or three years they are generally in a ftate to bear fruit. See HEADING DOWN TREES.

Planting the Trees.—In chufing this fort of tree, Mr. Forfyth well obferves, that fuch plants fhould be preferred as have the ftrongeft and cleaneft ftems; and if fuch as have been headed down, and are of two or three years growth, they will bear and fill the walls much fooner than thofe that have not been managed in this way. Where they have only one ftem they are better than with two, as, in the latter cafe, one of them muft be cut off; for, if planted with both, the middle of the tree would be left naked, and a large portion of the wall remain uncovered. He is aware that it is frequently the practice to chufe the trees with the fmalleft ftems; but, he thinks, they always afford weaker fhoots than the others.

The feafons of planting are either the Autumn or the Spring. In dry, warm foils, October or November, as foon as the leaves begin to fall, may be the belt periods for this bufinefs; but in very moift or wet foils the Spring months, as February and March, are to be preferred.

In whatever feafon the work is done, if the borders be new, the ground fhould be well trenched before the trees are planted; and where they are to fupply the places of fuch as have been removed, or where the trees have died, the whole of the old roots fhould be carefully removed, and freft mould put into the place where the old tree was removed from; the new earth being raifed fufficiently above the old, as where this is not the cafe, the trees are frequently injured by being planted too deep. Where they are not kept at firft above the level of the old ground, Mr. Forfyth fays, they feldom thrive well. After the trees have been planted, the roots fhould be well watered in order to fettle the mould round them, letting it remain in that ftate for feveral days till the whole of the water has been taken up. The earth is then to be well trodden round them, and the holes filled up to the top. The freft planted trees fhould remain without being pruned until the Spring when planted in the Autumn. The authors of the “*Univerfal Gardener*,” however, advife, that trees of this fort, as well as moft others that are defigned for walls, be planted out into their permanent fituations, when they are only of one year's growth from the bud, and with their heads entire, as in this way they may be more perfectly pruned and trained the two firft years, which are the chief points in forming good wall-trees. Where walls are to be immediately covered, trained trees from the nurfery muft, however, be procured, and of fuch fizes as may be the moft fuitable to the views of the planter. The proper diftance of planting peach trees is about fifteen feet from each other. Where the walls are high, half or full ftandards may fometimes be planted between the dwarfs to fill up the upper parts, until the dwarfs grow up fo as to cover them. The general rule is, where the walls are not more than fix or eight feet high, to plant none but dwarf trees at the diftance mentioned above; but when they are nine feet in height, half ftandards of three or four feet

ftem may be put betwixt; and when the walls are ten or twelve, full-ftandards of five or fix feet ftem may be had recourfe to, in order to cover the top parts; the lower branches of the ftandard trees being annually removed, as the branches of the dwarf trees advance, and the trees themfelves at laft wholly taken away, to admit the dwarfs to fpread over the whole fpace.

In removing the trees from the nurfery great care fhould always be taken to preferve their roots as much as poffible, and that fuch parts as are bruifed be cut away. The long fmall roots may alfo be a little fhortened. The trees are then to be planted three or four inches from the wall, with the buds outwards, and the heads inclining to the fence, to which they fhould be immediately tacked, in order to prevent the winds from injuring them. When the enfuing Spring proves dry, they fhould be moderately watered once or twice a week, according to circumftances. See PLANTING OF FRUIT-TREES.

When planted with their heads entire, they fhould be headed down about March, when they juft begin to bud. This is done by fhortening the firft main fhoot within a few eyes of the bud, in a floping direction next the wall, as before directed. This muft be done to all the trees that are to be planted againft fences, whether dwarfs, half, or full-ftandards; as by ftopping their upward direction, it induces them to fend out lateral fhoots near the parts where they are budded from, which, by proper training, are formed into good trees. Where this operation is then omitted they run up, leaving the ftem naked to fome height. The next thing is to attend to the fhoots that are made from the few eyes that were left, rubbing fuch off clofe, as come out *fore-right*, either from the front or back of the branches, only retaining thofe that are fent off laterally, which, about June, when of fufficient length to be laid in, ought to be nailed well to the fence, keeping them to it, without being fhortened during the Summer.

About November, when the leaves have fallen, or in the March following, they fhould have their firft Winter pruning. This is to be performed according to the number of fhoots that have been produced from the heading down. If there fhould be two fhoots, one on each fide, both of them may be retained, being fhortened to eight, ten, or more inches, in proportion to their ftrength, to promote a further fupply of wood, nailing them horizontally to the fence. When there are three fhoots, the middle one, if not regularly placed, or of too ftiong growth, fhould be cut out clofe to its origin, the others being fhortened and nailed as above; but when of a moderate growth, and regularly placed, it fhould be fhortened and nailed in an upright direction. When there are four fhoots, they muft be fhortened as above, and trained regularly two on each fide; the principle to be chiefly attended to at this period of their growth, being that of keeping the fhoots of as equal a ftrength as poffible, and of equal number and regularity on each fide; which is belt accomplifhed by leaving only two or four good branches, to be trained with exactnefs both to the right and left, as thefe will fupply others to cover the fence in an upward direction. See WALL-TREES.

In the fecond year's pruning, during the Summer, all the fhoots that proceed from the upper or under fides of the horizontal branches of the former year, are to be retained entire and trained, the whole of the *fore-right* fhoots arifing from both the front and backs being carefully rubbed off as ufelefs, referving all fuch as are regular to be trained in at full length, as in Summer the fhoots fhould, but in few inftances, be fhortened.

The second Winter pruning may be performed about the same periods as the first, in which the branches are to be shortened as directed above, and kept in as much regularity and uniformity as possible, both in number and size, by removing such shoots as are weak. By constantly keeping the lowest branches the most extended, where there are five, six, or eight branches on a side, and these trained at the distance of four, five, or six inches from each other, very handsome trees will be formed, from which some fruit may be expected in the summer following.

The trees being by these means brought to the proper form for bearing, they are to be preserved and kept in order by proper Summer and Winter pruning. It may be observed, that both the peach and nectarine trees constantly produce their fruit on the former year's shoots, or the shoots that are formed each Summer bear fruit the next; and that the same shoots seldom bear more than once, except sometimes, on very short casual lateral spurs; nor farther do the same shoots, after the first year, furnish a regular supply of successional bearing wood; it is most generally afforded by the year old shoots. Hence the great object in pruning is to procure an annual succession of young wood, in every part of the tree. This is principally effected by the shortening of each year's branches in the Winter prunings, as by this means they are made to afford both a supply of bearing wood and a crop of fruit.

The manner of pruning and training, so as to render these trees regular and uniform in their shape and appearance at first, has been already explained.

But the general Summer prunings chiefly consist in reforming the irregularity of the numerous shoots then produced, and training, to the wall at full length, in every part, an abundant supply of all the regularly placed ones as successional wood for the next year's bearing; and the general Winter prunings are intended to reform generally the branches and shoots of all ages, sizes, and situations, so as to render the trees healthy, beautiful, and productive. The times of performing these different prunings have been mentioned above. See PRUNING OF FRUIT-TREES.

After the trees have been pruned they should be immediately nailed to the fences, and the best method is to nail them as the pruning advances, that is, as soon as a tree is pruned to secure the branches by nails, before another is begun. In performing the operation care is to be taken that the branches be laid with order and regularity in a horizontal direction, having their extremities but very little higher than their bottoms, where there is sufficient room between the trees. And in other cases the degrees of obliquity should be as little as the nature of the situations will admit. Where more wood has been left than can be laid in, it must either be cut out altogether or down to an eye, for the purpose of a shoot the next year. See NAILING OF FRUIT-TREES.

Peach trees are very liable to be affected with the blight, a disease in which the leaves are shrivelled, or curled up, and considerably thickened. This arises from insects and other causes, and is to be remedied by removing the leaves that are most diseased, and washing the trees in hot weather well with water, by means of a garden engine, afterwards letting them be well fumigated with tobacco smoke, or sprinkled over with the powder of it. See FUMIGATION, and DISEASES OF FRUIT-TREES.

As these trees come into blossom early, it frequently becomes necessary to protect them from the effects of the frosts, in order to secure the fruit. For this purpose various means have been attempted, but those that seem the most effectual are either thin light mats nailed over them, or a strong open canvass. These should be nailed up in the

evenings, and removed during the sunny part of the day. Or in severe weather they may be kept on the whole day.

From the fruit of these trees setting too thick, or in clusters, it often becomes necessary to thin them, which should always be done according to the vigour and strength of the tree, and the size of the fruit. Where the trees are strong, and the fruit small, they may be left thicker than where they are weak and the fruit large. In each case the largest, fairest, and those that are best placed should be left; and where the leaves cover the fruit too much, they should also be thinned away, by being pinched off. Trees of this kind, from the period of their being headed down, to their sixth or seventh year, may be considered in the state of training, though in their second or third they will generally begin to bear fruit. When properly managed they are also much more durable than is commonly supposed, as they will continue thirty or forty years. It is likewise of much utility in the culture of peach trees, to dig a little dung occasionally into the borders in which they are situated, and to permit none but the smaller kind of garden plants to be grown about them.

Peach and nectarine trees are often cultivated in *houses*, *frames*, and *hot walls*, in order to obtain their fruit early. For these purposes the early sorts should always be procured. See PEACH HOUSE, FORCING FRAMES, and HOT WALLS.

The *double blossomed* and *dwarf peach trees* are mostly planted out in shrubberies and pleasure grounds, as beautiful or ornamental trees; the latter sometimes in pots, as being curious.

3. *Amygdalus Nuciperfica*, or the *Nectarine Tree*. This is now generally considered as a variety of the peach, but the two trees cannot by any circumstances in their growth, wood, leaves, or flowers, be distinguished from each other with any degree of certainty. The fruits are, however, readily discriminated in all their different stages of growth, that of the nectarine having a smooth, firm cuticle, or rind, while in the peach it is covered with a soft downy substance. Besides, the pulp or flesh of the former is much more firm than that of the latter.

There are many varieties of the nectarine that may be cultivated; but those that chiefly deserve attention are the *Fairchild's*, the *violet*, the *Elrouge*, the *Newington*, the *Roman*, the *Temple*, and the *Virmasls*. The white nectarine may also be cultivated both for the goodness of its fruit, and as being a curious variety.

The culture and management of this tree is, in every circumstance, the same as that of the peach. It also requires the same sort of soil and situation. See AMYGDALUS *Perfica*.

AMYLACEOUS, formed from "Amylum, starch;" a term applied to the fine flower of farinaceous seeds, in which consists their nutritive part.

AMYLON, in *Ancient Writers*, a kind of aliment answering, as some apprehend, to our firmity.

The word is Greek, *αμυλον*, thus called, because made *fine mola*.

AMYLUM. See STARCH.

AMYNTA, in *Literary History*, a beautiful pastoral comedy, composed by Tasso; the model of all dramatic pieces, wherein shepherds are actors. The *Pastor Fido*, and *Filli di Sciro*, are only copies of this excellent piece.

AMYNTÆ, in *Ancient Geography*, a people of Thesprotis. Steph. Byz.

AMYNTAS, in *Entomology*, a species of HESPERIA in the Fabrician system, with tailed wings: above blue, margin black; beneath cinereous with black points. Two ferruginous spots at the anal angle of the posterior wings. This is

a small insect, and inhabits Austria. Fabricius.—This is the *PAPILIO TIRESIAS* of Esper.

AMYNTICA *emphyltra*, in *Pharmacy*, defensive, or strengthening plasters.

AMYNTOR, properly denotes a person who defends or vindicates a cause. The word is *αμυντορ*, formed of the verb *αμυνω*, *I defend or avenge*.

In this sense Mr. Toland entitles his defence of Milton's life, *Amyntor*, as being a vindication of that work against Mr. Blackhall, and others, who had charged him with questioning the authority of some of the books of the New Testament, and declaring his doubts that several pieces under the name of Christ and his Apostles, received now by the whole Christian church, were supposititious.

AMYNTOR, in *Entomology*, a species of *HESPERIA*. Wings indented, tailed, black: a fulvous spot at the base, and yellow stripe at the tip. The wings are entirely black above, except the fulvous spots and yellow stripes: beneath yellow, with an arched black band; posterior end of the lower wings black with white dots. A native of India. Fabricius.

AMYOT, JAMES, in *Biography*, was born at Melun in 1514, and rose from an obscure original to the high station of bishop of Auxerre, and great almoner of France. At the age of ten years he fled, for fear of chastisement, from the house of his father, who, as some say, was a currier; but according to Thuanus and others, a butcher; and being taken ill on the road, he was removed to the hospital at Orleans, where he was not only restored to health but charitably furnished with 16*l.* for defraying the expence of his journey home. This relief was requited, on his subsequent prosperity, by a legacy of 1200 crowns to the hospital. He was afterwards a diligent student in the university of Paris, where he was maintained either by the industry of his parents or the charity of a lady, whose sons he attended at college; and at the age of 19 he attained the degree of Master of Arts. In 1537 he left Paris and accompanied the abbot of St. Ambrose to Bourges; and being recommended as preceptor to the children of William Bouchetel, secretary of state, he was thus introduced to the patronage of the princess Margaret, sister of Francis I. who obtained for him the chair of public lecturer in Greek and Latin at the university of Bourges, where, for ten years, he read two lectures a day, one in Greek and the other in Latin. Here he translated the ancient Greek romance of Heliodorus, intitled, his "Ethiopic History, or the Loves of Theagenes and Charicles," which performance was much admired, and procured for him the abbey of Bellofana. At Venice, whither Amyot went in pursuit of preferment, after the death of Francis I. he was employed on a commission to the council of Trent, and having executed it with honour, he spent two years at Rome, prosecuting his studies, and ingratiating himself with those who were likely to serve him. By Cardinal de Tournon he was recommended to the king of France, and undertook the charge of educating his two sons in 1558. When the eldest of these pupils succeeded his father, under the name of Charles IX. in 1560, he immediately upon his accession to the throne, advanced Amyot to the dignity of great almoner, appointed him curator of the university of Paris, and conferred on him the honours and emoluments of the abbey of St. Corneille, and the bishopric of Auxerre. When the younger of his pupils, Henry III. came to the crown, Amyot was continued in his other offices, and in 1578 appointed master of the order of the Holy Ghost, then instituted. During the commotions and civil war which ensued, he remained in his diocese, and closed his life in 1593, in the 79th year of his age. In

proof of the avarice, with which Amyot has been accused, and which enabled him to amass 200,000 crowns, it is alleged, that, when he was soliciting from Charles IX. another benefice, in addition to the lucrative dignities which he possessed, the king said to him, "How now, master? you told me, if you had 1000 crowns a year, you would be satisfied: I believe you have that and more."—"True, sire," replied the bishop; "but appetite comes by eating." Of the learning of Amyot we have ample evidence in his translation of Heliodorus, and also of Plutarch's Lives, which is still held in high estimation in France; the best edition is that of Vacossan, printed in 1567 and 1574, in 13 volumes, 8vo.; and Racine says of it, that this old translation possesses a grace not to be equalled in modern language. As an apology for not complying with the request of those who wished him to write a history of France, he humorously urged, "that he loved his masters too well to write their lives." Amyot translated seven books of Diodorus Siculus, some Greek tragedies, and the pastoral of Daphnis, of which a beautiful edition, with plates, in 8vo. was published in 1718. His miscellaneous works were printed in 8vo. at Lyons, in 1611. Gen. Dict.

AMYRALDISM, in *Ecclesiastical History*, a name given by some writers to the doctrine of universal grace, as explained and asserted by Amyraldus, or Moses Amyraut, and his followers, among the reformed in France, towards the middle of the seventeenth century.

This doctrine principally consisted of the following particulars, *viz.* that God *desires* the happiness of all men, and none are excluded by a divine decree; that none can obtain salvation without faith in Christ; that God refuses to none the *power of believing*, though he does not grant to *all* his assistance, that they may improve this power to saving purposes; and that many perish through their own fault. Those who embraced this doctrine were called UNIVERSALISTS, though, it is evident, they rendered grace universal in words, but *partial* in reality, and are chargeable with greater inconsistencies than the SUPRALAPSARIANS.

Amyraldism is said to have been a system formed with a view of producing a reconciliation with the Lutherans.

AMYRAUT, MOSES, in *Biography*, an eminent protestant divine, was born of a good family at Bourgueil in Touraine in 1596. He was designed by his father for the profession of the civil law, which he assiduously studied in the college of Poitiers; but preferring that of a divine, he applied himself to theology at Saumur in 1626, and obtained the professorship of divinity in the university of this place. With his two colleagues in office he lived in perfect harmony; and the three professors cordially concurred in their exertions for the credit of the seminary in which they presided. In 1631 he was deputed by the protestant synod at Charenton to present to the king their complaints concerning the violation of the edicts which had been passed in their favour; and being instructed not to deliver his address on his knees, which had been the usual mode, he was allowed to decline it; and the ability and address with which he conducted this business were admired by Cardinal Richelieu. His treatise "On Grace and Predestination," written at the request of a Roman catholic of rank, who was favourably disposed towards the protestants, excited much attention. This attempt, on the part of Amyraut, for reconciling the doctrine of predestination with that of universal grace, was violently opposed by the Calvinistic divines, and particularly by Du Moulin. Although Amyraut was enjoined silence with regard to these subjects of debate by the synod of Alençon, he persevered in the contest; and such was, ultimately, his success, that the sentiments which he inculcated, and which

which nearly coincided with those of the Pelagians and Arminians, were received in all the universities of the Hugonots in France, and disseminated by the French protestants, who fled from the rage of persecution, through all the reformed churches of Europe. The talents, learning, and moderation of this able polemic, were much respected by the clergy and laity of all professions. His political opinions, which were favourable to the high pretensions of absolute monarchy, and which militated against those which were generally avowed by the Hugonots, and the advocates of religious liberty, served to recommend him to the particular notice and esteem of Cardinal Mazarine. In his Apology for the Protestants of France, published in 1647, he declares, that he will not pretend to justify the taking up arms against one's prince on any occasion whatever; and that he always believed it to be much more agreeable to the nature of the gospel and the practice of the ancient church, to have recourse to no other arms than patience, tears, and prayers. In his book "On the Sovereignty of Kings," published in 1650, on occasion of the tragical death of Charles I. he expresses, in the strongest terms, his approbation of the doctrine of passive obedience. He excepted, however, those cases of conscience, in which he regarded the authority of God as superior to that of man: and he so strenuously resisted an order of the council of state, which required all the protestants to put out hangings before their houses on Corpus Christi day, that the order was soon revoked.

The principal works of Amyraut, besides those that have been already mentioned, are, "A Treatise on Religions," published in 1631; "On the Nature and Extent of the Gospel," 1656; "The Elevation of Faith, and Abatement of Reason," 1641; "A Defence of Calvin in relation to the Doctrine of Absolute Reprobation," in Latin and French, 1644; "Paraphrases on the Scriptures;" "An Apology for the Protestants;" "A Treatise on Free-will;" "On Separation from the Church of Rome," in Latin, in 1647; "Irenicon," for promoting a reunion of the Lutherans and Calvinists," in 1648; "Of the calling of Pastors," 1649; "Christian Morality," in 6 vols. 8vo. 1652; "A Treatise on Dreams;" "A Treatise on the Millennium;" "The Life of La Noue;" and a poem intitled, "St. Stephen's Apology to his Judges;" these pieces are written in French; those excepted which are mentioned to be in Latin.

Amyraut was eminently distinguished both by his writings and character. His moderation and candour secured the respect of persons of different sects; and his liberality to the poor comprehended alike the catholics and reformed, and it was so extensive, that he distributed in charity the whole salary of his ministry during the last ten years of his life. He died, much respected and regretted, in 1664, bearing testimony, in his last moments, to the truth and importance of those religious principles, by which the course of his life had been uniformly regulated. Gen. Dict. Mosheim's Eccl. Hist. vol. v. p. 364, &c.

AMYRBERIS, in *Botany*, a name used by some authors to express the *Barberry-tree*.

AMYRIS, a genus of the *oëandria monogynia* class and order, and of the natural order of *terebintaceæ*, Jusseu. Its characters are, that the *calyx* is a perianthium, one-leaved, four-toothed, acute, erect, small, and permanent; the *corolla* consists of four, oblong, concave, and spreading petals; the *filamina* have awl-shaped, erect filaments, anthers oblong, erect, of the length of the corolla; the *pyfillum* has a germ, superior ovate, style thickish, of the length of the stamens, and stigma four-cornered; the *pericarpium* is a drupaceous and roundish berry; and the *seed* is a round, shining nut.

Martyn, in his edition of Miller, enumerates 9, and Gmelin, in his Linneus, 13 species. 1. *A. elmsifera*, cornus of Plum. icariba of Marcgr. frutex trifolius of Catesby, with leaves ternate and pinnate, with five lobes, downy underneath. The height of this tree is about six feet; the leaflets pointed, stiff, and shining; and leaves opposite on peduncles two inches long; at the ends of the branches grow four or five slender stalks, set with many very small white flowers, in a little corymb; the petals are inflex at the tip. It has a small trunk, covered with a smooth, grey bark, and grows almost in the manner of a beech-tree. The fruit is of the size and figure of an olive, and the colour of a pomegranate, having within it an odoriferous pulp. A native of Carolina and Brazil. The resin of this tree is the *Gum ELEMI*. 2. *A. sylvatica*, with leaves ternate, crenate, and acute. This is an erect, leafy shrub, from 2 to 15 feet high, according to the soil and situation, abounding with a turpentine of a strong disagreeable smell: it is found plentifully about Carthage in woods near the sea, and flowers in August. 3. *A. maritima*, small, shrubby sweet-wood, with leaves ternate, crenulate, and obtuse. This is a dwarf shrub, yielding a juice like that of the former, but more agreeable, and smelling like rue: the berry is of the size of black pepper, black when ripe, inclosing a globular, brittle nut, in which is a white kernel. Swartz doubts whether the preceding be a distinct species from this. It grows in very barren coppices, in a calcareous rocky soil, both near the sea, and on the interior mountains of Jamaica, Hispaniola and Cuba; and flowers from June to September. 4. *A. Gileadensis*, balsam of Gilead-tree, with leaves ternate, quite entire, and peduncles one-flowered, and lateral. This species is a shrub with purplish branches, having protuberant buds loaded with balsamic resin: the flowers proceed from the same buds by threes; the bracte minute and slightly bifid. It is doubted whether this be distinct from the next species. See *BALSAM of Gilead*. 5. *A. Opobalsamum*, balsam of Mecca tree, balsamum of Bellon. and Alpin, opobalsamum, or balsamum Judaicum of Geoffroy, has pinnate leaves, and sessile leaflets. See *BALSAM of Mecca*, and *OPOBALSAMUM*. 6. *A. toxifera*, poison ash, elemifera of Linn. Hort. Cliff. toxicodendron of Catesby and Miller, with leaves pinnate, and leaflets petiolate and plane. Catesby describes his poison-wood as a small tree, with a light-coloured, smooth bark, the mid-rib of the leaf, as seven or eight inches long, and the pedicles as an inch in length; the fruit as hanging in bunches, shaped like a pear, of a purple colour, covering an oblong hard stone; from the trunk distils a liquor as black as ink, which the inhabitants say is poison: birds feed on the fruit. It is a native of America. 7. *A. protium*, protium Javanicum of Burm. tingulung of Rumph. with leaves pinnate, and leaflets petiolate and waved. It is perennial, and a native of the East Indies. 8. *A. ambrosiaca*, icica heptaphylla of Aubl. Guian. with leaves pinnate and petiolate, and panicles crowded and axillary. This is a tree, with a trunk 30 feet high, branching at the top, with brancklets leafy and showery: leaves alternate, with two or three opposite, ovate leaflets on each side, ending in long points, smooth, entire, on short-petioles, gibbous at the base; flowers yellowish white, axillary, and corymbed; perianth very small and four-toothed; petals lanceolate, spreading at the tip; filaments filiform, half as long as the calyx, inserted into the tube; germ, superior, subglobose, style cylindrical; stigma capitated, depressed and four-cornered: fruit ovate, oblique, four-celled, resembling that of the laurel; the nucleus involved in a brittle covering, four-celled, with four stones wrapped up in a viscid red pulp, having a balsamic smell and taste, hardening into a grey resin, and used for burning as a perfume. The whole tree is very

sweet-scented, and yields a very odoriferous balsam from the wounded trunk or branches, which is used in the dysentery; the dose is one dram in red wine; it is also used in houses and churches for burning as a perfume. It grows in the wood of Guiana, and by the sea-shore, flowering and fruiting in September. The Caribbee name is arouaou, and the French *arbre de l'Encens*. 9. *A. balsamifera*, lucinium of Plak. Sweet amyris, white candle-wood, or rosewood, with leaves two-paired. This grows to a considerable size, and is one of the most valuable trees in the island of Jamaica; the wood is white, and of a curled grain when young, but grows of a dirty, clouded ash colour with age, bearing a fine polish, and having a pleasant smell; it is heavy, and much esteemed among cabinet-makers. All the parts of this tree are full of warm aromatic particles, and may be used in baths and fomentations; the berries are oblong, and have the taste of the balsam Copaiba. An infusion of the leaves has a pleasant flavour, is highly cephalic, strengthens the nerves, and is particularly restorative to weak eyes. In Jamaica there are several species of *amyris*, the leaves and bark of which yield a fine balsamic juice; and if the body were tapped at the proper season, a thick liquor would transude, resembling that of the Gilead balsam, to which the taste of the bark and wood of the smaller branches bears a very exact relation. Dr. Wright apprehends that this wood, by distillation, would yield a perfume equal to the oleum rhodii. 10. *A. kataf*, with leaves ternate, ferrate at the tip, and dichotomous peduncles. Fork. Fl. Æg. Arab. 11. *A. balsamea*, with leaves ternate, and pinnate, with five lobes, and flowers fasciated and pentapetalous. Gleditch. Schr. Berl. Naturf. 12. *A. Zeylanica*, with leaves pinnate, petiolated and smooth, racemes interrupted and axillary, and flowers involucred and hexandrous. Koenig apud Retz Obf. Bot. 13. *A. Guianensis*, with leaves pinnate, the pinnae two-paired, and ovate-oblong, and racemose berries. Sloan. Hist. Jam. Gmelin's Linnæus, and Martyn's Miller.

AMYRIS. See XIMENIA.

AMYRUS, in *Ancient Geography*, a town of Greece in Thessaly; its precise situation is not known. There was also a river of the same name.

AMYSTIS, a river of India, so called by Arrian.

AMYTHAONIA, a district of Elis, so called from Amythaon. Steph. Byz.

AMYTON, a town of Caria, according to Ptolemy.

AMYTRON, a town of Thrace, according to Hesychius.

AMYZON, a town of Asia Minor, in Caria, according to Strabo.

AMZEL, in *Ornithology*, the name of a bird found in the northern parts of Great Britain; but which is better known by the name of ring-ouzel. This is the *Turdus torquatus* of Linnæus. See *TORQUATUS*.

ANA, in *Commerce*, the name of an Indian coin, in value somewhat more than one penny sterling.

ANA, ANAH, or ANNA, in *Geography*, a town of Asia, in Arabia Deserta, situate on the Euphrates, in a pleasant and fertile country, which produces plenty of corn, olives, dates, oranges, lemons, pomegranates, figs, &c. It is under the government of an emir, tributary to the grand signior. It is the general resort of the robbers, who plunder the caravans that pass to and from Bagdad, Aleppo, Damascus, &c. 260 miles east of Damascus, and 300 south-east of Aleppo. N. lat. 33° 35'. E. long. 42° 4'.

ANA, ãã, in *Medicine*, denotes an equal quantity of any things, whether in liquid, or in dry measure.

Hence *anatica proportio* is used by some writers to signify the *ratio*, or *proportion of equality*.

ANA, in *Matters of Literature*, a Latin termination, adopted into the titles of several books in other languages. *Anas*, or *books in ana*, are collections of the memorable sayings of persons of learning and wit; much the same with what we otherwise call *TABLE-talk*.

Wolffius has given the history of books in ana in the preface to the *Casauhoniana*. He there observes, that though such titles be new, the thing itself is very old; that Xenophon's books of the deeds and sayings of Socrates, as well as the dialogues of Plato, are *Socraticana*; that the apophthegms of the philosophers collected by Diogenes Laertius; the sentences of Pythagoras, and those of Epictetus; the works of Athenæus, Stobæus, and divers others, are so many *anas*. Even the *Gemara* of the Jews, with several other oriental writings, according to Wolffius, properly belong to the same class. To this head of ana may likewise be referred the *Orphica*, the *Pythagoreæ*, *Æsopica*, *Pyrrhoneæ*, &c.

Scaligerana was the first piece that appeared with a title in ana. It was composed by Jan de Vassan, a young Champenois, recommended to Jos. Scaliger, by Casaubon. Being much with Scaliger, who was daily visited by the men of learning at Leyden, De Vassan wrote down whatever things of any moment he heard Scaliger say. And thus arose the *Scaligerana*, which was not printed till many years after, at Geneva, in 1666. Patin. Let. 431. Soon after came the *Perroniana*, *Thuana*, *Naudæana*, *Patineana*, *Sorberiana*, *Menagiana*, *Anti-Menagiana*, *Furetiana*, *Chevæana*, *Leibnitziana*, *Arlequiniana*, *Poggiana*, &c.

Ana is used among some occult philosophers to denote the human mind. Hence, according to some, is derived the word *anasapta*, a dæmon invoked to the assistance of a sick person.

ANAB, in *Scripture Geography*, a town of Palestine, situate in the mountainous parts of the tribe of Judah. Josh. xi. 21. xv. 50.

ANABAGATAS, in *Ancient Geography*, a city of Asia, and the see of an archbishop under the patriarch of Antioch.

ANABAO, in *Geography*, one of the Molucca isles south west of Timor, from which it is separated by a canal capable of receiving vessels of any burden. At the extremity of this canal are two points; the southern, called *Gupang*, belongs to Timor; and that on the northern side to Anabao.

ANABAPTISM, see ANABAPTISTS, *infra*.

ANABAPTISTON. See ABAPTISTON.

ANABAPTISTS, in *Ecclesiastical History*, a name given to Christians who maintained that baptism ought always to be performed by immersion; that it ought not to be administered to children before the age of discretion, or that at this age it ought to be re-administered to those who have been baptized in their infancy, because they say the administration of this sacrament is neither valid nor useful, if it be done by sprinkling only, and not by immersion; or if the persons who receive it be not in a condition to give the reasons of their belief.

The word *Anabaptist* is compounded of *ana*, *new*, and *βαπτιστης*, a *baptist*, and this general denomination has been indiscriminately applied to people of very different principles and practices; though many of them object to the name, because the baptism of infants by sprinkling, is, in their opinion, no baptism; and they hold nothing in common excepting some one or other of the above mentioned opinions concerning BAPTISM.

The NOVATIANS, the CATAPHRYGIANS, and the DONATISTS, may be considered as a kind of Anabaptists in the earlier ages, though not then denoted by this name; for they contended that those Christians of the catholic church, who joined themselves to their respective parties, should be rebaptized.

rebaptized. But we must not class under the same denomination those bishops of Asia and Africa, who, in the third century, maintained, that baptism, administered by those whom they called heretics, was not valid; and therefore that such of them as returned into their churches ought to be rebaptized. Nor does it appear that there is sufficient authority to affirm, that the *Vaudois* and the *Albigenses* were predecessors of the modern *Anabaptists*; though some of them adopted the practice of adult baptism.

It was not till a little after the time when the Lutherans separated from communion with the Romish church, that the Anabaptists began to make a noise in Germany. Storek, Stubner, and Munzer, were the first disciples of Luther, who, about the year 1521, were styled Anabaptists. But well knowing that their opinions were very different from Luther's doctrine, they availed themselves of his absence to disseminate them in Wittemburgh, and had the address to over-reach the piety of Melancthon. Their principal purpose was to gain over the populace, and to form a considerable party. To effect this, says Bayle, they were industrious and active, each in his own way. Storek, wanting knowledge, boasted of inspiration; and Stubner, who had both genius and erudition, laboured at commodious explications of Scripture. Not contented with discrediting the court of Rome, and decrying the authority of consistories, they taught, that men being entitled under the Gospel to equal liberty, could not be justly subjected to any civil power, nor erect superiorities over each other; that, as all magistracy was an usurpation on Christian freedom, no true Christian could be either magistrate or subject, nor consequently pay any impost, give any oath, or bear arms; that violence and arms ought never to be made use of, excepting against princes, and people in power, from whom they were permitted to revolt, as from so many usurpers, who were to be pulled down, in order to erect the kingdom of God. They pretended that Christians, being all free, equal, and independent, there ought to be no tribunal among them, nor laws, nor any distinction of property, but that every thing should be in common, nor any restraints with regard to the number of wives whom they might marry. In other respects they affected singular austerity, recommending macerations, fastings, and the utmost simplicity of apparel. Their sermons were, for the most part, declamations against the communion of the reformed; and they were incessantly exhorting every body to join with them, who, as they said, were sent of God, to re-establish the kingdom of his Son. They made high promises to all who would unite with them to exterminate the impious, if this massacre proved the epocha for the commencement of Christ's reign upon earth, when the just, meaning themselves, were to reign also, instead of the unrighteous usurpers of authority. They moreover affected to speak with a kind of contempt concerning external worship, the sacraments, the ministry, and even the word of God, with a view to enhance the merit of the extasies, visions, and inspiration, to which they pretended, and on which they valued themselves. They dealt much in predictions, especially concerning the nearness of the last judgment; and, finally, to give a greater eclat to their party, they rebaptized all those who joined them; and to make their practice succeed, they taught that baptism administered to infants was void.

Munzer took the lead of this party; and, in 1525, assembled a numerous army of associates; but this insurrection was soon suppressed, and Munzer put to an ignominious death. Many of his followers, however, survived, and propagated their opinions through Germany, Switzerland, and Holland. In the year 1533 they formed a new community

at Munster, under the direction of two Anabaptist prophets, John Matthias, a baker of Haerlem, and John Blockholdt, a journeyman tailor of Leyden. Having made themselves masters of the city, they deposed the magistrates, confiscated the estates of such as had escaped, and deposited the wealth they amassed together in a public treasury for common use. They made preparations of every kind for the defence of the city, and sent out emissaries to the Anabaptists in the Low Countries, inviting them to assemble at Munster, which was now dignified with the name of Mount Sion, that from hence they might be deputed to reduce all the nations of the earth under their dominion. Matthias, who was the first in command, was soon cut off in an act of phrensy by the bishop of Munster's army; and was succeeded by Blockholdt, who was proclaimed, by a special designation of heaven, as he pretended, king of Sion, and invested with legislative powers, like those of Moses. The extravagancies of Blockholdt were too numerous to be recited: it will be sufficient to add, that the city of Munster was taken after a long siege and an obstinate resistance; and Blockholdt, the mock monarch, was punished with a most painful and ignominious death. The *Baptists* in England and Holland, or, as they are there called, the *Mennonites*, are very different from those who first gave rise and name to the sect.

It must be acknowledged, that the first insurgents in Germany had been grievously oppressed; and that they took up arms principally in defence of their civil liberties; nor should subsequent extravagancies of violence be attributed to their religious principles, much less charged on their successors.

The sequel of their history, and distinguishing tenets, may be seen under the article ANTI-PÆDO-BAPTISTS, BAPTISTS, MENNONITES, WATERLANDIANS, &c.

ANABASII, in *Antiquity*, the couriers who travelled on horseback, or in chariots, for the greater expedition.

The word comes from the Greek *αναβασις*, mounting.

ANABASIS, in *Botany*, a genus of the *pentandria digynia* class and order, of the natural order of *holoraceæ* and *atriplices* of Jussieu: its characters are, that the *calyx* is a three-leaved perianthium, the leaflets roundish, concave, obtuse, and spreading; the *corolla* five-petalled, petals ovate, equal, less than the calyx, and permanent; the *stamina* have filaments filiform, longer than the corolla, and anthers roundish; the *pistillum* has a germ roundish, acuminate, ending in two styles, and obtuse stigmas; the *pericarpium* is a berry, roundish, surrounded by the calyx and dilated; the *seed* is single and serew-shaped. There are four species. 1. *A. aphylla*, leafless *A. fassola* baccifera of Gmel. Siber. kali bacciferum of Buxb. without leaves, and the joints emarginate. This is a perennial plant, and has been found wild on the shores of the Caspian. The berry, in a state of maturity, is large; it is red, the pulp is watery, and it dyes a yellow colour. Gmelin makes the anabasis retacea of Pallas and Gærtner a variety of this species. 2. *A. foliosa*, leafy *A. fassol. foliis incrassatis*, &c. of Gmel. and Pallas, kali bacc. fol. clavatis of Buxbaum, with leaves subclavate. It is seldom more than half a foot high; annual; found wild on the shores of the Caspian. 3. *A. tamariscifolia*, tamarisk-leaved *A.* with awl-shaped leaves and juiceless pericarpia. This is a shrub with white branches, very smooth; a native of Spain. 4. *A. spinosissima*, thorny *A.* shrubby, branches without leaves, but full of spines: the native place of growth is unknown.

ANABASIS, in *Medicine*, the state of a disease in its growth.

ANABASIUS, a name given by Pliny to a plant, which he calls also *ephedra*, and describes as hanging down
FROM

from the branches of large trees, in form of tufts of hair. The plant described by Pliny, and others of the ancients, under this name is the *USNEA*, or long hairy tree moss.

ANABATA, in *Ancient Customs*, a cope, or sacerdotal veil, to cover the back and shoulders of the priest.

It is otherwise called *anabolium*, formed of *αναβαλλομαι*, to *cover*.

The word *anabala* seems to be used in the same sense.

ANABATHRA, from *αναβαινω*, *I ascend*, in *Ancient Writers*, denote a kind of steps or ladder, whereby to ascend some eminence. In this sense we read of the *anabathra* of theatres, pulpits, &c. *Anabathra* appears to have been sometimes also applied to ranges of seats rising gradually over each other.

ANABATHRA is more particularly applied to a kind of stone-blocks raised by the highway sides, to assist travellers in mounting or alighting, before the use of stirrups was invented. The first author of this contrivance, among the Romans, was C. Gracchus, brother of Tiberius.

ANABIBAZON, in *Astronomy*, the *DRAGON'S tail*.

ANABIS, in *Ancient Geography*, a town of Spain, in the territory of the *Lacetani*, according to Ptolemy. Eusebius mentions a village of Egypt under this name, in which a man was the object of worship.

ANABLATA, a town of Palestine, near Bethel.

ANABLATUM, in *Botany*, a name used by some authors for the *squammaria*, or tooth-wort, called *dentaria* by others.

ANABLEPS, in *Ichthyology*, a species of *COBITIS*, having a depressed head, prominent eyes, and two beards; one at each angle of the mouth. Linn. This fish inhabits the sea shore of Surinam, and is described by Seba and Gronovius. It has six rays in the gill membrane, seven in the dorsal fin, twenty in the pectoral fin, seven in the ventral fin, and nine in the anal fin.

In the system of Fishes of Artedi, ANABLEPS is a genus of the malacopterigious kind.

ANABOA, in *Geography*, a small island situate near the coast of Loango in Africa, in S. lat. 1° and E. long. 8° 30'. This island has several fertile vallies, in which are produced bananas, oranges, lemons, pine-apples, citrons, cocoa-nuts, &c. and abundance of cotton. It has two high mountains, almost always covered with clouds, which occasion frequent rains.

ANABOLEUM, in *Antiquity*, denotes any kind of upper garment worn over the coat or tunic.

This is otherwise called *anabole*, from *ανα* and *βολω*.

ANABOLEUS, among the *Ancients*, a servant whose office was to assist in mounting on horseback. These were in use before the invention of stirrups, or of those stones called *anabathra*.

ANABOLEUS is also used by Eustathius, to denote a small piece of iron, whereon the foot was set, in order to mount; from which Budeus infers, that the ancients had stirrups or foot-boards; to which Lipsius objects, that it does not appear this *anaboleus* was any pendant part fixed to the saddle, after the manner of our stirrups, but rather a portable engine brought by a servant, and placed by the horse's side.

ANABROCHISMUS, from *ανα*, *upwards*, and *βροχος*, a *loop*, in the *Ancient Physic*, the operation of taking away offensive hairs in the eye lids.

The manner of performing the *anabrochismus* is described by Gorræus.

ANABROSIS, *αναβροσις*, q. d. *erosio*, in *Medicine*, otherwise called *diabrosis*, the issuing of blood at a hole worn in a vein by corrosion.

ANABUCIS, in *Ancient Geography*, a place of Africa,

situate, according to Antonine, in the route from Carthage to Alexandria. As it lay to the east of *Macomades*, it must have been in the Cyrenaic territory.

ANABUM, a town of Germany, situate, according to Ptolemy, in an island of the Danube.

ANABURA, a town of Phrygia in Asia Minor, probably the same which some authors have placed in Pisidia.

ANACA, in *Ornithology*, the name of a species of *PSITTACUS*, or parrot, that inhabits Brazil and Guiana, and is called at the latter place the common parrot, being the most frequent species of that genus. It is green, beneath ferruginous-brown, crown of the head chestnut, spot on the back, and tail pale brown, margins of the wings red. Linnæus, Gmel.

This is ANACA BRASILIENSIS of Ray and Willoughby; ANACA of Buffon, and chestnut-crowned parakeet of Latham. It is likewise *la petite perruche brune du Bresil*, of Brisson. It is the size of a lark. Bill and orbits brown; crown of the head chestnut, throat cinereous: hind part of the neck, back, rump, sides, thighs, scapulars, upper wing and tail coverts, green: breast, belly, and under tail coverts, rufous brown: legs and claws blackish.

In the British Museum there is a specimen, which varies in having the spot on the back of a deep chestnut; no red on the edge of the wings: tail green, the upper tail coverts brown, and the under tail coverts of a brown still paler. Vide Dr. Latham Gen. Svn.

ANACALYPTERIA, in *Antiquity*, feasts celebrated among the Heathens on the day that the bride was permitted to lay aside her veil, and to be seen in public.

They were thus called from *ανακαλυπτειν*, to *uncover*.

According to Suidas, it also means the presents which were made to the bride by her husband's relations and friends on that day.

ANACAMPSEROS, in *Botany*. See CLAYTONIA, PORTULACA, and SEDUM.

ANACAMPTERIA, in *Ecclesiastical Antiquity*, denote little hospitals, or inns, for the entertainment of the poor and strangers, built adjoining to the ancient churches.

ANACAMPTIC, from *ανα* and *καμπη*, *flexio*, *I bend*, signifies as much as *reflecting*; and is frequently used in reference to echoes, which are said to be sounds produced *anacampically*, or by reflection.

Hence, also *anacampitics* is used by some for the science of reflecting rays; otherwise called *CATOPTICS*.

ANACANDAIA, in *Zoology*, the name of a species of serpent found in the island of Ceylon, and very mischievous among the cattle, whence it is called *BUBALINUS*.

ANACARDII, in *Entomology*, a species of *PAPILIO* of the tribe *Paraffius*. The wings are transparent, or glassy and greenish. Posterior pair brown at the tips, with two eye shaped spots. Inhabits South America. Linn. and Fabric.

ANACARDIUM, formed of *ανα*, *without*, and, *καρδια*, *heart*, because the pulp of the fruit, instead of having the seed inclosed, as is usually the case, has the nut growing out at the end of it, in *Botany*, *acajou* of Tournefort, *acajuba* of Gærtner, a genus of the *polygamia monoecia* class and order, (*enneandria monogynia* of Gmelin and Willdenow,) of the natural order of *boloraceæ*, and *terebinaceæ* of Jussieu; its characters are, that it has hermaphrodite flowers and male flowers, either mixed with the hermaphrodites, or on a distinct tree. The *calyx* of the former is a perianthium five leaved, leaflets ovate, concave, coloured, erect, and deciduous; the *corolla* has five petals, lanceolate, acute, three times as long as the calyx, upright at bottom, reflex at the end; the *stamina* have ten filaments, united at the base and upright, nine of them capillary, shorter than the calyx,

calyx, one thicker, double the length of the others, lying on the germ in front, anthers roundish, in the longer filament large and fertile, in the rest small; the *pyllium* has a germ kidney-shaped, obliquely emarginate in front, style subulate, bent in, the length of the corolla; stigma small, roundish, depressed, and concave; no *pericarpium*; receptacle fleshy, very large and obovate; the *seed* a nut kidney-shaped, large, at the top of the receptacle, with a thick shell, cellular within, and abounding in oil. The *calyx*, *corolla*, and *stamina* of the male flowers as in the hermaphrodites; the *pyllium* has either no germ, or one that is abortive. There is one species, viz. *A. occidentale*, acajuba occidentalis of Gærtner, acajou of Piso, acajuba of Marcgrave, cassivium of Rumphius, cashou of Merian, kapa-mava of Rheed, anacardium fructu obversè ovato nucce reniformi, racemis terminalibus of Browne, Jamaic. Cashew-nut, castu or acajou. The cashew is an elegant tree, 12 or 16 feet high, spreading much as it rises, and beginning to branch at the height of five feet, according to Browne; but Long affirms, that in good soils it spreads to the size of a walnut tree, which it resembles in the shape and smell of the leaves: the trunk seldom exceeds half a foot in diameter; the leaves are coriaceous, subovate, shining, entire, petioled, and scattered alternately; the panicles corymbd, diffused, and terminating, containing many small, sweet-smelling flowers, on an oblong receptacle, scarcely distinguishable from the peduncle; the corolla red, with commonly 10 stamens, one of which has no anther, but it has frequently eight or only seven all fertile; and there are sometimes female flowers entirely destitute of stamens. The fruit has an agreeable subacid flavour, in some degree restraining; in some of a yellow, and in others of a red colour, which difference may be probably owing to the soil or culture. The juice of the fruit, fermented, affords a pleasant wine, and distilled, yields a spirit exceeding arrack or rum, and serves to make punch, and also to promote urine. The ripe fruit is sometimes roasted, and sliced, and thus used for giving an agreeable flavour to punch. The restraining of the juice has recommended it as a remedy in dropical habits. From one end of the apple proceeds the nut, which is kidney-shaped, inclosed in two shells, the outer of an ash-colour, and smooth, and the inner covers the kernel. Between these shells is lodged a thick, inflammable, and very caustic oil, which, incautiously applied to the lips and mouth, inflames and excoriates them. This oil has been successfully used for eating off ring-worms, cancerous ulcers, and corns; but it should be very cautiously applied. Some of the females have used this oil as a cosmetic, in order to remove the freckles and tan occasioned by the scorching rays of the sun, but it proves so corrosive as to peel off the skin, and cause the face to inflame and swell; but after enduring the pain of this operation for about a fortnight, their new skin, as it may be called, appears fair like that of a new-born infant. This oil also tinges linen of a rusty iron colour, that can hardly be got out; and when smeared on wood, it prevents decay, and might therefore serve for preserving house timber and ships' bottoms. The fresh kernel has a delicious taste, and abounds with a sweet milky juice; it is an ingredient in puddings, &c. and is eaten raw, roasted, and pickled. The negroes of Brazil, who are compelled by their masters, the Portuguese, to eat this nut, for want of other sustenance, obtain relief from this involuntary use of it in various disorders of the stomach. When the kernel is ground with cacao, it improves the chocolate; but if it be kept too long it becomes shrivelled, and loses its flavour and best qualities. The milky juice of the tree, obtained by tapping or incision, will stain linen of a deep black, which cannot be washed out; but whether this

has the same property with that of the eastern anacardium, has not yet been fully ascertained; for the inspissated juice of that tree is the best sort of lac which is used for staining black in China or Japan. Phil. Trans. vol. xlix. part ii. p. 872. Lewis Comm. Phil. Techn. p. 329, &c. This tree annually transudes from five to ten or twelve pounds weight of a fine semi-transparent gum, resembling gum-arabic, and not inferior to it in virtue or quality, except that it has a slight astringency, which may probably, in some respects, render it more valuable. It is a native of both Indies, *e. g.* Malabar, Ceylon, Brazil, Guiana, Jamaica, and the Caribbee islands; and was cultivated in Kew Garden in 1699, by the dukes of Beaufort.

Culture.—The cashew tree is easily raised in its native country from the nut; and it is of quick growth, bearing fruit in two years after it has been planted. But in England the plants are preserved with difficulty. They are easily raised from the nut supplied from America; and they should be planted in small pots filled with light sandy earth, and plunged into a hot-bed of tanner's bark, which should be preserved from moisture. Fresh nuts will yield plants in about a month, and in two months these will be four or five inches high, with large leaves, but they seldom advance much farther in the same year. The plants must be constantly kept in the stove, as they are too tender to live abroad in England, even in the warmest seasons. They should have little water in Summer, and in Winter, water once in a fortnight will be sufficient. When they are transplanted, the pots should be broken, that the earth which cleaves to their roots may not be disturbed; and they should then be put into larger pots, filled with light sandy earth, and plunged into the hot-bed. They must not be removed oftener than once a year, and the pots should not be too large, for unless their roots are confined they will not thrive. With this management they may be kept several years, but they seldom exceed two feet and a half in height, and are seldom half as high. Martyn's Miller. Murray's Mat. Med. vol. iv. p. 413.

ANACARDIUM Orientale. See *AVICENNIA*.

ANACARDIUM Officinorum. See *SEMECARPUS*.

ANACATHARSIS, in *Medicine*, properly denotes a purgation by spitting; in which sense it stands contradistinguished from *catharsis*, or evacuation downward.

In this sense is the word used by Hippocrates and Galen; agreeably to this Blasius restrains *anacatharsis* to expectoration. Only Blancard, on what authority does not appear, extends *anacathartic* medicines to all those which work upwards, by the glands of the head, whether vomitories, sternutatories, or masticatories.

ANACATHARSIS is also a name given by *civil lawyers* to the *Basilicon repetita Prelectionis*, made by order of the emperor Constantine Porphyrogenitus.

It was thus called, as being a review or correction of the *Basilicon*.

ANACATHARSIS, among *Divines*, denotes the clearing up some obscure passage, by a spiritual or analogical interpretation.

ANACATHARTIC, from *ανω*, upwards, and *καθαρσις*, I purge, is usually understood of a vomit, or a purging medicine that works upwards.

ANACEIA, an Athenian festival in honour of the Dioscuri. It took its name from those deities, who were also called *Ανακτες*, and honoured with a temple called *Ανακειον*, *Anaceum*. The Anaces, Anaetes, or Dioscuri have been thought by some writers to be the same with the Cabiri of the ancient Carthaginians, but others are of a different opinion. However this may be, they were undoubtedly descended from the Anakims of Moses; and Inachus was also

of this race, as his name imports. Some have supposed, that the appellation Anactes was given to those princes of the line of Itachus, who had distinguished themselves by their heroic actions.

The sacrifices offered at that time were named *ἑπισημαίαι*, because those deities were *ξένοι*, or *strangers*; and consisted of three offerings, which were called *ἑπισημαίαι*. Athenæus mentions plays acted in honour of these deities.

ANACEPHALÆOSIS, formed of *ἀνα*, which in composition signifies *again*, and *κεφαλήν*, *head*, in *Rhetoric*, a recapitulation, or a short and summary repetition of the heads of a discourse.

ANACHARSIS, in *Biography*, a Scythian philosopher, was the son of a Scythian chief by a native of Greece, and flourished about 600 years before Christ. Having acquired an early acquaintance with the Greek language, he was entrusted by his sovereign with an embassy to Athens; and in the first year of the 47th Olympiad, i. e. 592 B. C. he was conducted by Toxaris, one of his countrymen, to the house of Solon. Anacharsis availed himself of the opportunities which free and familiar intercourse with Solon afforded him for gaining wisdom: he was introduced to the society of the principal persons at Athens, and he was the first stranger upon whom the Athenians conferred the honour of citizenship. After the death of Solon, and probably not before, Anacharsis left Athens, and travelled into other countries; and at last returned to Scythia, with a design of communicating to his countrymen the knowledge he had acquired, and of establishing among them the deities and the worship of Greece. But his attempts were ineffectual. Whilst he was performing sacred rites to Cybele, in fulfilment of a vow which he had made upon his way home, he was killed by an arrow levelled against him, as report says, by the king's own hand; so that he fell a sacrifice to the envy and folly of his countrymen, who would not condescend to be instructed by Grecian wisdom. The phrase, "Scythian eloquence," was derived from the manly and nervous kind of language for which he was distinguished. He is said to have been the inventor of the anchor and potter's wheel, but these instruments were known before his time; however, he might have introduced the use of them among the Scythians. Of his ingenious sayings that are recorded, the following deserve to be mentioned: "The best method of teaching a youth sobriety is to set before his eyes a drunken man." "The vine bears three sorts of fruit: the first, pleasure; the second, intoxication; the third remorse." "An ape is by nature ridiculous; man, by art and study." To an Athenian of infamous character, who reproached him for being a Scythian, he said, "My country may be a disgrace to me; but you are a disgrace to your country." As he was one day considering the thickness of the planks of a ship, he cried out, "Alas! those who go to sea are but four inches distant from death." Being asked what was the most secure snip, he replied, "That which is arrived in the port." He often repeated, "That every man should be particularly careful to make himself master of his tongue and his belly." Being asked what was the best and what the worst part of a man, he answered, "The tongue." "It is much better," said he, "to have but one friend, if he be faithful to us, than a great number of those who are always ready to follow the change of fortune." He used to compare laws to spider-webs; and to ridicule Solon, who pretended to restrain the passions of mankind by pieces of writing. He observed, "That the prince who is wise is happy; and that that city is best wherein all things else being equal, virtue hath the better condition, vice the worse." The epistles that bear his name are probably spurious. Herodotus, lib. iv. Plut. Vit. Solon, apud Opera, tom. i. p. 80. Diog. Laertius,

lib. i. tom. i. p. 64. Strabo, lib. vii. tom. i. p. 461. Brucker's Hill. of Philos. by Enfield, vol. i. p. 104. The Travels of Anacharsis the Younger in Greece, by the Abbé Barthelemi, comprised in seven volumes, 8vo. with a volume of maps, &c. in 4to. is a work in high estimation.

ANACHIMOUSSE, in *Geography*, a province of the island of Madagascar, having on the east the river Jonghainon, which runs through it, the country of Manan Loule on the south, on the west large and lofty mountains, and on the north the river Mangharac and the country of Eringdrata. This province produces great quantities of rice and yams, with plenty of cattle, and other necessaries of life, and is extremely populous.

ANACHIS, in *Mythology*, one of the four deities, to whom the Egyptians imagined the peculiar care of each person was committed at his birth: the other three were *Dymon*, *Tyche*, and *Heros*. They were also called *Dynamis*, *Tyche*, *Eros*, and *Ananche*; i. e. Power, Fortune, Charity, and Necessity.

ANACHORESIS, denotes a withdrawing from society, or retiring into solitude. The anachoresis was not allowed to persons before they had spent thirty years in the community.

ANACHORET, from *ἀναχωρέω*, *I retire into a solitary place*, a hermit or devout person, living alone in some desert, to be farther out of the reach of the temptations of the world, and more at leisure for meditation. Such were St. Anthony, St. Hilarion, &c. Paul the Hermit was the first of the tribe of anachorets.

When many of the habitations of anachorets were placed together in the same wilderness, at some distance from one another, they were all called by one common name *laura*, which, as Evragnius informs us, differed from a *canobium*, or *convent*, in that a *laura* consisted of many cells divided from each other, where every monk provided for himself; but a *canobium* was one habitation, where the monks lived in society, and had all things in common. Anachorets, popularly anachorets, were very numerous among the Greeks, consisting principally of monks; who not caring for the fatigues and offices of the monastery, purchased a little spot of ground, with a cell, whither they retreated, and never appeared in the monastery again excepting on solemn days. These are sometimes also called *ascetes* and *solitaries*.

They had their chapel, and after prayers applied themselves to the culture of their vineyards, olives, fig-trees, and the like, which afforded them provision for the year.

These anachorets only differed from the conventual monks, in that they had less intercourse with the world, and lived but in small bodies.

The anachorets of Syria and Palestine retired into the most obscure and unfrequented places; hiding themselves under rocks and mountains, without either tents or cottages, reposing wherever the approach of night happened to find them, and living on the spontaneous productions of the earth. This course of life they pursued, that they might avoid the view and the society of mortals.

There have also been anachorets in the West. Peter Daimon, who was of the order of hermits, frequently speaks of them with great praise. He represents them as by far the most perfect sort of monks; holding them in much higher opinion and veneration than the *canobites*, or monks residing in monasteries.

Many of these retire, with the leave of their abbots, and have an allowance from the monastery. The people, on account of their piety, present them with good sums of money, which they carefully hoard up, and at their death bequeath to the monastery they had belonged to.

ANACHORETA, in *Entomology*, a species of *PHALÆNA*, of the *bombyx* tribe, which, till lately, was confounded

with phalæna curtula, from which it chiefly differs in having a white streak across the brown spot at the tip of the anterior wings. Its specific character is, wings grey, with white streaks; at the tip a ferruginous-brown spot, marked with a waved streak of white. Fabricius. Feeds on the willow and poplar in the larva state. The larva is hairy, brown with a flesh-coloured stripe along the back; two elevated warts, and lateral dots of rufous colour. Inhabits Austria.

ANACHORITA, in *Ecclesiastical Writers*, a name sometimes given to the cells of recluses.

By the ancient canons, no anachorita could be erected without consent of the bishop.

ANACHRONISM, compounded of *ανα*, higher, and *χρονος*, time, in *Chronology*, an error in computation of time; whereby an event is placed earlier than it really happened.

Such is that of Virgil, who placed Dido in Africa at the time of *Æneas*; though, in reality, she did not come there till 300 years after the taking of Troy. An error on the other side, whereby a fact is placed later or lower than it should be, is called a *parachronism*; though this distinction is not commonly observed.

ANACHYTIS, in *Natural History*, a species of *ECHINUS*, of the second order of *VERMES*, *Mollusca*; it is heart-shaped, rather oblong, and somewhat conic, base flatish. Spaces and divisions ten; mouth subrotund, surrounded with an elevated margin; vent oval, notched below. Klein and Linn. Found in a fossil state.

ANACIUM, in *Ancient Geography*, a mountain of Attica, on which was a temple of Castor and Pollux.

ANACLASTIC glasses, *vitra anaclastica*, a kind of sonorous phials or glasses, chiefly made in Germany, which have the property of being flexible, and emitting a vehement noise by the human breath. They are also called vexing glasses, by the Germans *vexier glaser*, on account of the fright and disturbance they occasion by their respiration.

The anaclastic glasses are a low kind of phials with flat bellies resembling inverted funnels; whose bottoms are very thin, scarce surpassing the thickness of an onion-peel: the bottom is not quite flat, but a little convex. But upon applying the mouth to the orifice, and gently inspiring, or as it were sucking out the air, the bottom gives way with a horrible crack; and from being convex becomes concave. On the contrary, upon expiring or breathing gently into the orifice of the same glass, the bottom with no less noise bounds back on its former place and becomes gibbous as before.

The anaclastic glasses first taken notice of were in the castle of Goldbach; where one of the academists *Natura Curiosorum*, having seen and made experiments on them, published a piece expressly on their history and phenomena. Rosini Lentilii Oribasii Sched. de Vitris Anaclasticis. Vid. Ephem. Acad. N. C. Dec. 2. Ann. 3. p. 489, seq. Their figure may be seen in the book above cited.

They are all made of a fine white glass. It is to be observed in these, 1. That if the bottom be concave at the time of inspiration, it will burst, and the like will happen if it be convex at the time of expiration. 2. A strong breath will have the same effect even under the contrary circumstances.

ANACLATICS, or ANACLASTICS, derived from *ανα*, and *κλω*, *I break*; that part of *OPTICS* which considers refracted light, and is the same with what we more usually call *DIOPTRICS*.

ANACLETERIA, formed of *ανα*, and *κλεω*, *I call*, in *Antiquity*, solemn feasts celebrated in honour of kings and

princes when they came of age, and took upon them the administration of the state, and made a solemn declaration thereof to the people.

ANACLETICUM, in the *Ancient Art of War*, a particular blast of the trumpet, whereby the fearful and flying soldiers were rallied, and recalled to the combat.

ANACLETUS, or CLETUS, or ANENCLETUS, *i. e. irreprehensibile*, in *Biography*, a pope, reckoned by Roman Catholics the third; succeeded Linus as bishop of the church of the Romans; and, according to Eusebius, (*Hist. Eccl. lib. iii. c. 13. 15.*) in the second year of the reign of Titus, or in 79, A. D. and governed that church 12 years. This bishop has been enrolled among the saints and martyrs, though there is no satisfactory evidence of his martyrdom. Dupin. *Bower's lives of the Popes*, vol. i. p. 13.

ANACLETUS was also the name of a competitor for the popedom against Innocent II. He was the grandson of a circumcised Jew, named Peter of Leon. When Innocent II. was acknowledged as successor to the papal chair by the emperor Lotharius II. upon the death of Honorius II. in 1130, Roger, King of Sicily, did homage to Anacletus, who was for some time master of Rome. After the defeat of Roger, upon whom he had conferred the title of king of Naples and Sicily, he was obliged to yield to his more fortunate competitor. He died in 1138, and his memory has been reproached with scandalous vices. Dupin.

ANACLINOPALE, from *ανα*, *κλινω*, *I incline*, and *σπλον*, *arms*, in *Antiquity*, a kind of wrestling, wherein the champions threw themselves voluntarily on the ground, and continued the combat by pinching, biting, scratching, and other methods of offence.

The anaclinopale stood contradicting with the *ortobopale*, wherein the champions were erect. In the anaclinopale, the weaker combatant sometimes gained the victory.

ANACLITES, the denomination of those Britons, who are placed by most of our antiquaries in that district of Berkshire which is adjacent to Henley.

ANACLINTERIA, in *Antiquity*, a kind of pillows on the dining-bed, whereon the guests used to lean.

The ancient triclinary beds had four *επιπλατα*, one at the head, another at the feet, a third at the back, and a fourth at the breast. That on which the head lay was properly called by the Greeks, *ανακλινητρον*, or *ανακλινητρον*; by the Romans *fulcrum*, sometimes *phuteus*.

According to other writers, anaclinteria is more properly understood of the backs of chairs whereon we lean.

ANACOINOSIS, from *ανα* and *κοινω*, *I communicate*, *communicatio*, a figure in *Rhetoric*, when we consult the adversary, or appeal to the judges what ought, or could have been done on such an occasion.

Such is that of Cicero, *Quero, si te hodie domum tuam redeuntem, coacti homines et armati, non modo limine tesloque adiumtuarum, sed primo aditu vestibuloque prohibuerint, quid acturus sis?* Cicero pro Cecin.

ANACOLLEMA, formed of *ανακολλω*, *conglutino*, in *Physic*, denotes a liniment or other medicine applied to the forehead, to stop or prevent defluxions of the eyes.

Anacollemata make a species of medicines called *frontalia*.

The qualities required are, to be drying, cooling, thickening, astringent, conglutinant, &c.

To the class of anacollema belong bran, manna, myrrh, terra sania, acacia, &c.

Junker describes an *anacollema frontale* for stopping hæmorrhages at the nose.

ANACOLUTHON, from *ανακολουθος*, *incoherent*, among *Ancient Grammarians*, denotes an incoherence, or a construction which does not accord. This is usually signified by

the appellation of a figure which ought rather to be denominated an inaccuracy.

ANACONDA, in *Zoology*, a name given in the isle of Ceylon (and adopted by some naturalists) to a very large and terrible snake, which, it is said, often devours the unfortunate traveller alive, and is itself accounted excellent and delicious fare. This creature is described as a species of rattlesnake, but it is far more probable that it is not of that genus. It is generally believed that rattlesnakes are altogether peculiar to the American continent; nor is there any known species of rattle-snake that corresponds with the description of this tremendous creature; the largest kinds scarcely exceeding four, five, or at most six feet in length.

Perhaps the snake in question may be *boa constrictor* of Linnæus, which it is known sometimes grows to the length of twenty or thirty feet, and is of such prodigious strength, that it is able to destroy almost any other animal. It is a species found in the Indian islands, and is eaten by the inhabitants.

ANACOPHA. See *ΑΝΚΗΑΣ*.

ANACREON, in *Biography*, a Greek lyric poet, was born at Teos, a sea-port of Ionia, and flourished during the reign of Polycrates, tyrant of Samos, at whose court he resided, in the sixth century before Christ. His fame was such, that Hipparchus, the son of Pisistratus, as we are informed by Plato, (in Hipparchus) sent a vessel of 50 oars to bring him to Athens. After the death of Hipparchus he returned to Teos, and afterwards removed to Abdera, the place of his youthful residence, where he died at the age of 85 years. Report says, that his death was occasioned by a grape-stone, which choked him whilst he was drinking new wine. He was a professed voluptuary, and habituated to the unrestrained gratifications of wine and love. He is censured even by Ovid for devoting his chief attention to Bacchus and Venus—

“ Quid, nisi cum multo Venerem confundere vino
Præcipit lyrici Teia musa Senis ?”

His attachment to Cleobulus is recorded by Maximus Tyrius, (Orat. ii.) and the ardour of his passion for Bathyllus is mentioned by Horace. *Epod. xiv. v. 9.*

“ Non aliter Samio dicunt arsisse Bathyllo
Anacreonta Teium,
Qui persæpe cava testudine flevit amorem.”

Ælian (in his *Var. Hist. lib. ix. c. 4.*) has endeavoured to vindicate his character; but the charges against him are too well founded to admit of refutation. During his residence at Samos, Polycrates made him a present of 5 talents, equal to about 5625l. sterling. Unaccustomed to the possession of such a sum, he could not enjoy his usual repose, and he therefore hastened to restore it to the generous donor, alleging, that while he had so great a charge in his custody, he should never be able to write or sing again. The poems of Anacreon, that are extant, consist chiefly of Bacchanalian songs, and love-sonnets. They are mostly composed in verses of seven syllables, or rather of three and a half feet; spondees and iambs, and sometimes anapests; and hence verses in that measure are sometimes called *Anacreontics*, or *Anacreontic verses*. The odes of Anacreon abound in suavity, sprightliness, and elegant fancy; they are sweeter, says Scaliger, than Indian sugar; and, according to Mad. Dacier, the chief beauty and excellence of Anacreon consisted in his imitations of nature, and in his following reason; so that he presented to the mind no images that were not noble or natural. The odes of Anacreon, says Rapin, are flowers,

and perpetual graces; it is familiar to him to write what is natural and to the life; and he possessed an air so delicate, easy, and graceful, that, among all the ancients, there is nothing comparable to his method, nor to the kind of writing which he pursued. He flows, adds this writer, soft and easy, diffusing the joy and indolence of his mind through his verse, and tuning his harp to the smooth and pleasant temper of his soul. The character of his writings is justly given by the God of Love, directed to speak by Mr. Cowley:

“ All thy verse is softer far
Than the downy feathers are,
Of my wings, or of my arrows,
Of my mother's doves and sparrows;
Graceful, cleanly, smooth, and round,
All with Venus' girdle bound.”

The authenticity of some of those poems, which have been distinguished by his name, has been suspected, but they have been acknowledged by ancient writers; nor is it probable that imitations, composed at different times by different authors, should invariably retain the same style and dialect. Of these odes we have had translations and imitations in various languages. Of the original the best editions are those of Barnes and Pauw; and the free versions of Cowley are the most approved English imitations. The odes of Anacreon have been lately, in 1801, translated into English verse, with notes, by Thomas Moore, Esq. 4to. Gen. Dict.

ANACRISIS, from *ἀνα* and *κρίσις*, *I judge*, among the *Ancient Greeks*, is used for a kind of trial or examination, which the archons, or chief magistrates of Athens, were to undergo before their admission into that office. The anacrisis stands distinguished from the *docimasia*, which was a second examination in the forum. The anacrisis was performed in the senate-house. The questions here proposed to them were concerning their family, kindred, behaviour, estate, &c. Some maintain that all magistrates underwent the anacrisis.

ANACRISIS, in the *Civil Law*, denotes a search or inquiry into the truth by examination of witnesses.

ANACROSIS, in *Antiquity*, denotes a part of the Pythian song, wherein the combat of Apollo and Python is described.

The anacrosis was the first part, and contained the preparation to the sight.

ANACTON *padon*, a festival held at Amphyssa, the capital of Locris, in honour either of the Dioscuri, or of the Curetes, or Cabiri, about which authors are not agreed.

ANACTORIA, now *Vonizza*, in *Ancient Geography*, a town of Acarnania, at the extremity of the peninsula, at the entrance of the gulf of Ambracia. Stephanus Byz. says, that it was founded by a colony of Corinthians. Augustus transported its inhabitants to Nicopolis.

ANACUIAS, in *Geography*, a people of America, in Brazil, on the borders of the country possessed by the Portuguese, under the appellation of *Capitania de Seragippe*.

ANACYCLUS, *santolinoides* of Vaillant, and *cotula* of Tournefort, in *Botany*, a genus of the *syngenesia polygamia superflua* class and order, of the natural order of *compositæ discoideæ*, and *corymbifera* of Jussieu; its characters are, that the *calyx* is common, hemispherical, and imbricate, with many ovate, flat sharp scales; the *corolla* is compound and radiate, with numerous hermaphrodite corollas in the disk, from five to ten females in the ray, scarcely higher than the disk; hermaphrodites funnel-shaped, with a quinquefid, spreading

Spreading border; females with a flatted tube, and an ovate entire border; the *stamina* in the hermaphrodites; filaments five, capillary, and very short; anther cylindrical; *pisillum* a germ flatted, stigma bifid, in the hermaphrodites, with a membrane on each side, style, filiform, of the length of the corollet, and two slender reflex stigmas in the stocules; no *pericarpium*, calyx unchanged; *seed* in the hermaphrodites solitary, oblong, compressed, naked, or without down; in the females with a very broad, membranaceous wing on each side, and emarginate at top, but without down; the *receptacle* chaffy, chaffs obtuse with a point. There are four species. 1. *A. creticus*, cotula cretica, &c. of Tournefort, *fontaniloides annua*, &c. of Vaillant, trailing anacyclus, "with leaves decomposed, linear, and folioles divided and flat." 2. *A. orientalis*, chamæmelum orientale, &c. of Tournefort, eastern a. "with leaves compound, bristly, acute, and straight." These two species grow naturally in the islands of the Archipelago, from whence their seeds were sent by Tournefort to the Royal Garden at Paris: their seeds have been also received from Portugal. They are low plants, with branches trailing on the ground. The first sort has fine-cut leaves, like those of chamomile; the flowers are small, white, and grow single, with their head declining, like those of the common May weed. The second has leaves like those of the ox-eye; the flowers are white, and like those of chamomile. 3. *A. aureus*, chamæmelum luteum capite aphylo of Bauhin, anthesis chrysanthemum of Lob. golden-flowered a. "with leaves bipinnate, roundish, hoary, and hollow-dotted." This species is a native of the south of Europe and the Levant, and was cultivated here in 1570. 4. *A. valentinus*, chrysanthemum valentinum of Clafius, buphtthalmum lanuginosum, foliis millefolii of Bauhin, chamæmelum tenuifolium, flore bulbato aureo of Barr. "with leaves decomposed and linear, folioles divided, roundish, and acute; the flowers stoculose." This grows a foot and a half high, sending out many side-branches; the leaves are finely divided and hairy; the flowers are single at the end of the branches, and are of a bright yellow colour, with a silvery, fealy calyx; they are as large as those of the ox-eye. It is a native of Spain and Italy; cultivated in 1636 by Tradescant; flowering in June and July.

Culture.—All these plants are annual; the seeds should be sown early in the Spring, in a border of light earth, where they are designed to remain, and need no other care than to be thinned and kept free from weeds; they flower in July and August, and their seeds ripen in September. Martyn's Miller.

ANADARA, in *Conchology*, a name by which some naturalists have distinguished the species of ARCA, called *antiqua* by Linnæus. Adanf. Seneg.

ANADAVADÆA, in *Ornithology*, the name of a small bird of the East Indies, which has the beak of a chaffinch, and the feet of the lark. It is sometimes brought over to England alive in cages, and will live here very comfortably.

ANADEMA, formed of *αναδισμας*, to be bound round, among the *Ancients*, denotes an ornament of the head, wherewith victors at the sacred games had their temples bound.

Some confound the *anadema* with the *diadema*, worn by the ancient Persian kings.

Anademata are also mentioned by ancient writers among the ornaments of the heads of women.

According to some, *αναδεμα*, answers to what the Latins call *redimiculum*.

ANADIPILOSIS, *αναδιπλωσις*, from *ανα*, again, and *δι-*

πλω, I double, in *Rhetoric* and *Poetry*, denotes a repetition of the last word of the former verse or member in the beginning of the next; *e. gr.*

"Addit se sociam timidisque supervenit Ægle.

Ægle Naiadum pulcherrima—

—sequitur pulcherrimus Astur,

Astur equo fidens—"

"If children, then heirs, heirs of God, and joint heirs with Christ."

ANADIPILOSIS, in *Medicine*, denotes the redoubling or return of the paroxysm of a fever, chiefly of a semitertian.

This is otherwise called *epanalepsis* and *epanadiplosis*.

ANADOSIS, from *ἄνα* and *δίδωμι*, I give, in the *Ancient Medicine*, denotes the distribution of the aliment by the vessels of the body.

In this sense, anadosis makes a part of nutrition or DIGESTION.

ANADROMOUS, in *Ichthyography*, a term of distinction applied by some early naturalists to those migratory fishes that have their stated times of going from the fresh-water to the salt, and afterwards returning back to the fresh water again.

The word is derived from *ανα*, back again, and *δρομος*, a course. Many of the *salmo* genus are of this kind, and particularly *salar*, or the common salmon, whose periodical returns from the sea to deposit its spawn in fresh-waters is well known. The method nature has appointed for their course of changes seems to be this: they are first produced from the spawn in fresh-water rivers; they live there till they acquire some strength and size, and then seek the salt-water to feed more at large in, and grow to their full extent; at which period they return to the fresh-water again to lay their spawn, that the young brood may have the same advantages which they had before, of being placed in fresh-water. Some use the word *catanadromi* in the same sense.

ANADUOMENE *Venus*, in the *Grecian Mythology*, answered to the *Sea-Venus* in the Roman, and was the appellation given to one of the chief deities of the sea. The most celebrated picture in all antiquity was that of this goddess by Apelles; and the famous Venus of Medici is a *Sea Venus*.

ANADYR, in *Geography*, a river of Siberia, that rises in the country of the Tchuktchi, out of a lake (N. lat. 68° 20'. E. long. 179° 14') among the frontier mountains which are a continuation of Stanovoi-Krebet, and discharges itself into that part of the Eastern or Pacific Ocean, which is called the *Sea of Anadyr*, Anadyrskai gulf, or bay of Anadyr. N. lat. 65°. E. long. 177° 34'. This river receives many streams, besides the brook Yablona, which gives the name of Yablonoï-Krebet to the range of mountains where it springs, but none of them are very large. Its bed is in general sandy, and its current by no means rapid; its channel is very broad, and contains a considerable number of islets, but of so little depth, that it can scarcely be crossed in any part with the common ferry-boats of that country, called *shitiki*, which are sewed together, have no iron in their construction, and draw no more than two feet of water. From the source of the Anadyr to the brook Yablona, the country is mountainous and bare; below the Yablona are some stripes of meadow-land and some poplar-trees; and on the mountains to the left, for at least 100 versts above Anadyrskoi-ostrog, are thin woods of larch trees and dwarfish Siberian cedars. The whole of the northern region, as far as the Anadyr, is in general destitute of standard trees, and has scarcely any pieces fit for pasture;

whereas, south of the river, at no great distance, especially about the head of the main, the Peninsula, and the Aklan, are forests of tall timber in abundance. From the Anadyr to the Kolyma and the Frozen Ocean, and throughout the whole country of the Tchuktehi, no more forest has been discovered; the meadow shrubs scarcely shoot above a span high, as in the whole tract along the northern coast of Siberia. But so much the more frequent are the flats, overgrown with yellow and white moss, on which innumerable herds of wild rein deer find pasture. Tooke's View of the Russian Empire, vol. i. p. 229.

ANADYSKAJA GULF, a bay of the Pacific Ocean, on the coast of Siberia, extending from Cape Apofrola Thadra, E. long. $178^{\circ} 14'$. N. lat. 63° , to the bay of Saint Lawrence, E. long. $187^{\circ} 14'$. N. lat. 65° .

ANADYRSKOI, a fortified town of Siberia, on the river Anadyr. E. long. $165^{\circ} 14'$. N. lat. 66° .

ANADYSIS, among *Ancient Divines*, denotes the ceremony of the emersion in BAPTISM.

In which sense *ανανυσις*; stands contradistinguished from *ανανυσις*, or immersion.

ANÆA, in *Ancient Geography*, a town placed by Stephan. Byz. in Caria, opposite to the isle of Samos, which took its name from one of the Amazons who was buried there; and which was the birth-place of Menelas, a peripatetic philosopher and celebrated historian.

ANADÆIA, in *Antiquity*, a denomination given to a silver stool placed in the aræopagus, on which the defendant or person accused was seated for examination.

The word is *ανανδεια*, which imports *impudence*; but according to Junius's correction, it should rather be *ανανια* q. d. *innocence*.

The plaintiff or accuser was placed on an opposite stool, called *hybris*, or *injury*; here he proposed three questions to the party accused; to which positive answers were to be given. The first, are you guilty of this fact? The second, how did you commit the fact? The third, who were your accomplices?

ANAERETA, in *Astrology*, a place in the heavens, at which the *apheta* arriving, an infant born at that time, is pronounced by astrologers in danger of death.

The word is Greek, and literally imports a *cutler off*.

In this sense, *anaereta* stands opposed to *apheta*.

ANAERETA, among the Greek *Astrologers*, amounts to the same with what the Arabs call *ahazin*.

ANAESTHESIA, *αναισθησια*, in *Medicine*, a privation of sense, or of the faculty of perceiving external objects. The species or degrees of this are *stupor*, *habetudo*, *depravatio*, &c. The sense of feeling may be injured by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touch, as pressure, extreme cold, &c. It may likewise be impaired by too great a degree of sensibility, when the nerve is not sufficiently covered by the cuticle or scarf-skin, or where there is too great a tension of it, or it is too delicate. Whatever disorders the functions of the brain and nerves hurts the sense of touching; and hence it seems to proceed from the same general causes, as palsy and apoplexy, and requires a similar treatment. In a *stupor*, or defect of touching, which arises from an obstruction of the cutaneous nerves, the patient must be first purged, and then recourse should be had to such medicines as excite the action of the nerves, or stimulate the system. For this purpose the spirit of hartshorn, either by itself or combined with essential oils, horse-radish, &c. may be taken inwardly; and the disordered parts may, at the same

time, be frequently rubbed with fresh nettles, or spirit of sal-ammoniac. Blisters and sinapisms applied to the benumbed parts will likewise be of use; and also warm bathing, especially in the natural hot-baths.

ANÆTHETUS, in *Ornithology*, a name which has been sometimes given to a species of tern found in Jamaica, and described by Brown. This is *STERNA SOLIDA* of Linnæus, which see.

ANAFÀ, or DAR BEYDA, in *Geography*, a town of Africa, on the western coast of Morocco, situate in one of the most beautiful parts of the kingdom, formerly possessed by the Portuguese, and populous, but now a heap of ruins; 30 miles south-south-west of Sallee.

ANAGADA, an island in the West Indies, so low as to be almost covered with high tides. N. lat. $18^{\circ} 38'$. W. long. $64^{\circ} 18'$.

ANAGALLIDASTRUM, in *Botany*. See CENTUNCULUS.

ANAGALLIS, derived from *αναγελαιω*, to laugh, because, as it is said, by curing the spleen it disposes persons to be cheerful, a genus of the *pentandria monogynia* class and order, of the natural order of *rotaceæ*, and *lysimachia* of Jussieu. Its characters are, that the *calyx* is a perianthium five-parted, sharp, and permanent, and divisions keeled; the *corolla* is wheel-shaped, border five-parted, divisions ovate-orbiculate, with the claws connected; the *filamina* have erect filaments, shorter than the corolla, shaggy below, anthers simple; the *pisillum* is a globose germ, style filiform, slightly bending, and stigma capitate; the *pericarpium* is a globose, one-celled capsule, opening transversely; the *seeds* are very many and angular; the *receptacle* globose, very large, (fungose, alveolate, and free, G.) Martyn enumerates 7, Willdenow 6, and Gmelin 8 species. 1. *A. arvensis*, A. flore phœniceo of Ray, and A. mas of Ger. common or scarlet pimpernel, with leaves undivided, stem procumbent, and corolla finely notched; or with stem procumbent, leaves ovate-lanceolate, and segments of the calyx serrated; or, according to Dr. Smith, with leaves ovate, punctated underneath, and stem procumbent. Dr. Smith reckons three varieties, viz. *β. A. phœnicea*, foliis amplioribus ex adverso quaternis of Ray; *γ. A. fœmina* of Ray and Ger. A. cerulea of Abbot, blue pimpernel; and *δ. A. terrestris* flore albo of Ray. The root is small; the stem procumbent, very branching at the base, tetragonous, smooth, and foliose; the leaves opposite, (those of *β* in a rich soil being four) sessile, ovate, entire, smooth, and underneath dotted with purple; the peduncles axillary, solitary, one-flowered, longer than the leaves; the lacinia of the calyx lanceolate, acuminate, membranaceous at the margin; the corolla deeply quinquefid, minutely ciliated, mostly scarlet, with a violet mouth; the stamina hairy and violet; the anthers yellow; the stigma obtuse and crenated; the capsule globose and diaphanous, (marked with five lines as if the seams of so many valves, but always separating transversely into two parts, Withering); the seeds angular, and heaped together; the flowers in the variety *γ* are blue, but Dr. Smith has perceived scarcely any other difference. Dr. Withering observes, that every part of this plant is singularly beautiful; and will amply repay the trouble of a minute examination. It is an annual plant, frequent in ploughed grounds and gardens, particularly in sandy soils, and flowers in June and July. The variety *γ*, female or blue pimpernel, grows wild in Sweden, Germany, and Switzerland, and is found between Stockwell and Camberwell, near London, near Mitcham in Surrey, and Histon in Cambridgeshire, on Bredon-hill, in a corn-field at the top of Oyerbury-wood in Worcestershire, at Dawlish in Devonshire.

shire, and between Bath and Bradford. Ray, Linnæus, and others, take the blue pimpernel to be only a variety of the red. Haller, after Blair and Boehmer, and followed by Allioni and Gmelin, considers it as a distinct species; observing, that it is a taller plant, with smaller leaves and larger flowers; that the capsule is more ovate, but the divisions of the calyx are narrower, and the petals ferrate about the edge. Haller mentions a blue sort, with three and four leaves together. The variety δ has been found in Cowley field. The blossoms of the male or common pimpernel open about eight in the morning, and close in the afternoon; and from this circumstance it is denominated the *shepherd's*, or *poor man's weather-glass*. But with rain, or much moisture in the air, the flowers either do not open, or close up again. Small birds are very fond of the seeds; swine and goats feed on it, but sheep are said (in the *Amæn. Acad.*) to refuse it, whereas Schreber says, that sheep eat it readily. It was formerly celebrated for its medicinal qualities, and given in maniacal cases, and in the hydrophobia. It is now fallen into disuse, though Lewis observes, that it is not wholly destitute of medicinal powers; as the expressed juice of the leaves, on being depurated by settling, and then inspissated to the consistence of an extract, affects the organs of taste with a pungent saline astringency; and therefore these herbs have some claim to the resolvent and detergent virtues ascribed to them by some writers, though neither a decoction, nor tincture of them, nor their juice in its dilute state, and much less their distilled water, can exert those virtues in any considerable degree. Murray has cited several cases, adduced by Gelin, which favour the efficacy of the anagallis as an antidote to the bite of mad animals. It has also been recommended as affording relief in cancerous complaints. 2. *A. monelli*, upright pimpernel, with leaves undivided, and erect stem. This is a very beautiful, small plant, and produces a great number of fine blue flowers in April and May. It is a native of Verona, and cultivated in 1648 in the Oxford garden. 3. *A. latifolia*, broad-leaved P. with leaves heart-shaped, stem-clasping, and stem compressed. This is nearly allied to the first species, but distinguished by its large broad leaves and compressed stem. It was sent to Mr. Miller in 1759 from Spain, and is a trailing annual plant. 4. *A. linifolia*, flax-leaved P. with leaves linear, and stem erect. A native of Spain and Portugal. 5. *A. tenella*, lysimachia tenella of Sp. Pl. Hudson, Miller, and Dickson; nummularia minor, flore purpurascente of Ray, Gerard, and Parkinson, bog P. or purple-flowered loose-strife, or money-wort, with leaves ovate and sharpish, and creeping stem. This has the habits of lysimachia, the corolla almost of centunculus, but the stamina and fruit of the anagallis. It is not uncommon on wet heaths and turfey bogs in France, Italy, and England, in Suffolk and Staffordshire, is perennial, and flowers in July and August. 6. *A. verticillata*, verticilled P. with stem-leaves verticilled, and stem erect. 7. *A. pumila*, dwarf P. with stem erect, and leaves roundish, acute and sessile. It is annual and a native of Jamaica in the high mountains and marshes.

Culture.—The four first sorts being annual, are propagated from seeds which should be soon sown after they are ripe. The first, though beautiful, is a common weed, and never cultivated except in botanic gardens. The second, third, and fourth require being sheltered from extreme cold. The fifth is a bog-plant, and cannot be cultivated in gardens, but will flourish well enough in pots of bog-earth plunged in water. The sixth, if it be a distinct species, has not yet been cultivated with us. Martyn's Miller. Smith's Flor. Brit. Willdenow. Gmelin's Linn.

ANAGALLIS. See CENTUNCULUS, EVOLVULUS, LYSIMACHIA, and PÆDEROTA.

ANAGALLIS *Aquatica*. See GRATIOLA, MONTIA, PEPPLIS, SAMOLUS, and VERONICA.

ANAGALLIS *Carulca*. See GRATIOLA.

ANAGLYPHA, in *Ancient Writers*, denote vessels, or other things adorned with sculpture in *basso relievo*; and hence the *anaglyphic* art is the art of carving, chasing, engraving, or imbossing plate.

ANAGLYPHICE, or ANAGLYPTICE, denotes that species of sculpture wherein the strokes or figures are prominent, or imbossed; and is contradistinguished from *diaglyphice*, where the strokes are indented.

The word comes from the Greek *ανηγλυφω*, *exculpo*.

ANAGNIA, in *Ancient Geography*, a town of Italy, in Latium, south east of Terracina, the capital of the Hernici; distinguished among the ancients by the appellation of rich, noble, and illustrious. It submitted, after a feeble resistance, to the Romans, and obtained the freedom of the city. It was afterward by Drusus Cæsar walled round, and its territory assigned to the veterans. It is now *Anagni*, about thirty-six miles east from Rome. N. lat. 42° 48'. E. long. 13° 45'.

ANAGNOSES, or ANAGNOSMATA, from *ανα* and *γνωσκω*, *I know*, in the *Greek Church*, denotes an ecclesiastical book, containing the lessons read at divine service in the several feasts, &c. of the year.

ANAGNOSTA, or ANAGNOSTES, among the *Ancients*, denotes a kind of servant retained in the families of persons of rank to read to them at meals.

These are called by the Greeks *αναγνωσται*, and by the Romans *lectores*; sometimes also a *studius*.

Even private families who lived in any degree politely, were not without this kind of literary servants. Servius makes mention of a female agnosta, under the denomination of *lectrix*. Sometimes the master himself performed the office of reader. The emperor Severus himself read at table. Martial mentions one Ligurinus, who read his own poems at dinner to the great disgust of the guests.

Among the Greeks there were also anagnostæ in their theatres for public reading of the poets.

Some speak of the anagnostæ as a species of acroamata, from which, however, in propriety, they differed.

Cornelius Nepos relates of Atticus, that no acroama was ever heard at his meals, but an agnostes. He never supped without reading, so that the minds of his guests were no less agreeably entertained than their appetites. The same custom, Eginhard observes, was kept up by Charlemagne, who at table had the histories and acts of ancient kings read to him. This custom seems to have been a relique of that of the ancient Greeks, who had the praises of great men and heroes sung to them, while at table. The ancient monks and clergy kept up the like usage, as we are informed by St. Augustin. Sidonius praises a man of quality in his time, who, in this respect, lived a clerical life, though he was no priest.

Bilbergius, and Th. Raynaud, have dissertations express on anagnostæ.

ANAGNOTSA, JOHN, in *Biography*, a Byzantine historian, flourished in the reign of the emperor John Palæologus, and was present in Thessalonica in the year 1430, when that city was besieged by Sultan Morad, and reduced under the Turkish yoke. As he relates events that occurred two or three years after that siege, he must have lived at least to the year 1433. His work "De rebus Constantinopolitanorum Macedonicis," records the particulars of the siege of Thessalonica and its surrender to the Turks. This history was published in Greek, with a Latin translation, by Allatius in Svo. at Cologne. A. D. 1653.

ANAGNOSTIC, in *Middle Age Writers*, is sometimes used for an epistle, or other writing.

ANAGOGIA, in *Antiquity*, solemn sacrifices to Venus at Eryx, in Sicily, where she was honoured with a magnificent temple.

The name of this solemnity was derived, *απο της αναγωγης*, i. e. *from returning*; because the goddess was said to leave Sicily, and return to Africa at that time.

ANAGOGICAL, *transporting*, something that raises the mind to things eternal and divine; the great objects of the next life.

The word is derived from *αναγωγη*, *carrying away*, which is formed of the preposition *ανα*, *upwards*, and *αγωγη*, *leading*.

The term is principally used in speaking of the divers senses of Scripture.—The *literal* sense is the first, and natural sense; the *mystical* sense is founded on the natural sense, from whence it is taken by analogy or comparison, by similitude or resemblance of one thing to another; and is divided into several kinds.

Where it regards the church, and matters of religion, it is called the *allegorical* sense. Where it regards our morals, it is called the *tropological* sense; and where it regards eternity, or the life to come, it is called the *anagogical* sense.

ANAGOGY, ANAGOGE, a rapture or elevation of the soul, to things celestial and eternal.

Anagogy, in a more particular sense, denotes the application of types and allegories of the Old Testament to subjects of the New; thus called, because the veil being here drawn, what before was hidden is exposed to open sight. Some of the fathers place *αναγωγη* in opposition to *ιστορικη*, *history*.

ANAGOGY, in *Medicine*, denotes a return of humours, or the rejection of matter upwards, or by the mouth.

Anagogy amounts to the same with what is otherwise called *anabol*.

ANAGOGY, *αναγωγικη*, in *Ancient History*, denotes a loose education or discipline.

ANAGOMBRI, in *Ancient Geography*, mountains of Africa, placed by Ptolemy in Marmarica. M. d'Anville places them west of the temple of Ammon.

ANAGRAM, ANAGRAMMA, formed from *ανα*, *backwards*, and *γραμμα*, *letter*, a transposal of the letters of a name, with a combination thereof in some new manner, so as to exhibit one or more words, either to the advantage or disadvantage of the person to whom it belongs.

Thus the anagram of Galenus is *angelus*; that of Logica, *caligo*; that of Alstedius, *sedulitas*; that of Sir Edmundbury Godfrey, *I find murdered by rogues*; or, *by Rome's rude finger die*; that of Loraine, is *alerion*, on which account it was, that the family of Loraine took *alerions* for their armoury.—Calvin, in the title of his Institutions, printed at Strasburgh in 1539, calls himself *Alcuinus*, which is the anagram of Calvinus, and the name of an eminently learned person in the time of Charlemagne, who contributed greatly to the restoration of learning in that age. Barclay, in his *Argenis*, anagrammatizes Calvinus by a less creditable name *Ufivalca*; and Rabelais, to be revenged of the same Calvin, who had made an anagram of his name, found in that of Calvin, *Jan. Cul*.

Such as keep close to the definition of anagram take the liberty to omit or retain the letter H, and that letter only; but such as stand up for the poetical licence, make hold sometimes to use E for Æ, V for W, S for Z, and C for K; and *vice versa*.

This way of writing was scarcely known among the ancients: Daurat, a French poet in the reign of Charles IX.

is usually said to be the first that broached it; yet Lycophron, who wrote under Ptolemy Philadelphus, about 280 years before Christ, appears to have been no stranger to the art of making anagrams. Canterus, in his *Prolegomena* to Lycophron, gives us two of his pieces in this kind; the first on the name of king Ptolemy, *Πτολιμαχος*, in which he found *απο μαλιτος*, *of honey*; to insinuate the sweetness and mildness of that prince; the second was on queen Arsinoe, *Αρσινω*, of whom he made *το ιτεας*, *Juno's violet*.

There are two ways of making anagrams: for, 1. Some only consist in dividing a single word into several: thus the *enigma* of the God Terminus, mentioned by Anulus Gellius, lib. xii. cap. 6. is founded on the anagram *TER MINUS*; and thus *syllineumus* yields *sus tinea mus*. This kind alone seems to have been used among the Romans.

The second is, where the order and situation of the letters are changed; such are those above mentioned; and also these, *Roma, Maro, Amor*; *Julius, Livius*; *Corpus, Porcus, Procus, Spurco*.

To find all the anagrams any name will admit of, *algebraically*, see *COMBINATION*.

The finest and happiest of all the anagrams extant, is that on the question put by Pilate to Jesus Christ; *Quid est veritas?* which anagrammatically makes *Est vir qui adijt*: the anagram here is the best and justest answer that could possibly be given.

Besides the ancient kind of anagrams, there have been new ones invented: as, the mathematical anagram, invented in 1680, by which the abbot Catelan found, that the letters of the name Lewis XIV. made *vrai heros*, i. e. *true hero*.

We are now likewise furnished with the numerical anagram, more properly called *chronogram*; where the numerical letters (i. e. such as in the Roman cyphering stood for numbers) taken together, according to their numerical values, express some epocha: of which kind is that distich of Godart on the birth of Lewis XIV. in the year 1638, on a day wherein there was a conjunction of the eagle with the lion's heart:

*eXorIensDeLpblnaqVILæCorDIsqVeLeonIs
CongressVgaLLospeLatItIaqVereseCit.*

ANAGRAMMATIST, a maker or composer of anagrams; Thomas Billon, a Provençal, was a celebrated anagrammatist, and retained by Lewis XIII. with a pension of 1200 livres, in quality of anagrammatist to the king.

Lipenius gives a long list of anagrammatists.

Thomas Billon has given a set of prophecies in anagrams; Gul. Blancus, the art of composing anagrams.

ANAGROS, or ANEGROS, a measure for corn used in some cities in Spain, containing somewhat more than the Paris *mine*.

Four *anegros* make a *cabi*, four *cabis* a *tanega*, and 46 *anegros* are equal to about 10½ quarters of London.

ANAGYRIS, in *Botany*, a genus of the *decandria monogynia* class and order, and of the natural order of *papilionacea*, or *leguminosa*: its characters are, that the *calyx* is a bell-shaped perianthium, mouth five-toothed, the upper pair of teeth more deeply divided; the *corolla* papilionaceous, standard obcordate, straight, emarginate, broader than the other petals, twice as long as the calyx, wings ovate-oblong, flat, longer than the standard, keel straight and very long; the stamina have filaments parallel, distinct, rising, anthers simple; the *pistillum* is an oblong germ, the style simple and rising, the stigma villose; the *pericarpium* an oblong, large, roundish, obtuse legume, a little reflex; the *seeds* six or more, kidney-form. Obs. The essential character consists in the very short, straight standard, and in the great length of the

the keel. Martyn enumerates three species, which are hardy deciduous flowering shrubs. 1. *A. fetida*, stinking bean trefoil, with leaves ovate and flowers axillary. This is the only species mentioned by Gmelin in his edition of the Linnæan System, and also by Willdenow. It grows wild in the South of France, Spain, Italy, and Sicily, and also about Smyrna. It rises to the height of eight or ten feet, and produces its flowers in April and May; they are of a bright yellow colour, growing in spikes, somewhat like those of the laburnum; the seeds are never perfected in this country, and therefore it is scarce in England; it was cultivated in 1570 by Mr. Hugh Morgan. 2. *A. cretica*, with leaves oblong, and racemes longer. This is a native of Candia, and some of the islands of the Archipelago, and is at present very rare in English gardens; it has longer leaves than the former, and flowers later in the Summer, so that it never produces seeds; and it is probably only a variety. 3. *A. inodora*, with leaves pinnate, calyxes inflated and coloured, legumes compressed and straight, racemes terminating and oblong. This is equal to a middle sized tree, with branches hanging down, and frequently scandent; leaves unequally pinnate, leaflets oblong, acuminate, smooth, and without smell; flower white; a native of the woods of Cochinchina. It is doubted whether Loureiro's anagryis foetida, found wild near Canton, in China, be the same with our European one.

Culture.—These plants may be propagated by laying down their tender branches in the Spring, tinging them in the same manner as the layers of carnations, and watering them in dry weather. By this management the layers will take root by the following Spring, and should be cut off from the old plants before they begin to put out their leaves, and planted in a warm situation.

If the plants are propagated from seeds, they will be much handfomer, and rise to a greater height. For this purpose the seeds should be sown in a moderate hot-bed in the beginning of March, or in a border of good rich earth, in a well-sheltered place, sitting over them about half an inch of fine mould, and covering them with a common frame, in order to protect them in severe weather. When the seeds are good, the plants will appear in a month after the seeds are sown; they should then be inured by degrees to the open air, and removed into a sheltered situation towards the end of May. With this view the seeds may be sown in pots, and plunged in a hot-bed, because the plants will not bear transplanting till the following Spring; and it will be proper, during the two first Winters, to shelter them under a common frame, the glasses of which may be drawn off every day in mild weather, that the plants may be thus prepared for being planted abroad, when they have acquired proper strength. They should be kept in pots for three years, and they will then be fit for removal to the places where they are to remain; the best time for which is about the beginning of April, just before they begin to put out new leaves. At this time they should be turned out of the pots with good balls of earth to their roots; and some of them may be planted against walls with warm aspects, so as to be secure from the frost; and others in warm situations, where by covering the surface of the ground about their roots with tanners bark in severe winters, and screening their heads with mats, they may be preserved for several years. In the fourth year from sowing these plants will begin to produce their flowers, and will continue flowering every year; and they will be proper for intermixing with other flowering shrubs of the same growth in warm situations. Martyn's Miller.

ANAGYRIS. See CYTISUS LABURNUM.

ANAGYRIS, or ANAGYRUS, in *Ancient Geography*, a dis-

trict of Attica, in the tribe of Erechtheis, between Phalereus and the promontory of Sunium, to the east of Æxona. Some derive the name from a hero called Anagyrus, who overthrew the houses in this district, because the inhabitants had destroyed a chapel that had been dedicated to him. Others say, that its appellation was derived from the foetid plant called Anagyris, which grew here, and which had the property of yielding a stronger smell the more it was handled; and hence arose the proverb, *Commovere Anagyrin*, or *Anagyrum*, to bring a misfortune upon one's self.

ANAHARATH, a town of Judæa, in the tribe of Issachar. Josh. xix. 19.

ANAÏTICA, a district of Asia in Armenia, situate upon the Euphrates. It is said to have derived its name from the goddess *Anaitis*, to whom the Armenians rendered peculiar worship. The Anaïtic lake, mentioned by Pliny, was situated near this place, of which he says, that the best reeds that were used in writing grew upon its banks.

ANAIÏSIS, called also *TANAIS*, in *Ancient Mythology*, a goddess held in great veneration by the Armenians. Strabo (lib. xi. tom. 2. p. 805.) says, that the Armenians principally worshipped this goddess, and that the most illustrious persons of the nation dedicated their virgin daughters to her, who, after having been for a long time prostituted in her service, were given in marriage; none disdaining to marry them, but rather thinking it an honour to be thus allied to them. Pliny (lib. xxxiii.) informs us, that when the temple of this goddess at Acilifene was plundered by the Romans, under Marc Antony, her statue of massy gold was carried off, and broken to pieces. A report prevailed, that the first man who presumed to touch the goddess, was struck with an apoplexy, and instantly fell down dead. Augustus, being at Bologna a long time after this event, and supping with an old soldier who had shared the plunder, questioned him concerning the truth of the fact, and the soldier replied, "Cæsar, it is the goddess Anaitis's leg you are now eating for supper, and all I have in the world I owe to her."

ANAK, in *Scripture History*, the father of the Anakims, was the son of Arba, who gave his name to Kirjath-Arba, of Hebron. Josh. xiv. 15. Anak had three sons (Josh. xv. 14.) Shishai, Ahiman, and Talmi, who, as well as their father, were deemed giants; and they with their posterity were denominated Anakims, and reputed as a fierce and warlike people, and also of extraordinary stature. To this purpose the Hebrews, who were sent to view the land of Canaan, returned with a report, that they found there the giants, the sons of Anak, in comparison of whom they were both, in their own sight, and also in that of the Anakims, as grasshoppers. Numb. xiii. 33. When the city of Arba, the father of Anak, was assigned to Caleb, in the distribution of Canaan, he drove out the Anakims about A.M. 2559. Josh. xv. 13—15.

ANALATIVA, in *Geography*, a small island near the north-west point of the island of Ceylon.

ANALECTA, in *Antiquity*, the fragments, or offals of meat, which dropped from the table on the ground.

Analecta was also used for a servant appointed to gather up the offals of the tables.

In this sense the word is sometimes also written *analectes*. Satellius Quadratus, in the way of derision, advised Calvinius Sabinus, a man of great wealth, and much affectation of learning, but with little memory, and less genius, to keep *analectæ*, ut *grammaticos haberet analectas*; a phrase which has occasioned much dispute among critics and antiquarians.

ANALECTA is likewise, in a literary sense, used for a collection of small pieces or compositions.

The word is formed of *αναλεγω*, *I gather*.

ANALEMMA,

ANALEMMA, in *Mathematics*, derived from ἀναλημμα, of ἀναλαμβάνω, *resumo*, *I take backwards*, a planisphere, or projection of the sphere, on the plane of the meridian, orthographically made, by perpendiculars from every point of that plane, the eye being supposed to be at an infinite distance, and in the east or west point of the horizon. In this projection, the solstitial colure, and all its parallels, are projected into concentric circles, equal to the real circles of the sphere; and all circles whose planes pass through the eye, as the horizon and its parallels, are projected into right lines equal to their diameters; but all oblique circles are projected into ellipses, having the diameter of the circle for the transverse axis respectively.

The analemma was invented by John de Royas, a Spaniard. The advantages of this above the astrolabes of Ptolemy and Gemma Frisius, are, that all the lines proceeding from the eye are parallel to each other, and perpendicular to the plane of projection; consequently not only the equator is a right line, as in the astrolabe of Gemma Frisius, but all the parallels to the equator are so too; since, in virtue of the infinite distance of the eye, they are all in the same case, as if their plane passed through the eye: for the like reason, the horizon and its parallels are also right lines. On the other hand, whereas in the two former astrolabes the degrees of circles converted into right lines become very small towards the centre, and large towards the circumference, they become here small towards the circumference, and large towards the centre: so that their figures will be no less altered in this than in the others. Add, that most of the circles here degenerate into ellipses, which are often difficult to describe. See **ORTHOGRAPHIC PROJECTION**.

ANALEMMA is also used for a *gnomon* or *astrolabe*, consisting of the furniture of the same projection, drawn on a plate of brass, or wood; with an horizon, or *cursor*, fitted to it.

Its use is for finding the time of the sun's rising and setting, the length of the longest day in any latitude, and the hour of the day. The analemma is also of considerable use among *Diallists*, for laying down the signs of the zodiac, with the length of the days, with other matters of furniture, upon dials.

The most accurate treatise on the analemma now extant, was written by Ptolemy, and printed at Rome in 1562, with a commentary by F. Commandine. Since that time many authors, as Agulonius, Tacquet, Dechales, Witty, &c. have written on the same subject.

ANALEPSIS, the restoration of a body wasted by disease, by the use of a nutritious diet.

ANALEPSIS is also used for the method of hanging a broken or dislocated member, especially the hand, in a sling. This operation to the arm is called *analepsis*; to the foot, *thefis*.

ANALEPTICS, derived of ἀναλαμβάνω, *I re-establish*, in *Medicine*, restoratives; or remedies proper to restore the body, when wasted or emaciated, either by the continuance of a disease, or by want of food.

This term is sometimes applied to stimulants, but more commonly to those substances which supply a deficient nourishment. As a term, however, says Dr. Cullen (*Mat. Med.* vol. i. p. 166.) attended with some ambiguity, it should not be employed at all.

ANALIS, a specific name that occurs in several genera, both in the *Linnean* and *Fabrician* arrangement of *Entomology*.

ANALIS, a species of *SCARABÆUS*. It is black, with three equal tubercles on the head: ends of the wing cases ferruginous-brown. Fabricius. Inhabits India.

ANALIS, a species of *COCCINELLA*. It is black, red at the end, and without spots. Inhabits Europe. Fabricius.

ANALIS, a species of *CHRYSOMELA*. It is black, wing-cases brown, outer margin testaceous. Inhabits Europe. Fabricius.

ANALIS, a species of *CERAMBYX* of Linnæus, and *SAPERDA* of Fabricius. Its colour is testaceous, ends of the shells and tail black. Inhabits Africa.

ANALIS, a species of *CRYPTOCEPHALUS*. The general colour is reddish-brown; antennæ, spot on the wing-cases and tail black. Inhabits Tranquebar. Fabricius and Gmelin.

ANALIS, a species of *STAPHYLINUS*. It is shining black, except the antennæ, wing-cases, tail, and legs, which are testaceous brown. Fabricius and Paykull.

ANALIS, a species of *CIMEX*. It is oblong, green, abdomen red, and black at the end. Inhabits India. Thunberg and Gmelin.

ANALIS, a species of *PHYGANEÆ*. Wings brown, a white anal spot, nape of the head and neck covered with golden hair. Found in the north of Europe. Fabricius.

ANALIS, a species of *SPHEX*. The general colour is shining black, end of the abdomen ferruginous, wings white. Inhabits India. Fabricius.

ANALIS, a large species of *VESPA*. It is blackish, first and second segment ferruginous at the base, sixth segment entirely yellow. Found at the Cape of Good Hope. Fabricius.

ANALIS, a species of *APIS*. Thorax hairy, and ash-coloured, abdomen bluish, and black at the end. Inhabits America. Fabricius.

ANALOGICAL syllogism. See **SYLLOGISM**.

ANALOGISM, in *Medicine*. See **ANALOGY**.

ANALOGISM, among *Logicians*, the arguing from the cause to the effect.

ANALOGISTA, among *Civil Law Writers*, a tutor who is not obliged to give an account of his conduct. Persons dying sometimes appointed friends to be tutors to their children, with this clause, that they should be analogistæ. Some lawyers hold, that this did not exempt a tutor guilty of glaring mismanagement from being called to an account, and punished accordingly.

ANALOGIUM, in *Ecclesiastical Writers*, denotes an *ambo*, or reading-desk.

ANALOGIUM is sometimes also used for a *martyrology*, or *obituary* of a monastery.

ANALOGY, in *Philosophy*, a term denoting a certain relation, proportion, or agreement, which several things bear to each other in some respects, though different in others.

The word is Greek, which the Latins usually render by *comparatio*, and *proportionalitas*.

The schoolmen define analogy to be a resemblance, joined with some diversity: its foundation, according to them, is laid in the proportion of several things, considered as that proportion proceeds upon different considerations.

Thus, a sound animal, a sound food, and a sound proposition, agreeing in this, that they have a common denomination, but the reason or quality whereon the denomination is founded, different, are said to have an analogy, or to be analogous. Accordingly, analagous things are defined to be such as have a common name, but the thing immediately signified by that common name different, yet with some correspondence or relation discernible therein.

Philosophers usually distinguish three kinds of analogy, *viz.* of *inequality*, where the reason of the common denomination is the same in nature, but not in degree or order: in

which sense animal is analogous to man and brute.—Of *attribution*; where, though the reason of the common name be the same, there is a difference in its habitude or respect thereto; in which sense healthy is analogous both to a man and an exercise. Of *proportionality*; where, though the reasons of the common name do really differ, yet they bear some proportion to each other. In this sense, the gills of fishes are said to be analogous to the lungs in terrestrial animals; and thus the eye and the understanding are said to bear an analogy to each other.

Reasonings by analogy may serve to explain and illustrate, but not to prove any thing; and yet a great part of our philosophizing has no better foundation.

From a few *data*, a few points known and allowed, we reason by analogy, and deduce a number of others. It is thus that most branches of knowledge are extended to their present dimensions. There are but few things actually observed, few experiments made; and all the observations and experiments we have are only singular. Such an effect was found from such an individual body, under such and such circumstances. We infer, that what has been observed of one body under such circumstances, will, from the analogy and uniformity in the works of the Creator, equally hold in all other bodies of the same species under the like circumstances. Thus, without having recourse to experiment, we never hesitate to conclude, that the fruit of trees of the same species will have the same taste and properties. This has many times drawn us into great errors; it continues every day to lead us into new ones, and may be said to be the source of most of the mistakes committed in pursuit of science. But nevertheless, while mankind extend their thoughts toward unknown and inaccessible objects, they have no other guide to direct their researches but the supposed correspondence between the objects they are acquainted with, and those which are the subjects of their investigation.

The analogy between the three kingdoms of plants, animals and minerals, has been the source of a variety of discoveries, either real or imaginary: hence it is we have learnt, that stones vegetate; that plants breathe; that the sap circulates in them; that generation is performed by eggs in the human kind; that the planets have their atmospheres, their inhabitants, their trees, their seas, &c. Indeed, if we will follow whither analogy, real or imaginary, will lead us, there is no end of science.

As to divine and supernatural matters, it is asserted we know nothing of them but by analogy; that is, by the mediation and substitution of those ideas we have of ourselves and other natural beings. Our ideas of God himself arise from this spring; we have no direct and immediate perception of him. The knowledge we have of the Supreme Being is only an observation of his works, and a reflection of the mind, which shews what power, wisdom, &c. appear necessary to enable him to produce them. Having no proper ideas of his perfections, we give them the names of those faculties of men, which we judge necessary.

It is natural to men (says Dr. Reid, in his *Essays on the Intellectual Powers of Man*, *Ess. i. ch. iv. p. 52, &c.*) to judge of things less known, by some similitude they observe, or think they observe, between them, and things more familiar or better known. In many cases we have no better way of judging; and where the things compared have really a great similitude in their nature, when there is reason to think that they are subject to the same laws, there may be a considerable degree of probability in conclusions drawn from analogy. Thus, we may observe a very great similitude between this earth which we inhabit, and the other planets. They all revolve round the sun, as the earth does, although

at different distances, and in different periods. They borrow all their light from the sun, as the earth does. Several of them are known to revolve round their axes, and, by that means, must have a like succession of day and night. Some of them have moons, that serve to give them light in the absence of the sun, as our moon does to us. They are all, in their motion, subject to the same law of gravitation as the earth is. From all this similitude it is not unreasonable to think, that those planets may, like our earth, be the habitation of various orders of living creatures. There is some probability in this conclusion from analogy. In medicine, physicians must, for the most part, be directed in their prescriptions by analogy. The constitution of one human body is so like to that of another, that it is reasonable to think, that what is the cause of health or sickness to one, may have the same effect upon another. And this generally is found true, though not without some exceptions. In politics, we reason, for the most part, from analogy. The constitution of human nature is so similar in different societies or commonwealths, that the causes of peace and war, of tranquillity and sedition, of riches and poverty, of improvement and degeneracy, are much the same in all.

Analogical reasoning, therefore, is not, in all cases, to be rejected. It may afford a greater or a less degree of probability, according as the things compared are more or less similar in their nature. But it ought to be observed, that as this kind of reasoning can afford only probable evidence at least, so unless great caution be used, we are apt to be led into error by it. For men are naturally disposed to conceive a greater similitude in things than there really is. E. G. Anatomists, in ancient ages, seldom dissected human bodies; but very often the bodies of those quadrupeds, whose internal structure was thought to approach nearest to that of the human body. Modern anatomists have discovered many mistakes into which the ancients were led, by their conceiving a greater similitude between the structure of man and of some beast than there is in reality. By this, and many other instances that might be given, it appears, that conclusions built on analogy stand on a slippery foundation; and that we ought never to rest upon evidence of this kind when we can have more direct evidence.

Analogical reasoning may be of excellent use in answering objections against truths which have other evidence. It may likewise give a greater or a less degree of probability in cases where we can find no other evidence. But all arguments, drawn from analogy, are still the weaker, the greater disparity there is between the things compared; and, therefore, must be the weakest of all when we compare body with mind, because there are no two things in nature more unlike. There is no subject in which men have always been so prone to form their notions by analogies of this kind as in what relates to the mind. We form an early acquaintance with material things by means of our senses, and are bred up in a constant familiarity with them. Hence we are apt to measure all things by them, and to ascribe to things most remote from matter the qualities that belong to material things. It is for this reason that mankind have, in all ages, been so prone to conceive the mind itself to be some subtle kind of matter: that they have been disposed to ascribe human figure, and human organs, not only to angels, but even to the Deity. Though we are conscious of the operations of our own minds when they are exerted, and are capable of attending to them so as to form a distinct notion of them; this is so difficult a work to men, whose attention is constantly solicited by external objects, that we give them names from things that are familiar, and which are conceived to have some similitude to them; and the notions we form of them are no less analogical

gical than the names we give them. Almost all the words, by which we express the operations of the mind, are borrowed from material objects. To understand, to conceive, to imagine, to comprehend, to deliberate, to infer, and many others, are words of this kind; so that the very language of mankind, with regard to the operations of our mind, is analogical. Because bodies are affected only by contact and pressure, we are apt to conceive, that what is an immediate object of thought, and affects the mind, must be in contact with it, and make some impression upon it. When we imagine any thing, the very word leads us to think that there must be some image in the mind of the thing conceived. It is evident that these notions are drawn from some similitude conceived between body and mind, and between the properties of body and the operations of mind. The influence of analogical reasoning from a supposed similitude of mind to body as a fruitful cause of error, with regard to our mental operations, may be illustrated by the following instance. When a man is urged by contrary motions, these, on one hand, inviting him to do some action, those, on the other, to forbear it, he deliberates about it, and at last resolves to do it, or not to do it. The contrary motives are here compared to the weights in the opposite scales of a balance; and there is not perhaps any instance that can be named of a more striking analogy between body and mind. Hence the phrases of weighing motives, of deliberating upon actions, are common to all languages. From this analogy some philosophers draw very important conclusions. They say, that as the balance cannot incline to one side more than the other, when the opposite weights are equal, so a man cannot possibly determine himself if the motives on both hands are equal; and as the balance must necessarily turn to that side which has most weight, so the man must necessarily be determined to that hand where the motive is strongest. On this foundation some of the schoolmen maintained, that if a hungry ass were placed between two bundles of hay equally inviting, the beast must stand still and starve to death, being unable to turn to either, because there are equal motives to both. This is an instance of that analogical reasoning that ought never to be trusted: for the analogy between a balance and a man deliberating, though one of the strongest that can be found between matter and mind, is too weak to support any argument. A piece of dead, inactive matter, and an active intelligent being, are things very unlike; and because the one would remain at rest in a certain case, it does not follow that the other would be inactive in a case somewhat similar. The argument is no better than this, that because a dead animal moves only as it is pushed, and, if pushed with equal force in contrary directions, must remain at rest; therefore the same thing must happen to a living animal; for surely the similitude between a dead animal and a living one, is as great as that between a balance and a man.

No author has made a more just and a more happy use of the analogical mode of reasoning than Bishop Butler, in his admirable treatise, entitled, "The Analogy of Religion, natural and revealed, to the Constitution and Course of Nature." Instead of indulging in idle speculations how the world might possibly have been better than it is, or forgetful of the difference between hypothesis and fact, attempting to explain the divine economy with respect to intelligent creatures from preconceived notions of his own, this excellent writer first inquires, what the constitution of nature, as made known to us in the way of experiment, actually is; and from this, now seen and acknowledged, he endeavours to form a judgment of that larger constitution, which religion discovers to us. If the dispensation of Providence which

we are now under, considered as inhabitants of this world, and having a temporal interest to secure in it, be found, upon examination, to be analogous to, and of a piece with, that further dispensation, which relates to us as designed for another world, in which we have an eternal interest depending on our behaviour here, if both may be traced up to the same general laws, and appear to be carried on according to the same plan of administration; the fair presumption is, that both proceed from one and the same Author. And if the principal parts objected to in this latter dispensation be similar to, and of the same kind with what we certainly experience under the former; the objections, being clearly inconclusive in one case, because contradicted by plain fact, must, in all reason, be allowed to be inconclusive also in the other. This way of arguing from what is acknowledged to what is disputed, from things known to other things that resemble them, from that part of the divine establishment which is exposed to our view to that more important one which lies beyond it, is, on all hands, confessed to be just. By this method Sir Isaac Newton has unfolded the system of nature; and by the same method Bishop Butler has explained the system of grace, and, as Mr. Mainwaring (in the dissertation prefixed to his volume of sermons, p. 12.) expresses it, "formed and concluded a happy alliance between faith and philosophy." Although the argument from analogy be allowed to be imperfect, and by no means sufficient to solve all difficulties respecting the government of God, and the designs of his providence with regard to mankind; yet surely it is of importance to learn from it, that the natural and moral worlds are intimately connected, and parts of one stupendous whole or system; and that the chief objections which are brought against religion, may be urged with equal force against the constitution and course of nature, where they are certainly false in fact. This information we derive from the bishop's work; the proper design of which is not to prove the truth of religion, either natural or revealed, but to confirm that proof, already known, by considerations deduced from analogy; and to answer objections against those truths, which are established upon their proper evidence. When objections are made against the truths of religion, which may be made with equal strength against what we know to be true in the course of nature, such objections can have no weight. The ingenious author has premised the following summary of the contents and plan of his work, which we shall here transcribe for the information of those readers who may be desirous of pursuing the investigation of subjects of this nature. "The divine government of the world, implied in the notion of religion in general, and of Christianity, contains in it—that mankind is appointed to live in a future state—that there every one shall be rewarded or punished; rewarded or punished respectively for all that behaviour here, which we comprehend under the words, virtuous or vicious, morally good or evil—that our present life is a probation, a state of trial, and of discipline, for that future one; notwithstanding the objections which men may fancy they have, from notions of necessity, against there being any such moral plan as this at all; and whatever objections may appear to be against the wisdom and goodness of it, as it stands so imperfectly made known to us at present—that this world being in a state of apostacy and wickedness, and consequently of ruin; and the sense both of their condition and duty, being greatly corrupted amongst men, this gave occasion for an additional dispensation of Providence, of the utmost importance; proved by miracles; but containing in it many things appearing to us strange, and not to have been expected; a dispensation of Providence, which is a scheme or system of things, carried

by the mediation of a divine person, the Messiah, in order to the recovery of the world; yet not revealed to all men, nor proved with the strongest possible evidence to all those to whom it is revealed; but only to such a part of mankind, and with such particular evidence as the wisdom of God thought fit." Such are the contents of this treatise; and the design of it is, to shew, "that the several parts principally objected against in this moral and Christian dispensation, including its scheme, its publication, and the proof which God has afforded us of its truth; that the particular parts principally objected against in this whole dispensation, are analogous to what is experienced in the constitution or course of nature or providence; that the chief objections themselves which are alleged against the former, are no other than what may be alleged with like justness against the latter, where they are found, in fact, to be inconclusive; and that this argument from analogy is, in general, unanswerable, and undoubtedly of weight on the side of religion, notwithstanding the objections which may seem to lie against it, and the real ground which there may be for difference of opinion, as to the particular degree of weight which is to be laid upon it." See Butler's *Analogy of Religion*, by the Bishop of Gloucester, 8vo. 1783, Preface, p. 34, &c. and Introduction, p. 13, &c.

Analogy, according to the derivation of the word, says Professor Castillon, of Berlin, (*Haarlem Memoirs* for 1786, or vol. xxii.) indicates a resemblance discernible by reason; and its principal use in the investigation of physical and moral truth, may be reduced to the four following particulars: 1. By means of our senses to improve, first, our own judgment, and afterwards that of others, with respect to intellectual subjects. 2. To deduce a general from a particular truth. Having discovered and proved the truth of a proposition with respect to any particular object, examine whether this truth flows from a quality peculiar to this single object, or common to several objects. In the latter case, all these objects may be comprehended under one general idea, founded on their common quality. Substitute this general idea instead of the particular object, and the proposition will become general without ceasing to be true; because whatever evidently and solely results from the identity on which an analogy is founded, must necessarily be true with respect to all those objects in which the analogy is the same. 3. To prove the truth or falsehood of propositions which cannot otherwise be demonstrated. 4. To discover new truths in both natural and moral philosophy.

For the difference between analogy and experience, see EXPERIENCE.

ANALOGY, in *Botany*, is a term that has been used to denote the resemblance or similarity which plants bear to each other, with regard to their medical properties and uses; and the study of botanical analogy, or the arguing from the known properties and effects of one species to those of its congeners, has been recommended as a means of investigating the powers of medicines derived from the vegetable kingdom. See a *Short Attempt to recommend the Study of Botanical analogy*, &c. 8vo. 1784.

ANALOGY, in *Geometry*, denotes a similitude of ratios, or proportions.

ANALOGY, in *Grammar*, denotes the suitableness or agreeableness of a word or phrase to the common rules or forms of language.

In this sense, *analogy* stands opposed to ANOMALY.

ANALOGY, in respect to language, denotes a conformity with other points already established, serving as a rule or model for the making of new words and phrases similar to those already in use.

Or, analogy may be considered as a general or established usage, applied in similar cases to certain words, phrases, or constructions not yet established. Or, analogy is only a particular usage, which, in certain cases, is inferred from a general usage already established.

Grammarians are divided into two parties. Some, with Sanctius, contend, that the analogy or reason reigns through all the parts, all the phrases and dictions of the Latin tongue. On the contrary, others, with Perizonius, assert, that there are many phrases, contrary to analogy and reason, derived all originally from the populace. Such, *e. gr.* are, *Nemo, homo, deorsum, versum*, &c.

Varro and Cæsar wrote expressly on the analogy of Latin words, but their works are now lost. Jac. Operarius has endeavoured to supply that loss, by tracing the analogy of 20,000 Latin words. *Fab. Bib. Lat. lib. i. cap. 10.*

ANALOGY of conjugation, *analogia conjugationis*, is not only when a verb is conjugated like another, but agrees with it in the quantity of the syllables.

Thus *clamo* is conjugated like *amo*, and *clamabam* pronounced like *amabam*.

ANALOGY of declension, *analogia declinationis*, is not only when a noun, pronoun, or participle is declined like another, but agrees with it in respect of the quantities of the syllables.

Thus, *e. g.* *mater* is declined like *pater*, *saltans* as *amans*, *suus* as *tuus*. So *pennarum* is pronounced as *mensarum*, and *funeris* as *muneris*.

ANALOGY of doctrine, among *Critics*, is one of the great rules to which regard is to be had in the interpretation of authors.

We are first to learn from the author himself the general system which he follows; and as no writer is to be easily supposed to contradict himself, our interpretation is to be so conducted, as that nothing be admitted which is contrary to, or tends to overthrow this system.

Thus, in interpreting an author who follows the Platonic scheme, we are to prefer a sense which is consistent with the Platonic doctrine to another which is contrary to it, unless there be some evident proof, that the author contradicts himself, or asserts things which are inconsistent.

ANALOGY, in *Rhetoric*. See COMPARISON.

ANALOGY of faith, among *Divines*, denotes that relation which the several articles of faith bear to each other.

Analogy of faith stands opposed to tradition and authority, which is the great rule of interpretation among catholics. By this it is required, that whether we interpret Scripture, or explain the doctrines of Christianity, all our positions and explanations be consistent with the analogy of our faith, and those evident propositions deduced from Scripture.

Tortschius, Antonius, Franckius, &c. have written expressly on the analogy of faith.

ANALOGY, in *Medicine*, is a certain relation or resemblance between diseases, in virtue whereof, we may reason and conclude from one to another, and treat them all much in the same manner; *e. gr.* pleurisy being a species of inflammation, produced like inflammations of other parts, is to be treated like them, relaxing the solids, which are too much stretched, and giving free passage for the humours.

This method of deduction was called by the ancients *medicina rationalis*, or *dogmatica*, in opposition to the *empirica*, called also *epilogisin*, which was conducted by appearances only without theory.

ANALYSIS, derived from *αναλυω*, *to resolve*, in a general sense, is the resolution of something compounded into its constituent parts.

ANALYSIS, in *Chemistry*. The whole of the practical and experimental part of chemical science may be properly included under the art of analysis, a complete account of this, therefore, would require the enumeration of almost every known fact in chemistry; and the inferences and general deductions from these facts would comprehend all that is valuable in the philosophy of chemistry. To treat the subject thus fully would, however, be inconsistent with the plan of this work, and would be little satisfactory to the reader, except such a system of arrangement was adopted, as would admit of reference to any particular part without the necessity of consulting the rest. For these reasons we have thought it upon the whole most convenient to subdivide all that relates to the subject of analysis in the following manner. For the general method of analysing animal matters, see **ANIMAL matter**; of vegetable matter, see **VEGETABLE matter**; of minerals in general, see **MINERAL analysis**; of mineral waters, see **WATERS, mineral**.

The analysis of metallic ores will be treated of generally under **ORES**, and particularly under each metal.

ANALYSIS, grammatical, is that employed about words, their etymons, homonyms, or various acceptations, synonyms, constructions, uses, and the like.

Pafor has given a grammatical analysis of the difficult words in Hesiod, &c. Sturmius has published a method of making the analysis of Latin words.

ANALYSIS, in Logic, is a method of applying the rules of reasoning to resolve a discourse into its principles, in order to a discovery of its truth or falsehood. Or it is an examination of some discourse, proposition, or other matter, by searching into its principles, and separating and opening its parts; in order to consider them more distinctly, and arrive at a more precise knowledge of the whole.

Analysis makes one great branch or species of method; and as it resolves a complex idea into its component principles, it is called also **RESOLUTION**.

It is particularly used for the reduction of an imperfect syllogism to a perfect one. This is otherwise called **REDUCTION**.

The order of the *synthesis* is contrary to that of the *analysis*, one beginning where the other ends. The two methods cannot always be used indifferently; the *analysis* is most proper for the discovery of truth, and *SYNTHESIS* for teaching and explaining it in a systematical way. Hence some call *analysis* the method of invention. See **METHOD**.

ANALYSIS of ideas, that whereby an idea is resolved into the ideas of its ingredients, and the ideas of these again into simple ones, till at length we arrive at the most simple.

ANALYSIS, in Mathematics, is properly the method of resolving mathematical problems, by reducing them into equations; and may be divided into *ancient* and *modern*.

The moderns are at some loss concerning the *ancient analysis*, i. e. concerning the art and method whereby the ancients resolved problems, and invented theorems. Some traces of their method are extant in Pappus, Apollonius, and Euclid; and Dr. Hooke suspects, that their analysis went backwards through almost all the same steps by which their demonstrations went forwards.

That this might often be the case, seems evident to any one who has studied Euclid with care. They have indeed left us no precepts of their art. This, like almost all others, must be acquired by imitation, and the excellent examples left us by the Greeks. Men of genius among the moderns, who had studied the works of the ancient geometers, have been thereby enabled to imitate them, and penetrate into their methods: the works of Huygens and Newton, and also the treatise of Conic Sections by Mr. Simpson, profes-

for of mathematics in the university of Glasgow; as also several parts of Mr. Maclaurin's Treatise on Fluxions, are evident proofs of this. Weigelius has endeavoured to retrieve the ancient analysis of Aristotle, from Euclid and other ancient geometricians.

The *ancient analysis*, as Pappus has described it in his "Mathematicæ Collectiones," lib. vii. p. 157, ed. Commandini, Pisaur. 1588, is the method of proceeding from the thing sought taken for granted, through its consequences, to something that is really granted or known; in which sense it is the reverse of synthesis or composition, that commences with the last step of the analysis, and traces the several steps backward, making that in this case antecedent, which in the other was consequent, till we arrive at the thing sought, which was assumed in the first step of the analysis. The principal authors on the ancient analysis, enumerated by Pappus (*ubi supra*) are Euclid in his "Data," "Porismata," and "De Locis ad Superficiem;" Apollonius, "De Sectione Rationis," "De Sectione Spatii," "De Tactionibus," "De Inclinationibus," "De Locis Planis," and "De Conicis;" Aristæus, "De Locis Solidis;" and Eratosthenes, "De Mediis Proportionalibus." Pappus himself, who has given many examples from the preceding writers, may be added to the above number. This analysis has also been cultivated by many of the moderns, as Fermat, Viviani, Ghetaldus, Snellius, Huygens, Simson, Stewart, Lawson, &c. and particularly by Hugo d'Omerique, in his "Analysis Geometrica," in which he has endeavoured to restore the analysis of the ancients. Sir Isaac Newton, as we are informed by Dr. Pemberton, ("View of Sir Isaac Newton's Philosophy," preface,) always professed himself a great admirer of the ancients, and even censured himself for not following them more closely than he did. He also regretted his mistake at the beginning of his mathematical studies, in applying himself to the works of Des Cartes and other algebraic writers, before he had considered the Elements of Euclid with that attention which so excellent a writer deserves. He used to commend the laudable attempt of Hugo d'Omerique to restore the ancient analysis; and very much esteemed Apollonius's book, "De Sectione Rationis," for giving us a clearer notion of that analysis than we had before; and he particularly recommended Huygens's style and manner. In the application of the ancient analysis for the solution of geometrical problems, strict rules cannot be laid down, nor any previous instructions be delivered, from which it may not be necessary to deviate. Some preparation is necessary in order to form a connection between the data and *quæsitæ*, which must be suggested to the mind of the analyst by a due consideration of the nature of the problem; and the skill of the analyst was manifested in discovering the most proper preceding operations, on which his analysis was to be founded. As an example we may give the 15th proposition of the 7th book of Pappus, p. 257. From the extremes of the base A and B (*Plate I. Geometry, fig. 14.*) of a given segment of a circle, let it be required to draw two lines AC, BC, meeting at a point C in the circumference, which shall have to each other the given ratio of F to G. Pappus resolves this problem in the following manner: *Analysis*. Suppose the thing done, or that the point C is found: and draw CD a tangent to the circle at C, and meeting AB produced in D. By the hypothesis AC : BC :: F : G; and AC² : BC² :: DA : DB; which may be thus proved. DC touches the circle, and BC cuts it; and therefore by Euclid, lib. iii. prop. 32, the angle BCD = BAC, and the angle D being common to both the triangles DCA and DCB; these triangles will be similar; and DA : DC :: DC : DB; and consequently DA² : DC² :: DA : DB. Moreover, DA : AC ::

DC : CB, and DA : DC :: AC : CB, or DA' : DC' :: AC' : CB' ; and therefore by equality, AC' : BC' :: DA : DB. But the ratio of AC' to BC' is given by prop. lvii. of Simson's edition of the "Data;" because the ratio of AC to BC is given, and consequently that of DA to DB is given. Then by Data vi. the ratio of DA to AB is given; and hence by Data ii. DA is given in magnitude. Here the analysis properly ends. For it has been shewn that DA is given, or that a point D may be found in AB produced, such, that a tangent being drawn from it to the circumference, the point of contact will be the point sought; and therefore we may begin the composition, or synthetical demonstration, by finding the point D, or laying down the line AD, which was given in the last step of the analysis.

Synthesis. Construction. Make $F' : G' :: AD : DB$, which may be done, as AB is given, by making $F' - G' : G' :: AB : DB$, and then by composition, it will be $F' : G' :: AD : DB$; then from the point D thus found, draw a tangent to the circle, and from the point of contact C drawing CA and CB, the thing is done.

Demonstration. Since by constr. $F' : G' :: AD : DB$, and $AD : DB :: AC' : BC'$; we shall have $F' : G' :: AC' : BC'$, and consequently $F : G :: AC : BC$. Q. E. D.

In this problem we have an instance of the method of resolution and composition practised by the ancients, the solution here given being that of Pappus himself. But as the method of referring to the "Data" may appear operose, and as it is not absolutely necessary, the rigour of the ancient method of solution may be abated, whilst its admirable elegance and perspicuity are preserved. This may be exhibited in another solution of the same problem, which is as follows:

Analysis. Suppose again that the thing is done, *v. z.* AC : BC :: F : G, and draw BH, making the angle ABH = ACB, and meeting AC produced in H. Then as the angle A is common, the triangles ABC and ABH are equiangular, and therefore AC : BC :: AB : BH, in a given ratio; and, AB being given, BH will be given in position and magnitude.

Synthesis. Construction. Draw BH, making the angle ABH equal to that which may be contained in the given segment, and take AH to BH in the given ratio of F to G. Draw ACH and BC.

Demonstration. The triangles ABC, ABH are equiangular, therefore AC : BC :: AB : BH, which is the given ratio by construction.

Modern Analysis comprehends algebra, arithmetic of infinites, infinite series, increments, fluxions, &c. for an account of each of which, see the respective articles. The modern analysis is a general instrument by which the finest inventions and the greatest improvements have been made in mathematics and philosophy for the last two centuries. It furnishes the most perfect examples of the manner in which the art of reasoning should be employed; it gives to the mind a wonderful skill for discovering things unknown by a few things given; and by employing short and easy symbols for expressing ideas, it presents to the understanding things which would otherwise lie beyond its sphere. By means of this, geometrical demonstrations may be abridged: a long train of reasoning, aided and facilitated by visible symbols, and the various operations which it requires, performed by the arrangement and combination of these symbols. By this artifice a great number of truths may be expressed in a single line, whereas, in the ordinary process, they would occupy pages, or even volumes: and thus by the contemplation of one line of calculation, we may acquire in a short time the knowledge of a whole science, which, without this aid, could scarcely be comprehended in several years.

Sir Isaac Newton, indeed, who well knew the advantages of analysis in geometry and other sciences, frequently lamented, that the study of the ancient geometry should be neglected and abandoned; and it must be allowed that the method employed by the ancients in their geometrical writings is more rigorous than that of the modern analysis; and though it be greatly inferior to that of the moderns, in point of dispatch, and facility of invention, it is nevertheless highly useful in strengthening the mind, improving the reasoning faculties, and accustoming the young mathematician to a pure, clear, and accurate mode of investigation and demonstration, though by a long and laboured process, to which he would reluctantly have submitted, if his taste had been vitiated, as it were, by the modern analysis. On this circumstance were principally founded the complaints of Newton, who feared, lest by the too early and frequent use of the modern analysis, the science of geometry should lose that rigour and purity, which characterise its investigations, and the mind become debilitated by the facility of our analysis. He was therefore fully justified in recommending, to a certain extent, the study of the ancient geometers; whose demonstrations, being more difficult and operose, afford greater exercise to the mind, accustom it to a closer application, extend its views, and habituate it to patience and resolution, so necessary for making discoveries. This, however, is the only or principal advantage resulting from it; for, if we were restricted to the method of the ancients, it is probable that persons of the most acute and comprehensive genius would have made few or inconsiderable discoveries, in comparison of those obtained by means of the modern analysis. And even with regard to the advantage attending investigations, pursued in the manner of the ancients, which is that of being more rigorous, it may perhaps be doubted whether this pretension be well founded. As for those of Newton himself, who conducted his demonstrations in the manner of the ancients, it is evident that he investigates his theorems by a method different from that employed in the demonstrations, which are commonly analytical calculations, disguised by substituting the name of lines for their algebraical value; and though it must be acknowledged, that his demonstrations are rigorous, it is no less true that they would be the same when translated and delivered in the algebraic language; and what difference can it make in this respect, whether we call a line AB, or denote it by the algebraic character *a*? Indeed, this last designation has this peculiarity, that when all the lines are denoted by algebraic characters, many operations can be performed upon them, without thinking of the lines or the figure. And this circumstance is very advantageous, as it relieves the mind, so that its whole energy may be employed in overcoming the natural difficulty of the problem itself. Upon a comparison of the ancient and modern analysis, the result seems to be, that the method of the ancients is the best adapted to the commencement of our studies, as it serves to form the mind, and to fix proper habits; and that of the moderns should succeed, and is best suited to extend our views beyond the present limits, and to assist us in making new discoveries and improvement. Montucla Hist. des Mathematiques, tom. i. p. 166. p. 195. Hutton's Math. Dict. tom. i.

ANALYSIS is divided by some authors into *simple* and *compound*.

ANALYSIS, *simple*, is that employed in solving problems reducible to simple EQUATIONS.

ANALYSIS, *compound*, or *complex*, that which gives the expressions or solutions of problems in compounded EQUATIONS.

ANALYSIS is farther divided, with regard to its object, into that of *finites*, and that of *infinites*.

ANALYSIS of finite quantities, is what we otherwise call *specious arithmetic*, or ALGEBRA.

ANALYSIS of infinites, called also the new analysis, is particularly used for the *method of fluxions*, or the *differential calculus*.

The great advantage of the modern mathematicians beyond the ancients arises chiefly from the use of this modern analysis.

The chief writers upon the analysis of infinites are, its inventor Sir Isaac Newton, in his "Analysis per Quantitatum Series, Fluxiones, & Differentias, cum Enumeratione Linearum tertii Ordinis;" and "De Quadratura Curvarum;" and M. Leibnitz, in Act. Eruditor. an. 1684. The Marquis De l'Hôpital, in his "Analyse des Infiniments petites," 1696. Carre, in his "Methode pour la Mesure des Surfaces, la Dimension des Solides, &c. par l'Application du Calcul Integral," 1700. G. Manfredi, in a posthumous piece, "De Constructione Aequationum differentialium primi gradus," 1707. Nic. Mercator, in Logarithmotechnica," 1668. Cheyne, in "Methodus Fluxionum inversa," 1703. Craig, in "Methodus Figurarum linearum rectis & curvis comprehensarum Quadraturas determinandi," 1685; and "De Quadraturis Figurarum curvilinearum & locis," &c. 1693. Dav. Gregory, in "Exercitatio Geometrica de Dimensione Figurarum," 1664; and Nieuwentijt, in "Considerationes circa Analyseos ad Quantitates infinite parvas applicatae principia, 1695. The sum of what is found in l'Hôpital, Carre, Cheyne, Gregory, and Craig, is collected into one volume, and very well explained, by C. Hayes, under the title of a "Treatise of Fluxions," &c. 1704. And the substance of most of the rest in Pere Reynau's "Analyse Demontrée, 2 vols. 4to. 1728. De Moivre also, Maclaurin, and Mr. T. Simpson, may be added to the number.

ANALYSIS of powers, denotes the resolving them into their roots. In this sense analysis amounts to the same with what we otherwise call EVOLUTION.

We find divers other kinds of analysis treated of by mathematical writers, as the *analysis of indivisibles*, &c. M. Leibnitz spoke of an *analysis situs*, different from the analysis of magnitudes.

The analysis of geometrical curves shews their properties and internal constitution, their curvature, points of inflection, station, retrogradation, variation, &c. In this analysis curves are usually considered as polygons, composed of an infinite number of infinitely little sides, but this supposition is neither accurate nor necessary, though it sometimes affords convenient hints for invention.

F. Reynau, of the *Oratory*, has given a large system of algebra, under the title of analysis. F. Casse censures it as not sufficiently methodical or systematical. The great divisions and members are lost in the multitude of particular rules and methods.

ANALYSIS, in *Rhetoric*, is that which examines the connections, tropes, figures, and the like, inquiring into the proposition, division, passions, arguments, and other apparatus of rhetoric.

Several authors, as Freigius and others, have given analyses of Cicero's Orations, wherein they reduce them to their grammatical and logical principles; strip them of all the ornaments, and additions of rhetoric, which otherwise disguise their true form, and conceal the connection between one part and another. The design of these authors is to have those admired harangues, just such as the judgment disposed them, without the help of imagination; so that here we may coolly view the force of each proof, and admire the use Cicero made of rhetorical figures, to conceal the weak part of a cause.

A collection has been made of the analyses formed by the

most celebrated authors of the sixteenth century, in three volumes folio.

ANALYSIS of Soils, in *Agriculture*. See SOILS.

ANALYSIS of Vegetables. See VEGETABLES.

ANALYSIS is also used as a kind of syllabus, or table of the principal heads or articles of a continued discourse; disposed in their natural order and dependency.

Analyses are more scientific than alphabetical indexes; but they are less used, as being more intricate.

ANALYSIS is likewise used for a brief, but methodical illustration of the principles of a science; in which sense it is nearly synonymous with what we otherwise call a *synopsis*.

ANALYST, a person who analyses a thing, or makes use of the analytical method. In which sense analyst amounts to much the same with *computist* or *calculator*.

Some restrain the word more peculiarly to denote a mathematician, who makes a great use of the algebraic method or *calculus* in geometry, in exclusion of the *synthetic*, or strict geometrical method.

In a sense not unlike this Dr. Berkeley, an ingenious writer, gives the title *analysis* to a book against the modern *geometry*, or doctrine of *fluxions*.

ANALYTIC, *ANALYTICAL*, something that belongs to, or partakes of, the nature of analysis.

Thus we say, an analytical demonstration; analytical inquiry; analytical table, or scheme; analytical method, &c. The analytic method stands opposite to the *synthetic*. See METHOD.

ANALYTICS, *ANALYTICA*, the science or doctrine and use of *ANALYSIS*.

To the modern analytics principally belongs *algebra*; the history of which, with the several authors thereof, see under ALGEBRA.

ANALYTICS, in *Literary History*, is particularly used to denote certain writings of Aristotle under this title.

Aristotle's Analytics consist of four books, two under the denomination of *former*, *Αναλυτικων προτερων*, and as many under that of *latter*, *υστερων*. They belong to the class of his acroamatic works. Fabr. Bibl. Græc. lib. iii. cap. 6.

ANALYTICS is also used by some for a part of *LOGIC*, which teaches to decline and construe reason, as grammar does words.

ANAM, in *Geography*, is called by the Portuguese COCHIN-CHINA, and bends its hollow curvature along the coast, from lat. 13° to 17° 30'.

ANAMABOA, or *JAMISIA*, a large and populous town in the kingdom of Fantin, on the gold coast of Africa, where the English have a fort. The inhabitants are generally deceitful and fraudulent, and are very artful in debasing and counterfeiting their gold coin. Anamaboa is reckoned the most powerful town upon the whole coast. It is divided into two parts; one part inhabited by the fishermen of Elmina, the other by those of Fantin, who pay a certain duty to the brass for the liberty of pursuing their occupation. The greatest inconvenience attending the situation of the English fort at this place, arises from the difficulty of landing from the ships, as the shore is covered with rocks projecting into the sea, and the surf rises to a great height; and, on this account, those that trade here, are landed by means of canoes upon a sandy point, surrounded by a wall, which is built by the company, and rendered convenient by lodgings for the negroes under the cannon of the fort. The soil is adapted for making bricks; the shells upon the coast furnish excellent lime; and the country affords great plenty of timber. The adjacent country is mountainous, but the hills are at a distance from the town, serve as land-marks at sea, and being covered with trees, afford an agreeable prospect. The country is populous, and very rich in gold, slaves, and all the necessaries of life, but more particularly

particularly in corn; and the palm wine is excellent. Their opulence has rendered the inhabitants haughty and arrogant. In the woods of this country are found the most beautiful paroquets, and a great variety of other birds. Fruits, roots, and vegetables of every kind abound, and are cultivated with little trouble. The English fort is a large edifice, flanked by two towers, and fortified towards the sea with two bastions; it is constructed of brick and stone cemented with lime. It stands upon a rock at the distance of 30 paces from the sea; it is mounted with 12 pieces of cannon, and 12 patereroes, and defended by a garrison of 12 whites and 18 blacks, under the command of the chief factor.

The natives formerly treated the English garrison with so much insolence, as often to block them within their walls, and frequently, if they disliked the governor, they sent him in a canoe to Cape Coast, with marks of the utmost contempt. The negroes of Fantin are the most turbulent upon the coast. In 1701 they declared war against the English, and, assembling in a tumultuous manner, set fire to the exterior building, and proceeded with their outrages, till they were dispersed by a discharge of the cannon from the batteries. The English, however, took their revenge, by laying the greater part of the town of Anamaboa in ashes; and hostilities continued for some time, till at last the natives were obliged to sue for peace. The fort was abandoned in 1733, but again resumed by the English, who have maintained possession of it ever since.

ANAMANI, ANAMANES, or AMANES, in *Ancient Geography*, were friends and allies of the Romans, who inhabited Cisalpine Gaul, at the foot of the Apennines to the south of the Po, having Trebia to the west, and Tarns for their principal rivers. In the extent of their country were found Placentia, Veleia, Florentia, and Julia Fidentia.

ANAMARI, a people mentioned by Polybius, and placed in the vicinity of Marseilles.

ANAMASCIA, or ANAMATIA, a town of Lower Pan-
nonia, and placed by M. d'Anville south of Acinova.

ANAMBA, in *Geography*, an island in the Indian sea, west of Borneo. N. lat. 2° 58'. E. long. 106° 44'.

ANAMIM, the second son of Mizraim, Gen. x. 13. Broughton takes his descendants to be the Numidians, amongst whom he finds Anubis. Others suppose that they were the Anaitæ of Ethiopia. But as they were the descendants of Mizraim, and must be sought for about Egypt, the opinion of Bochart is more probable, who conceives them to be the Nomades, who lived about Ammon and Nasamonitis; and were called Anamii, from Anam, which signifies a sheep among the ancient Egyptians, as it does among the Arabians. For the Nomades fed sheep, as Herodotus informs us, and lived upon them, whereas, they abstained from eating cows or swine; and their garments also were of sheep-skins.

ANAMIS, in *Ancient Geography*, a river mentioned by Arrian (cap. xxxiii.), and supposed to be the same with that which is called Andamis by Pliny and Ptolemy. It belonged to Carmania. M. d'Anville places this small river on a strait, which forms the communication between the sea and the Persian gulf.

ANAMMELECH, in *Scripture History*, an idol of the Sepharvites, who are said (2 Kings, xvii. 31.) to have burned their children in honour of this deity and Adrammelech. These were the same gods with Moloch, to whom the same sacrifices were offered. The Jewish rabbins represent one in the form of a peacock, and the other of a pheasant; but they were probably only different names of Moloch, which was the sun: the addition of Addir, signifying magnificent or potent, makes Adrammelech or the mighty Moloch, and of Ana, denoting to answer, forms Anam-

melech, or the Oracular Moloch. Dr. Hyde (Rel. Vet. Perf. cap. ii. p. 63.) is of opinion, that Adrammelech signified the king of the flock; *Adre* denoting *greges*; and *Ana* being the same with *pecus* in the Persian language, and expressing the lesser cattle, *viz.* the sheep and goats; Anammelech was of much the same signification. These gods, he conceives, had the care of the flocks; and as the riches of these people consisted in cattle, were made the objects of their worship. They were also celestial constellations, as he observes, which, as the people imagined, promoted the breed and growth of cattle. Others make Adrammelech the sun, and Anammelech the moon.

ANAMNESEIS, from *ανα* and *μνησειν*, *I remember*, in *Ancient Writers*, denote encomiums of persons who had behaved well in war, or on other occasions, rehearsed before the emperors of Constantinople, to put them in mind of bestowing suitable rewards.

ANAMNESTICS, in *Medicine*, are used by some writers to denote those signs which help to discover the past state of a patient's body in which sense it stands opposed to **PROGNOSTICS**.

These are otherwise called *rememoratives*.

Some have used this term for medicines that are supposed to improve the memory, or restore it when lost. But this is a general title, says Dr. Cullen (Mat. Med. vol. i. p. 166.) which seems to have no foundation at all, or which, if it had, is too general, and would be very improperly employed.

ANAMOOKA, or ROTTERDAM, in *Geography*, one of the Friendly islands, in the South Pacific Ocean. It is situated in S. lat. 20° 15', and W. long. 174° 31', about 18 leagues distant from Tongataboo, or Amsterdam; which it resembles in its aspect. Its form is triangular, and none of its sides exceed the length of four miles. Its extent is also diminished by a large salt lagoon which almost cuts off its south-eastern angle from the rest. Its walls are surrounded by small islets, sand banks, and reefs, by which is formed a harbour on the south-western side of the island, with anchorage in 10 and 12 fathom, the bottom being coral sand. It is well sheltered, but no fresh water is to be obtained near the shore. On the north-west side are two coves, to which are narrow passages for boats through the reefs. To the southward of these is a bank, free from rocks, with 20 and 25 fathom depth, one or two miles from shore. The coast rises nearly perpendicular, 15 or 20 feet from the sea, and the interior appears level, excepting some small hillocks, and a more considerable one toward the centre of the island. It is similar to Tongataboo in soil and productions, but less cultivated, even in proportion to its size. It is, however, better furnished with water, though somewhat brackish, having a pond about three quarters of a mile from the landing-place on the north-west side, of half a mile in circuit. This island was discovered by Tasman, in 1643, and called Rotterdam. Captain Cook arrived at it in 1774. Thefts were more frequently committed here than at the southernmost islands of the group; the character of the women appeared also to be more licentious, and that of the men more daring. Some of the natives distinguished themselves by their good conduct, and most of them behaved well, except when they were tempted to steal some of the novelties possessed by their visitors. Capt. Cook returned to this island in 1777. Lieutenant Bligh, in the *Bounty*, anchored at Anamooka in 1789. Pine apples, which had been planted in the islands visited by Capt. Cook, were found here at that time in a flourishing state. Capt. Edwards twice visited Anamooka in 1791. No subsequent visit to this island has been made known. It is ranked by the natives amongst the smaller islands of their Archipelago, which

which contains 35 larger than this. A disease of the leprous kind, which seems to be common to all the islands of this ocean, is said to prevail more at Anamooka than in any other part of this group. The venereal disease, introduced here by the English, has made a lamentable progress. As wood is an article procured here by all the ships, care should be taken to avoid an accident, which may occur in cutting a tree, called by the natives *saitanoo*. This is a species of pepper, and yields a milky juice that injures the eyes and skin of the workmen. Missionary Voyage, Prelim. Disc. p. 56—60.

ANAMORPHOSIS, compounded of *ana* and *μορφή*, form, in *Perspective* and *Painting*, a monstrous projection; or a representation of some image, either on a plane or curve surface, deformed and distorted: which at a certain distance shall appear regular, and in proportion.

To make an anamorphosis, or monstrous projection on a plane. Draw the square ABCD (*Plate 1. Perspective, fig. 1.*) of any size at pleasure, and subdivide it into a number of areolas, or lesser squares. In this square, or reticle, called the *craticular prototype*, let the image to be distorted be drawn. Then draw the line *ab* (*fig. 2.*) equal to AB; and divide it into the same number of equal parts, as the side of the prototype AB; and in E, the middle of it, erect the perpendicular EV, so much the longer, and draw VS perpendicular to EV, so much the shorter, as the image is designed to be more distorted. From each point of division draw right lines to V, and join the points *a* and S, by the right line *a S*. Through the points *d, e, f, g*, draw lines parallel to *ab*; then will *abcd* be the space in which the monstrous projection is to be delineated; called the *craticular ectype*.

Lastly, in every areola, or small trapezium of the space *abcd* draw what appears delineated in the correspondent areola of the square ABCD; by this means you will obtain a deformed image, which yet will appear in just proportion to an eye distant from it by the length of EV, and raised above it by the height VS.

It will be diverting to manage it so that the deformed image may not represent a mere chaos but some other image: thus, we have seen a river with soldiers, waggon, &c. marching along the side of it, so drawn, that when viewed by an eye in the point S, it appears to be the satirical face of a man.

An image also may be distorted mechanically, by perforating it here and there with a needle, and placing it against a candle or lamp; and observing where the rays, which pass through these little holes, fall on a plane, or curve superficies; for they will give the correspondent points of the image deformed; by means whereof, the deformation may be completed.

Let the image, whatever it be, e. g. IHS, be drawn upon a cylinder of paper or pasteboard, AFCD (*fig. 3.*); and the perforations being made as now described, place a candle G, behind the cylinder, and mark upon the ground the points corresponding to the perforations of the image, which will be distorted more or less, according to the position of the candle, or the plane, &c. Then, let the picture that is formed be an exact copy of this distorted image, and substitute a metallic speculum in the place of the cylinder, and let the eye of the spectator have the same position before the cylinder that the candle had behind it, the distorted image will, by reflection from the speculum, be restored to its proper shape.

ANAMORPHOSIS, to draw the, or deformation of an image, upon the convex surface of a cone.—It is manifest from the former case, that here it is merely required to make a craticular ectype on the superficies of the cone, which shall

appear to an eye duly placed over its vertex equal to the craticular prototype.

Let the base, or periphery, ABCD, therefore, of the cone (*fig. 4.*) be divided by radii into any number of equal parts; and let some one radius be likewise divided into equal parts; and through each point of division draw concentric circles: thus will the craticular prototype be made. With double the diameter AB, as a radius, describe the quadrant EFG (*fig. 5.*) so that the arch EG may be equal to the whole periphery: then this quadrant, duly folded, will form the superficies of a cone, whose base is the circle ABCD. Divide the arch EG into the same number of equal parts as the craticular prototype is divided into; and draw radii from all the points of division. Produce GF to I, so that FI = EG: and from the center I, with the radius IF, draw the quadrant FKH; and from I to E draw the right line IE. Divide the arch KF into the same number of equal parts as the radius of the craticular prototype is divided into; and draw radii through each of the points of division, from the centre I, meeting EF, in 1, 2, 3, &c. Lastly, from the centre F, with the radii, F 1, F 2, F 3, &c. describe the concentric arches. Thus will the craticular ectype be formed, the areolæ of which will appear equal to each other.

Hence what is delineated in every areola of the craticular prototype, being transferred into the areolæ of the craticular ectype, the images will be distorted or deformed; yet an eye raised above the vertex of the cone, at a height equal to that of the cone itself, will perceive them in just proportion.

If the chords of the quadrants be drawn in the craticular prototype, and chords of the four parts in the craticular ectype, all things else remaining the same, you will have the craticular ectype in the quadrangular pyramid.

And hence it will be easy to deform any image, in any other pyramid, whose base is any regular polygon.

Because the eye will be more deceived, if from contiguous objects it cannot judge of the distance of the parts of the deformed image; therefore, these kinds of deformed images are to be viewed through a small hole; and when they are made to appear like the objects which they are intended to represent, by means of a mirror of any particular construction, these anamorphoses are said to be reformed. See MIRROR.

The original author of this ingenious device is not known. Simon Stevinus first wrote upon it, without informing us from whom he acquired it. The principles of it are laid down by S. Vauzelard, in his "Perspective Conique et Cylindrique;" and Gasper Schottus, professing to copy Marius Bettinus, in his description of this piece of artificial magic. Other methods more exact and geometrical than that above described, in which a lamp or candle was used, were afterwards invented, and rules laid down for drawing the requisite figures. Schottus quotes one of those methods from Bettinus, another from Hevignonius, and another from Kircher, which may be seen in his "Magia," vol. i. p. 162, &c. He also gives an account of the methods of reforming pictures by speculums of conical and other figures. The method given by Dr. Smith, (in his Optics, vol. i. p. 250.) is, without doubt, the best; and from this any person may easily make a drawing of the same kind. The same description answers to two mirrors, one of which, *fig. 6.* is convex, and the other, *fig. 7.* is concave. In order, therefore, to paint upon a plane a deformed copy, ABCDEKIHGF, of an original picture, which shall appear regular, when seen from a given point O, elevated above the plane, by rays reflected from a polished cylinder, placed upon the circle,

circle, *lup*, equal to its given base; draw from the point R, which is supposed to be directly under O, the place of the eye, two lines *Ra*, *Re*, which shall either touch the base of the cylinder, or else cut off two small equal segments from the sides of it; as the copy is intended to be more or less deformed. Then taking the eye, raised above R, to the given height RO, somewhat greater than that of the cylinder, for a luminous point, describe the shadow *ackf*, of a square *acxz*, *fig. 8.* or parallelogram standing upright upon its base *ac*, and containing the picture required, any where behind the arc *lup*. Let the lines drawn from R to the extremities and divisions of the base *a*, *b*, *c*, *d*, *e*, cut the remotest part of the shadow in the points *f*, *g*, *b*, *i*, *k*, and the arc of the base in *l*, *m*, *n*, *o*, *p*; from which points draw the lines *lAf*, *mBg*, *nCh*, *oDi*, *pEk*, as if they were rays of light that came from a focus R, and were reflected from the base *lup*; so that each pair, as *lA*, *lR*, produced, may cut off equal segments from the circle. Lastly, transfer the lines *luf*, *mvg*, &c. and all their parts, in the same order, upon the respective lines *lAf*, *mBg*, &c. and having drawn regular curves, by estimation, through the points A, B, C, D, E, through F, G, H, I, K, and through every intermediate order of points; the figure ACEKHF, so divided, will be the deformed copy of the square, drawn and divided upon the original picture, and will appear similar to it, when seen in the polished cylinder, placed upon the base *lup*, by the eye in its given place O.

The practical methods of drawing these images seem to have been carried to the greatest perfection by J. Leopold, who, in the Leipzig acts, for the year 1712, has described two machines, one for images to be viewed with a cylindrical, and the other with a conical mirror. The person, who has this instrument, may take any point at pleasure, and whilst he goes over the outlines of it with one pen, another traces the anamorphosis.

By methods of this kind, groves of trees may be cut, so as to represent the appearance of men, horses, and other objects from some one point of view, which are not at all discernible in any other. This might easily be effected by one person placing himself in any particular situation, and giving directions to other persons, what trees to *lup*, and in what manner. In the same method it has been contrived, that buildings, of circular and other forms, and also whole groupes of buildings, consisting of walls at different distances and with different positions to one another, should be painted so as to exhibit the exact representation of particular objects, which could only be perceived in one situation. Bettinus has illustrated this method by drawings, in his "Apriaria."

In the cloister of the Minims, in the Place Royale, at Paris, there are two anamorphoses traced upon two of the sides of the cloister, one representing a Magdalen, and the other St. John, writing his gospel. They are so managed that when viewed directly, they appear like a kind of landscape, but from a particular point of sight they appear very distinctly, like human figures. These two figures were executed by Nicéron, a Minim, who published a treatise, entitled "Thaumaturgus Opticus," in which he has described the manner of tracing anamorphoses on any surfaces. In tom. iv. of the Memoirs of the Imperial Academy of Petersburg we have the description of a similar anamorphosis, by Mr. Lutman, in honour of Peter II., emperor of Russia. On the subject of this article, see Wolfii Elementa Mathematicos, &c. vol. iii. cap. v. p. 99, &c. Priestley's History, &c. of Vision, &c. p. 93—96.

ANAMSAGAR, in *Geography*, a town of Hindostan, in the county of Vitiapoor, 51 miles east of Baddamy, and 71 south-east of Galgala.

ANANAS, in *Botany*, by some called *nans*, and by others *jayama*, and popularly the *pine-apple*, on account of the resemblance it bears to the cones of pines and firs, is a species of BROMELIA.

ANANAS, in *Natural History*, a species of MADREPORA, in the fourth order of VERMES, *Zoophyta*, the stars of which are angular, convex, and concave in the disk. Linnæus. This kind inhabits the Mediterranean and South American seas, and is often found in a fossil state.

ANANCITIS, in *Antiquity*, a kind of figured stone, otherwise called synochitis, to which superstition ascribed a magical virtue in raising the shadows of the infernal gods.

ANANDRIA, in *Botany*, a species of TUSILAGO.

ANANES, in *Geography*, three small islands in the Grecian Archipelago, about three leagues south-west of the island of Milo.

ANANISABATA, or ANANISAPTA, in *Antiquity*, a magical word inscribed on coins and other amulets, and supposed to have efficacy in preserving the wearer from the plague.

ANANTHOCYCLUS, in *Botany*. See COTULA.

ANANTPOUR, in *Geography*, a town of Hindostan, in the Mysore country, 85 miles north-east of Chitteldroog, and 140 north-north east of Srirangapatam.

ANANUS, the YOUNGER, in *Biography*, a Sadducee, was appointed high-priest of the Jews by Agrippa, the younger, about A. D. 60. Josephus (*Antiq. lib. xx. cap. 8. § 1.*) represents him as fierce and haughty in his behaviour, and extremely resolute and daring; and as belonging to the sect of the Sadducees, who were above all other Jews cruel in their judicial sentences. Upon the death of Festus the Roman governor, and before the arrival of Albinus, appointed to be his successor, Ananus called a council, and bringing before it James, our Lord's brother, and some others, he accused them as transgressors of the laws, and had them stoned to death. Josephus says, that many were offended at this proceeding. Some, he says, went running to meet Albinus, who was coming from Alexandria, and put him in mind, that Ananus had no right to call a council without his leave. Albinus approving of what they said, wrote a very angry letter to Ananus, threatening to punish him for what he had done, and king Agrippa took away from him the priesthood, after he had enjoyed it three months, and put in Jesus, the son of Damnaeus. Dr. Lardner infers from this circumstance, as well as others, that the Jews had not at this time the power of life and death. Works, vol. i. p. 81.

ANANUS, a learned Jewish Rabbi, who flourished about the year 760. He was denied the title of gaon or excellent, though a man of great learning, on account of some material error of which his doctrine was suspected; and the suspicion appears to have been well founded, as he became the reviver and chief of the Sadducean sect, which, after having been long almost extinct, became formidable to that of the Pharisees. Gantz Tzemach David, p. 725.

ANAON PORTUS, in *Ancient Geography*, *Santo Hospitio*, an obscure port, which the author of the "Itinerarius Maritimus," commonly supposed to be Antonine, places between the Portus Herculis and Nicæa. Clavier has confounded it with Avifio. M. d'Anville places it in a small creek, at the extremity of a small peninsula, to the east of Nicæa, and forming to the west the Portus Divula, and to the east the Portus Avifio.

ANAPÆST, ANAPÆSTUS, a foot in the *Greek and Latin poetry*, consisting of two short syllables, and one long, being the reverse of the dactyl.

The word is derived from *ἀναπαύω*, *contra ferio*, because in dancing this measure, the ground was struck in a contrary order from what it was in the dactyl. Whence the Greeks called it *ἀναπαύωτος*. *Dion.* in. p. 74.

Such are the words *ἀναπαύωτος*, *ἀναπαύωτος*.

Hæc Vossius (de *Viribus Rhythm.* p. 56) has said that the English have no perfect anapaest in their language. But Dr. Burney (*Hist. Music.* vol. i. p. 79) observes, that the change is easily confuted by the mere mention of the words *recommend* and *disappoint*.

ANAPÆSTIC, or ANAPÆST, is sometimes used in a substantive sense.

Such is the *anapaestus Aristophanicus*, in Cicero, which is a verse consisting of eight feet, as

“Axena ponti per freta colchos denique delatus adhæsi.”

Vide Cic. in *Orat.* cap. 56. *Fabr. Thef.* in voc. *Anapaestus*.

This is otherwise called *anapaestus ædonarius*.

ANAPÆSTIC, in an adjective sense, something relating to or composed of *anapaests*.

ANAPÆSTIC kind, *genus anapaesticum*, is a sort of verse composed of pure Aristophanic or Parthenaic *anapaests*.

Anapaestic verses are either Aristophanic or Pindaric.

Anapaestic Aristophanicus, called also *Parthenaicus*, consists of three anapaests, and one long syllable, but so as that instead of the first two anapaests, as many spondees may be used.

Its type stands thus :

“Venient cito secula quum jam
Socius calor ossa revifet
Animataque sanguine vivo
Habitacula pristina geslet
Lacrymas suspendite cuncti
Mors hæc reparatio vita est.” *Bona.*

Pindaric Anapaest admits, in the first place, either of an anapaest or a spondee; in the second, only of an anapaest; in the third, of an anapaest or a spondee; in the fourth, either of a spondee or a trochee.

As in the following type :

“In summa pericula venturi
Multos timor ipse mali mittit.”

ANAPAUMENE, in *Ancient Geography*, a fountain of Greece, in the Molossis, which was part of Epirus. It was situated near that of Dodona, and was also denominated “fons Jovis.”

ANAPES, in *Geography*, a town of Flanders, one league from Lille.

ANAPHE, in *Ancient Geography*, an island of the Cretan sea, supposed to be one of the Cyclades to the east of Thera. *Steph. Byz.* says, that it was one of the Sporades. Its first name was *Memliaros*, which it derived from Membliaros, the Phœnician, who, when his relation went in quest of Europa, accompanied him, and settled in the neighbouring island of Thera. It was afterwards called Anaphe, a Phœnician word, which, according to Bochart, signifies shaded and dark, an epithet given to this island, on account of its gloomy and thick forests. But the most commonly received

opinion is, that it owes this name of Anaphe to the Greek word *ἄνα*, to *appear*, from the thunder having on a sudden occasioned it to rise from the bottom of the waters, in order to receive the fleet of the Argonauts, on its return from Celebis, when assailed by a furious tempest. The fable of antiquity is the history of the formation of this island, now called Nansio, which a volcano caused to appear suddenly above the sea, in the midst of a violent agitation of the ætæosphere and the waves, which has happened to some other islands of the Archipelago. In memory of this event was built a temple, mentioned by Strabo, which was consecrated to Apollo Ægletes, or dazzling with light. Slight vestiges of this temple still remain on the place which it occupied, in the south part of the island; and the marble of which it was constructed was taken from a very steep rock, of a terrifying aspect, on whose summit is now seen a chapel, dedicated to our lady of the reed; in modern Greek “panagia kalamitosa.” For a further account of the present state of this island, see NANFIO.

ANAPHYLYSTUS, a small maritime town of Attica, in the tribe of Antiochides, very near Athens, towards the cape Colias, and north-west of CEXORA. It had temples of Pan, Ceres, Venus Colliades, and the goddesses called Genetylides. This place is now called *Limos*.

ANAPHORA, *ἀναφορά*, signifying *repetition*, in *Rhetoric*, a verbal figure, whereby one or more words are repeated in the beginning of several sentences or verses.

This is a lively and elegant figure, and serves very much to engage the attention; for by the frequent return of the same word the mind of the hearer is held in an agreeable suspense till the whole is finished.

Such, *e. gr.* is this of the Psalmist, “The voice of the Lord is powerful: the voice of the Lord is full of majesty: the voice of the Lord shaketh the wilderness.”

“You do nothing,” says Cicero to Catiline; “you attempt nothing, you think nothing, but what I not only hear but also see, and plainly perceive.” This figure is frequently used by way of interrogation, which renders it not only beautiful, but likewise strong and nervous. Thus Cicero, at the beginning of the same speech: “Does neither the night-guard of the palace, nor the city-watch, nor the people’s fear, nor the agreement of all good men, nor the meeting of the senate in this fortified place, nor the countenances and looks of this assembly, at all move you?” And in another of his orations: “What is so popular as peace, which seems to afford a pleasure, not only to beings endowed with sense, but even to inanimate nature? What is so popular as liberty, which even beasts as well as men seem to covet and prefer above all things? What is so popular as ease and leisure, for the enjoyment of which you and your ancestors have undergone the greatest labours?” *Contra Rull.* ii. c. 4. *Ward’s Oratory*, vol. ii. p. 56.

ANAPHORA is used in the *Ancient Medicine*, for the rejection of matter by the mouth.

Hence also we met with the term *anaphorici*, *ἀναφορικοί*, used for those labouring under an *hæmoptoe*, who bring up blood from the lower part of the mouth.

ANAPHORA, among *Ecclesiastical Writers*, denotes the host, or species offered in the *eucharist*.

ANAPHORA is also used to denote the rehearsing of a person’s name from the *DIPTYCHS* in the liturgy.

ANAPHORA is also a title given to those little Syriac liturgies, wherein are contained the prayers after the *osculum pacis*. Ignatius, patriarch of the Maronites, enumerates forty of these anaphoræ.

ANAPHORA, in *Astrology*, denotes the second house, or that

that part of heaven which is thirty degrees distant from the HOROSCOPE.

The term anaphora is sometimes also promiscuously applied to some of the succeeding houses; as the second, fifth, eighth, and eleventh. In this sense anaphora amounts to the same with *epanaphora*, and stands opposed to *cataphora*.

ANAPHORA is also applied by some to the oblique ascensions of the stars.

ANAPHRODISIA, from *ανα* and *Αφροδίτη*, *Venus*, denotes impotency in respect of venery. Some also use it for a want of desire or inclination to the sex.

In this sense the academists *Natura Curiosa* give an extraordinary instance of this kind in a person otherwise healthy and robust. Eph. Acad. N. C. Dec. i. ann. 8. Obs. 94. See IMPOTENCY.

ANAPHUS, in *Entomology*, a species of PAPHILIO, in the division *Plebeii Urbicolæ*, that inhabits Surinam. It has no tail, and is uniformly brown, except the apex of the lower wings, which is yellow. Fabricius.—The antennæ are hooked at the end.

ANAPHYSEMATA, from *ανα*, and *φυω*, *I send forth*, in some *Ancient Writers*, denote winds issuing from under ground, at the clefts or apertures thereof.

These are sometimes called by later writers *σφογαι*.

ANAPLASIS, from *ανα* and *πλασσω*, *I form*, in *Surgery*, the complete restitution of a broken bone, so that the two ends meet, and close exactly together. This is the same with what is otherwise called *diaplysis*.

ANAPLASIS also signifies a re-nutrition of the extenuated flesh.

ANAPLEROSIS, in the general sense, denotes REPLETION. Anaplerosis is more particularly used to denote that part of surgery whereby things wanting are supplied.

In which sense anaplerosis amounts to the same with what we otherwise call apposition, or PROSTHESIS.

ANAPLEROSIS, in the *Civil Law*, is a name which some give to the four last books of Justinian's Code.

ANAPLEROTICS, from *αναπλερωω*, *I fill up*, in *Medicine*, such remedies as incarnate and fill up ulcers and wounds with new flesh.

Anaplerotics are the same with what we otherwise call INCARNATIVES.

ANAPODARI, in *Geography*, a river of the island of Candia, which rises at Castell Bonifacio, runs near Castell Belvedere, and discharges itself into the sea between Cape Matola and Castell de Girapetra. The ancients called it *Cataractus*.

ANAPODOPHYLLUM, in *Botany*. See PODOPHYLLUM.

ANAPUIA, in *Geography*, a province of Venezuela, in South America, towards the mountains of St Peter, and the source of the Buria.

ANAPUS, or ANAPIS, in *Ancient Geography*, the name of a river of Sicily, which ran from west to east at the distance of about two miles from Ortygia, and somewhat less than a mile and a half from Neapolis, and discharged itself into the great harbour of Syracuse. This stream, which is only 24 feet wide, and 12 or 15 deep at its mouth, flows, in a serpentine course, through a small extent of country, which, though slightly elevated in its south or south-western side, on the north and north-west consists of an extensive marshy plain. This plain lying between the river and the city, is terminated by two fens or moors, the one called Syrac, whence the city was named, and the other Lyfimela. Between the Anapus and the promontory of Plenyrum, was situated the little suburb of Olympia, surrounding the site of the ancient temple of Jupiter Olympus, built upon an eminence, and bounded

on either side by the vast Lyfimelian marshes, extending from the head of the great harbour, half covered with water in the vernal months, and exhaling, under an almost vertical sun, the most unwholesome and pernicious vapours. To this river the ancients gave the name of ALPHEUS.

ANAPUS was also a river of Illyria, which ran near Liffus.

ANAPUS was also a river of Epirus, in Chaonia. Thucydides reckons So Italia from this river to Stratos, or Stratus, a considerable place of Acarnania.

ANAQUITO, in *Geography*, a country of America in Peru and in the province of Quito.

ANARA, in *Ancient Geography*, a town of India, on this side the Ganges, according to Ptolemy.

ANARACI, a people of Scythia, on this side Mount Imaus, according to Ptolemy.

ANARCHI, people of Scythia, placed by Ptolemy below the Agathyrsi.

ANARCHI MONTES, mountains of Scythia, forming part of the chain of Imaus.

ANARCHI, in *Antiquity*, a name given by the Athenians to four supernumerary days in the year, during which they had no magistrates.

The Attic year was divided into ten parts, according to the number of tribes, to whom the presidency in the senate fell by turns.

Each division consisted of 35 days; what remained after the expiration of these to make the lunar year complete, which, according to their computation, consisted of 354 days, were employed in the creation of magistrates, and called *αναρχοι ημεραι*, and *αρχαιεστια*.

ANARCHY, derived from the Greek privative *α*, and *αρχη*, *principality*, the want of government in a nation, where no supreme authority is lodged, either in the prince or other rulers; but the people live at large, and all things are in confusion.

All kinds of states are subject to anarchies. We read of civil anarchies, ecclesiastical or spiritual anarchies, and even anarchies in the republic of letters.

Anarchy is supposed to have reigned after the deluge, before the foundation of monarchies. We still find it obtain in divers parts, especially of Africa and America; *e. gr.* among the Itinois, who are observed by travellers to live in a perfect independency of any superior; among the Californians, where every family makes its own laws as well as religion; in Chili, where every master of a family is a king; in the Marian islands, where neither prince nor law is known, but every person governs himself according to his own will; and to mention no more, among the Hottentots, where the only resemblance of government is, that in each neighbourhood, the eldest is the first in honour, and his advice chiefly followed, not from any civil authority he is vested with, but on account of his superior experience.

Some extend the idea of anarchy farther, so as to make it comprehend all the more popular governments. In this sense anarchy amounts to much the same with DEMOCRACY. Hobbes, in this sense, calls the Roman commonwealth an anarchy.

It has sometimes been controverted which of the two is best, a state of anarchy, or of tyranny and arbitrary power. This controversy, however, does not appear to be of any great use; it is of little purpose to determine which is best, since a state of anarchy, naturally, nay, necessarily, paves the way for despotism; and confusion is always the parent of oppression.

ANARCHY is also applied to certain troublesome and disorderly

disorderly periods, even in governments otherwise regular. In Germany, the interval from the election of Richard, duke of Cornwall, to that of duke Rud. of Hapsburg, is commonly called the anarchy, or interregnum.

In England, the period between the death of Cromwell and king Charles's Restoration, is commonly represented as an anarchy. Every month produced a new scheme or form of government. Enthusiasts talked of nothing but annulling all the laws, abolishing all writings, records, and registers, and bringing all men to the primitive level. No modern nation has been more subject to anarchies than Poland; where every interval between the death of one king, and the election of another, was a perfect picture of confusion, inasmuch that it became a proverb among that people, Poland is governed by confusion.

The Jewish history presents numerous instances of anarchies in that state usually denoted by this phrase, *that in those days there was no king in Israel, but every man did that which was right in his own eyes*, which is a just picture of an anarchy. The first anarchy we read of in that commonwealth, is that which ensued on the death of Joshua, who leaving no successor, the government devolved to the elders of the tribes, who ruled each according to his own will. After the death of these elders the anarchy became complete.

ANARGYRI, in *Ecclesiastical History*, is an appellation given to certain saints in the Greek church, who having been physicians, gave not only their advice but their remedies gratis. They are also called *argentinos*.

ANARGYRUS, from α and $\alpha\gamma\gamma\upsilon\sigma\iota\omicron\nu$, money, in *Ancient Writers*, denotes a person without money, though otherwise sufficiently accommodated with land and other effects.

In a like sense we sometimes also meet with the word anargyria, used by lawyers for the condition of a person without ready money.

Mart. Phil. Fabricius has a dissertation *De Exceptione Anargyriae*.

ANARHAPHE, from $\alpha\alpha$ and $\rho\alpha\phi\eta$, future, in *Surgery*, denotes a kind of future or retraction of the upper eye-lid, when relaxed and hanging over the eye.

This is by some also called *futura blepharica*, by others *abreviatio, contractio, collectio, or suspensio superioris palpebrae*. It is used in the *phalangosis, ptosis, or chalasis*; where the sight is obstructed by a *prolapsus* of the part, or the eye-lid itself is too thick beset with bristly hairs both within and without.

ANARHICHAS, in *Ichthyology*, a genus of the order Apodes. The head is obtuse, fore teeth in each jaw conic, large, divergent, six in number or more grinders in the lower jaw, and palate rounded: Six rays in the gill membrane. Body roundish, tail fin distinct. Linn. Gmel.—The species of this genus are LUPUS, MINOR, and PANTHERINUS, which see.

ANARIA, in *Ancient Geography*, *Ischia*, an island south-east of Baia. Augustus gave it to the inhabitants of Neapolis, in exchange for the island of Caprae. It was also called Pythecusa.

ANARIACA, a town which, according to Strabo, was near the Caspian sea. It is supposed to have been situated between Albania and Hircania.

ANARIS MUNDI PROMONTORIUM, was situated, according to Ptolemy, in the island of Taprobana.

ANARIUM, a town of Asia, in Greater Armenia, according to Ptolemy.

ANARPI, a people placed by Ptolemy in Germany.

ANARRHINON, in *Botany*, a name given by some of the ancients to the plant called by others $\lambda\upsilon\chi\eta\iota\varsigma$ *agria*, and by others *antirrhinum*. Pliny tells us, that this plant

resembled flax, that it had scarce any root; that its flower was the colour of the hyacinth, and its fruit resembled the nose of a calf. It is from this resemblance that we at this time call the plant *calves' snout*. Dioscorides says, that it was like the *anagallis*.

ANARTES, or ANARTI, in *Ancient Geography*, a people who inhabited the north-west part of Dacia, according to Caesar and Ptolemy.

ANARTHRA, from α and $\alpha\epsilon\theta\epsilon\rho\alpha$, joint, in *Natural History*, a class of naked insects, distinguished from all others by having neither wings nor limbs. To this class, belong all kinds of worms and leeches.

ANARTOPHRACI, in *Ancient Geography*, a people placed by Ptolemy in Sarmatia, adjacent to the Ombrones, in European Sarmatia.

ANAS, now called GUADIANA, a river of Spain in Bætica.

ANAS, in the Linnæan system of *Ornithology*, the name of an extensive genus of birds, of the order ANSERES, and known in England by the general names of SWANS, GEESE, and DUCKS. The Linnæan character of this genus is taken from the form of the bill and tongue; the bill being convex, obtuse, and the edges of both mandibles beset with lamellated teeth: the tongue ciliated and obtuse. Linn. Gmel. To this concise general distinction some authors add, that the bill is strong, broad, depressed, and commonly furnished at the end with an additional piece or nail; nostrils small and oval; tongue broad, and fringed at the edges, near the base; toes four in number, three being placed before, and one behind, and the middle one longest. Latham. Gen. Syn.

The species of this genus, according to the latest authorities of Linnæus, Latham, Gmelin, &c. are,

<i>Acuta</i> , pintail duck	American teal
<i>Adunca</i> , hooked bill duck	<i>Casarca</i> , ruddy goose
<i>Egyptiaca</i> , Egyptian goose	<i>Cinerea</i> , ash-coloured, or loggerhead goose
<i>Africana</i> , African teal	<i>Circia</i> , summer teal
<i>Albeola</i> , buffel-headed duck	<i>Clangula</i> , golden-eyed duck
(Latham).	<i>Clypeata</i> , shoveller
<i>Allicans</i> , brown-necked duck	<i>Coromandeliana</i> , Coromandel teal
<i>Albifrons</i> , white-fronted goose	<i>Coscoroba</i> , Chili goose
<i>Alexandrina</i> , Alexandrian duck	<i>Crecca</i> , common teal
<i>Americana</i> , American duck	<i>Cristata</i> , crested duck
<i>Anser</i> , wild goose, or grey-lag	<i>Curvirostra</i> , curve-billed duck
<i>Antarctica</i> , Antarctic goose	<i>Cygnoides</i> , Chinese goose
<i>Arabica</i> , Arabian teal	<i>Cygnus</i> , wild or whistling swan
<i>Arborea</i> , black-billed whistling duck	<i>Damiatia</i> , Damietta duck
<i>Atrata</i> , black swan (Philips)	<i>Difcors</i> , blue-winged teal
<i>Autumnalis</i> , red-billed whistling duck	<i>Dispar</i> , western duck
<i>Babauensis</i> , Ilithera duck	<i>Domestica</i> , common tame duck
<i>Balbul</i> , cahira duck	<i>Dominica</i> , St. Domingo duck
<i>Beringii</i> , Bering goose	<i>Dominicana</i> , Dominican duck
<i>Bernicla</i> , Brent, or Brand goose	<i>Erythropus</i> , Bernacle goose
<i>Borealis</i> , Gulaund duck	<i>Erythrorhyncha</i> , crimson-billed duck
<i>Boschas</i> , wild duck	<i>Falcaria</i> , falcated duck
<i>Brasilienfis</i> , Mareka duck	<i>Ferina</i> , pochard, or red-headed wigeon
<i>Bucephala</i> , buffel-headed duck (Gmel.)	<i>Ferruginea</i> , ferruginous duck
<i>Cerulefcens</i> , blue-winged goose	<i>Formosa</i> , Baikal teal
<i>Cana</i> , grey-headed goose	<i>Fuligula</i> , tufted duck
<i>Canadensis</i> , Canada goose	<i>Fulva</i> , Mexican pochard
<i>Capensis</i> , Cape wigeon	<i>Fusca</i> , velvet duck
<i>Carolinensis</i> , Carolina, or	<i>Fuscifcens</i> , brown duck
	<i>Galericulata</i> , Chinese teal
	<i>Gambensis</i> ,

<i>Gambensis</i> , spur-winged goose	<i>Mollissima</i> , eider duck
<i>Gaittoir</i> , Gattair duck	<i>Monacha</i> , white and black variegated duck
<i>Georgica</i> , Georgia duck	<i>Montana</i> , mountain duck
<i>Glacialis</i> , long-tailed duck (Latham)	<i>Moschata</i> , Muscovy duck
<i>Glaucion</i> , grey-headed duck	<i>Nigra</i> , black duck
<i>Glocians</i> , bimaculated duck	<i>Nigricollis</i> , black-necked swan
<i>Gmelini</i> , Russian teal	<i>Nilotica</i> , Nilotic duck
<i>Grandis</i> , great goose	<i>Novæ Hispaniæ</i> , Mexican duck
<i>Hina</i> , Hina teal	<i>Novæ Seelandiæ</i> , New Zealand duck
<i>Histrionica</i> , harlequin duck	<i>Nyræa</i> , Tannain tufted duck
<i>Hybrida</i> , Hybrid swan	<i>Obscura</i> , dusky duck
<i>Hyemalis</i> , long-tailed duck (Edwards)	<i>Olor</i> , mute swan
<i>Hyperborea</i> , snow goose	<i>Orientalis</i> , Muscovy gander (Gmelin)
<i>Jacquini</i> , chestnut-coloured duck	<i>Penelope</i> , wigeon, or whim
<i>Jamaicensis</i> , Jamaica shoveller	<i>Perispicillata</i> , black duck
<i>Indica</i> , barred-headed duck (Latham)	<i>Pisina</i> , painted goose
<i>Islandica</i> , Iceland duck	<i>Poecilorhyncha</i> , spotted-billed duck (Latham)
<i>Kagolka</i> , Kagolka duck	<i>Querquedula</i> , garganey
<i>Kekuschka</i> , Kekuschka duck	<i>Regia</i> , white-collared blue duck
<i>Labradorica</i> , pied duck	<i>Rubens</i> , red-breasted shoveller
<i>Leucephala</i> , white-headed duck	<i>Rufa</i> , rufous-necked duck
<i>Leucoptera</i> , bustard goose	<i>Ruficollis</i> , red-breasted goose
<i>Lurida</i> , lurid duck	<i>Rufina</i> , red-crested duck
<i>Madagascariensis</i> , Madagascarean teal	<i>Ruslica</i> , little brown duck
<i>Magellanica</i> , Magellanic goose	<i>Scandiaca</i> , Lapmark duck
<i>Malacorhynchos</i> , soft-billed duck	<i>Segetum</i> , bean goose
<i>Manillensis</i> , Manilla teal	<i>Sirfair</i> , Sirfair duck
<i>Marilla</i> , scaup duck	<i>Spectabilis</i> , king duck
<i>Marsa</i> , ural duck	<i>Spinosa</i> , spinous-tailed teal
<i>Melanocephala</i> , black-headed swan	<i>Sponsa</i> , summer duck
<i>Melanotos</i> , black-backed goose	<i>Stelleri</i> , western duck
<i>Melanura</i> , black-tailed duck	<i>Strepera</i> , gadwall, or grey
<i>Mexicana</i> , Mexican duck	<i>Superciliosa</i> , supercilious duck
<i>Minuta</i> , minute duck	<i>Tardona</i> , shieldrake
	<i>Torquata</i> , ringed goose
	<i>Torrída</i> , torrid duck
	<i>Variiegata</i> , variegated goose
	<i>Viduata</i> , Spanish duck; which see respectively.

ANASARCA, from *ana* and *σαρξ*, *flesh*, in *Medicine*, a sort of universal dropsy, wherein the whole or considerable part of the body is stuffed or bloated with watery fluid.

This distemper is sometimes also called *catasarca*, sometimes *hypofarcidium*, sometimes *epifarcidium*, sometimes *aqua inter cutem*, or *intercus*, because the humour spreads itself through the flesh. Serenus Samonicus elegantly calls it *lymphaticus error*; Albucasis calls it a dropsy by infiltration.

Prænatural collections of water in any part of the body, except the urinary bladder, are called DROPSIES. Some of these are confined to particular cavities, and take their name from that of the cavity, as, *hydrothorax*, or a dropsy in the chest; *ascites*, a dropsy of the ABDOMEN, &c. but anasarca may take place in any part of the body where there is *cellular membrane*. Dr. Cullen places it in his third class, *CACHEXIÆ*, order, *Intumescentiæ*, aquosæ, and admits several species of it, depending on the remote cause. The most usual and general Cause of anasarca is debility, whether induced by fatigue, or watching without lying down, by hæmorrhage, by eruptive fevers, or by deficient or watery food. It is sometimes believed to arise during pregnancy, from the

pressure of the uterus on the veins which return the blood from the lower extremities.

The *Essential Character* of this disease is founded on the swelling being pale, soft, and leaving a pit after pressure with the fingers.

Symptoms. As anasarca affections differ much in degree or severity from a slight swelling of the feet and ankles towards night, to a general diffusion of water throughout the cellular membrane of the whole body and extremities; so the symptoms or degrees of distress experienced by the patient are greatly diversified. That which first attracts his attention is a stiffness of the ankles, after remaining long in the erect posture. This increases daily till the feet, legs, and thighs become so large, that the skin seems in danger of bursting. When the disease approaches towards this magnitude, the water shifts its place with the posture of the body; so that after lying in the horizontal posture all night, the swelling of the legs will be much diminished, while that of the trunk, arms, and face will be increased. In this stage the patient often experiences *dyspnea* and thirst, with loss of appetite; the secretion of urine is diminished; the *scrotum*, or *labia* are so distended, that walking becomes impracticable, when the swelling and stiffness of the feet alone would not have rendered it so. This is the usual progress of anasarca; but it sometimes supervenes so suddenly, that the whole body will partake of the swelling in twenty-four hours. There is no doubt that it may often exist alone, without any other species of dropsy; we however very commonly find it combined with HYDROTHORAX, or ASCITES; and it is then of course more difficult of cure. The *prognosis* is generally unfavourable, in old people especially, or those who have injured their constitution by the abuse of spirituous liquors. Where the affection is slight, and brought on by sitting up for several days and nights, in a good constitution we may always expect a cure.

The *treatment* should be adapted to the state and degree of the disease. In slight affections of short standing, flannel rollers to the feet and ankles, with bark or steel internally, will generally succeed. In severe cases we attempt the cure on the following plan, *viz*.

1. We obviate all causes of debility by diet, air, and exercise; and we endeavour to restrain all debilitating evacuations.

2. We should then employ the means which are found most successful in evacuating the collected fluid. The first of these is to promote its absorption; which is done,

A. By the *pressure* of bandage and friction, with or without mercurial ointment.

B. By *Emetics*; especially hydrarg. vitriolatus, cuprum vitriolatum, pulvis antimoniæ, and, above all, elaterium in powder.

C. By *Purgatives*, such as calomel, gamboge, elaterium and jalap combined with crystals of tartar, nitre, or kali acetatum. The absorption, in this case, most probably, is a consequence of the increased excretion from the intestines.

When the aqueous fluid is absorbed and carried into the blood, the secretion by the kidneys is commonly increased, by which it is carried out of the body. But if this should not take place, we have recourse to those medicines called

D. *Diuretics*. Whether these exert their action on the kidneys alone, or whether they produce their effect by promoting the activity of the absorbent system, is not ascertained. The most successful diuretics are mercury, whether introduced by friction or taken internally; and it appears to be a good preparation

tion for the employment of all other remedies of this class. Squills, recent or dried, or an infusion of them in Lisbon wine; the tincture of digitalis, which being a medicine of great power, requires diligent watching; kali saturated with vinegar of squills; the juice of leeks: the extract of broom tops; the infusion of juniper berries with sweet spirit of nitre, infusion of tobacco, &c. &c. The *doses* of these medicines are not set down, as practitioners know them, and they are too powerful to be prescribed by others. If these remedies fail of producing the desired effect, and the skin of the legs, scrotum, &c. seems in danger of burbling, we may have recourse to punctures. These should be made in depending parts, that the water may drain off more freely, and very small, on account of the danger of gangrene, which is a frequent consequence of large and deep incisions.

3. When by such means as these we have evacuated the water, or a great part of it, we must attempt to invigorate the system by bark, steel, bitters, riding, sea bathing, and a generous diet.

Dr. Dover's cure for an anasarca is an electuary composed of steel prepared with sulphur and crude antimony, each an ounce; *diagridium*, four ounces; make a fine powder of these; then add as much of any syrup as will make a soft electuary.

ANASCHOUADI, in *Botany*. See ELEPHANTOPUS.

ANASSA. See BROMELIA.

ANASSAS, in *Natural History*, the name of a fruit very common in Guinea, and in some other parts of Africa. It is very beautiful to the eye, and not less agreeable both to the taste and smell, and is by some accounted the finest fruit in the world. The descriptions we meet with of it are very imperfect; but as there is nothing in them that contradicts its being the pine-apple, it may be that fruit, and if so, it deserves all the praise that is given it. See BROMELIA.

ANASSUS, or ANAXUS, in *Ancient Geography*, a river of Italy, in the territory of Venice, now the *Piave*. According to M. d'Anville, it runs from the north to the south, and falls into the bottom of the gulf, to the west of Aquileia, near Muranum.

ANASTAMIA, in *Geography*, a considerable sea-port town of Japan, the principal commerce of which is wood.

ANASTASIA, in *Ancient Geography*, a town of Mesopotamia, nearly south of Nisibis. It was for a long time a small place known by the name of Dara. When the Persians and Romans concluded a treaty, the emperor Anastasius fortified Dara, enlarged and beautified it, and called it Anastasia.

ANASTASIOPOLIS, a name given to five cities; one in Syria, another in Phrygia, a third in Caria, a fourth in Galatia, and a fifth in Thrace.

ANASTASIS, a Greek word adopted into the English language, which denotes a resurrection.

Chiffet has given us a dissertation on Childeric's tomb, under the title of *Anastasis Childerici*. Truer has published the figure of a man and woman in the ancient German habit, as found in an ancient urn, under the title of *Anastasis veteris Germani Germanaque Faminae*.

ANASTASIS, among *Ancient Physicians*, denotes a rising up to go to stool. It likewise signifies a migration of humours, when expelled from one place and obliged to remove to another.

ANASTASIUS I. in *Biography and History*, emperor of the east, was born at Duras, in Illyricum, A. D. 430; and, from being one of the officers of the great chamberlain,

called *Silentiarii*, and before he had obtained the rank of senator, was advanced to the empire, A. D. 491. His promotion was owing to the interest and influence of Ariadne, the widow of Zeno, who prevailed upon the senate to acknowledge Anastasius, in opposition to the claims of Longinus, the brother of Zeno, as his successor. As soon as he had attained this dignity he married Ariadne, being then in the 60th year of his age. Such was the estimation in which he was generally held, on account of his temperance and integrity, before his advancement, that, upon his receiving the purple and diadem in the circus, the people, applauding his promotion, exclaimed with one voice, "Reign, Anastasius, as you have lived." The first act of his reign confirmed their expectations; for he immediately remitted whatever was due to the treasury, and entirely abolished the invidious tax, called the *CHRYSARGYRUM*. He also expelled all informers from Constantinople, and put a stop to the enormous abuse, introduced by his predecessor Zeno, of expelling to sale all public offices, and bestowing, to the great oppression of the people, the best governments on the highest bidders. The tranquillity of his reign, though thus popular at its commencement, was soon interrupted by the rebellion of Longinus and the Isaurians, who, seizing the arms and money lodged by Zeno in a fort of Isauria, were enabled to raise and equip an army of 150,000 men. Conon, bishop of Apamea, in Syria, abandoning his flock, joined his countrymen, and became one of the ringleaders of the revolt. The emperor, however, soon collected a force, which, under the conduct of two of the most renowned generals of that age, *viz.* John, the Scythian, and John, surnamed Gibbus, or the lurch-backed, encountered the rebels in the vicinity of Cocytea, in Phrygia, cut off a great number of them, and obliged the rest to seek refuge among the inaccessible mountains of Isauria, where they maintained themselves for six years, notwithstanding the utmost efforts of the best generals of the empire. In the following year the emperor, whose temper was naturally avaricious, deviated from the liberal plan with which he commenced his reign, and laid a heavy tax on the inhabitants of Constantinople, called *evagrius chrysetelia*, which, being unexpected, incensed them to such a degree, that they resorted to arms, demolished the emperor's statues, and dragged them through the chief streets of the city, together with those of the empress Ariadne, uttering very injurious invectives against her and Anastasius. This tumult was no sooner suppressed than it was succeeded by others equally mischievous and dangerous; in one of which the emperor narrowly escaped being murdered in the circus by the populace, because he refused to release some prisoners who had been concerned in a riot. In 499 the Bulgarians invaded Thrace, and defeated the Romans; and in 502 the Persians entered Armenia with a powerful army, took Amida, pillaged the town, and put most of the inhabitants to the sword. In the mean time Anastasius dispatched a strong force against the enemy, which was defeated. However, in the following year, Amida was again besieged, and upon the conclusion of a truce between the Romans and Persians, the city was restored to the former, on condition of their paying to the king of Persia fifty talents. This truce between the two empires was concluded A. D. 505. About this time, Mondo, a Goth, having settled, with many of his countrymen, in some uninhabited places beyond the Danube, seized on a fortress called Herta; and from hence, by frequent incursions into the Roman territories, continued to harass the subjects of the empire, and assumed the title of king. Anastasius dispatched against him Sabinianus, at the head of 10,000 chosen men; and this circumstance obliged Mondo to seek the favour of Theodoric, the Gothic king

of Italy, who had the year before reconquered Pannonia, and recovered Scrinium out of the hands of the Gepidae. Mondo, by this alliance with Theodoric, was enabled to defeat Sabirianus in a pitched battle, near Margus, in Lower Dacia, and forced him to take refuge in the castle of Nato. The consequence of these hostilities was a misunderstanding between Anastasius and Theodoric. Such were the dangers that threatened Constantinople and the adjacent country, that Anastasius was obliged to betray the impotence of his arms by building a bulwark, called the *long wall*, and the *wall of Anastasius*, of which the Byzantine historians make frequent mention. This wall was distant from Constantinople about 40 miles, and extended about 60 miles from the Propontis to the Euxine, inclosing not only the metropolis, but the city of Selymbria, and the neighbouring country, which was a cultivated garden, with an incredible number of stately villas and houses of pleasure, richly furnished and adorned. It was 20 feet broad, and defended by towers at small distances from each other, by which means the inhabitants, upon the shortest warning, had an opportunity of putting themselves in a posture of defence, and of easily repulsing the barbarians. He likewise caused the city of Daras, a frontier town towards Persia, to be repaired and fortified, in order to prevent the Persians from invading the empire on that side. The other difficulties with which Anastasius struggled were inconsiderable, compared with those in which he was involved by a religious war, the first that disgraced the Christian name. The emperor, who was a zealous patron of the doctrine of Eutyches, abolished the orthodox addition, "who was crucified for us," that had been made by the devotion of Antioch to the "Trifagion," *i. e.* thrice holy, "Holy, holy, holy, Lord God of hosts," which was a hymn used in public worship. This alteration occasioned a violent tumult, in which many persons lost their lives; and the emperor was compelled to take refuge in his galley, till the orthodox patriarch, Macedonius, had pardoned and interceded for him. Macedonius was afterwards banished, and upon his exile the sedition was again renewed; the statues of the emperor were broken, and his person was concealed in a suburb, till, at the end of three days, he ventured to implore the mercy of his subjects. Accordingly Anastasius, without his diadem, and in the posture of a suppliant, appeared on the throne of the circus, and was happy to reconcile himself with his people by the sacrifice of two unpopular ministers who were condemned to the lions. These furious but transient seditions were encouraged by the success of Vitalian, one of the emperor's generals, who, espousing the cause of Macedonius, and the other orthodox bishops, persecuted by Anastasius, approached Constantinople with a numerous army of Huns and Bulgarians, and threatened to depose the emperor, if the banished bishops were not restored, and the Eutychians expelled. As the emperor hesitated in complying with this demand, Vitalian, the champion of the catholic faith, depopulated Thrace, besieged Constantinople, and exterminated 65,000 of his fellow Christians, till at length he obtained the recall of the bishops, the satisfaction of the pope, and the establishment of the council of Chalcedon. In consequence of this treaty, which Anastasius was compelled to sign, A. D. 514, Vitalian withdrew from Constantinople, and disbanded his troops. Pope Symmachus, it is said, engaged in this quarrel, and, by excommunicating Anastasius, set the first example of the employment of spiritual thunder against sovereigns. Anastasius, delivered from his fears, renewed his persecution of the catholics; but he did not long survive the humiliating act to which he was obliged to submit. In the year 518, the 88th year of his age, and the

28th of his reign, he suddenly closed his life, being as much hated and reproached by his subjects in his latter years, as he had been beloved and extolled in his earlier days. By the Catholic historians he is charged with avarice and cruelty, and almost all the crimes that could disgrace a sovereign; but his want of orthodoxy, which, in their judgment, was one of his greatest crimes, might possibly induce them to exaggerate his other bad qualities. The vast treasure which he possessed at his death was accumulated by the sale of public offices, and by sharing with his governors the spoils of an oppressed people. *Anc. Un. Hist.* vol. xiv. p. 443—451. *Gibbon's Hist.* vol. vii. p. 129. vol. viii. p. 314.

ANASTASIUS II. whose proper name was Artemius, was advanced by the free voice of the senate and people, to the throne of Constantinople, A. D. 713, from the low condition of a secretary to his predecessor Philippicus, who had been deposed.

He was a man of learning and prudence, and had been from his youth employed with singular success in the management of public affairs. In the beginning of his reign he appointed Leo, the Isaurian, a person of great military experience, commander in chief of all his forces, and sent him with a powerful army to the frontiers of Syria, in order to protect Asia Minor against the incursions of the Saracens. He also prepared for defeating their design of laying siege to Constantinople by a naval armament, by repairing the walls, by filling the public granaries, and by ordering those citizens, who had not laid up provisions for three years, to quit the city. When news was brought that the enemy's fleet had sailed to Phœnicia, he ordered his to assemble at Rhodes; but the admiral by his endeavours to maintain strict discipline, occasioned a mutiny, and lost his life. The seamen, dreading the punishment which they deserved, and knowing that they could not avoid it, openly revolted, declared Anastasius unworthy of the empire, and obliged Theodosius, a person of mean extraction, and receiver of the revenue at Adramyttium, to accept of the purple. Anastasius, when he heard of this revolt, fled to Nice; and Theodosius hastened to besiege Constantinople, which he reduced after a defence, on the part of the garrison, for six months. Anastasius, being promised his life by the conqueror, renounced all claim to the empire; and, assuming the habit of a monk, was banished to Thessalonica, after he had enjoyed the title of emperor about two years. In 719, whilst Leo was emperor, Anastasius quitted his retirement, and induced the Bulgarians to acknowledge and support his claim to the crown. With a numerous army of these barbarians he laid siege to Constantinople; but his followers, being disappointed in their expectation of easily becoming masters of the city, seized the unfortunate Anastasius, and delivered him up to the emperor, who put him and his accomplices to death. *Anc. Un. Hist.* vol. xv. p. 35, &c. *Gibbon's Hist.* vol. ix. p. 24. vol. x. p. 8.

ANASTASIUS, pope, succeeded Syricus in the papal chair, A. D. 398. During his pontificate a dispute arose between Jerom and Rufinus, occasioned by the following circumstance. Rufinus, being an admirer of Origen, had published a Latin translation of his "Periarchon," or treatise of principles, which was much read at Rome, and served to disseminate the distinguishing sentiments of this celebrated father. Having published this translation, without any animadversions on the part of Syricus, he left Rome, and returned to Aquileia, where he was presbyter. Upon the elevation of Anastasius, Marcella, a Roman matron, complained to the new pope of the prevalence of new doctrines, requested his interposition for preventing the evil, and accused

Rufinus

Rufinus is the author of the translation to which it was owing. Anastasius for some time declined either proceeding a second Revision, or certifying his translation; but at length Jerom, in a new version of the work, undertook to prove that several opinions of Origen were heretical, and as such ought to be condemned by the church. He also inveighed against Rufinus, suggesting, that he had translated the work of Origen merely for the purpose of propagating the errors which it contained. A council was convened, which condemned the errors of Origen, and Origen himself as a heretic, and forbade all persons, under the jurisdiction of several of the bishops, who were assembled, either to read or to retain in their possession, any of his works. Origen being thus condemned as an heretic, about 150 years after his death, Anastasius, at the instigation of Marcella, and some of Jerom's friends, summoned Rufinus to Rome, and demanded an account of his faith. Rufinus sent a confession of his faith to Anastasius, but it was not satisfactory; and the pope was at last prevailed upon to separate himself from communion with him. Anastasius has no other claim to notice than that of being a zealous defender of the catholic faith. He died in 402; and his epistle to John, bishop of Jerusalem, who had written to him in behalf of Rufinus, is extant. Fabr. Bib. Græc. lib. v. c. 35. § 8. Dupin's Ecc. Hist. vol. iii. p. 58. Bower's Lives of the popes, vol. i. p. 277. &c.

ANASTASIUS II. pope, was the son of a Roman citizen, and succeeded Gelasius, A. D. 496. He was more peaceably disposed than either of his two predecessors, and was desirous of effecting a reconciliation between the see of Rome and that of Constantinople, which had for some time been at variance. With this view he wrote a humble and respectful letter to the emperor Anastasius, and sent two bishops, accompanied by Festus the patrician, as legates, to execute his purpose. Although the bishops were well received by the emperor; he chose to confer with Festus rather than with them; and he contrived to persuade him to use his interest with the pope for reconciling the eastern and western churches, upon such terms as he thought proper to propose. The pope himself was disposed to acquiesce; and to allow the name of Acacius to remain in the Diptychs, as well as to receive and sign the HENOTICON; but this condescension on his part gave great offence to the Roman clergy. The church of Alexandria, availing themselves of the peaceable disposition of the pope, sent deputies to Constantinople in order to negotiate a reconciliation with Rome. But these pacific measures were defeated by the premature death of Anastasius. Whilst the legates were on their return to Italy, and before they reached Rome, the pope died, A. D. 498; and this unpropitious event was a great disappointment and mortification to Festus, who, depending on his inclination to peace, and the confidence reposed in him by the pope, had entertained hopes of soon restoring the ancient harmony between the east and west, and of being himself instrumental in accomplishing so desirable an object. The disposition and conduct of Anastasius, who was ready to sacrifice even the pretensions of his see to the welfare of the church, however laudable in themselves, were no recommendation to the honours that were conferred in that age of ignorance and bigotry. He was not thought worthy of a place in the calendar; and his memory has been aspersed, as if he were an enemy to the Catholic faith; and his death, before he had completed two years of his pontificate, has been represented by Platina and others as a judgment from heaven. His letter to the emperor, and another to Clovis, the first Christian king of the Franks, congratulating him on his conversion to the Chris-

tian religion, are still extant in the Books of councils. Cave's Hist. Lit. vol. i. p. 465. Fabr. Bib. Græc. lib. v. c. 35. § 8. Bower's Hist. Popes, vol. iii. p. 236, &c. Dupin, Eccl. Hist. vol. iv. p. 181.

ANASTASIUS III. pope, was by birth a Roman, and succeeded Sergius, A. D. 911. This pope, at the request of Berengarius, king of Italy, sent many rich ornaments to the church of Pavia, and granted to the bishop of that city the use of a canopy, the privilege of riding a white horse, with the cross carried before him, and of sitting in all councils at the pope's left hand. He died in 913, and was buried in the Vatican. He is commended in his epitaph for the mildness of his government, his integrity, and the purity of his manners. He died nothing blame-worthy, says Platina, which, in the popes of those days, was a subject of commendation. Bower, vol. v. p. 88.

ANASTASIUS IV. pope, was a native Roman, of the name of Conrad, and succeeded Eugenius III. A. D. 1157. His temper was mild and peaceable; of which he gave evidence in his method of compromising a difference that had arisen in the last pontificate between the emperor Frederic and the Court of Rome. For this purpose he sent cardinal Grad into Germany, whose imperious behaviour incurred the displeasure of the emperor, so that he was ordered to quit the country. The cardinal, it is said, died of grief in his way to Rome. This pope took no notice of the affront, but yielded to the emperor the point in dispute. This conciliatory conduct, which might possibly have been the means of preventing the horrors of war, has been condemned by the advocates of the dignity of the papal see, as an instance of irresolution and pusillanimity. Anastasius restored William, archbishop of York, who had been deposed by Eugenius, to his see; and in the same year he also issued a bull, confirming and enlarging the privileges of the Knights of the Hospital at Jerusalem, since known by the name of the Knights of Malta. In a great scarcity of corn, which happened during his pontificate, he manifested his humanity by liberally contributing to the relief and supply of the poor. After a Pontificate that lasted little more than a year, Anastasius died, A. D. 1154; and was buried in the church of the Lateran, in a tomb of porphyry, exquisitely wrought, in which had lain the body of St. Helena, the mother of the emperor Constantine. Ten letters of this pope are preserved in the Collections of Councils by Labbè and Harduin, and in Du Chesne's History of France. Fabr. Bib. Græc. lib. v. c. 35. § 8. Bower's Hist. vol. vi. p. 72, &c.

ANASTASIUS, anti-pope, was elected in 855 by the envoys of the emperors Lotharius and Lewis in opposition to Benedict III.; but the bishops of Ollia and Albano, alleging that he had been deposed in a council, refused to consecrate him: upon which the envoys abandoned Anastasius, and he was obliged to relinquish his pretensions. Bower's Hist. vol. iv. p. 260, &c.

ANASTASIUS *Sinaita*, a monk of Mount Sinai, lived in the sixth century, in the year 561 was promoted to the dignity of patriarch of Antioch, and died in 599. Evagrius represents him as a person eminently skilled in sacred literature, exemplary in his conduct, and scrupulously attentive to the duties of piety. He was the author of several works in Greek, which are still extant; such as "Ὁδηγός; or, "A Guide in the Way against the Acephali;" printed in 4to. at Ingolstadt in 1606. "Questiones et Responiones de variis Argumentis in S. Scripturam," numero 154; printed in Greek and Latin at Ingolstadt in 1617, 4to. "Anagogicarum Contemplationum in Hexameron, libri ii." or, "Mysterious Contemplations on the six Days' Creation," published

published in Latin, at Paris, in 1609; the 12th book was published in Greek and Latin by Alix, in London, in 1682, 4to.; a treatise, which, according to the opinion of Motheim, betrays the levity and ignorance of the author. Other tracts are preserved in the "Bibliotheca Patrum." Cave's Hist. Lit. vol. i. p. 531. Mosheim's Ecl. Hist. vol. ii. p. 127. Fabr. Bib. Græc. lib. v. c. 35. § 1.

ANASTASIUS, THEOPOLITANUS, was bishop of Antioch, and flourished in the sixth century. He espoused the opinions of a sect denominated ΑΡΗΘΑΡΤΟΔΟΞΕ, and on this account Justinian designed to depose him; but being prevented by death from executing his purpose, Justin the younger banished him in 570, and he remained in exile twenty-three years. Mauritius restored him to his see in 593. He died in the year 599, and was succeeded by another Anastasius, who was killed in a tumult by the Jews in 609. This bishop of Antioch has left some sermons, and treatises on the Trinity, and other points of faith, which were published in Latin at Ingolstadt in 1616, in 4to.; and also the "Annunciation of the Virgin Mary, and Transfiguration of Christ," published in Greek and Latin, in the first volume of "Combesii Auctarius," fol. Paris, 1648. Fabr. Bib. Græc. lib. 5. c. 35. § 1. tom. ix. p. 312. p. 332.

ANASTASIUS, the *Librarian*, was a Roman abbot and presbyter, and flourished in the ninth century. He had the charge of the Vatican Library under several popes; in 869 he assisted at the general council of Constantinople, and translated into Latin the acts of that council, and also the acts of the council of Nice, held in 787, which are still extant. To this translation he prefixed "A History of the Schism of Photius and the Council." He also wrote, or compiled, the lives of the popes down to Nicholas I. continued by others, and published with the ecclesiastical history of Nicephorus Syncellus, and Theophanes, at Paris, in 1649, fol. An enlarged edition of this work has been since published by Bianchini, in four volumes folio, at Rome, in 1718. Anastasius was a learned man, and a tolerable writer. Cave's Hist. Lit. vol. ii. p. 56. Fabr. Bib. Græc. lib. v. c. 35. § 8. tom. ix. p. 339.

ANASTATIA, *Str.* in *Geography*, a small island near the coast of East Florida, south of Matanzas inlet, where the river Matanzas forms two islands of the same name at its mouth. St. Anastatia island is bounded on the north by St. Augustine's bar. It has a quarry of fine stone for building.

ANASTATICA, formed from *αναστασις*, *resuscitating*, from its quality of reviving in water, in *Botany*, a genus of the *tetradynamia filiculosa* class and order, of the natural order *siliquose*, or *cruciformes*, and the *crucifera* of Jussieu: its characters are, that the *calyx* is a four-leaved and deciduous perianthium; leaflets ovate, oblong, concave, erect and deciduous; the *corolla* is tetrapetalous and cruciform, the petals roundish, flat and spreading, with claws nearly as long as the calyx, but more spreading; the *stamina* have six filaments, subulate, of the length of the calyx, from erect spreading; anthers roundish; the *psillum* has a bifid, very small germ, subulate style of the length of the stamens, and permanent, the stigma capitate; the *pericarpium* is a very short silicle; partition ending in a subulate point, oblique and longer than the silicle itself, the valves parallel, making a cell of the lower half, but standing out from the upper, rounded, concave, gaping, and oblique, and hence having the form of a sheep's hoof; the *seeds* are solitary and roundish. There are two species. 1. *A. hierochuntica*, thlaspi rosa de hiericho of Mor. Hist. rosa hierochuntica of Bauhin and Ray, &c. common anastatica, or rose of Jericho, with leaves obtuse, spikes axillary and very short, silicles hooped and thorny. This plant grows naturally on the coasts of the Red Sea, in Palestine, and near Cairo, in sandy places; and was cultivated in Kew Garden

by Tradescant in 1656. It has had the epithet of the *rosa Mariæ* given to it by the monks, who have superstitiously imagined that the flowers open on the night in which our Saviour was born. But the truth is, that the dry woody plant being set for some time in water, will dilate and open, so as to disclose the seed vessels and feed. This has been done when the plants have been many years gathered; so that some curious persons preserve them in their repositories of curiosities, for the singularity of this property. 2. *A. syriaca*, buniæ syriaca of Gærtner, myagram rostratum of Scop. Zan. and Pallas, thlaspi, &c. of Boec. Mus. rosa lieiicontea fylvestris of Bauhin, Syrian anastatica, with leaves acute, spikes longer than the leaf, silicles ovate, beaked, and not at all bifid. This is a native of Austria, Stiria, Carniola, Syria, and Sumatra, and was introduced in 1788 by M. Thouin. It flowers in May and June.

Culture.—These plants, being annual, can only be propagated by seeds, which rarely ripen in England, unless they be sown on a hot-bed in the Spring, and the plants afterwards put into pots, which should be plunged into another hot bed, in order to bring them forward. They will not perfect seeds unless the Summer is very hot and dry; but if they are kept in a frame, with free air in warm weather, they will flower in June, and the seeds will ripen in September. Martyn's Miller.

ANASTATICA, in *Natural History*, a species of *VORTICELLA*, in the fifth order of *VERMES*, *INFUSORIA*. It is compound, with bell shaped flowers; foot-stalks scaly and rigid. Linn. and Mull.

This is the second species of clustering polype described by Trembley. These polypes form a group resembling a cluster, or more properly an open flower; this flower or cluster is supported by a stem, which is affixed by its lower extremity to some of the aquatic plants, or extraneous bodies, that are found in the water; the upper extremity forms itself into eight or nine lateral branches perfectly similar to each other; these have also subordinate branches, whose collective form much resembles that of a leaf. Every one of these assemblages is composed of one principal branch or nerve, which makes with the main stem of the cluster an angle somewhat greater than a right one; from both sides of this nerve the smaller lateral branches proceed; these are shorter the nearer their origin is to the principal branch.

At the extremity of the principal branch, and also of all the lateral ones, there is a polype or vorticella. There are others on both sides of the lateral twigs, but at different distances from their extremity. These polypes are all exceedingly small, and of a bell-like figure; near their mouth a quick motion may be discerned, though not with a sufficient distinctness to convey an adequate idea of its cause; upon the branches of these clusters are round bodies.

Every cluster has eight or nine of these branches or leaves; they do not all proceed from the same point, but the points from whence they set out are not far asunder; each of these branches is bent a little inwards, so that all of them taken together form a kind of shallow cup. If the eye is placed right over the base of this cup, the appearance of the whole eight or nine branches is like that of a star, with so many rays proceeding from the center. If the cluster is slightly touched, all the branches instantly fold up, and form a small round mass. The stem which supports the cluster contracts also at the same time, folding up like a workman's measuring rule, that consists of three or four joints. This extraordinary assemblage constitutes one organised whole, formed of a multitude of similar and particular ones. A new species of society, in which all the individuals are members of each other in the strictest sense, and all participate of the same life.

A few days after one of these clusters is formed, small
Z round

round bodies or bulbs may be perceived to protrude in several places from the body of the branch; these grow very fast, and arrive at their greatest growth in two or three days. The bulbs detach themselves from the branches out of which they spring, and go away, swimming till they can settle upon some substance which they meet with in the water, and to which they affix themselves by a short pedicle; the bulbs are then round, only a little flatted on the under side, the pedicle continues to lengthen gradually for about twenty-four hours, during which time the bulbs also change their figure, and become nearly oval; there are in a cluster but few of these bulbs compared with the number of vorticellæ, neither do all the bulbs come out at the same time. The bulb then divides lengthways into two smaller ones, but which are still much larger than the vorticellæ themselves. It is not long before these are separated like the first, and thus form four bulbs on the same stalk; these again divide themselves and form eight, which again subdivide, and consequently make sixteen. They are all connected with the stalk by a proper pedicle, but they are not all of an equal size; the largest continue to divide, and the smallest begin to open, and take the bell-formed shape. Mr. Trembley observed from one round bulb in about twenty-four hours, by repeated divisions, one hundred and ten vorticellæ to be formed. Vide Phil. Trans. Adams Microsc. &c. &c.

ANASTOMOSIS, or **ANASTOMOSIS**, formed of *ανω*, through, and *σους*, mouth, in *Anatomy*, is sometimes used to express such aperture of the mouths of the vessels as lets out their contents.

ANASTOMOSIS is more frequently used to denote the opening of two vessels into one another; or the union and juncture of the mouths of two vessels, whereby they come to communicate with one another.

Anastomoses take place in considerable number in the absorbing and circulating vessels of animals. For an account of their number, situation, and uses, the reader is referred to the articles **ABSORBING Vessels**, **ARTERY**, *Circumstances observable in the Ramification of*, and **VLIN**, *Circumstances observable in the Distribution of*.

ANASTOMOSIS, in *Botany*, a species of **PHALLUS**.

ANASTOMOSIS, in *Entomology*, a species of **PHALÆNA** of the bombyx tribe. Thorax reddish-brown; anterior wings grey, with three whitish, anastomosing streaks. Linnæus.

The larva is brown, with white spots on the back, lateral line yellow, with a red dot on each ring; a bifid protuberance on the shoulders and tail; pupa black, with two red, longitudinal streaks; feeds on the willow.

ANASTOMOTICS, formed from *αναστομος*, I unstop, or **ANASTOMOTIC medicines**, are, in a general sense, the same as aperients; but in a more special sense, the term denotes such as are suited to open the extreme orifices of blood-vessels, so that the blood may circulate the more freely.

ANASTROUS signs, in *Astronomy*, an appellation given to the *dodecatimoria*, or the twelve portions of the ecliptic which the signs possessed anciently, but have deserted by the precession of the equinox.

ANASTROPHE, from *ανω* and *στρεψω*, I turn, in the *Ancient Military Art*, denotes the turn of a battalion to its former station, after a turn or evolution either to the right or left. The anastrophe stands opposite to the epistrophe.

ANASTROPHE also denotes a grammatical figure, whereby a preposition, which regularly ought to precede, is placed after its case, e. gr. "Saxa per et scopulos," for "per Saxa et scopulos."

ANASTROPHE, in *Rhetoric*, denotes a quaint inversion of the order of the words in a sentence, e. gr. "ut scire possis ad quo te expediat loqui," for "quo ad expediat te loqui."

ANASUS, or **AMISUS**, in *Ancient Geography*, now the

Enis, a river of Norica, which fell into the Danube. See **ENIS**.

ANATAJAN, in *Geography*, called also the island of St. Joachim, one of the Ladrone or Marianne islands, is about 30 miles in compass, and is the first of those called the northern isles. N. lat. 16° 42'. E. long. 145° 50'.

ANATHEMA, from *ανω* and *θηνω*, I lay up, in *Antiquity*, denotes a present offered to some god, and hung up in his temple.

Making presents to the gods was a custom even from the earliest times, either to pacify them when angry, or to obtain some future benefit, or as a grateful acknowledgment of some past favour. They consisted of crowns and garlands, garments, cups of gold, and other valuable metals, and any other things which conduced to the ornament, or to the enriching of the temples.

These were commonly termed *ανθηματα*, and sometimes *αυθυμια*; from their being deposited in the temple, where they were sometimes laid on the floor, sometimes hung upon the walls, doors, pillars, or the roof, or any other conspicuous place. Sometimes the occasion of the dedication was inscribed either upon the thing itself, or when the matter of that could not bear inscription, upon a tablet hung up with it.

When any person left his employment, or way of life, it was customary to dedicate the instruments belonging to it, as a grateful commemoration of the divine favour and protection. Thus in an ancient Greek epigram we find a fisherman makes a present of his nets to the nymphs of the sea. Shepherds hung up their pipe to Pan, or some of the country deities, as we find done by one in Tibullus. So Lais, decayed with age, dedicates her mirror to Venus. Pausanias has left us a particular description of the anathemata, in the Delphian temple, which was the richest of any in Greece.

The term anathema also occurs in a like sense, applied to Christian offerings.

The anathemata, or ornaments of the ancient churches, are otherwise called in ecclesiastical writers donaria.

Such in particular were those called *επιτοματα*, answering to the votive tablets of the heathens. Also pictures, mosaics, inscriptions, and at length images, statues, crucifixes, &c.

Cebes's beautiful tablature of Human Life, is said, in the introduction to it, to have been among the *ανθηματα*, in the temple of Saturn.

ANATHEMA, in an *Ecclesiastical sense*, denotes an **EXCOMMUNICATION**, attended with execrations and curses. In this sense the word is usually written in Greek *αναθημα*, to distinguish it from an offering to the gods, called *ανθημα*; though it is certain several of the Greek fathers do not observe this distinction; but use *ανθημα* indifferently for either.

There are two kinds of anathemas; the one *judiciary*, the other *abjuratory*.

The former can only be denounced by a council, a pope, bishop, or other qualified person; and differs from a simple excommunication in this, that an excommunication only prohibits the criminal from entering within the church, or from holding communion with the faithful, whereas an anathema cuts him off from the body, the society, and even the commerce of the faithful, and delivers him over to the Devil.

The latter kind of anathema usually makes a part of the ceremony of **ABJURATION**; the convert being obliged to anathematize the heresy he abjures.

The critics and commentators are divided about the manner wherein St. Paul wishes to be anathema for his brethren. Romans ch. ix. 3. See **ACCURSED**.

In ancient censures we meet with an extraordinary formula,

mula, called *marantha*; and authors are divided concerning its import and use.

St. Chrysostom says it is a Hebrew word, signifying *the Lord is come*; and he particularly applies it to the confusion of those who still abuse the privilege of the gospel, notwithstanding that the Lord was come among them.

St. Jerom says it was more a Syriac than an Hebrew word, though it had something in it of both languages, signifying *our Lord is come*. But he applies it against the perverseness of the Jews, and others, who denied the coming of Christ, making this the sense of the apostle; *if any man love not the Lord Jesus Christ, let him be anathema, the Lord is come*.

According to this sense, *marantha* could not be any part of the form of excommunication, but only a reason for pronouncing the anathema against those who expressed their hatred against Christ, by denying his coming, either in words, as the Jews did who blasphemed him, and called Jesus anathema, or accused; or else by wicked works, as those who lived profanely under the name of Christians. Others of the ancients interpret the word of the future coming of Christ, particularly St. Austin, who says, *marantha* is a Syriac word, signifying *the Lord will come*. And he particularly applies it against the Arians, who could not be said, as he uncharitably thought, to love the Lord, because they denied his divine nature. Dr. Hammond and others will have *anathema marantha* to have answered to the third and highest degree of excommunication among the Jews, called *hamnatha*.

Balduinus, Deutrohmanns, Durius, Stevartius, and others, have written expressly concerning *anathemas*. Her. Labertus, a German writer, has given an *Anathematologia*, or a discourse on the church curses. See a form of the anathema denounced against robbers in the middle ages, in Bouquet's Recueil des Hist. tom. x. p. 517. cited by Robertson, in Hist. Charles V. vol. i. p. 598. That which was issued A. D. 988, after the usual introduction, and mentioning the outrage which gave occasion to it, runs thus: "Obtenebrascant oculi vestri, qui concupiverunt; arefcant manus, quæ rapuerunt; debilitentur omnia membra, quæ adjuverunt. Semper laboretis, nec requiem inveniat, fructuque vestri laboris privemini. Formidetis, et paveatis, a facie persequentis, et non persequentis hostis, ut tabescendo deficiatis. Sit portio vestra cum Juda traditore Domini, in terra mortis et tenebrarum; donec corda vellra ad satisfactionem plenam convertantur.—Ne cessant a vobis hæ maledictiones, scelerum vestrorum persecutrices, quamdiu permanebitis in peccato pervasionis. Amen. Fiat. Fiat."

Pope Clement VIII., immediately after his election, published a bull against duelling, denouncing an Anathema against all those who should give, receive, or carry a challenge, and a sentence of interdiction against the places where duels should be fought.

ANATHEMATISING, the act of pronouncing an *anathema*. In which sense it amounts to the same with *excommunicating*. The term is not only applied in speaking of persons but of doctrines and opinions.

ANATHEMATISM denotes the same with *anathema* or imprecation.

ANATHO, or ANNAH, in *Ancient Geography*, a city of Mesopotamia, the actual residence of an Arabian Emir, was composed of two long streets, which inclosed, within a natural fortification, a small island in the midst, and two fruitful spots on either side, of the Euphrates. It was situated to the south-east of Circesium. The warlike inhabitants of Anatho shewed a disposition to stop the march of a Roman emperor; till they were diverted from such

fatal presumption by the mild exhortations of prince Hormisdas, and the approaching terrors of the fleet and army. They implored, and experienced, the clemency of Julian, who transplanted the people to an advantageous settlement near Chaleis, in Syria, and admitted Pegasus, the governor, to an honourable rank in his service and friendship. See ANAH.

ANATHOTH, a city of Palestine, north-east of Jerusalem, and not far from it. This city had been given to the Levites, and was one of the cities of refuge. It belonged to the tribe of Benjamin; and was the birth-place of the prophet Jeremiah, and the inheritance of many of the Jewish pontiffs.

ANATHREPSIS, in *Medicine*, amounts to much the same with ANALEPSIS.

ANATICULA, a diminutive of *anas*, and used by the old Roman Authors, as a term of fondness, to express the passion of love. There is another of the same kind from a different bird, *palumbula*.

My little duck, my little dove, were the most endearing terms the lovers of those times could use; nor was this the custom of the Romans only, but the Greeks, as far back as Aristophanes, have it.

ANATIFERA, in *Conchology*, a species of LEPAS, called bernacle, that adheres by means of its membranaceous pedicle to the bottoms of ships, timber, and other substances floating in the water. The shell is compressed, and consists of five valves, is smooth, and affixed to a pedicle. Linnæus.

This curious marine production consists of many unequal membranaceous branches, or arms, at the ends of which the shells are disposed in an irregular manner; the larger clustering with the smaller in groups, and forming bunches of various sizes. The branches are of a fine red; the shells of a bluish violet. The animal within is a *triton*, and is furnished with many *cirri*, or *tentacula*, with which it takes its food. These tentacula are pectinated like feathers, and hang out of the shells when open. In the 16th century they were in fact supposed to be feathers, and hence arose the whimsical belief that these shells produced geese, of the species called bernacles. (*Anas Erythropus* of Linnæus.) Nor was this a vulgar opinion only; it was sanctioned by the grave details of naturalists of that time, and particularly by Gerard, whose observations are worthy of notice.

"What our eyes have seen, and hands have touched, we shall declare. There is a small island in Lancashire, called the *pile of Foulders*, wherein are found the broken pieces of old and bruised ships, some whereof have been cast thither by shipwreck, and also the trunks and branches of old and rotten trees, call up there likewise; whereon is found a certaine spume, or froth, that in time breedeth unto certaine shells, in shape like those of the muskle, but sharper pointed, and of a whitish colour, wherein is contained a thing in form like a lace of silke, finely woven as it were together, of a whitish colour; one end whereof is fastened into the inside of the shell, even as the fish of oysters and muskles are; the other end is made fast unto the belly of a rude masse, or lump, which in time commeth to the shape and form of a bird. When it is perfectly formed, the shell gapeth open, and the first thing that appeareth is the foresaid lace or string; next come the legs of the bird, hanging out, and as it groweth greater it openeth the shell by degrees, till at length it is all come forth, and hangeth onely by the bill; in short space after it cometh to full maturitie, and falleth into the sea, where it gathereth feathers, and groweth to fowle bigger than a mallard, and lesser than a goose, having blacke legs and bill or beak, and feathers blacke and white, spotted in such manner as is our magpie, called in some

places a pie-annet, which the people of Lancashire call by no other name than a tree goose; which place aforesaid, and all those parts adjoining do so much abound therewith, that one of the best is bought for three-pence. For the truth hereof, if any doubt, may it please them to repair unto me, and I shall satisfy them by the testimony of good witnesses." GERARD'S HERBAL.—Vide DONOV. Brit. Shells, &c.

ANATILII, in *Ancient Geography*, a people of Gallia Narbonensis, mentioned by Pliny. Their situation is disputed. Martin says, that they were situated to the left of the mouth of the Rhon, near the side of the lake called *Stagnum Tauri*, and he supposes that they were the same with the Atlantici of Avienus. Some authors have inferred from an inscription of questionable authority, that their capital was Heraclea. M. d'Anville places them at the mouth of the Rhine, more to the right than to the left.

ANATINA, in *Conchology*, a species of MYA. Shell globose, snowy-white, and pellucid; primary tooth of the hinge prominent and roundish. Gmelin. This shell is found on the shores of Guinea, and other parts of Africa, and bears some affinity to *solen anatinus*. It is marked with streaked lines that intersect each other.

ANATINA, is likewise a species of OSTREA, that inhabits the Nicobar islands. The shell is pellucid, lamellated and laterally incurved. Gmel. It is thin and fragile, and variegated with white and violet, and about three inches in length, including the incurvature, which is nearly half of that length. From a fancied resemblance of this shell to a duck when sitting it has acquired the specific name *anatina*.

ANATINUS, in *Conchology*, a species of SOLEN. The shell is ovate, membranaceous, and covered with pile or soft hairs; a hooked rib at the hinge. This species is found on the sandy shores of the Indian ocean, and is named by Romphius *rostrum anatis*. It is pellucid, white, and very thin; one end rounded, the other gaping. Tooth in both valves of the figure of an ear-picker. Gmel.

ANATINUS, is likewise a species of MYTILUS, of an oval shape, somewhat compressed fragile, with a membranaceous margin, and decorticated beaks. Gmel. This species has been frequently confounded with *Mytilus cygneus*; from which it differs in several particulars. It is very common in the rivers of England, and is known by the name of duck or small horse muscle. Vide DONOV. Brit. Shells, pl. 113.

ANATIS, in *Ancient Geography*, a river, which, according to Pliny, belonged to Mauritania Tingitana.

ANATIS, in *Entomology*, a species of PEDICULUS that infests the wild duck. It is whitish; first segment of the thorax orbicular, truncated on each side, the other and the abdomen long and narrow. Schrank.

ANATIS, in *Natural History*, a species of ASCARIS, of the order Intestina in the VERMES class, that is found in the intestines of the wild duck, (*anas boschas*). It is from four to six inches in length, and is viviparous. The specific character, according to Gmelin, is, white, posterior part flattened.

ANATIS is also the specific name of another creature that is found in the intestines of the velvet duck. The body is scarlet, its form ovate, thorax and proboscis covered with hooked points, and it has a long smooth intermediate neck. Gmelin. This belongs to the genus *echinorhynchus*, in the order Intestina and Vermes class.

ANATIS is likewise the specific name of a third creature of the order of the Intestina in the class of Vermes. This is FASCIOLA ANATIS of Gmelin. The body is reddish, and of a

roundish form, with a single pore. This kind is found in the intestines of the domestic duck. It is small, somewhat pellucid, and usually white, the forepart truncated and triangular, behind roundish, intestines flexuous and blackish. This is *cuculanus conoides* of Bloch, and *hirudo fasciolaris* of Mull. Z. ol. Dan.

ANATOCISM, ANATOCISMUS, an usurious contract, wherein the interest arising from the principal sum are added to the principal itself, and interest exacted upon the whole. The word is originally Greek, but used by Cicero in Latin; whence it has descended into most other languages. It comes from the preposition *ana*, which in composition signifies *repetition or duplication*, and *τοκος*, usury.

Anatocism is what we properly call *interest upon interest*, or *compound interest*.

This is the worst kind of usury, and has been severely condemned by the Roman law, as well as by the common laws of most other countries. See INTEREST.

ANATOLIA, in *Geography*, a province of Turkey, in Asia. See NATOLIA.

ANATOLIUS, in *Biography*, patriarch of Constantinople, succeeded Flavian in the year 449. Before his preferment to this dignity, he favoured the Eutychians; but after the accession of Marcian, he attached himself to the party, which he patronized, and which held the orthodox faith of two natures in Christ, and thus ingratiated himself both with the emperor and with pope Leo. Whilst he was supported by the imperial power, he maintained a vigorous contest with Leo, for the equality of the two churches of Rome and Constantinople, but when Marcian seemed to be inclined to allow to the see of Rome the supremacy in the church, he acquiesced. In order farther to engage Leo's favour, he called a council at Constantinople, which denounced an anathema against Nestorius and Eutyches; and then sent deputies to the pope to assure him of the purity of his own faith. He afterwards concurred with the emperor Marcian and the pope in hostile measures against those who did not openly profess the doctrine of the church. Upon the whole, Anatolius seems to have been a time-serving ecclesiastic, whose character claims no commendation. Dupin's Eccl. Hist. vol. iii. p. 2. p. 228.

ANATOLIUS, bishop of Laodicea, in Syria, was a native of Alexandria, flourished under the emperors Probus and Carus, and succeeded Eusebius about the year 270. He was the most eminent person of his time, for his acquaintance with philosophy and the Greek literature, and for his skill in arithmetic, geometry, astronomy, grammar, rhetoric, and logic. His distinguished qualifications recommended him to the citizens of Alexandria, and at their request he is said to have set up a school for the Aristotelian philosophy. The tenets of the Peripatetic sect were the basis of his system, and with them he incorporated other doctrines, both Pagan and Christian, thus forming a new school, in which Aristotle was the chief master. Some have doubted whether he actually complied with the request of the Alexandrians, and set up such a school; however this be, none of his commentaries upon Aristotle are extant, and, therefore, the particular manner in which he philosophized is unknown. Whether he was a native christian or a convert from paganism, is not certain; but he was undoubtedly a christian long before he became bishop of Laodicea, for he was upon terms of intimate friendship with Eusebius, his predecessor in that see, about the year 263, when Bruchium, or Pyruchium, one of the quarters of the city of Alexandria, in which was the citadel, was besieged. A circumstance occurred on this occasion, which reflects peculiar honour on his character. See ALEXANDRIA. Eusebius

Eusebius says of him, that with universal consent he had pre-eminence above all the magistrates or senators of Alexandria, that were in Bruchium. Soon after this siege, Anatolius left Alexandria, and went into Syria; and he was ordained bishop by Theocletus, bishop of Cæsarea, designed by him for his successor, and actually appointed his colleague; but in his way to a council at Antioch, held by the Christian brethren upon the concerns of Paul of Samosata, he was detained at Laodicea, and appointed bishop of that city. Anatolius appears to have been a distinguished ornament of the Christian church; and though he did not write many books, yet his eloquence and extensive knowledge and learning are sufficiently manifest in those that are extant. His work on Easter, entitled, "The Paschal Canon," is cited by Eusebius; and an ancient Latin version of it, said to be Rufinus's, was published by Ægidius Bucherus, in folio, at Antwerp, in 1634. Of his ten books of "Institutes of Arithmetic," extracts are preserved in a collection, entitled "Theologumena Arithmetica." Some fragments of his philosophical writings are collected by Fabricius, from which it appears, that, after the example of Pythagoras, Plato, and Aristotle, he made mathematical learning subservient to philosophy. This learned Alexandrian concurred with other Christians, in a high respect for the scriptures of the Old and New Testament. The time and manner of his death are not certainly known; but some have supposed that he died a martyr. Euseb. Hist. Eccl. lib. vii. c. 32. p. 284. ed. Valef. Cave's H. L. vol. i. p. 136. Fabr. Bib. Gr. lib. iii. c. 11. tom. ii. p. 273—278. Brucker's Hist. Phil. by Enfield, vol. ii. p. 306. Lardner's Works, vol. iii. p. 265—269.

Fabricius (B. G. lib. v. c. 1. tom. v. p. 277.) has mentioned several other persons of the same name, who ought to be distinguished from Anatolius, of whom we have given an account. Cave also (*ubi supra*) shews, that this Anatolius is different from him, whom Eunapius mentions as master of Jamblichus; though they are confounded by Valefius, and his opinion has been approved by Basnage. Anatolius, of Berytus, in Phœnicia, was a man of great learning, good judgment, and much candour. He was a faithful subject and able officer, under the emperor Constantius, being præfect of Illyricum, from the year 358 to the time of his death in 360. Photius, speaking of his work concerning agriculture, says, that it is a collection out of several writers upon the same subject, such as Democritus, Africanus, Tarantinus, Apuleius, Florentius, Valens, Leon, and Pampholus, and also from the paradoxes of Diaphones. The work consists of 12 books or sections. It contains, says Photius, many useful directions for agriculture and husbandmen, and may be reckoned one of the best books written upon the subject. There are inserted at the same time many strange and incredible things, favouring of the error of Gentilism; but he adds, a pious husbandman may let those things alone, and select only what is useful. Anatolius is highly commended for his integrity and eloquence, for his knowledge of the laws, and for his patronage of learning. Lardner's Works, vol. ix. p. 8—11.

ANATOMY. The word signifies simply dissection, yet there are usually comprehended under this term all those artifices by which the structure of animal bodies is developed and exhibited. As a science, anatomy must be admitted to be highly interesting and important; while other sciences lead us abroad in pursuit of knowledge, in this we are engaged at home, in concerns truly interesting, in enquiring into the means by which we live, and move, and have our being. Anatomy also furnishes us with knowledge which teaches

how to preserve health, to correct disease, and rectify the effects of those injuries to which we are inevitably exposed.

Anatomy is divided into human and comparative; in the former our researches are restricted to our own bodies, but in the latter, we may range over the whole field of animated nature.

The anatomical description of the body is technically arranged under the following heads, to which we refer the reader for more particular information.

1st. Osteology, or the description of the structure, shape, and uses of the bones.

2d. Syndesmology, or a description of their connection by ligaments, and the structure of the joints.

3d. Myology, or a description of the moving powers or muscles.

4th. Angiology, or a description of the vessels engaged in nourishing the body, in absorption, and in the removal of superfluous parts.

5th. Adenology, or a description of the glands, in which various liquors are separated or prepared from the blood.

6th. Splanchnology, or a description of the different bowels, which serve various and dissimilar purposes in the animal economy.

7th. Neurology, under which title the brain, the nerves, and organs of sense must be comprehended.

This arrangement, which is not very well adapted to the purposes of anatomical description, is, however, not at all suited to the views of physiology; for this subject, therefore, we must refer the reader to another series of articles. The functions carried on in animals, in the explanation of which physiology consists, may be thus arranged.

The terms, however, by which they are distinguished, do not correctly express the nature of each function, as will be shewn more at large under their respective titles.

1st. Digestion, or the conversion of extraneous matter into the nature of their own bodies.

2d. Circulation, or the distribution of the converted matter to every part of the animal for its repair and augmentation. The process is named circulation, from the mode in which it is carried on in the generality of animals.

3d. Secretion, or the separation and deposition of the particles composing the structure of animals and vegetables, as well as various substances which they produce from the circulating fluids.

4th. Absorption, by which external matter is imbibed, and that which is deposited by secretion more or less removed.

5th. Respiration, or the exposure of the nutritive fluid to the action of the atmosphere.

6th. Irritability, or the action which is exerted in carrying on the circulation, secretion, and absorption, and which is more strikingly manifested in the occasional motions of the muscular powers.

7th. Sensation, by which animals become conscious of the existence of external objects, and also of their own.

8th. Generation, by which new beings, similar to the parents, are formed and produced.

Most of these powers are observable in vegetables.

ANATOMY, History of. The writers on the history of medical science, and of anatomy, as forming a part of it, generally divide it into four portions. The first contains the state of these sciences previous to the life of Hippocrates, who was born about 460 years before the Christian æra; the second contains an account of the additions and alterations that were made before, and by the labours of Galen, who lived about one hundred and fifty years

years after the birth of Christ. The third part comprehends the declension of these sciences, with learning in general, in the sixth and seventh centuries, and their revival in the fourteenth and fifteenth, to their more perfect establishment by Harvey's discovery of the circulation of the blood. The fourth part contains an account of the more perfect state of these sciences from Harvey to the present time. The desire of investigating the structure of the body seems so natural a kind of curiosity, and so intimately connected with self-preservation, that we cannot wonder if a considerable portion of such knowledge should be acquired, even where the opportunities of research may have been very limited and inadequate. Omai, who was brought by Capt. Cook from Otaheite, when he surveyed Dr. Hunter's Museum, manifested considerable acquaintance with the subjects before him, and a great desire of further information. The slaughter of animals for food, the preparation of them for sacrifice, and accidental opportunities of examining the human skeleton, &c. were the first sources of anatomical information.

Amongst the Egyptians, the most ancient nation, of whose manners we have authentic memoirs, the rites practised in honour of the dead, by embalming their bodies, would familiarize the people to anatomical inquiries. The custom of carrying about, at their feasts, a skeleton, left their guests, in the midst of feasting and merriment, should forget the frail tenure of life and its enjoyments, seems a sufficient proof of this assertion. It is also related, that one of their kings left writings on anatomy.

Our accounts of this science are, however, very slight and imperfect, till it was cultivated by the enlightened inhabitants of Greece. If the pursuit of anatomical knowledge is so natural and important as to interest even barbarous nations, it was likely to be prosecuted with greater ardour and success as knowledge increased, and the powers of the mind in obtaining it became strengthened by exertion. At the time of Homer the Grecians seem to have possessed much general anatomical knowledge, as the writings of that poet evince. We read, that the stone, which Diomedes threw at Æneas, not only crushed the bone of his thigh, but also tore the ligaments of the acetabulum. Merion was wounded in one of the large veins, which return the blood to the heart, known to anatomists by the name of vena cava; and Ulysses meditated to wound the Cyclops just where the liver adheres to the diaphragm. Anatomical facts were collected, and the physiology of animals investigated by the philosophers of Greece, who taught these subjects, as well as other branches of science, at the philosophical schools of Rhodes, Cos, Cnidos, Cyrene, and Crotona. The first dissection on record, is one in which Democritus, of Abdera, was engaged, in order to ascertain the sources and course of the bile. It is natural to suppose that anatomical and medical knowledge would be hereditary in families; the father would instruct the son how to explore the structure of animals by dissection, and the son would communicate his knowledge to his children. Thus would medical science be retained and augmented in such families. This was the case in the family of Hippocrates, who was said to be the fourteenth descendant from Esculapius. In the eightieth Olympiad, about 460 years before Christ, Hippocrates formed medicine into a distinct science, and collected, arranged, and published all the anatomical and medical information which mankind then possessed. Anatomical knowledge was considerable for the age in which he lived, and it has been disputed whether he dissected human subjects; but if he did, the number must have been very small, his anatomy seeming to be of that kind and extent which the contemplation of the

human skeleton, and the dissection of brutes, would naturally produce.

No important additional knowledge of anatomy was obtained, till the formation of a medical school at Alexandria, in Egypt, where the dissection of human bodies was patronized by the descendants of Alexander. Here Herophilus and Erasistratus flourished about 200 years before the birth of Christ. They seem to have been accurate dissectors, and some minute parts of the body are still named after them as discoverers. Their writings have been lost, and it is chiefly Galen who has made us acquainted with their labours and their merits. The Alexandrian school long flourished, and medical men resorted to it for a knowledge of anatomy, which they could obtain in no other place. Here even Galen received his education. It is quite unnecessary to notice the important anatomical remarks made in the writings of the Roman authors before or after the time of Galen.

Galen, however, greatly deserves our attention and praise; not merely because he collected and arranged all the then acquired information, but because he was also an industrious dissector, and considerably enlarged the limits of anatomical knowledge. He also investigated physiology by experiments, of which it may be right to mention one instance; he refuted the opinions of the Alexandrian anatomists, that the arteries were tubes, distributing air throughout the body. By laying bare one of these vessels in a living animal, tying it in two places, and opening it between the ligatures, he ascertained that it contained blood and nothing else. He therefore concluded, that both veins and arteries served the same purpose, that of distributing blood for the supply of the body, but that the florid arterial blood contained more air than the purple blood of the veins. In an history of this kind it seems right to mention the effect of anatomical studies on the mind of Galen: after contemplating the structure of the hand and foot, and their adaptation to their different functions, he breaks out into an apotrophe, which has been much admired, and in which he is said to have exceeded any ancient in pointing out the nature, attributes, and proper worship of the Deity. In explaining these things, he says: "I esteem myself as composing a solemn hymn to the author of our bodily frame, and in this, I think, there is more true piety than in sacrificing to him hecatombs of oxen, or burnt-offerings of the most costly perfumes: for I first endeavour to know him myself, and afterwards to shew him to others, to inform them how great is his wisdom, his virtue, his goodness." There was no addition made to anatomy worth remarking by the writers who succeeded Galen: the science gradually diminished, and afterwards seemed almost lost amongst the Arabians.

The first Arabian physicians appear to have employed themselves in compiling systems from the Grecian writers, and the later ones in copying from each other. Medicine certainly declined amongst them, and their religious notions made them almost entirely neglect anatomy. In the tenth century Constantine, a native of Bagdat, brought with him the Arabian doctrines on medicine to the Salernitanian school in Sicily; and here anatomy began slowly to revive. In the fourteenth century Mundinus dissected human bodies in Italy, and by degrees other nations acquired that useful boldness.

Anatomical knowledge, on its revival in Europe, was greatly promoted by the exertions of eminent painters, who were early and accurate dissectors, correctly delineating the muscles, after they had removed the integuments which covered them. Raphael, Titian, and Leonardo da Vinci were famous for their anatomical skill, which is indeed sufficiently evident in their paintings. A number of sketches, designed

as studies by Leonardo da Vinci, are still extant in his Majesty's collection of drawings, and are spoken of by Dr. Hunter in the most encomiastic terms. Albert Durer, who also is ranked by Haller among the restorers of anatomy, published many plates representing the proportions and gestures of the human form and countenance.

When the Turks had subdued Greece, the inhabitants fled for safety to the western nations of Europe, bringing with them the Grecian authors on medicine, and translating them; which works the invention of printing, that happened about the same time, greatly conduced to disperse throughout Europe. People had now an opportunity of becoming acquainted with the writings of Galen and the ancients, and, by these means, of arriving at the source of that knowledge which they had hitherto obtained only through the channel of the Arabian physicians. The superiority of the former was soon discovered, and the opinions of the Grecian writers were considered, even in anatomy, as unimpeachable.

In the middle of the sixteenth century several eminent anatomists flourished, particularly Sylvius and Vesalius, Fallopius and Eustachius. Sylvius taught anatomy in Paris in 1532. Vesalius first advised anatomists to inject coloured fluids into the vessels of the body, in order to facilitate the labour of minutely tracing them. Whilst he was a young man in college, he pursued anatomical inquiries with great ardour and assiduity, and published some of his discoveries before he was twenty-five years of age, and seven books on the anatomy of the human body before he was twenty-nine, A. D. 1542. These books contain great discoveries, and, in many circumstances, correct the ancients. But although they have entitled their author to the gratitude of posterity, they procured to him scarcely any thing but animosity from his contemporaries. At that time the authority of Galen was held in high veneration; but when Vesalius exposed his errors, the hatred of all seemed turned against him. People could not bear to be set right by so young a man, and even Sylvius denounced perpetual enmity against him. But knowledge was increased by these contentions, all parties were obliged to refer for the materials and support of controversy, to the book of nature, which they could not consult without receiving instruction. Even Vesalius was detected, in some instances, in the error with which he charged Galen; that of describing the anatomical structure of the human body from the dissections of brutes. In 1561 Fallopius, in Italy, published his *Observationes Anatomice*; he was an indefatigable anatomist, and made great discoveries. About the same time Eustachius made himself conspicuously eminent by promoting anatomical knowledge. He seemed calculated for subtle investigations; he drew many figures of the human body, and engraved his own plates, the accuracy of which cannot fail of exciting surprise in an anatomist of the present day. When the labours of these eminent men had, as it were, smoothed the path, anatomy was taught with a moderate degree of correctness and minuteness in the different schools of Europe.

Shortly after, as Haller has observed, the different nations being engaged in war, the same attention was not paid to public institutions and dissections. Anatomists had therefore recourse to the examination of the bodies of brutes, from which they derived many important discoveries.

In the year 1628 Harvey published his discovery of the circulation of the blood. The principal facts relating to this subject were known before his time: it remained for him to reject the specious conjectures then maintained concerning the blood's motion, and to examine the truth of those facts which were then known, and by experiments to discover

those which remained to be detected. This he did, and thereby rendered his name immortal. His doctrines were at first opposed; but when they could no longer be contended against, the merit of the discovery was assigned to former anatomists.

It seems proper, in this place, to review the several steps which were made in the investigation of this important subject. Hippocrates believed that all the vessels communicated with each other, and that the blood underwent a kind of flux and reflux from and to the heart, like the ebbing and flowing of the sea; and he mentions the throbbing of the temporal arteries, as an evidence of this fact. The anatomists at Alexandria adopted a wrong, but ingenious opinion; as they found the arteries empty, and the veins containing blood, in their dissections, they imagined that the former were tubes for the distribution of air, and gave them that name which they have borne ever since; and that the veins were the only channels for the blood. The heart of man, consisting of two sets of cavities not communicating with each other, and its connection with the lungs, were to them delusive circumstances, and seemed to favour their opinions. It is true they sometimes found blood in the arteries, and in the left cavities of the heart, but then they believed that the air or spirit had escaped, and that the blood had oozed through the sides of these air vessels, and supplied its place. Galen, as has been said, refuted this opinion by experiment, and ascertained that blood flowed both by the arteries and the veins, though he knew not then its natural course. On the revival of anatomy in Europe, the pulmonary circulation was known to many eminent men. The valves at the mouth of the pulmonary artery proved the course which the blood must take in that vessel, and it seemed naturally to follow, that it must return to the pulmonary veins. This appeared to be the case to Realdus Columbus, Michael Servetus, and the celebrated Sarpi. But when Vesalius afterwards examined the subject of the blood vessels, we can only attribute his failure in discovering the truth of the circulation to his mind being more directed to expose the errors of Galen, than to a candid examination of the subject. Fabricius ab Aquapendente, the preceptor of our famous Harvey, particularly described the valves of the veins, the mechanism of which would absolutely prevent the blood from flowing in those vessels towards the extremities. When Harvey returned from his studies in Italy, his attention being excited to the subject, he began those experiments, by which he learned and demonstrated the fact of the circulation. Harvey's first proposition of the subject impresses conviction so strongly on the mind, that we are left in perfect astonishment, that a circumstance so luminously evident should so long remain unobserved. It must be granted, that the heart projects about two ounces of blood into the aorta at every pulse; what, then, it may be asked, becomes of this large quantity of blood, unless it circulates? It must be granted, that the heart receives that quantity prior to every pulse. From whence is it received, unless the blood circulates? Harvey tied an artery, and the corresponding vein received no blood: he tied a vein and all its branches, and those of the corresponding artery were choked with blood, even to the entire obstruction of circulation and motion. But Harvey was not acquainted with the direct communication which exists between these systems of vessels. He imagined that the blood transfused from the arteries into the veins through a spongy, or parenchymatous substance. Much yet remained to be ascertained by microscopical observations, and subtle anatomical injections and dissections.

In 1621, a little before the publication of the circulation, the lacteal absorbents of the intestines were discovered.

covered by Afelli; and shortly afterwards, the lymphatic or general absorbents of the body were brought into notice by Rudsee and Bartholin. In 1654 Pecquet published his discovery of the trunk of this system of vessels, by which all the matter absorbed from every part of the body, as well as the urine when imbibed from the intestines, is poured into the left subclavian vein. (See the article ABSORBING VESSELS.) Swammerdam, about the year 1660, taught anatomists to use wasen injections, which, hardening when cold, enable us to trace and examine the intertexture of minute vessels with certainty and exactness. Shortly after, in the art of injecting and making anatomical preparations, Ruysch, who was professor at Amsterdam, particularly excelled; and by the anatomical artifices which he instituted, he was enabled to develope the vascular structure of the body, with a degree of minuteness and exactness hardly credible.

Malpighi, a great anatomist and professor at Messina and Bononia, in 1666, broached very ingenious and clear ideas respecting secretion. He believed that the minute arteries poured a liquor into little cells contained in glands, from which it passed off by other tubes, called excretory ducts. Ruysch denied the existence of cells, and affirmed, that the secretory and excretory vessels were continuations of the same tube. These eminent men had each numerous partizans, but the opinion of Ruysch, which is most simple, and drawn from accurate observations, is now considered as ascertained. Ruysch also contributed to our knowledge of the absorbing system, by particularly describing the structure of its vessels, and Nuck had no inconsiderable share of merit on the same account. Leuwenhoeek, who greatly promoted anatomy, not merely by his own microscopical observations, but by shewing what important discoveries might be made by the microscope, saw the circulation in the transparent parts of fish and amphibia, and thus was the knowledge of the circulation perfected.

By these discoveries much light is thrown on the animal economy; and we are enabled clearly to discern many circumstances which before either escaped observation, or were imperfectly seen. By the discovery of the circulation we see the truth of the scriptural expression, that in the blood is the life of an animal; for from this vital fluid every part is formed and maintained. By the discovery of the absorbents we perceive how the blood itself is supplied, from the food, which is converted into a milky fluid, by the digestive organs; and how the old particles of our bodies, which are no longer fit to remain in it, are removed and conveyed into the blood, to be eliminated by the excretory organs.

When anatomy had thus become a clear and distinct science, it was inculcated and taught, in the different nations of Europe, by numerous professors, with a zeal and industry highly honourable to themselves and useful to mankind. It would occupy a volume to relate their labours and discoveries; we must restrict ourselves to mention only the names of the most eminent, and the principal subjects, which engaged their attention. The celebrated Harvey led the way in investigating one of the most curious processes in the animal economy, that is, the procreation of the species. Leuwenhoeek and Buffon observing certain genera of microscopic animalcules in the seminal fluid, formed rather wild speculations respecting them, which, however, considerably excited the public attention. De Graaf, in 1672, was the proposer of the most rational opinion on this subject. In viviparous animals he shewed the existence of minute ova formed in the ovaria, which, when fecundated, pass through the fallopian trumpet into the uterus, and there grow to maturity; the late experiments of Spallanzani, in Italy, and some in this country, seem to have confirmed his opinion,

and proved that the female of almost every species prepares an ovum, which contains parts, which are, as it were, animated, and set in motion by the semen of the male. As a prosecution of the history of the same subject, we may mention, that Dr. Hunter, in this country, has given a most complete history, with beautiful explanatory engravings, of the growth of the human ovum, and of the changes which the uterus undergoes after the ovum has been received into that cavity.

The more conspicuous parts of the body, the bones and the muscles, have been most accurately described and delineated; the former by Albinus, Cheselden, and Sue: the latter by Albinus and Cowper. Albinus, as a minute anatomist, also deserves the highest praise.

In 1672, Diemerbroeck, professor at Utrecht, published a system of anatomy; and in 1711, Winslow published a very excellent and accurate work of the same kind in Paris, which long served as a kind of text book for students. But when Albinus and Haller had greatly simplified the description of the body, and improved the knowledge of its minute structure, some other systematic work became necessary, but none for a long time appeared.

In the mean while Haller published, at Gottingen, in 1743, his *Icones Anatomicae*, with a view to supply the deficiencies and correct the errors of Winslow. The description of the arteries particularly deserves our praise and gratitude. Professor Walthen, of Berlin, has with equal, or even superior diligence, traced the distribution of the most important nerves, and published splendid representations of them; and lately Mascagni has given to the public a most elaborate and complete account, with elegant plates, of the absorbing vessels. Haller not only promoted anatomical knowledge by his accurate dissections, but discovered and established physiological truths by experiments made on living animals. In like manner Mr. John Hunter pursued his enquiries; he was an accurate and minute dissector, a patient experimentalist; and in his researches surveyed the whole field of animated nature. To him we owe in anatomy the descent of the testis, and the natural history of the teeth; by him physiology has been greatly promoted, and the structure and economy of animals displayed and explained. In Germany the brain has been examined, and the nerves traced with the most sedulous attention; and of late Vic D'Azyr, in France, an anatomist equally comprehensive and minute, has published representations of the brain, which are allowed to excel all others. Dr. Monro, in our own country, has also published on these subjects. Some anatomists seem to have directed their attention chiefly to the investigation of some single organ. Zinn has examined and explained the structure of the eye with surprising minuteness and accuracy. Cotuninus, Meekel, and Scarpa, the ear; and the latter has also paid attention to the organ of the smelling sense. Of late some excellent systems of anatomy have been published by Sabatier, in France, and Soemmering and Hildebrand, in Germany.

Morgagni, the pupil of Valsalva, professor of anatomy in Padua, who had very extensive opportunities of observation, and who much improved anatomy in his old age, in the year 1761 published the result of his observations *De Sedibus & Causis Morborum per Anatomien indagatis*, a work of the greatest utility. Doctor Baillie has of late, in this country, prosecuted the same subject, though in a different manner. He has published on the morbid anatomy of the body, and illustrated his descriptions by many elegant, expressive, and accurate plates; the prosecution of this subject promises the greatest advantages.

We have thus cursorily mentioned the principal subjects, in which the most eminent anatomists have been engaged. The names and employments of numbers of men of high

desert have, however, been omitted; indeed, they could not be properly noticed unless this article were of itself to make a volume. Chronological order has been much trespassed against, and we therefore return to mention the most remarkable anatomists, in a series, according to the time in which they lived. As it is difficult to adjust their precedence in this respect, we shall rely on the authority of Haller, whose knowledge and judgment will not perhaps be called in question. He considers Benedictus, Berengarius Carpenfis, Nicolaus Massa, Sylvius, Vesalius, Servetus, and Columbus, as the chief restorers of anatomy, whose writings are dated from the beginning to the middle of the sixteenth century. After the restoration of anatomy, the schools in Italy particularly excelled, and most anatomists received their education in them. From amongst the most eminent of the Italian school we may select the names of Fallopius, Eustachius, Aurantius, Cæsalpinus, Varolus, Plater, Caspar Bauhinus, Aldrovandus, Casserius, Fabricius ab Aquapendente, Riolanus, Hoffman, and Spigelius, whose writings extend from the middle to the conclusion of the 16th century.

In the beginning of the 17th century the dissection of human bodies began to decline in the Italian schools, and more attention was paid to comparative anatomy and physiology. Amongst the most eminent in this department of science we may recite the names of Afellius, Harvey, Marcus Aurelius Severinus, T. Bartholin, C. V. Sneider, Van Horne, Highmore, D. de Marchettis, Rudbec, Glisson, Wepfer, Blasius, Malpighi, Steno, De Graaf, Herborn, Ruysch, Swammerdam, C. Bartholin, Brunner, Leuwenhoeck, Duverney, Bidloo, and of those who confined themselves chiefly to human anatomy, R. Vieussens, Cowper, Raw, &c. all of whom flourished in the 17th century. In the beginning of the 18th century, Haller considers anatomists as having attained a greater degree of learning and knowledge in the science which they studied, and under the title of the more learned in anatomy he gives an account of the works of Morgagni, Winslow, Cheselden, &c. which were dated in about the first 30 years of that century, except Morgagni's work, "de Sedibus et Causis Morborum," which he published at an advanced age. Under the title of the perfect state of anatomy Haller reviews the works of Albinus, Senac, Monros, (the father and son), Haller, Nicholls, Lieutaud, Ludwig, Leiberquyn, Dr. Hunter, and his brother Mr. Hunter, Daubenton, Camper, Walther, Meckel, Zinn, Fontana, Wrisberg, Spalanzani, Hewson, Portal, Sabatier, Scarpa, Blumenbach, Troja, &c. whose writings extend to the present time. The History which is given must necessarily be brief, and cannot, in consequence, be otherwise than imperfect. We therefore refer the reader for more ample and correct information on this subject, to the writings of Le Clerc, Freind, Goelicke, Portal, and to the Bibliothecæ of Haller.

ANATOMY, Comparative.—By this term is popularly understood the anatomy of animals, compared with the structure of the human body as a standard.—This definition, however, is not sufficiently comprehensive. The organization of every animal forms a part of our knowledge of nature, and as far as it exemplifies or explains any of the functions exercised by animal bodies, furnishes those data which constitute the basis of physiology. The anatomy of the human body is not more applicable to this purpose than that of other animals, and many of the most important functions can only be understood by comparing the organs by which they are performed in the different classes of animals.

The agreement which necessarily exists between the structure and the habits of animals, renders comparative

anatomy an essential branch of zoology. No classic division of the subjects of natural history can be either permanent or useful, which is not founded upon internal structure as well as external characters, and in proportion as this is attended to, we come nearer to that natural arrangement, which should be the chief object of all classification. It is in comparative anatomy, then, that the physiologist principally discovers the laws which determine the phenomena of organized matter, and that the naturalist finds all his observations upon the appearances and manners of animals verified and explained.

The anatomy of animals must have formed one of the very first subjects of human investigation, because in the most simple and early stages of society, almost all the means of subsistence or of enjoyment which mankind possess, are drawn from other animals. The savage, therefore, in killing his prey, and preparing it for the different purposes to which it is to be applied, is necessarily led to distinguish the structure and appearance of the several parts, one serving for food, another for raiment, a third for a weapon or an ornament, and so on; it cannot be supposed that this examination should be frequently made, even by the most ignorant, unaccompanied by some reflections upon the uses of those parts to the animal in which they are found, or without comparing in some degree the anatomy of one animal with that of another:—a very considerable portion, therefore, of knowledge on this subject must have been obtained in savage society, but which has been lost to after ages, from the want of any record of human knowledge.

The sacrifice of animals which has always made a part of the religious worship of uncivilized nations, afforded also many opportunities of observing the internal structure of animals.

The first account that we possess of comparative anatomy being studied as a branch of philosophy is amongst the Greeks. Democritus is reported to have directed himself to this subject with so much ardour, that he at first incurred the suspicion of insanity, but when his objects were explained, the utility of his pursuits was fully acknowledged.

Aristotle may be considered as the first professional anatomist; his zoological researches were carried so far that his works are read with pleasure and improvement, even at the present day: his opportunities of studying the subject were indeed unparalleled; for we are told that Alexander bestowed upon him 100 talents, (a sum equal to 50,000l.) to be solely employed in procuring animals for dissection.

Herophilus and Erasistratus, who succeeded Aristotle in the school of Alexandria, are said to have dissected human bodies; but it is more probable that the anatomy of Alexandria was still taught by the dissection of animals, as besides the natural feelings to be conquered, there prevailed at that time a notion, that the touch of a dead body communicated a moral pollution: notwithstanding which, this school became so celebrated, that it was not only visited by the learned men of Greece, but by those of all nations. During the dark ages, comparative anatomy suffered nearly an equal depression, with the other sciences, and it was not until the latter part of the 15th, and the beginning of the 16th centuries, that it began again to be much cultivated; about this time flourished Rondeletius, Bellonius, Eustachius, Coiter, Fallopius, Fabricius ab Aquapendente, Casserius, Severinus, and several others, whose works may be still consulted with profit. The discovery of the circulation of the blood, and of the absorbent system, which may be reckoned as the commencement of another æra in anatomy, opened the door to physiological enquiry, from which com-

parative anatomy derived the greatest improvements, as many of these researches were most conveniently conducted upon animals about this time; also the application of the microscope to the observation of the more minute structure of parts, furnished a new field for investigation; amongst those who most illustrated the anatomy of animals during this period may be enumerated Afellius, Harvey, Stenon, Boerhaave, De Graaf, Redi, Willis, Ruysch, Malpighi, Swammerdam, Leuwenhoeck, Perault, Needham, Blasius, Ohgenuus Jacobæus, Liller, Boerhaave, and Tyson. Comparative anatomy continued to improve in a regular and steady manner, during the early part of the last century, which will appear in the works of Valisneri, Valentini, Geoffroy, De Reaumur, Bradley, Maitre Jean Petit, the elder Monro, Trembley, Baker, Bonnet, &c. but it was not until the middle, and towards the close of the last century, that the anatomy of animals became a connected science; the discourses of the preceding ages were then arranged, compared, and systematically applied to the purposes of physiology; many new and important facts were added, and several of the most curious and interesting circumstances in the animal economy were fully investigated and explained; collections of preparations to exhibit the structure of animals were formed in Paris, Padua, Gottingen, London, and some other parts of Europe; in the three first places, public lectures were delivered, by which a knowledge of the subject was diffused over the continent; this might be considered as the Augustan age of comparative anatomy, in which we meet the names of Camper, Daubenton, Vic d'Azir, Blumenbach, Pallas, Searpa, Comparetti, Hunter, Monro, Hewson, besides a great number of others of the first character.

Some of these eminent men are still living, to whom may be added, as the most distinguished anatomist of the present time, citizen Cuvier.

It would be impossible, within the limits of this article to give any detail of the several discoveries which have been made upon this subject; they have only in a very few instances been published in distinct essays, and are chiefly to be found scattered through works on natural history and human anatomy, or in the transactions of literary societies. The works of Collins, Valentine, and Blasius, which were published under the name of systems, are mere collections of facts, without any suitable arrangement, and although as a simple compilation no book can have more merit than the "Anatomie Animalium" of Blasius; it is, however, to citizen Cuvier we are indebted for the first systematic work on comparative anatomy; the want of such books, and of public lectures has hitherto made this science less an object of general attention than its utility and interesting nature would deserve; but it may be expected that these deficiencies will be supplied by the present age, in which the value of every kind of knowledge is duly appreciated.

All those who have lately written or lectured upon comparative anatomy, have very properly chosen to arrange the subject in a physiological manner, instead of describing the structure of each kind of animal separately. This mode, however, if strictly adopted, would prove highly inconvenient in a dictionary, in which the matter should be so distributed, that it could be immediately resorted to, under familiar heads or titles; on the other hand, to multiply divisions much is tedious and perplexing, and incompatible with the perfect understanding of this subject, which requires that a number of facts should be known before any comparison or conclusion can be drawn. The plan pursued in the present work, combines in some degree both methods of arrangement. Thus certain classes of animals are esta-

blished upon the basis of an agreement in their general anatomical structure; each of these classes forms a distinct article; and the faculties or functions belonging to the animals it contains, make so many subdivisions or lesser heads, under which the structure of the organs, subservient to these functions, is discussed.—See CLASSIFICATION OF ANIMALS AND FUNCTIONS.

ANATOMY, Vegetable.—All natural science consists in the discovery and application of facts; its usual progress, therefore, is gradual; history records no period in which nature has not been studied, and in which the foundation of most of the sciences has not been clearly laid. The internal structure of vegetables, however, during the early ages of mankind, was involved in almost perfect obscurity. It was not indeed until the latter part of the 17th century that the anatomy of plants was formed into a distinct science; before this period the same opinions were entertained upon the subject that were taught by the Greeks, and which were not established upon actual observation so much as the analogy that was very properly imagined to exist between animal and vegetable bodies. Thus they attributed four parts to all plants:

First, the *sap* or *juice*, which they considered similar in its uses to the blood.

Secondly, the *fibres* of plants, which they called nerves, from their resemblance to those parts in animals to which, however, they did not ascribe the property of sensation.

Thirdly, the *veins* or vessels that were supposed to contain the fluids.

Lastly, the *pith*, which they conceived to be analogous to the flesh of animals. A further account of the early state of this branch of science may be obtained in the writings of Aristotle, Theophrastus, &c. and in the phytologia of Du Val.

It was only by investigations, conducted with the microscope, that the real structure of vegetables could ever have been developed; it is to the invention of this instrument, therefore, that we owe almost all the knowledge that is at present possessed upon the subject.

The microscope was first made use of to discover the organic structure of plants by Grew and Malpighi, for what was done before them by Mr. Hooke, and some others, scarcely deserves to be noticed, as their attention was chiefly directed to the examination of the external parts of vegetables. In no instance, perhaps, have the first labours on any branch of science gone so far as those of Malpighi and Grew. The books which they published under the title of the anatomy of plants, rank amongst the highest authorities upon the subject at the present time. It is remarkable also that on the 7th December, 1671, the same day on which Grew presented to the Royal Society the first part of his Anatomy of Plants, the society also received the manuscript of the first part of Malpighi's "Anatomie Plantarum."

In consequence of the degree of perfection to which these eminent men carried vegetable anatomy, the writers who have followed them have been employed in the investigation of the functions, rather than the structure of plants. Some curious and highly important facts have, notwithstanding, been added with respect to the growth of timber, the anatomy of the bark, and the more minute organization of the vessels, leaves, flowers, seeds, &c.

These more modern discoveries in vegetable anatomy may be principally found in the writings of Leuwenhoeck, Bonnet, Duhamel, Relceuter, Gärtner, Hill, Baron de Gleichen, Reichel, Mayer, Guettard, Hedwig, Walther, Desaussure, Desfontaines, and Mirbel.

There is scarcely any branch of science more interesting

in the pursuit, or which holds out a more valuable end, than vegetable anatomy. The delicate, minute, and complicated arrangement of parts, which appears in the organization of vegetable bodies, presents a continual subject of admiration and amusement, in procuring which, the feelings are never wounded, nor the senses disgusted. But this science is not a subject of mere curiosity or idle speculation; it affords the greatest illustration of the structure and functions of animals, and tends in an eminent degree to improve the arts of agriculture and gardening, from which civilized man derives all his means of subsistence, either by his own immediate consumption, or the support which is obtained from domesticated animals.

There are certain parts of vegetables which may be termed common, on account of their being generally distributed throughout the system. These are the cortical substances usually included under the name of *bark*—the *wood*, the medullary part or *pith*, and the different orders of *vessels* for containing the sap, air, or secreted fluids.

There are other parts again which from possessing different external figures, and performing separate uses in the vegetable economy, might be called peculiar parts; these are the *root*, the *trunk* or *stem*, the *branches*, the *buds*, the *leaves*, the organs of reproduction contained in the *flower*, the *seed* or *fruit*. It is under these several heads that the anatomy of plants is discussed at large in this dictionary. Such an arrangement appears the most convenient, if not the most suitable, as by adopting its popular terms are obtained for most of the articles, a thing very desirable in conveying knowledge by means of a dictionary. This disposition of the subject also is nearly the same, that has been chosen by other systematic writers upon the anatomy of plants.

The functions of vegetable bodies are described, arranged, and their proper references pointed out, under the article *PHYSIOLOGY vegetable*, which see.

ANATOMY, Pictureque.—By this term is implied that degree and kind of anatomical knowledge, which is requisite for painters and sculptors, &c. comprehending chiefly the bones which support the figure, the muscles which move them, and the integuments with which they are covered.

Every considerate person will allow, that the painter, &c. who represents the human figure, cannot obtain any great celebrity in his art without some knowledge of anatomy; but it may not soon appear to every one, that there is a necessity for that considerable degree which it is requisite for him to know; and it may be concluded, that little or none of this kind of information will be absolutely necessary for those artists, who devote themselves to the representation of clothed figures. It may also be conceived, that however proper the knowledge of the external muscles may be to the painter of nudities, the bones, being mostly covered by them, will be no considerable object of his attention; and that statues, with the living model, will communicate all the information required.

The skeleton being the frame-work supporting the human fabric, it would be diametrically opposite to our opinion to think lightly of osteology. As the bones describe the grand points of the figure, and are acted upon by the muscles and tendons, a principal part of the painter's attention should be given to the configuration of the bones, especially of the joints; and although the knowledge of the muscles which move them and fill up the cavities demand much of the artist's consideration, yet it is presumed, that with the use of statues and living models, a person well informed in osteology would make a more rapid progress in the representation of figures, where great knowledge of the muscles has not been obtained,

than he who has well studied the myology, but had not a competent acquaintance with the bones. This observation will also apply to the supposition of clothed figures being painted without a prior acquaintance with anatomy; it being presumed, that however capable such a person may be of painting drapery, without a considerable degree of anatomical knowledge, his figures will resemble bundles of cloth or linen without that animation and grace, which are to be seen in the works of those artists who have been honoured with the approbation of the judicious.

It is certain that statues and living models are of great use to the painter; the antique figures will form his taste, and living figures are so continually used by all painters who strive to excel, that they form a very considerable branch of the education of artists in all their academies. It is, however, next to impossible that a painter should copy the object before him, if he do not understand it; for, let him be ever so diligent and attentive, he will fall into considerable mistakes. Although in attitudes without motion or exertion, the living figure may for a long time direct his pencil with success; yet, when violent motion and exertion are to be expressed, the living model can but assist him for a few moments; here the knowledge of anatomy lends its aid, without which the wearied figure before him will only perplex and render his representations inanimate.

“Nor is it, as some may be apt to imagine,” says Algarotti, “merely to represent athletic and vigorous bodies, in which the parts are most bold and determined, that anatomy is requisite: it should be understood, to represent persons of the most delicate frame and constitution, even women and children, whose members are smoothest and roundest, though the parts made known by it are not to be strongly expressed in such subjects; just as logic is equally requisite under the polished insinuations of the orator, and rough arguments of the philosopher. But it is needless to spend much time in proving, that a painter should be acquainted with anatomy, or in shewing how far his acquaintance with it should extend.

“He must be acquainted with the figure and connection of the bones, the origin, progression, and shape of the muscles, the different degrees with which they are covered with fat, which substance lies thicker upon them in some places than in others: but above all he should know in what manner the muscles effect the various motions and gestures of the body.” Count Algarotti wrote with judgment upon painting, and his remarks upon anatomy deserve respect. The following extract was written by a physician, who seems to have had a taste for painting; although some of his remarks may have been anticipated, it is thought proper to present them to our readers; they will be found, amongst other useful things, in Dr. Brisbane's *Anatomy of Painting*. After speaking, in the preface, to surgeons, the doctor observes, that “as the representation of the outside, or the surface of the human body, is the chief object of his art, he ought to study the structure of the body and its inward parts, chiefly for the sake of, or as they affect, or are referred to the external surface, and make their appearance there, or are assilant in the better drawing and representation of it. Hence the parts which shew themselves upon, or affect the surface of the body, ought to be the sole or chief object of the study of a painter. The parts, therefore, that lie nearest to the surface, or outside of the body, and consequently that are most immediately concerned in forming its outline, are first to be considered by a painter, *viz.* the external layer of the muscles, especially the larger ones, and these that are most subject to appear in the movement and attitudes of the body. As to the skin and fat under it, these are spread over

the whole body, and are to be considered merely as a drapery or covering to the more inward parts, which appear every where more or less through them, at some times and places in a stronger, and at other times in an obscurer manner. But though the parts nearest to the surface are the first and most obvious that belong to the study of a painter, yet nature has so contrived the human body, that the external parts cannot be well understood, without a just idea of the internal ones, even of those which are, as it were, buried in the centre of the body; I mean the bones or skeleton, which are the foundation and frame on which the whole fabric is built, and to which, as a basis, all the other parts are mediately or immediately referred; particularly the muscles, so necessary to be known by painters, which are chiefly inserted into the bones, and make considerable marks and impressions upon them; and consequently without the knowledge of the bones, the muscles, and other soft parts cannot be understood; but there is another reason why the bones must be studied by the painter, *viz.* because parts of the bones, though covered by the integuments, appear not obscurely to the eye in many places of the body, and, like the large muscles, are the cause of the outline, and of the character, proportion, beauty, and appearance of many parts; and when properly considered and understood, the bones, by so many fixed points, give the finest direction to a painter, not only how to find and place the muscles, but also how to draw the human body; nor can it be so justly or readily drawn by any painter, as by one who understands anatomy in a masterly manner, particularly the bones and external muscles, and can point them all out upon a living man, and, by means of that knowledge, determines all his points, and the forms and proportions of every part and member, adding one part to another as he knows they lie upon the body; this is the true and natural method of drawing the human figure. But though the bones and external muscles are the most necessary part of the anatomical study of a painter, yet it must be confessed, that at least a general knowledge of the whole fabric is of great use, in order to a more complete and masterly representation of the human body, and in order to be able to diversify, and give reason for every appearance; and not only the solids must be known by a painter, but he ought likewise to have some idea of the fluids, as on these chiefly depend the various tints and colours of the skin that appear in the different sexes and ages of life, in different characters and occasions, climates, and nations. And as the human frame is so contrived, that the movements and passions of the mind affect the body, and are evidently seen and distinguished upon the countenance, and are expressed there and in other parts of the body by strong and certain characters; and as this is the most delicate and highest part of the painter's art, by which he is capable to move, to delight, and to instruct mankind, and to recommend himself and his art to their esteem and admiration; therefore, the study of the mind, and its various characters, passions, and movements, so far as they are marked upon and expressed by the body, ought to be above all things the study of a painter; for as the members of the human body, in a good picture, beautifully appear through the drapery; and as the bones and muscles appear through the skin, so the mind itself, in all its characters and passions, appears upon the countenance, and in the expressive proportions, attitudes, and tints of the various parts. A lover of the arts of design, or indeed any anatomist of true taste, will look upon the human body, and all its parts, with the eye of a painter; otherwise, he will see and describe it in an ignorant and rustic manner. Observing the human body with the eye of a painter, enables us to see all its beauty and perfection, and

raises in our minds a thousand ideas of the uses and propriety of the several parts, whereof one ignorant of painting will be totally insensible; and, in describing the human body upon this plan, we naturally do it in the most clear, short, and agreeable manner." We wish to impress upon the mind of the young painter, that he *must* absolutely obtain a competent knowledge of anatomy, and therefore have strengthened by quotation what we before observed. At the same time we have purposely omitted Dr. Prichard's reprehension of the method adopted by all artists, *viz.* that of proportioning the figure by heads, &c. (see Adrian's measures of the antique figures) which, if he had well considered and understood, he could not have rejected.

In a well-formed figure, all its parts are in proportion to each other: if the head be the tenth part of the height of a perfect model, its imitation cannot be well, or with certainty, made without this being used as a scale for the other parts: if the face be divided into three parts, and one of these parts be allowed to be the length of the nose, which it is in all the fine specimens of beauty and proportion, either ancient or modern, then may the figure be said to measure eight heads in height, or thirty times the length of the nose; and this scale will give a right proportion to figures of all dimensions. It is well to caution the student against departing from the revered *ancient* path by the hasty determination of any person, as the young artist may be seduced by his adherence to *individual* instead of the *generale* of nature. See Reynolds's Discourses to the Students of the Royal Academy. See also Fuseli's Lectures. While he is beginning this pursuit, at the very time when he is the most liable to err, we present our caution. It is not intended to speak of picturesque anatomy, merely to amuse persons who wish to have some conception of it, but to endeavour so to treat the subject, as to assist those who desire to be directed into the right path of attaining necessary information in order to practice; to point out the method, by which the study is to be pursued; what books, tables, and casts are conceived to be most proper; and which, by experience, have been found the most useful. Some observations will also be made that we apprehend are very much required, and which are not to be found in any printed work upon this subject, that we know to be exact. Some of our readers may think too great stress is laid upon anatomy for artists, while to others these instructions will seem superficial. To the former, we recommend a second consideration of what has been said; to the latter we submit, and refer our readers, for deeper knowledge, to the anatomical labours of the gentlemen, to whom those parts of the Cyclopædia are committed; while at the same time we advise the student in painting not to pay too much attention to those curious parts of anatomy, which do not concern his profession. In excuse for any want of connection which may appear, though it is meant to be as methodical as the nature of the requirements will admit, it should be noticed, that some of our observations are meant to be impressed upon the memory, and retained as distinct maxims.

Having thus far offered general observations, we might now immediately proceed in the particular steps, by which the student is to pursue his practical knowledge, were it not for a consideration, that an attention to theory should in a slight manner, at least, precede practice, for which reason it is thought necessary to exhibit a general system of the bones and muscles in this place. This has been done by excellent writers upon anatomy, but many of them have been too particular for our present purpose. As we think it may not be in the power of our readers to procure those works which are written in a slight manner, such as is at present required, when it will be necessary; for this reason the following

A N A T O M Y.

lowing general systems of osteology and myology may be here introduced with great propriety.

The system of the bones or skeleton, is, as it were, the solid frame that contains, defends, and gives stability to the softer parts, and to which they are ultimately attached, and consequently this bony fabric has of itself the general form, size, and appearance of the entire body. This solid frame is most artfully composed of different parts, jointed to one another, so as to be capable of every useful and graceful motion in the whole and in all its parts: and the various bones and pieces of which it is composed differ in size, form, and strength, in position, connexion, and motions, according to the uses and exigencies, and even the beauty of every part, to which they often add a certain grace and character, by obscurely appearing here and there through the softer parts, even in the living body.

The head is, as it were, the dome or cupola to the whole edifice. In this highest part the senses are placed, and the brain defended by solid bone. The head, like the rest of the body, derives its size, form, proportions, and principal characters first from the bones; but the softer parts that cover them add life to the motions and the finishing beauty, in which last the hair also concurs; and it is surprising how so few simple organs, and so thin a covering to the soft parts, are capable of such infinite variety of forms and expressions as we see in the human countenance, affording an endless field of study. In the head the bony part is a more complete fabric, and comes nearer to the form of the living subject than any other part of the skeleton; being the seat of so many noble organs, and the chief part to be studied by the painter, it deserves the first place, according to the custom of some anatomists.

Here vestiges of the smooth polished bone shew themselves in the forehead, in the ridges all around the eye, in the hollow of the temples, on the nose and cheek bones, and margin of the jaw, giving great pleasure to the painter who understands anatomy.

Next comes the elegantly bent pillar of the spine, strong, yet flexible, by consisting of so many parts firmly tied together. This bony column, at the same time, gives size, strength, and motion to the body, attachment to many surrounding parts, and being hollow through its whole length, serves to conduct and secure the spinal marrow, and to transmit nerves to every part of the trunk and extremities. The spine consists of four and twenty vertebræ, generally increasing in size as they descend, and gradually varying in their figure; seven of these vertebræ belong to the neck, which admit of peculiar and considerable motion, and allow of many graceful movements to the head and neck. The next twelve belong to the back; these are almost rigid, and admit of very little motion: to these, as to a solid basis, the twelve ribs of each side are attached, which, together with the sternum and their own cartilages, form a kind of yielding cage or basket to contain the heart and lungs. This bony cage admits of a small motion when we breathe; to the lower margin of it all around is fixed the diaphragm, a transverse muscular partition, dividing the thorax from the abdomen, a main organ of respiration, and of other functions. The five lower vertebræ belong to the loins, admit of considerable motion, and are of great use in the firm and graceful attitudes, and flexions of the trunk, and in many offices of common life. Between the ribs and pelvis there is a great void in the skeleton, especially before. In this space lie many of the abdominal viscera, with the parts that contain and cover them, making on the fore-part the beautiful swell of the abdomen, elegantly marked by the containing parts.

To the superior part of the thorax, by means of the transverse clavicles, and of large and strong muscles, are appended the upper extremities, which, at the shoulders, give breadth to the thorax above, and serve many noble purposes of strength, of art, of defence, of expression, and of beauty. These are divided into the shoulder, consisting of the clavicle before, and the thin broad scapulæ behind, which, moving free among the muscles, by their means govern the motions of the whole arm, and its triangular form has a most beautiful effect, seen floating among the soft parts in the naked figure; and indeed the whole shoulder is a most noble part, and a fine exercise to a painter; for, besides many large muscles, the bones themselves also most beautifully and distinctly appear. Next comes the arm bone, capable of a large and free motion, whose round head at the shoulder, in lean persons, obscurely appears, and at the lower end its condyles are evidently seen, where it is joined to the fore arm; this consists of the radius and ulna, which move upon the arm bone with the more confined motion of flexion and extension; but for the sake of the hand, and its various and important uses, the radius and ulna likewise revolve upon each other lengthways, in a very curious and singular manner, turning the hand alternately prone and supine, as upon an axis. Lastly comes the hand itself; it consists of the carpus, metacarpus, and five fingers, the thumb being, as it were, an antagonist to the other four; the whole together, by its general form, and different parts and motions, serving almost every possible use, and its various attitudes being capable of great beauty and variety.

We come now to the pelvis and lower extremities; the pelvis supports and defends the lower viscera. The back part, or os sacrum of a triangular form is, as it were, the basis and continuation of the spine, whose vertebræ it obscurely resembles, and performs its offices by receiving the extremity of the spinal marrow, and transmitting nerves to the surrounding parts. The lateral and fore-parts of the pelvis, though fixed and immoveable, answer in some respects to the scapulæ and clavicles, as they afford sockets for the thigh-bones, and also a seat to many strong muscles that belong to the trunk and extremities. The upper margins of the ossa ilium appear gracefully in the living body on the fore-part, and form a kind of boundary between the belly and the thighs. The spines of the os isium, as of the vertebræ, obscurely appear in bodies not loaded with fat, and also the great trochanter is deeply immersed among large and strong muscles; but at the knee the bones make a very fine appearance, *viz.* the condyles of the thigh-bone, the tops of the tibia and fibula, and the patella, a bone so beautiful and so useful in the government and defence of this joint. The bone of the tibia appears through the whole length of the leg, and at the lower part of the tibia and fibula, the two ankles elegantly appear, and fix the bounds between the leg and foot. The foot, a thick and solid part, serving as a basis and support to the whole body, consists of the tarsus, metatarsus, and toes; in the whole, and in every part, it in some sort resembles the hand, and, although much inferior, comes next to it in beauty.

The skeleton is one simple system of solid parts, serving as a jointed frame on which to build the rest of the body. But the muscular or fleshy parts that clothe and move the skeleton are soft, and form a more various and complicated system, consisting of different strata or layers, one covering another, and divided into numerous portions of different size and figure, regularly disposed over the whole body, composing a great part of its bulk, and the chief cause of the size and form of the members; for when stripped of its uniform coverings, *viz.* the skin, and cellular or fatty membrane,

the external muscular figure nearly resembles that of the entire body.

The muscles differ greatly in their size, figure, and other particulars, according to the parts where they are situated, and the uses to which they are applied. But in general they are composed of fibres; the middle part or belly being large, soft, and red, and the extremities or tendons, which are generally inserted in bones, being smaller and harder, white and shining. The red part is properly the moving power, and acts by contraction, during which it swells, and becomes hard and shorter, sometimes to a great degree, and thereby pulls the parts to which its extremities are affixed. The muscles are governed by the power of the will, except the fibres of the heart and of the intestines, &c. which are of all others the most irritable; the muscles of respiration act in both ways. The muscles can act in a most gentle and delicate manner, and also with great strength and velocity, though much of their power is lost by the places and manner in which they are often situated and inserted on the parts to be moved. The causes of muscular motion are difficult to be accounted for.

The muscles are arranged in their places, and allowed to slide upon each other by means of the cellular or fatty membrane; and their fibres are lubricated every where by the oil it contains, and in the fabric of the body, and of the muscles themselves, many contrivances are used to assist their actions. The muscles are in sufficient number, and so disposed and contrived, as to be a warm covering and defence to the more inward parts, as well as to move the joints in all the directions they are capable of, to assist in many functions of the body, and to place and retain it in every possible attitude; in doing which the particular muscles seldom act alone, but in the most various manner co-operate with, or oppose each other; so that the whole muscular system may be considered as one muscle, every fibre being under the power of the will, at the pleasure of which the whole body, and all its parts, are at once or alternately moved and governed, as it were, by so many bridles. Besides this grand purpose of the muscles, they likewise serve the general uses of the animal machine, being the chief cause of respiration, and of the circulation of the blood and juices; also promoting digestion, absorption, secretion, excretion, nutrition, and growth; hence they likewise prevent and cure obstructions, and other diseases, and by their incessant action, are one great cause of the hardening and wasting of the body, and the decays of old age.

Although we think too great an attention to the minutiae should be avoided by the student, especially at the first, yet it will be worth the attention of the young artist to examine the nature of a muscle a little more carefully; and to know that the fleshy part of a muscle consists of a bundle of thin long threads, and is divided into a great number of fasciculi, or little muscles, each inclosed in its proper membrane. The fasciculi of muscular fibres have not always the same situation in regard to each other, nor run in the same direction, but sometimes run parallel to themselves and their tendons, and are sometimes disposed obliquely both to their tendons and to each other; but information respecting circumstances of this nature will be more completely obtained by inspecting the muscles themselves. A sight of the object will impress the knowledge conveyed by the anatomist in the most forcible manner upon the student's mind.

Some have thought that the most proper method for the painter to begin his studies is under the instruction of some able anatomist; but, unless the anatomist understand the arts of design, this we disapprove, and think it best that the assistance of dissections should rather follow than precede the

general practical knowledge. It is therefore recommended that the student provide himself with some of the tables which anatomists have published. The tables of Albinus are deservedly esteemed; and what are, perhaps, better, those cut in wood, and which illustrate the ancient folio volume of Vesalius, edited in 1543, said to be drawn by Titian; but whoever the artist was, they are delineated with great judgment, the figures are graceful, the muscles are represented in a robust state, and properly swelling to the action of the figures: if this be of no great consequence to surgeons it is to painters. These tables may be copied with great advantage. We suppose the student to be expert in drawing, which is the first step to be taken in the painter's art. Tinney's compendious treatise of anatomy is also to be recommended: it is a selection made with judgment, although the plates are copied; the shapes and situation of the external muscles, their names, attachments, and uses are mentioned. This compendium was published by Sayer, in Fleet-street, in 1772. While such representations as these are copying, which should not be in a careless but in a decided and determined manner, the student will attain a great deal of the general knowledge of anatomy, especially if he should write upon the margin of his different views of the skeleton the names of the principal muscles, which, in the complete figure, unite themselves by their tendinous attachment to the bones, with lines drawn to their origin and their insertion; and also if the drawings of the muscular figures in this work have in their margins the names of the muscles, to which may be added their characters as flexors or extensors, and the limb they bend, extend, or rotate, pronate, or supinate, &c. Tinney's compendium, before mentioned, will readily assist in this particular, although the original figures in Vesalius are more recommended as objects to copy after, if that work can be procured.

The next step we recommend is to obtain the use of a good skeleton, supplied with a careful imitation of the natural cartilages and its articulations. With this should be compared the drawings which the student has been directed to make, and the different views they represent, as in front, sideways, or behind, gratifying his curiosity, and imprinting the object upon his memory. To the complete bony fabric, the head, trunk, and limbs should be obtained separate, for convenience, and their more particular inspection; and some of the bones singly, that the joints, &c. may be more carefully observed. We advise the young artist to draw these in different views; first, the separate bones as large as nature, marking the tuberosities and ridges, which give attachment to the muscles, the condyles of the joints, &c. with written remarks on the margin. We conclude that the student has been initiated into the principles of grace, and knows, in some degree, how to produce a figure in easy progressive motion, or prepared for such motion, which is what painters mean by grace (see GRACE.) In the skeleton he will observe how the joints, &c. by their mechanism, admit the muscles to produce these effects in the living body: this will open a great field of contemplation respecting his art, and in the wonderfully contrived object before him, the profound wisdom of his *Maker*. When he has thus advanced to an examination of the skeleton itself, he may derive much assistance from an anatomist, who knows how to point out to the artist such parts as will be requisite in his art; adapting himself properly to the degree of attainment which the student has made. In the want of such a friend, however, the works of anatomists are recommended.

The following hints, we apprehend, will be of use; they are few and short, though they may be important, as we only mean to give directions respecting the manner in which the painter is to pursue his studies.

It is of no great consequence whether we commence with the head or the pelvis: but in conformity to the system already given, the head is first mentioned; in which it was observed, the bony part comes nearer to the form of the living head than any other part of the skeleton. This should, like the rest, be drawn carefully; the face being complicated in its parts demands great attention, which may be deferred for the present. Let the artist, however, examine the mastoid process of the head, which will be important to him in future; let him observe how the head is placed upon the atlas of the spine, which moves freely upon the tooth-like process of the second vertebra. Let him observe the general support which is given to the trunk and upper extremities by the basis of the several vertebrae, the degree of motion which is allowed to each part, much in the neck and loins, little in the back, and none in the vertebra of the sacrum; how near the centre of the body this is placed, although the spinal processes of the vertebrae in the back approach so near to the contour of the figure, forming that ridge which is usually called the back-bone; yet the pillar of support which is composed by the basis of the vertebrae, articulated in a peculiar manner to each other, is, upon the whole, much nearer to the centre of the body than will be supposed upon the first inspection. Although the figure of each rib, which is attached to the spine, may be examined in future with more attention, yet, at first, we recommend the consideration of the whole together, that is, the general figure of the ribs with the sternum and cartilages, as the student's proper object, for consideration; the sudden turns which the ribs take backwards from their connexion with the spine, after which their curvature is not so sensible; also that the capacity of the upper part of the trunk is very small when compared with that which is below, contrary perhaps to what might be expected from a sight only of the living figure: he may be inquisitive respecting the extent of motion of the ribs while breathing, in which his anatomical instructor can greatly assist him. Let him examine the junction and situation of the clavicle; the degree of elevation to which the other end of the clavicle being attached to the acromium of the scapula, is permitted to rise by the elevation of the shoulder. The scapula should be carefully drawn as well as inspected, the outside of the parts behind, and especially the spine of that important bone; how much it can be moved by the elevation of the arm above the head, and how much nearer the bases of the scapulae can approach each other, when the shoulders are drawn backward; also how distant from each other the bases are, when the shoulders are drawn forwards. Several views of the end of the scapula should be delineated, both in connexion with, and without, the bone of the arm, marking the acromium and coracoid process. The inside view of this bone should be sketched with the clavicle and humerus removed; that the mind may be clear in these parts, although they are very much hidden by muscles, &c. in the living figure. When the nature of the ball and socket-joint of the humerus with the scapula has been well observed, nothing need, at present, to be noticed, but to draw and mark that bone of the arm, and notice the parts upon it which give attachment to the muscles, until the student come to the extremity united to the ulna; which, we think, should have considerable attention paid to it, both as united with the bones of the fore-arm, and separate, that the hinge-joint may be well understood, being careful to examine the condyles, and also the smaller tuberosities, &c. If he can have an opportunity of drawing from a natural skeleton (a natural skeleton is one prepared with its own proper cartilages) it will be greatly advantageous to him; and more so, if he can inspect and draw from these parts when newly dissected. We

also advise that particular attention be given to the inner and outer protuberance of the humerus, giving attachment to some very important muscles with which artists ought to be acquainted.

The ulna should be drawn separate and in connection with the radius, its hinge-joint also with the humerus: this should not be past over hastily. Its extremity at the elbow should be very much considered, and the permission it receives by the hollow of the humerus, &c. of sinking, as it were, into that hollow, when the fore arm is extended. The same attention must be paid to the peculiar shape of the radius, the junction of the upper extremity of this bone with the ulna and humerus, the rotary motion which is admitted, in pronation and supination; the size of these bones at the elbow and at the wrist, the head of the ulna being larger above, smaller below, and the contrary in the radius; as well as the general shape and proportion when both are united together. Lastly, with respect to the present consideration of the radius, we call particular attention to the tubercle, in which is inserted the tendon of the biceps muscle. The compact bones of the wrist or carpus being articulated to the radius, with the considerable motion it allows, will be an object to which, even at first, the attention is due, and its union with the hand, &c. The metacarpal bones, and those of the fingers may be well understood by making careful drawings.

We now descend to the pelvis, composed indeed of several bones, but perhaps better understood by artists, when they are together, than when separate, as they admit of no motion in themselves, except at the coccyx: but the motions of the pelvis itself, upon the thighs, demands, we think, even at the very first, as much attention, if not more, than any other bone of the human body.

The understanding of the turns which this compages of bones take in standing or moving figures, will particularly assist the informed artist to produce graceful effects in his imitations, or, at least, without knowledge of this particular, it is by accident only that he can produce his figures in graceful postures. When by drawing this basin for the abdominal viscera (without concerning himself with its contents), he is become acquainted with its form, he should study in the following manner: let him observe the upright posture of a graceful figure, standing upon one leg, right or left; let him next consider how the spine of the ilium will appear in that state; then place the pelvis so before him, and draw it carefully, the inclination of that important part being according to the posture. This hint will do for a person who is eager in the pursuit of knowledge, in all other states in which the action moves the pelvis; and will exhibit to him the different nature of the study of anatomy, in a surgeon or a painter, or to what different ends the same study may be applied.

The ball and socket-joint should be well considered, where the femur is articulated with the ilium, the whole form of the thigh-bone should have due attention paid to it: particular notice should be taken of the great trochanter, and also some observation should be made upon the ridges in the femur. This should be studied by the artist; being set in the different postures that it sustains, under particular actions, as was before directed for the pelvis; but the condyles, and the nature of the joint, and its tuberosities, demand strict attention: in connection with the large bone of the leg. It should be observed, that this joint is very ridged when the leg supports the figure, and admits of no rotatory motion; this joint should also be studied without, as well as in connection with the patella. When the leg is firmly extended, as in supporting the body, the patella is drawn up by strong muscles, and rises above the joint, being then stationed on the outside of

the head of the femur; but when the leg is bent, the point of the patella again falls within the joint.

By carefully drawing the tibia and fibula they will be understood; but the protuberances forming the ankles must be observed, and the faithful delineation of them stored up in the mind; noticing that the inner ankle, formed by the tibia, is higher, and advances more forward than the outer ankle formed by the fibula. The heel and tarsal bones with the metatarsal, should be studied as they are united, noticing the manner in which the bones of the leg are placed upon them, together with the whole of that finely constructed arch that bears up the whole body.

In addition to what has been said upon the study of the knee, the aid which the natural skeleton affords, should lead the draftsman to correct knowledge of this important and beautifully formed and useful joint. If he has opportunity, it should be also studied after a fresh dissected subject, with the leg in extension, as well as in its state of flexion, and, as before hinted, his observations written on the margin should accompany the drawings.

In contemplating the articulations in the natural skeleton, it will be observed, that the lengthening of the body at one time more than another, is not by drawing out like a worm one part of the body from another, but by the muscles bringing the bones more perpendicularly over each other. This leads to the consideration of the *muscles*.

“A muscle is composed of two tendinous and slender parts,” as Count Algarotti expresses himself; “one called the head, and the other the tail, both terminating at the bones, and of an intermediate part, called the belly; the action of a muscle consists in an extraordinary swelling of this intermediate part, while the head remains at rest, so as to bring the tail nearer to the head, and consequently the part to which the head of the muscle is fixed, nearer to that part into which the head of it is inserted. There are many motions, to effect which several of the muscles (for this reason called co-operating muscles) must swell and operate together, while those calculated to effect a contrary motion (and therefore called antagonist muscles) appear soft and flaccid. Thus, for example, the biceps and the brachizus internus labour; and when the arm is to be bent, and become more prominent than usual, while the gemellus, the brachizus externus, and the anconæus, whose office is to extend the arm, continue as it were flat and idle. The same happens respectively in all the other motions of the body. When the antagonist muscles of any part operate alone and at the same time, such part becomes rigid and motionless; this action of the muscles is called tonic.” It is to be wished that the student may be informed by a dissected subject of the nature of the different sorts of muscles, as those whose fibres are direct, like the biceps, of others which are oblique, as the pectoral muscle, of those which are called penniform or feathery, as that which moves the thumb. Those which are round, being internal or little seen, do not belong to his studies. He should also be taught that the tendons admit of no contraction or extension; that they are long for convenience, and that they are in general confined near the centre of motion, by annular ligaments, to prevent deformity, and also to admit of a more quick motion, as in the wrist; but where the contrary arrangement renders them more useful, they are not thus confined as in the hamstrings, and the bend of the fore-arm.

He should know that the same muscles are used to draw the body to the arm, which draw that member to the body; also, that those muscles which bend the thigh on the body, when the feet are fixed, bend the body on the thigh; that some muscles have not all their motions engaged in every action in which such muscles are employed, but only part of

them, as the deltoid, the portions of which have various motions; such portions, however, never act without the concurrence of some other assisting muscle with them.

These things being premised, the student is to be directed how to proceed, and what are the readiest means. We before directed him to the tables published by anatomists: this advice, we suppose, to have been complied with. It is, therefore, recommended him to draw with care from a good cast of a muscular figure, after the skin and other integuments have been taken away by a skilful anatomist. In the Royal Academy there is a valuable figure of this kind, which is strongly recommended to those who can have access to it; and where he will also find other subjects of this nature worthy his attention, as well as proper instruction from a very respectable professor of anatomy; but in the want of the instruction which that institution has provided for its students, &c. and the use of the large anatomical casts, which it possesses, a cast should be procured from those shops which supply artists with anatomical and other figures in plaster of Paris. Mr. Banks made an excellent model after the original, which we mentioned to be in the Royal Academy, about three feet in height, which was cast in plaster; and we recommend it above any others that we know can be obtained. The figure (of which this is an admirable copy, though of reduced size) was prepared for the artists by the late Dr. William Hunter, to which every attention was paid both by him and the artists who assisted in placing the figure in a graceful attitude.

The unfortunate subject of that cast was executed for murder, the body was taken from the place of execution as quickly as possible, and while warm, and the muscles capable of contraction, to which their nature disposes them (even without the influence of the will), the body was set in the posture it now stands, and in which state it was dissected; then the cast, of which we speak, was produced. Many similar attempts have been made, but this appears to be by far the most successful of any figure we are acquainted with, which arises from several concurring circumstances; such as its being a well proportioned figure, its attitude graceful, the limbs so disposed as to shew each part distinctly, and its having been prepared by a great anatomist. Being a cast from nature itself, the mind has an unbounded confidence that he who studies from it cannot be misled by the mistakes of an artist; and that the figure being set while the muscles were warm, they have, in a great degree, the proper swell, comporting with the state of the limbs. Mr. Spong made a small model of this figure, the bronze casts from which, for their size, are excellent. There are several other casts to be met with which may greatly assist the student: that after the anatomical figure which was modelled by Mr. Rubiliac, is very natural and good; there are also some executed by the French Academy. We recommend the head and neck as large as life from the French, and also the trunk and upper extremities in a reduced size; one side having the external muscles taken off, and the other side retaining them for the sake of comparison. Another of the leg and thigh of a man with half the pelvis, exhibiting the psoas muscle; the last which we particularize, and deserving as much notice as any, are two dissected arms, cast under Dr. Hunter, which are fine exhibitions of muscular strength. While the student is in practice, and as his judgment expands, or his fellow practitioners recommend, he will find assisting objects of this nature presented to him in abundance. These hints concerning the casts, &c. may be of use to some of our readers, especially those who are situated at a distance from the metropolis.

Whatever cast of the muscles the student's judgment or
con-

convenience has selected, he ought to examine and copy different views, writing upon the margin (as we directed concerning the study of osteology) the names of the muscles, their origin, insertion, and their use, as flexors, extensors, and rotators; observing, with the same attention, the situation of the bones behind the muscles, and where the projections on the surface are caused by them. While the young artist is making such drawings, he will do well continually to examine and compare the living figure with the anatomical cast; the figure being placed in the same attitude with the object of his imitation; tracing with the finger the bones and muscles of the living subject to ascertain the causes of the effects he observes, and which he cannot otherwise account for. This will greatly facilitate his knowledge.

A common-place book for anatomical sketches, as well as the complete drawings he has been advised to make, will be very useful, in which the separate parts may be delineated; beginning with the head, and descending to the lower extremities, in the following manner. First, suppose it to be the front view of the head and face of the skeleton; then he may draw from a plaster cast of the head, &c. with the skin taken off; such as the large dissected head, from nature, which we mentioned as being prepared by the French academy; or if this be not at hand, the head from any of the before-mentioned anatomical figures. Then a drawing should be made in the same view from a living person, one in whom the muscles are to be distinguished, the subject not being covered too much with fat. Several views of the face should be treated in this manner.

What has been said of the head will apply to the neck, trunk, the arms, hand, thighs, legs, and feet; this practical method will be of considerable use to the artist, and if the separate parts in different views be also drawn from some of the antique figures, such as are placed in a similar posture, his taste and style will, at the same time, be greatly improved; it will naturally suggest itself, that such of the antiques as are robust and herculean, will be most proper for him at first to select, for such purposes; these objects will lead him not only into the knowledge of the parts, but he will naturally imbibe the right style of representing muscular motion from them. We are acquainted with no critic who has observed any anatomical error in the antique statues, or an instance in which the profound knowledge of anatomy does not appear; none who have detected a false swelling of the muscles, or any ostentatious display of anatomy; for those well-informed artists exhibited no more of their knowledge than was proper, as it respected the character of the subject, either delicate or robust, at rest, in motion, or in violent exertions.

This remark, we believe, is strictly due to the statues and fragments of the ancients, though it may not be so applicable to the valuable works, in other respects, of the great *Michael Angelo* himself; whose figures will, notwithstanding, be of a very improving nature, especially while the artist is in pursuit of anatomical knowledge; but he should be cautioned not to follow even this extraordinary man in representing these appearances too strong, where it is not requisite; nor in giving the swelled motion of the muscles to the whole body and limbs, flexors, and extensors, at the same time,—which cannot be, but in rare instances, as in sudden starts of surprise or agony. A common-place book of the nature which has been recommended, besides the original exercise, will restore to his memory the impression which time may efface from it. This being the student's own work, a sight of it, and his other studies of the same nature, will more assist his recollection, concerning the subject he has formerly considered, than a much

longer examination of prints or drawings by other persons can be supposed to do.

In order to prevent embarrassment amongst the great number of muscles, the following arrangement is made; by which the student's attention at first may be circumscribed, and *these* demand his particular attention, *viz.*

<i>Temporalis</i>	<i>Rectus abdominis</i>
<i>Zygomaticus</i>	<i>Latissimus dorsi</i>
<i>Masseter</i>	<i>Teres major</i>
<i>Sternohyoidæus</i>	<i>Infraspinatus</i>
<i>Sternomastoideus</i>	<i>Splenius</i>
<i>Latissimus colli</i>	<i>Sacrolumbaris</i>
<i>Cleidomastoideus</i>	<i>Longissimus dorsi</i>
<i>Trapezius or cucularis</i>	<i>Gluteus major</i>
<i>Rhomboides</i>	<i>Gluteus medius</i>
<i>Pectoralis</i>	<i>Triceps</i>
<i>Deltoides</i>	<i>Psoæ</i>
<i>Biceps</i>	<i>Membranosus</i>
<i>Brachialis internus</i>	<i>Sartorius</i>
<i>Gemellus</i>	<i>Gracilis</i>
<i>Axonæus</i>	<i>Biceps femoris</i>
<i>Pronator teres</i>	<i>Seminervosus</i>
<i>Supinator radii longus</i>	<i>Semimembranosus</i>
<i>Flexor carpi radialis</i>	<i>Vastus internus</i>
<i>Flexor carpi ulnaris</i>	<i>Vastus externus</i>
<i>Palmaris</i>	<i>Rectus femoris</i>
<i>Perforans</i>	<i>Tibialis anticus</i>
<i>Perforatus</i>	<i>Peronæus</i>
<i>Extensor digitorum</i>	<i>Gastrocnemius</i>
<i>Extensor minimi digiti</i>	<i>Soleus</i>
<i>Extensor pollicis manus</i>	<i>Extensor digitorum pedis</i>
<i>Serratus major anticus</i>	<i>Extensor pollicis pedis.</i>
<i>Obliquus descendens</i>	

These muscles selected, and thus arranged, are few in number, and will not perplex the student; considering how important they are to his art, he should not be discouraged when informed, that with most of these he ought to be intimately acquainted. With respect to the psoæ, and one or two more of the internal muscles, it is necessary only to know that they exist, and where they are situated; but most of the other muscles, thus particularised, should be very familiar to him, not only where they are placed, but how they appear when at rest, in common action, or in violent exertion; and if the method we have recommended be adhered to, a tolerable capacity will attain a great degree of knowledge respecting the muscles, as well as the bones of the human figure.

In the Royal Academy will be seen, beside that already mentioned, another muscular figure, prepared by Dr. Hunter, one side only of which has the skin, fat, &c. taken off, that a comparison may be made with the other side of the figure, in which it may be seen how much thicker some parts of the human body are covered than others. The student ought to have information respecting this circumstance by other means, if he has not access to this figure. It should also be known that although there is a considerable difference in the size of the muscles in different subjects, between those who are accustomed to labour and exercise, and those who are more sedentary; yet it is the cellular membrane, or fat, which principally constitutes the difference between corpulence and meagreness, and not the muscular fleshy substance of the body; and also that children's muscles are in proportion with adult, according to their size and age: the painter will see the propriety of this remark.

One more observation is necessary to be made respecting the covering of the muscles, which is concerning those tendinous expansions that wrap up and bind them together

in many parts; these are usually strong, although thin and transparent; on that account they cannot in general be so well expressed by casts or drawings, but in the dissected subject, which the student should inspect if possible; the skin and fat being taken off, the expansions are discovered by their white and shining appearance. We advise all young artists to obtain instruction respecting these aponeurotic expansions, and particularly the fascia, which arises from the tendon of the biceps muscle inserted into the radius, and also from the palmaris covering the palm of the hand, and the expansion from the glutens, where it is united with the trochanter, covering the muscles of the thigh; he should consider this as no trivial object of his concern. In the fore-arm the structure from the aponeurosis is so strong as greatly to affect the form of that part of the limbs where it passes over the pronator teres, flexor, carpi radialis, palmaris, &c. and it is strong enough to shew itself, even in casts from nature; in the cast from an arm prepared by Dr. Hunter, this is beautifully preserved, although a dissected arm will shew it better. It will perplex the student to account for such appearances in general, although he may have the most perfect knowledge of the bones and muscles, unless he be informed respecting this circumstance also.—In various parts of the body some of the larger veins appear, such will be found upon the surface of the subjects, from which the painter makes his studies, and therefore he need not to be particularly directed, nor concerning those which reddens the parts upon exertion, as the fore-arm, when the hand is strongly grasping a sword, &c. or the redness and paleness occasioned by the different passions of the soul. See P A S S I O N S.

We might describe the action of the muscles we have selected, and in the order they are arranged; but this would be descending to particulars more than we proposed, especially as they are best learned under the immediate instruction of an anatomist, pointing them out on the living figure, or which the student may observe upon his own person in a glass, (a method much recommended by the late Dr. Wm. Hunter,) or upon a living muscular subject. We shall, however, particularize a few muscles as specimens, in order to lead him into the proper method, by which he is to proceed with the rest, and also present some observations for his consideration.

A figure standing gracefully cannot, with propriety, be said to be in motion or exertion, but many of the muscles are in exertion to produce even this effect, *i. e.* those which support the figure in the erect position, especially the muscles of the standing leg and of the loins.

When the body is prepared by the mind to receive and support a weight, the muscles are in exertion, prepared to support what it expects to be received: should a man offer to another any heavy weight, covered with a light substance, as cork, &c. bringing it with such an air as to imply it was not heavy; from the mind being thus deceived, there would not be a preparation or exertion of the muscles adequate to support it, and consequently it would fall and endanger his toes, although the person would be more than capable of supporting it under other circumstances. On the contrary, if a body of a light nature be thus presented, covered so as to represent a very heavy substance, and the person conveying it seems to exert himself as bearing a considerable weight, so soon as the palms of the hand come in contact with the pretended heavy substance, the muscles would be so prepared to exert themselves, as immediately to heave it into the air. This may be seen also in the muscular exertion of a person catching a ball projected with a strong degree of force. An artist may obtain information respecting the propriety

of muscular exertion, from the ancients, by placing a living person in the action of any of the antique figures, as performing what they represent the figure doing; strictly comparing with the figure the several muscles and limbs, as well as the general form; whether standing gracefully, as the Antinous, more exerted as the Apollo Belvedere, or in violent exertion, as the Laocoon.

This method is the best we can recommend for the improvement of the student's taste and judgment, other methods will conduce to his knowledge of the parts; but this will communicate the idea of graceful motion and the proper expression of the figure. Studies from the living figure should be continually made, and those who are wise and are not prevented by other avocations, should in England, as in France and Italy, never forsake the life academy, in which school much of practical knowledge will be learned; but the student's taste must be formed from the antique figures, in all that relates to proportion, elegance of form, and anatomical propriety. A sound knowledge of anatomy, is the ground of the painter's art; it is, however, better to know and produce the effects like the ancients, after their deepest researches, so as to hide the artifice by which those effects are produced. *Ars est celare artem.*

Although it is not our intention to describe the minutiae of the muscles, included in the list, yet we shall notice a few of them and some other circumstances, as a specimen. Dr. Hunter has often been heard to say, that the principal method he used in order to attain the knowledge of muscular motion was by consulting his own body, because he could give the action to those muscles he wished to examine, and he strongly recommended this method to others. This trial, from so eminent a character, will be adopted so far at least, as it respects the intricate muscles of the fore-arm, and by a glass he may inspect the front of the whole figure; but such parts as cannot thus be examined, must be sought for in another person. When a living muscular subject is placed before the student, (with an assistant to oppose the effort which he is to make, in order to retain the muscles in action for a short space of time, while they are under immediate notice), the commencement may be with the head. The masseter and temporal muscles will be in exertion when the teeth are strongly pressed together; this exertion will be seen in a man when he is lifting a great weight; these muscles should be felt as well as seen, that the mind may be quite satisfied respecting them. The effect of the zygomatic muscles in drawing up the corners of the mouth will be perceived when the subject is smiling, &c. Although these muscles do not always shew themselves, they ought to be considered attentively, as they have a great influence in expressing the passions. Sternohyoideus will be in action when there is an attempt to swallow any thing. We suppose all the muscles in our arrangement have been well considered; and that the student has become acquainted with their form, origin, and insertion, and also with the use of the separate muscles.

The sterno-mastoideus draws the head downwards, forwards, and sideways; now in order to notice the action of this muscle, first let the man turn his head over the right shoulder, when it will be found that the portion of this muscle, which is on the left side, will belly out, consequently it will grow tense, and shorten itself, while that portion which is on the right side, will be longer and flaccid; this will be evidently seen, and may be felt and measured with a string, that the student may be perfectly informed respecting a muscle so important to all artists. The face should be then placed in the centre, and the person must be then directed to endeavour to bring his face down upon the breast,

Breast, while an assistant places his hands upon the forehead of the living model, to oppose his bringing it down; while making this attempt the sterno-mastoideus will be seen in strong action in both portions, and be very conspicuous; but when the head is in the centre, and in each way in the same direction with the body, and that perfectly upright, this muscle will not so visibly shew itself, excepting near the insertion in the sternum.

The pectoralis will be seen in very strong action, by the man endeavouring to bring the fore-arm to his breast, the hand being lifted up about the height of his shoulder; if the assistant, at the same time, make an effort to keep the arm outwards. If the man with his arm thus raised, move it inwards and outwards several times, an opportunity will be given to observe the motion of this muscle: so also if the hand be lifted higher than the head, then brought downwards and inwards, he will also perceive that the pectoralis should properly be considered as a muscle belonging to the arm, notwithstanding it is situated upon the breast.

Thus the flexors and extensors, pronators and supinators, should be examined in motion, after their place and use have been rendered familiar by the order and method of study we have been detailing. What has been advanced upon the study of muscular motion in a few instances, we hope, will be a proper clue to all the other external muscles; many errors may be avoided, and much time will be saved, if the several parts be pointed out to the student, by a skilful anatomist, who will demonstrate to him, that although it may be proper to remark the action of the separate muscles by themselves, yet still no action of a limb is performed without the co-operation of several muscles. This should become as evident to the mind of the artist, as that the deltoid elevates the humerus, or that the biceps is a flexor of the fore-arm.

He will, by such an instructor, be informed that some of the muscles, or parts of them, are so thin, as to shew the motion of those which lie underneath, as the latissimus dorsi; and although others are deeply seated, yet they have great expression in some actions, as the longissimus dorsi, which will become very conspicuous, when the body of the figure, being bent downwards, endeavours to regain an erect position.

The student should let the figure before him raise his head and depress it again; turn it over one shoulder, then over the other; this may be done quickly and repeatedly, while he makes his observations on the muscles in the neck.

He should direct the man to bow his body downwards, and bring it up again repeatedly, at one time more quickly than at another, while he observes the motion of the rectus abdominis, &c.

The model should also be directed to draw in his breath, to shew the boundary of the true and false ribs, which must be well observed. He should make him stand upon one leg, then upon the other, shifting them continually more or less quickly, while he notices, with great strictness, the change this will cause in the spine of the ilium, and the other parts of the pelvis; on this we lay particular stress, as in a preceding instance, when directing the study of the bones, without the muscles.

He may now examine the motion of the patella, and the muscles rectus and vastus of the thigh, with the same care.

He should cause the man to lift up one foot, and bring the heel to the other knee, in order to exhibit the motion of the sartorius muscle.

By quickly moving the toes, the man will shew the muscles in action, which give them their motion.

He should be directed to elevate and depress the arms, as

well as bend the fore-arm, to shew the performing muscles of those parts; to turn the palm of the hand upwards and downwards, which will exhibit the pronators and supinators. The wrist bent and extended, and the fingers quickly moved will shew their muscles.

When the back of the figure is seen, the same method should be pursued to express those muscles which are behind upon the trunk, and the extremities; carefully noticing the motion of the scapula, especially the different situations of that bone, when the arm is lifted upwards, and brought downwards; likewise examining the motion of the muscles in the side view of the figure in the same manner.

Particular attention should be given to those muscles which form the edges of the armpits, and of the hamstrings of the thighs; and lastly, as study and drawing ought to be considered by the painter as synonymous words; we advise that such things as strike the mind, when they are newly discovered, should be noted by the student in a book kept for the purpose, with such sketches as may tend to recal to his mind in future, or describe to others, what cannot be so well conveyed by words alone. Advice of this sort has been repeated under each head of study, as we know the consequence it may be of to some of our readers.

Dr. Brisbane judiciously observes, respecting comparative anatomy, "that the painters should at least be acquainted with the anatomy of those animals which are most commonly introduced into their works, particularly of that noble and useful animal, the horse, and of that faithful companion of mankind, the dog; as for other animals, as they more rarely appear in pictures, and are less particularly known and attended to, a slighter representation of them may generally suffice." We, however, believe that birds should be examined in the interior, as opportunity offers, especially the skeleton. In respect to the horse, we recommend the painter to read, and examine the valuable labours of Mr. Stubbs and Mr. Blaine, which we conceive to be an honour to our country. He may also be furnished with an anatomical cast of an horse, which is sold at the shops; from whence information in this respect may be derived, especially after the human figure has been well understood; for, by knowing which are flexors, and which are extensors, in general, the student will be in a great measure informed how they will act in this animal. Assistance will be also gained by observing the animal itself, which he will have before him while he is painting it. Some animals, but especially leopards and tigers, are formed so much like a cat, that this common animal will be very useful to him; their muscles may be judiciously expressed, if a dead cat be put into the posture of the animal to be represented, before its muscles are cold, and then the skin being taken off, it will be an almost perfect direction to the painter, who is familiarly acquainted with the action of the muscles in general.

See the names of the MUSCLES of the human body in the Cyclopaedia, their character, nature of their fibres, origin, insertion, and uses, to which our readers are referred for more particular directions concerning them.

ANATOMY, *Veterinary*.—Human anatomy, in point of interest and importance to mankind, evidently holds the first place; that of brutes, particularly such as are domesticated and employed for various important purposes in society, in respect to their anatomy, holds the second place. The anatomy of these, without being entered upon so circumstantially as the human anatomy, deserves a due share of regard equal to its importance. To describe each part of the horse individually and separately, would be often only repeating the more elaborate

descriptions of the human anatomy more frequently than those but little conversant with this subject would suspect; many of the viscera, and even the myology of the trunk and extremities, often correspond in their principal circumstances: there are, however, great and various differences in the structure of the two animals, which it will be our duty more particularly to describe. For the same reason that the study of the human anatomy is useful, as it tends to preserve the health and lives of men, equally so is that of brutes, inasmuch as it tends to save the lives of these useful and often costly animals. Nor will it be necessary to descend far down the chain of quadrupeds; the few only which from their domestication are rendered serviceable to mankind, deserve this particular notice; in carrying anatomical research farther among the brutes, and in descending into the more subordinate orders of animated beings, the study of their anatomy receives its share of importance, in proportion only as it serves to illustrate the uses and functions of particular organs and parts of the more complicated and noble animals, from the very various figure and structure these parts are found to assume in them, from which much information of their use may be obtained; and then, instead of *veterinary anatomy*, it becomes properly the subject of, and arranges under the head of *comparative anatomy*.

This science may be properly termed *veterinary anatomy*, which, in strict propriety, should include only those animals employed as beasts of burden, as the root of the word (*veho veño*) from whence it is derived implies; but it is necessarily extended to all domesticated animals employed in the service of man. The horse, the ass, the camel, the ox, the hog, the dog, the sheep, &c. rank principally under this class. The anatomy, however, of the horse has only been much cultivated, and that but of late years; various establishments of considerable munificence have appeared within the present century for the cultivation of this study, as that of Charenton near Paris, Lyons, Berlin, London, Copenhagen, Vienna, &c. These institutions, together with the exertions of individuals, have begun to advance this science into respect and estimation; the anatomy and surgery have already received a high state of cultivation, as being more easily attainable by direct mechanical means; the progress of medicine is more slow, and it will be more readily admitted by those most conversant with the subject, to be at present in a state of great obscurity; and from certain difficulties attending the culture of medical science in general, and particularly in these animals, a long period will be necessary for it to obtain much consistency or precision; small effects are with difficulty traced in mute animals, and no feeling or change in them can be described or known, unless powerful enough to be externally visible. On the other hand it is but just to remark, there is a more free and unlimited opportunity of experimental inquiry and research, as their diseases are fewer, and arise from less complicated causes, than those of men.

This science, though it has long lain in a neglected and degraded state in this country especially, and throughout all Europe, yet has not wanted men of refinement for its cultivators. Among the writers who have distinguished themselves in this line of science are to be enumerated among the ancient Romans, Vegetius; he is supposed to have lived about the time of the emperor Valentinian the Third, in the fourth century, and is generally considered the same writer, whose book "*De Re Militari*," has been so much admired, as giving the best account of the military tactics and warlike weapons of the ancients; his treatise "*De Arte Veterinaria*," is not less curious in the present age, as handing down to us the practice and opinions on the veterinary art

at a very refined period of the Roman empire: his work is principally a compilation from the most esteemed authors of his own time, and especially the Greeks; the prefaces, or introductory chapters to his four books carry with them sufficient evidence of their author, and are remarkable for strong and elegant language. Better reasons or apologies for the cultivation of this science have, we believe, never been penned; and though medical reasoning and physiology were at this period in a low state, still we view with surprise, that the practice was very often not materially different from that which would be suggested by the most refined reasoning of the present day. Columella has treated largely on this subject; he lived prior to Vegetius, in the second century, under the emperor Tiberius. Cornelius Celsus, about the same period, is also understood to have written on this subject, but of his work there are unfortunately no remains. At a still more remote period than this we find Greek writers on this subject of considerable note; no less than seventeen are enumerated by Ruellius, who was physician to Francis First, king of France. The surviving fragments of these authors were edited by Ruellius, by the orders of his munificent patron, first in Latin, in folio, in the year 1550; afterwards the original Greek text, in 8vo. in the year 1537; both splendidly printed, so as scarcely, in this respect, to be surpassed by any thing of the present day. To this collection of essays, Absyrtus, Eumelus, Hierocles, Pelagonius, Theomnestus are among the chief contributors: their writings consist of dissertations on the various diseases of the horse, beginning mostly in the epistolary form, with the usual salutations in use among the Greeks. We learn from Sudas, that Absyrtus was a Bithynian by birth, and served under Constantine in the Scythian war. Hierocles appeared in the courts of law in trials respecting those animals, and did not, like Theomnestus and Absyrtus, serve in the armies of the emperor. The period in which the others lived there are no means left of ascertaining; it appears, however, to be most probable that they lived at an early period after the formation of the eastern empire. In these writers the symptoms of some disorders are pointed out with much acuteness, in which consists the great value of their writings. Their prescriptions are often ill-digested farragoes, composed of many incongruous ingredients, some but little known, and others altogether disused at present in medicine. In the administration of remedies of a surgical nature they were more happy, especially that of topical bleeding, which they well understand, from every part of the body. Xenophon has also treated expressly on these subjects in twelve short essays or chapters respecting the training, management, and external figure of horses, and is the most ancient of all the writers extant on horses, being between three and four hundred years before Christ. At the decline of the Roman empire this science underwent the general fate of all the other sciences, and suffered an occultation longer than almost any of them. A period of more than a thousand years elapsed without adding as much to the human knowledge of this subject as has been done within the last twenty only in Europe: during this period, however, of the obscuration of science, at an uncertain date, was propagated the art of shoeing horses' feet with iron, and which at length became general; an art that has been variously practised, and never yet reduced to certain rules. It appears also, that, during this period of declining literature, the veterinary art ceased to exist as a distinct profession, or was practised so feebly, that, on the discovery of the art of shoeing, what knowledge then remained of it was easily transferred to the working smiths, who alone could practise this art. Its sister science, human surgery (it would hardly now be credited), underwent a similar fate; and, for the

want of schools to teach, and professors to practise, passed into the hands of the barbers, from whom it has not been entirely removed till within the last century. These smiths became at length from habit, and the custom of mankind in seeing them so employed, as it were, the legitimate sons of veterinary science; their labours, through a long period of years, have not advanced the science a single step, and they were necessarily employed in this art when it had no regular professors, as being more likely to be skilled in these matters than those less deeply engaged in them, though it would be clearly seen, on reflection, that the good practice of medical knowledge, even on brutes, would require as much knowledge of anatomy and the principles of medicine as the same practice in the human being. Therefore, for the liberal practice and advancement of it previous information on these points was absolutely necessary. In the modern revival of this science the French appear to have led the way; and in taking a short review of those men who have principally promoted it, we shall first mention the name of Bourgelat, (*Les Elements de l'Art Veterinaire*) and Lafosse (*Cours d'Hippiatrique*) as among the earliest useful authors on this subject. The Earl of Pembroke very much promoted the science in this country by a small treatise on the manege, in which he first suggested the idea in England of schools being formed expressly for the cultivation of this subject, having seen those in France about this time. Many expensive and ostentatious works were published on the manege, which nevertheless did not appear in the smallest degree to promote the medical branch of this art. Berenger's work in 4to. 1771, "on the history and art of horsemanship," is filled with interesting matter respecting the manege, and must highly gratify every inquirer after this branch of the art. We cannot recommend too strongly the writings of Mr. James Clark, of Edinburgh, on these subjects, as possessing much good sense, and none of that fulsome sufficiency which marked most of the later writings of our countrymen previous to his time. In France Vitet (*Medicine Veterinaire*) has laboured the anatomy of the ox, and added it to that of the horse, which had not been much cultivated before. Our countryman, Mr. Stubbs, has, however, done the greatest service to the science by his excellent anatomical engravings of the bones, muscles, and many of the blood vessels and nerves of the horse, a work in port folio size, which, for faithful design and good engraving, will not easily be exceeded. Snape's work is also respectable on the general anatomy of the horse. Blundeville published a useful treatise on all the different branches of this art in the reign of Queen Elizabeth, written with considerable learning and modesty; and there is another publication of this description by Leonard Mascall, in the year 1662. Soon after this a bad style of writing on these subjects crept in, and has too much held its place to the present time. Gervase Markham, in the reign of Charles II., published his "Master-piece," and here appear to begin the presumptuous style and empty knowings which has characterised the greatest share of the works which have followed; these have not promoted the science in the smallest degree, but have grossly declaimed against and abused what they were pleased to denominate the ignorance of grooms, the ignorance of smiths, and the ignorance of all their predecessors, taking all unfair advantages of their works, in judging concerning them by the improvements of succeeding times. In this way we find Markham, Burdon, Bracken, following each other with uncharitable asperity and "puny criticism;" and to this list others might be added of the present day. They have written page on page in this abusive way, without adding one single discovery or useful fact to that art they so arrogantly pretend to teach.

And in this place we cannot help noticing a singular barbarism, that appears to have been the offspring of the above writers, which has found its way into common use, in one of the terms belonging to the veterinary science, and which we conceive ought no longer to pass uncorrected, as terms misapplied in science always confuse, and often lead to error. The word *farrery* is at this present time universally in this country employed to signify the whole veterinary art, and is a barbarous mode of spelling the word *ferriery*, as it is immediately derived from *ferrer*, French, to shoe a horse, and that from the radical *ferrum*, Latin, iron; and should signify no more than what the word implies, the application of the iron shoe to the horse's foot. The want of regular practitioners in the veterinary art rendered it necessary that the *ferrer* should adopt the art; and hence the whole art became included in the general term *ferriery*. In reducing this word to its proper spelling, for there can be no authority to justify the present mode of spelling it, and in expunging it, we commit no violence on the usage, or introduce any innovation on the English language, for there exists sufficient testimony to prove that the old English writers did not spell it as we do at present; as in Blundeville, who wrote during the reign of Queen Elizabeth, which, according to Johnson (see preface to his Dictionary), was the purest era of the English language, we find it spelt, with great propriety, with an *e*; see book fourth, in his "Address to the Gentlemen of England:" he writes, "All horses, for the most part, do come into their decay sooner than they should do, by one of these four waies: that is to say, either for lacke of being well bred, or through the rashness of the rider, the negligence of the keeper, or else through the unskillfulness of the *ferrer*." Again, in the same chapter, "Martin Ghelly, of Arton, called Martin Alman, chiefe *ferrer* to the Queen's majestie;" and so on throughout the work. The title of Earl of Ferrers and Derby might also be adduced in proof of this being the ancient and proper mode of spelling this word, the arms of this nobleman being quartered with the horse-shoe, and formerly accompanied with some singular privileges to the family. This word, therefore, reduced to its original and proper signification, only relates to the art of making and applying the iron shoe to the horse's foot; and in this sense we shall have occasion to employ it, as the veterinary art embraces this and all the other branches of the science.

Indeed, on pursuing an historical retrospect of the state of this science in England, it has seemed to us, for the last hundred years and upwards, to have been taking a retrograde course, which we feel rather disposed to attribute to the unbounded rage for horse-racing, which, while it was of great service to the British nation, by encouraging the best breeds of strong and fleet horses, was of disservice, by promoting an artificial vitiated taste with regard to these animals, which overawed all attempts at modest inquiry respecting their diseases. The knowledge of horses was supposed to consist in a sort of intuition, which was not to be defined or taught to others. Jockeys, sharpers, and gamblers, were supposed principally to possess this knowledge, which was all that was thought necessary respecting them, and all farther information could be of no use. Jockeys before this period were of small note, but from being entrusted with the secrets of the course, soon became engines of great importance in pursuing this species of traffic, and men at length were brought to resign their understandings to them, imagining it a subject too mysterious and difficult for them to comprehend; hence also appears to have arisen the great difficulty of founding a seminary for the study of veterinary medicine and surgery in this kingdom, which was almost the last country in Europe that adopted this salutary step for the improvement of the art.

A more free and candid mode of considering this subject let now appear; and a style of writing and enquiry, which must (however it may labour under difficulties for a time) bring forth light, and, with the great improvements in chemistry, and all the arts and sciences which can promote it, will soon place it on a footing far beyond what was known in ancient or modern times.

Having gone through what appears to us to be the outline of the history of the art, as far as we are at present acquainted with it, we shall immediately pass to a description of the skeleton of this useful animal.

On taking a general survey of the bones of the horse, (see *Plate I.*) we may divide them into those of the head, spine, trunk, fore and hind extremities; and here it will be proper, in pursuing this general view of the skeleton, to remark a circumstance that is not universally known, *viz.* that the horse, when in the best possible proportion and shape, comes within the square, the head and upper part of the neck only being excepted; and this applies alike to horses of every description, as well the race-horse as the dray-horse: to explain this assertion, the dotted line is given, pointing out the limits of the square. If this principle was more generally known to the painters and statuaries, we should not have so many ugly and miserably disproportioned animals from their hands. This subject we propose to treat of more extensively under the article *SYMMETRY of Horses.*

On a further examination into the general properties of the skeleton, we propose to shew also, that the weight of the horse is supported by a *contraposition* of the angles of the superior part of the fore and hind extremities, as the shoulder-blade, or scapula, *a, b, c, d, e*, from the withers, leans obliquely forward, forming an obtuse angle with the arm, or humerus, *f, g, c, h*; in the hind extremity the reverse of this structure is observable in the position of the bones, as the hip-bone, or ilium, *a, b, c, d, g*, and the ischium, *f, f*, which pass in a sloping direction backwards, and form with the thigh-bone, or femur, *h, m, k, n*, an obtuse angle forwards. Now it is evident, that the angular position of these bones being opposed to that of the shoulder and arm, will readily, by acting in opposition to it, sustain the weight of the body which is placed between the two angles; the rest of the two extremities are disposed nearly in the perpendicular line to these angles, and support the weight as simple columns, still, however, following, in a slight degree, at the hocks and knees the above angle of support. From this cursory view of the entire skeleton, it will be necessary to pass to a more detailed examination of the bones which compose it, without being too minute for an elementary work of this kind; and we shall begin with the *head*, which is formed of the skull, face, and jaws, and which are divisible into about 32 distinct bones; the *skull* consists of 11 bones; the two *frontal* (see *Plate I.*) bones, *a, b*, the two *parietal, c*, four *temporal, h, i, k*, one *sphenoid*, one *ethmoid*, and one *occipital* bone, *d, e, f, g*. The temporal bone in the horse is made up of two distinct portions, the squamous and petrous, which in this animal always remain distinct. The occipital bone differs much from the corresponding one in the human skull, forming the top of the head, and is possessed of very great strength and thickness, with a deep depression on the centre, where the cervical ligament is attached. The *face* is made up of 21 bones, as follows, two *nasal* bones, (see *Plate I.*) *r*, two *angular* bones, *m*, two *malar*, or cheek bones, *l*, two superior maxillary, *n, o, p*. The inferior maxillary bone, *q*, is not found in the human skeleton, and has been termed by Professor Blumenbach, the *inter-maxillary* bone: it was supposed by him for a considerable time to be peculiar to the brute, and would serve for a dis-

tinctive mark by which every animal genus of the *mammalia* might be distinguished from the human; his latter researches have, however, discovered that no such bone existed in some of the long-tailed monkeys, though it is worthy of remark, the same bone is found in several of this tribe of animals with short tails. There are two superior palatine bones, two inferior palatine, two superior turbinate, two inferior, two pterygoid bones, and the vomer. The turbinate bones are particularly large in the horse, as are also the maxillary cavities; and by the elongation of the face, the head of the horse is extended in length beyond almost every other quadruped. Two thin plates of bone, almost distinct from the palatine bones, and divided by a suture, following the same direction as the large palatines, are observable in the space between the incisor and molar teeth of the upper jaw: these might be termed the lesser palatines; they are, however, merely processes of the intermaxillary bones, and not divided from them by any suture. The intermaxillary bones in this animal contain the whole of the incisor teeth, but not the canini, or tusks, the suture passing between them. The inferior maxilla, or rather, in the horse, the posterior, or jaw bone, is formed of one bone, at least in the adult, and is not, as in the human, made up of two bones, united by symphysis at the chin; it is necessarily longer and deeper than the jaw of most other quadrupeds. The jaws are furnished with alveoli, or excavations, which receive 40 teeth, *viz.* 12 nipping, or incisor teeth; 4 tusks, or canine teeth; and 24 grinders. The tusks are never shed in the horse, though they are in the dog, and some other carnivorous animals; the three first pair of molar teeth are also shed in the horse, and receive a second set; the three last pair are permanent; the first set of incisors, or milk teeth, are also shed as in all other animals. For the growth, structure, and other particulars of these bones, and some remarks respecting the indications of the age, we refer the reader to the article *TEETH of Horses.* The *spine* is a canal of bone, of a very elongated conical figure, and, in the horse, is made up of about 32 pieces, independent of the bones of the tail, which is formed of about 14 bones. The cervical vertebræ are seven in number, which number it has been remarked by anatomists, prevail in all quadrupeds, whether the neck be long or short. These bones in the horse are altogether different from those of the human skeleton in their formation: the body of the bone is considerably more elongated, and the processes of a different figure.

The first vertebra in the horse is termed, as in the human skeleton, *atlas*, but evidently with not so much propriety, as the head of the horse is rather suspended from this bone than resting upon it; it differs essentially in figure from the other vertebræ of the neck, being more extended laterally, and in being without any dorsal apophysis; it is also much shorter than any of this range of vertebræ; it receives anteriorly the condyloid processes of the occipital bone, and likewise posteriorly the tubercle of the second vertebra within its articulating cavities.

The second cervical vertebra is in figure almost the reverse of the former, being long and narrow in its body, the dorsal process, or crista, very elevated and enlarged, rough on its upper surface, for the strong insertion of ligament; and this spine, or elevated plate of bone, at its posterior part, is bifid, or cloven, with a middle depression, or fossa, affording a stronger and wider surface for muscular and ligamentous attachment. This vertebra has no superior oblique processes, and enters the former bone by a half tubercle, or capitulum, exposing the spinal marrow on its upper part, and is kept in its situation by two broad lateral articulating surfaces.

The other five bones, which compose the neck, are of a more uniform figure than the two former, consisting of a body of bone, somewhat lengthened, having a large cylindrical perforation for the passage of the spinal marrow, externally of an irregular, almost quadrangular, figure, having various angular and spinous elevations of bone, which are termed according to their situation, as the spinal apophysis, the superior and inferior oblique processes, the transverse and anterior processes, which are intended for the strong insertion of muscles, tendons, and ligaments for the support and motions of the neck. The articulating process of these bones consists of a round head of bone, the posterior articulating surface of a suitable indentation to receive it. This knob of bone is observed by Stubbs to be wanting in the sixth vertebra of the neck: these bones possess also various perforations for the transmission of blood vessels and nerves.

The dorsal vertebrae are 18 in number, sometimes 19, and are remarkable in the horse for the length of the dorsal or spinous processes, extending from the first to the eighth, and which form what is called the withers of this animal, and against which the superior part of the shoulder is brought to recline.

The dorsal vertebrae differ in structure from the cervical, being much shorter in the body or solid part of the bone, the spinous apophysis being longer, the anterior process is wanting for the underside of these vertebrae, and those of the loins present a smooth rounded semicircular surface to the viscera. The interposing cartilage, or elastic ligament, in the cervical vertebrae, is not considerable in the dorsal vertebrae; it makes in the recent skeleton more than an eighth part of the whole length of this part of the spine.

A dorsal vertebra of the horse possesses almost a similar number of processes as are found in those of the neck, though very differently situated and proportioned; these processes are all placed superiorly to the two articulating surfaces of the ribs; and it is almost unnecessary to repeat that they possess foramina for the passage of nerves and blood vessels, and the spinal marrow.

The lumbar vertebrae. Where the ribs terminate, begin the lumbar vertebrae, which are six in number, and possess very much the same processes and character as those of the back. The spinous processes are stronger, the lateral processes broader and longer, and sometimes articulate with the body of the vertebra, and in some measure serve the purpose of spurious ribs. These bones are often united into one mass in the horse, by ossific deposit, as are also those of the back.

The five next bones of the spine are united into one mass in the adult, to give strength and energy to the various motions of the hind quarter, and in their consolidated state are called the os sacrum. The interstices occasioned by the union of these bones on their underside, form what, at first sight, appear to be huge foramina, being rounded, as these generally are.

The superior part of this bone possesses longer spinous processes than those of the loins, and admits a vast surface for the attachment and deposit of muscles; and here are placed the muscles of *loco-motion*, which, in all animals, are the largest in the body.

On the superior surface of the transverse processes of this bone rests the flat inferior surface of the ilium, to which surface it is attached by strong ligaments, so that the body of the horse is, as it were, entirely suspended by ligamentary and muscular substance, for the scapula has no other than this species of attachment; hence the entire exclusion

of a solid bony articulation of the extremities with the spine, must soften every motion of the animal to itself, and consequently to what it has to carry.

The remaining portions of the spine, consisting, in the horse, of 18 pieces, gradually lose the structure and properties of the foregoing parts of the spine, and become simple rounded cylinders of bone, solid and enlarged at the points of articulation, and towards the extremity of the tail are of a consistence nearly cartilaginous.

Of the trunk. The costae, or ribs, are bones of a curved figure and elastic, serving to defend the principal part of the thoracic and abdominal viscera; and in the horse are generally 18 in number, sometimes 19; these are articulated by one extremity to the dorsal vertebrae by two surfaces, a lateral and terminating articulating surface. The eight first of these ribs terminate on the sternum itself by an *offo-cartilaginous* substance; the others do not reach the sternum, but are attached to each other by a long surface of adhesion of the same kind.

The sternum in the horse is composed of seven pieces of bone firmly united, and differs widely from the human in being curved, and, instead of being flattened, is anteriorly acute, like the prow or keel of a vessel. This anterior part is also of an *offo-cartilaginous* consistence, terminating above by an obtuse eminence above the articulation of the first rib, and inferiorly by the scrobicular cartilage of an oblong figure. This structure enlarges the chest, and gives room for a stronger attachment of the fore extremities to the shoulder for the support of the body.

Of the ilium, ischium, and os pubis.—These we may consider as forming part of the trunk; they are, however, only attached to the spine by ligaments, having no actual articulation, and might be referred to the hind extremities. These bones form collectively the haunch, the thigh being included, and internally the pelvis.

The ilium, or hip-bone, in the horse, is not of a rounded figure, as in the man, but is extended in three directions, forming three powerful branches or processes, which may be denoted, by way of distinction, the superior, inferior, and posterior rami, the three exterior margins or edges of the bone included; between the above rami we propose to distinguish by the terms anterior, superior, and inferior cristae. The ramus inferior is shorter than the others, and obtusely truncated, giving an anterior and posterior pointed angle. The extended branches and wide upper surface of the ilium give a place for the attachment of several strong muscles which are thus situated, to the greatest mechanical advantage, to the points on which they are to act, giving with the ischium a magnitude and power to the buttock not equalled perhaps by any other animal.

The ischium in the horse is remarkably extended, forming a strong process posteriorly for the reception and attachment of powerful muscles, and which process is entirely wanting in the human skeleton. This elongation of the ischium may be denominated the *processus triquetrus ischii*, from its figure: this singular process disposes the muscles attached to it very advantageously for powerful action on the thigh and leg, by removing them to a distance from the centre of motion.

In the os pubis there is to be remarked the very extraordinary depth of the symphysis, affording an extensive surface for muscular attachment.

The above three bones unite in forming the acetabulum, or cup, which receives the head of the thigh bone, in both the human and equine skeleton.

There appears to be a slight degree of motion of the ilium on

on the transverse processes of the sacrum, arising from the ligamentous connection between these bones; in the dog this motion of the ilium is more evident, and on dissecting this part we have observed a singularity which, we believe, has not been generally noticed, and which is worthy of remark in this place. The os ilium in this animal rises so considerably above the transverse processes of the lumbar vertebrae on its interior part, that the middle of it, instead of being occupied as in other animals with the iliacus internus muscle, is entirely filled up by the muscles of the back, and the above muscle is entirely wanting. We may, perhaps, illustrate the cause of this peculiar structure by remarking, that the action of the dog, as in galloping, is performed principally by the muscles of the back, in the horse it is more effected by the action of muscles of the extremities.

In taking a view of the figure of the pelvis in this animal we may observe its depth is greater, its area wider, and axis more in the line of the spine than in the human.

Of the extremities.—The great variety of accidents and diseases to which the extremities are liable, and the peculiarity of structure which attends these parts in the horse, render a knowledge of them more interesting and necessary to the veterinarian or amateur in these matters than any other part, and will engage us to consider them with more minuteness and detail than we have done in executing the preceding imperfect outline of the description of the other parts of this animal.

The extremities of the horse are constructed of much the same members as the human, though very differently distributed and proportioned; the human hand, the first of all executive instruments, is here converted into the solid foot, useful only for support and progression: the hand grows more complex towards its termination, while the horse's foot becomes more simplified, following the purpose for which it is designed. Notwithstanding, these parts in all quadrupeds have a relation to each other, and possess rudiments which even appear superfluous, but serve to point out the connexion between the different families of them; as the styloid bones of the horse are evident rudiments or relics of the two outside metatarsal bones of the digitated animals, and appear to serve no very important purpose, as the mammæ or nipples of the male quadrupeds are rudiments void of use of the same parts, which are highly useful in the female.

Of the fore extremity. The scapula, blade bone, or shoulder of the horse is considerably lengthened, and is proportionably narrower than the human, being of an oblong triangular figure, possessing neither acromion nor coracoid process, though there is a prominent, obtuse point of bone in the situation of the latter, and a rounded eminence often on the spine of the scapula, which denotes the situation of the former. The horse, we may observe, possesses in this part no proper back, for the withers can hardly be considered as such, therefore the scapula does not materially pass out of the plane of the os humeri, or arm, as in the human, but is simply reclining on the side, its upper part reaching near the extremities of the dorsal apophyses or withers, its lower part directed forwards, and approaching the first rib and upper extremity of the sternum. The under side of this bone is concave, and is found in old horses covered with asperities for muscular attachment: the upper surface is divided longitudinally into two unequal parts by a bony ridge, called its spine, affording surface for the attachment of various muscles and tendons; the base or broad extremity of the scapula is furnished with a cartilage, which embraces the muscles of the withers; its small end possesses an articular cavity which

receives the head of the humerus, and is termed the glenoid cavity. The motion of this bone is different from any other in the body, not moving upon either extremity, but librating round a point which is situated near the centre of the bone.

Of the humerus, or arm. This bone is particularly short when compared with the bone of the human arm, scarcely passing beyond the line of the chest, and is proportionably stronger, passing from the point of the scapula in an oblique direction backwards; and instead of partaking of the various motions of the above bone, possesses but one motion, that of being brought from its inclined position forwards to the perpendicular line of the body. This bone possesses various strong elevations and depressions for the lodgment and insertion of muscles, of which there is hardly any trace in the bone of the human arm. It articulates inferiorly by two strong condyles with the radius. It is this bone, often by being too long, that brings the horse's fore-legs too much under his body, a fault much disliked by the amateurs of riding horses; this may also arise from the shoulder being too upright. The fore-limb of the horse not requiring any rotatory motion, as in the human arm, we find no distinct os ulna, but the point of the elbow, or olecranon, being very much enlarged and extended in length, is firmly fixed to the back of the radius, sending off a process of bone downwards, which is brought to a point about the middle of the radius, uniting firmly with it; from its position being fixed in respect to the radius, it can perform but one of the offices of the human ulna, and serves for the attachment of those muscles, which bring back the fore-arm, from its bent position forwards, to the straight line, under the pressure of the weight of the body. For the os radius, see *Fig. I. l. l.* The radius or fore-arm of the horse is nearly straight towards its middle and inferior extremity, bending a little forwards; it is usually mistaken for the arm of the horse by casual observers, its posterior surface is flattened, it grows broader at its extremity, forming two condyles, possessing motion, upon the bones of the knee, admitting an extent from the perpendicular of the leg, considered together with the bones of the knee, to a very acute angle backwards.

Bones of the carpus, (see *Plate I. fig. 1, 2, 3, 4, 5, 6,*) are the bones which compose the carpus, vulgarly called the knee of the horse, and correspond to the bones of the human wrist; these bones do not afford a similar extent of motion with the same bone in the human carpus, not admitting any motion forward beyond the perpendicular line, nor of any lateral motion whatever.

On a first view of the bones of the knee of the horse, their position seems reversed to the human wrist, the olecranon or elbow being placed at the back of the radius, and the flexion taking place in a direction towards it; and the bones which form the back of the wrist appear to form the front of the knee. This inversion, however, is only apparent, and not really so, as by a slight rotation of the radius, the human wrist may be placed in the same relative position to the ulna, as the bones of the knee of the horse are with respect to it.

The knee of the horse is made up of seven bones, sometimes eight, a very small, round bone being often superadded on the side, about the size of a pea, and is not preserved in the generality of the skeletons of the horse.

This joint is formed of two regular layers or phalanges of bone, the upper phalanx or row being placed upon and between the divisions of the other three in each phalanx, the 7th being thrown behind.

The first layer, *viz.* that placed on the cannon, has little

or no motion; the second layer has considerable motion on the first as those have also on the radius, making in their total flexion about 30 degrees of a circle.

To strengthen this joint, and to secure these bones more firmly in their situations, they are formed with alternate elevations and depressions both in their upper and lower surfaces; this joint is also rendered stronger from having an articulation, which admits of motion in one direction only, that of flexion, and that in the opposite direction to the flexion of the hock, tending by this means to support the animal, as we have before observed.

The weakness of this joint, called *knuckling* in horses, observable in those that have been overworked, or grown old, does not, we believe, proceed from any defect of the joint itself, but from the rigidity of those muscles which serve to bend it, and especially those which pass to the foot, the extensors, which are comparatively small, not having sufficient power to counteract it.

These bones have but little resemblance to those of the human wrist, though they occur in the same number; it will therefore answer no good purpose to force an analogy between them by calling them by the same names; for the use of the names deduced from the human anatomy makes a perpetual recurrence to those bones necessary to see where they may, without impropriety, be introduced, and where they cannot be admitted; it is this circumstance which has rendered it absolutely necessary to compare both the skeletons in this present essay.

These bones might very naturally be denominated from their situations as follows; the *os externum superius* and *inferius*, *os internum superius* and *inferius*, *os medium superius* and *inferius*, *os pollicum*, *os accessorium*, and this would be a very desirable thing, for they would belong to a great number of quadrupeds without being misapplied. There is, however, a considerable objection to their adoption, which is, that in describing the attachment or insertions of ligaments or muscles, it would render a circumlocution necessary if any other language was used, which would be attended with inconvenience, and for which reason we decline the use of them.

Mr. Stubbs, in his excellent work, in following too closely the names of the bones after the human skeleton, has been betrayed into the use of names, which cannot well be admitted in the equine anatomy. The *pisiforme* is a very small rounded bone in the human, not larger than a pea; the *os pollicum*, though a perfectly distinct bone, and differently figured from any in the human anatomy, has been described by Mr. Stubbs under that name.

If it were desirable to make any analogy between these bones and the human *carpus*, we should on comparing them remark, that in the horse's knee there is a consolidation of some of the human *carpal* bones, and a separation or division of others; there is, however, the small *accessorium* bone included, the same number in each, *viz.* eight bones.

The *os trapezoides* and *magnum* appear conjoined in the horse, forming one large flat bone, whilst the bone in the horse, which serves the purpose of the *unciform* bone at the back of the knee, is made of two distinct bones; the human *unciform* bone appears in front of the wrist as well as behind and is one single bone. This curved bone also differs in the horse in being removed to the upper row or phalanx, for the bone, serving the same purpose in the human wrist, is seen in the lower row of the *carpal* bones.

In this way they may be compared and understood, as, after this explanation, the others fall in very naturally in their proper situations in both. Were it not on account of the names, it would not be necessary at all for the veterinarian to pursue any comparison with the human skeleton, and we

think it would be advantageous to avoid it; for the alteration of their figure, on which the human names are founded, renders the same names in the horse totally inadmissible.

A nomenclature for the osteology, which would include nearly, or quite all the quadrupeds known, might be constructed, and would be attended with great utility; such a nomenclature, however, would require, that neither figure nor situation should supply the names, as these would be perpetually varying.

It is no easy matter to give appropriate and unexceptionable names to all these bones, nor should we be desirous of undertaking it, if the above circumstances, and others that might be adduced, did not point out the absolute necessity of it; we are aware of the circumspection necessary in such a measure; and after as much consideration as we have time to devote to this subject at present, venture the following as the best adapted which at present occur to us.

The middle bone in the upper phalanx we propose to name *os intermedium*, being found near the middle of the upper range of bones in all the animals we have examined.

The large internal bone of the same phalanx we propose to denominate *os parietinum*, which, not conveying any precise geometric figure, will apply, without glaring impropriety, to a great variety of shaped bones: the external bone of this range, *os gibbosum*, having some gibbous elevations on its surface.

Of the lower series, the central one we should be led to express by the term *os majusculum*.

The external one, *os pollicare*, carrying the thumb in all digitated animals, and resting even in the horse on the internal styloid bone, which appears evidently the corresponding rudiment of this member in the horse, and is actually elevated above the level of the shank bone, and is placed higher than the styloid bone on the opposite side, serving to confirm the resemblance. It is this bone which so frequently becomes diseased with osseous deposit, termed splints.

The external bone of this range we would denominate *os subunciforme*, being provided with various elevated points, rudiments of the hook-like process, and corresponding to the human *unciform* bone.

The bone serving the office of the *unciform* bone in the horse, and holding nearly the situation of the *pisiform*, connecting and supporting the tendons, &c. which pass through it, being altogether a different bone from that of the human serving the same office, which has a curved process on the inside the wrist; that no confusion might arise with this bone, we change the terms *unciform*, or *pisiform*, in the horse, and call this additional bone, which is found in most quadrupeds, and even in the feline tribe, whose digitated extremity is a much nearer approach to the human hand, the *os pollicum*, or the *post-carpal* bone.

This bone gives great force and support to the tendons which pass through it, or are attached to it, allowing depth and solidity to the knee. It is this bone which occasions the prominent point at the back of the knee, affording a strong and handsome outline to this part; it also serves for the attachment of a very strong tendon at its extremity, which being then removed farther from the centre of motion in the joint, is empowered to act with very great force, and resembles, in this respect, the office of the *os calcis* on the hind extremity.

The *os accessorium* is a small round bone, about the size of a pea, which articulates with the posterior surface of the *os pollicare*.

The *os posticum* has been termed by Vitet, a celebrated French writer on this subject, *os hors de rang*, a name perfectly

fectly inadmissible in any other language. *Médecine Vétérinaire*, Lyon, 1783, tom. 1. p. 100.

We shall only farther observe on the bones of the present joint, that the surfaces for motion between the second phalanx and the first are particularly disposed to the outside of the joint, tending by this means to separate the legs when in action from each other, and prevent cutting. This is particularly remarkable in the *os subunciforme* and *majusculum*. The flexion of the upper phalanx upon the radius is directly backwards only, and forwards to the perpendicular of the extremity.

Of the metacarpal or shank bone.—The great difference of proportion in the parts which compose this extremity to the human is no where more conspicuous than in the metacarpal bones. The range of bones which form the wide palm, or the paws, of animals, is here for the principal part condensed into one solid cylindrical bone, longer considerably than the humerus itself, the rudiments considerably abbreviated of the two exterior metacarpal bones remaining to point out the general connection among quadrupeds; the cow has the shank bone destitute of splint bones, but at its inferior extremity is divided, forming two condyles for the reception of the two claws, and in this way forms as near an approach to the fingered animals, though in a different way.

The shank bone is flattened posteriorly for the reception of the suspensory ligament and tendons going to the foot, which we may observe is more considerable in the fore extremity than the hind one; the latter is longer, and of a more cylindrical figure, being generally described as having no perceptible difference. The styloid, or splint bones, adhere to the shank bone strongly, and are mostly united to it by ossific depositions, otherwise every where preserving a divided outline between the two bones. In the fore extremity these mostly dwindle to a point, about two-thirds down the length of the shank bone, and are not so large as in the hind extremity. These splint bones, though so often productive of disease, tend to strengthen the joint laterally; and perhaps by their elastic yielding to the perpendicular pressure of the limb, being elevated above the general articulating surface of the shank, may act as cushions in a slight degree in preventing concussion; they also serve to strengthen the limb, by affording a surface for ligamentary attachments. The inferior extremity articulates with the pattern bone by a condyle, having an elevated ridge of bone in the middle to support it, which enters a corresponding depression in the pattern bone. This joint, though strongly fortified with ligament and tendon, is more subject to suffer from violent usage than any in the body. In the cloven footed animals the division begins in this part.

Ossa sesamoidea. Sesamoid bones, *fig. 1. p. p. v. v.* are placed at the back of the pattern joint, and resemble, in their figure and properties, the same bones in the human foot; diminishing friction, powerfully assisting the tendons going to the foot, and at the same time supporting the pattern joint by their pressure.

Of the os suffragineum, or pastern bone. This bone corresponds to the first phalanx of bones of the fingers, the five bones of which may be considered as consolidated into one single bone; its general figure resembles sufficiently a bone of this part.

The pastern bone, at either end, is indented for the reception of the prominent condyles of both the shank and coronet bone, *fig. 1. o, o, u, u.*

The *os coronæ*, or coronet bone, *fig. 1. r, r, w, w,* is, like the former, a similar condensation of the five bones of the second phalanx of the fingers, and is proportionably

shorter than it; it articulates by a divided condyle with the coffin bone.

This and the preceding are rough on their sides, with depressions for the strong insertion of ligament, especially laterally, in the point of the axis of the condyle, where a deep indentation is observable.

Of the os basis, or coffin bone. *Fig. 1. s, s, x, x.*—This name, and that of the two former bones, have been taken from those Latin writers who have treated on this subject, and, we conceive, will not require any alteration.

A distant resemblance may be traced between the enlarged rounded point of the extremity of the bone of the finger and this bone. The particular structure, however, of this bone and the shuttle bone, and their various appendages and integuments, is sufficiently important to form a separate description. See *Foot of the Horse*.

Of the hind extremity.—The femur, or thigh bone, of the horse, compared with the human, and, indeed, with most other quadrupeds, is unusually short, so as scarcely to appear beyond the *parietes* of the abdomen externally on a cursory view, and is therefore overlooked by those unaccustomed to this subject; and the bone below is usually mistaken by them for the thigh of the horse.

This bone is of vast strength, possessing several elevated and depressed points for the strong insertion of tendons and muscles, which serve to distinguish it from the thigh bone of every other animal. See *Plate I. fig. 1. b, i, k, l, m, n.*

The head of the thigh bone in the human is carried by an oblique process, or neck, to a distance from the bone, whereas, in the horse, the head is without any length of process of this kind, placed at right angles, nearly to the bone, not affording that variety of motion which the human structure of this part does; a motion directly backwards and forwards, being for the most part the only movement requisite in this animal.

In a state of rest the thigh bone is not nearly in the perpendicular line of the body as in the human thigh, but inclines forwards, making an angle with the body of about 45 degrees, and forms posteriorly an obtuse angle with the rest of the extremity. This circumstance is necessary to be observed with attention previously to understanding the design of the muscles of this extremity, concerning the uses of which we propose to advance some ideas, which, as far as we know, have not before been entertained respecting them.

The muscles which are attached to the posterior part of this bone are called its extensors, serving to draw it from the oblique line it describes forwards, backwards to the perpendicular of the body, being attached near its head, and rather laterally.

Those muscles also which render this angle more acute, by drawing it forwards under the belly, are called its flexors, and are attached to its anterior superior part. We mention these rules respecting the functions of the muscles of this part the more particularly, as the terms flexion and extension but ill express the operation of these two classes of muscles on this bone, for the inversion of the terms would apply almost equally well; adduction and abduction are also generally attributed to other muscles, as they are found to attach to the inside or outside of the limb. We propose to demonstrate that such are rarely or never necessary among quadrupeds; and that such a vast body of muscles as there are to be found in both extremities of this description, have a much more important purpose to perform.

The great trochanter of the horse, see *fig. 1. Plate I.* rises considerably above its articulation with the acetabulum. This removal of the surface of attachment of the glutæus muscle farther from the head of the bone, must bestow uncommon power

power on this muscle in the horse, in extending the thigh backwards.

The lesser trochanter in the human thigh is placed almost behind it, in the horse laterally internally.

The most notable circumstance in the thigh bone of the horse is a strong, curved process of bone on the outside opposite the lesser trochanter, see *fig. t. k*, which receives in its curvature the *vastus externus* muscle, *musculus fasciæ latae*, and *musculus fasciæ glutæalis* send off portions of tendon, which are inserted in this curved process.

As this process is altogether wanting in the human, and in the ox, hog, dog, and in most quadrupeds, it is without a name; we have, in our description of muscular and tendinous attachments, termed it the *processus recurvatus femoris*. Mr. Stubbs terms it the protuberating part of the *linea aspera*; and Vitet *l'apophyse recourbée*, tom. i. p. 121.

On the posterior and inferior part of this bone, near its exterior condyle, there is a deep cavity, in which the *perforatus* muscle takes its rise.

The condyles of this bone are remarkable for their magnitude and strength; the outer condyle is larger, and is placed posteriorly to the inner condyle.

In the dog, and also in the cat, we have observed a small, round, moveable bone attached to the exterior condyle by a ligament not observable in the horse.

Of the patella.—The knee-pan, or tibia bone, is particularly large, elevated, and thick in the horse, having the lubricous cartilage on its inside where it meets the femur possessing correspondent, impressed condyles for this purpose. This species of cartilage is common to all surfaces of bones which are contiguous; therefore the continual repetition of this circumstance, in describing the articulations of the bones of the skeleton, has been omitted.

This bone serves to increase the surface for tendinous insertion of the muscles of the thigh, &c. passing over an angle on which it can easily glide; it elevates the tendons high above the point they are destined to act upon, and in this way vastly increases their force on the principle of the pulley and block: and we may here observe a property of this bone not generally observed, that it serves to unite in one focus the action of the muscles lying on the opposite sides of the bone, as the *vastus externus*, *internus*, and *anterior*, bringing them to act for one purpose on a single point, in which is clearly seen an instance of a principle we are about to deduce respecting the adductor and abductor muscles.

Of the tibia, or leg-bone of the horse.—This bone corresponds in structure with the human much more than the *femur*; it is, however, shorter, *cet. par.* There is near its head a sharp apophysis, which might be called its anterior crista; its external side is concave, in which lie the bodies of several muscles; its internal side convex, posteriorly it is flattened; its epiphysis may be divided into two condyles, external and internal, in the young foal; from the latter springs a small, spinous process of bone, the rudiment of the human *fibula*, which is totally wanting in the ox; the hog, cat, and dog possess a perfect *fibula*.

Of the tarsus, hough, or hock of the horse.—This important joint in the horse is made up of six bones, sometimes seven; the internal cuneiform being sometimes divided in two parts, as in the preparation at present before us. This joint in the ox, deer, and sheep appears to have no more than four bones, which seems to point out an extraordinary provision in the horse to increase the perfection of the joint, and prevent the ill consequences of violent concussion, as the additional bones in the joint of this animal are evidently well calculated for such a purpose.

The human tarsus makes a right angle with the tibia, and,

in the act of standing or walking, meets the ground; in the horse it makes a very open angle with the tibia, and is very far elevated above the ground: and here we may remark, that all the bones from the hock downwards are used for walking on by different tribes of animals; where the metatarsal bones are elongated, it is raised above the ground. The kangaroo, however, appears to be a remarkable exception to this general rule.

The astragalus bone in the horse possesses two very strong, prominent condyles, which are not observable in the human astragalus.

The *os cubiforme* is found holding the same figure and situation in both animals resting by its inferior surface upon the external styloid and shank bone, its upper surface receiving the inferior extremity of the *os calcis* by an articulation not possessing motion.

The two central cuneiform bones of the human tarsus appear to be united in the horse to form one flat extended bone, which rests upon, and covers greatest part of the articulating surface of the head of the shank bone.

The *os naviculare* also of the human tarsus is here converted into a flat extended bone, resting on the former; these two bones together equal in height the *os cuboides*. By these two flat plates of bone, with their interposing cartilages, a species of cushion is formed, which renders the effect less severe of the violent efforts and concussions this part is exposed to: that they have a purpose of this kind may be inferred from their taking no part in the flexion of the joint.

The internal cuneiform bone, or a bone that holds its situation in this animal, is found resting on the head of the internal styloid bone, which appears to correspond with the bone of the great toe in the human anatomy.

We are again subject to the same difficulty in giving appropriate names to the bones of this joint as we were respecting those of the knee. The bone, called in the human anatomy *os naviculare*, in no respect in the horse resembles a boat, nor the one beneath it a wedge, therefore to continue these names would be absurd; their situation also as little corresponds as does the purpose they serve in the two animals.

The cuboid bone, the *astragalus*, the *os calcis*, and the internal cuneiform bone may, without any impropriety, continue to receive those names in the horse, and particularly as it will be attended with convenience to hold as many names as can be admitted corresponding to the human anatomy, by which, at all times, a more ready communication can be held between the two sciences, but not so as to press this comparison too far by a servile copy of it, and a comparison between things which have little or no resemblance, or relation, by which the greatest confusion may be created, and the science at its commencement be clogged with improprieties.

The only changes it will be necessary to make in this joint from the human anatomy respects the two flat bones, which may be termed, with propriety, the *os planiforme superius* and *inferius*. These are the bones which often become diseased with the deposition of ossific matter, forming an enlargement which is termed spavin, and also the internal cuneiform bone.

The metatarsal, or shank bones of the hind extremity do not differ in any respect, so as to deserve a separate description, from those of the fore extremity; to the differences there adduced, we may perhaps add, that the styloid bones in general descend lower in the hind extremity, and are often clavated at the extremity instead of being pointed.

Of the muscles of the horse, &c. The following is a brief account and explanation of a large portion of the most interesting muscles of the horse; the short space of time al-

lowed for the preparation of this article, and the pressure of other affairs have prevented us from considering more accurately this subject; the muscles of the extremities, as being the most interesting and important, are more particularly selected; they are accompanied with descriptions taken from actual dissection, during our studies, in the year 1793. The remainder is an explanation of two of the principal muscular figures, given by Mr. Stubbs.

This account is necessarily imperfect; it may nevertheless afford those who are desirous only of an elementary knowledge of the subject sufficient information; those who wish to descend deeper into the study will do well to consult the following writers: Bourgelat, *Elemens de l'Art Veterinaire*; Lafosse, *Cours d'Hippiatrique*, and especially the useful work above mentioned of Mr. Stubbs: a good monograph on the muscles of the horse, giving a proper description of their figure, attachment, insertion, and use, still remains a desideratum in veterinary science, to which should be subjoined the synonyma of the different writers on this subject.

Our description of the muscles of the hind extremity is with diffidence presented to the public, as a specimen of the manner we conceive such a work should be executed.

Of the panniculus carnosus. The fleshy pannicle is the most exterior and general of all the muscles of the body; it is found in most or all quadrupeds, and often serves them in lieu of hands, lying immediately underneath the skin, to which it is attached, and over the cellular membrane covering the muscles; it is of a pale red colour, and envelopes a large part of the body; as it passes towards the extremities it forms a thin expanded tendon or *aponeurosis*, which descends to the superior part of the extremities, enveloping the muscles, and losing itself in the cellular membrane of those parts, and by attachment to the tendons and elevated points of bone.

When this muscle contracts it corrugates the skin, and assisted perhaps by other muscles, it can shake the whole frame with considerable violence, thereby dislodging from the coat dust, dirt, flies, and other offending matters.

The butchers are careful in exposing this muscle on their meat, which serves to give it a more agreeable appearance; it is seen of a pale red colour, and here and there they cut through it a longitudinal nick or slit to expose the white cellular membrane and fat which lye beneath.

The muscles of the fore extremity of the horse are about 34.

They are disposed about the limb when detached from the body so as to form a pyramidal figure, whose base is attached to the body, and whose apex is resting on the ground: on the base of this pyramid, if we may be allowed the expression, or upper end of the extremity, the muscles are found to possess a four-fold position, *viz.* an exterior, interior, anterior, and posterior position; such is especially their arrangement about the scapula and humerus; as we descend they become more simple, and occupy at length only a two-fold position, serving for mere flexion and extension, as is observable about the *radius*; at the apex of the cone no muscles are observable but merely the tendons of the last series of muscles, with the bones and ligaments to which they are attached.

Abduction and adduction have been the use imputed to such muscles as are attached to the inside or outside of the scapula, extension and flexion to such as are attached behind or before it; it will, however, we believe, be obvious on reflexion that the scapula can have no occasion for such movements as adduction or abduction, and so also respecting those of the *humerus*; therefore we are disposed to conclude that these muscles in whatever direction situated have their

principal effect in producing a combined operation, promoting the grand object in view, the support and progression of the animal; and we shall endeavour to shew hereafter, that an abductor and adductor contracting at the same instant of time with equal force, will not produce an effect in either of those directions, but will co-operate according to the position of the bone in an extensor or flexor motion.

The muscles of the scapula are six: *trapezius, rhomboideus, levatorius, pectoralis anticus, triangularis, serratus major.*

1. The *trapezius*, is a thin extended muscle of a triangular figure, whose point or termination is fixed on the spinous ridge of the *scapula*, rather above its middle, its base extending from the cervical ligament along the ligament of the 1st, 2d, 3d, 4th, 5th, 6th, 7th, spinous apophyses of the dorsal vertebræ or withers. It sends off an aponeurosis which envelopes great part of the abdominal muscles, terminating at length on the *linea alba*; it also sends off a fleshy portion to the muscles of the neck. Le Trapeze, Vitet. tom. 1. p. 155. Stubbs, *Anat. Horse*, tab. 1. o. p. q. r. f. t. w. x. y. z.

2. The *rhomboideus* is a short almost square, fleshy muscle between the former, takes its attachment to the cervical ligament and ligament connecting the spinous apophyses of the dorsal vertebræ, and passes underneath the cartilage at the base of the scapula, which it almost wholly occupies by its fleshy adherence.

This muscle possesses no tendon, and serves, independent of its effects on the motion of this part, strongly to attach the scapula to the body.

See Plate II. letters *a, a, b.* Triangulaire, Vitet. Med. vet. i. p. 157. Stubbs, *Anat. Horse*, pl. ii. *a, a, b.*

3. *Levatorius, or extensor scapulae.* This muscle is of considerable length, and of a conical figure, its base being fixed to the superior and anterior angle of the scapula, its fibres mixing with those of the *rhomboideus*, from which in some subjects it can hardly be separated; it passes tapering along the neck, adhering to the cervical ligament till it terminates in a point or tendon on the same ligament about the second vertebra.

4. *Triangularis.* The triangular is a fleshy muscle arising from the occiput; where it embraces the neck it grows narrower as it approaches the scapula, where it terminates by a flat tendon, uniting itself to the *rhomboideus*, and to the tendinous insertion of the *serratus major*; its fibres are straight, and the muscle is divided into distinct fasciculæ by interposed cellular membrane.

5. *Serratus major.* This very large muscle forms collectively the figure of a fan inverted, the point thereof being towards its insertion beneath the scapula, its circumference on the ribs.

It takes attachment by numerous digitations of muscle from the first to the 10th or 11th rib, the posterior digitations of this muscle interweave themselves with the digitations of the oblique muscles of the abdomen, and the anterior portions or *radii* with the intercostal muscles. The *triangularis* above described may also be considered as a part of this very extensive muscle; the fibres converging from this vast circumference at length terminate by a transverse fleshy adherence to the superior interior part of the scapula between the *rhomboideus* and *subscapularis* muscles. There is a fascia arising from the upper surface of this muscle which runs to the *linea alba* over all the muscles of the abdomen.

These digitations of the *serratus major* may act in succession, as so many separate muscles, or in masses, the motion being transferred from one to the other, by which it can co-operate with any other series of muscles or alone, by producing a species of rotation of this bone about its axis.

It is also in quadrupeds a powerful suspender of the body, raising it on its contraction upon the extremities. *Plate II. c, d, e, f.* Vitet, Le grand Deuntlé. Stubbs, Anat. H. *Plate II. c, d, e, f.*

6. *Pectoralis anticus.* This is a fleshy muscle of considerable length, of the figure of a very elongated cone; its base being attached by fleshy fibres to the sternum and first rib, anteriorly to the large pectoral, from whence it grows narrower till it terminates on the anterior *crista*, or edge of the scapula, it also contracts a strong adherence to the pectoralis minor, and its aponeurosis covers all the muscles of the scapula. *Plate II. c, d, e, f.* Vitet I. p. 155. Le pectoral antérieur. Stubbs Anat. Horfe. *Plate II. c, d, e, f.* Ser-ratus minor anticus, p. 12.

Note. The human *subclavius* muscle is only wanting, all the other muscles belonging to this part in the human anatomy are found in the horse.

The muscles of the humerus of the horse are 12: *Elevator, antepinatus, communis, pectoralis major, depressor, dorsalis major, latissimus dorsi, subscapularis, pectoralis brevis, adductor, postea spinatus abductor, abductor brevis.*

1. *Elevator proprius* lies immediately before the *antepinatus*, uniting itself with it. Its attachment is along the anterior *crista* of the scapula; passing with the *antepinatus* it terminates on the lateral internal part of the humerus. This muscle is so closely connected with the *antepinatus*, that one tendinous expansion is common to them both. It terminates on the anterior process of the head of the humerus by a tendon which surrounds it.

2. *Antepinatus.* This muscle fills the whole space of the scapula anterior to the spinous ridge, adhering to its whole surface by fleshy fibres; it terminates by a strong tendon on the head of the *os humeri*, covering entirely the protuberance representing the coracoid process.

Plate II. a, b, c, d, e, f. Vitet. Med. Vet. L'Anti-epineux. tom. i. p. 159. Stubbs, Anat. Horfe. *Plate II. a, b, c, d, e, f.* supra-spinatus scapulæ.

3. *Communis.* This muscle is of considerable length and nearly uniform size throughout, and is common to the *humerus* and neck; the panniculus carnosus forms strong fleshy adhesions to this muscle; its first attachment is by a small tendon to the side of the atlas; it there forms attachments to the muscles of the neck by fleshy portions sent to them, and lower down the neck it sends off similar portions, mixed with tendon, to be inserted in the oblique processes of the 4th, 5th, and 6th cervical vertebræ, passing fleshy over the articulation of the *humerus* with the *scapula*, it terminates on the anterior part of the humerus, about its middle, by a short tendon; it sends off a large aponeurosis, which unites several muscles together, and forming at the joints the annular ligaments. It also contracts a very strong adhesion to the lesser pectoral muscle. Vitet. Med. Vet. i. p. 158. L'Humero-cervical.

The above three muscles come under the denomination of extensors.

4. *Pectoralis major.* On removing the skin and fleshy pannicle this muscle is seen taking its attachment along the sternum and ribs, from the middle of it, between the fore-legs, to its posterior extremity, growing smaller as it approaches the humerus, terminating on the internal surface of the superior condyle of the humerus.

Plate II. 1, 1, 2, 3, 5, 6. Vitet Med. Vit. i. p. 160. Le grand Pectoral. Stubbs, Anat. Horfe. *Plate II. 1, 1, 2, 3, 5, 5, 6.* Pectoralis, p. 12.

5. *Latissimus dorsi.* This vast muscle is situated above the *ferratus major*, and under the *panniculus carnosus*: its aponeurosis is covered by that of the *trapezius*. It takes rise by a

very strong aponeurosis on the spinous processes of the last dorsal vertebræ, extending to the loins; on the back it becomes fleshy about its middle, covering part of the false ribs, and part of the surface of the *ferratus major*; passing between this last muscle, and the scapula, it terminates by a thin tendon on the lateral internal part of the humerus: it has likewise a strong attachment by tendon to the middle of the *depressor* muscle, passing with the tendon of that muscle to the small prominence on the inner side about the middle of the humerus, going between the extensors of the *ulna*. *Plate II. r. r. f. t. w. w.* Vitet, Le grand Dorsal. i. p. 160.

6. *Depressor, or teres major.* This muscle is of some length, oval, and somewhat flattened, lying on the under side of the scapula, and closely embracing the *subscapularis*, having its attachment to the superior and posterior edge of the scapula; passing over the articulation, it terminates by a flat tendon with the preceding muscle, observing the same direction in its course as the long abductor does on the opposite side of this bone. Le grand rond. Vitet. i. 159.

The above three muscles are depressors or flexors of the humerus.

7. *Abductor proprius seu coraco-humeralis.* This is a small muscle, cylindrical, and tapering at each extremity, forming a tendon; the uppermost takes its attachment to the lateral internal part of the coracoid process of the scapula, the lower tendon to the inferior and anterior part of the humerus, passing over the articulation, and in contact with the inside of that bone. This muscle acting singly draws the lower part of the humerus to the body, as the *subscapularis* does the upper part of this bone. Vitet. Med. Vet. Le Coraco Humeral. i. p. 161.

8. *Pectoralis brevis.* This muscle will admit of being variously divided, and is strongly attached to the *panniculus carnosus*. This muscle forms the breast like prominence between the fore-legs of the horse; it is of a figure nearly square, divisible into distinct parallel fasciculæ, from the point of the sternum, where it joins the muscles on the opposite side, it passes, forming a flattish tendon to the humerus. We have seen this muscle deficient on the one side, and full on the other.

9. *Subscapularis.* It occupies the under side of the scapula, with which it accords in figure, and needs not any particular description, growing narrower with this bone it descends, forming a broad tendon in the large inner process of the head of the humerus, and will admit of being separated into several smaller muscles. Vitet. Med. Vet. Le sours scapulaire, i. 160.

There are also two other small muscles, which may be considered as adductors, or perhaps rather inflexors; the first of these is not so small as the other, and takes its rise at the interior projection of the scapula, or rather superior part of the glenoid cavity by a flattish tendon passing over the joint on the inside, and taking an oblique direction over the humerus; it terminates in the cavity formed by the condyles of the humerus. We give it the name of *M. articularis major*. The other, which is much smaller (*M. articularis minor*) arises from the tendon of the preceding muscle, or the superior and internal side of the glenoid cavity, and terminates on the head of the humerus by a fleshy attachment. This muscle is not found, we believe, in every subject. These small muscles, it is clear, cannot produce any motion of the limb; their bulk is too small, and they are situated too near the centre of motion to operate with any force in this way. Some have imagined these small muscles about the articulation were designed to move the capsular ligament out of the way of being pinched, an idea we cannot subscribe to: those ligaments surrounding the cavity of the joint not being

is enough to be in any danger of this sort, and with their inner surface too well lubricated to be caught hold of by an oblique round head of bone. The above three muscles may be considered, with the two small ones when acting singly, as adductors.

10. *P. minor* occupies the osseous part of the scapula behind the spinous ridge; it grows narrower with the bone till it reaches the joint, where it forms a lubricous cartilage, which is kept in its situation by two round prominences in the head of the os humeri, acting like the sides of a pulley-block: it then terminates on the external round process of the head of the humerus. *Plate II. b, i, k, l, m, n.* Vitet. i. p. 101. le petit épineux.

11. *Abductor longus* takes its attachment at the superior part of the posterior edge of the scapula; in descending it closely adheres to the *postspinatus*, becoming gradually broader and more fleshy; it terminates on the curved process, which is observable on the upper part of the exterior surface of the humerus, following the same direction on this side as the adductor does on the opposite side of the bone. *Plate II. o, p, q, r.* Vitet. Le grand rond. i. 159. Stubbs. *Teres Minor, Plate II. o, p, q, r.*

12. *Abductor brevis* takes its rise at the inferior and posterior edge of the scapula, or rather from the fibres of the *postspinatus* muscle, lying between it and the *longus abductor*. This and the former pass over the extensors of the cubitus, and terminate between the above muscles on the large crooked process of the humerus. It only differs from the former in being considerably shorter. It sends a tendon to the scabrous edge of the cotyloid cavity. Vitet. *Med. Vet.* i. p. 162. Le petit rond. The effect of the principle we wish to establish respecting the co-operation of muscles on opposite sides of the bone, is no where more obvious than in the two foregoing muscles, with their congeners, the adductors on the inside. This mode of operation of these muscles appears to have escaped entirely the writers hitherto on this subject. Vitet has remarked respecting them, "ils font executer a l'humérus des mouvemens, de flexion, et de demirotation en dehors."

The muscles of the radius and ulna are seven; two to bend, five to extend them.

1. *Extensor longus seu posterior*. This muscle is the most exterior of those which fill up that triangular space formed by the humerus and scapula. It takes attachment at the superior and posterior edge of the scapula, and passing down closely, adhering to the large extensor, it terminates on the extreme point of the olecranon. This muscle is the most powerfully situated of any of this extremity. *Plate II. P.* Stubbs Vitet. *Med. Vet.* p. 165, Le long anconé.

2. *Extensor magnus*. This is nearly the largest muscle of the extremity, of a triangular figure, and occupies great part of the angle between the humerus and scapula posteriorly; it rises by tendinous fibres from two-thirds of the posterior and lower edge of the scapula, growing narrower, it terminates on the inner side of the olecranon by strong and short ligamentous fibres. *Plate II. fig. 1.* N. Vitet. *Med. Vet.* Le Moyen anconé, p. 164. Stubbs, *Plate II. N.*

3. *Extensor transversus*. This muscle is of a figure nearly square; passing obliquely across the other muscles, it rises from the interior part of the crooked spinous process of the humerus, and terminates on the point of the ulna, uniting often with the preceding. *Plate II. O.* Vitet, *Med. Vet.* p. Le Court anconé.

4. *Extensor pygmaeus*, is situated beneath the others, of a cylindrical figure, tapering to either extremity, rising from the middle part of the humerus, and terminating by tendon on the inside of the olecranon. Le petit anconé. Vitet, *Med. Vet.* 165.

5. *Extensor minimus*. This is a small muscle of a pyramidal shape, whose base is fixed by fleshy fibres to the olecranon on its anterior edge, growing narrower, it terminates by fleshy fibres on the back part and inside of the humerus, rather below its middle; this muscle fills up the cavity formed by the two condyles of the humerus posteriorly. Stubbs, *Anat. Horse.* tab. 5. c. Vitet, *Med. Vet.* L'Oli-cranién, p. 165.

These muscles straighten the limb after it has been carried forward by the flexors, raising the body upon the extremity as a fixed point.

6. *Coraco-radialis*. This beautiful muscle is externally covered with a ligamentous coating, which gives it a silvery appearance, especially on its inside, a strong tendinous fascia enveloping it; it occupies the front of the humerus, extending from the coracoid eminence of the scapula to the anterior part of the head of the radius, to which it is fixed by strong, short, ligamentous fibres. Near its lower extremity it sends off a strong tendon, which, passing along the radius, inserts itself into the tendon of the extensor muscle of the shank. This muscle, in passing the joint, is lodged between the two circular, smooth prominences on the anterior part of the head of the humerus, and is provided with a lubricous cartilage beneath. This muscle is the biceps of the human anatomy, which name will not apply in the horse, having but a single origin. Its body is very deeply cleft. Stubbs, *Anat. Horse, Plate VIII. i, k, l, m, n.* Vitet. *Med. Vet.* Le Coraco-Cubital, p. 166.

7. *Flexor convolutus*. This muscle lies in contact with the bone, filling the large cavity or neck of the humerus; formed by the curved process on its exterior part it rises under the posterior part of the head of the humerus, making a spiral turn, it passes over the bone, filling the cavity above-mentioned, and terminates anteriorly in the hollow of the head of the radius. Stubbs, *Anat. Horse.* tab. 9, r, s. *Brachialis internus.* Vitet. *Med. Vet.* p. 165. La brachial.

The two last muscles are termed flexors; they carry the lower part of the extremity forwards, and the extensors serve the purpose apparently of removing the body to it as a fixed point on the ground.

The muscles of the knee and shank are six, two to extend, four to bend them.

1. *Extensor carpi*. It is the body of this muscle which forms the handsome rotundity observable on the lateral and rather external part of the radius. It is attached superiorly to the anterior condyle, uniting to the extensor of the foot; it decreases, suddenly, forming a flat, broad tendon lying close to the bone, passing under the lateral extensor tendon, and over the bones of the knee, it terminates on the superior part of the shank bone, on the anterior tuberosity, by strong ligamentous fibres. Stubbs, *Plate a, a, b.* *Plate II. d, e.* *Extensor carpi radialis.* Vitet. *Med. Vet.* Le Cubital externe antérieur, p. 168.

2. *Extensor lateralis*. This muscle takes its attachment for a considerable length along the sharp edge on the external side of the radius; forming a flat tendon, it takes a direction across the leg, and passing over the tendon of the principal extensor, pursuing an oblique direction over the bones of the knee, it terminates on the inside this joint on the os pollicare. *Plate II. g.* Stubbs, *Plate II. q.* L'extenseur de Genou, Lafosse.

3. *Flexor carpi posterior*. This muscle has an attachment by strong tendons to the posterior and lateral external part of the humerus; increasing in size, and becoming very flat, it descends, keeping an uniform size, down the radius, forming a large flat tendon, dividing into two parts; one is strongly

strongly inferted in the crooked bone, (*os posticum*,) the other passes to the shank, and is inferted on its head. Stubbs, *Plate II. m, n, o, p, q, r, s.* Vitet. i. p. 169. Le Cubital externe postérieur.

4. *Flexor ossis postici.* This muscle takes its attachment on the opposite side of the humerus to the former, sending off a considerable branch to the inside of the *olecranon*, it terminates by strong tendon on the external convexity of the post-carpal bone. Stubbs, *Plate XII. f.* Vitet, Le Cubital interne postérieur.

5. *Flexor internus.* This muscle is smaller than the two former, and is placed more internally; it takes attachment at the lateral internal condyle of the *humerus*, and, passing along the radius, forming a thin tendon, which passes through the capsular ligament, it at length terminates on the posterior part of the cannon or shank bone, and suspensor ligament of the perforans muscle. Vitet. Med. Vet. Le Cubital interne.

6. *Flexor postremus.* This small muscle is the most posterior of those about the head of the radius, extending from the point of the ulna on its inside to the annular ligaments of the knee, uniting to the cartilage which furrounds the flexors of the foot, its aponeurosis covers the whole surface of the extensors of the cubitus. Le cubital grêle, Vitet. i. p. 170.

Besides the above muscles, there are two others belonging to the shank bone which are very minute; they are termed by LaFosse *les canoniers*, and by Vitet *lombrieaux*, p. 175. These very small muscles, which are not always described, are found between the suspensory ligament and the styloid bones, one on each side; they rise under the knee, are fleshy about two or three inches, then form a tendon, which terminates on the cellular membrane of the fetlock joint. They appear of little use, and may rather be considered as the effete rudiments of the interossei muscles, or *lumbricales* of digitated quadrupeds.

The muscles of the pastern, coronet, and foot are five; two to extend, and three to bend them.

These three bones always forming one line and making an angle to the rest of the limb, we consider as one bone in describing the muscles and their effect, as any division would tend to confuse rather than elucidate the general purpose of the muscles going to these parts. LaFosse has, we think, erred in being too minute in this respect by subdividing parts necessarily connected.

1. *Extensor suffraginis* is a small, thin muscle, rising by fleshy fibres from the external condyle of the humerus; it passes fleshy about half way down the *radius*; adhering to its external sharp edge, it passes in a groove through the annular ligaments and capsular ligaments of the knee, and continues its course along the outside of the shank to the fetlock, where it becomes wider, and terminates by a broad tendon on the superior anterior part of the pastern bone. It sends off a branch of tendon which passes round the knee to the flexor tendons under the post-carpal bone. Vitet. i. 1752. L'extenseur antérieur du Paturon.

2. *Extensor pedis.* This is the largest of that assemblage of muscles which furrounds the head of the radius. It arises from the external condyle of the humerus uniting its fleshy fibres with those of the extensor of the cannon or shank, it becomes tendinous above the knee, being lodged and confined by ligaments in a groove; it perforates the capsular ligaments of the joint, and, passing down the front of the shank at the fetlock joint, it forms an union with the extensor of the pastern, and growing broader, and enveloping almost the whole front of the coronet, it finally terminates on the anterior eminence of the coffin bone. Stubbs, Anat.

Horse, tab. viii. 1, 2; 2, 3, 4, 5, 6, 6. Extensor Digitorum Communis. Vitet Med. Vet. i. p. 173.

The two former muscles serve to bring the three bones of the foot forward, and we may remark are, when compared with the flexor, disproportionately small, for the weight of the horse operates as a powerful extensor of this part, and renders great muscular power unnecessary.

3. *Perforatus.* This muscle takes its attachment by fleshy and tendinous fibres to the internal condyle of the humerus; uniting with the *perforans* near the knee, it forms a strong tendon, which, at the back of the knee, (within the concavity of the post-carpal bone,) is received within a strong ligamentous groove, passing down the shank behind the tendon of the *perforans*; at the pastern it forms a remarkable ligamentary *annulus* for the reception and passage of the *perforans* tendon, expanding into a broad flat tendon at the back of the pastern, and, covering the *perforans*, it divides, forming two tendons which pass obliquely over the joint, and terminate on the upper part of the coronet. Stubbs, Anat. Horse, tab. 13. *m, n, o.* Sublimis, p. 42. Vitet. Med. Vet. i. p. 173. Le Perforé.

4. *Perforans*, is a considerable muscle rising with the former, and lying more internally; it will admit of division into three parts, which Monf. LaFosse has described, with his usual bounty, as three distinct muscles. This muscle is fleshy till it reaches the knee, when it forms a flat tendon joined by the *flexor postremus cubiti*, and *radialis* tendons inferted into a flat, smooth cartilage under the *os posticum*, forming here a large cylindrical tendon, when about half way down the shank it is joined by a ligament from the posterior part of that bone arriving at the fetlock, it passes through the *annulus* of the *perforatus*, and continuing between its divided tendon, terminates by a broad, flat tendon on the inferior surface of the coffin bone being covered by the frog. Stubbs, Anat. Horse, Profundus. Vitet. Med. Vet. i. p. 174. Le Perforant.

5. *Aljutorius.* This is a flat muscle lying close to the *radius*, and filling the hollow on the posterior part of that bone, it soon becomes tendinous, uniting with the tendon of the *perforans*.

Of the Ligaments of the Fore Extremity. 1. *Ligamentum suspensorium*, suspensory ligament, takes its rise a little below the head of the shank by muscular and ligamentous fibres, lying between the heads of the styloid bones, it passes down the posterior surface of this bone, quitting its adherence to it about the middle, and, becoming detached, it divides at the fetlock into two branches, which closely and strongly embrace the sesamoid bones; it forms one ligament again at the back of the pastern, filling its hollow cavity, and finally terminates on the head of the coronet bone. At the fetlock it also sends off two branches in an oblique direction downwards, which unite with the extensor tendon of the coffin bone, and preserves it firmly in its situation. Stubbs, Anat. Horse. Interosseum. LaFosse has made a muscle of it. Flechisseur du Paturon.

This ligament is the main support of the fetlock joint, and this joint, though so strongly fortified, is, for obvious reasons, the most subject to be injured of any part of the body.

There are many other ligaments belonging to this extremity, which the proposed limits of this article will not allow us to give a description of, as the lateral ligaments, the capsular ligaments, the burial ligaments, the restraining ligaments, crucial ligaments, &c.

The muscles of the abdomen, allowing for the magnitude and depending position of this part in the horse, are much resembling those of the human.

Obliquus externus, see *Pl. II.*—I. I. I. K. K. L. *m. n.*
Obliquus

Glutæus externus. This muscle lies the most exteriorly of all the muscles of the buttock, and is of a small size: it extends from the second and third spinous processes of the sacrum to the anterior angle of the inferior *ramus* of the ilium, where it joins the *fascia lata*; from thence it extends to the *processus recurvatus externus* of the thigh. This muscle is surrounded on all sides by *aponeurosis*, that on its superior part, covering over the muscles of the rump, is affixed to the spinous processes of the loins; the *aponeurosis* of its posterior part passes underneath the *sacro-tibialis externus*, to which this muscle is contiguous in passing to the external curved process of the thigh.

The *glutæus externus* is so small in quadrupeds, that a doubt might arise whether this was not a part of the *fascia lata*, and the muscle beneath it the corresponding one to the *glutæus maximus* of the human anatomy. From a farther investigation of this subject, we believe that not to be the case, and that it is the real representative of the *glutæus maximus*.

The singular diminution of this muscle in the quadruped may be, perhaps, explained on the following principles of the difference of structure necessary to the two animals. In the man, the legs have to perform a greater variety of motions, as abduction, adduction, rotation, &c. which the horse, whose motions are principally confined to going straight forwards in a line, does not require, so we see this great abductor of the human anatomy becoming a very small one in this animal, while the muscles of the rectilinear progression are vastly increased in bulk, as we may see by looking on the *glutæus medius*, which is the *maximus* of the horse in point of size, and from its attachments, is evidently a direct extensor of the thigh. Others might say it was diminished on account of the increase of the purchase obtained by its insertion into the extended point of the curved process of the thigh being taken farther from the centre of motion, which would compensate for its want of power; for it seems pretty nearly the same thing whether we make a muscle very large, or give it a powerful insertion; sometimes bulk, sometimes power only is necessary, but the consideration of the circumstance in which power should be obtained by accumulated muscular fibres, or by favourable insertion, would lead us beyond our present purpose.

This point once admitted, *viz.* that it is the *glutæus maximus* of the human body, the others follow naturally, and admit of a nearer comparison. The anatomy of the thigh of the dog, which has no curved process, seems to confirm this opinion.

Its use. The direction of this muscle seems to point it out as an abductor; the best way, however, of considering it is to regard it in this animal as a *tensor aponeurosis* of the buttock, assisting the muscles of this part, by its gentle compression and elastic springing and reaction, in their motions.

In the ox it exists with pretty much the same characters.

In the dog it is much larger than in the horse, *cæt. par.* and more fleshy, having a strong attachment to the sacrum underneath the muscles of the tail, and terminating in the back of the thigh by a long tendon.

In the cat the same as in the dog; but here it might well be denominated the *glutæus posticus*.

Synonyma. Stubbs Anat. Horse, p. 23. *Tab. II. m, n, o, p.* *Glutæus externus.* Lafosse, Cours D'Hippiatrique, p. 118. Le moyen fessier. Lafosse, Dictionnaire, p. 456. Bourgelat Elemens D'Hippiatrique, p. 278. Le petit fessier extenseur de la Cuisse. Vitet. tom. i. p. 181. Le fessier externe. Winslow, Exposition Anatomique, p. 135. Le grand fessier. *Glutæus magnus seu maximus omnium auctorum humanæ anatomix.*

2. *Glutæus medius.* This vast muscle lies immediately un-

der the preceding, occupying great part of the upper surface of the ilium; it takes its rise by a point on the lumbar muscles, growing more fleshy as it reaches the ilium; it takes a strong adherence, by fleshy fibres, to the external angle of the inferior *ramus*; after passing the ilium it becomes smaller, and dividing itself into two bodies, one terminates on the superior posterior trochanter, the other by a very strong tendon on the inferior external trochanter, which is covered by the tendon of the external *glutæus*. This muscle may be divided into two distinct parts, one of which might be considered by some as the *maximus* of the human; however, the nature of its attachments seems fully to prove its agreement with the *medius*.

Its use. To draw back the thigh, or (the leg being made a fixed point on the ground) to advance the body upon it.

In the ox. This muscle is more distinctly divided into two bodies, nor does it pass so far over the muscles of the loins. There is also a small almost linear muscle not found in the horse.

In the dog. It is not at all attached to the muscles of the loins, but fills up the ilium entirely, and terminates on the posterior trochanter; and in the cat the same.

Synonyma. Stubbs Anat. Horse, p. 18. *tab. 3. a, a, a, b, b, b, c, d.* *Glutæus Medius.* Lafosse, Cours D'Hippiatrique, p. 18. Dictionnaire, 457. Vitet, Medecine Veterinaire I. Le grand et le moyen fessier. Bourgelat, Elemens D'Hippiatrique, p. 278. Le grand fessier. Monf. Sainbel, first professor of the Veterinary College of London, in his lectures, principally adhered to the names and arrangement given by Bourgelat. Douglas, Myographia comparata, p. 130. *Glutæus medius.* Winslow, Exposition Anatomique, p. 329. Le moyen fessier. *Glutæus medius omnium auctorum hum. anat.*

3. *Glutæus parvus.* This is a short, strong, (and though small, compared with the former) not inconsiderable muscle, lying immediately over the joint; it takes attachment round the posterior ramus of the ilium; passing over the head of the femur it fills the anterior concavity formed by the superior trochanter of the thigh.

Its use. It operates in the combined effect of extending the thigh; its position is that of an abductor.

In the ox, nearly the same. Le petit fessier, Vitet. p. 185.

In the dog, it is of a different shape, being more pyramidal, and attached at the anterior superior part of the thigh.

In the felis, it is attached to the inferior and posterior ramus of the ilium, and terminates at the anterior part of the thigh in a nick or excavation. Stubbs Anat. Horse, *tab. 4. b, i, k, l, l, l, l.* Vitet. Med. vet. p. 181. Le petit fessier. Lafosse, Cours d'Hippiatrique, p. 118. Dictionnaire, p. 457. Le petit fessier. Bourgelat. il n'a rien dit la dessus. Douglas, Myologia comp. p. 131. *Glutæus internus.* Winslow, Exposé Anatomique. Le petit fessier. *Glutæus minor, Albinus. minimus, Innes.*

4. *Psoas magnus.* On removing the intestines from the abdomen and the peritoneum, this beautiful muscle presents itself; it is attached to the inside of the two last ribs, and to the transverse apophyses of the lumbar vertebrae, passing to the edge of the pelvis it joins the iliacus, and is with it inserted into the little trochanter, running between the iliacus major and minor: this muscle can never be mistaken for any other in any animal; it is rather depressed at its origin, but becomes cylindrical and pointed going to its termination; this muscle, near its insertion, is confined by a ligament which binds it and the iliac muscles in their situation.

The *psoas parvus* we consider as a flexor of the loins, by bending the pelvis (to which it is always attached) on the lumbar vertebrae.

Veterinary writers have mostly described this muscle as belonging to the thigh; it, however, generally terminates where the sartorius begins, forming together a digastric muscle of great length.

Ox nearly the same. Le grand Psoas. Vitet. p. 188.

Dog. It is attached to the four last lumbar vertebrae; is vastly larger, and more fleshy in proportion to the animal; it terminates in the same place; but the iliacus parvus, we may observe, does not in this animal terminate where the sartorius begins, for this muscle rises from the anterior angle of the ilium.

In the cat there are three very distinct muscles of this description.

Vitet. Med. Vet. Le grand Psoas l. 179. Lafosse, Cours D'Hippiatrique. Le grand Psoas, p. 117. Dict. 455. Bourgelat, Elemens D'Hipp. Le Psoas, 281. Stubbs, p. 18. tab. 9. a, b, p. 34. Psoas magnus omnium auctorum hum. anat.

5. *Iliacus major*. This muscle takes attachment to the whole inferior ramus of the ilium growing cylindrical, and tapering it is joined to the *psaos magnus*, passing with it through Poupert's ligament to the little trochanter of the thigh.

In the ox it is more intimately blended with the iliacus parvus.

In the dog it is remarkable this muscle is entirely wanting. The ilium is elevated so far above the lumbar vertebrae, that the muscles of the back occupy its place: it is singular, that this circumstance should have escaped the notice of Douglas, who has expressly treated of the anatomy of this animal.

In the felis the same as in the dog.

Stubbs Anat. Horfe. p. 18. tab. 3. tab. 9. p. 34. Lafosse, Cours D'Hippiatrique. p. 117. Dict. Hipp. 455. Bourgelat, Elem. D'Hipp. L'Illiaque. Iliacus internus auctorum hum. anat.

6. *Iliacus minor*. This muscle, which, in general, is quite separate from the iliacus major, takes its rise from the inside of the first sacral apophyses all the length of the posterior ramus of the ilium, passing over the head of the femur it terminates with the psaos and iliacus on the little trochanter; it permits the psaos to pass between it and the iliacus major, and might be considered as a portion of the latter; it is connected by aponeurosis with the muscles which line the pelvis.

These three last muscles have all the power of bending the femur; the two last on the pelvis, the psaos, on the loins, bending both femur and pelvis.

Ox. Not a distinct muscle.

Dog. Is altogether wanting, but appears to be compensated for by having three psaos muscles.

Cat. The same as in the dog.

Lafosse, Cours D'Hippiatrique. Planche 22. Dict. 456.

7. *Adductor teres* is a cylindrical muscle, which makes its appearance on the inside of the thigh; the integuments being removed, it takes its rise on the os pubis, near the symphysis, attached to the same ligament with the rectus abdominis; it terminates along with the adductor magnus, about half way down the inside of the thigh, or rather on the back part of this bone.

Stubbs, Anat. Horfe. tab. 5. s. s. Le pectineus. Lafosse, Cours d'Hippiatrique. p. 118. Le pectineus. Vitet. Med. Vet. p. 180. Le petit pectiné. Bourgelat, Elem. Hipp. Le pectineus. Douglas Pectineus. p. 153.

Comparison of this muscle with the human pectineus. We see by its attachments that it is by no means the same muscle; it is much more nearly allied to the triceps adductor primus,

which it also differs from; it rises too near the symphysis; instead of the brim of the pelvis to be the pectineus, and terminates by insertion along with the large adductor low down the thigh; it is also a more external muscle than the pectineus; but as there is no real pectineus, nature seems to have united in this one muscle the properties of the pectineus and adductor longus, so that we have chosen to call it by a different name from either, viz. *adductor teres*.

The ox has a much flatter muscle, and it sends off a slip to the ligaments of the knee.

Dog. This muscle is rounded, and much resembles the human long head of the triceps.

The cat. There are four adductors, one of which resembles more nearly the human pectineus.

8. *Adductor magnus*. There are three distinct muscles of this description in the horse; this portion of it is seen very distinctly by removing the adductor planus of the leg, taking attachment to the symphysis pubis, and extends down to the posterior and inner part of the thigh, and sending off another portion which is attached to the tibia, or rather to the joint of the femur and tibia by a flat tendon. This muscle may be divided into two portions; one has been called by veterinary writers, *la portion moyenne, et la portion anterieure*; but this we consider as unnecessary and unnatural; for after such division it does not correspond to the three portions of the triceps muscle in the human.

Stubbs, Anat. Horfe. p. 18, 15. 36. 36. &c. tab. 3. p. 46. tab. 14. p. p. q. r. s. t. Lafosse, Cours D'Hippiatrique, le gros et le moyen extenseur. p. 117. Dict. 454. Bourgelat, Elem. Hipp. p. 282. triceps. Vitet. Med. Vet. La Portion anterieure et moyen du triceps crural. p. 182.

Comparison with the human. On actually comparing this muscle with those of the human thigh, it is difficult to decide whether it most resembles the short or great head of the triceps, but it certainly is not much like either of them; therefore, to prevent confusion, we have given it a different name, and left out the term triceps altogether; this muscle, and the *sacro-ischio tibialis internus* both agree in some points with the great head of the triceps, and differ in others. Stubbs considers it one, and the French writers the other; in this confusion I think it best, for distinctness, to avoid the comparison, and give it a name that will not interfere with either.

Dog. This muscle lies underneath the long head of the triceps, and is the largest of the extremity.

Cat. In this animal the artery perforates the tendon of the *adductor magnus*, as it does in the human body, to pass to the gastrocnemius, which serves to identify the muscle in this animal.

Ox. No such portion appears.

9. *Adductor brevis seu quadratus*. This muscle lies immediately underneath the former, and is of a linear figure, being throughout of nearly equal size, rising on the *os ischium* near the edge of the *foramen ovale*; it takes an oblique direction, and terminates on the posterior flat part of the thigh, on the back of the posterior trochanter.

Ox. It exists of the same figure. Vitet. L'Ischio-crural, p. 186.

The dog possesses it, and also a muscle which exactly corresponds to the short head of the triceps in the human.

Stubbs, Anat. Horfe, tab. 15, p. 47. Vitet. Le rond. p. 183. Lafosse, Cours D'Hippiatrique, p. 117. Le petit extenseur. Dict. 454.

10. *Tenforius, or M. fascia lata*. This is considered by some a muscle of the leg, others of the thigh; in this animal, however, it is common to both, and might be very well placed with the common muscles before mentioned. This muscle often varies in figure, but is generally of a triangular shape,

shape, formed of two or three fleshy bodies, the superior point of the triangle is affixed to the *os ilium* on the external angle of its inferior ramus, its posterior point is affixed to the *processus recurvatus femoris* with the *gluteus externus*, with which it forms an intimate union, its inferior part terminates by *aponeurosis* which covers all the muscles of the inside the thigh, and its anterior part, extending also over the patella and tibia.

Ox. This muscle not so completely divided into two portions.

Dog. Besides this muscle there is another strong muscle above it, and which has been noticed by Douglas.

Cat. The same as in the dog.

Stubbs, Anat. Horse, tab. 2. fascia lata.

Lafosse, Cours d'Équippatrique, p. 120. Le fascia lata abducteur de la jambe.

Vitet, Med. Vet. p. 185, Lileo-crural.

Bourgelat, Elem. d'Hipp. abducteur de la cuisse.

Tenon varixæ femoris, Innes et aliis.

Douglas, Myolog. comp. 164.

Although the utmost brevity has been observed in the foregoing descriptions and remarks, and nothing introduced which was not of importance in establishing this science on a rational basis, yet have we already passed the limits we had proposed in treating of this article; if the remaining muscles were considered as the subject at present demands, it would extend beyond the proper bounds for a communication of this sort, we shall, therefore, confine ourselves for the remainder of this extremity, to give only the names as we find them in our MSS. and conclude this article by a description of a few of the most interesting viscera of the horse.

11. *Obturator externus*.

12. *Obturator internus*.

13. *Pyramidalis*.

14. *Articularis*.

15. *Genelli*.

16. *Vastus externus*.

17. *Vastus internus*, Plate III. 7, 8, 9.

18. *Vastus anterior*, Pl. III. 1, 1, 2, 2, 3, 4, 5, 6.

19. *Adductor planus tibiæ*, Pl. II. e, e, f. *Gracilis*, Stubbs.

20. *Adductor longus*, Pl. II. c, d. *Sartorius*, Stubbs.

21. *Poplitealis*, Pl. III. b, b, i.

22. *Sacro-tibialis externus*, tab. 2. i, k, l, u, u, w, w, x, y,

z. *Biceps Cruris*.

23. *Sacro-tibialis posticus*. Bourgelat and Vitet consider this as the *biceps cruris*, and Stubbs the *femitenosus*, Pl. II. 16, 17, 17, 18, 19.

24. *Sacro-tibialis internus*. We insert the synonyma of this muscle, to shew the confusion that is likely to arise from pursuing too close a parallel with the human anatomy.

Lafosse, Cours D'Équippatrique, le gros adducteur de la jambe, p. 119.

Bourgelat, Le Demimembraneux.

Sainbel, Semimembranosus.

Vitet, Med. Vet. p. 182. La Portion posterieure du triceps.

Stubbs, Anat. Horse, adductor magnus femoris. We have here an equal division of opinions, whether it should be considered as part of the triceps, or the semimembranosus. Stubbs has also given a muscle which he calls semimembranosus. The writer of this article is at a loss to understand what is there intended, but is disposed from the figure to believe that the short portion of the sacrotibialis has been divided and taken for that purpose.

These three immense muscles evidently co-operate to one effect, and are better denoted and understood by considering

them in this way, and by the above names than by the human names, even supposing their corresponding muscles in the human body could be clearly ascertained, as those names would only serve to convey the confused and erroneous idea of a detached office to each of those muscles, and as though they were in no way connected; it was the consideration of the three muscles last mentioned that first gave us the idea of the real effect of abductor and adductor muscles, in promoting animal locomotion. That such vast masses of muscle as these should be carried about by the animal to perform such trivial offices as abduction or adduction it would be highly absurd to imagine: for it may be laid down as an axiom that the bulk of the muscle always bears some proportion to the importance of its office, and pursuing this reasoning a step farther, we may conclude that even abduction and adduction itself are often performed by the co-operation of what are termed extensor and flexor muscles.

25. *Tibialis anticus*, Pl. II. tab. 1. Pl. III. 10, 11, 12, 13, 15, 16.

26. *Tibialis internus*. a muscle not always distinct.

27. *Gastrocnemius*, Pl. II. m. m. m.

28. *Linearis*, seu *tibialis externus*.

29. *Extensor brevis pedis*.

30. *Extensor longus pedis*, Pl. II. 36, 36.

31. *Peroneus*, Pl. II. 37, 37.

32. *Perforatus*, Pl. III. k, l, m, n, o, p.

33. *Perforans*, Pl. III. 23, 24, 25, 26, &c.

34. *Perforans minor*.

Of the lungs of the horse. This viscus in the horse consists of three lobes, two large ones which occupy the sides of the chest, having at their anterior presentation two elongated auriform appendages which closely envelope the heart; the third or central lobe is much smaller, lying between the other two, and presents itself to the sternum. It is not unfrequent in the lungs of horses that small red patches are observable that will not inflate like the other parts of the lungs, and are therefore, not improbably, obliterated cells from colds, inflammation, &c. the settling of the blood will also give an appearance of this kind, but this does not prevent the lungs from inflating.

The trachea of the horse, where it passes into the chest, and previous to its entering the lungs, has a singular duplication of the cartilaginous rings which is more flexible than the rest of this tube, so as to admit by very slight pressure, the sides of the tube to be brought in contact, and the total obliteration of its cavity: this structure may perhaps adapt the diameter of the trachea to any quantity of air that is passing through it to the lungs.

Of the liver. This viscus in the horse is large, deeply cleft into lobes, and possessing no gall bladder. The ductus venosus of the human fœtal circulation is also wanting in the equine fœtus.

Of the stomach. The stomach of the horse consists of a pouch or bag of the usual obcordate or reniform figure without, within, it is lined with membranes, which more resemble the coats of the different stomachs of ruminating animals than the inside of the generality of stomachs of this external figure.

There is distinguishable on the inside a white rugose coat, (see Plate IV.) not vascular, which appears to be a continuation of the elastic insensible white tissue, which lines the œsophagus; this spreads over the upper part and broad end of the stomach, till it abruptly terminates about its middle; this part of the stomach corresponds very much to the paunch, or first stomach of ruminating animals.

The second division occupying the lower part or great arch of the stomach, extending high up the sides, towards

the small arcl., and reaching nearly to the cardiac orifice is lined with a smooth red membrane, and is highly vascular, resembling more the stomach of carnivorous quadrupeds; the rest of the stomach extending from the termination of the former to the entrance into the duodenum consists of a pale red membrane, extremely loose, and thrown into longitudinal folds or duplicatures, intermixing with the former by almost imperceptible gradations of colour; this coat is thickly covered with a slimy mucus, not observable on the other coats; this part of the stomach has a strong resemblance to the fourth, or last stomach of ruminating quadrupeds.

The exact purpose of these three constructions of membrane in the same stomach is not easily assigned; whether they all unite in one common purpose, as though the stomach consisted of one common membrane for its lining, or whether the food is changed by the successive operation of each of these membranes, we know not: we may observe on opening the stomach that the food makes pretty much the same appearance against whatever part of the stomach it may lie, that one should be hardly led to conclude they have in the horse distinct functions, but combine in one common effect, and are in reality the rudiments only of the structure of the stomach, peculiar to the generality of granivorous quadrupeds, without producing any precise effect here; for it seems difficult to imagine how the different operations should take place in the same sack without disturbing each other. Nature seems to observe a connected system, not only in the entire animal, but also in each particular organ, forming an insulated system of structure and operations.

It is generally imagined there is some valvular apparatus to this viscus, which prevents the horse from vomiting, and much has been written on this subject; we never could discover any thing of the kind, and are disposed at present to believe, that as the form of the horse would render vomiting inconvenient, the power of receiving the impression which excites this operation is withdrawn from the animal, as it would be idle to suppose a power given to vomit with a structure of parts not admitting of it; it would be as inconsistent as placing the head of the lion on the shoulders of the hare, or giving the disposition of the hare to the lion's form, by which the very purposes of nature would be defeated. It was, however, an opinion entertained with some confidence, at the Veterinary College of Copenhagen, that the root of the white hellebore (*veracrum album*) would occasion a horse to vomit, being placed under the skin!

In an ass's stomach I have seen a valvular apparatus at the cardiac orifice, and the insensible white membrane extended into the inside of the stomach, about one inch, forming a loose fold, which served to mark the divisions of the stomach more strongly, but could not in the smallest degree operate as a valve; this lusus is, however, not very frequent. The stomach of the hog also partakes of this sort of structure, though not so distinctly marked as in the horse.

Of the chyle duct of the horse. This duct in the horse is not very difficult to find, both from its magnitude and situation, lying on the aorta, at the loins, very much exposed as it passes forward towards the thorax, it dips lower beneath the surface passing nearly under the aorta, it is much smaller in the middle and enlarging to each end; about the 4, 5, 6 ribs, it is as large as a man's thumb, it becomes narrower again as it passes into the axilla, but enlarges again at its termination, where it enters the vena cava, or rather the vessel formed by the union of the two jugular veins, and anterior to the subclavian, it there forms a large round head or cyst, and is provided with a valvular apparatus to prevent the return of the chyle or the blood

from entering the duct. Toward the loins it has a strong adherence to the coats of the aorta, and lower down is strongly embraced by the tendon of the diaphragm; it then enlarges, and passing upon and by the side of the lumbar veins, discharges itself by several openings into them, which openings are also provided with valves.

The openings of this duct into the lumbar veins which have never been before remarked, seem to point out a double circulation in this vessel, *viz.* from the middle to each end as the smallness of it in the middle would also seem to indicate; we have, however, in some subjects found a valve opening anteriorly, or towards the jugular veins, within six inches of its posterior termination; this duct, however, is subject to very great variation.

In another subject we found this duct terminate about the second lumbar vertebra, where it divided one branch forming a sharp curvature, circumscribing a portion of the insertion of the diaphragm, the other seemed to be lost about the fourth or fifth lumbar vertebra in smaller ramifications. In another subject which we injected, the duct was discovered on the left side, about the situation of the last dorsal vertebra, it crossed the aorta, and passed to the right side, immediately before and resting against the superior mesenteric artery; it then divides into several small canals, which appeared to be passing to their termination in the lumbar veins.

Parts of generation. No animal whatsoever is more richly provided with the various apparatus belonging to these parts than the horse, for nature here seems to have lavished with profusion whatever can tend to perfect the generative act; there is no part of the human construction of these parts but is found in the horse; the most essential difference appears to us to consist in the male, of the penis being suspended from the integuments of the abdomen, and not immediately from the pubis as in the human; hence the acuteness of the angle where it passes the pubis, is such as to render the passage of the catheter almost impracticable.

We have remarked that the penis of the horse possesses a voluntary power of erection, not known to the human, or perhaps most other animals; this power is exerted on making water, and though the erection is not very considerable, it is yet sufficient to bring the penis from its sheath, which is effected apparently by its increased gravity from blood accumulating in the cavernous cells of this part. After staling this semi-erection of the penis subsides, and it again is retracted within the sheath: this operation, though occurring daily to the sight of every one, has not, it is apprehended, been noticed by any veterinary writer.

The urethra of the horse is muscular from one extremity to the other, being formed on the outside of strong transverse fleshy fibres and supported by a strong ligament.

Naturalists were long at a loss to discover the *mammæ*, or teats of this animal; in the male they were at length detected by Buffon, on the sheath of the penis. Mr. John Hunter also made the same remark without knowing that Buffon had previously noticed it; these teats are largest in the foetus and young foal.

In the glans of the penis, immediately over the opening of the urethra externally, there is a large cell or cavity, smooth on the inside, and lined with a membrane, which secretes a brown unctuous substance for the lubrication of the penis, and defending it from the corrosive effects of the urine; another cell of a similar description with the former is observable, on the side of the urethra, and nearly surrounding it, it is separated from the former by a membranous partition.

The apparently unctuous secretion above described is miscible with water; it burns, however, in the fire like an oily

oily substance, and is not soluble in spirits of wine or nitrous acid, nor does it dry on exposure to the air during several weeks.

There is nothing resembling a frænum to the penis of the horse.

The cavernous body of the penis has no longitudinal septum; its cells are divided by transverse fibres, which are probably muscular; it terminates in a point near the extremity of the glans, where it is surrounded on every side by the venous body, termed in the human corpus spongiosum.

Another singularity in the genital parts of this animal is, that there is an immense congeries of veins, lying on the back of the penis, which are filled during copulation, forming an elevation nearly as large as the penis itself; these veins communicate with both the cavernous and spongy bodies.

The *vesiculae seminales*, and the bladders attached to them, are very large in the horse, having integuments of considerable thickness.

There is a great peculiarity in the structure of the *vas deferens* of the horse, which in passing over the bladder, enlarges to the size of the human thumb; this amplification extends from its entrance into the urethra to the distance of five or six inches from this point, where it again becomes of its ordinary diameter.

The inside of this enlargement is composed of cells, and somewhat resembles in construction the cells of the *corpus cavernosum penis*, passing in a transverse direction across the tube. In the centre of this enlargement passes the small canal of the *vas deferens*, each cell communicates by one, two, or more small pores with the canal of the *vas deferens*, these cells diminish as they approach the neck of the bladder till they are lost in a smooth passage entering the urethra.

What the purpose of this structure is does not appear; it must retard the passage of the *semen*, and probably adds some fluid to it, secreted from the cells themselves.

On a first view of the pudenda of the mare the position of the clitoris appears to be inverted, compared with the position of the same part in the human, being found on the lower part of the vagina; this apparent difference is removed when both are considered in the same position.

That the present article may not be too far extended we refer the consideration of the other viscera and parts of the horse to be introduced under their proper heads.

ANATOMY is also used for an artificial representation of the structure and parts of the human body in metal, plaster, wax, or the like. In this sense we say, the wax-work *anatomy*. R. Dickenfon, statuary, finished an human *anatomy* in plaster of Paris, representing a man standing upright with his skin flayed off.

There is likewise a wax-work *anatomy*, said to have been invented by Gaetano Giulio Zumbo, a Sicilian of Syracuse. Yet M. des Noues, who learnt it of him, and probably made some improvements in it, bringing it to Paris, arrogated the chief honour of it to himself. Some prefer, above all the rest, for public lectures and courses, the use of real parts of dead bodies prepared by injection. Anatomical injections are either of mercury, or mixtures of equal parts of bismuth, lead, and tin. Neumann. The inconveniences that attend the dissecting of dead carcases, have occasioned the invention of another cleaner and more durable kind of subjects. Reifelius contrived a human statue, wherein the circulation of the blood was represented to the sight, and some hing of the like kind was shewn by M. Chovet; and more lately still by Madame Bacheron, who has brought this art to great perfection. See her observations on the artificial anatomy, in the Memoirs of the Acad. des Scienc. an. 1759. Hist. 94.

ANATOMY is sometimes used to denote the subject to be anatomized. Thus (by 39 Hen. VIII. cap. 22.) the company of barbers and surgeons may have and take yearly four persons condemned, adjudged, and put to death for felony, for *anatomies*; and to make incision of the same dead bodies.

And by 25 Geo. II. cap. 37. the bodies of felons convicted of murder, in the county of Middlesex, or city of London, are, after execution, to be delivered to the hall of the surgeons company, to be dissected and anatomized; and in case such conviction and execution shall happen to be in any other county, or place, in Great Britain, then the body of such murderer shall be delivered by the sheriff, &c. to such surgeon as the judge shall direct.

ANATOMY is also used, in an improper sense, for the ANALYSIS of mixt bodies.

In this sense the chemists sometimes call their art *Spagyric anatomy*, *anatomia Spagyrica*.

In which sense we sometimes say the *anatomy* of vitriol, the *anatomy* of sulphur, the *anatomy* of Rhenish wine, &c.

ANATOMY is also used in a less proper sense, to denote the art of resolving compound bodies into simple ones.

In this sense any kind of compound body may be considered as the object of anatomy; that is, any body wherein there are divers parts joined together; even the taking asunder an artificial, political, or moral being, may, in this sense, come under anatomy.

ANATOMY is also used, *figuratively*, for an exact search or examination of the parts of a discourse, business, or the like: in which sense, we say the *anatomy* of a book, a doctrine, or the like.

ANATORIA, in *Geography*, a small town of Greece, anciently TANAGRA.

ANATRIPSIS, from *ανα* and *τριψω*, *I wear*, in the *Ancient Medicine*, denotes friction.

The word is sometimes also written simply TRIPSIS.

ANATRON, or NATRON. See NATRON.

ANATRON is also used for GLASS Gall.

ANATROPE, *ανατροπη*, from *ανατρεπω*, *to subvert*; a subversion literally, or relaxation of the stomach, attended with the loss of appetite, vomiting and nausea.

ANATTOM, in *Geography*, an island in the southern Pacific Ocean, and the most southern of those called New Hebrides. S. lat. 20° 3'. E. long. 170° 4'.

ANATZARTHON, in *Ancient Geography*, an archiepiscopal see of Asia, under the patriarchate of Antioch.

ANAUA, or ANAVA, a city placed by Herodotus in Phrygia, between the rivers Marfyas and Meander, but nearer their sources than their confluences. To the south-west of this city, and near it was a lake, from which they obtained salt.

ANAUDIA, among *Naturalists*, denotes dumbness, or a want of the use of speech.

Anaudia is, by some, made to differ from *aphonia*, as the former is owing to a defect of the nerves of the tongue, the latter to that of the nerves of the larynx.

Infants and mutes are *anaudi*, *αναυδοι*, not *aphoni*, *αφωνοι*.

ANAUDOMA, or ANADOMA, in *Ancient Geography*, a town of Ethiopia, near Egypt.

ANAVINGA, in *Botany*, a genus of plants, with incomplete flowers, comprehending some trees of the East Indies, which are not much known to botanists. The generic characters, according to La Marck, are, that the flower has a calyx of five oval, concave leaves, opening in a rose, and permanent; it has no corolla, but at the base of each foliola of the calyx are seen two pedicles shorter than the folioles of the calyx, and somewhat hairy; the stamina are ten, of the length

length of the calyx, and have their filaments inserted alternately, between the pedicles, upon the base of the folioles of the calyx; the anthers are small, ovate, and divided into two by a furrow or suture; the ovary is superior, globular, or oval, seated on a short style, and terminated by a stigma, with a sphenoidal head. The fruit is an oval or globular berry, marked by five slight channels, and containing ovate and reddish seeds in a pulp. There are two species; 1. *A. lanceolata*, with alternate leaves, lanceolated, slightly serrated, subpubescent beneath, with oval berries longer than the peduncle. 2. *A. ovata*, with alternate leaves, ovate, acuminate, and ferrulate, and globose berries equal to the peduncle. This is also called *tabana* and *a. barbata*. The anavanga is a tree of middle size, that grows in the sandy soil of Malabar, in the East Indies, especially about Cochin. It is an evergreen, and its fruits or berries are ripe in August. Its leaves, bark, and fruit have a bitter taste.

The juice of the berries drank excites sweat, cures malignant humors, and keeps the body soluble. A decoction of the leaves in water makes a sit bath for such as are afflicted with boils in the joints.

ANAUNACHION, from *α, ναυς, slip*, and *μαχημα, I fight*, in *Antiquity*, the crime of refusing to serve in the fleet. The punishment assigned for this offence was infamy.

ANAURUS, in *Ancient Geography*, a river of Greece, in Thessaly; also a river of Syria; and a river of the Troas, near mount Ida.

ANAX, in *Ancient Writers*, denotes a hero or god. The word seems formed of the Hebrew *anacim*, or *enacim*, which signifies the same. Some will have it originally to import giants, called also *γηνεῖους, earth-born*. Cicero assures us, that the three eldest sons of Jupiter, called *Διοσκυδοί*, were also denominated *anaces*.

ANAXAGORAS, in *Biography*, one of the most illustrious philosophers of antiquity, was born at Clazomene, in Ionia, in the first year of the 70th Olympiad, or the 500th year before Christ. In the ardent pursuit of knowledge he left his native country, where he possessed a patrimony sufficient for securing him distinction and independence, and went to reside at Athens. Having surrendered his lands to his relations, "he devoted himself wholly," as Cicero says, (*Tusc. Qu. lib. v.*) "to the divine pleasure of learning and inquiry." At Athens he diligently applied himself to the study of eloquence and poetry, and was particularly conversant with the works of Homer, whom he admired as the best preceptor, not only in writing but in morals. From Athens he removed to Miletus, that he might attend upon the public instruction of Anaximenes. At the age of 20 years he left Miletus, and entered upon the study and profession of philosophy at Athens, where, according to Diogenes Laertius, he remained 30 years. As a teacher of philosophy he acquired high reputation, and his pupils were some of the illustrious men of the age in which he lived; such were Euripides the tragedian, Pericles the orator and statesman, to whom some add Socrates and Themistocles; but the date of the birth of the latter is several years prior to that of this philosopher. In process of time his reputation excited jealousy and envy, and exposed him to severe persecution. Cleo accused him with impiety for teaching that the sun was a burning mass of stone, and thus robbing it of its divinity; and Thucydides charged him with treasonable practices. But the chief offence of Anaxagoras was, probably, the propagation of new opinions concerning the gods. There can be no doubt that he contradicted and opposed the vulgar opinions and superstitions; accordingly, it is related, that he ridiculed the Athenian priests for predicting an unfortunate event from

the unusual appearance of a ram which had but one horn; and, in order to convince the people that there was nothing preternatural in the phenomenon, he opened the head of the animal, and shewed them that it was so constructed, as necessarily to prevent the growth of the other horn. Anaxagoras, however, was thrown into prison, and condemned to death; and it was with difficulty that Pericles obtained from his judges the milder sentence of fine and banishment. Upon receiving his sentence of condemnation, he comforted himself by saying, "Nature long ago pronounced the same sentence against me;" and to one of his friends, who expressed regret on account of his banishment, he said, with a mixture of fortitude and vanity, "It is not I who have lost the Athenians, but the Athenians who have lost me." When news of the death of one of his sons was brought to him, as he was delivering a lecture of philosophy, he calmly said, "I knew that I begat him mortal."

After his banishment he passed the remainder of his days at Lampfacus, where he employed himself in instructing youth, and obtained great respect and influence among the magistrates and citizens. At length the infirmities of age terminated his labours in the year before Christ 428. Through his whole life he appears to have supported the character of a true philosopher. Superior to motives of avarice and ambition, he devoted himself to the pursuits of science; and, in the midst of the vicissitudes of fortune, preserved an equal mind. Being asked, just before his death, whether he wished to be carried for interment to Clazomene, his native city, he said, "It is unnecessary; the way to the regions below is every where alike open." In reply to a message sent him, at that time, by the senate of Lampfacus, requesting to be informed in what manner they might honour his memory after his decease, he said, "By ordaining that the day of my death be annually kept as a holiday in all the schools of Lampfacus." His request was complied with, and the custom remained in Lampfacus in the time of Diogenes Laertius. The festival Anaxagoria was instituted on this occasion. The inhabitants expressed their veneration for his memory, by erecting a tomb, and inscribing upon it the following epitaph:

“Ενθάδε, πλαστον ἀληθείας ἐπι τεμα πειρασκι,
Οὐρανόε κοσμου κείηαι Ἀναξαγόρας.

“This tomb great Anaxagoras confines,
Whose mind explor'd the paths of heav'nly truth.”

It is also said, that two altars were raised in honour of his memory, one dedicated to "Truth," and the other to "Mind," an appellation which was given him on account of the doctrine which he taught concerning the origin and formation of the world.

With the credible records of Anaxagoras many fabulous relations are intermixed; nevertheless, it is sufficiently attested, that this philosopher possessed a very extensive and accurate knowledge of nature, considering the age in which he lived, and allowing for the strange and erroneous conceptions which are blended with his more rational opinions. Of the heavens he seems to have had no other idea than that of a solid vault in which luminous bodies are fixed; and these bodies he conceived to be stones, raised from the earth by the rapid motion of the ambient æther, set on fire by its heat, and kept in their places by the swift circular motion of the heavens. On the other hand he is said to have taught, that wind was produced by the rarefaction of the air; that the rainbow is the effect of the reflection of the solar rays from a dense cloud placed opposite to it like a mirror; that the moon is an opaque body enlightened by the sun, and an habitable

habitable region, divided into hills, vales, and waters; that the comets are wandering stars; and that the fixed stars are in a region exterior to those of the sun and moon.

Of the opinion of Anaxagoras concerning the origin of the material world, the information transmitted to us is more correct. Having learned in the Ionic school that bodies are composed of minute parts, and having observed in different bodies different and often contrary forms and qualities, he concluded, that the primary particles of which bodies consist, are of different kinds; and that the peculiar form and properties of each body depend upon the nature of that class of particles, of which it is chiefly composed. A bone, for instance, he conceived to be composed of a great number of bony particles, a piece of gold of golden particles; and thus he supposed bodies of every kind to be generated from similar particles, *ὁμοιομεγεθῆσι*, and to assume the character of those particles. This system is thus exhibited by Lucretius, lib. i. v. 380, &c.

“ — Principium rerum quam dicit homœomeriam,
Ossa videlicet è pauxillis atque minutis
Ossibus: sic et de pauxillis atque minutis
Visceribus viscus gigni; fanguenque creati
Sanguinis inter fe multis cœeuntibus guttis;
Ex aurique putat micis consistere posse
Aurum; et de terris terram concrefcere parvis;
Ignibus ex ignem; humorem ex humoribus esse,
Cætera consimili fingit ratione, putatque.”

“ With Anaxagoras, great Nature’s law
Is similarity; and every compound form
Consists of parts minute, each like the whole;
And bone is made of bone, and flesh of flesh;
And blood, and fire, and earth, and massy gold,
Are, in their smallest portions, still the same.”

The absurdity of this notion is evident; it admits of no simple, uncompounded principles; it makes no provision for production or dissolution, the formation of any new body being, according to this doctrine, nothing more than the collecting together of a number of small similar bodies; and it gives no explanation of the original formation of the small compound bodies of which the larger consist. The invention of the system, however, evinced the ingenuity of the author, who had recourse to the notion of similar particles, with a view of obviating the objections which lay against the doctrine of atoms, as he had received it from Anaximenes. But the most important improvement which Anaxagoras made upon the doctrine of his predecessors, was that of separating, in his system, the active principle in nature from the material mass upon which it acts, and thus introducing a distinct intelligent cause of all things. The similar particles of matter which he supposed to be the basis of nature, being without life or motion, he concluded that there must have been, from eternity, an intelligent principle, or infinite mind, existing separately from matter, which, having a power of motion within itself, first communicated motion to the material mass, and, by uniting homogeneous particles, produced the various forms of nature. That Anaxagoras maintained an infinite mind to be the author of all motion and life, is attested by many ancient authorities. Plato (Phæd. Hippias major) expressly asserts, “that this philosopher taught the existence of a disposing mind, the cause of all things.” Aristotle says, (Metaph. lib. i. c. 3.) that Anaxagoras taught, that mind was “the cause of the world, and of all order,” and that “while all things else are compounded, this alone is pure and unmixed; and that “he ascribes to this principle two powers, to know and to move,

saying, that mind put the universe into motion.” Cicero (De Natura Deor. lib. i. c. 10, 11. tom. ii. p. 511. Tuscul. Quæst. lib. iii. c. 24. tom. ii. p. 404. De Orator. lib. iii. c. 34. tom. i. p. 351. ed. Olivet.) also asserts, though not without some inconsistency, with what he had before said of Thales, that Anaxagoras was the *frst* who taught that the arrangement and order of all things was contrived and accomplished by the understanding and power of an infinite mind. Plutarch (in Pericl. Oper. tom. i. p. 154. ed. Xylandri) confirms this account of the doctrine of Anaxagoras. “The Ionic philosophers,” says he, “who appeared before Anaxagoras, made fortune, or blind necessity, that is, the fortuitous or necessary motion of the particles of matter, the first principle in nature; but Anaxagoras affirmed, that a pure mind, perfectly free from all material concretions, governs the universe.” To the same purpose Diogenes Laertius (lib. ii. n. 6. tom. 1. p. 82.) represents Anaxagoras as teaching, that “the universe consists of small bodies composed of similar parts, and that mind is the beginning of motion.” “He was the first,” says the same writer, “who superadded mind to matter, opening his work in this pleasing and sublime language,” “All things were confused, then came mind, and disposed them in order.” Dr. Davies in his note on the passage, in which Cicero seems to be charged with inconsistency, observes, that Thales supposed God to be the soul of the world, mixed and united with matter; whereas, Anaxagoras held him to be a pure mind, free from all material union and mixture. From these and other concurrent testimonies, it sufficiently appears that Anaxagoras was the first among the Greeks who conceived mind as detached from matter, and as acting upon it with intelligence and design in the formation of the universe. The infinite mind or deity which his predecessors had confounded with matter, making them one universe, Anaxagoras supposed to have a separate and independent existence, and to be simple, pure intelligence, capable of forming the eternal mass of matter according to his pleasure. Thus he assigned an adequate cause for the existence of the visible world. Diogenes Laertius, lib. ii. in Anaxagor. Plutarch in Pericle, *ubi supra*. Suidas, Gen. Dict. Brucker’s Hist. of Philos. by Enfield, vol. i. p. 148—153.

ANAXAGORIA, in *Antiquity*, a festival observed in honour of ANAXAGORAS.

ANAXANDRIDES, in *Biography*, a comic poet, was a native either of Rhodes or Colophon, and flourished during the reign of Philip of Macedon, B. C. 370—80. Suidas says he was the first who introduced on the stage love-adventures, turning upon the mishaps of young damsels. He was a personable man, and affected great magnificence in his dress and equipage, and he is said to have once recited a piece at Athens on horseback. His temper was morose and splenetic; and he was much chagrined at the ill success of his performances, which were often incorrect, and which he would not take pains to amend and polish. Of 65 plays which he composed, ten only were crowned. The Athenians condemned him to die of a famine for a line in which their government was censured. An “Odyssey” of this poet is mentioned by Athenæus. Casaubon suggests, that Anaxandrides was the Alexandrides of other writers. Gen. Dict.

ANAXARCHUS, a Grecian philosopher, was a native of Abdera, and belonged to the Eleatic sect. He flourished about the 110th Olympiad, or 340 years before Christ, and enjoyed the confidence of Alexander, whom he treated with the freedom of a friend in some instances, but with the servility of a sycophant in others. On one occasion, when Alexander aspired at the honours of divinity, this philosopher checked his vanity by pointing to his finger when it bled, saying,

taving, " See the blood of a mortal, not of a God ;" and on another occasion he recited a verse from Euripides at a banquet, in order to admonish him of his mortality. For an instance of his misapplied and unseasonable adulation, see **ALEXANDER**. Anaxarchus was addicted to pleasure ; and on this account, not from the apathy and tranquillity of his life, he obtained the appellation of *Ευδαίμωνος*, " The Fortunate." Diogenes Laertius, lib. ix. tom. 1. p. 579. Brucker's Hist. Phil. by Enfield, vol. i. p. 436.

ANAXILAUS, a native of Larissa, lived in the time of Augustus, and professed himself a follower of Pythagoras. That his pretensions to an intimate acquaintance with the mysteries of nature, and to the exercise of magical powers might obtain credit, Phny (Nat. Hist. lib. xix. c. 1. lib. xxviii. c. 11. lib. xxxv. c. 15.) relates several curious arts by which he astonished and alarmed the ignorant multitude; and of these one was that of giving a livid and ghally hue to the countenance by means of sulphureous flame. He was banished from Italy in the 28th year before Christ, by order of Augustus, for the crime of magic. Brucker's Hist. Phil. vol. ii. p. 40.

ANAXIMANDER, a famous Greek philosopher, was the disciple and friend of Thales, and was, probably, born at Miletus, in the 3d year of the 42d Olympiad, or in the 610th year before Christ. An anecdote is related concerning him, from which it has been inferred, that he was employed in the instruction of youth. Being laughed at for singing or reciting his verses ill, he said, " We must endeavour to sing better for the sake of the boys." He was the first among the Greeks who taught philosophy in a public school; and is often spoken of as the founder of the Ionic school, though this honour really belongs to Thales. The mathematical and astronomical sciences are, without doubt, much indebted to Anaximander. He framed a connected series of geometrical truths, and wrote a summary of his doctrine. He is said to have been the first who delineated the surface of the earth, and marked the divisions of land and water upon an artificial globe. The invention of the sundial has been ascribed to him; but Herodotus (lib. ii. c. 32.) with greater probability, ascribes the origin of this instrument to the Babylonians. He might possibly have used a gnomon, in order to ascertain more correctly than Thales had done, the meridian line, and the points of the solstices. Pliny (lib. ii. c. 1.) refers to this philosopher the discovery of the obliquity of the ecliptic; but if Thales was acquainted with the method of predicting eclipses; he could not be ignorant of this obliquity. It is related of him that he predicted an earthquake; but we need not say, that, as this is impossible, the relation must be fabulous. Among the physical notions imputed to Anaximander are these: That the stars are globular collections of air and fire, borne about in the spheres in which they are placed; that they are gods, that is, inhabited and animated by portions of the divinity; that the sun has the highest place in the heavens, the moon the next, and the planets and fixed stars the lowest; that the earth is a globe, placed in the middle of the universe, and remains in its place; and that the sun is 28 times larger than the earth.

The doctrine of this philosopher concerning the first principles of things, and the origin of nature, is so obscurely and variously related, that it cannot be well ascertained. His general system seems to have been, that infinity, *τὸ ἀπείρον*, is the first principle of all things; that the universe, though variable in its parts, is immutable as a whole; and that all things are produced from infinity, and terminate in it. What Anaximander meant by infinity, and whether he understood by it the material subject, or the efficient cause of

nature, are subjects of controversy. Plutarch asserts, (Plu. Phil. lib. i. c. 3. Oper. vol. ii. p. 875.) that the infinity of Anaximander was matter; and Aristotle (Nat. Aufc. lib. i. c. 5. lib. iii. c. 4. Oper. tom. i. p. 319—331.) explains it in the same manner; and several modern writers adopt the same idea. Others suppose that he used the term infinity to denote the humid mass of Thales, together with the divine principle by which he supposed it to be animated. This opinion is supported by the authority of Hermias, who asserts (Iris. Gen. § 10. apud Tatian.) that Anaximander supposed an eternal mover or first cause of motion, prior to the humid mass, or *τὸ ὑγρὸν* of Thales. And Aristotle himself speaks of the infinity of Anaximander, as comprehending and directing all things. Anaximander is said to have been the first who laid aside the defective method of oral tradition, and committed the principles of natural science to writing. Anaximander lived 64 years. Diog. Laert. lib. ii. Strabo, lib. i. Pliny, lib. vii. c. 56. Suidas. Euseb. Prap. Ev. lib. x. c. ult. Brucker, by Enfield, vol. i. p. 145—147.

ANAXIMANDRIANS, a name given by some writers to the followers of Anaximander. These are otherwise denominated *hylopathii*; and stand opposed to the *atomists*. The *Anaximandrians* make the most ancient sect of *philosophical atheists*; they allow of nothing in nature but bodies. These bodies, they assert, admit of qualities which produce and destroy each other, in a circle without beginning or end. See **ANAXIMANDER**.

ANAXIMENES, a philosopher of Miletus, was born about the 56th Olympiad, or 556 years before Christ, and was a disciple and companion of Anaximander. On his inquiring into the nature and origin of things, he traced the footsteps of his master, and endeavoured to throw new light upon his system. According to him the first principle of all things is air, which is infinite or immense, and perpetually active. This air is a subtle æther, animated with a divine principle, whence it becomes the origin of all things, and is God. His doctrine, therefore, was a continuation of that of Thales and Anaximander, with this difference, that he supposed the divine energy to reside in air or æther. He also taught, that all minds are air; that fire, water, and earth proceed from it by rarefaction or condensation; that the sun and moon are fiery bodies of a circular form; that the stars, which are fiery substances, are fixed in the heavens, like studs in a crystal plane; and that the earth is a plane tablet resting upon the air. Plut. Plac. Phil. lib. i. c. 36. lib. ii. c. 11. lib. iii. c. 10. Oper. tom. ii. p. 876—888—894. Cicero de Nat. Deor. lib. i. c. 10. Oper. tom. ii. p. 511. Academ. lib. ii. c. 37. tom. ii. p. 64. Suidas. Diog. Laert. lib. ii. Brucker, by Enfield, vol. i. p. 147.

ANAXIMENES, a Greek rhetorician and historian, was the son of Aristocles, of Lampascus, and the disciple of Diogenes the Cynic, and of Zoilus of Amphipolis, who railed against Homer. He was born about 580 years before Christ; and employed by Philip of Macedon to instruct his son Alexander in the art of rhetoric. Some have ascribed the treatise on rhetoric, which bears Aristotle's name, to Anaximenes. This learned man, with many others, accompanied Alexander in his expedition against the Persians; and he contrived by a smart and seasonable retort, mentioned under **ALEXANDER**, to preserve the city of Lampascus. On another occasion having conceived a grudge against the historian Theopompus, he revenged himself by writing a severe satire against the Spartans and Thebans, exactly in the style of Theopompus, and addressing it, under his name, to the Athenians. By this deception, though not of the most honourable kind, he gratified his resentment, and exposed his adversary to reproach and ill-will throughout almost all Greece.

Greece. Anaximenes wrote a history of the life and actions of Philip, and another of those of Alexander; and he also wrote 12 books on the early history of Greece, beginning with the theogony, or fabulous history, and ending with the battle of Mantinea, which was fatal to Epaminondas. But none of these works are extant. Suidas. Paulan. Eliac. lib. ii. c. 19. p. 495. ed. Kuhnii. Gen. Dict.

ANAZARBUM, in *Ancient Geography*, a city of Asia, in Cilicia Proper, or Cilicia Campestris. It was situated on the river Pyramus, at some distance from the sea. Suidas informs us that it was first called Cyinda, and afterwards Anazarbum, from its founder Anazarbus, who was sent by the emperor Nerva to rebuild it, after it had been quite ruined by an earthquake; but he is certainly mistaken, since Pliny, who died long before the reign of Nerva, calls the inhabitants of this city *Anazarbeni*. The etymology of Stephanus Byz. is therefore more probable, who derives its name from mount Anazarbus, at a small distance from the place where this city stood. The territory adjacent to Anazarbum was very fertile, and produced abundance of grain and fruit. The symbols of this fertility were expressed on the coins of the city; such as the cornu-copia, ears of corn, branches loaded with fruit, &c. This city is distinguished by an æra, marked on its medals, called the æra of Anazarbum. The Abbè Belley, (Mem. de Lit. tom. xxx. p. 714.) proves that this æra ought to commence with the year of Rome 735, 19 years before the Christian æra. By a decree of the senate it had permission to assume the name of Cæsarea, in acknowledgment of the privileges conferred upon it by Augustus. It also took the name of Justinopolis and Justinianopolis, in honour of the emperors Justin and Justinian. When this city was nearly demolished by an earthquake, it was repaired by Nerva; and after a similar catastrophe, it was raised from its ruins under the reign of Justin or Justinian. The citizens of Anazarbum were divided into three classes or orders, comprehending the people, the council, and the senate. At the commencement of the fifth century Cilicia was divided into two provinces; and Anazarbum was the metropolis of the second province. This division contained nine cities, and Anazarbum exercised the jurisdiction of a metropolis, and its bishops had the rank and jurisdiction of metropolitans. It possessed the distinguishing privilege of autonomia, *i. e.* of choosing its own magistrates, and of being governed by its own laws. When the provinces of Asia were divided under the emperors of Constantinople, after the reign of Heraclius, into *themæ*, or military departments, Anazarbum was comprised with Cilicia in the theme of Seleucia. When this city embraced the Christian religion, it became dependant on the patriarch of Antioch; and it is said to be still the see of a Jacobite bishop. The Turks call it *Ain-Zerbeh*. This city was the birth place of Dioscorides, and of the poet Oppian.

ANAZEIA, in *Geography*, a town of Asia, in Greater Armenia, near Mount Taurus. It is in the government of Van, not far from a lake which bears this name.

ANAZZO. See GNATIA.

ANBAR, in *Geography*, a town of the province of Chaldæa, or Irac-arabi, on the Euphrates, called also Anchemiah.

ANBERTKEND, in the *Eastern Language*, a celebrated book of the Brachmans, containing the Indian philosophy and religion. The word in its literal sense denotes the cistern, wherein is the water of life. The *ambertkend* is divided into fifty beths, or discourses, each of which consists of ten chapters. It has been translated from the original Indian into Arabic, under the title of *Morat al Maani*, q. d. "the marrow of intelligence."

ANBORD, in *Geography*, a town of Persia, in the province of Khorasan, 50 leagues north-east of Meshid.

ANBURY, in *Agriculture*, is a disease in the roots of

turnips, which is described by Mr. Marshall, in his *Rural Economy of Norfolk*, in the following manner: "It is a large excrescence, which forms itself below the apple. It grows to the size of both the hands, and, as soon as the hard weather sets in, or it is by its own nature brought to maturity, becomes putrid, and smells very offensively. At present (says he) the state of three specimens which have been taken up and examined attentively, is this: the apples of the turnips are just forming (about the size of walnuts in the husk), while the anberries are already as big as the egg of a goose. They are irregular and uncouth in their form, with inferior excrescences (resembling the races of ginger) hanging to them. On cutting them, their general appearance is that of a hard turnip; but on examining them through a magnifier, there are veins, or string-like vessels, dispersed among the pulp. The smell and taste somewhat resemble those of turnips, but without their mildness, having an austere and somewhat disagreeable flavour, resembling that of an old string turnip. The tops of those which are much affected turn yellow, and flag with the heat of the sun: so that in the day time they are obviously distinguished from those which are healthy. It seems to be an idea among farmers, that the cause of the anbury is the soil's being tired of turnips; owing to their having been too often sown on the same land. This, however (he contends), is positively erroneous; for the piece from which these specimens were drawn was an old orchard, and never before bore turnips in the memory of man."

The nature and cause of this *vegetable disease* do not appear to be yet fully explained; but it is probable that drought has much effect in producing it, as it is found to be the most prevalent in such seasons. The author just mentioned, however, seems to suspect that it may be induced by some sort of grub or other, wounding the vessels of the tap-root, and thus diverting the course of the sap-juice, by which means excrescences of this kind are formed, instead of the apple of the turnip. Whatever may be the causes of the disease, experience has shewn, that the most effectual remedy is that of frequent hoeing, or stirring the ground about the plants, in order to admit air and moisture more freely.

ANCA, in *Middle Age Writers*, denotes the thigh, or hind-leg.

In which sense the word is also written ANCUS.

ANCEUS, in *Entomology*, a species of PAPILIO found in India. The wings are entire, black, with a blue bar on the anterior pair, and a ferruginous one on the posterior pair. Under side green. Gmelin. This is the PAPILIO OBRINUS of Fabricius. Spec. Inf.

ANCALE, or ACALE, in *Ancient Geography*, a town of Arabia Felix, according to Ptolemy.

ANCALITES, inhabitants of Britain, were seated near the Atrebatii, and were probably a clan of that nation. Mr. Baxter (Gloss. p. 14.) thinks they were the ceangi, or herdsman and shepherds of the Atrebatii, and possessed those parts of Oxfordshire and Buckinghamshire which were most proper for pasturage. After they were subdued by the Romans, the government of them, with that of some of their neighbouring states, was bestowed upon Cogidunus, the British king of the Dobuni, as a reward for his early submission, and great fidelity to the Romans.

ANCAMARES, or ANTAMARES, in *Geography*, a people of South America, who live near the banks of the river Madera, which discharges itself into the river of the Amazons.

ANCANICUM, in *Ancient Geography*, a district of Spain in Bætica.

ANCAON, *Serra de*, in *Geography*, a chain of mountains in Beira, a province of Portugal, which joins to another called Serra d'Estrella.

ANCARA, in *Ancient Geography*, a town of Italy, mentioned by Stephanus Byz.

ANCARANO, PETER DE, in *Biography*, a celebrated civilian of Bologna, flourished in the 15th century. He rivalled Baldus, his master, in the knowledge of the civil and canon law. In 1409 he defended the council of Pisa against the ambassadors of Robert duke of Bavaria, and evinced its right to proceed against Gregory XII. and Benedict XIII. in order to terminate the schism. He died at Bologna in 1417, and left behind him in Latin, "Commentaries on the Decretals and Clementines," printed at Lyons, Venice, Bologna, &c. On his tomb was inscribed an epitaph, in which he is called "the mirror of the canon law, and the anchor of the civil."

ANCARANO, in *Geography*, a town of Italy, in the marquisate of Ancona, situate on the Tronto, six miles east of Ascoli. N. lat. 42° 48'. E. long. 14° 54'.

ANCASTER, a village of England, in the county of Lincoln, was formerly a Roman station, of which many vestiges are now visible: 116 miles from London.

ANCENIS, a town of France, and principal place of a district, in the department of the Lower Loire. It is situated on the Loire, in a very agreeable and fertile country. It is the ancient *Ancanifium*, the capital of the Anmites, a people who lived about the mouth of the Loire. The place contains 2,923, and the canton 11,109 inhabitants. The territory includes 200 kilometres and 7 communes. N. lat. 47° 22'. W. long. 1° 15'.

ANCEPS, in *Botany*, denotes two-edged.

ANCEPS, in *Conchology*, a species of PATELLA. It is solid, glossy, and rather pointed, outside pale chestnut, within white tinged with flesh-colour. Gmelin.

ANCERVILLE, in *Geography*, a town of France, in the department of the Meuse, and chief place of a canton in the district of Bar-le-duc; one league east of St. Dizier, and three leagues south-west of Bar-le-duc. The place contains 2,200, and the canton 9,699 inhabitants. The territory comprehends 220 kilometres and 18 communes.

ANCERVILLE is also a town of France, in the department of the Moselle, and chief place of a canton, in the district of Morhange, three leagues and a half west-north-west of Morhange, and three east-south-east of Metz.

ANCESTORS, *progenitors*, are those from whom a person is descended, exclusively of his immediate parents.

The word is derived from the Latin *anceffor*, written, by contraction, for *antecessor*, q. d. *goer before*.

Most nations have paid honour to their ancestors. It was properly the departed souls of their fore-fathers that the Romans worshipped under the denomination of *lares*, *lemures*, and household gods. Hence the ancient tombs were a kind of temples, or rather altars, wherein oblations were made by the kindred of the deceased. The Russians have still their anniversary feasts in memory of their ancestors, which they call *roditoli sabot*, q. d. *kingsfolk's sabbath*, wherein they make formal visits to the dead in their graves, and carry them provisions, eatables, and presents of divers other kinds. They interrogate them with loud lamentable cries, What they are doing? how they spend their time? what it is they want? and the like.

The Quoijas, a people of Africa, offer sacrifices of rice and wine to their ancestors, before they ever undertake any considerable action. The anniversaries of their deaths are always kept by their families with great solemnity. The king invokes the soul of his father and mother to make trade flourish, and the chase succeed.

The Chinese seem to have distinguished themselves above all other nations in the veneration they bear their ancestors. By the laws of Confucius, part of the duty which children

owe their parents consists in worshipping them when dead. The service, which makes a considerable part of the national religion of the Chinese, is said to have been instituted by the emperor Kun, the fifth in order from the foundation of that ancient empire.

The Chinese have both a solemn and ordinary worship which they pay their ancestors. The former is held regularly twice a year, viz. in Spring and Autumn, with much pomp. A person who was present at it gives the following account of the ceremonies on that occasion.

The sacrifices were made in a chapel well adorned, where there were six altars furnished with censers, tapers, and flowers. There were three ministers, and behind them two young acolytes; he that officiated was an aged man, and a new Christian. The three former went with a profound silence, and frequent genuflexions towards the five altars, pouring out wine; afterwards they drew near to the sixth, and when they came to the foot of the altar, half-bowed down, they said their prayers with a low voice. That being finished, the three ministers went to the altar, the priest took up a vessel full of wine, and drank; then he lifted up the head of a deer or goat; after which taking fire from the altar, they lighted a bit of paper; and the minister of the ceremonies turning towards the people, said, with a high voice, that he gave them thanks in the name of their ancestors for having so well honoured them; and in recompence he promised them, on their part, a plentiful harvest, a fruitful issue, good health and long life, and all those advantages that are most pleasing to men.

All the Chinese, Pagans as well as Christians, give their ancestors another simpler and more private worship. To this end they have in their houses a niche or hollow place, where they put the names of their deceased fathers, and make prayers and offerings of perfumes and spices to them at certain times, with bowing, &c. They do the like at their tombs.

It has been a question warmly agitated of late years, whether the worship which the Chinese pay their ancestors be religious, or only of a civil nature. The Jesuits, who not only allow their neophytes, or new converts, to join in it, but even assist in it themselves, are necessitated to maintain the latter, to screen themselves from the charge of idolatry; the Dominicans and other missionaries maintain the former, and prohibit the service as absolutely unlawful.

The Jesuits argue, that with relation to the first institution, those honours might be given to our ancestors, since at first they appear to have been only civil; even though they should since, through the superstitious disposition of the people, have degenerated into idolatry. But it is answered, that, by this argument, the most gross worship of idols might be authorized, because all idolatry appears at first only to have been civil worship, as is maintained in the book of Wisdom, chap. xiv. ver. 15.

The Jews settled in China are said to worship their ancestors like the heathens, and with the same ceremonies, except that they offer not swine's flesh. Near their synagogue they have a hall, or court of ancestors, wherein are niches for Abraham, Isaac, &c. The Jesuits also conformed, and were permitted by their general to conform to this, and many other superstitious customs of the Chinese. See the proof of this in Paschal's Provincial Letters, *passim*.

There is one peculiarity of another kind, wherein the Chinese shew their regard for their ancestors; in proportion as any of their descendants are preferred to a higher degree or dignity, their dead ancestors are at the same time preferred and ennobled with them. The kings Ven, Van, Veu, Van, Cheu, and Cum, who were descended from vassal kings, when they mounted the imperial throne, raised their ancestors from the

vassal or depending state wherein these had lived, to the dignity of emperors; so that the same honours were for the future rendered them as if they had been emperors of China. The same example was followed by the subsequent kings, and now obtains among the *grandees* and *literati*: all now worship their ancestors, according to the rank which they themselves hold in the world. If the son be a mandarin, and the father only a doctor, the latter is buried as a doctor, but sacrificed to as a mandarin. The like holds in degradations, where the condition of the fathers is that of their sons.

The law distinguishes between *ancestor* and *predecessor*: the former being applied to a natural person, as such an one, and his *ancestor*; and the latter to a body politic or corporate, as a bishop, and his *predecessors*.

ANCESTOR, *disability by the act of*. See DISABILITY.

ANCESTREL, in *Law*, something relating to a man's ancestors.—Thus,

ANCESTREL, *homage*, signifies homage that has been done or performed by one's ancestors.

ANCESTREL, *action*. See ACTION.

ANCHA, in *Geography*, a town of Asia, in Mingrelia, 120 miles north-east of Trebisond.

ANCHA is also a town of Asia, in the country of Georgia, and province of Satabago, 68 miles south west of Akelzika.

ANCHEDIA, an island near the western coast of India.

ANCHESMUS, in *Ancient Geography*, *Aghios Georgios*, or *Mount St. Georges*, a mountain of Attica, upon which was placed a statue of Jupiter Anchesmus. Pausanias, in *Attic. lib. i. c. 32. p. 78*.

ANCHIALE, a town of Asia, in Cilicia Campestris, situated near the sea, to the south-west of Tarsus. Some authors say, that it was built by Sardanapalus. Athenodorus pretends, that it was founded by Anchiale, the daughter of Japhet.

ANCHIALE was also a town of Illyria, built by the Parians.

ANCHIALEUS, a river of Cilicia, which watered the town of Anchiale.

ANCHIALOS, or ANCHIALUS, called by Pliny *Anchialum*, a town of Europe, in Thrace, situate upon the Euxine sea, south-west of Mesembria. It was an episcopal see, dependent upon the patriarchate of Constantinople.

ANCHIALOS was also a place in Greece, towards the Pelagic gulf, according to the Argonautics of Orpheus.

ANCHIALOS was also a town of Epirus, the inhabitants of which pretended that Anchises died in their town. Others refer it to Illyria.

ANCHILOPS, or ANCHYLOPS, in *Surgery*, from *ανχι*, near, and *ωψ*, the eye; a tumor in the lacrymal sac, near the inner angle of the eye, forming an incipient FISTULA LACRYMALIS. See that article, and ÆGILOPS. These swellings are of different kinds. The most common kind is a tumor, situated in the cellular texture immediately surrounding the lacrymal sac, and combined with redness, heat, and pain, which rises the external skin, and bears a considerable resemblance to an inflamed fistula lacrymalis. This resemblance frequently becomes more marked by the cutaneous inflammation acting upon the lacrymal duct in such a manner, as to obstruct the passage of the tears through it; the consequence of which is a flow of tears from the eye, and a swelling of the lacrymal sac.

The inflammatory tumor soon goes on to suppuration; an event which, provided we can do it early enough, we should endeavour to prevent by the external application of a saturnine wash, and other remedies that promote resolution

of the inflammation, as well as by cooling evacuants. When suppuration has already taken place, and produced an abscess at the inner canthus of the eye, we are still more liable to be led into error, as we may easily mistake the fluctuation of the pus for the motion of some fluid contained in the lacrymal sac. This error, which might possibly induce us to make an incision into the sound lacrymal sac, may, however, be easily avoided, by recollecting that the lacrymal passage was not previously diseased, that the tumor was at first hard, and that the lacrymation and fluctuation only supervened afterwards. Moreover, in this disease, the matter cannot be squeezed with the finger out of the tumor, through the puncta lacrymalia, or the nose, (as it may when the lacrymal sac is filled with matter) unless the matter has already corroded the lacrymal duct, so as to produce a communication between it and the abscess. We may also distinctly observe, that both the inflamed and the subsequent suppurating tumor lies flat under the skin, and that at first the collection of matter is surrounded with inflammatory hardness; whilst, on the contrary, the lacrymal sac, when filled with matter, is soft, and affords the sense of fluctuation throughout its whole extent, from the very commencement of the disorder. This complaint, however, may at times produce a real inflammation of the lacrymal ducts, and consequently also a true fistula lacrymalis.

When, in an inflammatory tumor of the angle of the eye, symptoms of incipient suppuration make their appearance, the surgeon may apply, during the night, the Empl. Litharg. vel diachyl. comp. and, in the day time, emollient and somewhat stimulant poultices, in order to invite the matter towards the surface. These must be applied warm and frequently; in doing which, care should be taken that they do not come into contact with the eye, which, on that account, should previously be covered with compresses dipped in rose-water. As soon as there is the least reason to suppose that pus has been formed, the tumor must be cut open; for, in these cases, it is of great consequence that the pus should be discharged as soon as possible, as otherwise it easily makes its way downwards, by which not only the lacrymal sac may be laid bare and corroded, but also the neighbouring bones, &c.

The incision is made with a lancet, but as remote as possible from the inner canthus of the eye, and proportionate to the magnitude of the tumor. The lancet must not be introduced in a perpendicular direction, but obliquely, for fear of injuring the lacrymal sac. When the matter and blood have been discharged, we should introduce some loose lint into the orifice, and cover it with a simple plaster. Over this we may lay a compress, dipped in rose-water. The ulcer is afterwards to be cleaned with mild digestive ointment, and suffered to heal up.

When the surgeon is not called in till the abscess has already been completely formed, he should immediately lay it open, and examine the state of the bone. When the bone is bare, some tincture of myrrh or aloes may be used, and dry dressings applied, in order that we may not increase the ulceration, which is generally already considerable. When the exfoliation of the bone, and the cleansing of the ulcer have been completed, the healing of the sore should be promoted by the proper applications.

The anchilops may at times consist in a hard tubercle or knot, from which a cancer may be produced. This disease is to be treated like other ferruginous tumors. See SCIRRHUS.

Sometimes the tumor is of the encysted kind, most generally of the species of ATHEROMA. In this disease no pain is felt, the tumor is of an uniform colour, circumscribed, smooth, and moveable. Such a tumor also, like every other

anchilops, may by its mere pressure impede the functions of the lacrymal ducts, and occasion an *EPIPHORA*, or watery eye. It may generally be softened by means of Empl. diach. comp. and brought to suppuration; otherwise it is to be dissected out with the knife.

This tumor may also arise from an accumulation of serous fluid between the lacrymal sac and the external skin. Such a serous, uninfamed tumor seldom opens itself spontaneously outwards; it more commonly happens, that it is connected with one of the two *PUNCTA LACRYMALIA*, or lacrymal ducts, generally the lower; in which case the fluid may indeed be pressed out through one of the puncta lacrymalia; but it may, nevertheless, be easily distinguished from a swelling of the lacrymal sac, by the circumstance that the latter generally yields to the slightest pressure, whilst the former cannot be made to collapse, unless by pressing it from below upwards, and its tension cannot be diminished except in a gradual manner. When the serous anchilops is not yet in communication with the lacrymal ducts, (as generally is the case,) it may readily be distinguished from the distension of the lacrymal sac, by the single circumstance of its not being by any means practicable to squeeze out the fluid.

There are certain circumstances under which the lacrymal tumor does not yield to pressure; namely, when the lacrymal ducts are contracted or inflamed, so as to prevent the recession of the fluid contained in the lacrymal sac. But when these passages are in a sound condition, and when the tumor of the larger canthus does not yield to pressure, there can be no doubt that the disease is situated without the lacrymal sac.

When the resolution of such a serous tumor, which we may at first attempt to bring about, does not soon take place, the safest and most expeditious method is to open it, and discharge the matter by means of a lancet, which must here also be introduced in an oblique direction. The wound should be filled up with dry lint, which, in the subsequent dressings, ought to be dipped in some detergent and drying solution, such, for example, as a very weak solution of *lapis infernalis*, and secured by means of a plaster.

Finally, in the venereal disease there is sometimes produced, in the region of the larger canthus of the eye, an exostosis from the *os unguis coronale*, or maxillare; by which a tumor is formed in this part that may easily be distinguished from other kinds of anchilops, by its being hard, immoveable, and generally of an uneven surface. It occasions a compression of the lacrymal passages, which gives rise to a constant *EPIPHORA*. We may, in such cases, employ internally mercurial remedies, and a decoction of *Cost. Mezerei*, and, at the same time, rub mercurial ointment upon the tumor, apply mercurial plasters, &c. by which a speedy cure is frequently produced: but, for the treatment of venereal disorders, see *SYPHILIS* and *LUES VENEREA*.

ANCHIROMACUS, in *Middle Age Writers*, denotes a kind of vessel, which, on account of its nimble sailing, was used for the conveyance of anchors, and other necessary utensils of ships.

In this sense, the word is also written *ancyromagus*, *anchiromachus*, *ansyromacus*, *angromagus*, *anquiromagus*, and *anquiromagus*.

ANCHISÆ PORTUS, a name given by the ancient Romans to the port of Onchestus, in Epirus, to the east of Corcyra.

ANCHISES, in *Entomology*, a species of *PAPILIO* (Eq. Tr.) that inhabits America; it is black both above and beneath, with seven ovate scarlet spots on each of the posterior wings. *Linnæus*. The larva from which this butterfly is

produced, is said to be gregarious, spinous, brown with white rings, and yellow tentacula; the pupa brown, with four teeth at the anterior part. Vide. *Fab. Gmel. Metian*, &c.

ANCHISES, in *Fabulous History*, a Trojan prince, descended from Dardanus, and the son of Capys. Venus appeared to him in the form of a beautiful nymph, and made love to him. Their intercourse produced *Æneas*, the hero of Virgil's *Æneid*. It is said that he lived to the age of 80, and was buried on Mount Ida, where shepherd paid honours to his monument. According to Virgil, *Æneas* took his father on his shoulders, and made his escape with him the night on which Troy was taken. See *ÆNEAS*. Some say, that Anchises lived till his son's arrival in Italy, that land of promise, which the destinies had ordered him to go in search of, through a thousand dangers. Cato, Dionysius Halicarnassensis, and Strabo, adopt this opinion. Gen. Dict.

ANCHISIUS, in *Ancient Geography*, a mountain of Peloponnesus, in Arcadia, to the north of Mantinea.

ANCHITÆ, a people placed by Ptolemy in Arabia Felix, near mount Climax.

ANCHOA, a town of Greece, in Bœotia, placed by Pliny at the mouth of the Cephissus. Strabo mentions also a lake of the same name.

ANCHOR, *ANCHORA*, from the Latin *ancora*, or *anchora*, of the Greek *ἄγκυρα*, which comes from *ἄγκυλος*, *incurved*, *crooked*, a large, strong, and heavy piece of iron, composed of a long shank, having at one end a ring to which the cable is fastened, and at the other two arms or flukes, with barbs or edges on each side, and used for fixing and retaining a vessel in a harbour, road, or river.

The anchor is an instrument of very ancient use. Pliny (lib. viii. c. ult.) ascribes the invention of it to the Tuscans; and Pausanias (Attic, lib. i. c. 4. p. 12.) refers it to Midas, the son of Gordius, who built the city Ancyra. The most ancient anchors were of stone, and sometimes of wood, to which a quantity of lead was attached; in some places they used baskets full of stones, and sacks filled with sand. These were suspended by cords, and their weight regulated the course of the ship. Afterwards anchors were constructed of iron, and furnished with teeth or flukes, which fastening to the bottom of the sea, kept the ship immoveable; hence *οὐράς*, teeth, are used for anchors. The first anchors had only a tooth or fluke, on one side; and on this account they were denominated *ἑίροσσομοί*; the contrivance was completed, according to Pliny, (*ubi supra*.) by Eupalamus, who made them fluked both ways, or according to Strabo (lib. vii. ex Ephor, tom. p. 464.) the second tooth or fluke was added by Anacharsis, the Scythian. The anchors with two teeth were called *αμφιβόλοί*, or *αμφισομοί*. Every ship had several anchors, the largest of which was called *μεγα*, sacred, and was never used but in extreme danger; whence the phrase "sacram anchoram solvere," is proverbially applied to such as are reduced to their last refuge.

All anchors have now two arms; not but they might still be used with only one arm, which structure would have this advantage, that they would be lighter, and yet in fine weather would hold equally firm with the double kind. The reason of having two arms is, that the anchor may always take, in order to which it is necessary that it be very heavy; besides, that anchors with a single arm would require more preparation for service.

Travellers tell us of people who make use of wooden anchors in their navigation. The inhabitants of the island of Ceylon, in lieu of anchors, use large round stones, and

A N C H O R.

in other places, their anchors are a kind of wooden machines, loaded with stones. Sometimes bags of sand have been made use of, but these chiefly obtained in rocky places, where anchors would not take hold. In England, France, and Holland, anchors are made of forged iron; but in Spain, they are sometimes made of copper, and likewise in several parts of the South sea.

The anchors now made are so contrived as to sink into the ground as soon as they reach it, and to hold a great strain before they can be loosened or dislodged from their station. The parts of which an anchor is composed are the ring, into which the cable is fastened, the beam, or shank, which is the longest part of the anchor, the two arms, at the end of which are the two flukes or flukes, by some called the palms, which with their barbs fasten into the ground, and the stock, which is a long piece of wood, fastened across the beam, near the ring, and serving to guide the flukes in a direction perpendicular to the surface of the ground; so that one of them sinks into it by its own weight, as soon as it falls, and is still preserved steadily in that position by the stock, which, together with the shank, lies flat on the bottom. In this situation it must necessarily sustain a great effort before it can be dragged through the earth horizontally. This, indeed, can only be effected by the wind or tide, or by both of them; the effect of which is sometimes increased by the turbulency of the sea, and acts upon the ship so as to stretch the cable to its utmost tension, and may thus dislodge the anchor from its bed, especially if the ground be soft, and oozy, or rocky. When the anchor is thus displaced, it is said, in the sea-phrases, "to come home."

The several parts of the anchor, above enumerated, bear the following proportions. The length of the arm, from the inside of the throat to the bill, is the distance marked on the shank for the trend, taken from the inside of the throat; and three times that is the length of the shank from the tip of the crown; and the shank, from the tip of the crown to the centre of the ring, is the length of the iron stock; when made, the two arms, from the inside of the throat to the extremity of the bill, should form an arc of a circle, containing 120 degrees. See *Plate XI. Ships.*

Of anchors there are the sheet, best bower, small bower, and spare anchor. These do not vary in form or weight from each other, in the navy. Stream and kedge anchors are smaller, and grappels are only for boats. Ships of 110, 100, 98, and 90 guns, have seven anchors; from 80 to 20 guns inclusive, six anchors; ships of 300 tons, and sloops have five; and brigs and cutters three anchors.

ANCHORS, method of making. The goodness of the anchor is a point of great importance; the safety and preservation of the vessel depending principally upon it. The shank, arms, and flukes, are first forged separately; then the hole is made at one end of the shank for the ring, which being also previously forged, is put into the hole of the shank, and the two ends shut together. After which the arms are shut to the shank, one after the other, and the anchor is finished.

The shank is made of many long bars of the best tough iron, well wrought together; and great care should be taken, that the iron be neither too soft nor too brittle; the latter rendering it liable to break, and the former to straiten. The number of bars sufficient to make the shank of the intended size must be regulated by experience. Several parts of the anchor are governed by the size of the trend, which is marked on the shank at the same distance from the inside of the throat as the arm measures from the inside of the

throat to the extremity of the bill. The shank is rounded to the square of the upper part, and is there called the small round, being the smallest part. The two sides in the direction of the arms are flatted surfaces, about an inch less than the trend, in large anchors, and something less in smaller ones. The squared part is of the same size as at the trend each way, and hanches into the small round, one-sixth of the length of the shank. The hole, or eye, for the ring, is punched through the square part, or the flatted side, once and a half the thickness of the ring, from the upper extremity of the shank, which has its corners flatted or diamonded, on the same sides nearly, in the middle. Between the hole for the ring and lower part of the square are two small prominences, raised across from the solid, called nuts, for securing the stock in its place. At the lower part of the shank is left a scarf, or flatted surface, with a shoulder on each side, for shutting on the arms.

In making every part of an anchor the nicest attention should be observed, as to its being smooth, fair, and even; and that the edges and angles are preserved straight in their direction, as well-made anchors should possess beauty as well as strength. The ring, being previously forged, is put through the fore-mentioned hole in the shank, and the two ends are well shut together. The arms are made of shorter bars than the shank, but as good in quality, and as well put together; they are rounded and flatted on the different sides, to resemble the shank, and are of the same size as the shank, at the throat and small round. The rounding part is continued to the palm, which is nearly in the middle of the arm; from thence it is made with a square tapering to the bill on the flatted side; and, on the inner rounded side, is made a square seat for shutting on the palm, that the palm, when shut on, should project its thickness at the base or inner part, the outer part making a straight surface with the peak or bill. The back or outer side of the arm is made straight from the rounded part, or hanch, to the snape, and there kept to half the substance of the inner part. The snape resembles the bill of a duck, and is one-third the breadth of the palm in length. The thickness of the ring is to be half the diameter of the small round. The diameter of the ring, including the thickness, reaches from the hole in the upper part of the shank to the hanch of the small round. The inner part of the arm is mostly made straight, from the bill to the throat; and it is thought stronger for having a small angle in its length, inclining to the shank. Shanks taper in their length, one and one-half inch in small anchors to three inches in large, keeping their proper size at the trend; and three-fourths of an inch to two inches in the flatted way. The arm in its length inclines to the shank, and forms a small angle, the touch or point thereof being in the middle. The throat-end of the arm is scarfed, or flatted, to answer the scarf in the shank, to which the two arms are united (after the palms are shut on) in the firmest manner possible; and it is elevated above the horizontal plane, or inclined to the shank, that each arm may spread at the peak or bill. The length of the arm, from the inside of the throat to the extremity of its bill, is then taken, and that length from the inside of the throat is set upon the shank, and called the trend: from the trend to the bill is formed an angle of about 60 degrees. The palms, or flukes, are two thick plates of iron, made of various pieces, well wrought together, in the form of an isosceles triangle; one and one-half inch to one and one-fourth inch longer than the breadth of the base, and curve about as much in their sides. The base or lower part, is to be straight; the inner flat surface curves a little in the breadth, but is straight lengthways;

lengthways; the palms, being finished thus far, are lally shut firmly into the inner side of the arm, in the seat before mentioned, the base inclining inwards.

The stock is composed of two long beams of oak, strongly bolted and tree-nailed together, and secured with four strong iron hoops, two on each side of the middle, and one near each end. It is fixed on the upper end of the shank, transversely with the flukes or palms; and the nuts are let into the middle of the stock. The length of the stock is the length of the shank and half the diameter of the ring; the depth and thickness in the middle are as many inches as the stock is feet in length. The ends are to be kept square, half the depth or thickness in the middle. The upper side next the ring is always kept straight, as is the lower side half the depth on each side the middle; and thence it tapers to each end in the above proportion. It is necessary to leave an opening in the middle of one and one-half inch, between the two pieces, that the hoops may be driven nearer the middle, in case the stock should shrink. The making of anchors is a very laborious business, and has been much facilitated by the invention of two machines, called the **HERCULES** and the **MONKEY**.

Proof is made of anchors, by raising them to a great height, and then letting them fall again on a kind of iron block placed across for the purpose. To try whether the flukes will turn to the bottom, and take hold of the ground, they place the anchor on an even surface, with the end of one of the flukes, and one of the ends of the stock resting on the surface; in case the anchor turns, and the point of the fluke rises upwards, the anchor is good.

For the proportions of anchors according to Manwaring, the shank is to be thrice the length of one of the flukes, and half the length of the beam. According to Aubin, the length of the anchor is to be four-tenths of the greatest breadth of the ship; so that the shank, *e. gr.* of an anchor in a vessel thirty feet wide, is to be twelve feet long. When the shank is, for instance, eight feet long, the two arms are to be seven feet long, measuring them according to their curvity. As to the degree of curvity given the arms, there is no rule for it; the workmen are here left to their own discretion.

Aubin, in his Marine Dictionary, gives a table from a Flemish writer, wherein the lengths of the shanks of anchors for vessels of all widths, is computed, as well as the weights of the anchors, from a vessel eight feet wide within, which requires an anchor three and one-half feet long, weighing thirty-three pounds, to a vessel forty-five feet wide, which demands an anchor eighteen feet long, and weighing 5832 pounds. He likewise observes, that the anchor of a large heavy vessel is smaller, in proportion, than that of a lesser and lighter one. The reason he gives is, that though the sea employs an equal force against a small vessel as against a great one, supposing the extent of wood upon which the water acts to be equal in both, yet the little vessel, by reason of its superior lightness, does not make so much resistance as the greater; the defect whereof must be supplied by the weight of the anchor.

From these and other hydrostatic principles, the following table has been formed; wherein is shewn, by means of the ship's breadth within, how many feet the beam or shank ought to be long, giving it $\frac{1}{4}$ or $\frac{2}{5}$ of the ship's breadth within; by which proportion may be regulated the length of the other parts of the anchor. In this table is represented likewise the weight an anchor ought to be for a ship from eight feet broad to 45, increasing by one foot's breadth; supposing that all anchors are similar, or that their weights are as the cubes of the lengths of the shanks.

Breadth of the Vessel	Feet	Feet.	Pounds.

M. Bouguer directs to take the length of the shank in inches, and to divide the cube of it by 1160 for the weight. The reason is obvious; because the quotient of the cube of 201 inches, which is the length of an anchor weighing 7000lb. divided by the weight is 1160, and therefore by the rule of three, this will be a common divisor for the cube of any length, and a single operation will suffice. The same author, in his *Traite de Navire*, gives the following dimensions of the several parts of an anchor. The two arms generally form the arch of a circle, whose centre is three eighths of the shank from the vertex, or point where it is fixed, to the shank; and each arm is equal to the same length or the radius; so that the two arms together make an arch of 120 degrees: the flukes are half the length of the arms, and their breadths two-fifths of the said length. With respect to the thickness, the circumference at the throat, or vertex of the shank, is generally made about the fifth part of its length, and the small end two thirds of the throat, the small end of the arms of the flukes, three fourths of the circumference of the shank at the throat. These dimensions should be bigger, when the iron is of a bad quality, especially if cast iron is used instead of forged iron.

See Murray's Treatise on Ship-building, &c. Elements and Practice of Rigging and Seamanhip, 4to. 1794, p. 77—82.

The distinctions of anchors are taken from their use, and the proportions they bear in the ship, where they are employed; for that which in one ship would be called but a *kedger*, or *kedje-ANCHOR*, in a lesser would be a *sheet-ANCHOR*.

ANCHOR, kedje, is the smallest, which, by reason of its lightness, is first to stop the ship in *kedging* a river.

This is what the Dutch sailors call *werp-ANCHOR*, the French *ancre a touer*. It ought to weigh 450 pounds.

The *grapnel* is an anchor for a small ship or boat. See *KEDGE* and *GRAPNEL*.

ANCHOR, stream, is a small anchor fastened to a stream-cable, wherewith to ride in rivers, and gentle streams, and to stop a tide withal in fair weather.

ANCHOR, sheet, or *sheet*, is the biggest and strongest, being that which the seamen call their last hope; never to be used but in great extremity.

This is what the Romans call *anchora sacra*; the Dutch *plegt-anker*, and *stop-anker*; the French *maitresse-ancre*, or *grand ancre*.

The other anchors are called by the name of the first, second, and third anchor; by any of which the ship may ride in any seasonable weather, sea-gate, or tide.—These are something bigger one than another, and usually when they fail in any freights, or are near a port, they carry two of these at their bow; in which respect they are also called by the name of first and second bows.

ANCHOR, second, called by the Dutch *borg-anker*, or *daagelyks-anker*, is that ordinarily made use of.

ANCHOR, cross, called by the Dutch *tuy-anker*, or *vertuy-anker*, and by the French *ancre d'affouche*, is a middling anchor thrown across or opposite to another.—This ought to weigh 1500 pounds, or nearly as much as the second anchor.

ANCHOR, floating, is a simple machine, which is made to dive beneath the swell of the sea, and retain the vessel where there may be no other anchorage. It consists of two flat bars of iron, each in length half the breadth of the

midship beam of the vessel for which it is used, and rivetted together in the middle by an iron saucer-headed bolt, clenched at its point, that they may be swung parallel to each other for easy stowage. At each end of the bars is a hole for a rope, or swifter to pass through, which must be hove tight to extend the bars at right angles. To this swifter is marled a double or four-fold canvas cloth, so as to be on that side of the iron bars nearest the vessel when used. In each bar are two holes, at equal distances from the centre, and to these holes the ends of two pieces of rope are fastened; the ropes are seized together in the middle so as to form a crow-foot, having an eye in the centre, which is well sewed with spun-yarn, and to this is bent, when the anchor is used, a cable or hawser, by which it is made to sink and incline in the water. See *Plate XI. Ships*. In the end of one of the bars is fitted an iron ring to which a buoy is made fast, by a rope about 12 fathoms long, to prevent the anchor from sinking to the bottom. When it is thrown over-board, the cable and a rope made fast to the head of a buoy, are carried away sufficiently to ride the vessel. To get it on board, haul upon the buoy-top, which will bring it to the water's surface so as to be easily drawn to the vessel. Have the mizen stay-fail ready to hoist, so as to keep the vessel to the wind, till the anchor is hauled on board.

A *floating* or *swimming anchor* will serve to prevent a ship, in a storm, from driving to leeward in deep water. Dr. Franklin suggests that an anchor, effectual for this purpose, ought to have the following properties. It should have a surface so large as being at the end of a hauler in the water, and placed perpendicularly, should hold so much of it, as to bring the ship's head to the wind, in which situation the wind has least power to drive her. It should be able by its resistance to prevent the ship's receiving way. It should be capable of being situated below the heave of the sea, but not below the undertow. It should not take up too much room in the ship. It should be easily thrown out, and put into its proper situation. And lastly, it should be easy to take in again, and stow away. Many contrivances have been suggested

suggested for this purpose. One for a large ship might have a stem of wood 25 feet long and four inches square, with four boards, 18, 16, 14, and 12 feet in length, and one foot wide, with a hole in the middle of each, about four inches square, so that it might be occasionally slipped upon the stem at right angles with it; and when these boards are fixed at the distance of four feet from each other, the anchor would have the appearance of the old mathematical instrument called the forestaff. This thrown into the sea, and held by a hawser veered out to some length, would bring a vessel up and prevent her driving, and when taken in it might be stowed away by separating the boards from the stem. Such a swimming anchor would have some good effect, but as it lies on the surface of the sea, it is liable to be hoze forward by every wave, and then only give so much leave for the ship to drive. Dr. Franklin has proposed two machines for this purpose, which he conceives, would be more effectual and more manageable. The first of these is to be formed, and used in the water on almost the same principles, with those of a paper kite in the air; only that as the paper kite rises in the air, this is to descend in the water; and its dimensions must be different for ships of different sizes. The other machine is to be made more in the form of an umbrella. See a particular description of both these machines, with figures, in the Transactions of the American Philosophical Society, vol. ii. p. 311—314.

ANCHOR, to back an, in *Sea-language*, is to let go a small anchor a-head of a large one, to which it is fastened, that it may partake of the strain, and serve as a check upon it, should it come home. The backing anchor is carried out in a long boat, to the buoy of that which is already down, whose buoy-rope is cast off and bent to the cable or hawser of the backing anchor; when that is done, the boat is rowed further a-head, till the buoy-rope and cable of the backing anchor become tight, when it is let go, the buoy that was taken from the large one being previously bent to it. In this situation, should the large anchor come home, the scope of cable from it to the anchor a-head, participating of the strain communicated to the innermost one, checks its progress, and ensures to the vessel a greater security. Where there is more room to drive without danger, and it blows so hard, that the sea runs too high for boats to work, an anchor is backed by clenching round that part of the cable next the hawse-hole, the end of a cable bent to another anchor on board; this being done, the second anchor is let go under foot; the ship is then suffered to drive, and the cable thus becomes tight from the ring of the anchor laid down to its own anchor, which also, by the driving, is now become a cable's length a-head of the former anchor.

ANCHOR, riding at, the state of a vessel moored and fixed by her anchors at some proper station.

Where a great number of vessels are moored in the same port, care is to be taken by the pilots, or those who have the command, that each ship be at a due distance from the rest, to prevent their running foul of each other; also that they be neither too near, nor too far from land. The proper space betwixt vessels is, from two to three cables' length. See *MOORING*.

ANCHOR, dropping, or let fall the, otherwise called casting anchor, imports the letting it down into the sea.

In some cases it is necessary to drop two anchors opposite to each other, one of them to keep the ship firm against the tide, or flow, the other against the ebb.

On approaching an anchorage, the anchor and buoy are got clear, and a range of cable, stretched along the deck, suitable to the depth of water. Care should be taken that nothing is in the way to check the cable, or stop its running

out; then, at a proper distance, a turn is taken round the bits with the cable, thus: first pass the cable from the anchor underneath the cross-piece, then take up a bight of the cable abaft the bits, and throw it over the bit-head. The end of the cable is clenched round the orlop beams in the royal navy, and round the main-mast in the merchant service. It is necessary to have water near the bits to prevent its firing by the friction. *STOPPERS* and *RING-ROPEs* of all kinds should be ready for use. The flock-lashing being cast off, and nothing but the anchor-stopper and shank-pointer retaining the anchor, men are stationed to stand by them, and let go at the moment when the order is given.

A ship should generally be brought to anchor under an easy fail, such as the three top-fails, jib, or fore topmast stay-sail, and sometimes the mizen, according as the vessel has more or less inclination to fall off or come to the wind. An anchor should never be dropped to leeward of the place you mean to bring up in; because that would often render it necessary to cast two anchors at once, for fear of dropping still more to leeward. When the wind is so violent as to bring the anchor home, and make the vessel drive, the cable is veered away; and in veering away, the turns of the stopper lariards are slackened, and a portion of the cable suffered to go out of the hawse, to let the vessel further astern of her anchor; in which situation she bears less strain on the flukes, and is less liable to drag the anchor; for, the more cable is out, the flukes become deeper buried, and the ship rides in greater safety. In letting go an anchor, care should be taken that the water be not so shoal as to endanger the ship hurting herself upon it, and that the anchor be not fouled by the cables getting about the fluke or stock. Nor should the water be too deep, because the cable, when out, should approach as nearly as possible to an horizontal direction. This principle is so true, that three cables spliced together on end of each other, are kept bent to the best bower anchor, to be used in cases of necessity; and it is found, that one good anchor, with a long range of cable, is a safer anchorage than two anchors with short cables. However, when the ship has not room to drive, and in a dark night, let fall a second anchor under foot, with a range of cable above the deck. At all events, the deep-sea lead should be thrown over the gun-wale, and the line frequently handled, to be certain that the ship does not drive. In hard and rocky bottoms, where anchors cannot have much hold, cables are chafed and cut to pieces. When necessity requires anchoring in such places, a chain should be run up the cable from the ring of the anchor to a certain distance, in order to secure it from danger. When a chain is not to be had, empty casks, well bunged, are good substitutes, slung and fastened to the cable at equal distances, to support and keep it from the bottom. When ground is soft and oozy, and anchors will not hold securely, but come home with little wind, it is common to cover the flukes with a broad triangular piece of plank, much larger than the fluke. Sometimes the anchor is backed, or retained, by carrying out the stream, or kedge, a-head of the anchor by which the ship usually rides. In this situation, the bower anchor is confined by the stream, or kedge, in the same manner as the ship is restrained by the bower anchor. In preparing to come to anchor, when the wind is not violent, the top-fails ought always to be clued up at the mast-heads; that is, let go the sheets, and haul the clue-lines and bunt-lines close up; lower away the top-fails, and take in the slack of the braces as the yards come down. In this manner you run less risk of splitting and tearing the sails than by any other method. For the various methods of anchoring in different circumstances, see *Elements of Rigging*, &c. vol. ii. p. 292—296.

ANCHOR.

ANCHOR, weighing, imports the act of withdrawing, or recovering the anchor into the vessel, in order for sailing. The anchor is ordinarily weighed, or recovered by means of a capstan or windlafs.

In large ships which have a main and jeer capstan, and the strain is thought too great for the messenger alone, the viol is used thus: three or four turns are taken round the jeer capstan with one end, so as to leave that side clear on which the cable is coming in; and pass the other end through the viol-block, which is lashed round the mainmast on the lower deck. It is then carried forward, and passed round the rollers in the manger near the hawk-holes; then brought aft, and spliced to the other end with a short splice; and the ends marled down tight. That side of the viol on which the cable is coming in is fastened to the cable by nippers; and thus the continued efforts of the capstan are conveyed to the cable, until it is hove in. The nippers are clapt on in the manger, from one to two fathoms asunder; and the viol is applied to the midship, or inside of the cable. Nippers are clapt on by taking three or four turns round the viol, four turns round the cable and viol, and then three or four turns round the cable. This method is very suitable to quick heaving; but when the strain is great, and the cable muddy, the nippers clapt on after this method will not nip sufficiently; in which case recourse is had to the following method: throw sand or ashes upon the cable, and take a long dry nipper, which middle, and pass one half aft, racking it in and out round the cable and viol; then worm its end round the viol only. After this pass the other half in the same manner forward, but worm its end round the cable only, and let each end of the nipper be held on. The advantages of this method are, that, as the strain of the cable lies forward, and that of the viol aft, the nipper will be drawn so tight as effectually to hold the cable till something give way. Besides, they can never jamb, for both ends are clear for taking off.

Ships without a jeer capstan heave in their cables by the messenger, which has an eye spliced in each end; one of which ends is passed with three or four turns round the capstan on the upper deck, and the other end is passed forward round the rollers, at the forepart of the manger; then brought aft to the other end, and lashed thus: several turns are passed through the eyes, crossing each other in the middle, then a half hitch is taken round the parts, and the ends stopped with spun-yarn. What remains of the operation is performed as by the viol, excepting that the messenger is applied to the outside of the cable, and when the nippers are insufficient, the messenger may be hitched by fastening its bight round the cable at the manger with a rolling hitch, and fishing the bight round the cable before the hitch.

When the starboard anchor has been gotten up, and the cable of the second anchor enters the larboard hawk-hole, the operation of getting up this anchor is the same, observing only, that the messenger must be shifted, and the turns on the capstan reversed; and the men, who before held on the larboard side in the first operation, will hold on the starboard side now; the motion of the capstan is performed the contrary way, and the cable on the larboard side is fixed and hove in.

Most merchant ships and small vessels heave up their anchors by a windlafs, round which are taken three turns of the cable, and held on by hand, or by a jigger, thus: the end of the rope which has the sheave is passed round the cable, with a round turn, close to the windlafs, the leading part of the rope coming over the sheave, and stretched aft,

by means of the fall passing through the jigger block; the standing part of the fall is made fall round a stantion, at the fore part of the quarter-deck, and the leading part is bowled upon, which jams the turns taken round the cable; when the jigger arrives a-breast of the hitchway, it constantly removes forward, and the cable is jammed by a hand-speck at the windlafs, until the jigger is refixed.

The anchor is weighed with the long boat, by taking the boat to the buoy of the anchor, and putting the buoy rope over the davit of the long boat, and a tackle on the buoy rope; by which, with the assistance of men on the fall, the anchor is weighed out of the ground. When this is done, the cable is hove in on-board; the buoy rope and tackle being secured in the boat, they approach the ship as the cable is hove in, and the anchor catted and stowed. Small anchors and grapnels are got up by the davit, hauling upon the cable or grapnel rope by hand.

An anchor is weighed by under-running, when the cable is placed over the davit-head, and it is under-run, till it is nearly a-peek, when it is tripped by means of tackles, as in the former case by the buoy rope. This method is troublesome, and is only adopted when the buoy is gone, and a ship cannot get near her anchor for want of water. See Elements of Rigging, &c. vol. ii. p. 306, &c.

ANCHOR, dragging, is when the anchor gives way, or loses its hold in the ground by the force of the wind, or sea, and the vessel drives from the place.

ANCHOR, to cat the, is to hook the cat-block to the ring of the anchor, and haul it up close to the cat-head. See Stowing of ANCHORS.

ANCHOR, clearing the, signifies the getting of the cable off the fluke.

Generally also, when they let fall the anchor, they use this term, to see that neither the buoy rope, nor any other ropes, hang about it.

ANCHOR, fetching, or bringing home the, denotes the weighing it in the boat, and bringing it aboard the ship.

The anchor is said to come home, when the ship drives away with the tide or sea.—This may happen, either because the anchor is too small for the burden of the ship, or because the ground is soft, and oozy; in such places shoeing is used.

When a ship is compelled to anchor on a lee-shore, or in a narrow road where there is deep water, with an apprehension that the ground is either too hard or too light for good holding ground, drop the common riding bower, first keeping 25 or 30 fathoms of cable on board, and throw over the lead. If by this means, or by the land, it appears that the anchor drags, let fall the best bower, and at the same time veer out the rest of the common bower cable, till the best bower gives her a check; after which bend a sufficient rope or hawser to the common bower, without the hawk-hole, and pass it through another hawk-hole to the windlafs, making it fast. Then cast off the common bower, and pass the cable end through the hawk-hole, and take a running clinch with it round the best bower cable, and let it go. As soon as you think the vessel has dragged her best bower cable far enough to straiten the common cable on the ground, veer out as much of the best bower as may be agreeable; when, however violent the weather, the vessel will never drag them home. A small vessel, which rides hard in a head sea, will be powerfully assisted by fastening an empty butt to the cable, about 10 fathoms from the vessel; for that will first receive the motion of the sea, and check it before it comes to the vessel, so as to cause its rising up to the swell, and effectually aiding it to resist the violence.

ANCHOR, *to ffb the*, is to draw up the flukes of it towards the top of the bow, in order to stow it, after having been catted.

ANCHOR, *gimbleting the*. See GIMBLETING.

ANCHOR, *shoring*, denotes putting boards on the flukes, in the form of flukes themselves, to make it broader than before, used when they are obliged to anchor in bad ground to prevent the ship from driving. This is what the French mariners call *breder l'ancre*, and the Dutch *l'anker bekleeden*.

In some cases they have been known to tallow the anchors, where the ground being soft, the ordinary would not hinder them from coming home. Manwaring saw an instance of tallowing the anchor in Porto Tareen by Tunis. The reason of the advantage is hard to assign; he supposes it to be that the tallow sinks deeper into the ooze, and finds some harder ground at the bottom than the other.

ANCHOR, *to trip the*, is to loosen it from the ground, either by design or accident. See A-TRIP.

ANCHOR, *to sweep an*, is to seek at the bottom for one lost, by means of a rope called a sweep. This rope has its two ends made fast to two boats, abreast of each other, at a small distance asunder. On the bight of the sweep is fixed a weight of shot, ballast, &c. to keep it at the bottom. The two boats row on toward the place where the anchor is supposed to be, and consequently draw along the sweep; which taking the bottom, hooks or entangles itself with the object of their search. The boats then row across each other twice, so as to take a round turn with the sweep, which being a hawser, both parts are brought into the hawse-hole, and to the capstan, or if small, to the long boat; and hove in upon as before.

Other terms and words of command relating to the anchors are, the "anchor is a-peek," that is, when heaving up the anchor, the cable is drawn so tight as to bring the ship directly over it; "the anchor is cock-bill," when the anchor hangs right down from the cat-head, by the ship's side, ready to be sunk at a moment's warning; this word is given by the masters, when they are ready to bring the ship to an anchor; "the anchor is foul," that is, when the cable, by the turning of the ship, is hitched, or got about the fluke: which will not only cut the cable asunder, but hinder the anchor from holding. On this account, when they come to an anchor where there is a tide, they lay out two anchors, by which means on the turning of the tide the ship winds up clear of either.

ANCHORS, *stowing of*. In fitting out ships, the anchors are brought in craft near the bows, being most convenient to the hawse-holes, through which the cables pass to be clenched. The bower anchors are first catted, which is performed by hooking the hook of the cat-block into the ring of the anchor, and bowling upon the fall that leads in through a snatch-block on the fore callie; the cat-falls being previously reeved through the sheaves of the cat-head and cat-block, keeping the hook of the cat-block downwards, and its point inwards. They are then fitted, by means of the fore-davit, pendant, and tackle, thus: the davit is first stopped in the channel on the side wanted, and supported by guys; the mast-head guy goes over the end of the davit, with an eye; the other end fastens round the fore-mast head, with a round turn and two half hitches. The fore-mast guy goes over the end of the davit, the other end fastens round the cat-head, with two half hitches, and securely flopt. The after guy goes over the end of the davit, and makes fast with two half-hitches through an eye bolt in the after part of the fore channel. At the outer end of the davit is hung, by its strap, a large single block, through

which is reeved the pendent, with a large iron hook spliced in the lower end, to hook the anchor within the flukes; then to the inner end of the pendent is made fast a tackle, by thrusting a toggle through an eye in the block-strap; after that has passed through an eye in the pendent, the other block of the tackle is hooked in an eye-bolt in the fore part of the quarter-deck; the effect of the tackle is communicated to the hook, by means of the pendent, by men's bowling on the tackle fall. Thus, the flukes of the anchor are raised and placed on the gun-wale, where it is made fast by the shank-painter chain. That the flukes may lie level, the stock is bowled upon by the anchor-stock tackle, the double block of which is hooked to a selvage, fastened round the stock of the anchor under the first hoop, and connected by its fall to a single block, hooked to a selvage fastened round the laniard of the main stay: the fall leads in upon the fore-castle. The best bower is then placed forward near the bows on the starboard side; the small bower near the bows on the larboard side, a little abaft their respective cat-heads; and are secured by their stoppers, from the cat-heads and shank-painters. The stopper has one end clinched round the cat-head; the other end passes through the ring of the anchor, returns upwards, and leads over a large thumb cleat bolted to the cat-head, and is made fast with several turns, and the end hitched round the head-rail and timber head, on the fore-side of the cat-head. The shank-painter hangs the shank and fluke of the anchor to the ship's side out-board; and when stowed, the shank-painter is passed under the inner fluke round the shank of the anchor, and made fast with two or three turns, and the end stopt round timber-heads on the fore-castle. With these two bower anchors ships are generally moored, when lying in a tide's way, or in a fleet.

The sheet and spare anchors are hoisted by runners and tackles, main-stay, and yard tackles, and are stowed securely with stock and bill lashings at the after part of the fore-shrouds, before the chefs-trees on each side of the ship, with one of the arms resting on a chock, bolted to the gun-wale; the stock being bowled-to by the anchor-stock tackle. The sheet-anchor is stowed on the larboard side, and is the first resource in a gale of wind, after parting with either of the bowers; for which reason, when in port, the sheet cable is kept bent, and the anchor is over the side, supported by the stopper and shank-painter, ready for cutting away in case of necessity. The spare anchor is stowed on the starboard side, and is seldom used, but when one of the others is lost.

The stream anchor is stowed on the spare anchor; and, when used, it is sent in the long boat, or launch, with its cable bent, and let go at any particular spot, either for steadying the ship, when riding by only one bower, or to assist a ship when in-shore, or to warp her, &c.

The kedgè is stowed on the stream and spare anchors, and is frequently used to stop a slip for a tide, in little winds; but, if the wind be too powerful for the kedgè, the stream anchor is substituted. The kedgè is sometimes used in moderate weather to warp the ship, so as to shift her birth. Elem. of Rigging, &c. p. 287, &c.

ANCHOR, in *Architecture* and *Sculpture*, denotes an ornament in form of an anchor, or arrow's head; frequently carved on the ovolo of the capital, in the Tuscan and Ionic orders, as well as in the bed-moulding of Ionic and Corinthian corniches.

The anchors are usually intermixed with representations of eggs; whence the *celinus* or ovolo itself is popularly called *eggs* and *anchors*.

ANCHOR, *anchors*, in *Literary Matters*, the figure of an anchor,

anchor, represented in ancient books; which is of two kinds, *superior* and *inferior*. The *superior*, &c. is where the crooked part is uppermost, used to denote a thing or passage strongly expressed. The *inferior* is where the crooked part is at the bottom, to denote a thing poorly or meanly set forth.

ANCHOR is also used, in a less proper sense, for any thing that holds another thing fast, to prevent its driving.

In this sense sea-muscles are said to *ride at anchor*, by a sort of threads the thickness of a large hair, which they emit out of their body, to the number sometimes of a hundred and fifty, which fastening to the stones and other adjacent bodies, keep them firm in their place. The same is done by the *PINNA marina*.

ANCHOR, in *Heraldry*, is the emblem of Hope; and is taken for such in a *spiritual*, as well as in a *temporal* sense.

ANCHOR, a measure. See ANKER.

ANCHOR Island, in *Geography*, an island in Dusky Bay, in New Zealand, visited by Captain Cook in 1773, and by Captain Vancouver in 1791. The harbour was particularly surveyed by the latter navigator, who observes, that it appeared to be perfectly secure, and may be found convenient, when accidents prevent vessels from getting into Facile harbour. It has two entrances; that to the north of the Petrel Islands is a fair, clear, and very deep channel; its general soundings were from 33 to 38 fathoms; in the narrowest part it is about a cable's length wide, and free from danger; as the shores are steep, without any sunken rocks or shoals, excepting within the passage close under the south side of large Petrel Island, where they are discoverable by the weeds growing upon them, and are quite out of the way of its navigation. The other passage is to the southward of the Petrel Islands; and if a strong northerly wind compels any person to make choice of this in preference to Facile harbour, the south-west point of large Petrel Island should be kept close on board, in order to weather the rock that appears above water in the middle of the harbour, and to avoid a sunken one, which does not appear, and over which there is no greater depth than 12 feet at low water. Anchor Island harbour, though a very secure port, is not very convenient to get to sea from, on account of its narrow limits, great depth of water, and the above mentioned sunken rock in its western entrance. The mountains of Anchor Island, and others round the bay, which, on Vancouver's arrival in November, were perfectly free from snow, were, after a storm which they experienced, covered with it. In a few days the greater part of it disappeared; and it is probable that such falls of snow are not frequent, as they do not check the luxuriance of vegetation. S. lat. 45° 45' 36". E. long. 166° 16'. E. variation, 15°. Vancouver's Voyage, vol. i. p. 68.

ANCHORA, in *Entomology*, a species of CIMEK, discovered by Professor Thunberg in Japan. It is of a roundish form with six black spots on the thorax and wing-cases, and a white anchor-shaped mark on the scutellum. Gmelin.

ANCHORA, in *Ancient Geography*, a small island of Peloponnesus, which the ancients called Asine, and sometimes Fanaromini. It was situated near the gulf of Modon, or of Coron. It is mentioned both by Strabo and Ptolemy.

ANCHORAGE, in *Sea Language*, ground fit to hold a ship's anchor, so that she may ride safely. The best ground for a ship to anchor in is stiff clay, or hard sand; and the best riding at anchor is when a ship is land-locked, and out of the tide.

ANCHORAGE, in *Law*, denotes a duty taken of ships for the use of the haven where they cast anchor. The ground in all ports and havens being the king's, no man can let an anchor fall in any port without paying for it to the king's officers.

ANCHORAGO, in *Entomology*, a species of the Fabrician genus BRENTUS, found in India. It is linear, wing-cases striated with yellow, and thorax elongated. Fabricius. This insect is described by Linnæus as a species of CURCULIO, under the same specific name as Fabricius has adopted: his description is, beak long, thighs dentated, wing-cases striated with yellow, and thorax elongated. Gmelin has removed this species from the CURCULIO to the BRENTUS genus in the last edition of the *Systēma Naturæ*.

ANCHORAGO is likewise a species of CIMEK that inhabits North America; the general colour is blue, apex and base of the scutellum yellowish, margin of the abdomen yellow with black spots. Fabricius and Gmelin.

ANCHORED, ANKERED, in *Heraldry*. See ANCRÉE.

ANCHOVY, in *Ichthyology*, a little sea-fish much used by way of sauce or seasoning; it is the *Clupea maxilla superior longiore* of Artedi, and *CLUPEA ENCRASICOLUS* of Linnæus. See ENCRASICOLUS.

The word anchovy is derived from the Spanish *anchova*, or rather from the Italian *anchioe*, which signifies the same.

The anchovy is caught in the months of May, June, and July, on the coasts of Catalonia, Provence, &c. at which season it constantly repairs up the straits of Gibraltar into the Mediterranean, where they are taken in large quantities. The great fishery is at Gorgona, a small isle west of Leghorn. Collins says, they are also found in plenty on the western coasts of England and Wales. Near a century ago the anchovy was found at the mouth of the river Dec, by Mr. Ray; but since that time it has been found very rarely and only by Mr. Pennant, in 1769, on our coasts.

The fishing for them is chiefly in the night-time; when a light being put on the stern of their little fishing-vessels, the anchovies flock round, and are caught in the nets. But then it is asserted to have been found by experience, that anchovies taken thus by fire, are neither so good, so firm, nor so proper for keeping, as those which are taken without fire.

When the fishery is over, they cut off the heads, take out their gall and guts, and then lay them in barrels, and salt them. The common way of eating anchovies is with oil, vinegar, &c. in order to which they are first boned, and the tails, fins, &c. slipped off. Being put on the fire, they dissolve almost in any liquor; or they are made into sauce by mincing them with pepper, &c.

Some also pickle anchovies in small delf, or earthen pots, made on purpose, of two or three pounds weight, more or less, which they cover with plaster, to keep them the better. Anchovies should be chosen small, fresh pickled, white on the outside, and red within. They must have a round back; for those which are flat or large are often nothing but sardines. Besides these qualities, the pickle, on opening the pots or barrels, must be of a good taste, and not have lost its flavour.

ANCHOVY pear, in *Botany*. See GRIAS.

ANCHUSA, Ἀγχουσα, παρὰ τὸ ἀγγεῖον, from its supposed *consoling* quality, or, as others say, because it *strangles serpents*, in *Botany*, buglossum of Tournefort and Gærtner, a genus of the *pentandria monogynia* class and order; of the natural order of *asperifolia*, and *borraginæ* of Jussieu: its characters are, that the *calyx* is a perianthium five-parted, oblong, round, acute, and permanent; the *corolla* is monopetalous and funnel shaped, tube cylindrical, of the length of the calyx, limb semiquinquesid, from erect expanding and obtuse; throat closed with five small scales; convex, prominent, oblong, and converging; the stamina have very short filaments, in the throat of the corolla, anthers oblong, incumbent,

incumbent, and covered; the *pisillum* has four germs, style filiform, of the length of the stamina, stigma obtuse and emarginate; no *pericarpium*, but the calyx, enlarged and erect, contains the seeds in its bosom; the *seeds* are four, oblongish, obtuse, and gibbous. Martyn enumerates ten, and Gmelin sixteen species. 1. *A. officinalis*, buglosa, buglossa italica, b. longifolia, b. vulgaris, *echium italicum spinosum*, officinal, or common alkanet or bugloss, with leaves lanceolate, second spikes imbricate, and ovate bractes. This species is a perennial, and flowers in June and July. The stem is about two feet in height, erect angular, foliose, somewhat branched and panicled, the root is fusiform, and externally black; the herb is hairy and rough; the leaves are lanceolate, acute, and slightly decurrent; the upper ones, subovate at the base; the racemes are mostly double, and revolute; the bractes ovate, and not as in the *A. angustifolia*, linear-lanceolate; the flowers purple and funnel-shaped. It grows wild in Italy, Spain, France, Germany, Sweden, Denmark and Siberia, by road sides and in corn fields. It is found also with us amidst rubbish or in marshes; as on the links near Hartley Pans, in Northumberland. Miller cultivated it in 1748. When it is tender in the Spring, it is boiled and eaten in Upland. The tube of the corolla is melliferous, and the bees are very fond of it. This is not the anchusa, but the bugloss of officinal writers; but it does not appear that our bugloss possesses the same properties with that of the ancients; for it has no claim to the title of *euphrosynum* given to theirs (see Pliny. Hist. Med. lib. 25. c. 8.), as it has no exhilarating quality, although its flowers have been long referred to the class of the four cordials. This plant, says Dr. Lewis (Mat. Med. p. 167.) appears to be nearly similar to borage, in its medicinal qualities as well as in its external form. The principal difference seems to consist in the leaves being somewhat less juicy, and the roots more mucilaginous. The roots, leaves, and flowers are ranked among the articles of the *materia medica*, but they are very seldom used. In China this plant is said to be much esteemed for gently promoting the eruption in the small pox. 2. *A. angustifolia*, borago of Zan. hist. buglossum angustifolium of Allion. and Mor. buglossum foliis linguiformibus asperis, &c. of Haller, *echii facies buglossum* of Lob.; narrow-leaved alkanet, with racemes almost naked in pairs. Haller thinks that this is not a distinct species from the first. In gardens it grows to the height of two feet, but in its wild state does not attain more than a foot. The leaves are narrow, and not so hairy as the first; the spikes of flowers are double, and have no leaves; the flowers are small, and of a red colour; the roots will continue three or four years in poor land. It is found wild in Italy, Germany, and Switzerland: flowers in July and August by way sides, and in the borders of ploughed lands; cultivated here by Miller in 1759. Boerhaave recommended the juice in the pleurisy and maniacal cases. 3. *A. italica*, buglossum of Haller, Ray, and Bauhin, Italian alkanet, with leaves lucid and strigose, racemes two-parted, two-leaved, flowers somewhat unequal, bearded at the throat. This differs from the first species in size, in that the flowers are equal and funnel-shaped; whereas in this they are salver-shaped; they are much more imbricate in that, the segments of the calyx being broader and shorter; those of the corolla ovate; with the scales of the throat only slightly tomentose. 4. *A. undulata*, waved *A. strigose*, leaves linear toothed, pedicels less than the bractes, fruit-bearing calyxes inflated. This plant is three feet high, with many strong lateral branches, produced from the main stem near the ground; the leaves are stiff, rough, six or seven inches long, and about half an inch round at the top, closely embracing the branches at the base, and two

inches broad, indented and waved on their edges, the upper surface beset with hairs, and rough to the touch: spikes of flowers axillary, a foot or more in length, reflex: corollas fine blue; the root decays after the seeds are perfected, though sometimes, in gravel, or the joints of stone walls, it will live three or four years; but such plants are seldom more than a foot high, and have small narrow leaves, so that they appear like a different species. It is a native of Spain and Portugal, and Gmelin found it in Siberia; cultivated in 1739 by Mr. Miller. 5. *A. tinctoria*, buglossum tinctorium of Allion. Dyer's *A.* downy, leaves lanceolate, obtuse, and stamens shorter than the corollas. This species is perennial, and resembles the first in its leaves and branches, only that they are more woolly; the root is red. It much resembles the seventh species, and is entirely covered with a white down. It grows about Montpellier in France, in Silesia, Spain, and Italy; and was cultivated here in 1683 by Mr. James Sutherland. The roots of this plant, when in perfection, are externally of a deep purplish red colour. The red cortical part, separated from the whitish woody pith, imparts a fine deep red to oils, wax, and all unctuous substances and also to rectified spirit of wine; but to water it gives only a dull brownish hue. The spirituous tincture, when inspissated to the consistence of an extract, changes its fine red to a dark brown. The root has little or no smell, and scarcely any taste; extracts made from it, by water and by spirit, are bitterish and roughish, but in too low a degree to be regarded as medicines, though they were formerly in repute as aperient, for dissolving coagulated blood, restraining diarrhæas, and drying inveterate ulcers. Its chief use at present is for colouring oils, plasters, lip-salves, &c. which receive a fine deep red from one-fortieth their weight of the root. For this purpose the consistent unctuous materials are to be liquefied in the heat of a water-bath, the powdered anchusa added, the mixture stirred now and then till sufficiently coloured, and then strained through a linen cloth. The roots of bugloss boiled in a decoction of Brasil wood are sometimes substituted for those of alkanet; but these will not dye oils red. Lewis and Murray. 6. *A. virginica*, lithospermum virginianum of Morison and Ray, virginian *A.* with flowers scattered, and stem smooth. This is perennial, and a native of North America, where it grows in the woods, covering the earth with bright yellow flowers, and known by the name of *puccoon*. 7. *C. lanata*, woolly *A.* with villose leaves, shaggy calyxes, and stamens longer than the corollas. This species was found by Brander near Algiers, and is very like the fifth. 8. *A. sempervirens*, buglossum latifolium sempervirens of Dillon in Ray's Synop. borago sempervirens of Gerard, evergreen *A.* with ovate leaves, and axillary two-leaved and capitated peduncles. The root is thick, and externally black; the herb stem evergreen and hispid; the stems angulate round, and foliose; the leaves alternate and ovate; the peduncles axillary, solitary, capitated, and two-leaved at the apex; the limb of the corolla blue, rather salver-shaped than funnel-shaped, segments rounded, tube at the base four-cornered; the germs imbedded in a hollow glandular receptacle; seeds one or two, generally abortive, rough, and very hard. In habit and character this plant approaches to myofotis. It is found wild in Spain and Italy. With us it has been found by road-sides, among rubbish, and in the joints of old walls, in several places about Norwich, at Haddiscoe in Suffolk, near Birmingham, Worcester, and Sidmouth, near Rochester and London, and in the ruins of Maes Glas monastery in Flintshire. It is perennial, and flowers in May and June. Withering's Bot. Arr. vol. ii. p. 227. Smith's Flor. Brit. vol. i. p. 215. 9. *A. barrelieri*, buglossum barrelium of Allion. buglossum

buglossum sylvestre minus, &c. of Barr. with leaves ovate, lanceolate, erect stem, racemed peduncles, pointing one way. This species was found in Piedmont by Bellardi. 10. *A. paniculata*, paniced A. or bugloss, with leaves lanceolate, strigose, quite entire, panicle dichotomous and divaricate, flowers peduncled, calyxes five-parted, with tubulate segments. It is biennial; flowers in May and June; a native of Madeira, where it was found by Mr. F. Masson, and introduced into Kew Garden in 1777. 11. *A. tuberculata* of Forskahl, referred to this genus by Gmelin, with tuberculated nuts. This, says Mr. Dryander (Linn. Transf. vol. ii. p. 222.) is *LITHOSPERMUM orientale* of Gmelin. 12. *A. echinocarpus* of Forst. with muricated nuts, and single anther covered at the top. 13. *A. flava*, of Forst. with rugose nuts, procumbent stems, and axillary, decurrent peduncles. This, says Mr. Dryander (*ubi supra*), is the *ASPERUGO Ægyptiaca* of Gmelin's Linnæus. 14. *A. hispida* of Forst. with smooth nuts, short axillary peduncles, stem hispid, and the lower leaves petiolate. 15. *A. saxatilis*, with leaves oblong, linear, on both sides hairy, the floral leaves lanceolate, with flowers scattered, axillary and subsessile. 16. *A. amara*, with undulated leaves and triquetrous nuts.

Culture. All the ten preceding species of anchusa, enumerated by Martyn, may be easily propagated by seeds, sown in the Autumn, upon a bed of light sandy earth; and in the Spring, when the plants are strong enough to be removed, they should be planted in beds, at the distance of two feet, and, in a dry season, watered till they have taken root; and afterwards they will only need to be kept clear from weeds. If the seeds of the common sorts be allowed to scatter, the plants will rise in plenty. Gmelin's Linnæus. Martyn's Miller.

ANCHUSA. See **BARLERIA**, **BORAGO**, **LITHOSPERMUM**, **MYOSOTIS**, **ONOSMA**, and **PULMONARIA**.

ANCHYLE, or **ANCYLE**, in *Surgery*. See **ANCHYLOSIS**.

ANCHYLOBLEPHARON. See **ANCYLOBLEPHARON**.

ANCHYLOPS. See **ANCHILOPS**.

ANCHYLOSIS, in *Surgery*, (from *αγκυλωσ*, *curvo*) *Anchyle*, *Ancyle*, *Ankylose*, *Acinesia*, immobility of the joints. This term is used when any joint of the body becomes, whether from external or internal causes, stiff and inflexible. It is divided into the *true* and the *spurious* anchylosis. By the true anchylosis is understood that disease, in which the bones of the joints form such a synostosis with each other, that they appear to consist of a single piece. In the spurious anchylosis, the motion between two bones at the joint is in some degree, though not entirely, lost.

The mobility of a joint may be more or less interrupted by various causes, amongst which are different diseases of the bones, particularly a tumefaction of their extremities, caries, fracture, near to or within the joint, dislocation, twisting, and crushing of the bone; as well as several kinds of tumors, such as fleshy excrescences, aneurisms, hydropical accumulations, &c. The muscles may also give rise to the stiffness of a joint, when the flexors contract so strongly that the extensor muscles lose their force, in which case a **CONTRACTION**, as it is termed, is produced. This generally arises from internal causes; sometimes, however, from external, or diseases that have attacked the joints, in which cases the ligaments and other surrounding parts of the joints are likewise affected. To the internal causes belong the swelling of the bones, the rickets, a metastatical deposition of corrupted fluids in the joint, a deficiency of the synovia or mucus which lubricates the joints, a continued pain, under which the patient finds relief from a certain position of the limb, in which he conse-

quently keeps it for a long time, the colica saturnina, gout, chronic rheumatism, and paralysis. Some indeed have assigned, as causes of impeded motion in joints, the inspissation and accumulation of the mucus which lubricates their cavities; but even though we should admit that this synovial mucus might become preternaturally thick by the limb being left too long without motion, it cannot, however, be proved that its inspissation may increase to such a degree, as entirely to prevent the motion of the joint, as even the thickest mucus is still able to lubricate smooth surfaces, and facilitate their motion upon each other. On the contrary, a too long continued and violent exertion and motion of the body, as well as long continued repose, may deprive the fibres of their natural flexibility, as in both cases more earthy particles are deposited, and the fibres themselves rendered more dense, in consequence of which the ligaments also resist the extension and flexion of the joint.

The true anchylosis may easily be known by the impossibility of moving the bones in their joints, by the insurmountable difficulty which opposes their flexion or extension; but we may also with equal ease discover the false anchylosis by both seeing and feeling that the part still retains some power of motion at the joint. The prognosis depends upon the knowledge of the true cause of the disease, according to which the cure is either perfect or imperfect. By the imperfect cure we can only alleviate the inconveniences of the true anchyl. namely, the incurable synostosis of the bones; so that the perfect cure can only be successfully accomplished in the spurious anchylosis.

In general the method of cure is to be determined according to the different causes which have given rise to the incurvation and impeded motion of the joint. When the proximate cause consists in a contraction, we must endeavour to discover and remove the cause by which the contraction has been produced, and afterwards assist the cure by means of external applications; for frequently, even though the internal causes may have been removed, the contraction of the muscles still remains. The contraction may be discovered by the tendons of the muscles, which keep the limb bent or extended, being very much stretched. Moreover, all that has been said concerning the internal causes and diseases, with a view to the cure of the immobility of the joints, applies also to the external causes and diseases; such as white swellings, suppuration of the joint, preternatural excrescences in the joints, caries, dryness of the joints, burns, cicatrization, &c.

When now the internal or external causes have been removed, the surgeon must apply the proper remedies for restoring the motion of the joint itself. These remedies consist in endeavouring to soften the muscles, tendons, adipose membrane and ligaments, afterwards slowly and gradually to extend them, and progressive efforts to move them to restore them by degrees to their former condition; for which, however, a long space of time is generally required.

In an anchylosis arising from a fracture of the bones of the joint, besides prescribing a light diet, we should rub the diseased parts about the joint with flannel, in order to attenuate the fluids, and increase the effect of the remedies peculiarly adapted for the cure of the disease. For, in order to restore the mobility, it is particularly necessary that the muscles, ligaments, skin, and cellular texture should be softened and relaxed by emollient remedies, which ought to be employed very liberally, and persisted in for a great length of time. Contracted muscles should be rubbed, throughout their whole extent, with emollient applications, for the space of half an hour or more at a time, and three times every day.

The limb itself should constantly be kept moistened with the same applications, by wrapping it, every time after it has been rubbed, in flannel dipped in the emollient fluid.

Whilst we are applying the frictions, we should endeavour to extend the limb as much as the patient can bear, slowly, but with perseverance.

When the contraction is situated in the knee-joint, we may make use of a machine, with the view of preventing the shortening of the muscles. The extension should by no means be performed too quickly, as pain and inflammation might easily be the consequence. Mr. B. Bell, in his System of Surgery, has recommended a useful machine for this purpose; Mr. Koehler (*Anleitungzum Verband, &c. Leipzig, 1796, S. p. 168.*) recommends a bench; and Mr. Trampel (*Arnemaun's Magazin fuer die Wundarzneiwissenschaft, B. i. St. 1. p. 23, fig. 1.*) a machine similar to that of Mr. Koehler.

Amongst the emollient remedies adapted for the cure of this disease are particularly to be enumerated all sorts of animal oils, such as the fat of ducks, geese, and hogs; the steam of warm water, warm baths; fresh expressed oils, the Ungt. althæ. Some recommend also an ointment made of the dripping of hares, turpentine, and oleum ovi; also baths and embrocations mixed with brandy; and finally, the vapour bath. When the substance of the fibres has become too dense, repeated embrocations, with a warm solution of sal ammoniac in water, are particularly useful. When these remedies are not found adequate to the removal of the stiffness, we may employ more powerful ones, such as embrocations with the brine of herrings with vinegar, vitriol, and alum; also with a solution of the balsam. vitæ extern. the empl. de galbano & de ammoniaco; especially the gumm. ammoniac. boiled in wine vinegar to the consistence of a plaster, spread thick upon leather, and applied to the diseased part.

Previously to every use of the vapour-bath, we may rub the part with a solution of Venice soap, or also with ol. majoranæ, ol. tartari. fetid. or some other similar oil. In proportion to the effects which it produces on the patient, the vapour bath may be applied for the space of half an hour or an hour, twice or thrice a day, or only every other day. The fluid employed for forming the vapour bath may contain, dissolved in it, sal ammoniac, balsamum vitæ externum, &c. In the intervals, the embrocations are to be applied. Fumigations, with volatile substances, have also been employed with great advantage.

Where the stiffness of the joint owes its origin to a dislocation that has been reduced, and where the soft parts have been bruised, repeated blood-letting, with emollient and discutient poultices should be used, till the tumor and swelling have disappeared, after which the parts may gradually be moved. But when the dislocation has not been reduced we must attend to the tumor, hardness, and inflammation, which are to be treated with general remedies. Where these obstacles do not stand in our way, we may let blood, and attempt the reduction, provided the disorder is not of too long standing.

When symptoms of a deficiency of the synovia are observed, or the blood is inadequate to its secretion in the glands of the joints; we must not only put our patient upon a proper regimen, but also employ general remedies adapted to the complaint; such as gentle evacuants, moderate frictions to the diseased part, baths with decoctions of emollient herbs, or also emollient poultices, to which we may add a quantity of black soap. When, on the contrary, there is too great an abundance of synovia, particularly when the diseased parts are affected with pain and swelling, we must let blood,

and before using discutient poultices or baths, rub the diseased parts with warm flannel, and, at the same time, gently move the joint. But should this not be sufficient, we may mix stimulating herbs with the poultices, and add to the baths a quantity of lime-water, kitchen-salt, or sal ammoniac.

Distortion of the limbs is sometimes a congenital disease, which most frequently occurs in the foot. See VARI & VALET.

ANCI, in Greek *γανυσελας*, *wæsel-elbowed*, from *γανυς*, a *wæsel*, and *αλκων*, an *elbow*, a name given by Hippocrates to those who, from slipping the head of the *os humeri* into the *ala*, have an arm shorter and smaller than it ought to be, and the cubit or elbow of a *wæsel*; whence they are called by some *muffehani*, which fully expresses the Greek word, or barely *anci*. The disorder that gives occasion for the name, happens either in the womb, where the *os humeri* suffers a luxation, from too much moisture; or in tender years by means of an abscess deeply seated about the head of the *os humeri*. See DISLOCATION and LUXATION.

ANCIÃO in *Geography*, a small town of Portugal, in Beira, containing one parish, and about 1200 inhabitants.

ANCIASMUS, in *Ancient Geography*, a town of Greece in Epirus, which was an episcopal see. It is thought to be the same with the *Onchesmus* of Ptolemy.

ANCIENT, or ANTIENT, in its usual sense, denotes a thing which existed in times long ago; and thus it is opposed to *modern*.

We say ancient nations, ancient architecture, sculpture, philosophy, &c. ancient manners, ceremonies, poets, physicians, and the like.

ANCIENTS, in *Church Discipline*. See ELDERS.

ANCIENTS, in *Inns of Court*, imports a distinction of a certain degree. Thus, the society of Gray's Inn consists of benchers, ancient, barristers, and students under the bar: here the ancient is the elder barrister.

In the inns of chancery there are only ancient, and students, or clerks; and among the ancient one is yearly the principal, or treasurer. In the Middle Temple ancient is such as have gone through, or are past their reading.

ANCIENT is sometimes also used, in a *military sense*, for the colours, or an ENSIGN.

ANCIENT, or ANSHENT, in the *Naval armament*, a small flag or streamer set upon the stern of a ship, or on a tent, similar to the guidon used at funerals, which was called an anshent.

ANCIENT *demesne or domain*, in *Law*, is a TENURE, whereby all manors belonging to the crown in William the Conqueror's and St. Edward's time were held.

The number of names of all manors, after a survey made of them, were entered in a book called "*Domesday Book*," yet remaining in the Exchequer; so that such lands as by that book appeared to have belonged to the crown at that time, and are contained under the title "*terra regis*," are called ancient demesne. The tenants in ancient demesne are of two sorts; one who hold their lands freely by charter; the other by copy of court-roll, or by the verge, at the will of the lord, according to the custom of the manor. The advantages of this tenure are, 1. That tenants holding by charter cannot be rightfully impleaded out of their manor; and when they are, they may abate the writ by pleading the tenure. 2. They are free from toll for all things relating to their livelihood and husbandry; nor can be impanelled on any inquest. These tenants held originally by ploughing the king's lands, plashing his hedges, and the like service, for the maintenance of his household; and it was on this account that such liberties were given them, for which they may

may have writs of *monstraverunt* to such as take the duties of toll, &c. No lands are to be accounted ancient demefne, but fuch as are held in focage. Whether land be ancient demefne or not, fhall be tried by the Book of DOMESDAY.

ANCIENT differences, in *Heraldry*. See BORDURES.

ANCIENTLY, in fome *Ancient Statutes*, is ufed for elderfhip or feniORITY. The elder fifter can demand no more than her other fifters, befide the chief mefne, by reafon of her ancienty. This word is ufed in the ftatute of Ireland, 14 Hen. III.

ANCIGNE, in *Geography*, a town of France, in the department of the two Seves, and chief place of a canton, in the diftrict of Malle; five leagues and a half fouth-fouth-eaft of Niort.

ANCILLA, in *Entomology*, a fpecies of PHALÆNA, of the Bombyx tribe. The wings are brown, with three tranfparent white fpoats on the anterior pair: abdomen yellow, with a black ftreak. Gmel. This is the fame infect as Fabricius describes under the fpecific name OBSCURA. *spec. inf.* and is likewise the NOCTUA ANCILLA of Wien. Schmettler. It inhabits Germany, according to Gmelin, and feeds on the lichen parictinus; Fabricius notes it in the cabinet of Dr. Allioni as a native of Italy. In fome fpecimens the pollerior wings are without fpoats, in others yellow, with a brown margin and curved mark.

This fpecies muft not be confounded with the PHALÆNA ANCILLA of Cramer, Pap. t. 149, which is an Indian infect, and the variety (γ) of the NOCTUA FULLONICA of Gmelin, and NOCTUA DIOSCOREÆ of Fabricius.

ANCILLON, DAVID, in *Biography*, a French Proteftant divine, was born at Metz in 1617. In early life he applied to his ftudies with fuch diligence, that it was neceffary, on fome occafions, to refrain, what his biographer calls, the excefs and intemperance of his ftudious difpofition. From the age of 10 years he purfued his courfe of learning at the college of the Jefuits at Metz; and at this time many attempts were made by the directors of the institution to gain him over to their religion and party; but all their efforts were ineffectual. Having determined to devote his life to the profefion of divinity, he removed in 1632 to Geneva; and, during a refidence of feven or eight years in that place, he acquired an extenfive and accurate knowledge of philofophy and theology. In 1641 he underwent an examination before the Synod of Charenton; and fo far approved himfelf by the fpecimens which he exhibited of his talents, learning, and modetty, that he was appointed to the church of Meaux, which was one of the moft confiderable benefices then vacant among the reformed. Here he exercifed his miniftry with very great fatisfaction both to himfelf and to thofe with whom he was connected for 12 years; and fuch was his reputation, that he was admired and efteemed by perfons of all perfuafions, both Catholic and Proteftant. His popularity as a preacher recommended him to the attention of a wealthy perfon, who had one daughter, to whom he was affectionately attached, and he was induced by the refpect which he entertained for him to declare to fome of his friends, that if Ancillon would come and demand her of him in marriage, he would be happy in admitting him to an alliance in his family. In procefs of time a negotiation commenced, and it terminated in 1649 in an union, which was the fource of much domeftic felicity. Four years after his marriage, Ancillon availed himfelf of a vacant benefice in his native city to remove thither. Here he uniformly maintained the fame character, and purfued his ftudies with unabating ardour. The fortune he had acquired by marriage enabled him to indulge his favourite propenfity, which was that of the purchafe of books, fo that his library became

both large and curious; and as it was one of the fineft private collections in France, it was vifited as an object of curiofity by travellers who paffed through Metz. Ancillon purchafed the beft editions of books, for which he gave thefe good reafons: that the lefs the eye is fatigued in reading a book, the more is the mind at liberty to judge of it; and that as the beauties and faults of a work are more clearly feen in print than in manuſcript, fo the fame beauties and faults are more clearly feen when it is printed on good paper and in a fair character, than when the paper and type are bad. Ancillon was no lefs indullrious in the ufe than curious in the choice of his books, and his reading was very various and extenfive; but he diftinguifhed between thofe books which he read for amufement or for general information, and fuch others as were ufeul to him in his profefion. The former he read but once, curiofity, according to the Latin proverb, "ſicut canis ad Nilum bibens et fugiens," like the dog that drinks at the ſtream as it runs; the latter he read over feveral times with attention and care, and omitted no means of impreſſing their contents correclly upon his memory. He marked his books with a pen as he read them, and placed in the margin references to other authors. Ancillon, though he was uncommonly indullrious in his purfuit of knowledge, did not allow his fondnefs for ftudy to occaſion a neglect of the duties of his profefion; but in order to reconcile the one with the other, he addicled himfelf in too great a degree to a reclufe and ſedentary life; and he could never be prevailed upon more than three or four times to viſit a country-houſe which he had near the city. He ſcarcely ever left his own habitation, unlefs to go to church, or to perform the functions of his office; but he never neglected the ſervices of religion, nor difregarded the calls of humanity. He diſcharged all the important and ufeul duties of a Chriſtian miniſter without ostentation, without ambition, and without avarice.

After having enjoyed the ſweets of literary retirement for upwards of 40 years, and occupying the ſtation of miniſter to the Proteſtant church at Metz, with great reputation and ufeulnefs, for 22 years, Ancillon's repoſe was diſturbed by the demon of perfecution. Upon the revocation of the edict of Nantes, in 1685, this excellent perſon was reduced to the neceſſity of abandoning his library, his church, his friends, and his country, and of ſeeking refuge, from the phrenzy of religious bigotry, among ſtrangers. He fled into Germany; and his library, a few books which he had concealed excepted, fell in ſmall parcels, and for very inadequate payments, into the hands of the monks and clergy of Metz, and the adjacent towns. Thus deprived of the fruits of an attention beſtowed on his collection of books for 44 years, and of the pleaſure and benefit which he derived from them, he might well exclaim:

"Impius hæc tam culta novalia miles habebit,
Barbaras hæc fegetes?" VIRG. Eclog. i. v. 71.

"Did we for theſe barbarians plant or ſow?
On theſe, on theſe our happy fields beſtow?"

In the city of Hanau, Ancillon found an aſylum; and here he had an opportunity of exerciſing his miniftry, at the requeſt of the French church, with great acceptance, till the jealouſy of the other two miniſters of the church, excited by his popularity, rendered his ſituation extremely uneaſy, and induced him to withdraw from Hanau, and to retire to Frankfort. With a view to the ſettlement of his family, he ſoon afterwards removed to Berlin, where he was favourably received by the elector of Brandenburg, and obtained the charge

charge of a French church. In this situation he remained, enjoying the comfort of seeing his children and other relations well established, and supporting the character, which he had maintained through life, of a learned scholar, an excellent minister, and in all respects a truly worthy man, till death finished his course in the year 1692. His literary works are few. In 1657 he published, at Sedan, in 4to. "A Relation of the Controversy concerning Traditions, held between the Author and M. Bedacier, a Doctor of the Sorbonne." At Hanau he printed in 1666, "An Apology for Luther, Zuinglius, Calvin, and Beza." He also wrote, "The Life of William Farel, or the Idea of a faithful Minister of Christ," of which only a surreptitious copy was printed in Holland. Some of his learned conversations were published by his son in a miscellany, mentioned in the next article. Gen. Dict.

ANCILLON, CHARLES, an advocate, the son of the subject of the last article, was born at Metz in 1659, and was a learned and zealous defender of the Protestant cause. After the revocation of the edict of Nantes, he was commissioned by the reformed at Metz to solicit at court an exemption in their favour; but he only succeeded in obtaining a mitigation of the treatment of his persecuted brethren. At Berlin, whither he removed, he was appointed inspector of the tribunal of justice, instituted for the French in Prussia, historiographer to the king, and superintendent of the French school. In this city he died in 1715, at the age of 56 years. He wrote, in French, "An History of the Establishment of the French Refugees in the States of Brandenburg," printed in 8vo. at Berlin, in 1690; "A critical Miscellany of Literature, collected from the Conversations of his father, Minister of Metz," 3 vols. 8vo. 1698; "The Life of Soliman II.," 4to. 1706; "A Treatise on Eunuchs," 4to. 1707; "Memoirs of many literary Characters," 12mo. 1709. Gen. Dict.

ANCINALE, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria Ultra; seven miles south-south-east of Squillace.

ANCISA, one of the chief places in the Val di Arno in Tuscany.

ANCISTRUM, from *αγκυρον*, a hook, in *Botany*, a genus of the *dianthia monogynia* class and order, and of the natural order of *rosaceae*, Juss. Its characters are, that the calyx is a perianthium one-leafed, (four-leafed, H. K.) turbinate, truncate, four-toothed, teeth cylindrical, awned, erect, terminating in four-revered hooks; corolla (none, H. K.) superior, one-petalled, funnel-shaped with a very short tube, and a spreading quadrifid border; the divisions nearly equal, obtuse, of the length of the tube; the *stamina* have filaments fastened to the base of the tube, longer than the corolla, capillary; anthers roundish; the *pyllium* has an oblong germ, filiform style of the length of the corolla; stigma pencil-shaped; *pericarpium* none, but the calyx, in the bottom of which is the fruit (a drupe, dry, hispid, one-celled, H. K.), the seed single and oblong. Martyn reckons three, and Gmelin two species. 1. *A. decumbens*, (*A. asperinæfolium* of Forst. Gen. *A. diandrum* of Forst. fl. Austr. *A. sanguiforbæ* of Linn. Suppl.) "with stems decumbent, peduncle scape-form solitary, flowers in a globular head, leaflets wedge-form, deeply serrate, hoary beneath, seed covered with the thickened calyx." It resembles burnet in the herb and manner of flowering, and is remarkable for the yellow awns to the calyx, like fox's nails; a native of New Zealand. 2. *A. lucidum*, shining A., "with stems subdemerged, peduncles scape-form, spikes ovate, and leaflets oblong, quite entire, acute, and subsaccate." This species is a native of Falkland Islands, and introduced in 1777 by Dr. J. Fothergill.

VOL. II.

It flowers in May and June. 3. *A. latebrosum*, (*agrimonia decumbens* of Linn. Suppl.) hairy A. "with stems demerged, duncles scape-form, spikes elongate, leaflets oblong, gashed, and villose, and fruits armed on every side." The calyx closes as the seed ripens, and thickens into an ovate globose, fibrose, white-tomentose bark, armed every way with short bristles, thickening outwardly, and having four revered barbed little prickles. The seed single, ovate-globose, produced at top into a boss, smooth and pale; covered with a thin membranaceous skin, and on the outside of that with a coriaceous, hard, thick, integument, resembling a shell. Martyn's Miller.

ANCIZAN, in *Geography*, a town of France, in the department of the Higher Pyrenees, and chief place of a canton in the district of La Barthe de Neste, five leagues south-south-east of Bagneres.

ANCLABRIS, in the *Religion of the ancient Romans*, denoted a table in temples, whereon the priests eat their portion of the sacrifices and oblations.

ANCLACÆ, in *Ancient Geography*, a people placed by Ptolemy in Asiatic Sarmatia.

ANCLAM, in *Geography*, a town of Germany, in the Circle of Upper Saxony and duchy of Pomerania, situate on the river Peene, in a fertile country. On one side of it are swamps and meadows, with a stone-dyke, a quarter of a German mile in length, and on the other deep moats and walls. It has two parish churches, has a good trade both by land and water, and has thriven under the Prussian government. It is the capital of the circle to which it gives name, and the territory belonging to the town is near three German miles long, and contains 17 villages and two farms. It is eight leagues south of Gripwald, and 14 north west of Stettin. N. lat. 54°. E. long. 14° 9'.

ANCLE. See ANKLE.

ANCLOTE Point, in *Geography*, on the peninsula of California, coast of the North Pacific Ocean, lies in N. lat. 30°. and W. long. 116°, southerly from the town of Veliceta, and north-east from the small island of Guadaloupe.

ANCOBARITIS, in *Ancient Geography*, a country of Mesopotamia, known to Ptolemy, and placed by Strabo in Arabia Deserta.

ANCOBER, ANKOBAR, COBRE, or GOLD RIVER, in *Geography*, a river of Africa, which runs into the Atlantic, between the Gold Coast and the country of Axim. At its mouth is a good harbour. N. lat. 4° 48'. W. long. 45°.

ANCOBER, or ANKOBAR, a town and district of the Gold Coast, extending from north to south about 18 or 20 leagues along the river of this name. In this small kingdom there are women who never marry, but devote themselves, by certain ceremonies of an infamous kind, to public prostitution.

ANCOCUS Creek, in *Geography*, lies in New Jersey, being a water of the Delaware, six miles south-west from Burlington. It is navigable 56 miles, and considerable quantities of lumber are exported from it.

ANCOE, a small town of South America, three leagues from the city of Guamanga.

ANCON, in *Anatomy*, denotes the curvation or flexure of the arm, whereon we rest in leaning.

This is otherwise called OLECRANUM.

ANCON, in *Architecture*, is used to denote the corners or quoins of walls, cross beams, or rafters.

ANCON is also used in the *Ancient Architecture*, to denote the two parts or branches of a square, which meet in an angle resembling the letter L.

ANCON is also used by Vitruvius, to denote a kind of *mensule*, or tables before doors, bent somewhat after the manner of *volutæ*, so as to resemble the letter S.

In this sense *ancons* amount to the same with what the Greeks call *αγκυλίδι, prothyrides*.

ANCON is particularly applied in the *Ancient Architecture* to the brackets, or shoudering-pieces, called CONSOLES and CORBELLS by the moderns.

ANCON was also used by the Carthaginians, to denote a dark prison or dungeon. Suidas mentions one of this kind, in which Gelimer used to put all who displeas'd him; from which Belisarius delivered many merchants of the east, whom the tyrant intended to put to death.

ANCON is also applied to the angles or flexures of rivers; sometimes also to the tops of mountains.

ANCON, in *Ancient Geography*, a town of the Leuco-Syrians, in Cappadocia. M. d'Anville places it upon the Euxine Sea, between Amifus to the west, and the Promontorium Heracleum to the north-east.

ANCONA, a town of Italy, in Picenum to the north, situate on a small isthmus, which joins the promontory of Cumerium to the continent. As *αγκυλ* denotes curvature, its name is probably deduced from its situation. Some say that it was first built by the Syracusans, when they fled from the tyranny of Dionysius, towards the year 405 before Christ. It was famous for the beauty of its dyeing, and the purple of Ancona was only inferior in estimation to that of Phœnicia. It became a Roman colony probably after the war of Tarentum, about the year of Rome 485, when the consul P. Sempronius conquered the Picentines, and extended the frontiers of the Roman possessions as far as Ælis. The emperor Trajan constructed a good port, in commemoration of which a triumphal arch of fine veined marble was erected to him on the mole, which stills makes a beautiful appearance. Ancona was ineffectually besieged by the Goths under Totila, A.D. 551; but it was taken by Ariulf, king of the Lombards, and duke of Spoleto, in 592. In 839 it was taken and pillaged by the Saracens. It is now the capital of a country of the same name; a free port, with a convenient harbour, secured by a strong mole, on which are generally mounted 8 or 10 guns; and its chief exports are grain, wool, and silk. It is the see of a bishop, immediately under the pope. The Jews are very numerous in Ancona; however they live in a particular quarter of the town, and are obliged, by way of distinction, to wear a bit of red cloth in their hats. The exchange in Ancona has a beautiful front, and over the entrance an equestrian statue; and within it is a lofty spacious apartment, in which, among other statues, are those of Faith, Hope, Charity, and Religion. The inhabitants of Ancona, says Keyser (vol. iii. p. 209.), especially the female sex, so far excel those of the other parts of Italy, in shape and complexion, that they seem to be a different race of mankind. In the shallows near Monte Comero, or Conaro, about 10 Italian miles from Ancona, there is a singular species of testaceous fish, called ballani, or ballari, which are found alive in large stones. The shell of this fish is thin, rough, and of an oblong figure, resembling a date; and hence they are called Dattili del Mare, or sea dates. These ballari are laid within the mole, and come to perfection. In fishing for them, such stones are selected as have the surface full of little holes, which indicate that these fishes have insinuated themselves into them. When the stones into which the spawn has penetrated are taken, several of these fishes are found in them. Both the fish and its juices are so luminous in the dark, that one may see to read by the light they afford; and even the water in which this fish has been squeezed, when put in a glass, emits an effulgence which lasts from eight to twelve hours. Great quantities of the ballari are brought to Rome, where they are reckoned "beccone di cardinale," or, dainties fit for a car-

dinal. Oysters are preserved here alive in sea-water for several years; but the oysters of Ancona, though large, are flabby and unpalatable. Here is also a kind of sea-craw fish, called noechia, resembling our lobsters, but of a more delicate flavour. In the harbour of Ancona there is also a fish called the sepi, which has a longish white shell on its head: these shells are often found along the shore, and, when pulverized, are used for cleaning plate. Ancona is 107 miles north-north-east of Rome. N. lat. 43° 38'. E. long. 13° 30'.

ANCONA, *Marquisate of*, a province of Italy, in the pope's territories. It is bounded on the north and east by the Adriatic, on the south by Umbria and Abruzzo Ultra, and on the west by the duchy of Urbino. The air is indifferent, but the soil is fertile, particularly in hemp and flax, and there is plenty of wax and honey. The province is about 22 leagues in length, and 16 in breadth: and along the coasts towers are erected, and furnished with cannon, in order to keep off the corsairs. The chief rivers are the Fiumelino, Aspido, Tingo, or Tenna, Ragnola, and Tronto. The principal towns are Ancona, Ascoli, Camerino, Fermo, Jesi, Loreto, Macerata, Montalto, Osimo, &c.

ANCONÆUS, or ANCONIUS *Musculus*, in *Anatomy*, arises tendinous from the back part of the external condyle of the os brachii; it becomes fleshy, and terminates by a thin fleshy attachment in a ridge on the outer and back part of the ulna. Its use is to assist in extending the forearm. Formerly all the extensor muscles of the elbow were called anconci, and that which now exclusively bears the title was the anconæus quartus, or minor.

ANCONY. See IRON, *Manufacture of*.

ANCORARIUS MONS, in *Ancient Geography*, a mountain of Africa, in the Hither Mauritania. According to Pliny the wood which grew upon it had the smell of citron, and was called citrus.

ANCOURT, FLORENT CARTON D', in *Biography*, an eminent actor and comic writer, was born at Fontainebleau, in 1661, and educated at the Jesuits' college in Paris. Destined for the law, he became an advocate at the age of 17 years; but falling in love with an actress, whom he married in 1680, he then devoted himself to the stage as an actor; he excelled in the graver comic parts; and, as a dramatic writer, his particular line was humorous farce. He was distinguished by his exhibition of rustic characters; his dialogue, though filled with the jargon of the peasantry, was gay and lively, and abounded with smart sallies; and his plots generally consisted of little incidents, contrived to ridicule the follies of the day. His pieces were popular, and attracted numerous auditors. His prose was much better than his verse. His company was much sought by the gay and great, and Louis XIV. was fond of him. In 1718 he quitted the theatre, and retired to an estate in Berry, where he employed himself in those religious duties, pertaining to his spiritual safety and welfare, with which, according to the maxims of the Roman Catholic religion, the profession of a player is incompatible. He died in 1726, and left two married daughters. His works were printed in 1729, in nine vols. 12mo. A selection of the best of them has been published in three vols. 12mo. Gen. Dict.

ANCRE, in *Geography*, a small town in France, in the province of Picardy, upon a small river of the same name, five leagues north-east of Amiens. N. lat. 49° 59'. E. long. 2° 45'.

ANCRE'E, ANCREFD, or ANCHORED, in *Heraldry*, is said of a cross where its extremities turn back like the flukes of an anchor, or terminate like the *cross patonce*, but in a sharper turn. Care must be taken not to mistake the cross ancrée for the cross moline, which is of the same form, and by some of the old heralds called a cross ancrée, or anchored.

ANCRINA,

ANCRINA, in *Ancient Geography*, a town of Sicily, according to Ptolemy, at some distance from the sea coast.

ANCTERES, in the *Ancient Medicine*, seem to have been the same, at least to have answered the same uses as our **SUTURES**.

Some also speak of a strong kind of sticking plaster under this denomination.

ANCTERIASMUS, in *Medicine*, the operation of applying a *fibula* to close the two patent lips of wounds.

This is also called by Latin writers, *infibulatio*.

ANCTERIASMUS is more particularly used to denote the passing a *fibula* through the prepuce of the ancient stage-players and buffoons.

ANCUAH, in *Geography*, a town of the province of Alovahat, to the north of Egypt and of the Thebaid.

ANCUBITUS, among *Ancient Physicians*, denotes a disease of the eyes, wherein there is an appearance of sand, or little stones sprinkled on them.

This is otherwise called **PETRIFICATION**.

ANCUD, in *Geography*, an archipelago or cluster of islands in a part of the Pacific Ocean, between the coast of Ancud, that of Chili, and the island of Chiloé.

ANCUD is a name given to a coast of South America in the province of Chili, between the archipelago of Ancud to the west, the Andes to the east, the country of Osorno to the north, and the Terra Tagellanica to the south.

ANCUROPOLIS, or the city of Anchors, in *Ancient Geography*, was one of the cities of the Heptanomis in Egypt, mentioned by Ptolemy, and so called from a neighbouring quarry, out of which stone anchors were cut.

ANCUS, a name for such as have an arm bent crooked, so that they cannot extend it. See **ANCI**.

ANCUS MARTIUS, in *Biography*, the fourth king of Rome, was grandson of Numa Pompilius by his daughter Pompilia and Marcus his relation, the son of that Marcus who persuaded Numa to accept of the kingdom, and who afterwards killed himself, because he was not chosen in his room. His name Ancus was derived from the Greek word ἀγκύων because he had a crooked arm, which he could not stretch out to its full length. He succeeded Tullus Hostilius, according to the common computation, in the year before Christ 634. He began his reign by endeavouring to restore the religious ceremonies, which had been neglected in the time of his predecessor, to their former use, to revive husbandry, and to promote the arts of peace. Nevertheless his natural disposition was martial, and he gained various advantages for his country by his arms. The Latins gave him an early opportunity of exercising his military talents. Having violated the treaty which had been made with Tullus, by invading the Roman territories, Ancus declared war against them with all the religious solemnity enjoined by Numa, and took the field with an army consisting entirely of new-raised troops. After having taken several cities, he defeated them in a pitched battle, obliged them to sue for peace, and obtained a triumph at Rome for the advantages which he had gained. He also recovered Fidenæ, which had revolted; defeated the Sabines, and obtained victories over the Veientes, for which a second triumph was decreed him by the senate. During his reign Rome was greatly enlarged, by carrying the walls round the Aventine Hill, and inclosing the hill Janiculum, which was on the other side of the Tiber, and which was now made a fort of citadel for Rome. A communication was also opened between this citadel and the city, by means of the bridge Sublicius, which Ancus erected over the Tiber, and that part of the river which washes the foot of the Aventine Hill. He also built a large prison in the Roman forum. Ancus likewise extended the

territories of Rome as far as the sea, and established the port and city of Ostia, in order to secure to his subjects the advantages of trade. About this town he caused many salt-pits to be dug, and distributed salt among the more indigent classes of his subjects. He rebuilt the temple of Jupiter Feretrius in a very magnificent manner; and having spent the latter years of his reign in improving the city, and enriching its inhabitants, he died, after a prosperous reign of 24 years. Livy, lib. i. c. 32, 33. t. i. p. 134—144. Dion, Hal. lib. iii. t. i. p. 170, &c. ed. Oxon.

ANCY, in *Geography*, a small town of South America, three leagues from the city of Guamanga.

ANCY LE DUC, a town of France, in the department of the Saone and Loire, one league north of Marcigny les Nonains.

ANCY LE FRANC, or **ENCRE**, a town of France, in the department of the Yonne, and chief place of a canton, in the district of Tonnerre, eight leagues east of Auxerre, and three south-east of Tonnerre.

ANCYLE, in *Antiquity, denotes a small kind of brazen shield, supposed to be the shield of Mars, and said to have fallen from heaven into the hands of Numa Pompilius, at the same time that a voice was heard, that Rome should be mistress of the world while she preserved that shield. Though there was but one ancyle that fell from heaven, yet there were twelve preserved; Numa, by the advice, as it is said, of the nymph Egeria, having ordered eleven others, perfectly like the first, to be made by Veturius Mamurius, so that if any should attempt to steal it, as Ulysses did the Palladium, they might not be able to distinguish the true ancyle from the false ones. These ancylia were preserved in the temple of Mars; and were committed to the care of 12 priests or *falii*, instituted for that purpose. They were carried every year, in the month of March, in procession all round Rome; and the 30th day of that month they were again deposited in their place.*

ANCYLE, see **ANCHYLOSIS**.

ANCYLOBLEPHARON, or **ANCHYLOBLEPHARUM**, (from ἀγκύλη, *hæmus*, and ἔλφαρον, *palpebra*) in *Surgery*, an adhesion of the eye-lids. This may either be a natural or a congenite defect, or it may be produced by accidents, such as burns, violent inflammations, and ulcers. The eye-lids may either adhere to each other only, or they may adhere to the eye-ball itself; and sometimes both kinds of adhesions are present together.

There are properly three degrees of this disease. The *first* is, when the eye-lids are only glued together by means of pus or thick mucus, as happens in many inflammations of the eye, particularly in the suppurating inflammation, whilst the patient is asleep; also in the small-pox, when the eye-lids have been kept close for several days in consequence of the general swelling of the face; in such cases, therefore, it is also termed the *spurious* species of the disease. The *second* degree is when the edges of the eye-lids not only adhere together, but are even connected by means of a cicatrix. The *third* degree is where the eye-lids have also formed an adhesion with the conjunctive coat, or the ball of the eye. This third degree is also particularly termed **SYMBLEPHARON**. These two last degrees are accounted the *genuine* species of the disease.

In the first degree, when the eye-lids are glued together by a purulent or tough mucous matter, we must employ emollient applications. The eye-lids should be moistened with a luke-warm mixture of milk and water, or with an infusion of rad. althææ, or with an emollient decoction, applied upon a piece of linen, till they spontaneously separate from each other. We may also rub them gently with an ointment consisting of syr. papav. ol. Amygd. and camphor, and after-

wards apply an emollient poultice of lb. sal. sem. lini and milk. Should these remedies not produce the desired effect, we may cautiously introduce a probe with a knob between the eye-lids, and thereby prevent their adhesion.

In the second degree the edges of the eye-lids either adhere together at all points from one canthus to the other, so as to form a perfect concretion, or they are only more or less connected together at one or the other angle of the eye. In the first case, the patient is entirely deprived of sight; in the second he can see by turning the ball of his eye sideways, so that if the disease be not speedily removed, squinting may easily be the consequence. The method of cure in this disease is to separate the eye-lids from each other by means of an incision.

In this operation the surgeon must use great caution in directing his instrument, so as to avoid the ball of the eye, and prevent its injuring the eye-lid in such a manner as to lay bare the tarsus, the consequence of which might be a very troublesome ulceration. This may be accomplished without difficulty, when the eye-lids do not entirely adhere together, but are still separate at some point; as for example, when there still remains an opening at the internal canthus. Some use for this purpose a small grooved probe, which they introduce between the eye-lids, and then carry along the groove a thin and somewhat crooked-bladed knife, or a small pair of scissors, or only a lancet. But in preference to the probe we may use, as a more convenient and safe instrument, a small knife, with a straight back, but somewhat curved at the edge, and terminating at the point in a very small probe with a knob, about two lines in length.

For performing the operation the patient is placed upon a chair, in a convenient posture; an assistant secures his head, and, at the same time, draws the superior eye-lid upwards, whilst the surgeon draws the inferior downwards with two fingers, or else draws it with a small forceps downwards, and, at the same time, off from the eye. Sometimes the surgeon himself may stretch both eye-lids from each other with the fingers of one of his hands. With the other hand he introduces the scalpel abovementioned under the eye-lids, in such a manner, that the back is directed towards the ball of the eye, and the edge to the place where the preternatural adhesion is situated; that is, to the interval between the two edges of the eye-lids, or between both rows of eye-lashes, which frequently remain uninjured by the disease, pushes it forwards, and thus divides the preternatural adhesion. In case of necessity he may also use a small pair of eye-scissors, though this instrument is not so safe and convenient as the blunt-pointed scalpel.

When the eye-lids are entirely closed they must first be opened at some external point, by drawing out the skin into a cross fold, and introducing a lancet into it, so as to form an aperture through which a scalpel or probe may be introduced; which being done, the rest of the operation is performed after the manner already described. But lest the ball of the eye might be injured, the first aperture should be made with caution, and always either at the inner or outer canthus of the eye, for fear of wounding the transparent cornea, which might thereby be rendered opaque. The safest method of proceeding will therefore be to draw at the same time the eye-lids from each other. This incision, however, but seldom becomes necessary; for even in a complete adhesion an opening may always be perceived at the inner canthus of the eye, through which a scalpel or probe may be introduced. When the puncta lacrymalia are likewise obstructed, a species of fistula lacrymalis remains after the operation, unless the puncta can be opened. See FISTULA LACRYMALIS.

When the division of the preternatural adhesion has been per-

formed, we should apply to the eye a piece of very fine soft linen spread with Goulard's cerate, or some other cooling ointment; and after the first dressing we should daily rub between the eye-lids a quantity of ointment made with fresh butter and *flor. zinci*, or *tulia*, either with or without bals. Peruv. or else some faturnine ointment. The patient should likewise repeatedly open and move his eye-lids during the day; and in the first night after the operation he should let himself be frequently awakened, in order to prevent the formation of a new adhesion. In this, as in all other operations on the eye, we should do all that is in our power to prevent inflammation, and to relieve any that may have taken place.

But, before we operate upon a complete adhesion, we should carefully examine whether the ball of the eye be perfectly sound, and whether the eye-lids have not formed adhesions with the ball of the eye also; which may happen in cases of burn, or when quicklime has fallen into the eye, in which cases not only the edges of the eye lids, but the ball of the eye itself is generally injured, and often the cornea rendered entirely opaque. For when the cornea is entirely opaque, and the eye-lids adhere not only with each other, but also with the ball of the eye; when the patient perceives no sensation of light while a candle is held close to his eye in a dark room, and in general cannot distinguish light from darkness; when the eye-ball is felt under the eye-lids small and collapsed; and when from the cause, by which the disease has been occasioned, there is reason to suspect that the cornea has been rendered opaque—the patient's sight cannot be restored by an operation, which consequently will be superfluous. We may conclude that the eye-lid adheres to the ball, and that an operation will consequently be difficult, if not impracticable, when the eye-lid cannot be moved backwards and forwards upon the ball, or when we feel that the patient cannot move the ball of his eye, or when, in moving it, the eye-lid contracts itself into wrinkles. However, when the eye-lid does not adhere throughout, but only at particular points, and not on the cornea, to the ball, it is worth our while to attempt the operation, for which purpose we must first draw the eye-lid asunder, and then separate the adhering lid from the ball.

In the third degree, which consists in a preternatural adhesion of the eye-lids with the ball of the eye, there sometimes also exists an adhesion of the edges of the eye-lids with each other; in many cases, however, the adhesion subsists only between the eye-lids and the ball, forming what is termed *SYMBLEPHARON*. Of such adhesions several varieties are observed; they are sometimes firm, or fleshy; at others, loose or membranous. Either the whole surface, or a single part of one or the other eye-lid adheres to the ball. In the first case, which is very rare, the patient is altogether unable to open his eye; in the second he can only open his eye-lids partially, and see when he turns the ball of the eye to the aperture; in which case he may easily become subject to *STRABISMUS* by habit. The adhesion of the upper eye-lid occurs far more frequently than that of the lower.

The separation of the preternaturally united parts can here be performed only by the knife. A small crooked knife, formed like a probe, at the point, has been proposed for this purpose. In performing this operation, we must take care that we may not injure either the eye-lid or the ball of the eye, which it is the more difficult to avoid, as we frequently cannot see how we carry the knife, on account of the hæmorrhage. By pressing the ball of the eye with the blade of our instrument backwards from the eye-lid, and at the same time drawing, or letting an assistant draw the eye-lid forwards from the ball, we may in many cases not only perform a part of the separation without cutting; but also, if in-

cision should be necessary, we may use our instrument with greater safety, and without injuring any of the parts. With this view Mr. Kaltsehmidi has recommended to use a small lancet in such a manner, that its surface lies firm upon the surface of the eye, the edge being steadily directed against the fibres which form the adhesion, so as to divide them more by pressure than by moving the lancet to and fro. Moreover, we ought, in performing this operation, to be particularly cautious not to injure the inner surface of the eye-lid, it being better to cut away a part of the conjunctiva of the eye, than to injure the eye-lid itself. But when the eye lid adheres to the cornea we must spare the latter, and press the knife more upon the eye-lid. For performing this operation a steady and experienced hand is particularly necessary.

This operation, however, is always very difficult, and it will be attended with no benefit when the cicatrification is firm and fleshy, and when the eye-lid adheres closely to the ball. Neither will it be productive of any benefit when the eye-lid, though adhering only at one part, is connected with the cornea, and the adhesion is of a muscular nature; so that it is highly probable the cornea will be rendered opaque, unless we can hope afterwards to restore its transparency. In this case, however, as in every case where the adhesion is muscular and cicatrified, it is very difficult to prevent the parts from forming new adhesions with each other. It is, therefore, only in those cases where the adhesion is loose and membranous, and only a small part of the ball connected with the eye-lid, and that at the side, that the operation can be performed with facility, and with a sure hope of a fortunate event; though even here it is often very difficult to prevent a new adhesion from taking place. When the adhesion is very loose, we may frequently dispense with cutting instruments, and effect the separation by means of a small blunt knife, shaped like a SPATULA.

In order to prevent the formation of a new adhesion, after the operation, some introduce lint into the eye, others a piece of linen or fine leather in the form of a crescent, others a thin, smooth plate of ivory, lead, or horn, shaped so as to correspond with the form of the eye, or only a thin, flat piece of wax. All these foreign substances, however, when introduced between the ball and lid of the eye, irritate, press, and inflame the eye; neither do they keep their situation. It is therefore better to direct the patient frequently to roll the ball of his eye, and not to sleep too long at a time; and when the hæmorrhage has ceased, frequently to introduce upon the inner surface of the eye, with a hair pencil, a little cream, oil of almonds, saturnine or tutty-ointment; or to drop, into the space, between the lid and the ball, some gently astringent and drying collyrium. We may also (as Heister advises) introduce repeatedly towards the termination of the cure a blunt probe between the lid and ball of the eye, and move it gently backwards and forwards; but this must be done with the utmost caution. Any remaining opacity of the cornea must be treated with the proper remedies.

The method of treatment, practised by Fabricius Hildanus (Observat. Centur. v. Obs. 7.) might also in some cases be attempted. His method was gently to introduce a crooked probe at the inner angle of the eye, under the upper eye-lid, between the lid and ball of the eye, till its point projected out of the outer canthus. He then fastened a fine silk thread to the point of the probe, and introduced the probe again in the same manner as before; and the ends of the thread he tied together under the eye, and fastened a small lump of lead to them. During the day time the lead was suffered to hang to the thread, but it was taken off when the patient went to bed. By means of this thread, and the weight suspended to it, the adhesion was separated

in the space of nine days, the eye-lid and ball of the eye completely recovered their motion, and nothing of the disease remained behind except a small speck upon the cornea.

Vide C. F. Kaltsehmidi, Diss. de pueri xii. annorum anchylopharo laborante curato. Jen. 1764. Resp. C. G. Barchowitzi.—G. I. Badendyk, Diss. de Anchylopharo. Jen. 1785.

ANCYLOGLOSSUM, or ANCHYLOGLOSSUM, in Surgery, (from ἀγκύλη, hamus, and γλῶσσα, lingua) *Anchyloglossæ, Anchyliosis*, and adhesion of the tongue, or the being TONGUE-TIED. This term is applied to that mal formation of the parts, in which the frenulum of the tongue confines its apex too much, and impedes its motion, either by its being continued too far forwards towards the extremity of the tongue, or by its being too short, considered in its perpendicular direction. Both these defects are generally natural ones, and are therefore most commonly observed in new-born infants. However, even in adults, the frenulum may sometimes be shortened, and the motion of the tongue impeded in consequence of a wound, ulcer, &c. We discover the existence of this defect, when we find that we cannot introduce the finger under the tongue, and raise it up; when the infant neither sucks the finger, when it is introduced into its mouth, nor the nipple of the mother; when the child, after it has begun to speak, cannot properly pronounce the letters which are principally articulated with the apex of the tongue, namely, *f, l, r*, (a very complete adhesion of the tongue, whether by means of the frenulum, or any other preternatural connecting substance, may even occasion complete dumbness); and when the apex of the tongue cannot be drawn forwards, beyond the teeth, to the gums or lips.

The cure of this defect consists in the operation of dividing the frenulum, which, however, is very frequently performed without necessity, and to the very great detriment of the infant. (Fabricius ab Aquapendente) Chirurg. Operat. cap. xxxvi.) asserted, that among a 100,000 children that were born, scarce one actually required this operation. See also Jourdain on the diseases of the Mouth, vol. ii. p. 594. and 602.) For only in that very rare case, in which the infant is unable to suck, in consequence of the immobility of the tongue, are we authorized and obliged to perform the operation. Should even the frenulum be something too short, and the apex of the tongue not sufficiently moveable, so that there is cause to apprehend that the child, when he learns to speak, will not be able properly to articulate the lingual letters, we ought, provided he be not prevented from sucking by that defect, to defer the operation to a future period, for it is unnecessary to perform it at present; and should it afterwards become necessary, for the purpose of enabling the child to articulate his words properly, it may then be performed with greater facility, safety, and accuracy; besides, that the frenulum often becomes spontaneously elongated, and sufficiently extended in consequence of the mere motion of the tongue. As there are various other causes, which may be impediments to the infant in sucking, we must not always look for the fault in the state of the frenulum. Nay, though we should even find the tongue actually immoveable in an infant that either cannot or will not suck, we are not authorized immediately to suppose that the defect of the frenulum is the cause of it, and so undertake the operation without farther examination. For we sometimes find that preternatural membranes and ligaments, which proceed from the lateral edges of the tongue, and connect it with the gums, were the cause of the impeded motion of the tongue; and that, after these have been divided, the infant is able to suck. In new-born infants the tongue sometimes adheres so strongly to the gums, by means of a viscid mucus, that

that the patient cannot suck, nay, scarcely draw breath; this mucus may easily be removed by means of a spatula.

In performing the operation, we have principally to take care to make the incision into the frenulum of the proper length; for if we make it too long, that is too far on towards the root of the tongue, the tongue becomes too movable, and another defect, of which we shall treat hereafter, is produced; whilst, if we do not make it long enough, the tongue does not acquire sufficient mobility, and the intention of the operation is not completely answered. However, it is always better rather to make the incision too short than too long, as in the former case the operation may be repeated, and the division made longer, whilst, in the latter, the fault cannot be remedied. Moreover, we ought always to make the incision as much as possible in the middle, between the tongue and the subjacent soft parts, and avoid the blood-vessels, nerves, and salivary ducts.

When it is determined to perform the operation, we proceed in the following manner: The patient being properly secured, and his mouth opened, we introduce the common mouth-spatula under the apex of the tongue, in such a manner that the frenulum lies in the slit of the spatula. Instead of this spatula we may also use a grooved probe, with a flat and slit handle. Some recommend, instead of the spatula, to use a small two-pronged fork, with knobs at the points. With one or other of these instruments, which we hold in the left hand, we raise the apex as much as possible, and stretch the frenulum. This manœuvre, as well as the rest of the operation, may be facilitated by applying external pressure under and behind the chin, by which means the soft parts under the tongue are elevated. We then divide the frenulum with a round-pointed pair of scissors, which we hold in our right hand. The crying of the child greatly facilitates the operation; in performing which we may also compress his nostrils, which will compel him to keep his mouth open.

Various other complicated instruments have been proposed for performing this operation, but they may all be dispensed with, as none of them have any advantage over the more simple ones, the spatula, and scissors: indeed we have often performed the operation with no other instrument than the scissors. When the frenulum has been properly divided, there is seldom any necessity for employing any peculiar treatment; it may, however, be useful, during the first period after the operation, to draw a linen rag, neatly spread with fine-pounded sugar or honey, several times a day under the tongue, in order to prevent the formation of a new adhesion. Sometimes also it happens, especially when the frenulum is uncommonly fleshy, or has been divided too far back, that a hæmorrhage ensues, which, though of itself insignificant, may frequently be rendered dangerous, nay, even fatal in consequence of the sucking usual with new-born infants, upon awaking, when the breast is not soon given them. This accident may be prevented by attending to the infant for the first twenty-four hours after the operation, and as soon as it awakes, taking it up, and laying it to the breast till it falls again asleep. But there is still greater cause to apprehend a dangerous hæmorrhage, when, through want of the proper caution, any considerable blood-vessel under the tongue has been injured. This must immediately be stopped by strong astringent remedies, *e. g.* concentrated vinegar, spir. vin. rectif. or Theden's aq. vuln. with which small compresses should be wetted, and laid under the tongue; or with blue vitriol, or agaric, pressure being at the same time applied. In order to prevent the fatal hæmorrhage, which might afterwards supervene, it is necessary that the child should be attended to during the first days after the operation, that we

may see whether it moves its lips or appears to suck or swallow any thing; and when it does so, we must immediately examine whether any blood is discharged, in order that we may be able immediately to stop the hæmorrhage. We have known a very troublesome excrescence arise under the tongue of an infant, after it had been cut too deeply by an officious nurse.

The frenulum may also, in some cases, possess too great a facility of motion; namely, when, by a fault of the original conformation it is too long in its perpendicular direction, or when it does not extend far enough from the root towards the apex of the tongue. This fault is not to be discovered till the child begins to speak. Little or nothing can be done to remedy it, though it sometimes spontaneously disappears as the child grows older. A similar defect is produced when the frenulum has been divided without necessity, or when, in performing the operation from proper indications, the incision has been made too long. When either this or the preceding defect is present in a high degree, it sometimes happens that the infant, which is in the habit of sucking as soon as it awakes, sucks down the apex of its tongue, and is suffocated. If we discover the accident in time, and extricate the tongue with our finger, the infant immediately recovers: it will, however, be necessary that we should prevent the recurrence of a similar accident. This we may do by two different means. As soon as the infant awakes, and begins to suck, we must either let it have the breast immediately, or we must put a finger or some other substance into its mouth till the breast can be given it. When it has been weaned it gradually loses the habit of sucking its tongue, and then there is no more danger to be apprehended. When circumstances do not admit of such attention being paid to the infant, or when the child, after it has been weaned, still retains the habit of sucking its tongue, we may prevent the tongue from being drawn down into the throat, by applying an ivory stick between the jaws of the child, which is to be fastened behind the neck and under the chin with strings. With adults, whose frenulum is either too loose, or does not extend far enough towards the tip of the tongue, we may employ the tongue-bandage of M. Petit or Pibrac, of which we shall take notice under the article *WOUNDS of the Tongue*.

Finally, by frequent and forcible suction of the retroverted tip of the tongue, adults may sometimes stretch, elongate, and relax their frenulum, which before was quite perfect, in such a manner as to produce all the defects above-mentioned.

Instead of a frenulum we sometimes find, in infants, a fleshy excrescence under the apex of the tongue, which frequently is so large as to prevent both suction and deglutition, and can only be removed by excision. In this operation we have chiefly to apprehend the hæmorrhage, which sometimes is so profuse as to occasion the death of the patient. As the remedies above-mentioned are not applicable in such cases, we ought to employ the actual cautery, or sometimes we may succeed with compression. It might, perhaps, be advisable to cut out, at first, only a part of the excrescence, so as to enable the infant to suck and swallow; after which, as he grows older, the rest of it may be extirpated with greater ease and safety, if it produce any inconvenience. Both in children and adults, suction, deglutition, speech, and mastication are sometimes impeded by painful excrescences on the frenum, which ought to be removed by cutting, tying, or caustic. Ulcers, fistulas, and encysted tumors, which are frequently found on the frenulum, must be treated in the same manner as when situated in other parts of the body.

Vide Chr. Car. Lang. *Diff. de frenulo linguæ, ejusq. incisione*—Præf. Juit. Chr. Loder. Jenæ, 1785. I. F.

Schweighauser Diff. de Affectib. linguæ. Argentor. 1789.

ANCYLOMELE, ἀγκυλομήλη, from ἀγκυλος, *crooked*, and μέλη, a *probe*: a surgeon's crooked probe or a probe with a hook.

ANCYLOSIS. See ANCHYLOSIS

ANCYLOTOMUS, (from ἀγκυλωτός, *uncut*) Fr. Ancylo-tome. A knife for loosening the tongue. This instrument is no more in use. The term is also applied in general to all crooked-bladed knives.

ANCYLOS, in *Conchology*, a name given by Geoffroy to the PATELLA LACUSTRIS of Linnæus. See LACUSTRIS.

ANCYRA, now called by the Turks ANCOURI, in *Ancient Geography*, a city of Asia Minor, and formerly the capital of Galatia, situate near the small lake Cenaxis, and not far from the river Halys, and belonging to the Tectosagi. Pausanias (Attic. c. iv. p. 12.) intimates that it was founded by Midas, and that it derived its name from an anchor which was found there, and which was preserved in the temple of Jupiter. It was afterwards greatly enlarged and adorned by Augustus, who, on this account, might be deemed the founder of it. In the time of Nero this noble city received the title of the metropolis of Galatia; and it is still populous. Its inhabitants, according to Suidas, were denominated Hellenogalatæ, or Græco-Galli. See ANGORA.

ANCYRA, *Ancyra Abastidis* of Strabo, a town of Phrygia, mentioned by Pliny (l. v. c. ult.) and confounded by Steph. Byz. with the Ancyra of Gallo-Græcia of the preceding article.

ANCYRÆ, a town of Sicily, mentioned by Diodorus Siculus, lib. xiv. c. 49.

ANCYREUM, a promontory of Asia Minor, noticed by Dionysius Periegetes, as situated where the Euxine Sea terminate, and where the Bosphorus commenced.

ANCYROIDES, ἀγκυροειδής; is used by some writers in *Anatomy* for the process or shooting forth of the shoulder-bone, in form of a beak; otherwise called *coracoides*.

ANCZAKRISH, in *Geography*, a river of Podolia, which discharges itself into the Black Sea, near Oczakow.

ANDA, in *Botany*, is a tree of Brasil, found, according to Pison (Hist. Nat. Racened.), in the forests, at a small distance from the sea-coast; the wood of which is spongy and light; the leaf longish, fibrous, and pointed; the flower large and yellow; and the fruit a grey nut, which incloses, under a double rind, two kernels of the taste of chestnuts. The fruit is said to be purgative, and a little emetic: two or three of the kernels are a dose. The Indians extract oil by expression from these kernels, with which the natives anoint their limbs. The rinds of the fruit are esteemed proper to stop a looseness; thrown into ponds they kill the fish.

ANDA, in *Ancient Geography*, a town of Africa, according to Appian.

ANDABATÆ, in *Antiquity*, a kind of GLADIATORS, who fought hookwinked; having a sort of helmet that covered the eyes and even the face.

They were called *andabate*, quasi ἀνάβαται, *ascensores*, because they fought mounted on horseback, or out of chariots. Others derive the word from ἀνά, *against*, and βία, *I go*.

Some say, the *andabate* fought in the dark, or late at night, after the *circensia* were over. There were two men in the chariot, viz. the driver, or *auriga*, and the παραβάτης, who was also called ἀνάβατης, q. d. *adscensor*, or *mounter*; whence by corruption the Latins formed the *andabata*.

It has been disputed among critics whether the *andabatæ* were a people who actually fought blindfold in their wars,

or a set of combatants who only practised this method of fighting for the sake of exercise.

ANDABATIS, in *Ancient Geography*, a town of Cappadocia, according to Antonine.

ANDACA, a town of India, which surrendered to Alexander, but its situation is unknown.

ANDAGUAYLAS, in *Geography*, a jurisdiction of the empire of Peru, in South America, subject to the archbishop of Lima: situate east by south of the city of Guananga, extending between two branches of the Cordillera above 20 miles, and watered by several small rivers. It abounds in sugar plantations, grain of most sorts, and fruits. This province is one of the most populous in these parts; and its climate is partly hot, and partly temperate.

ANDAGYRI, or ANDIGRI, a district of the island of Sumatra, with a populous town of the same name, situate on a river commodious for trade; the chief article with which this district abounds is pepper.

ANDAJA, a river of Spain, in Old Castile, which joins the Duero.

ANDALUSIA, a province of Spain, which formerly comprehended the kingdom of Granada, then called Upper Andalusia; but the name is now appropriated to Lower Andalusia, which is the most westerly province of the southern part of Spain. It is separated, on the north, from Estramadura and New Castile by the Sierra Morena Mountains; on the east, from Portugal by the river Chanca, and on the west, from Algarve by the Guadiana; on the south, it has the ocean, the Straits of Gibraltar, and part of the Mediterranean; and along the south-east it has the kingdom of Granada. Its utmost length from Ubeda to Ayamonte, is ninety leagues, and its breadth about sixty. Its chief cities and towns are Seville, the capital, Baeza, Gibraltar, Corduba, Cadiz, Medina Sidonia, Jaen, Port St. Mary, &c. Its principal rivers are, the Guadalquivir, Xenil, Odier, or Odiel, Guadalate, and Tinto, or Azeche. Andalusia is reckoned the richest and most fertile province of Spain; abounding in exquisite fruits of all kinds, honey, excellent wine, grain, silk, sugar, fine oil, numerous herds of cattle, particularly horses, metals, cinnabar, and a species of quicksilver. The air, though warm, is refreshed by cooling breezes, and the great extent of sea coast is favourable to commerce. The wool of Andalusia, says Keyser, (Travels, vol. iii. p. 20.) is known to surpass all other; though the sheep on which it grows were originally natives of England. The name of Andalusia is applied by the Arabs not only to the modern province, but to the whole peninsula of Spain. Some have derived the name from Vandalusia, the country of the Vandals; but the Handalusia of Casiri, which signifies in Arabic the region of the evening, or of the west, or the Hesperia of the Greeks, is perfectly apposite. Gibbon's Hist. vol. ix. p. 467.

ANDALUSIA, New, a district of South America, in the eastern part of the province of Terra Firma, situate on the coast of the Atlantic, opposite to the Leeward Islands. The boundaries of this territory are indefinite, as the Spaniards pretend a right to countries in which they have never established any settlements. If the districts of Camana and Paria are included, it extends, according to the most reasonable limits, 500 miles from north to south, and about 270 from east to west. The interior country is woody and mountainous, variegated with fine vallies that yield corn and pasturage. The produce of the country consists chiefly in dyeing drugs, gums, medicinal roots, Brazil wood, sugar, tobacco, and some valuable timber; to which may be added pearls, for which the Spaniards used to fish along this coast to Carthageua. The capital of Andalusia is Camana, Cu-

mana, or as some writers call it, New Corduba, situate in N. lat. $9^{\circ} 5'$, about nine miles from the North sea. As the place was naturally strong, the Spaniards laid the foundation of a town in 1500, and fortified it with a castle, which was capable of making a vigorous defence; and this was actually the case in 1670, when the Buccaneers assaulted it, and were repulsed with great slaughter. *Mod. Un. Hist.* vol. xxxv. p. 176.

ANDALUSICUS, in *Ornithology*, a species of TETRAO that inhabits Andalusia. It is rufous, variegated with black; under-side reddish white; legs and bill flesh coloured. Gmelin. The black marks on the plumage are irregular, but partly disposed in bars; the neck and breast are slightly tinged with yellow; the quills dusky. It has only three toes, which are all placed forwards. Latham. This is the ANDALUSIAN QUAIL of the latter author.

ANDAMANS, two islands in the Gulf of Bengal, opposite to the coast of Malacca, though at a considerable distance. They are denominated the Great and the Little Andaman, which is about eight leagues in length, and five in breadth. The former is about 140 miles long, and its greatest breadth about 20; its deep bays afford excellent harbours, and one of its numerous creeks passes through the island, and is navigable by small vessels. The soil is chiefly black mould, and the cliffs are composed of a white arenaceous stone. The forests, which are extensive, afford some valuable trees, as ebony, and the Mellori, or Nicobar bread fruit. The only quadrupeds are wild hogs, monkeys, and rats. The fish, supplied by the sea, are, for the most part, mullets, soles, and good oylers. The conduct of the inhabitants manifests very little civilization; they are brutal, deceitful, and ferocious; and they are probably cannibals. They have woolly heads, and perfectly resemble negroes. As to their origin, report says, that they are descended from a crew of African slaves. Soon after the Portuguese had discovered the passage to India round the Cape of Good Hope, one of their ships, having on board a number of Mozambique negroes, was lost on the Andaman islands, which, it is said, were till then uninhabited. The blacks remained in the island, and settled it; whereas the Europeans made a small shallop, in which they sailed to Pegu. But this account is not compatible with the description given of these islanders by the Mahometan travellers in the ninth century. Canoes, however, might have been driven from the African coasts by a south-west monsoon; and this desert isle might have been thus occupied. A British settlement has been lately formed on the Greater Andaman, and some convicts have been sent thither from Bengal. The natives are about 2000, and are now profiting by the example of English industry. The limits of these islands are in N. lat. $14^{\circ} 0'$. $10^{\circ} 8'$ E. long. $93^{\circ} 3'$. $93^{\circ} 35'$. Asiatic Researches, v. ii. and iv.

ANDAMAS, a town of Persia, in the province of Kuzistan, 45 leagues west of Ispahan.

ANDAMENTO, in *Music*, the *motivo*, or movement in giving out the subject of a fugue; a theme, longer and more important than a POINT, which see.

ANDANASAR, in *Geography*, a town of India, on this side the Ganges, in Decan.

ANDANCE, a town of France, in the department of the Ardèche, and chief place of a canton, in the district of Mezen, on the Rhone, 20 miles north of Valence, and 12 north of Tournon.

ANDANIA, in *Ancient Geography*, a town of Messenia, south-west of Messene. It was one of the most ancient cities, and had probably been the capital of the country. Pausanias (Messenica. c. i. p. 282. 323.) has given a particular account of its origin, and of its decline and desolation.

ANDANIS, a river of Carmania, so called by Pliny and Ptolemy, but denominated by Arrian, Anamis.

ANDANTE, in *Music*, from *andare*, Ital. to walk, &c. neither to run nor to creep, but the medium between both those motions. *Andantino*, the diminutive of *andante*, is applied to movements somewhat quicker, and bordering on *allegretto*, or rather *grazioso*.

ANDARÆ, a people of India, on the other side of the Ganges, who formed, according to Pliny, a very powerful nation. Hardouin is of opinion, that the country which Pliny meant to describe was the kingdom of Pegu.

ANDARAX, in *Geography*, a town of Spain, in the country of Granada, six miles north-west of Almeria.

ANDARBA, in *Ancient Geography*, a town placed by Antonine in Dalmatia.

ANDARGE, in *Geography*, a river of France, which rises in the valleys of Uffan, and joins the Arnon near Verneuil.

ANDARIACA, a town of Asia Minor, which was situated, according to Ptolemy, in Lycia.

ANDARINI, a paste of vermicelli, reduced into five grains, like amulets.

ANDARISTUS, in *Ancient Geography*, a town of Europe, in Macedonia. Ptolemy refers it to the Pelagonians.

ANDARO Island, in *Geography*, lies on the western coast of the peninsula of India. N. lat. 10° . and E. long. $73^{\circ} 35'$.

ANDASTES, an Indian nation, in Canada.

ANDATE, in *Mythology*, the goddess of Victory, was one of the principal deities of the ancient Britons; she had a famous temple at Camelodunum.

ANDATIS, in *Ancient Geography*, a town of Ethiopia, on the banks of the Nile, according to Pliny.

ANDAUTONIUM, a town of Higher Pannonia, upon the river Savus, north-east of Siscia.

ANDAYE, in *Geography*, a sea-port town of France, in the department of the Lower Pyrenees, near the mouth of the Bidassoa, on the borders of Spain, with strong fortifications, and a good trade; five miles south-west of St. Jean de Luz. N. lat. $43^{\circ} 25'$. W. long. $1^{\circ} 45'$.

ANDEAH, a town of Hindostan, in the circle of Billah, 30 miles east-north-east of Billah, and 120 south of Agra.

ANDECRUM, or ANDETRUM, in *Ancient Geography*, a town of Dalmatia.

ANDEB, or ΑΙΝΤΑΒ, in *Geography*, a town of Turkey in Asia, in the government of Aleppo, situate on the road that leads from Aleppo to Erzerum, near the river Sefchar, in a valley that abounds with vines, various kinds of fruits and apples of a large size. This was anciently *Antiocha ad Taurum*.

ANDEGAN, the capital of Fergana, one of the provinces of great Bucharia.

ANDEGAVI. See ANDES.

ANDEIRA, in *Ancient Geography*, a town of Asia Minor, in Thebaic Cilicia, at some distance to the north of the small river Scilleus. Near this town there was a chapel consecrated to the mother of the gods, and a subterraneous grotto, which extended as far as Palæa.

ANDEL, in *Geography*, a town of France, in the department of the northern coast, and chief place of a canton, in the district of Lamballe, seven miles east of St. Brieuc.

ANDELANGA, in *Middle Age Writers*, occurs as part of the formula of divers donations.

In this sense we meet with *donare per andelangam* & *festucam*, *vendere* & *tradere per andelangam*. &c. Some will have the term properly to denote what we call an *and-iron*;

iron; others a long staff, or rod, which it is known was much used in the act of putting into possession.

The word is sometimes also written *andelangus*, *andelago*, *andilago*, or *andalagus*, &c.

ANDELINGEN, or ANDELINGEN, in *Geography*, a town of Switzerland, in the canton of Zurich; seated on an eminence in a vogtey of the same name, and near the river Thur; 17 miles north-north-east of Zurich.

ANDELLE, a river of France, in the province of Normandy, which rises near Ferté-en-Bray, passes by Vexin-Normand, and discharges itself into the Seine, about four leagues above Rouen.

ANDELOT, a town of France, in the department of the Upper Marne, and chief place of a caupon, in the district of Chaumont, on the river Rognon; 10 miles north-north-east of Chaumont.

ANDELPACH, a river of Germany, which runs into the Danube, near Scheir.

ANDELUS, in *Ancient Geography*, a town of Spain, placed by Ptolemy among the Valcones.

ANDELY, in *Geography*, a town of France, and principal place of a district, in the department of Eure. It is divided into two by a paved causeway; one of the parts is called *Le Grand Andely*, and the other *Le Petit Andely*; the one is upon the Seine, the other upon the river Gambon. It is 20 miles south-east of Rouen. N. lat. 49° 15'. E. long. 1° 14'.

ANDENA, in *Ancient Writers*, denotes a swath in mowing. The word is likewise used to signify as much ground as a man can stride over at once.

ANDENAS, in *Geography*, a small island of Norway, in the North Sea, with a town of the same name. N. lat. 69° 30'. E. long. 14° 54'.

ANDEOL, or ANDIOL, a small town of France, in the Vivarais, at the junction of the Ardeche with the Rhone. It is four leagues from Viviers. N. lat. 44° 24'. E. long. 2° 50'.

ANDERA, a beautiful village of Egypt, on the Nile, in which are found several monuments that indicate its former grandeur.

ANDERAB, the chief city of the province of Tokarestan, in Great Bucharia, situate near a pass through the mountains of Hindooh Koh, which separate India and Persia from Bucharia, and possessed by the Usbeck Tartars. As there is no other way of crossing the mountains towards India with beasts of carriage, except through this city, all travellers and goods from Bucharia are obliged to pay four per cent. On this account the khan of Balk maintains a considerable number of soldiers in this place, which is otherwise of no great strength. Anderab, though small, is very rich and populous. The neighbouring mountains yield quarries of lapis lazuli, which furnish a considerable trade between the Buchari and Persia and India.

ANDER-ESCH, a town of the duchy of Luxemburg, two leagues and a half south of Luxemburg.

ANDERITUM, or ANDERIDUM, in *Ancient Geography*, afterwards called *Gabali*, the capital of the Gabali, in Aquitania Prima. It was an episcopal see; but the city was ruined by an incursion of the Alemanni, and the see was transferred to Mende.

ANDERLECH, in *Geography*, a town of Brabant, three miles south-west from Brussels.

ANDERNACH, a town of Germany, in the circle of the Lower Rhine; in the archbishopric of Cologne, and in a prefecture of the same name. It was anciently called *Antoniacum*, *Antunacum*, and *Antonacense castellum*, and was a free imperial city. In the year 1496 it was by force of arms

rendered municipal by the elector of Cologne, to whom it now belongs. It is seated on the Rhine, and a toll is levied on travellers for the support of its walls. Its trade, for which it is advantageously situated, consists principally of stone ware, tiles, timber, and the soriff, a stone used in constructing dykes, which are conveyed to Holland by the Rhine. It is also remarkable on account of the large rafts which are here built upon the borders of the Rhine, the smaller ones being brought down the rivers Mayn and Rhine from Franconia and the country about Mentz, which are here united with those of Andernach. One of these rafts, when it arrives in Holland, whither they pass from the month of May to the end of August, is calculated to be worth about 80,000 guilders. They frequently require from 2 to 300 men to guide them. An irreconcilable animosity subsists between the inhabitants of Andernach and those of Lintz, and it is kept up by an annual sermon preached against the latter in the open market-place of Andernach. There are three medicinal springs in its vicinity. It is situated on the confines of the electorate of Treves, three leagues north-west from Coblenz, and eight and a half south-south-east from Cologne. N. lat. 50° 29'. E. long. 17° 9'. Rander's Tour, vol. i. p. 316.

ANDERNO *Port* lies on the east side of Scarpante, near the Archipelago Islands, nearly in the course from the east end of Candia Island to Rhodes, to the north-east.

ANDERO, *St.* a sea-port town in the Bay of Biscay, in Old Castile, seated on a small peninsula. It is a trading town, and contains about 700 houses, 2 parish churches, and 4 monasteries. Here the Spaniards build and lay up some of their men of war. N. lat. 43° 20'. W. long. 4° 30'.

ANDERO *Island, St.* See ANDRES.

ANDERSKOW, a town of Denmark, in the Island of Zealand, one mile south-east of Slagelle.

ANDERSON, ALEXANDER, in *Biography*, an eminent mathematician, was born at Aberdeen, in Scotland, and flourished at the latter end of the 16th, and beginning of the 17th centuries. He was professor of mathematics at Paris, where he published several ingenious works in geometry and algebra, both those of his own and of other persons. In 1612 was published in 4to. a supplement to Apollonius, written by Ghetaldus, under the title of "Supplementum Apollonii redivivi." His "Antilogia," treating of the analytic method of reasoning, and containing farther observations on the former work, was published at Paris in 4to. in 1615. About the same time he published two treatises of Vieta, "On Equations," with a dedication, preface, and appendix, and Vieta's tract of "Angular Sections," with demonstrations. A cousin of this gentleman, whose name was David Anderson, was also distinguished for his acquaintance with mathematical and mechanical science. His daughter was the mother of the celebrated James Gregory, and as soon as she discovered his propensity to these sciences, she took pains in giving him necessary instructions in the elements of mathematics. Hutton's Math. Dict.

ANDERSON, SIR EDMUND, an English lawyer, was descended from a Scots family, settled in Lincolnshire, and prosecuted his studies, first at Oxford, and afterwards in the Inner Temple, where in due time he became a barrister. In the 19th year of Queen Elizabeth, he was appointed the queen's serjeant at law, and soon after one of the justices of assize. In 1581 he went the Norfolk circuit, and distinguished himself by his zeal against Browne, who was the founder of the sect denominated Brownists. His continued zeal in support of the established church recommended him to the queen; and in 1582 he was advanced to

the dignity of lord chief justice of the common pleas. In the following year he received the honour of knighthood. In 1586 he was appointed one of the commissioners for trying Mary, queen of Scots, and he sat in the star-chamber when sentence was pronounced against her. He afterwards, viz. in 1587, sat in the same court, when Davidson, the queen's secretary, was charged with issuing the warrant for the execution of Mary, contrary to queen Elizabeth's command, and without her knowledge; and it was his opinion that the secretary had done "julum non julté," what was right but not in a due manner; upon which Mr. Grainger very properly observes, that this distinction was "excellent logic for finding an innocent man guilty, and drawn from the same mood and figure with the queen's order and no-order for Davidson's signing the warrant." The distinction, however, was admitted; and the secretary was sentenced to pay a fine of 10,000 pounds, and to be imprisoned during the queen's pleasure. Judge Anderson seems to have imbibed, in connection with this subserviency to the will of the court, an intolerant and persecuting spirit; and he has been reproached on this account, and not unjustly, by the Puritan writers. Mr. Pierce, in his "Vindication of the Dissenters," p. 129, (ed. Lond., 8vo., 1717,) charges him with very unjustifiable conduct with regard to Udal, a Puritan minister, who was confined in 1589, and tried and condemned the year following, and with endeavouring to trick him out of his life. Upon an examination of Udal, at the house of Lord Cobham, in January, 1589-90, the lord chief justice endeavoured to draw from him a confession that he was the author of certain books, which furnished the charges against him; though a law, 42 Edw. III. c. 3. to which Udal referred, says generally, that no man shall be put to answer without presentment before justices, or matter of record, or by due process, and writ original, &c. Udal, indeed, was not tried till July following; nevertheless the judge must know that, considering the disposition of government towards separatists, such a confession might endanger his life. He manifested a similar spirit in 1596; when he declared in his charges, in the northern circuit, that those who opposed the established church, opposed her majesty's authority, who was supreme in all cases ecclesiastical as well as civil, and on this account they were enemies to the state, and disturbers of the public peace; and he directed the grand juries to inquire concerning persons of this description, that they might be punished. At Lincoln, in his first and second charge, as we are informed by the letter of a clergyman, preserved in Strype's Annals, vol. iv. p. 267, he insinuated with wonderful vehemency, that the country is troubled with Brownists, with disciplinarians as he called them, and creators of Presbyteries. He also called the preachers knaves; saying, that they would start up in the pulpit, and speak against every body; he urged the grand jury to suppress, by the statute against Conventicles, a meeting held even with the bishop's allowance, at Lowth; and declared that he would complain to her majesty of any, though never so great, who should show themselves discontented with the jury for any such matter; in short, he conducted himself with so much wrath, so many oaths, and such reproachful revilings, upon the bench, that offence was taken at it by persons of principal credit and note, throughout all the circuits.

He was nevertheless an able lawyer, and adhered with rigorous exactness to the statutes; nor does it appear, that his obedience to the will of the sovereign proceeded, like that of others, from view of personal interest, or from a fear of losing his office, but from respect for what he deemed the constitutional right of the crown. In a case, when the queen would have stretched her prerogative beyond the limit

of the law, the lord chief justice and his brethren resisted, and by their steadiness obliged the queen to relinquish her claim. He also, together with the other judges, signed a remonstrance against the arbitrary proceedings of the court, by which at the command of a counsellor, or nobleman, subjects were frequently committed to prison, and detained without good cause, and contrary to the laws of the realm; a spirited measure which produced considerable effect; for we are told in Sir William Anderson's reports (Reports, part ii. p. 297,) that "after this there did follow more quietness than before." Upon the accession of James I., the lord chief justice was continued in his office; and he retained it till his death in 1605. "With a harsh and severe temper, and intolerant principles, which rendered him hostile to sectaries, and with notions of arbitrary power, which made him, in some cases, an instrument of tyranny, he appears to have possessed great firmness of temper, and independence of character. If his principles would not suffer him to be always an equitable judge, he was a great lawyer, and, on the whole, an honest man." His works are "Reports of Cases, adjudged in the time of queen Elizabeth, in the common bench," in folio, London, 1644; "Resolutions and Judgments in the Courts of Westminster, in the latter end of the reign of queen Elizabeth," published by John Goldeborough, Esq. 1653. The title is now extinct. Biog. Brit.

ANDERSON, JOHN, the son of a rich merchant, was born at Hamburg, in 1674. Having made great proficiency in canon law, natural history, and the languages, he was made syndic of the city of Hamburg, and he was employed in various negotiations in the principal courts of Europe. In the prosecution of his study and research, he directed a particular attention to the northern nations, and both by reading and conversation obtained a very considerable degree of information concerning them. By means of the Danish colonies established in Davis's Straits, he gained an accurate knowledge of those sequestered parts, and he was enabled to correct many erroneous and fabulous accounts, concerning the state of Iceland. The result of his inquiries was communicated to the public in a German work, entitled, "The natural history of Iceland, Greenland, Davis's Straits, and other northern regions;" since translated into other languages. Mr. Anderson died in 1743; and left behind him MS. pieces, that have not been published. Moreri.

ANDERSON, ADAM, a native of Scotland, was brother to Rev. James Anderson, D. D. editor of the "Diplomata Scotiæ," and "Royal Genealogies," minister of the Scots church, in Swallow-street, Piccadilly, and known in London, among his connections, by the name of bishop Anderson; a learned but imprudent man, who lost a great part of his property in the year 1720. Adam Anderson was for 40 years a clerk in the South Sea House; one of the trustees for establishing the colony of Georgia, in America; and one of the court of assistants of the Scots corporation, in London. His well known work, entitled, "An Historical and Chronological Deduction of the Origin of Commerce," was first printed in two volumes, fol., in 1764; and a new edition of it, with considerable additions, was published in four volumes, 4to., in 1789. Mr. Anderson died in Red Lion-street, Clerkenwell, Jan. 10, 1755.

ANDERSON'S *Island*, in *Geography*, a small island in the North Pacific ocean, discovered soon after Mr. Anderson, the surgeon of the Resolution, had breathed his last, and so called after his name. It was seen at some distance from a rocky point called Cape Newnham, situated in N. lat. 58° 42'. E. long. 197° 36'.

ANDES, in *Ancient Geography*, a small place of Italy, near Mantua, celebrated as the birth-place of Virgil; hence

he is called *Andinus*, according to some copies of Silius Italicus, lib. viii. v. 596; whilst others read *Aonius*. It is now the village of Banded, situate where the Veronese hills imperceptibly slope down into the plain of Mantua.

ANDES, ANDEGAVI, OR ANDICAVI, a people of Gaul, to the east of the Namnetes or Nannetes, and to the north of the river Liger. Pliny (lib. iv. c. 18.) calls them Andegavi, and they are denominated by Tacitus (Annal. iii. c. 41.) Andecavi, which Ptolemy has corrupted into Ondicavæ. Their chief city was called Juliomagus or Civitas Andicavorum. It is now Angers, and the territory of the Andes was the present Anjou. The Andes, or Andecavi, were valiant, and fought bravely in defence of their liberty; they entered into the conspiracy of Vercingetorix, under the conduct of Dumnaeus; and under the empire of Tiberius, when they were grievously oppressed with taxes, they raised the standard of rebellion.

ANDES, a chain of mountains in South America, called by the Spaniards Cordillera de los Andes, or great chain of Andes, which commences near the capes of Ildro and Pilares, in the southern extremity of the continent, and stretches along the Pacific ocean, at the mean distance of about 100 miles, traversing the kingdom of Chili, and the provinces of Buenos Ayres, Peru, and Quito, to the west side of the gulf of Darien, through an interval of not less than 4600 miles. From thence they continue their course through the extensive kingdom of New Spain, till they lose themselves in the unexplored countries of the north. The chief summits of this range of mountains are near the Equator, not far from the city of Quito. The highest of them is Chimborazo, about 100 miles south of Quito, and about 10 miles north of Riobamba; and its height was computed by the French mathematicians, who were employed from 1735 to 1743, in measuring a degree of the equator, to be about 3217 French toises, or 20,280 feet, above the level of the sea; that is about 5000 feet higher than Mont Blanc. But as these mountains are elevated on the high plain of Quito, which is elevated farther above the sea than the top of the Pyrenées, and constitutes more than one-third of the computed height, they are inferior in actual elevation to Mont Blanc. That part of Chimborazo, which is covered with perpetual snow, is about 2400 feet from the summit. The mountain next in height is supposed to be the volcano of Cotopaxi, which is estimated at about 18,600 feet, and is situated about 25 miles south-east of Quito. Other elevated summits are Pachincha, a few miles north-east of Quito; and the Altar and Sanga, south-east of Chimborazo. In the province of Quito, the Andes form a double chain, including the plain of Quito. The western ridge comprehends Pachincha, Illinssa, Chimborazo, &c.; and the eastern is composed of Cotopaxi, the Altar, Sanga, &c.; and this double ridge is extended for about 500 miles from the south of Cuenza to the north of Popayan. The highest of these ridges is barren, and covered with snow, although it lies in the torrid zone; the other, which is lower, is fruitful in woods, groves, &c. and abounds with wild hogs and sheep, called guanacos, which resemble a camel in shape, but of a smaller size, and bearing hair for softness, fineness, and colour, preferred to silk.

There are several arms, or ramifications, which proceed from the Andes, and which serve to consolidate the union of the southern with the northern parts of America. The most northern of these, or that of the coast of Venezuela, lying between nine and ten degrees of N. latitude, is the most lofty and narrow. This great chain of the Andes extends from the high plain of Quito, by Popayan and Choco, on the west of the river Atrato, towards the isthmus, where,

on the banks of the Chagrè, it forms mountainous land only about 1200 feet high. From the same Andes proceed several branches, one called the Sierra de Abibe, towards the province of St. Marta, covered with snow, and visible from the sea. This chain is restricted, as it approaches the gulf of Mexico, and cape of Vela, and afterwards runs due east towards the mountain of Paria, or even to the isle of Trinidad. The greatest height is in the two Sierras Nevadas of St. Marta, and of Merida; the first being near 5000 varas, and the second 5400 varas, about 2350 toises, or 14,000 English feet above the sea. Several mountains of this chain are perhaps equal in height to Mont Blanc; they are perpetually covered with snow, and frequently pour from their sides streams of boiling sulphureous water; and the highest peaks are elevated amidst mountains of little height, that of Meridan being near the plain of Caracas, which is only 260 feet above the sea. The general height of the chain of the coast is from six to 800 toises; the Nevada of Merida is 2350, and the Silla de Caracas 1316, lowering towards the east, so that cape Codera is only 176 toises. This depression, however, is only of the primitive rock; for there are secondary calcareous mountains from cape Unara, which are higher than the gneiss, or foliated granite, and the micaceous schistus. These calcareous mountains, covered with calcareous free-stone, follow this chain on its southern side, and increase in height towards the eastern point of the continent. The chain of the coast is more steep towards the north than the south; and there is a dreadful perpendicular precipice of 1300 toises in the Silla de Caracas, above Caravelledo, the northern part of this chain being perhaps broken by the gulf of Mexico.

The second chain, which is that of Parima, or of the cataracts of Orinoco, was scarcely deemed passable till within 30 years, since the expedition of Ituriaga and Solano. It leaves the Andes near Pupayan, and stretching from west to east, from the sources of the Guavian, appears to extend to the north-east of that river, forming the cataracts of Maypura and Atures, in the Orinoco, lat. 5°, which are truly dreadful, and nevertheless afford the only passage yet opened towards the vale of the Amazons. Thence this chain continues its course, with a breadth sometimes of 120 leagues, north-east to the river Caronis, but further to the east its continuation is little known. It has, however, been disclosed by Don Antonio Santos, who, under the disguise of an Indian, passed from the mouth of the river Caronis, to the little lake of Parima, and observed this range between 4° and 5° N. lat., where it is about 60 leagues broad, and divides the waters which fall into the Orinoco and Esquibo, from those that fall into the river of Amazons. Farther to the east, this range becomes still wider, descending south along the Mao, where the Dutch call a part of it Dorado, or the mountain of gold; as it is composed of bright micaceous schistus, which gives a similar character to a small isle in the lake of Parima. To the east of the Esquibo this range takes a south-east direction, and joins the granitic mountains of Guanaa, in which is the source of the river of Surinam, and also of other rivers. This last group of mountains is very extensive, the same gneiss being found at 8° 20' and 2° 14'. This wide range is inhabited by a number of savage tribes, which are not much known in Europe. It no where seems to rise to an equal height with the northern range of the coast; the mountain of Duida, whose volcano is in lat. 3° 13', not far from Esmeralda, being deemed the highest, and, by the measure of Humboldt, found 1323 toises above the sea. This is a picturesque and majestic mountain, ejecting flames towards the close of the rainy season, and situate near a beautiful plain, covered with palm-

trees and ananas. Towards the east it seems to terminate in broken rocks; but without any appearance of any secondary strata, the rocks being granite, gneiss, micaceous schist, and hornblende slate.

The third chain of primitive mountains, or that of Chiquitos, unites the Andes of Peru and Chili with the mountains of Brazil and Paraguay, and stretches from La Paz, Potosi, and Tucuman, through the provinces of Moxos, Chiquitos, and Chaco, towards the government of the Mines, and of St. Paul, in Brazil. The highest summits appear to be between 15° and 20° ; the rivers there passing to that of Amazons, or that of La Plata.

Between these three great ridges are three immense vallies; that of Orinoco, that of the river of Amazons, and that of the Pampas of Buenos Ayres, from 19° to 52° south lat. all opening to the east, but shut on the west by the Andes. The middle valley, or that of the Amazons, is covered with forests so thick, that the rivers alone form roads; while those of Orinoco and Pampas are savannahs or grassy plains, with a few scattered palms; and so level, that sometimes for 800 square leagues there is no elevation exceeding eight or ten inches. In the northern plain the primitive rock is covered with limestone, gypsum, and freestone, while in that of the Amazons the granite every where appears. The general inclination is to the north-west, which, according to Humboldt, is the usual arrangement of primitive rocks. In the Andes petrifications are uncommon, but there are sometimes patches of gypsum, and secondary limestone; while the range of Parima consists entirely of granite and other primitive rocks. But in the calcareous freestone of the northern ridges of the coast, Humboldt found many shells, seemingly of recent petrification, as they are those of the sea, now at the distance of nine leagues. In the plain of Orinoco are found petrified trees, in a coarse breccia. Granite forms the chain of Parima; but in that of the coast it is covered, or mingled with gneiss and micaceous schist. It is sometimes stratified in beds from two to three feet thick, and sometimes contains large crystals of felspar. The micaceous schist sometimes presents red garnets, and sapphires; and in the gneiss of the mountain of Avila green garnets appear. In the range of Parima there occur large masses of most brilliant talc, formerly imparting such reputation to the Dorado, situate between the rivers Esquibo and Mao, and other mountains, which like burnished gold, reflect the light of the sun, and have hence been denominated the shining mountains. Smeelite, or soft jad, is formed into idols: and Condamine discovered that hard jad, called Amazon stone. Schistose chlorite also occurs; and beautiful hornblende slate rises through the streets of Guayana, or S. Thome. Other substances are decomposed felspar or kaolin, primitive limestone and plumbago; and there are veins of quartz, which contain auriferous pyrites, and antimony, native gold, grey copper, and malachite. The copper mines of Aroa are alone wrought, and produce about 1500 quintals yearly. Slate is rare, but sometimes covers the micaceous schist; and in the northern chain there are rocks of serpentine, veined with bluish steatite. The grunstein of Werner sometimes occurs in that ridge. Among the rocks called transitive by Werner, as connecting the primitive with the secondary, are trap, green slate, amygdaloid, and the schistose porphyry of that author, green with crystals of felspar. The secondary rocks are limestone, gypsum, argillaceous schist, and freestone, or calcareous sandstone, with coarse breccia.

The eastern spurs of the Andes, according to Helms, a practical German mineralogist, who was employed for some years in the mines of Peru, sometimes present red and green

granite, and gneiss, as towards Cordova, and Tucuman, but the grand chain consists chiefly of argillaceous schist, or various kinds of thick slate, bluish, dark red, flesh colour, grey and yellow; on which, in many places, are incumbent strata of limestone, and large masses of ferruginous sandstone. No mountains, says this author, have been observed by him in Hungary, Saxony, or the Pyrenées, which are so irregular as the Andes, or broken into such alternate substances, manifesting such prodigious revolution of nature. Amid the argillaceous schist the metals sometimes occur in veins of quartz, sometimes in alluvial layers of sandstone, and iron sand. Near Potosi are irregular beds of large bullets of granite; and the celebrated mountain, so rich in silver ore, is chiefly composed of a firm yellow argillaceous slate, full of veins of ferruginous quartz, in which are found some of the best ores. In passing the highest ridge of the Andes, between Potosi and Lima, Helms still found argillaceous schist, the predominant substance; sometimes with strata of sandstone, sometimes with long extents of granite. Near the lake of Titicaca the Andes are of prodigious height, this being the centre of the chain, and perhaps equalling the summits near Quito; and Helms observed in some places the basis of argillaceous schist covered with alluvial layers of marl, gypsum, limestone, sand, fragments of porphyry, and even rock salt; and yet rich silver occurs in abundance. Near Guancavelica, the mountains are chiefly sandstone or limestone; but still equally high and equally rich. To the north of this place the ridge for 100 miles is said to be calcareous, yet fertile in metallic ores. According to Helms, the summits near La Paz are the highest of the Andes; but he did not travel so far as Quito.

It is said that the Andes have 16 volcanoes, which break out in various places, and by melting the snow occasion such torrents of water, that numbers of men and cattle have perished. Argillaceous schist, that predominates in a range so lofty and extensive as the Andes, where upon the common theories granite might have been expected, is probably the work of that prodigious subterranean fire that issues from so many volcanoes, and of the eruptions of mud, combined with subterranean waters; for this mud is the very matter of argillaceous schist, and thus ejected during thousands of years, has become superincumbent on the granite, which is perhaps the principal substance in such parts as are not volcanic.

The French mathematicians, who visited the Andes, for measuring a degree of the meridian, have given a particular account of the occurrences that befel them on this occasion. Having divided themselves into two bodies, Don George Juan and M. Godin, at the head of one party, went to the mountain of Pambamarca; and M. Bouguer de la Condamine, and Don Ulloa, with their assistants, ascended the highest summit of Pachincha. Both parties suffered from the extremity of the cold, and the impetuosity of the winds, which on these heights blow with incessant violence. They had commonly, in other uncomfortable situations, pitched a field-tent for each company; but on the top of Pachincha this was impracticable, and they were under the necessity of contenting themselves with a very small hut, which, like all the other adjacent parts, was soon covered with ice and snow. The air on this summit was also so subtle, as to render respiration very difficult. They generally kept within their hut; which they were obliged to do, on account of the intenseness of the cold, the violence of the wind, and the darkness occasioned by a thick fog. When the fog cleared up, the clouds descended towards the earth; and surrounded the mountain in such a

manner

manner as to represent the sea, with the rock on which they were situated like an island in the centre of it. When this happened, they heard the horrid noises of the tempests, which then discharged themselves at Quito, and the neighbouring country. They saw the lightnings issuing from the clouds, and heard the thunder rolling far beneath them; and whilst the lower parts were involved in tempests of thunder and rain, they enjoyed a delightful serenity; the wind abated, the sky was clear, and the enlivening rays of the sun moderated the severity of the cold. But when the clouds rose, respiration became difficult, and snow and hail fell continually, and the wind resumed its former violence; so that they were apprehensive, lest their hut should be overturned, and blown down the precipice, on the edge of which it was built, or that they should be buried under it by the accumulation of ice and snow. Their fears were increased by the dreadful concussions occasioned by the fall of enormous fragments of rocks, and the velocity with which the wind moved dazzled their sight. For their greater security they fastened the door of their hut with thongs of leather, and stopped every crevice on the inside; and they also completely covered it with straw; but all this precaution was not sufficient to prevent the wind from penetrating. They had no other light in this confined state, but that of a lamp or two, which they kept burning; but notwithstanding the smallness of their habitation, and the heat of the lamps, the cold was so intense, that each of them was obliged to have a chaffing-dish of coals. Such were the effects of the asperity of the climate, that their feet were swelled and so tender, that they could not even bear the heat, and walking was attended with great pain. Their hands were covered with chilblains; their lips were swelled and chapped; so that every motion, in speaking or the like, drew blood. Their common food in this inhospitable region was a little rice boiled with some flesh or fowl, which was procured from Quito; and instead of water, their pot was filled with ice; and whilst they were eating, every one of them was obliged to keep his plate over a chaffing-dish of coals, to prevent his provisions from freezing. When they attempted to augment their inward heat by drinking strong liquors, they felt no strength in them, nor were they any greater preservative against the cold than common water. The Indians, who attended them, could not by any encouragement, or threat of punishment, be prevailed upon to continue with them. Upon their first feeling the rigour of the climate, they immediately prepared for desertion; and such was the inconvenience resulting from this circumstance, that they were in danger of being confined in their hut, by the masses of snow, which it was the business of these Indians every morning to remove. Such, and similar to these, were the difficulties and inconveniences with which they encountered during the whole progress of their occupation in forming triangles for measuring degrees of the meridian. ANDESAGE, a town of France in the department of the Lot and Garonne, and chief place of a canton, in the district of Villeneuve d'Agen, 10 miles north-east of Agen.

ANDETHANA, in *Ancient Geography*, *Epternash*, a town of Gaul, belonging to the Treveri, in Belgia prima, between Augusta Treverorum to the east, and Orobannum to the west.

ANDETRIUM, (Pliny), ANDRETIUM, (Strabo), AN-

DERION, (Dion Cassius), and ANDRECIUM, (Ptolemy). a town of Dalmatia, situated on an almost inaccessible rock, surrounded with deep vallies and rapid torrents; whence it appears to be the citadel now called *Cliffa*. N. lat. 43° 20'. E. long. 17° 46'.

ANDEVALLO, in *Geography*, a small country of Spain, in Andalusia, on the frontiers of Portugal and Spanish Estremadura.

ANDEZEIOW, or DEDERZEIOW, a town of Poland, in the palatinate of Cracow, 52 miles south-south-west of Cracow.

ANDIANTES, a people, according to Ptolemy, of Lower Panponia.

ANDIATOROQUE, a lake of Canada, in North America, near New England.

ANDILLA, a town of Spain, in the province of Valencia, six leagues from Alicante.

ANDIRÁ, or ANGELIN, in *Botany*, *G. Pison*; a tree in Brazil, the wood of which is hard and proper for building. Its bark is of an ash colour; its fruit is of the shape and size of an egg, green at first, but growing blacker by degrees. It is covered with a hard rind, inclosing a grain, or yellowish kernel, of a bitterish, astringent taste. They pulverize this nut, and give it for worms; but not more than one scruple; for more than this is said to be poisonous. In the Linnæan system by Gmelin, *andira* is a genus of the *diadelphia decandria* class and order; the characters of which are, that the *calyx* is urceolated almost entire, or quinidentated; the *corolla* has two petals; and the fruit is a fleshy pod, ovate, furrowed, and containing a single seed.

ANDIRA, in *Zoology*, is an animal called also *andira-guacu*, a kind of bat in Brazil: the largest of which are as big as our pigeons: they call them horned bats, from a sort of excrescence, or pliant body, above their beak. Some of these are very dangerous; for they get into chambers in the night, and so subtilly open the veins in the feet of those who are in bed, that they are not perceived but by the flowing of the blood, which is difficult to be stopped. The inhabitants reckon the tongue and heart of that animal among poisons. The *andira* is the *VESPERTILIO SPECTRUM* of Linnæus. See *SPECTRE*.

ANDIRIAR, in *Botany*, the name by which Rhafes, and some others, express the *FABAGO*.

ANDLAU, in *Geography*, a town of France, in the department of the Lower Rhine, situated on a mountain, and defended by a castle. It was formerly an imperial free city, and has a nunnery, instituted for ladies of noble extraction. It is 18 miles south-south-west of Strasburg. N. lat. 48° 24'. E. long. 7° 24'.

ANDLAU is also a river of France, which rises near the town of the same name, and discharges itself into the Ill, near Fegerheim, in the department of the Lower Rhine.

ANDOCIDES, in *Biography*, an Athenian orator, was born at Athens, the first year of the 78th olympiad, or 468 years before Christ. He was attached to oligarchy, and not to popular government. When Alcibiades was tried for demolishing the statues of Mercury, Andocides was suspected, and he escaped by acknowledging the crime, and accusing his accomplices. The style of his orations is plain and simple, and almost entirely destitute of ornament. Four are extant, of which the two first are vindications of himself; the third is on the subject of peace with the Lacedæmonians; and the fourth against Alcibiades, who had sent him into exile. They were first published with those of Antiphon, Æschines, &c. by Aldus Manutius, in folio, at Rome, in 1513; and afterwards in a more splendid manner, in 1575, by Henry Stephens. The orations of Antiphon, Andocides,

cides, and Trees, were published in 8vo, with a Latin version, at Hovan, in 1619. *Plut. Alcibiades apud opera*, tom. i. p. 261. *Fabr. Bib. Græc. lib. ii. c. 26. § 3. tom. i. p. 811.*

ANDOLOGENSES, in *Ancient Geography*, a people of Spain, according to Pliny.

ANDOMADUNUM, ANDOMATUNUM, (Ptolemy). ANTEMATUNUM, (Antonine), CIVITAS LINGONUM, (Tacitus), now *Langres*, a city of Gallia Belgica, was a Roman colony, and appears, by many remains of antiquity, to have been considerable. It was situated on an eminence as the termination *dunum* imports. N. lat. 48°. E. long. 5° 22'.

ANDONY RIVER, in *Geography*, lies on the coast of Benin, in Africa, call from Cape Formosa, between the new and old Calabar rivers, in about N. lat. 4° 30', and E. long. 9° 55'.

ANDORA, a town of Italy, in Genoa, whose neighbourhood produces good wine; two miles north-east of Oneglia.

ANDORINHA, in *Ornithology*, a name by which the Portuguese in the Brasils call the Brazilian swallow, more usually known by its Brazilian name *tapera*.

ANDORISIPPO, in *Ancient Geography*, a town placed by Pliny in Bœtica. Hardouin calls it *Andoriscæ*.

ANDORNO, in *Geography*, a town of Italy, in the principality of Piedmont, and lordship of Verelli, 25 miles north-west of Verelli.

ANDORRA, a town of Spain, in Catalonia, situate in a valley of the same name, which is surrounded by the Pyrenées, and formerly made a part of the county of Foix, with which it joins; the valley is fertile, and watered by a small river, called Belira, that runs into the Segra, three leagues north of Urgel.

ANDOSILLA, a town of Spain, in Navarre; two leagues from Calahorra.

ANDOSINI, in *Ancient Geography*, a people placed by Polybius, in Spain, towards the Pyrenées.

ANDOVER, in *Geography*, a borough town of England, in the county of Hampshire, pleasantly situate near the river Ande. It has a manufacture of shalloons, and a considerable trade in malting. Its market is on Saturday. It is governed by a bailiff, steward, recorder, ten other persons of approved reputation, and 24 burgessees. It sends two members to parliament. A navigable canal is making from this town to Southampton; it is 63½ miles from London, and 17¼ from Salisbury. N. lat. 51° 20'. W. long. 0° 56'.

ANDOVER is also a large and thriving town of North-America, in Essex county, Massachusetts, containing two parishes, and 2863 inhabitants. It has a paper mill and powder mill, and an excellent academy, called "Phillips Academy," from the name of its founders. This town lies about 20 miles west of Newbury port, and about 22 north of Boston.

ANDOVER is also a town of Hillsborough, in New Hampshire, incorporated in 1779, and containing 645 inhabitants.

ANDOVER is also the south-westernmost township in Windsor county, Vermont, situate 32 miles north east of Bennington, and containing 275 inhabitants.

ANDOVER is also a place in Suffex county, New Jersey, near the source of Pequett river, five miles south-south-east from New-Town, and 16 in the same direction from Walpack.

ANDOVILLE, a town of France, in the department of the Mayenne, a chief place of a canton, in the district of Laval, near the river Eracé, six miles north of Laval.

ANDRAÆ, in *Ancient Geography*, a town of Asia Minor,

placed by Ptolemy in Cappadocia, in the prefecture of Chamaene.

ANDRACINE, in *Botany*, *Telephoides* of Tournefort, a genus of the *minocia gynandria* (*pentandria trigynia*, Gmelin's Linnæus) class and order; of the natural order of *tricoceæ* and *euphobiæ* of Jussieu; the characters of which are, that it has male and female flowers; in the former the *calyx* is a five-leaved, equal, marcescent perianthium; the *corolla* has five petals, emarginate, slender, and shorter than the calyx, the nectary has five leaflets, semibifid, herbaceous, one within each petal, and less than it; the *filamina* have five filaments, small, inserted into the rudiment of each style, and simple anthers; in the latter the *calyx* is a five-leaved, equal, permanent perianthium; the *corolla* has no petals, the nectary as in the male; the *pyllium* is a germ superior and globose, styles three, filiform, and two-parted, the stigmas globose; the *pericarpium* is a capsule globose-trilobate, three-celled, cells bivalved, of the size of the calyx, (tricoceous elastic, G.) the *seeds* are in pairs, rounded on one side, triangular and obtuse on the other. Obs. It is related to *clutia*.

Martyn enumerates three, and Gmelin two species. 1. *A. telephoides*, telephoides of Dill. and Buxb. glaucous of Boeck. procumbent and herbaceous. This is a low plant, with its branches trailing on the ground; the leaves are small, oval, and of a sea-green colour; found wild in some parts of Italy, and in the Archipelago, whence its seeds were sent by Tournefort to the royal garden at Paris; and cultivated in Kew garden by Dr. Sherard, in 1732. As it has no great beauty, it is only preserved in botanic gardens for the sake of variety. 2. *A. fruticosa*, β *clutia androgynua* of Linn. Mantiss. erect and shrubby. It rises 12 or 14 feet high, with branches bearing spear-shaped, pointed, smooth leaves; the flowers are small, and of an herbaceous white colour; some flowers are male, with a one-leaved round flat obtuse calyx, a little quinquefid, others on the same plant female, five-parted; a native of the East Indies, in China, and also of La Vera Cruz, in New Spain. 3. *A. arborea* of Miller, with arborescent stem, and leaves ovate, obtuse, hoary underneath. This has a strong woody stem, which rises more than 20 feet high, with branches from which proceed oval blunt leaves hoary on the under side, and furrowed on the upper, and placed alternately on the branches. This species grows naturally at Campeachy, and the seeds were sent from thence to England by Dr. Houstoun. There is another sort, raised from seeds, sent from Jamaica; the leaves of which resemble those of the laurel, except that they are much larger; this has not yet flowered in Europe.

Culture. The seeds of the first species may be sown on a moderate hot bed in March; and the plants, which spring up in about a month, may be removed, each into a small pot, and plunged into another moderate hot bed; in mild weather they should have plenty of air and be often watered; in June they will produce flowers, and the seeds will ripen in August and September, after which the plants decay. The second and third species are very tender plants; their seeds should be sown in pots, which must be plunged in a hot bed of tanner's bark, and watered; when the plants come up, each of them should be planted in a small pot, plunged into a tan-bed, and they should be shaded till they have taken fresh root, and afterwards in warm weather exposed to the air, but constantly kept in the bark stove.

ANDRACHNE. See ARBUTUS.

ANDRADA, DIEGO DE PAYVA D' OF ANDRADIUS, in *Biography*, a learned Portuguese divine of the 16th century, was born at Coimbra, distinguished in that University, and sent by Sebastian, king of Portugal, to the council of Trent, where he was celebrated for the understanding of a deep

deep theologian, and for the tongue of an eloquent orator. During the session of the council he wrote a treatise, entitled, "Orthodoxarum Explicationum Libri Decem," in answer to an attack upon the Jesuits by Chemnitius. This was answered by Chemnitius. Andrada prepared an elaborate rejoinder under the title of "Defensio Tridentinæ fidei," or a defence of the Catholic faith, &c. first published in 4to. at Lisbon, in 1578, and afterwards at Ingolstadt, in 8vo. in 1580. Andrada published also seven volumes of sermons. Although a champion for orthodoxy, he had the candour to allow that the heathen philosophers might be saved. Gen. Dict.

ANDRADA, FRANCIS, historiographer to Philip III. king of Spain, was the brother of the preceding Andrada. He wrote "The History of John III. king of Portugal," in the Portuguese language; which was published, in 4to., at Lisbon, in 1533.

ANDRAGATHIA, in *Ancient Geography*, a town of Italy, in the vicinity of Posidonium.

ANDRAGIRI, or GUDAVIRI, in *Geography*, a province and town in the island of Sumatra. The town is in the middle of the island, and belongs to the Dutch, who have built a fort for its security.

ANDRAMIT, ADRAMIT, or ANDRAMITI, a town of Natolia, in Turkey, in Asia. The Turks call it Palament. See ADRAMYTNUM.

ANDRAPANA, in *Ancient Geography*, a town of Asia, in India, ascribed by Ptolemy to the Indocythians.

ANDRAPODISMUS, in *Ancient Writers*, the selling of persons for slaves.

Hence also *andrapodistes*, ἀνδραποδιστης, a dealer in slaves, more particularly a kidnapper, who steals men or children, to sell them; a crime for which the Thessalians were noted.

ANDRAPODOCAPELLI, Mancipiorum Viuidictores, in *Antiquity*, dealers in slaves. They cleansed the skins of the slaves with baths prepared with barley and other kinds of meal, to which nitre, according to Galen, was occasionally added, they whipped them lightly with cords, and then smeared them with oil, and used various other acts to make them sleek and plump, and to give them an appearance of health. They were also called Mangones, and the art Mangoniam. Castelli Lexicon.

At Athens, several places in the forum were appointed for the sale of slaves. Upon the first day of every month, the merchants brought them into the market, and exposed them to sale, whilst the crier, standing upon a stone erected for that purpose, called the people together.

ANDRARUM, or ANDERUM, in *Geography*, a town of Sweden, in the province of Schonon; and also a town at Christianstadt.

ANDRASTE, in *Antiquity*, one of the principal divinities of the ancient Britons, supposed to have been the same with Venus or Diana.

ANDRE, St., in *Geography*, a town in the kingdom of Leon, in North America, near the mouth of Nassau river, which falls into the gulf of Mexico.

ANDRE, a small river of France, in Britany, which runs into the Loire, at Nantes.

ANDRE, a town of Phrygia in Asia Minor.

ANDRÉ, St., in *Biography*, born at Dijon, the 15th of February, 1704, received his education at Montpellier, and in 1729 was admitted member of the company of surgeons, at Versailles, and appointed one of the surgeons to the king. He applied himself particularly to the study of the diseases of the urethra, and was expert in the application of bougies, on which he placed his principal dependence in

these complaints, varying the ingredients of which they were composed, to make them more or less stimulating and eroding, as the circumstances of the cases required. In 1751, he published his "Dissertations pour les maladies de l'uretre, qui ont besoin de bougies," 12mo. Paris, and in 1758; "Maniere de faire usage des bougies antiverieennes," 8vo. also at Paris. For an account of other publications by this writer, see Eloy. Dict. Hist.

ANDREA, in *Geography*, a town of Africa, in Upper Guinea, about a quarter of a mile from the river Mesurado, and eight miles from its mouth; it contains about 40 or 50 houses; its chief riches are palm, wine, and rice; a trade is also carried on in ivory and slaves.

ANDREA ANDREANI, in *Biography*, an eminent engraver, was born at Mantua, and died A. D. 1623, at a very advanced age. Besides his own engravings, he procured many performed by other persons, and sold the impressions under his own name. He engraved only on wood, in a peculiar style, distinguished by the name of "Chiaroscuro," which is performed with two, three, or more blocks of wood, according to the number of tints required, which are stamped upon paper, one after another, so as to produce the effect of a washed drawing. The invention of this species of engraving was much prior to the æra of this artist. His great merit as an artist, is acknowledged by all who are conversant with his prints. His drawing is excellent, executed with great spirit, and in a very masterly style. The heads of his figures are characteristic and expressive, and he has displayed great judgment in the management of his various tints. His works are considered as admirable transcripts from the sketches of many of the greatest painters. Among his most finished prints may be reckoned, "Christ departing from Pilate," who is washing his hands; a large print lengthways, on two blocks, engraved from a bas relief of Giovan. Bologna; "An emblematical Print," representing the Christian, after his spiritual warfare in the present life, received as victorious into heaven, and crowned by Christ; "The triumph of Julius Cæsar," from Andrea Mantegna, the original of which is at Hampton Court; it is cut on 10 blocks of wood, dated 1598; "The entombing of Christ," from Raphael de Reggio; "The rape of the Sabines," from a group by Giovan. Bologna. The scarcest of all his works is said to be "The pavement of Sienna," after a drawing of Francesco Vanni. Strutt.

ANDREA DA PISA, a sculptor and architect, was born at Pisa in 1270. He built several castles, and the church of St. John, at Pitoli; but his skill in architecture was principally displayed at Florence, where he enlarged and fortified the palace of the duke, by erecting many mansions in it and surrounding it with magnificent towers and gates. On this account he obtained the right of citizenship. At the request of the duke of Athens, he made a model of a citadel, which he intended to erect for restraining the Florentines; upon which they took the alarm, and expelled the duke; but Andrea passed the remainder of his days at Florence, cultivating the fine arts, such as painting, poetry and music, besides those which were professionally his own, and died in 1345, aged 75.

ANDREA DEL SARTO. See SARTO.

ANDREA MANTEGNA. See MANTEGNA.

ANDREA, in *Geography*. See ANDROS, and ANDREW'S Cape.

ANDRÆ, JOHN GERHARD REINHARD, in *Biography*, an apothecary at Hanover, was born 17th December, 1724. By the attention of his mother he was well educated in the languages and sciences; and in 1744 he visited Berlin, where

where he attended lectures on chemistry, anatomy, botany, and natural history. In the following year he inspected the various mines in Saxony, and proceeded through Leipsick, Halle, the Hartz, and Cassel to Frankfort, where he resided till the Spring of the year 1746. From hence he removed to the university of Leyden, and studied chemistry under Gaubius, botany under Royen, and natural philosophy under Muschenbroek. In the year 1747, he visited England, and returned to Hanover where he succeeded to his father's business, in 1751, and distinguished himself by his skill and diligence. He wrote many useful papers in the Hanoverian Magazine, and other periodical works, by which he gained considerable reputation and esteem; in 1763, he made a tour to Switzerland, the original of which was published in 1776, in a 4to. volume, with engravings; and in 1765 he was charged by government to examine the principal kinds of earth and marl in the electorate, and to publish a work on their nature and use, for the benefit of farmers, which appeared in 1789, under the title of "A Treatise on various kinds of earth in his Britannic Majesty's dominions, &c. and their uses in agriculture." In December 1791, he was attacked by an inflammation of the urethra, which at length terminated in his death, on the first of May, 1793. His writings and collection of natural history procured for him an extensive acquaintance with men of literature and science, and an admission into many learned societies. Gen. Biog.

ANDREÆ, in *Entomology*, a species of CARABUS. The thorax orbicular, black, and glossy; wing-cases pale, with a black band in the middle. Fabricius. Inhabits Italy.

ANDREÆ, is likewise a species of CIMEX, that inhabits the West Indies. It is red, except the antennæ, flank of the legs, beak and wings, which are black. Linnaeus. The cimex ruficollis of Mus. Lud. Ulr., and cimex thoracæ nigro of Thunberg are supposed to be varieties of this species.

ANDREANOFSKIE-OSTROVA, or ANDRENOVIAN isles, in *Geography*, a cluster of islands, between Asia and America, which in a general view may be regarded as the same with the Fox islands, being the western part of the same range; or the Andrenovian isles, in a more limited sense, may be considered as forming a groupe of six or more isles, about 500 miles to the south-east of Beering's island. These, in both respects, are a kind of elongation of the American promontory of Alaska, and in the most recent maps of Russia they are comprehended under one general name of Aleutian isles.

ANDREAS, JOHN VALENTINE, in *Biography*, a Lutheran clergyman, was born in the year 1586; became dean of Vayhingen, chaplain to Everhard III. duke of Wurtemberg, abbot of Bebenhausen, and lastly of Adelberg; and died June 27th, 1654. His principal works are "Mythologia Christiana;" "De curiositate pernicie;" "De restitutione reipublicæ Christi, in Germania;" "Subsidia rei christianæ et literariæ;" "Theophilus, sive de religione christiana colenda;" "Menippus prior et posterior;" "Peregrinus in Patria;" "Fama Andream restitorem," which contains the life of his grandfather; and various poems in honour of Augustus, duke of Wolfenbuttel, inserted in a book, entitled "Scelenia Augustalia." Some have represented John Valentine Andreas, as the founder of the Rosicrucians. Gen. Biog.

ANDREAS, VALERIUS, a learned Brabanter, was born at the village of Dessel, November 25th, 1588. He studied the Greek language at Antwerp, under Andreas Schottus, and the Hebrew under John Hay, a Scots Jesuit; and his proficiency in the latter language was such that he was in-

vited to be professor of it at Louvain. He afterwards applied to the study of the law, and in 1621 obtained the degree of doctor. In 1625 he was appointed professor of the "Iustituta," and in 1638 librarian to the academy. His works are "Orthographiæ Ratio, ab Aldo Manutio collecta, nunc multis aucta; cum libello de ratione interpungendi ac cillinelis notis;" "De Initiis Collegii Bullidiani, deque vita et scriptis professorum ejusdem collegii;" "De Linguae Hebraicæ Laudibus, antiquitate, dignitate, necessitate;" "Dissertatio de Toga et Sago;" "Topographiæ Belgicæ." His principal work was "Bibliotheca Belgica, de Belgis vita Scriptisque claris;" first printed in 1623, and afterwards with considerable additions in 1643. Gen. Biog.

ANDREAS, JOHN, a famous canonist of the 14th century, was the natural son of a priest, and born at Mugello, near Florence. He prosecuted his studies at Bologna, and particularly that of the canon law, under the professor Guy de Baif, who procured for him the degree of doctor, gratis. He was a professor at Padua, about the year 1330, and also at Pisa; but he acquired the greatest reputation at Bologna. He is said to have led a very austere life, macerating his body with prayer and fasting, and lying upon the bare ground for 24 years successively, under a covering of bear-skin. He married a woman named Milantia, by whom he had a beautiful daughter, whom he called Novella, after the name of his mother, and who is said to have read lectures for him when he wanted leisure. Respect for his mother and affection for his daughter induced him to entitle his "Commentary upon the Decretals of Gregory IXth," the "Novellæ." Having lost his natural son Baricontius, who published several books, he adopted a learned canonist, whose name was John Calderinus, and gave him his daughter in marriage. Andreas died of the plague at Bologna in 1348, after having been professor 45 years, and was buried in the church of the Dominicans. He was the author of several books, such as "A gloss upon the sixth book of Decretals;" "Glosses upon the Clementines;" "A Commentary in Regulas Sexti," entitled "Mercuriales," either because it was written on Wednesdays, (dies Mercurii), or because it contained his Wednesday's disputations. He also enlarged the "Speculum of Durant," in 1347. However he has been accused of great plagiarism. Gen. Dict.

ANDREAS, JOHN, was born a Mahometan at Xativa, in the kingdom of Valencia, and succeeded his father as Al-faqi in that city. He was converted to Christianity by a sermon preached in the great church of Valencia, in 1487, and professing his faith was baptized, in memory of the calling of St. John and St. Andrew, by the name of John Andreas. Soon after his conversion, he became a priest and a public teacher, and was employed by king Ferdinand and queen Isabella, on a mission to the Moors of Grenada, many of whom he induced to abjure Mahomet, and to assume the profession of christianity. He was afterwards made a canon, and appointed to undertake the conversion of the Moors of Arragon; but the queen's death prevented the execution of this undertaking. However, he translated from the Arabick into the language of Arragon, the whole law of the Moors, that is, the alcoran and its glosses, and the seven books of the Suni. He also wrote a work, entitled "The Confusion of the sect of Mahmed," for the purpose of exposing the follies of Mahometanism, which was published first in Spanish, has been translated into many languages, and is often cited by those who have occasion to write against the Mahometans, as Hoornbeck, Hottinger, and Schultetus. Gen. Dict.

ANDREAS, TOBIAS, professor of History and Greek at Groningen, was born at Braunfels in the county of Solms, in 1604. He studied at Herborn under Alstedius and his uncle Piscator, and afterwards resided seven years at Bremen. After his return to his own country, in 1628, he removed to Groningen, where he read lectures on all parts of philosophy, and obtained the appointment of tutor to the sons of Henry Altius, his patron, and afterwards in the family of the Prince Palatine. In 1634 he succeeded James Gebhardus, as professor of History and Greek at Groningen, which office he retained till his death in 1676. He was distinguished by his attachment to Des Cartes, whom he vindicated by his writings, both during the life and after the death of that eminent philosopher. He instituted a prosecution against Martin Schookius, professor of philosophy at Groningen, for accusing Des Cartes of atheism. The result was, that the accuser acknowledged Des Cartes's innocence, but was himself acquitted. His "Methodi Cartesianæ Assertio," was published in the year 1653. Gen. Dict.

ANDREAS, JAMES, a famous Lutheran divine, was born at Waibling, in the dutchy of Wirtemberg, in 1528, and though of mean parentage, was encouraged in the prosecution of his studies first at Stutgard and afterwards at Tübingen, where he connected theology and Hebrew with philosophy, and took the degrees of bachelor and master of arts; and in 1546 he was appointed minister of the church of Stutgard; but upon the publication of the "Interim" he was obliged to retire to Tübingen, where he officiated as minister. In 1553 he took the degree of doctor of divinity, and was appointed pastor of the church of Gopping, and superintendent of the neighbouring churches. After performing several trusts that were devolved upon him, in order to promote the reformation from popery, he attended the diet of Worms in 1557, and was appointed one of the secretaries at the conference at Worms between the papists and the divines of the Augustan confession. In 1559 he attended the diet of the empire at Augsberg; and after his return from Paris, in 1561, he was made chancellor and rector of the university of Tübingen. In 1565 he established a church at Hagenaw, an imperial city, where he preached many sermons on the principal points of the Christian religion, which were afterwards printed. He took several journeys, in order to effect an union of the churches of the Augustan confession, and engaged in ineffectual conferences with Beza and others, with a view of terminating theological disputes. His last public act was a conference at Baden, in 1589, with John Pistorius, who then inclined to Calvinism, but afterwards revolted to popery. He had a presentiment of his death for some time before it happened; and upon its approach he expressed his constancy in the faith which he had asserted, and in the exercise of a lively devotion he expired in 1590, in the 62d year of his age. His character and learning were held in high estimation; and the books which he wrote were so numerous, that it was said that he left 150 works upon various subjects. Gen. Dict.

ANDREAS, ST. in *Geography*, a town of Germany, in the circle of Austria and dutchy of Carinthia, upon the river Lavant, with a bishopric suffragan of Saltzburg; 16 leagues east of Clagenfurt.

ANDREASBERG, a town of Germany, in the circle of Lower Saxony, and principality of Grubenhagen, having in its environs some considerable iron-mines, 12 miles from Goslar, and 12 from Northaufen.

ANDREE, YVES-MARY, in *Biography*, a French Jesuit, was born in 1675, at Chateaulin, in the county of Cornouailles. Having occupied the chair of professor

royal of mathematics at Caen, from 1726 to 1759, when he was 84 years of age, and enjoyed a repose of four years, he finished his laborious life in 1764. He was not only a good mathematician, but well acquainted with other branches of learning; and he also wrote elegant verses. Of his "Essay on the Beautiful," written in French, a new edition was given in a collection of his works, published in three volumes, 12mo. in 1766. The subject is treated with perspicuity of method, strength of argument, and dignity of style. Gen. Biog.

ANDREDCHESTER, a town of ancient Britain, supposed by Camden to be Newenden, in Kent, but by Somner to be Pevensey, or Hastings. It was besieged by the Saxons, under Ella, but relieved by the Britons. The town was afterwards taken and levelled with the ground, and the inhabitants were massacred without distinction of age or sex.

ANDREEVNA, in *Geography*, a town of Russia, in the government of Ekaterinoflav, 48 miles south-fourth-east of Ekaterinoflav. N. lat. 47° 50'. E. long. 32° 14'.

ANDREINI, ISABELLA, in *Biography*, a native of Padua, was one of the most celebrated actresses who appeared in Italy in the close of the 16th and beginning of the 17th century. Her person recommended her action: and she not only sung and played well, but possessed an excellent talent for poetry, so that she was universally admired. She was enrolled in the society of "Intenti" at Pavia; and Cinthio Aldobrandini, nephew of pope Clement VIII. wrote many verses in her praise. In France she was honourably received by the king and queen, and principal persons of the court, and in honour of them she composed several sonnets. She died in 1604 at Lyons, in the 42d year of her age, and was buried with distinguishing marks of attention. Her husband wrote an epitaph which bears testimony both to her morals and to her talents. An edition of her poems, consisting of sonnets, madrigals, songs, and eclogues, and a pastoral, intitled "Mirtilla," was published at Milan in 1605; and prefixed to it are many elegiac verses in Latin and Italian, written on occasion of her death. Some letters of hers were published at Venice in 1610. To her other qualifications were added some knowledge of philosophy, and an acquaintance with the French and Spanish languages.

Her husband, Francis Andreini, was a player, famous for rhodomontade parts; after his wife's death he left the stage, and became a writer of the same cast with that of his acting. Their son, John Baptist Andreini, was also an actor and a dramatic writer. A piece of his, called "Adamo," has been an object of curiosity, because it has been supposed to have afforded a hint to Milton in his Paradise Lost. See Hayley's Life of Milton. Gen. Dict.

ANDREJOF, in *Geography*, a town situate near the Borithenes, between Muscovy and Poland.

ANDRELINUS, PUBLIUS FAUSTUS, in *Biography*, a modern Latin poet, was born at Forli, in Italy, about the middle of the 15th century. His taste for poetry was manifested in early life; for his four books "De Amoris," written when he was only 22, were so well received, that he was solemnly crowned at Rome by the Roman academy. Here he became known to Ludovico Gonzaga, duke of Mantua, who patronized him, in 1484, as his own poet. In 1488 he was recommended by Gonzaga to the dauphin of France, and in the next year appointed public professor of belles lettres in Paris, an office which he held 30 years. To his public lectures he added private instructions; and he united with rhetoric and poetry the explanation of the sphere. He obtained honours and lucrative appointments from the kings, Charles VIII, Lewis XII, and Francis I;

and he was also pensioned by Queen Anne, of Bretagne, whence he styled himself, "Poeta regis ac regineus." Andrelinus was celebrated by many of his contemporaries as the first poet of the age, and as having contributed in an eminent degree, to promote literature in France. Erasmus, however, though he praised him when alive, gives an unfavourable account both of his talents and morals after his death. He charges him with licentiousness of manners, and with a tumultuous and quarrelsome disposition. Nevertheless he obtained a high degree of reputation as a professor and writer till the time of his death, which happened at Paris, in February, 1518; and his memory was honoured with elegies, inscriptions, &c. Vossius compares the poetry of Andrelinus, which consisted of sonorous verses and pompous expressions, without much meaning, to a river of words with a drop of sense, and Erasmus contests the grant of this drop. Most of his poems have been inserted in the first volume of the "Deliciae Poetarum Ital." They chiefly consist of elegies, eclogues, and panegyric pieces on various occasions. He also wrote moral and proverbial epistles in prose. Gen. Dict.

ANDRENA, in *Entomology*, one of the new genera in the Fabrician arrangement, consisting, for the most part, of such insects as belong to the *APIS* genus in the system of Linnaeus. The tongue is trifid, or three-cleft, lip cylindrical, and on each side two membranaceous bristles; antennae filiform. Fabricius. In the *Entomologia Systematica* of Fab. are thirty-one species of this genus. *viz.* caerulefscens, rufipes, spiralis, cornuta, labiata, florea, metallica, aenea, cyanea, marginata, helvola, bicolor, tricolor, curvipes, cincta, frigata, nigrita, fasciata, zonata, circulata, pilipes, carbonaria, hirsuta, hirtipes, haemorrhoidalis, gulosa, bidentata, nigricornis, virefscens, cingulata, and fuccinea, which see respectively.

ANDRENEH, in *Geography*. See ANDRONA.

ANDRENOVIAN ISLES. See ANDREANOFKIE-OSTROVA.

ANDRES, or ANDERO *Island*, is situated south-east by east from Cape Gracias a Dios, the farthest point eastward of the province of Honduras, not far from St. Catherine's, or Providence island, to the west-south-west, in N. lat. 12° 30', and W. long. 81° 40'.

ANDRES, a town of Asiatic Turkey, 60 miles east from Angora.

ANDRETTA, a town of Italy, in the kingdom of Naples, and Principato Ultra, six miles north of Conza.

ANDREW, in *Biography*, an apostle of Christ, was born of Jewish parents at Bethsaida, in Galilee. The name of his father, who was a fisherman of that town, was Jonas; and both he and his brother Peter followed that occupation. John Baptist, who was the herald of Christ, and who introduced him to the notice of the Jewish people as the promised Messiah, pointed him out to Andrew and Simon Peter, under the emblematic appellation of the Lamb of God; upon which they accompanied him to the place of his residence. Andrew seems to have been the first disciple of Christ; for he understood the sacrificial allusion of John, and said to his brother, "We have found the Messiah." John i. 35—41. He was afterwards chosen by Christ as one of his twelve apostles. To the brief account given by the evangelical writers of this apostle (Matt. iv. 18—20. Mark i. 16—18. i. 29. xiii. 4. John vi. 7. xii. 20—22.) tradition has added several particulars of less certain authenticity. Eusebius relates, (Eccl. Hist. lib. iii. c. i. p. 71.) that, when the apostles arranged the objects of their mission for the propagation of Christianity, Andrew made choice of Scythia. Other accounts are less worthy of credit than this.

"The Acts of the passion of St. Andrew," which mention his martyrdom at Patre, in Achaia, and said to be written by the priests of Achaia, are preserved in Surius's History of the Saints, and approved by Baronius, Bellarmine, and others of the Romish communion: but they are rejected by the best critics as spurious. The ancients, says Dupin (History of the Canon, &c. vol. ii. p. 149.), knew no other acts of St. Andrew besides those which had been corrupted by the Manichees, mentioned by Eusebius, (Eccl. Hist. lib. iii. c. 25.) Philastrius (Heres. 87.) Epiphanius (Heres. 47. n. 1. Id. 61. n. 1. Id. 63. n. 2.) and Augullin (de fide. cont. Manichaeos) and which pope Geladius has placed among the apocryphal writings. This work was not cited till the seventh century; and neither its doctrine nor language agrees with those of the early ages. Besides, these Acts of St. Andrew are not found in any of the ancient catalogues of the sacred books, nor are they appealed to by any Christian writers, nor read in any of their assemblies, but on the contrary expressly condemned as an impious forgery by every one who has mentioned them. As they contained some doctrines which were favourable to the Manichees, Encratites, Apotacticks, or Apostolicks, and Origenians, it is no wonder that they should have esteemed this apocryphal piece above other scriptures. The "Gospel of Andrew," and other books that have been sanctioned by his name, belong to the same class of apocryphal writings. The relation of those who say that he was crucified on a cross in the form of the letter X, hence vulgarly called St. Andrew's cross, or on an olive tree, which others have asserted, is entitled to no credit; nor indeed is it certain that he was crucified. According to Jerom (Adv. Vigil. p. 22.) his body was removed with St. Luke's to Constantinople in 357. The accounts of this apostle that are given by Gregory of Tours in the sixth century, by Nicephorus of Constantinople in the 9th, and by Nicephorus Callistus in the fourteenth, contain many fabulous particulars. The legend of Gregory, therefore, will claim no regard; which informs us, that streams of oil flowed from the tomb of this saint on the anniversary of his martyrdom, and sometimes swelled to the middle of the church. Dupin, ubi supra. Jones's Canon, vol. 1. p. 145—187. Fabr. Cod. Apoc. Nov. Test. p. iii. p. 526.

ANDREW, bishop of Caesarea, in Cappadocia, lived, according to Cave, about the year 500. He wrote a commentary upon the book of Revelation, prefacing it with asserting the inspiration of the book, for which he appeals to the authorities of Gregory the divine, Cyril of Alexandria, Papias, Irenaeus, Methodius, and Hippolytus, and dividing it into 24 larger, and 72 smaller sections. He appears to have received as authentic all the books of the New Testament which we receive; he mentions the symbols of the four evangelists, *viz.* the lion for John, the calf for Luke, the eagle for Mark, and the man for Matthew. After reciting some opinions with regard to the period of a "thousand years," mentioned in this book, he considers it as denoting the time of the preaching of the gospel, or the time of the gospel dispensation. Cave. Hist. Lit. tom. i. p. 467. Fabr. Bib. Graec. tom. vii. p. 791. Lardner's Works, vol. v. p. 249—252.

ANDREW, bishop of Samosata, was an intimate friend of Theodoret, and flourished in the fifth century. About the year 429 he was appointed by John, bishop of Antioch, to refute, on behalf of the eastern bishops, the "Anathematisms" of Cyril. Under the pretence of illness he declined attending at the council of Ephesus; however, he vigorously opposed the Nestorians, and for many years renewed his hostilities against Cyril. Some curious extracts from his first book against Cyril are found in Cyril's "Apologetics for his

his Anathematifms." Smaller fragments of his second book against Cyril are preserved by Anallafius the Sinaite in his "Hodegos." Eight letters of Andrew, in an ancient Latin version, are published in the collection of "Ephesian Epistles," by Lupus. Cave, Hist. Lit. vol. i. p. 419. Fabr. Bib. Græc. vol. x. p. 124.

ANDREW, bishop of Crete, was a native of Damascus, and flourished at the close of the seventh and beginning of the eighth century. Cave places him about the year 635. The early part of his life was spent by him as a monk at Jerusalem. Theodoret, patriarch of Jerusalem, invited him to attend the sixth general council of Constantinople; and he afterwards copied the acts of that assembly against the Monothelites. He was appointed bishop of Crete, and probably remained in that see till his death, about the year 720. He wrote several homilies, which are extant; and which, according to Mosheim, (Eecl. Hist. vol. ii. p. 174.) are destitute of true piety and cloquence. They were collected, and published in folio by Francis Combefius, at Paris, in 1644. Cave, Hist. Lit. vol. i. p. 582. Fabr. Bib. Græc. lib. v. c. xli. § 2. tom. x. p. 121.

ANDREW, JOHN, secretary of the Vatican library, was employed under the popes Paul and Sextus IV. when printing was first introduced into Rome, in revising MSS., writing prefaces and dedications, and correcting the prefs. Cardinal de Cusa, who had been his school-fellow, gave him the bishopric of Accia in Corsica; and pope Paul II. afterwards appointed him to that of Aleria in the same island, where he died. He published an edition of Livy, and of Aulus Gellius, printed at Rome, in folio, in 1469; of Herodotus, in 1475; and of Strabo, printed at Venice, in folio, in 1472. He was also the editor of the Epistles of Cyprian, and of the works of S. Leo. Nouv. Dict. Hist.

ANDREW, presbyter of Ratibon, was an historian of the 15th century, and flourished under the emperor Sigismund. He wrote in Latin "A Chronicle of the Dukes of Bavaria," published at Amberg; and "A History of Bohemia," in seven books. His countrymen called him a second Livy. Voff. de Hist. Lat. lib. iii. c. 5.

ANDREW I. king of Hungary, was a prince of the blood-royal, and eldest son of Ladislaus the Bald. When Peter was restored in the year 1044, he was obliged to take refuge in Russia; but the idolatrous Hungarians promised to kill Peter, and to expel all foreigners, provided Andrew would abolish the Christian churches. The compact was settled; and, after great slaughter and plunder, Andrew was placed on the throne in 1047, instead of Peter, who was imprisoned, lost his eyes, and soon died. Andrew, however, in violation of his promise, obliged all his subjects to profess Christianity. After having settled his disputes with Albert of Austria, he invited his brother Bela, with his family, to settle in Hungary, and assigned him a third part of his dominions. When the emperor Henry III. invaded Hungary, he was reduced to such straits by Andrew and Bela, that, in order to avoid total destruction, he entered into a treaty, of which it was one condition, that the daughter of Henry should be married to Solomon, the son of Andrew. This son was five years old, and he was then crowned; but, fearing that his brother Bela would disturb the succession, Andrew sent for him, and instructed two of his confidential servants how to act. "I shall offer him," said the king, "a crown, the symbol of the royal authority, and a sword, that of the church. If he chooses the former, instantly put him to death; if the latter, let him live." An officer, who overheard this order, whispered to Bela, "chuse the sword." Accordingly he took the sword, and his brother Andrew was satisfied; but Bela soon after retreated to Poland, and came from thence at the

head of an army to dethrone him. Andrew was protected by the emperor; but, meeting his brother on the banks of the Teifs, he was defeated, abandoned by his own men, and killed in the pursuit, A. D. 1059. Mod. Un. Hist. vol. xxxii. p. 107.

ANDREW II. king of Hungary, was the second son of Bela III. Having occasioned a rebellion against his elder brother Emerick, he was deserted by his army, and, in endeavouring to make his escape, taken prisoner, and brought to Emerick, by whom he was freely pardoned. From this time his sentiments were so changed, that he became a steady supporter of the throne. Upon the death of his nephew Ladislaus, Andrew succeeded, and was crowned by the universal consent of the states. During the first twelve years of his reign he enjoyed unmolested peace; but when pope Honorius III. ordered a new crusade to be preached, Andrew resolved to make an expedition into the Holy Land. He proceeded to Constantinople; but there he heard that during his absence a tragical event had occurred in his kingdom. The government had been entrusted to Banchanus, one of the nobles, and it was administered to universal satisfaction. But the wife of the governor, who was very beautiful, was debauched by Queen Gertrude's brother, who visited her during the king's absence, and the queen was accessory to the dishonour. The injured lady informed her husband of this atrocious act; upon which he revenged himself by slaying the queen; and, rushing out into the street with his bloody sword, he published his wrongs, and the revenge he had taken; declaring, at the same time, that he would not decline a trial, but go immediately to Constantinople to receive the sentence of the king. Andrew acquitted him, and ordered him back to his government. At the trial the accusation against the queen was found to be just. Banchanus was acquitted, but his family was ruined by the resentment of the king's sons. Andrew transported his troops into Syria, and displayed his courage in some conflicts with the Saracens; but, being weary of the expedition, he determined to return home, though he was threatened with excommunication by the patriarch of Jerusalem. He proposed, however, to leave one-half of his troops in Palestine, under the command of the duke of Austria, and with the other half he was allowed to return into Hungary. Accordingly he set sail on board the Venetian fleet, with a variety of precious relics, and with the title of the "Hierosolymitan;" and, in his visit to the prince of Este, by whom he was honourably entertained, he fell in love with his daughter, married her, and took her with him into Hungary. The remaining period of his reign was devoted to the business of healing the discontents of his subjects, and forming a system of legislation. Besides other measures which he adopted, he was the author of a famous decree, which confirmed and augmented the privileges of the nobility, and allowed them to take up arms in their defence, if he or his successors attempted to abridge them: a stipulation nugatory against a powerful monarch, and which has answered no other purpose than that of rendering the aristocracy factions, and the body of the people slaves. Towards the end of his reign the Tartars made some successful inroads into Hungary. Andrew, having reigned 31 years, died in 1235, and left the kingdom to his eldest son Bela, to whom he had ceded the sovereignty before his death. Mod. Un. Hist. vol. xxxii. p. 120—123.

ANDREW III. king of Hungary, was the grandson of Andrew II. and being born and brought up in Venice, obtained the surname of "Venetian." On the death of Ladislaus in 1290, he succeeded to the throne, in opposition to a number of competitors, by the unanimous consent of the Hungarians. In his way from Italy through Austria he was

detained by duke Albert; and obtained a release by promising to espouse Agnes, the duke's daughter. But in the year after his accession he declared war against Albert, and laid waste the country, till at length a peace was obtained by the intercession of the prelates. Upon his return to Hungary, Andrew found his kingdom in a distracted state; the pope and many of the ecclesiastics and nobles having acknowledged the right of Charles Martel, who, in consequence of their invitation, had set out for Hungary with his wife and son, Charles Robert, or Chaubert, then an infant. The majority of the Hungarians were attached to Andrew; but as the party of Charles was very numerous, and Andrew having no children, Charles continued in possession of part of Hungary for several years without opposition. The two rival kings are said to have both died in the same year, 1301. Charles, having gone to the jubilee at Rome, died at Naples. Andrew died at Buda, and, leaving no male issue, the line of St. Stephen terminated in him. Mod. Un. Hist. vol. xxxii. p. 129.

ANDREW, *Knights of St. Andrew, or the Thistle*, commonly called the *Order of St. Andrew*, in Scotland; according to John Lesley, bishop of Ross and others, was instituted by Achais, king of Scots, in memory of an appearance in the heavens of a bright cross in fashion of that whereon St. Andrew suffered martyrdom, and seen by that king the night before the battle which he fought with Athelstan, king of England, over whom prevailing, he went in solemn procession to the kirk of St. Andrew, to thank God and his apostle for the victory; promising that they and their posterity should ever have the figure of that cross in their ensigns and banners. Favin, in his Theatre of Honour, relates it to be instituted upon the famous league, offensive and defensive, made between Achais and Charlemagne, king of France; to preserve the memory of which alliance, Achais added the tressure of fleurs de lys to the lion, the then royal arms of Scotland, and took for device the thistle and rue, which he composed into a collar of his order; and for his motto, *Pour ma Defence*. Menenius makes these the symbols of two different orders; one of the Thistle, whence the Knights were so styled, and the motto, *Nemo me impune lacessit*; the other called *Sortium Ruta*, or Garland of Rue: nevertheless, to both collars hung one and the same jewel, that is, the figure of St. Andrew bearing his cross. Their solemn meeting was annually on St. Andrew's Day, in the church of the town dedicated to his name; at which the knights, thirteen in number, in allusion to our blessed Saviour and the twelve apostles, were richly habited, and wore their parliament robes, having thereon embroidered on their left shoulder an azure roundle charged with a saltier argent, St. Andrew's cross enfilled in centre, with a crown composed of fleur de luces or. The sudden death of James V. of Scotland, the rebellion against Queen Mary, and the troubles which ensued in that kingdom nearly extinguished the order, which continued to be neglected until it was revived by King James II. of England, who, on the 20th of May, 1687, issued his warrant for letters patent to be made out and passed *per saltum*, under the great seal of Scotland. In consequence of this revival several new knights were made, and the order continued to flourish during the remainder of that king's reign; but on his abdication, and the advancement of King William to the throne, the order was again disused.

Queen Anne, by her letters patent, bearing date at St. James's, 31st Dec. 1703, revived, continued, and re-established the order; and ordained by the statutes, "that the number of knights should consist of twelve besides the sovereign, making in the whole thirteen, as heretofore; that the sovereign's habit should be such as the sovereigns them-

selves should think fit to appoint; that the habit of the brethren should be a doublet and trunk-hose of cloth of silver, stockings of pearl coloured silk, with white leather shoes, garters and shoe-strings of green and silver; the breeches and sleeves of the doublet decently garnished with silver and green ribbons; a surcoat of purple velvet lined with white tassetta, girt about the middle, with a purple sword belt edged with gold, and a buckle of gold, at which a sword with a gilded hilt, the shell thereof to be in the form of the badge of the order, and the pomel in the form of a thistle, in a scabbard of purple velvet; over all a mantle or robe of green velvet lined with white tassetta, with tassels of gold and green; and upon the left shoulder thereof, in a field of green, the image of St. Andrew the apostle, bearing before him the cross of his martyrdom of silver embroidery, with a circle of gold round it, upon which the motto, NEMO ME IMPUNE LACESSIT, in letters of green; and at the lower part of it a thistle of gold and green, the flower reddish. That about the shoulder of each knight should be worn the collar of the order, consisting of thistles and sprigs of rue going betwixt, and at the middle thereof before should be hung the image of St. Andrew, chased and enamelled on rays of gold, the cross and feet resting upon a ground of enamelled green, or if of diamonds, to consist of just thirteen in number; and that the collar should be tied to the shoulders of the robe, and the knights have white ribbons upon their heads on days of solemn procession or feasting, where the sovereign is present, or has a commissioner for that effect. That they should wear, at the times of permission, a cap of black velvet, a little divided before, wide and loose in the crown, having a large plume of white feathers, with a black aigrette, or heron's top in the middle of it; the borders of the cap adorned with jewels. That the jewel of the said order should be worn at a green ribbon over the left shoulder, cross the body, and tied under the right arm; such jewel to have on the one side the image of St. Andrew, with the cross before, enamelled as is above said, or cut on stone, enriched with precious stones round it; and on the back, enamelled on a green ground, a thistle gold and green, the flower proper with the before mentioned motto round it.

That the medal of the order should be all of gold, the St. Andrew bearing before him the cross of his martyrdom, with a circle round, and then the motto of the order; and at the lower part of the circle, between the joining of the words, a thistle; and to be worn in a green ribbon as the jewel, at times when the jewel is not worn. That upon the left breast of the coat and cloak should be embroidered a badge of proportionable bigness, being a St. Andrew's cross of silver embroidery, with rays going out betwixt the points of the cross; on the middle thereof a thistle of gold and green, upon a field of green, and round the thistle and field a circle of gold, having on it the motto of the order in letters of green." This order is styled The most Ancient Order, was instituted in 787, restored in 1540, revived in 1687, and re-established in 1703, for the sovereign, twelve knights, and four officers, viz. the Dean, Lord Lyon, King of Arms, Secretary, and Gentleman Usher of the Green Rod. There being no installation of this order, the star and collar are worn immediately after the investiture. See Plate 9.

ANDREW, *St. Knights of*, in Russia. This order was instituted by Peter the Great of Muscovy, in 1698, soon after his return from his first expedition into foreign countries, and intended for animating the nobility in his war against the Turks. St. Andrew was chosen as patron of the order, from the Russian tradition, that he introduced Christianity among them. The Knights of this order, among whom were the kings of Sweden and Poland, wear the figure of the Saint on an enamelled cross, formed by the imperial eagle; at the corners of the cross are the four letters, S. A. P. R. "Sanctus Andreas Patronus

Patronus Ruffie;” and in the middle an A. the initial of the empress Anne, who framed the statutes, and assigned the habit of the order. The feast is held on the 30th of November. In 1790 it had 63 knights. The badge is fastened to a blue ribband, and suspended from the right shoulder; but at festivals is pendent to a collar of gold composed of square chains and roses.

ANDREW'S *Cross*, is a badge worn in the hat by the people of Scotland, on the day of the feast of that Saint.

It consists of blue and white ribbands, disposed into a cross, or *saltire*; and is intended as a commemoration of the crucifixion of St. Andrew, the tutelary Saint of Scotland.

ANDREW'S ST. in *Geography*, an ancient town of Scotland, in the shire of Fife, and formerly the metropolis of the kingdom of the Picts. It is seated on an eminence, and commands an extensive prospect. N. lat. 56° 18'. W. long. 2° 37'. The legendary account of the origin of this city is as follows: St. Regulus, a Greek of Achaia, being warned by a vision to leave his native country, and to visit Albion, an isle situated in the remotest part of the world, was instructed to take with him the arm-bone, three fingers, and three toes of St. Andrew. After a tempestuous passage he was shipwrecked on the coasts of Otholonia, in the territory of Hergulfus, king of the Picts, in the year 370. The king, as soon as he heard of the disaster, ordered the strangers to be respectfully received, and granted to the saint his own palace, near which he built a church, called St. Regulus. The place was then styled Mucrofs, or the Land of Boars. St. Regulus changed the name to Kilrymont, and established the first Christian priests of the country, called Culdees. This church was supreme in the kingdom of the Picts; and Ungus the king ordained that the cross of St. Andrew should become the badge of the country. In 518, after the conquest of the Picts, the episcopal see was established at St. Andrew's, and the bishop was styled, “Maximus Scotorum Episcopus.” It is said to have been erected into an archbishopric at the intercession of James III. This see contained the greatest part of the shire of Fife, with a part of Perth, Forfar, and Kincardine shires, and a great number of parishes and churches in other dioceses.

The town of St. Andrew's was erected into a royal borough by David I. in 1140, and its privileges were afterwards confirmed. The charter of Malcolm II. on a small piece of parchment, is preserved in the tolbooth; and here are also deposited the silver keys of the city, which are delivered to the king if he should visit the place, or to a victorious enemy. The axe, which in 1646 took off the heads of Sir Rt. Spotswood, and other distinguished loyalists, is shewn in this place. St. Andrew's is now much reduced as to the number both of houses and inhabitants, the latter being estimated at about 2000. It is still decorated with magnificent relics of its ancient splendour. The principal of these is the cathedral, which was founded by bishop Arnold in 1161, but it was not completed till the year 1318. Its demolition, however, was effected by John Knox and his followers, in 1559, in one day. The eastern end, with its two high pinnacles, is complete; and one turret of the west point yet remains, adorned with some curious carved work in a peculiar style; but the pillars and some of the arches of the side aisle, exhibit a specimen of the pure Gothic, when it admitted of very little ornament: the precinct of this church forms a common burial-place to the town. In the centre of the inclosure is a plain, square tower, of a very extraordinary height, different in its structure from the cathedral, and not unlike some of the relics of Norman architecture in England. This is the tower of the chapel of St. Regulus, the body of which remains, but the inside chapels are demolished. The arches of

the windows and doors are round, and some exceed semi-circles; whence we may infer the antiquity of the building. Some trace it to a very early period; but it is commonly thought to have been founded in the eighth century, and esteemed the earliest Christian church in Scotland. The priory was founded by Alexander I. in 1122; and the monks, who were canons regular of St. Augustine, were brought from Scone in 1140, by Robert, bishop of this see. By an act of parliament in the reign of James I. the prior had precedence of all abbots and priors; and on the festival days wore a mitre and all episcopal ornaments. The revenues of this priory were very considerable, being in money 2237*l.* 2*s.* 10½*d.* besides large quantities of different sorts of grain, and 480 acres of land. The ruins adjoin to those of the cathedral; and nothing now remains but the inclosing wall, which encompasses a large area, and one single arch, very much defaced. The inclosure extends from the cathedral to the shore. Above the harbour stood the collegiate church of Kirk-heugh, originally founded by Constantine III. who is said to have retired hither from the world, and to have become a Culdee. The remains of the castle occupy the summit of a high eminence, which overhangs the coast. Separated from the town by a deep chasm, over which was a draw-bridge, and from the country by an impetuous sea, foaming over a rocky bed, this castle was justly esteemed one of the strongest fortifications in the island. It was founded in 1401 by bishop Trail; and it was the residence of cardinal Beaton in the zenith of his power and prosperity: but with all his attention to render it, as he conceived, impregnable, it was not of sufficient strength to defend an ambitious ruler against the rage of an exasperated people. In this fortress the cardinal was surpris'd by Norman Leslie, with 15 attendants, in 1546, and assassinated in the midst of his numerous retinue. In 1547 the castle, possessed and guarded only by 150 men for five months, was at last reduced and demolished. The death of Beaton led to the downfall of the Catholic religion in Scotland; and with that religion the finest edifices of St. Andrew's mouldered into ruins, its castle was neglected, and the city deserted. The entrance into the castle is still visible; and strangers are shewn the window out of which, it is said, the cardinal leaned to enjoy the cruel martyrdom of George Wishart, who was burnt on an adjoining spot. Of the four great parallel streets of this city only one now remains entire; one being totally lost, and other two in a very decayed condition. The university of this city was founded in 1411 by bishop Wardlaw. It consisted once of three colleges. St. Salvator's was founded in 1458 by bishop Kennedy. This is an irregular pile of building, of considerable extent, united with a large church, which contains a fine old monument of the founder, who died in 1466. The interior of the college, though spacious, is gloomy, and consists of two large old halls, and a range of apartments in rather a more modern taste, of which, however, only one side is finished. The college of St. Leonard was founded by Prior Hepburn in 1522, but it is now converted into private houses, and the collegiate part is united with the last. The third college is the New, or St. Mary's, which was established by Archbishop Hamilton, in 1553; but the house was begun by James and David Beaton, who did not live to complete it. This has a far more cheerful aspect than the old college, though it is much smaller. The library belonging to the whole university is connected with this college. In this library are kept two curious maces, exquisitely carved in brass work, and a fourth is preserved in the audit-room of the old college. These maces were dug for under the great altar of the cathedral by the direction of an old man, who was said to have in his possession

possession many papers relating to the church and its environs; six were found, one of which was presented to each of the three universities of Edinburgh, Glasgow, and Aberdeen; and the other three are kept at St. Andrew's. On the site of this college formerly stood, as it is said, a "Schola illustis," long before its establishment into an university. It is called the "New College," because of its late erection into a divinity college by the archbishop.

This university is governed by a chancellor, who is elected by the two principals, and the professors of both the colleges. The rector is the officer to whose superintendance are committed the privileges, discipline, and statutes of the university. Each college has a principal; that of St. Salvador has nine professors, and the New College has five professors. The students in the former are generally about 100, and in the latter about 30. This university has many advantages to recommend it in point of situation, instruction, and discipline.

The comerece of St. Andrew's is inconsiderable; and its manufactures, whatever they might formerly be, are reduced to that of golf-balls, which maintains a great number of people.

ANDREW'S, *ST. Bay*, is situated between the Forth and the Tay. The haven is defended from the violence of the easterly sea by a stone pier; the entry is very narrow, and it has only seven or eight feet at neap tides, and ten or eleven at spring tides. The city is at the bottom of the bay close upon the shore.

ANDREW'S, *ST.* a small town of America, in the contested country between New Brunswick and the United States, situated behind an island of the same name, on the east side of the arm of the inner bay of Passamaquoddy, called Scoodick. The town is laid out in the form of an oblong square, and the inhabitants are chiefly employed in the lumber trade.

ANDREW'S, *ST.* is a township in Caledonia county in Vermont, 100 miles north-east from Bennington.

ANDREW'S, *ST.* is also a parish in Charlestown district, South Carolina, containing 2947 inhabitants, of whom 370 are whites, and 2546 slaves.

ANDREW'S, OR ANDRES, *ST. Bay*, a secure harbour in the gulf of Mexico, on the south coast of West Florida in North America. It is situated between Santa Rosa bay on the north-west, and St. Joseph's bay on the south; and being almost surrounded by land, it is well sheltered from almost all winds. N. lat. $30^{\circ} 15'$. W. long. $85^{\circ} 45'$.

ANDREW *Bay*, lies on the north shore of the Straits of Maghellan, between Port Holland on the east, and Cordes bay on the west, at the entrance of which there is a good anchorage in 12 fathoms water.

ANDREW'S, *ST.* OR ANDREA, *Cape*, lies on the west coast of Madagascar island, in the Indian or eastern ocean, and nearly east from Mozambique, on the coast of Africa. S. lat. $15^{\circ} 46'$. E. long. $45^{\circ} 22'$.

ANDREW'S, *ST. Cape*, lies also on the eastern coast of South America, between Rio de la Plata, on the north-north-east, and Anegada bay on the south-south-west. S. lat. $37^{\circ} 55'$. W. long. $60^{\circ} 45'$.

ANDREW'S, *ST. Cape*, is also on the north shore of Maghellan Straits, in the reach which trends from Cape Forward to the West.

ANDREW'S *Cape*, OR ANDREA, lies on the east point of Cyprus. N. lat. $35^{\circ} 31'$. E. long. $34^{\circ} 55'$.

ANDREW'S, *ST. Island*, OR ANDREA, is a small island in the gulf of Venice, on the west side of Lissa island.

ANDREW'S, *ST. River* and *Point*, lye on the coast of Africa, north-east by east from Cape Palmas, at the distance of 20 or 30 leagues. They are situated in that track

of coast, extending seven leagues, which is called the Red Cliffs, or Red Land. Although no ships go up this river, a considerable traffick is carried on by means of the canoes of the Negroes, who bring down teeth for sale. Wood and water may be procured here, but no provisions.

ANDREW'S, *ST. Sound*, lies south of Jekyl's island, and is formed by this and a small island at the mouth of the Great Sagilla River. The small river opposite to this sound separates Camden from Glynn county, in Georgia.

ANDREW'S, LANCELOT, in *Biography*, an English divine, was born at London in 1565, and was bishop of Winchester, in the reign of James I. and Charles I. From Merchant Taylors' school he was sent to Pembroke Hall in Cambridge; and by his assiduous application he became acquainted with the sciences and most modern languages, and he excelled more especially as a casuist, and was often consulted in cases of conscience. The following anecdote will illustrate this part of his character: a corpulent alderman of Cambridge, who had been often reproved for sleeping at church, and whose conscience troubled him on this account, applied to him for advice. Andrews told him it was an ill habit of body and not of mind, and advised him to eat little at dinner. The alderman tried this expedient, but found it ineffectual. He applied again with great concern to Andrews, who advised him to make a hearty meal as usual, but to take his full sleep before he went to church. The advice was followed, and the alderman came to St. Mary's church, where the preacher was prepared with a sermon against sleeping at church, which was thrown away, for the good alderman looked at the preacher during the whole sermon time, and spoiled his design. Andrews's lectures, as a casuist, were attended by a numerous auditory. His learning, popular talents as a preacher, and zeal for the Protestant cause, procured for him the patronage of Henry Earl of Huntingdon, and Sir Francis Walsingham, secretary of state to Queen Elizabeth; and he passed through several stages of preferment to the deanery of Westminster. Whilst he resided in London as prebendary and residentiary of St. Paul's, he read divinity lectures in that cathedral three times a week during term time; and he also maintained a connection with his college, of which he was chosen master, and to which he was a liberal benefactor. Andrews's style of preaching, which was pedantic and quaint, suited the taste of king James I. so that he was a great favourite with this prince. The king selected him in order to vindicate his sovereignty against the vehement attack of Bel-larmine, who, in reply to "James's Defence of the Rights of Kings," had written a tract under the fictitious name of Matthew Tortus. The dean's answer was intitled "Tortura Torti;" or Tortus Tortured, and printed in 4to. in 1609. This service was so acceptable, that in this year he was advanced from the see of Chichester, to which he had been promoted in 1605, to the bishoprick of Ely; and he was also nominated a privy counsellor, first for England, and afterwards for Scotland, where he attended the king in his journey to that kingdom. In 1618 he was raised to the bishoprick of Winchester, and the deanery of the king's chapel, which preferments he held till his death, which happened at Winchester-house, in Southwark, in 1626, in the 71st year of his age. He was buried in the parish church of St. Saviour's, Southwark, and a monument of marble and alabaster was erected over his grave, on which is an epitaph written by one of his chaplains in the highest style of panegyric. Bishop Andrews appears to have been a man of eminent talents, acquisitions, and virtues. He is said to have understood 15 languages: he employed a large portion of each day in devotion and study; and his learning and affability commanded the respect not only of his own countrymen,

men, but of foreigners, by whom he was visited; such as Vossius, Grotius, Casaubon, Cluverius, Erpinus, and Dumoulin. His first biographer, Isaacson, informs us, that in the distribution of preferment he was disinterested, impartial, and judicious; that he provided liberally for the descendants of his early instructors and benefactors; that, after he became bishop, he never visited either of the universities without leaving 50 or 100*l.* to be distributed among poor scholars; that his charity kept pace with his advancement, his private alms amounting in the last six years of his life to upwards of 1300*l.* and that, as he died a bachelor, he left large legacies to charitable uses; and among the rest, a great part of his estate to be distributed among his servants. Bishop Andrews was a faithful son and zealous defender of the church; at the same time he was moderate in his political principles, independent in his spirit, and superior to the mean adulation that disgraced the court of James, as the following anecdote, related in the life of Waller the poet, will shew. Mr. Waller, going to the king at dinner, overheard a conversation between his majesty and two prelates, the bishop of Winchester and Dr. Neale, bishop of Durham, who were standing behind the king's chair. His majesty asked the bishops, "My lords, cannot I take my subjects' money when I want it without all this formality in parliament?" The bishop of Durham readily answered; "God forbid, Sir, but you should; you are the breath of our nostrils." Whereupon the king turned and said to the bishop of Winchester, "Well, my lord, what say you?" "Sir," replied the bishop, "I have no skill to judge of parliamentary cases." The king answered, "No put off's, my Lord, answer me presently." "Then Sir," said he, "I think it lawful for you to take my brother Neale's money, for he offers it." Milton thought bishop Andrews worthy to be celebrated by his pen; and, at the age of 17, wrote an elegy on his death, abounding with that rich fancy which has rendered his works immortal. The works of bishop Andrews, besides that already mentioned, are, "A Manual of Private Devotions;" "A Manual of Directions for the Visitation of the Sick;" a volume of tracts chiefly in Latin, consisting of sermons, theological dissertations on the ecclesiastical rights of princes, tythes, usury, &c. published in 4*to.* in 1629; a posthumous volume of "Sermons," published in folio by direction of the king, and under the inspection of the bishops of London and Ely; "The Moral Law explained; or Lectures on the Ten Commandments," with other sermons, printed in folio in 1642; and "A Collection of Posthumous and Orphan Lectures," delivered at St. Paul's and St. Giles's, Cripplegate, printed in folio in 1657. The sermons of bishop Andrews, though learned and pious, afford many specimens of that pedantry and false wit which marked the period in which he lived, and cannot be read with pleasure in an age of more correct taste. Biog. Brit.

ANDRIA, in *Antiquity*, a name given by the Cretans to the public entertainments, at which whole cities, tribes, or other bodies of men, were present. They were first instituted by Minos of Crete, and, after his example, appointed by Lycurgus at Sparta. They were conducted with the greatest frugality and decorum, and persons of all ages were admitted to them.

The hall, or place of eating, where these entertainments were held, was denominated *andrion*, in the uppermost part of which was a constant table set apart for strangers.

ANDRIA, is also used by some naturalists, to denote a species of hermaphrodite, wherein the female sex has the predominancy.

ANDRIA, in *Ancient Geography*, now the *Indre*, a river

of the interior of Gaul, which, uniting with the *Caræ*, discharges itself into the *Liger*.

ANDRIA, a town of Greece, in the district of Elis.

ANDRIA is also a town of Macedonia.

ANDRIA, or ANDRI, in *Geography*, a town of Italy, in the kingdom of Naples and province of Bari; the see of a bishop suffragan of the archbishop of Trani. It is situated in a valley with hilly environs, about four miles from the coast of the Adriatic, five miles west-south-west of Trani. This town is said to have been built by Peter the Norman, and to have derived its name from the antra or caverns in which the first settlers took up their abode. N. lat. 41° 15'. E. long. 16° 17'.

ANDRIACA, in *Ancient Geography*, a town of Thrace, on the coast of the Euxine sea, near Salmydessus, according to Strabo.

ANDRIACA is also a town of Asia Minor, in Lycia. According to Appian this was the port of Mira; but M. d'Anville places it to the south-west of Mira.

ANDRIACA is a town placed by Ptolemy in Media.

ANDRICLUS, a high mountain in Cilicia Trachea, placed between the promontory of Anemurium, and the river Selinus.

ANDRICUS, a river of Cilicia, according to Pliny.

ANDRIMACHIDES, a people of Africa whose country is not known; but Alexander ab Alexandro reports, that their king obtained the first favour of the young women before they were introduced to their husbands.

ANDRINOÛLE, in *Geography*. See ADRIANOÛLE.

ANDRIPOURA, or INDRAPOOR, a country of the island of Sumatra, including a town of the same name, and several others; the chief article of commerce is pepper. The town is situated on a rapid river, 60 miles north-west of Bencoolen. S. lat. 2° 15'. E. long. 101°.

ANDRISCUS, called by the Romans *Pseudo-philippus*, in *Biography*, is said to have been a native of Adramyttium, and descended from mean parents. He assumed, however, the character of a natural son of Perfes, 16 years after the death of the king of Macedon, pretending, that his father had sent him to Adramyttium in disguise, and that he was not to disclose the secret of his birth till he arrived at the age of 14 years. Resembling Perfes in his person, the story was more credible; and accordingly he went to the court of Demetrius Soter, who had married a daughter of that king. Demetrius, either suspecting the imposture, or dreading the Romans, delivered him up to the republic. From Rome he made his escape, and sought refuge in Thrace. Here he assembled a number of persons, who became attached to his interest, and, marching to Macedon, he asserted his rightful title to the crown. Having made himself master of the country, he extended his conquests to the adjacent parts of Greece. Scipio Nasica was deputed by the Romans to restrain his progress; and, by the aid of a body of auxiliaries, he drove him back to Macedon. When the prætor Juventius Thallus was commissioned to terminate the war, he advanced to Macedon, and was attacked, defeated, and slain by Andriscus. In consequence of this advantage Andriscus was established on the throne, and the Carthaginians sent ambassadors to congratulate him, and to propose an alliance. Andriscus, however, could not endure prosperity; but became cruel and oppressive, and lost the affection of his subjects. At this time the Romans sent Q. Cæcilius Metellus to Macedon, and Andriscus was under a necessity of valiantly contending for his crown and life. After some trifling advantage which he gained at first, he was entirely defeated, and compelled to retire into Thrace. The Thracians enabled him to return with a numerous army, but he was again defeated by Metellus;

tellus; and seeking refuge with Byzas, a petty prince of Thrace, he was delivered by him to the Romans. Metellus led him in triumph, in the year before Christ 147; and he was afterwards put to death by the Senate. The Roman general, who succeeded in the war against Andrius, obtained the appellation of *Macedonicus*; and it has been doubted whether Andrius was an impostor, or the son of a king. Mod. Un. Hill. vol. viii. p. 98—105.

ANDRIUS, in *Ancient Geography*, a river of Asia, which, according to Strabo, ran into the Scamander.

ANDRO, PORT, in *Geography*, in the island of Belleisle, on the coast of France, is found the easternmost point of the island, called Point de Locmaria on the south side.

ANDROCALIS, in *Ancient Geography*, a town of Ethiopia, near Egypt, according to Ptolemy.

ANDRODUS, in *Ancient Writers*, denotes the sixty-third year of a man's life, otherwise called *annus ægypticus*, and *climacter magnus*.

ANDROGEUS, in *Entomology*, a species of PAPILO (Eq. Tr.) that inhabits Summam. The wings are black and bronzed; on the under side lunated spots of blue, red, and yellow. Fabricius and Gmelin. This species is very similar to papilio polydamas; and the PAPILO ACANTHUS of Cramer is considered as a variety (β) of it.

ANDROGYNA, in *Botany*, plants bearing male and female flowers on the same root, or bearing some flowers with stamens only and some with pistils only on the same root, without any mixture of such as are hermaphrodite. Of this we have examples in the melon and cucumber.

ANDROGYNUM, in *Ecclesiastical Writers*, is used to denote *matrimony*, or even one of the parties married.

ANDROGYNUM, *balneum*, denotes a bath common to both sexes.

ANDROGYNUS, or ANDROGYNOUS, *ανδρογυνος*, a compound of *ανρ*, man, and *γυν*, woman, q. d. *man-woman*, an appellation distinguishing those living creatures, which, by a monstrous formation of their generative parts, seem to unite in themselves the two sexes, that of the male and female, and synonymous with hermaphrodite. See HERMAPHRODITE. The term is also applied in *ancient mythology* to fabulous creatures, each individual of which possessed the faculties and distinguishing characters of both sexes, having two heads, four arms and feet. Some fanciful writers have reported, that the first man was created with two bodies, a male and a female, and that of these God made two persons, by separating one body from the other. See ADAM. It is generally said, that this was a fiction of the Rabbins; but there is reason to believe that it was of more early original. Plato's fable of the *Androgynes* indicates the tradition to which he had recourse; and it confirms the supposition, that a figment of this kind might have had its first rise in those early times, when the Egyptians and Phœnicians disguised the plain narratives which they found of the origin of things with their fables and mythology. See Euseb. Præp. Evang. lib. i. c. 10. According to Plato's account (in Conviv. Oper. vol. iii. p. 191. ed. Serrani) the Gods formed man with two bodies and two sexes. This fantastic being, possessing in itself the whole human system, was endowed with a gigantic force, and became insolent, so as to make war against the gods. Jupiter, exasperated at this insolence, determined to destroy it; but relenting, and averse from utterly annihilating the human race, he contented himself with debilitating this compound being by separating the male from the female, and leaving each half to subsist with its own powers alone. The office of reforming the separate bodies, and extending their skins so as to cover the whole

surface, was assigned to Apollo, who fastened it to the umbilicus. If this half rebelled, it was to be subdivided by another section, so that only one of the parts, which then composed it should be left; and even this fourth part of a man was to be annihilated, if it should persist in its obstinacy and mischievous attempts. The idea of these *Androgynes* might possibly be borrowed from a passage in Moses's account of the creation, in which he represents Adam as calling Eve "bone of his bone, and flesh of his flesh." A French poet has made an ingenious application of this fable of Plato. He attributes, as the philosopher does, the propensity by which the sexes incline to one another to the natural ardour which each half of the androgynes feels for re-union, and their inconstancy to the difficulty which each of the disjointed parts encounters in its efforts to recover its proper and original half. If a woman appears to us amiable, we instantly imagine her to be that moiety with whom we should only have constituted one whole, had it not been prevented by the infolence of our original double-sexed progenitor.

"The heart, with fond credulity impress'd,
Tell us the half is found, and hopes for rest;
But 'tis our curse, that sad experience shews,
We neither find our half, nor gain repose."

The astrologers also give the appellation *androgynous* to such of the planets as are sometimes hot, and sometimes cold; as Mercury, which is reputed hot and dry when near the sun, and cold and moist when near the moon.

ANDROIDES, in *Mechanics*, compounded of *ανρ*, *ανδρ*, man, and *ειδος*, form, an AUTOMATON, in the figure of a man; which, by virtue of certain springs, &c. duly contrived, walks and performs other external functions of a man. Albertus Magnus is recorded as having made a famous *androides*, which is said not only to have moved, but to have spoken. The construction of this machine must have been very ingenious and complex, if it be true that he was employed upon it 30 years. Thomas Aquinas is said to have been so frightened when he saw this head, that he broke it to pieces; upon which Albert exclaimed "Periit opus triginta annorum." Artificial puppets, which, by internal springs, run upon a table, and, as they advance, move their heads, eyes, or hands, were common among the Greeks, and from thence they were brought to the Romans. They were known by the name of "Neuropasta," and were much used at their shows. Aristotle (De Mundo, c. vi.) speaks of some which moved their heads, eyes, hands, and limbs in a very natural manner. They are also particularly mentioned by Galen, (De Ufu partium, lib. iii.) Xenophon, (Sympos.) Antoninus, (De Seipso, ii. 2. iii. 5. vi. 16. vii. 3. xii. 9.) Horace, (Sat. ii. 7. 82.) Gellius, (lib. xiv. 1.) and others. That Dædalus made statues which could not only walk, but which it was necessary to tie, that they might not move, is related by Plato, (Meno, Oper. tom. ii. p. 97. and Euthyphron, Oper. tom. i. p. 11.) Aristotle, and others. The latter speaks of a wooden Venus, and informs us, that the secret of its motion consisted in pouring quicksilver into it. The Chinese have used quick-silver for giving motion to puppets, and their method of doing it is described by Musæhebroke, (Introd. ad Philos. Nat. vol. i. c. iii. iv. lviii. p. 143, &c.) Figures or puppets, which appear to move of themselves, were formerly employed to work miracles; but this use is now superseded, and they serve only to display ingenuity, and to answer the purposes of amusement. One of the most celebrated figures of this kind was constructed by Vaucanson, and exhibited by him at Paris, for the first time,

in 1738; and a particular account of it was published in the Memoirs of the Academy for that year. This figure represents a flute-player, which was capable of performing various pieces of music by wind issuing from its mouth into a German flute, the holes of which it opened and shut with its fingers. The figure was about $5\frac{1}{2}$ feet high, placed upon a square pedestal $4\frac{1}{2}$ feet high, and $3\frac{1}{2}$ broad. The air entered the body by three separate pipes, into which it was conveyed by nine pairs of bellows, which expanded and contracted, in regular succession, by means of an axis of steel turned by clock-work. These bellows performed their functions without any noise, which might have discovered the manner by which the air was conveyed to the machine. The three tubes, which received the air from the bellows, passed into three small reservoirs in the trunk of the figure. Here they united, and ascending towards the throat, formed the cavity of the mouth, which terminated in two small lips, adapted in some measure to perform their proper functions. Within this cavity was a small moveable tongue, which, by its motion at proper intervals, admitted the air, or intercepted it in its passage to the flute. The fingers, lips, and tongue derived their proper movements from a steel cylinder turned by clock-work. This was divided into 15 equal parts, which, by means of pegs pressing upon the ends of 15 different levers, caused the other extremities to ascend. Seven of these levers directed the fingers, having wires and chains fixed to their ascending extremities, which, being attached to the fingers, made them to ascend in proportion as the other extremity was pressed down by the motion of the cylinder, and, *vice versa*; then the ascent or descent of one end of a lever produced a similar ascent or descent in the corresponding fingers, by which one of the holes of the flute was occasionally opened or stopped, as it might have been by a living performer. Three of the levers served to regulate the ingress of the air, being so contrived as to open and shut, by means of valves, the three reservoirs above mentioned, so that more or less strength might be given, and a higher or lower note produced as occasion required. The lips were, by a similar mechanism, directed by four levers, one of which opened them to give the air a freer passage, the other contracted them, the third drew them backward, and the fourth pushed them forward. The lips were projected upon that part of the flute which receives the air, and, by the different motions already mentioned, modified the tune in a proper manner. The remaining lever was employed in the direction of the tongue, which it easily moves so as to shut or open the mouth of the flute. The just succession of the several motions, performed by the various parts of this machine, was regulated by the following simple contrivance. The extremity of the axis of the cylinder terminated on the right side by an endless screw, consisting of twelve threads, each placed at the distance of a line and a half from the other. Above this screw was fixed a piece of copper, and in it a steel pivot, which, falling in between the threads of the screw, obliged the cylinder to follow the threads, and, instead of turning directly round, it was continually pushed to one side. Hence, if a lever was moved, by a peg placed on the cylinder, in any one revolution, it could not be moved by the same peg in the succeeding revolution, because the peg would be moved a line and a half beyond it by the lateral motion of the cylinder. Thus, by an artificial disposition of these pegs in different parts of the cylinder, the statue was made by the successive elevation of the proper levers to exhibit all the different motions of a flute-player, to the admiration of every one who saw it. Another figure, constructed by Vaucanson, played on the Provençal shepherd's pipe, held in its left hand, and with the right beat upon a drum, or tambour de

Basque. Another automaton, of the ingenious contrivance of Vaucanson, was a duck of the natural size, which moved its wings, exhibited all the gestures of that animal, quacked like a duck, drank water, ate corn, and voided something like excrement. We may here observe, that the flute-player of Vaucanson was not the first of its kind. In the beginning of the 16th century, the anonymous author of the poem, entitled, "Zodiacus Vitæ," saw at Rome a figure made in like manner by a potter, but no account is given of its construction. The performances of Vaucanson were imitated, and even exceeded, by M. de Kempelen of Pressburg, in Hungary. The androides constructed by this gentleman in 1769 was capable of playing chess. It was brought over to England in 1783 by its inventor, and remained here for more than a year. The figure is as large as life, in a Turkish dress, seated behind a table, with doors $3\frac{1}{2}$ feet long, 2 deep, and $2\frac{1}{2}$ high. The chair on which it sits is fixed to the table, which is made to run on four wheels. It leans its right arm on the table, and in its left hand holds a pipe; with this hand it plays after the pipe is removed. A chess-board of 18 inches is fixed before it. The table, or rather chest, contains wheels, levers, cylinders, and other pieces of mechanism, all of which are publicly displayed. The vestments of the figure are then lifted over its head, and the body is seen full of similar wheels and levers. There is a little door in its thigh, which is likewise opened; and with this, and the table also open, and the figure uncovered, the whole is wheeled about the room. The doors are then shut, and the automaton is ready to play; and it always takes the first move. At every motion the wheels are heard; the image moves its head, and looks over every part of the chess-board. When it checks the queen it shakes its head twice, and thrice in giving check to the king. It likewise shakes its head when a false move is made, replaces the piece, and makes its own move, by which means the adversary loses one. M. de Kempelen has exhibited his automaton at Petersburg, Vienna, Paris, and London, before thousands, many of whom were mathematicians and chess-players, and yet the secret by which he governed the motion of its arm was never discovered. He valued himself upon the construction of a mechanism, by which the arm could perform ten or twelve moves. It then needed to be wound up like a watch, after which it was capable of continuing the same number of motions. This automaton could not play unless M. de Kempelen, or his assistant, was near it, to direct its movements. A small square box was frequently consulted by the exhibitor during the game, and in this consisted the secret, which the inventor declared he could communicate in a moment. Any person who could beat M. de Kempelen at chess, was sure of conquering the automaton.

There have been many speaking machines, which seem to answer various questions proposed, sometimes in different languages, sing, and even blow a huntsman's horn. The figure, or perhaps only a head, is often placed upon a box, the fore part of which, for the better deception, is filled with a pair of bellows, a sounding board, a cylinder and pipes, supposed to represent the organs of speech. At other times the machine is only like a peruke-maker's block, hung round with a Turkish dress, furnished with a pair of arms, and placed before a table; and sometimes the puppet stands upon the table, or against a wall. The sounds are heard through a speaking trumpet, which the figure holds in its mouth. Some have pretended, that the voice of machines of this kind does not proceed from a man, but that it is produced by mechanism, like the music of an organ. Some affirm, that the voice issues from the machine itself; others, that the juggler answers, by speaking in the manner of ven-

triloquist, from the lower part of his belly, or by having the power to alter his voice; and some believe that the answers are given by a man somewhere concealed. It is, however, well known, that a child or a woman is concealed in the juggler's box; or that some person, in a neighbouring apartment, speaks into the end of a pipe, which proceeds through the wall to the puppet, and which conveys the answer to the spectators. The invention of causing statues to speak, by this method, seems so simple, that one can scarcely forbear conjecturing, that it was anciently employed to support superstition; and many have imagined that the greater part of the oracles were delivered in this manner. See Van Dale de Oraculis, 4to. Amst. 1700. p. 222. Whether the head of Orpheus spoke in the island of Lesbos, or, as is more probable, the answers were conveyed to it by the priests, as was the case with the tripod at Delphi, cannot be now ascertained. That the impostor Alexander, however, caused his Æsculapian to speak in this manner is expressly related by Lucian. He took, says this author, instead of a pipe, the gullet of a crane, and transmitted the voice through it to the mouth of the statue. In the fourth century, when Bishop Theophilus broke to pieces the statues at Alexandria, he found some which were hollow, and placed in such a manner against a wall, that a priest could slip unperceived behind them, and speak to the ignorant populace through their mouths. Theodoret, Eccl. Hist. lib. v. c. 22. p. 228. Ed. Valesii. Beckman's Hist. of Inventions, vol. iii. p. 317, &c. See AUTOMATON.

ANDROLEPSY, formed of *ανω*, man, and *λαμβανω*, capio, I take, in *Antiquity*, an action against those who protected murderers, by which if an Athenian were killed by a citizen of some other place, and such city refused to deliver up the criminal to punishment, it was held lawful to take three inhabitants of that city, and to detain them, till the murderer had either surrendered himself, or satisfied the law. This the Greeks called *androlepsia*, and the Romans CLARIGATIO. Some authors also use *androlepsia* for REPRISALS.

ANDROMACHA, in *Entomology*, a species of PAPHILIO (Parnassius) that inhabits New Holland. Wing above and beneath alike, dotted with black; anterior pair naked, posterior pair yellowish. Fabricius and Gmelin.

ANDROMACHA, a species of SPHINX, (zygaena of Fabricius) that inhabits America. It is black, wings transparent, margin and band black, tail red. Gmelin. The sphinx caenus of Cramer is supposed to be a variety of this species.

ANDROMACHE, in *Biography*, the wife of Hector, was the daughter of Aëtion, king of Thebes, in Cilicia. She lived in the happiest conjugal union with her husband till his death. At the siege of Troy she had the affliction of witnessing the precipitation of her son Astyanax from a high tower, and of being herself a captive slave to Pyrrhus, the son of Achilles, who was the deadly foe of Hector. She afterwards became the concubine of Pyrrhus, and had children by him. After the death of Pyrrhus, or, as some say, during his life, she married her fellow-captive Helenus, a son of Priam, and brother of Hector; and she reigned with him over part of Epirus, and perpetuated a race from whom Pyrrhus, king of Epirus, the antagonist of the Romans, is fabled to have sprung. Several tragedies, ancient and modern, have been composed on the subject of Andromache; but the interest of the most pathetic poem probably arises from sentiments foreign to her period and character. Gen. Dict.

ANDROMACHUS of Crete, was physician to the emperor Nero. He invented the composition, called after him, Theriaca Andromachi, which he dedicated to the service of

Nero, in a copy of Greek verses that have been preserved to the present time. Galen wrote two books in commendation of the medicine. It was given as an antidote against the poison of the viper, and was soon supposed to have equal power against all other poisons, and to prevent or cure malignant and infectious fevers. The emperor Antonine is said to have made daily use of the composition, and it was kept constantly prepared in the palace by several succeeding emperors. The formula, or process for making it, is described by Aræteus and by Galen, as well as by the inventor in his verses to Nero. The Venetians became so famous for making this medicine, which they sent for sale to all parts of Europe, that it is now more commonly known by the name of Theriaca Venetæ, Venice treacle, than by that of the inventor. Andromachus is said to have been the first physician who was dignified with the title of Archiater. Haller, Bib. Med. Pract.

ANDROMEDA, in *Astronomy*, a constellation of the northern hemisphere, representing the figure of a woman almost naked, with her feet at a distance from each other, and her arms extended and chained.

It is supposed to have been formed in memory of Andromeda, daughter of Cepheus and Cassiopeia, and wife of Perseus, by whom she had been delivered from a sea-monster, to which her father had exposed her to be devoured, in order to preserve his kingdom from the plague. Minerva translated her into the heavens.

Dr. Hook thinks he has discovered the hidden meaning of the story of Andromeda. Vide Poët. Works, p. 401. Andromeda is sometimes called in Latin, "Persea;" "Mulier catenata;" and "Virgo devota;" and the Arabians have changed the figure of this constellation from that of a woman to that of a sea-calf. Schickard has changed the name for that of "Abigail;" and Schiller calls it the "holy sepulchre;" and exhibits it under that figure. The stars in the constellation Andromeda, in Ptolemy's catalogue, are 23, in Tycho's 23, in Hevelius's 47, in Mr. Flamsteed's no less than 66. About 27 of these stars are visible to the naked eye, of which the principal are, α Andromeda's head, β in the girdle, called mirach, or mizar, and γ on the south foot, named alamac, and sometimes alhamec.

Some of the stars of Andromeda have been reckoned among the changeable stars, whose brightness varies. Mr. Pigott and Dr. Herschel have made observations on their relative brightness, for which see Phil. Transf. vol. lxxvi. p. 203. 212. vol. lxxxvii. p. 307. 321.

ANDROMEDA, in *Botany*, ledum of Mich. chamædaphne and polyfolia of Buxb. and erica of Tournefort, a genus of the *decandria monogynia* class and order, of the natural order of *bicornes* and *erica* of Jussieu. Its characters are, that the calyx is a perianthium, five-parted, acute, very small, coloured, and permanent; the corolla is monopetalous, campanulate, and quinquefid, clefts reflex; the *filamina* have subulate filaments, shorter than the corolla, and scarcely fixed to it, anthers two-horned and nodding; the pistillum is a roundish germ, style cylindrical, longer than the filaments, and permanent, stigma obtuse; the *pericarpium* is a capsule, roundish, five-cornered, five-celled, five-valved, opening at the corners, partitions contrary, and the seeds are very numerous, roundish, and shining. *Obs.* It differs from *erica* in number. In some species the corolla is ovate, in others perfectly campanulate. The anthers in some are awned, in others awnless.

Martyn enumerates 25, and Gmelin 21 species. 1. *A. tetragona*, with peduncles solitary and lateral, corollas bell-shaped, and leaves opposite, imbricate, obtuse, and revolute. This resembles the *passerina filiformis*, but the flowers are very different, and

and similar to those of the lily of the valley; the leaves are generally four-fold, whence its square appearance, and the name tetragona. Linnæus first observed it growing very sparingly in Lapland, in 1732; and Gmelin found it on the mountains of Siberia. 2. *A. hypnoides*, with peduncles solitary and terminal, corollas bell-shaped, and leaves crowded and awl-shaped. It has the appearance of a moss, spreads over large tracts of ground in the Lapland Alps, and adorns them with its beautiful red flowers, the anthers are awned; it is also found in Denmark and Siberia. 3. *A. cerea*, with peduncles axillary, two-leaved, and one-flowered, and leaves alternate, ovate, and serrate; the leaves are on short petioles, the corolla is bell-shaped, and the anthers oblong, yellow, two-horned at the back. It is brought from the island of Otaheite. 4. *A. cerulea*, erica folio abietis, flore arbuti of Buxb. with peduncles aggregate, corollas ovate, and leaves scattered, linear obtuse, and flat; the anthers are without awns. It grows wild on the mountains of Lapland, more plentifully on those of Dalecarlia and Jemtia, and is also found in Denmark and Siberia. 5. *A. Mariana*, Maryland A. with peduncles aggregate and branched, corollas ovate-cylindrical, and leaves oblong ovate, quite entire, and deciduous; the anthers are without awns; a native of North America; introduced here in 1736 by Peter Collinson, Esq. There are two varieties, α with oval leaves, and β with oblong leaves; the corollas are shaped like those of arbutus, are of an herbaceous colour, appear in June and July, and are sometimes surrounded by fruit, which seldom ripens in England. 6. *A. ferruginea*, rusty A. with peduncles aggregate, axillary, corolla subglobose, and leaves elliptic, quite entire, and beneath scaly-scarious. This is a native of North America, was cultivated here by Mr. J. Gordon in 1776, and flowers in July and August. 7. *A. polifolia*, polifolia of Buxb. erica humilis, &c. of Pluken, rhododendron polifolium of Scop. ledum palustre nostras arbuti flore of Ray, with peduncles aggregate and terminal, and leaves alternate, lanceolate, revolute, beneath glaucous. Martyn enumerates three varieties, *viz.* α *A. pol. latifolia*, broad-leaved marsh A. with leaves oblong, corollas ovate and flesh coloured, segments of the calyx spreading, ovate, and white, sometimes red at the tip. β *A. pol. media*, common marsh A. or wild rosemary; with leaves lanceolate, corollas oblong-ovate red, and segments of the calyx more erect. γ *A. pol. angustifolia*, narrow-leaved marsh A. with leaves lanceolate linear, and segments of the calyx oblong and red. This is an elegant little shrub, which rises from six or eight inches to a foot in height, erect and branched; the flowers are fleshy and nodding, the calyx is red, the corolla of a pink colour, the anthers awned, the capsule erect and five-furrowed, the style white, with a purple stigma, and the seeds very many and small. It is a native of America and the northern countries of Europe on turf bogs; in Russia, Sweden, Denmark, Germany, Switzerland, and in Britain, on the mooses of Cheshire, Lancashire, Westmoreland, Cumberland, Yorkshire, and Scotland, as on Brigflon moss, near Kendal, Middleton moss, by Lancaster, on Blackstone-edge, between Halifax and Rochdale, upon Solway moss in great quantities, and not unfrequent in peat-bogs in the lowlands of Scotland. It flowers in June, and is called mars chituns, wild rosemary, Poley mountain, moor-wort, and marsh holy rose. There is some difference in the varieties as found in North America (α), in Europe (β), and in Newfoundland and Labrador (γ), as above specified. 8. *A. bryantha*, bryantha of Gmelin, with flowers corymbed, leaves elliptic, and prostrate stem. This comes up in thick clumps, like wild thyme, on the rocks of Kamtschatka. 9. *A. dabocia*, erica dabocii, erica Hibernica, &c. of Ray, Irish whorts, Cantabrian heath, or trailing Andromeda, with ra-

ces pointing one way; flowers quadrifid, ovate, and leaves alternate, lanceolate, and revolute. This was formerly an erica, and wants one-fifth in the parts of fructification, and ought, perhaps, with droseroides and carnica, to be removed to that genus. This species has the habit or air of an andromeda, but the character of an erica. The seed-vessel is a four-celled, four-valved capsule; it has been observed to grow only in the Irish bogs, and flowers in June and July. 10. *A. droseroides*, erica glutinosa of Berg. chamæcilus roris folis foliis of Pct. clammy A. with racemes pointing one way, and leaves linear, hairy and viscid. The number of parts of fructification varies from 4 or 8 to 5 or 10; it is lighter to N° 9, and has all the habits of Andromeda; a native of the Cape of Good Hope. 11. *A. paniculata*, panicled A. with racemes terminal, panicled, corollas roundish, and leaves ovate, rather entire; the stem is about four feet high; the flowers grow in loose spikes from the ends of the branches, being shaped like those of arbutus, only a little longer, and appearing in July, but not producing seeds in this country; the anthers are awned; a native of Virginia, and cultivated here in 1748 by Archibald, duke of Argyle. 12. *A. japonica*, with racemes panicled, cylindrical and bracted, and leaves elliptic, reflex, and serrate at the tip. This is a tree, a native of Japan, near Nagasaki, and flowers in December. 13. *A. arborca*, tree—Andromeda, or forrel-tree, with panicles terminal, corollas rather downy, and leaves elliptic, pointed, and tooth-letted. This is in Virginia a shrub, growing 10 or 12 feet high, but in Carolina it rises 20 feet; the branches are slender, and bend downwards; the flowers grow in long, naked spikes from the sides of the branches, they are of an herbaceous colour, and ranged on one side of the stalk. Cultivated here in 1752 by Mr. Miller. 14. *A. racemosa*, branching or Pennsylvania Andromeda, with racemes terminal, simple, and bracted, corollas cylindrical, and leaves oblong-lanceolate, and serrate. This was found in Pennsylvania by Kalm, introduced here in 1736 by P. Collinson; flowers in July. 15. *A. axillaris*, notch-leaved A. with racemes axillary and simple, corollas oblong, leaves ovate, acute, and serrulate. A native of Carolina, introduced in 1765, and flowering from May to August. 16. *A. coriacea*, thick-leaved A. with racemes axillary and simple, leaves ovate, very entire, very shining, and branchlets three-cornered; found in North America, introduced in 1765, and flowering in July and August. 17. *A. acuminata*, A. lucida of Jacq. acute-leaved A. with racemes axillary and simple, leaves ovate-lanceolate, acuminate and serrate. This is a shrub about four feet high, upright and smooth, with round branches, leafy to a considerable extent; the flowers smell like honey, the perianthium is green, the corolla snow-white. It is a native of North America, was introduced in 1765, and flowers in July and August. 18. *A. calyculata*, calyced A. with peduncles solitary, axillary, and pointing one way, two bractes, and leaves oval, scaly-dotted, and obsoletely serrulate. There are three varieties: α *A. cal. ventricosa*, chamædaphne of Buxb. globe-flowered calyced A. with globose corollas, and oblong-lanceolate leaves; β *A. cal. latifolia*, broad leaved calyced A. with corollas oblong-cylindrical, and leaves oblong-oval, and obtuse; γ *A. cal. angustifolia*, narrow-leaved calyced A. with corollas oblong-oval, and leaves oblong-lanceolate. This is a low shrub, with leaves of similar shape and consistence to those of the box tree, with small punctures on them; the flowers grow in short spikes at the extremes of the branches, single, between two leaves, and white; the leaflets are oval on the racemes, and from the axil of each proceeds a solitary, pedicelled flower; the calyx is covered at the base, with two ovate leaflets; the anthers are oblong, bifid, and awnless; growing in Sweden, Ingria, Siberia, and North America, on mossy land;

land; cultivated in 1748 by Archibald, duke of Argyle. There is some difference in the varieties from Russia (α), Newfoundland (β), and North America and Siberia (γ).

19. *A. anastomozans*, with racemes crowded and leafy; leaves ovate, slightly ferrate, anastomizing underneath; and dotted. This is a shrub with hairy branches, ovate corollas, two-awned anthers, and obtuse capsules, gaping at the angles; found by Mutis in New Granada.

20. *A. rufeshris*, with leaves oblong, alternate and ferrulate. A native of New Zealand.

21. *A. faliifolia*, willow-leaved *A.* with racemes pointing one way, and naked, corollas subcylindrical, and leaves lanceolate, acute, and quite entire; found by Commerfon in the island of Mauritius.

22. *A. buxifolia*, box-leaved *A.* with racemes pointing one way, and naked, corollas subcylindrical, and leaves cordate-ovate, quite entire, with a little dagger point. This and the former species differ scarcely at all in their fructification, or in the structure of their leaves, and are distinguishable only by their form; this, however, has none of those lines parallel to the midrib that are so conspicuous in the other species. It is a native of the isle of Bourbon where it was found by Commerfon.

23. *A. fasciculata*, with peduncles aggregate, leaves alternate, ovate-lanceolate, obtuse, slightly crenulate and coriaceous.

24. *A. Jamaicensis*, with peduncles aggregate, corollas ovate transparent, leaves alternate, broad-lanceolate, obtuse, entire, beneath ash-coloured and membranaceous.

25. *A. olandra*, with peduncles aggregate, corollas cylindrical quadrifid, and leaves alternate, ovate-lanceolate, entire, and membranaceous. The three last species are natives of Jamaica. Gmelin enumerates the following species besides several of those above described, *viz.* *A. ferruginosa*, with flowers aggregate, axillary, and terminal, leaves rounded at the margin, revolute, and beneath ferruginous; suggested not to be distinct from the *A. ferruginea*; *A. nitida*, with peduncles aggregate and axillary, leaves alternate, lanceolate-ovate, entire and permanent; *A. catechxi*, with racemes ovate and axillary, leaves alternate, petiolate, ovate-lanceolate, ferrulate and permanent; *A. reticulata*, with racemes ovate and axillary, leaves ovate, acuminate, crenulate, alternate, petiolate, beneath reticulate and permanent.

Culture. Most of the species are hardy, deciduous shrubs, which delight in moist ground; they may be increased by their creeping roots, which put up suckers at a distance, that may be taken off with roots, and transplanted where they are to remain. Those that are imported from America may be propagated by seed sown in the spring in a bed of moist earth; they may be increased by layers in autumn. The 13th sort must be sheltered from frost in winter, and in summer frequently watered. It grows naturally in boggy places, and requires greater heat than that of this climate. Martyn's Miller.

ANDROMEDA, in *Entomology*, a species of PAPILO (*Parnassius*) found in India. The wings are roundish, transparent, white: posterior pair red at the tip, with a single eye-shaped spot on each side. Fabricius and Gmelin.

ANDROMEDA, in *Natural History*, is likewise a species of MEDUSA amongst the VERMES MOLLUSCA. It is hemispherical, without marginal arms; eight round, ramose, foliaceous arms on the under part. Foisk. Fn. Arab. Gmelin. This kind is extremely abundant on the coasts of the Red Sea. The body is transparent, and of a pale brownish colour with white rays; the margin is entire; in the middle is a black cross: the arms are white, and rather thicker than a goose quill at their base. Gmelin, &c.

ANDROMEDA, in *Middle Age Writers*, denotes a kind of garment made of ram-skins.

ANDRON, or ANDRUM, in *Antiquity*, an apartment in

houses assigned for the use of the men. This was otherwise denominated *androna*, and *andronitis*. The andron stood opposed to the GYNÆCÆUM, or apartment of the women. The Greeks also gave their dining-rooms the title andron because the women had no admittance to feasts with the men.

ANDRONA, in *Ancient Writers*, denotes a street, or public place, where people met and conversed together. In some writers androna is more expressly used for the space between two houses. In which sense the Greeks also used the term *αὐδῆων*, as for the way or passage between two apartments. The word is sometimes also written *andra*, *andron*, and *andronium*.

ANDRONA is also used, in *Ecclesiastical Writers*, for that part in churches destined for the men. Anciently it was the custom for the men and women to have separate apartments in places of worship, where they performed their devotions asunder; which method is still religiously observed in the Greek church. The *αὐδῆων*, or androna, was on the southern side of the church, and the women's apartment on the northern.

ANDRONICUS I. COMNENUS, in *Biography* and *History*, was the son of Isaac and grandson of Alexius Comnenus, and one of the most conspicuous characters of the age, so that his genuine adventures might form the subject of a very singular romance. He was strong and beautiful; the want of the softer graces was supplied by a manly countenance, a lofty stature, athletic muscles, and the air and deportment of a soldier; and the preservation of his health and vigour in old age, was the reward of temperance and exercise. Dextrous in arms, he was ignorant of fear; his persuasive eloquence could accommodate itself to every situation and character of life; and in every deed of mischief, he had a heart to resolve, a head to conceive, and a hand to execute. In his youth he followed the retreat of the Roman army, and in the march through Asia Minor he wandered into the mountains, was taken by Turkish huntsmen, and became a captive to the sultan. Both his virtues and his vices recommended him to the favour of his cousin, the emperor Manuel; and whilst he lived in public incest with his niece Theodora, Andronicus openly maintained a licentious intercourse with her sister Eudocia, who gloried in the name of his concubine. She accompanied him in his military command in Cilicia, where he pressed, with active ardour, the siege of Mopsuella; but he was surpris'd and thrown into disorder by a fall of the enemy. On his return to the Imperial camp in Macedonia, Eudocia attended his motions; and their tent was suddenly attacked at midnight by her brothers, who were impatient to expiate her infamy in his blood. Refusing to assume a female habit, in compliance with her advice, he started from his couch, and cut his way through the assassins with his sword. At this time he engaged in a treasonable correspondence with the king of Hungary and the German emperor; in consequence of which he was arrested, and strictly confined in a tower of the palace of Constantinople. In this prison he remained for more than 12 years; and after repeated and ineffectual attempts to escape, in which he manifested singular resolution and dexterity, he at last succeeded, and retired to the court of the great duke of Russia. Having gained this asylum, he solicited the Russian prince to join his arms to those of Manuel in the invasion of Hungary, and thus obtained forgiveness from the emperor; and, after a campaign on the Danube, he returned with Manuel to Constantinople. By refusing the oath of allegiance, which he was required to take to the prince of Hungary, who became the presumptive heir by marrying the emperor's daughter, he again incurred

curred his displeasure; and he was punished by an honourable exile to a second command of the Cilician frontier, with the absolute disposal of the revenues of Cyprus. Here he engaged the affections of Philippa, sister of the empress Maria, and daughter of Raymond of Poitou, the Latin prince of Antioch. In connection with her he pursued a course of dissipation for some time, till Manuel's resentment interrupted his pleasures. His intercourse with Philippa being obstructed, he collected a band of desperate adventurers, and undertook the pilgrimage of Jerusalem. In this military undertaking he so far succeeded as to captivate the esteem of the clergy and of the king, and to obtain the lordship of Berytus, on the coast of Phœnicia. In this neighbourhood resided Theodora, great grand-daughter of the emperor Alexis, and widow of Baldwin the Third, king of Jerusalem, who was young and beautiful, and a princess of his own family. Theodora became the third victim of his amorous seduction; and her shame was more public and scandalous than that of her predecessors. The emperor's resentment still pursued him; in Palestine he was no longer safe; and Theodora disclosed his danger, and accompanied his flight. Damascus was his first place of refuge; and having visited several other parts of the east, probably Bagdad and the courts of Persia, he made a long circuit round the Caspian Sea and the mountains of Georgia, and finally settled among the Turks of Asia Minor, the hereditary enemies of his country. He made frequent inroads in the Roman province of Trebizond, and seldom returned without an ample harvest of spoil and of Christian captives. Theodora was at length surpris'd by the governor of Trebizond, and, together with her two children, was sent to Constantinople; upon which Andronicus implored and obtained a final pardon; with leave to throw himself at the feet of his sovereign, who was thus satisfied. He acted the part of a humble and constant penitent with such success, that his sins were forgiven both by the church and state; and he was sent by the emperor to reside at a distance from the court, namely, at Oenœ, a town of Pontus, surrounded with rich vineyards, and situate on the coast of the Euxine.

Soon after this event the death of Manuel in 1177, who was succeeded by his son Alexis Comnenus, at the age of 12 or 14 years, without vigour, wisdom, or experience, opened a new career to his ambition. A civil war having been excited in Constantinople by the misconduct of the empress dowager, the views of the people were directed to Andronicus. Urged to interpose for quelling the disturbance that prevailed, and for restoring the public tranquillity, both by the patriarch and the patricians, he began his march from Oenœ towards Constantinople; his slender train insensibly swelled to a crowd and an army; and he soon reached the city, took possession of the palace, saluted the emperor, confined his mother, punished her minister, and re-established the public order and peace. His wicked designs were for some time disguised by his hypocrisy; but he hastened to manifest the cruelty of his disposition by putting to death many persons whom he thought ill-affected towards him, and by causing the empress herself to be tried and executed on a charge of treason, in corresponding with Bela, king of Hungary. After the coronation of the young emperor, at which Andronicus solemnly attended and vowed fidelity, with the sacrament in his hands, he found means to represent the necessity of committing the empire to the care of some person of experience, and to engage the people, as well as the emperor himself, to solicit the association of a colleague. Having successfully conducted this part of the farce, his adherents unanimously exclaimed, "Long live Alexis and Andronicus, Roman emperors!"

And the artful hypocrite was elevated, by acclamation, apparently against his own consent, and merely to protect the young emperor and to support his authority, to a partnership in the empire. This partnership, which was merely a preparatory step to the sole sovereignty, he soon terminated by the death of Alexis, whom he caused to be strangled with a bow-string; and the tyrant, insensible to pity or remorse, after surveying the body of the innocent youth, struck it rudely with his foot: "Thy father," he cried, "was a knave, thy mother a whore, and thyself a fool!" Having thus attained to the dignity of sole emperor, A. D. 1183, he swayed the sceptre about three years and a half, as the guardian or sovereign of the empire. His government exhibited a singular contrast of vice and virtue: when he listened to his passions he was the scourge, and when he consulted his reason he was the father of his people. In the exercise of private justice he was equitable and rigorous; the provinces, which had been neglected and oppressed, revived in prosperity and plenty; and millions applauded the distant blessings of his reign, while he was cursed by the witnesses of his daily cruelties. The noblest families, especially those who claimed any alliance to the Comneni, were either massacred or exiled. At length his throne was subverted by a rival without merit, and a people without arms. Isaac Angelus, a descendant, in the female line, from the great Alexis, being marked as a victim, defended his life and liberty, slew the executioner, and fled for refuge to the church of St. Sophia. The populace were roused, and Isaac was instantly raised from the sanctuary to the throne. Andronicus, who was indulging himself in the delicious islands of the Propontis, in the society of a young wife and a favourite concubine, returned with all speed to Constantinople; but he found, upon his arrival, that he was universally deserted, and that no condition which he proposed, however self-denying and humiliating, would be accepted. Accordingly he attempted to make his escape; but he was pursued and taken in his flight, and brought back, loaded with fetters, and with a long chain round his neck, to the presence of Isaac Angelus. "His eloquence, and the tears of his female companions, pleaded in vain for his life; but instead of the decencies of a legal execution, the new monarch abandoned the criminal to the numerous sufferers, whom he had deprived of a father, an husband, or a friend. His teeth and hair, an eye and a hand were torn from him; and a short respite was allowed, that he might feel the bitterness of death. Astride on a camel, without any danger of a rescue, he was carried through the city, and the basest of the populace rejoiced to trample on the fallen majesty of their prince. After a thousand blows and outrages, Andronicus was hung by the feet, between two pillars that supported the statue of a wolf and a sow; and every hand that could reach the public enemy, insisted on his body some mark of ingenious or bloody cruelty, till two friendly or furious Italians, plunging their swords into his body, released him from all human punishment. In this long and painful agony. 'Lord, have mercy upon me!' and 'Why will you bruise a broken reed?' were the only words that escaped from his mouth. His death, in the 73d year of his age, closed a reign of two years, and with him terminated the dynasty of the Comneni. *Anc. Un. Hist.* vol. xv. p. 158, &c. *Gibbon's Hist.* vol. ix. p. 93—108.

ANDRONICUS, CYRRETES, or of Cyrrhus, was an Athenian astronomer, and celebrated as the inventor of weathercocks. He erected an octagon tower of marble, on each side of which he engraved figures representing the eight winds mentioned by Vitruvius, under the names of:

Solanus, Taurus, Auler, Abent, Favonius, Cornu, Septentio, and Aquilo. A copper Triton, holding in its hand a disk, turned upon a pivot, and shewed the direction of the wind. Salmastius gives the form of this tower in his commentary on Solinus. Ant. Gell. lib. vi. c. 22.

ANDRONICUS, LIVIUS, the oldest of the Latin poets, is said to have been a Greek slave, and to have been emancipated by Livius Salinator, whose children he instructed, and whose name he assumed. His performances were chiefly dramatic and comic, and he acted in his own pieces; and, it is said, that when he became hoarse, he caused the words to be recited by a servant, while he himself exhibited the gesticulation. He also wrote hymns to the gods, one of which, in honour of Juno, is said, by Livy and Valerius Maximus, to have been sung through the city by girls. An odyssey is also attributed to him. Some lines, which are quoted by grammarians and critics, are the only relics of him, and they have been printed in the fragments of the other ancient Latin poets, in the "Comici Latini," and the "Corpus Poetarum." Andronicus represented his last piece on the stage, A. U. C. 514. B. C. 240, a year before the birth of Ennius. Vossius.

ANDRONICUS of *Rhodes*, a peripatetic philosopher, came to Rome in the time of Cicero, and served to revive and establish the philosophy of Aristotle. Andronicus collected the writings of Aristotle, by means of the library of Apellicon, sent to Rome by Sylla, and Tyrannio's use of it, arranged, corrected, transcribed, and published them; and, according to Plutarch, he annexed indexes to them; so that he may be considered as a restorer of these writings. Andronicus wrote a paraphrase of Aristotle's Categories and Physics, and probably of some other pieces, but none are extant, unless the paraphrase of Aristotle's Ethics, published under his name by Heinsius, 8vo. at Leyden, in 1617, and at Cambridge in 1679, be his, which Salmastius, Vossius, &c. dispute. It is doubted whether a small treatise "On the Passions," published by David Hoerschelius, in 1593, was written by this Andronicus. Plut. Vit. Sylla apud Oper. tom. i. p. 468. Gen. Dict.

ANDRONICUS of *Theffalonica*, flourished in the 15th century, and among other learned men, who left Constantinople when it was taken by the Turks, contributed to the revival of letters. He taught Greek at Rome, and was entertained in the house of Bessarion; but his salary was so inconsiderable that he was obliged to leave Rome and repair to Florence; whence he removed to Paris, where he died at an advanced age. His knowledge of the Greek language and of Greek authors exceeded that of any of his contemporaries; but he was disqualified for public speaking by a bad pronunciation. Gen. Dict.

ANDRONION, in *Physic*, the name of a pastil, invented by an ancient physician named Andro, said to have been of great efficacy against the carbuncle and HERPES. Its ingredients, according to Ægineta's prescription, are the *squama* of copper, *as ustum*, *sul ammoniac*, *alumen rotundum*, shavings of verdegris, and frankincense, all wrought up with wine. Celsus gives another recipe, and Aetius a third.

ANDROPHAGI, from *ανδρ*, man, and *φαγω*, I eat, among *Ancient Geographers*, denoted man-eaters. These were more usually called *anthropophagi*. Herodotus and Pomp. Mela speak of a nation of androphagi, in Scythia, who observed neither laws nor justice, and had nothing in common with the other inhabitants but their dress and occupation of feeding cattle.

ANDROPOGON, q. d. *man's beard*, in *Botany*, a genus of the *polygamia monoecia* class and order, and of the na-

tural order of *gramina*, or grasses. Its characters are, that the hermaphrodite flowers are sessile, that their *calyx* is a glume, one-flowered, two valved, oblong, obtuse, cartilaginous and awnless, the outer valve concave, flattish at the back, embracing the inner, which is narrower, with its edges; the *corolla* is a two-valved glume, less and more slender than the calyx; outer valve smaller, often very small, within the inner valve of the calyx, sharp or blunt at the end, in most of the species awned; awn terminating, or from the cleft of the glume, long, with a bent joint, and twisted at bottom; the inner valve lanceolate, doubled at the edges; necessary two leaved; leaflets thickish and diaphanous; the *stamens* have three filaments, capillary, very tender; anthers oblong, forked at both ends, and incumbent; the *pyllium* is an oblong germ, 4yles two, and capillary, stigmas oblong, and feathered; no *pericarpium*; glumes of the corolla and calyx involving, and inclosing the leed; the *seed* solitary, oblong, and covered, armed with the awn of the corolla, which easily falls off. The male flowers are peduncled, single, or in pairs to each hermaphrodite; the *calyx*, *corolla*, and *stamens* as in the others, except that the corolla has no awn. Martyn enumerates 35, and Grædin 33 species. 1. *A. caricifolium*, gramin ca-icolum of Rumph. with spikes solitary and imbricate, seeds shaggy, awns naked and contorted. *A.* native of Amboina and Japan. 2. *A. contortum*, Ægilops Maderas-patana, &c. of Scheuch. gramin fecalinum indicum, &c. of Pluk. and Mor. with spike solitary, male flowers awnless on the back of the spike, female flowers on the belly of it twice as long as the males, with twisted approximating awns, longer than the whole spike. A native of the East Indies; introduced into Kew Garden in 1779 by Anthony Chamier, Esq. 3. *A. crinitum*, with spikes solitary and shaggy; awns naked, jointed, and very long. A native of Japan; found by Thunberg. 4. *A. divaricatum*, lagurus humilior, &c. of Gron. Virg. &c. with spike oblong, flowers woolly, remote and divaricate; awn flexuose and naked. A native of Virginia. 5. *A. gryllus*, Ægilops bromoides spica purpurascens of Scheuch. gramin sparteum festucum, &c. of Barr. gramin avenaceum, &c. of Monti, with peduncles of the panicle entirely simple and three-flowered; the hermaphrodite floscule sessile, awned, ciliate, and bearded at the base. A native of Piedmont, Verona, Montpelier, Carniole, the Grisons, and Switzerland. 6. *A. saccharoides*, with branches of the panicle simple, florets in pairs, hermaphrodite awned sessile, the other awnless, pedicelled, withering, pedicel and rachis woolly. A native of Jamaica. 7. *A. nutans*, with panicle nodding, awns twisted and polished, glumes of the calyx shaggy. A native of Virginia and Jamaica. 8. *A. ciliatum*, with panicle nodding, outer calyx many-flowered and ciliate, awns contorted and hairy. Found by Thunberg on the mountains of Nagasaki in Japan; flowering in September. 9. *A. ferratum*, with panicle loose, one floscule sessile, villose at the base; the other pedicelled, with the pedicel villose, and shorter than the calyx. A native of Japan. 10. *A. cotuliferum*, with panicle spreading, villose, awn-twisted, naked, pedicels clubbed or swelling at top, and hollowed like a saucer or dish. A native of Japan. 11. *A. cymbarium*, with panicle scattered, bractes boat-form, flowers transverse, awned, and threefold. A native of the East Indies. 12. *A. squarrosum*, *A. muricatum* of Retz, with panicle crowded, glumes awl-shaped and rugged. Koenig observed it in Ceylon, swimming on deep pools; it is used by the natives for its pleasant smell; they also make fans of it. 13. *A. prostratum*, with peduncles in five-flowered umbels, without calyces, the hermaphrodite floscule awned. A native of the East Indies. 14. *A. fastigiatum*, with spikes of the panicle solitary, peduncles

riuncles elongate subfastigate, rachis woolly, floscules awned, and male fertile. A native of Jamaica. 15. *A. alopecuroides*, gram. dactylon, &c. of Sloane, with panicle loose; rachis woolly, and a twisted awn to each floscule. A native of Jamaica and Virginia. 16. *A. distachyum*, with spikes two, terminal, and eulm undivided. Linnæus says that it grows wild in Switzerland. Scheucher had it from Smyrna. 17. *A. schœnanthus*, lagurus of Fl. Zeyl. gram. ad juncum accedens aromaticum majus syriacum of Mor. gram. dactylon aromaticum, &c. of Pluken. schœnanthus of Bauhin and Ray, sweet rush, or camel's hay, with spike of the panicle conjugate, ovate-oblong, rachis pubescent, floscules sessile, with a twisted awn. It is brought over from Turkey and Arabia. In bundles about a foot long, consisting of smooth stalks, in shape and colour resembling barley straws, full of a fungous pith like that of rushes. It has an agreeable smell, and a warm, bitterish, not unpleasant taste. Distilled with water it yields a small quantity of a yellowish, fragrant, and pungent essential oil, and the remaining decoction is bitterish, and somewhat acrid. The spirituous extract is pleasantly aromatic and bitterish. This plant was formerly employed as a warm stomachic, and deobstruent; but in our country its use is superseded by more common aromatic vegetables. It is kept in the shops merely as an ingredient in the mithridate and theriaca; but these compositions being excluded from the pharmacopœias, the schœnanthus, or juncus odoratus is left out of our materia medica. Lewis and Murray. 18. *A. Virginicum*, gram. dactylon bicorne tomentosum minus of Sloane, with spikes of the panicle conjugate, peduncles simple, rachis woolly, floscules awnless, the male one wanting. A native of America. 19. *A. bicorne*, lagurus of Linn. hort. cliff. and Gron. Virg. gram. dactylon bicorne tomentosum maximum, spicis numerosis of Sloane, with spikes of the panicle conjugate, peduncles branching very much, rachis woolly, awn caducous, male floscule wanting. A native of the East Indies, on dry hills, and there called by the English fox-tail grass. 20. *A. hirtum*, gram. dactylon spica gemina of Scheuch. gram. dactylon siculum, &c. of Pluk. with spikes of the panicle conjugate, and calyces shaggy. A native of Portugal, Italy, Sicily, and Smyrna. 21. *A. insulare*, gram. avenaceum, &c. of Sloane, with panicle loose and smooth, floscules double and awnless, one pedicel shorter, calyces woolly. A native of Jamaica. See *Panicum lanatum*. 22. *A. barbatum*, with spikes digitate, calyces permanent, and corollas ciliate. A native of the East Indies; introduced into Kew gardens, in 1777, by Dr. Solander. 23. *A. pubescens*, chloris ciliata of Swartz, with spikes digitate, calyces subtriflorous, outer petals awned, keel and edge of the hermaphrodite flower ciliate. A native of Jamaica; introduced at Kew in 1779, perennial, and flowering from July to September. 24. *A. nardus*, lagurus of Fl. Zeyl. with branches of the panicle superdecompound and proliforous. See *Spikenard*. 25. *A. muticum*, with spikes digitate, mostly three, and floscules alternate, sessile, and awnless. A native of the Cape of Good Hope. 26. *A. ischaemum*, gram. dactylon, &c. of Scheucher, with many digitate spikes, sessile floscules, awned and awnless, and woolly pedicels. A native of the southern parts of Europe, growing on mountains, hills, and other dry situations; introduced to Kew, in 1778, by Mr. Thomas Blackie. 27. *A. fasciculatum*, chloris radiata of Swartz, gram. dactylon, &c. of Mor. many-spiked andropogon, with spikes fascicled, very many and smooth, calyces two-flowered, valves acute, smooth and even, the outer like petals, and awned, the inner floscule barren. A native of Jamaica; introduced in 1779, and flowering from July to September. 28. *A. polydactylon*,

chloris polydactyla of Swartz, gram. dactylon elatrus of Sloane, with spikes fascicled, outer petals awned, those of the lower floscule ciliate-bearded. A native of Jamaica. 29. *A. glaucum*, with panicle leafy, involuclcs and calyces two-flowered, calyces of the sessile flowers three-valved, of the peduncled ones two-valved. A native of the East Indies, whence it was sent by Koenig. 30. *A. serratum*, with spike simple, imbricate, with two rows of awned sessile flowers, and two of awnless pedicelled ones, calyces one-valved. A native of Bengal, where it was found by Koenig. 31. *A. incurvatum*, with spikes filiform, subdigitate, flowers twin, the female pedicelled and awned, the male sessile and awnless, the calyces one-valved. Found by Koenig in Tranquebar near rivers. 32. *A. binatum*, with spikes twin, woolly, one valve of the calyces acuminate, the other truncate, three toothed, the larger petal-awned. Observed in the East Indies by Koenig. 33. *A. aciculatum*, with panicle contracted upright, peduncles three-flowered, male-flowers two, pedicelled, and acuminate, female sessile and awned. A native of the East Indies in barren places. 34. *A. Bladhii*, with spikes about eight, hermaphrodite floscule, sessile, awned, neuter peduncled, ciliate, and awnless. A native of China, and sent from thence by Bladh. 35. *A. provinciale*, with spikes fascicled, smooth, floscules alternate subsessile, directed one way, and awned. A native of the south of France, where the seeds were sent by Dahl. Gmelin has omitted the 23d, 27th, and 28th species above enumerated, and introduced the following, viz. *A. brevifolium*, with spikes lateral and solitary, floscules alternate and remote, and stalk geniculated and compressed. *A. ramosum*, with spikes terminal conjugate, with double spiculæ, the male awnless and pedicelled, with ramos stalk. *A. annulatum*, with spikes at the top of the stalk crowded and alternate, flowers adpressed and germinate, the male awnless and pedicelled, and an erect, ramos stalk. *A. undatum*, with an erect, ramos panicle, spikes alternate, floscules by threes; the males inferior and later. *A. aser*, with spikes three and terminal, and floscules all awned. Gmelin suggests that this is the Gir Gir, or Geshe el Aube of Abyssinia, described by Bruce in his Travels, vol. v. Appendix, p. 47. Gmelin makes a distinct species of the *A. muricatum* of Koenig, which is above referred to the *A. squarrosolum*, and describes it as having a contracted panicle, verticillated spikes, and calyces awnless and muricated.

Culture. Few of these grasses have been cultivated in European gardens; as they are for the most part natives of the East or West Indies, they would require the protection of a stove. Martyn's Miller.

ANDROPOGON. See SACCHARUM and STIPA.

ANDROS, in *Ancient Geography*, now ANDROS, one of the most fertile and delightful islands in the Archipelago Sea, lies near the south end of Negropont. According to Pliny it was 93 miles in circumference, and had various names, viz. Cueros, Lafia, Nonagnia, Epagris, Antandros, and Hydrusia. It is said to have borrowed the name of Andros from one Andrius, who, according to Diodorus Siculus (lib. v.), was one of the generals whom Rhadamanthus appointed to govern the Cyclades, after their voluntary submission to him. Conon will have this Andrius to be the son of Anius, and grandson of Apollo and Creusa, and to have been the first who settled in this island. It received the name of Antandros, signifying "for one man," from its having been given as his ransom by Afcanius, the son of Æneas, when taken prisoner by the Pelasgians. The territory of Andros is still one of the most fertile and pleasant countries in the Archipelago, producing all kinds of delicious fruit, and watered with numerous springs, whence it

had;

had the name of Hydrusia, from *Hydrus*, *water*. The Andrians were the first of all the islanders who joined the Persians; and, therefore, Themistocles, after the victory at Salamis, resolved to attack the city of Andros, and put it under large contributions for the maintenance of his fleet. Having landed his men in the island, he acquainted the magistrates, that the Athenians were come, with two powerful divinities on their side, "Persuasion and Force;" and therefore they must part with their money, by either fair or foul means. The Andrians replied, that they likewise had two mighty deities, who were very fond of their island, "Poverty and Impossibility," and therefore could give no money. Herodotus, lib. viii. c. 3. Themistocles, dissatisfied with the answer, laid siege to the town. The event is not known; but it is probable that the Athenian general made himself master of the place, since Pericles, as Plutarch (in Pericl. Oper. tom. i. p. 156.) informs us, a few days after, sent thither a colony of 250 Athenians. It was not long after retaken by the Persians, and in vain besieged by Alcibiades, who, after having taken and fortified the castle of Gaurium, left Thrasybulus in it with a strong garrison, and retired, first to Rhodes, and thence to the island of Cos. (Diod. Sic. lib. xiii.) This, as well as the other Greek islands, submitted to Alexander; after whose death it took part with Antigonus, who was driven out by Ptolemy; and his successors held it to the Roman times, when Attalus, king of Pergamus, besieged the metropolis at the head of a Roman army; and having taken it, the Romans granted him the possession of the whole island; but upon his death Rome claimed this island, as well as his other dominions, in virtue of his last will. Livy, lib. xxxi. c. 43.

Andros is separated from Tino by a channel of a mile in breadth, into which vessels of burden are afraid to enter on account of the rocks and shoals which are there situated. Although it is lofty and mountainous like Tino, it has in proportion more lands fit for cultivation; its plains are somewhat more extensive, equally fertile, and as well watered. Here are to be seen 50 villages, and yet its population does not exceed 12,000 souls. Andros is the appanage of a sultana: a Turkish waiwode administers the police, and watches over the peace of the island. It pays about 30,000 piastres, as well for the duties of the sultana as for those of the captain-pacha. The principal produce of its territory is silk, of which the quantity annually exported is estimated at 6000 okes. A considerable quantity of oranges and lemons is also exported for Salonica, Athens, and the Morea. The wheat, barley, wine, and oil, are generally sufficient for the consumption of the inhabitants. The island also produces legumes, herbage, various fruits, honey, wax, and cotton. It wants only a good harbour, and a better government. N. lat. 37° 50'. E. long. 25° 25'. Olivier's Travels in the Ottoman Empire, vol. ii. p. 105.

ANDROS, or EDROS, a small island in the Irish sea, now called "Bardsey," about a mile from the coast of North Wales.

ANDROS, a town of Asia Minor, in Galatia.

ANDROS was also a small island situate upon the coast of Gallia Aquitania. It is now a heap of rocks, upon which is built the tower of Cordouan, at the mouth of the Garonne.

ANDROS Islands, in Geography, lie on the south-west of Providence, in the Bahama islands, called by the Spaniards "Yllas del Espiritu santo." They extend from N. lat. 23° 30' to 25° 0', and from W. long. 77° to 77° 58', and take up a space of 30 leagues in length, and 4 or 5 broad, intersected by many very narrow passages.

ANDROSACE, *Androsace*, the shield of a man, so called from the form of the calyx, which, in the common species, is large, in Botany, a genus of the *pentandria monogynia* class and order, of the natural order of *procy*, and *lythrace* of Jussieu: its characters are, that the calyx is an involucre many-leaved, many-flowered, and very small; the perianthium is one-leaved, five-cornered, semiquinquefid, acute, erect, and permanent; the corolla is monopetalous, and salver-shaped; tube ovate and involved in the calyx; border flat and five-parted; divisions ovate-oblong, obtuse, entire; throat beset with glands; the stamina have very short filaments within the tube; anthers oblong, erect, and included; the pistillum is a globose germ, stylic filiform and very short; stigma globose and included; the pericarpium is a globose capsule, sitting on a flat calyx, one-celled, opening into five parts at the top; the seeds are very many, roundish, gibbous on one side, and flat on the other; the receptacle is erect and free. Martyn enumerates 7, Willdenow 10, and Gmelin 11 species. 1. *A. maxima*, oval-leaved *A.* with the perianths of the fruit very large. The flowers of this species appear in April or the beginning of May; the seeds ripen in June, and the plants soon after perish. It grows naturally among corn, in Austria, Bohemia, and other parts of Germany, in the Valais, Piedmont, Carniola and Hungary; and was cultivated here, in 1596, by Gerard. 2. *A. elongata*, cluster flowered *A.* with leaves lanceolate, toothed, fruiting umbel elongate, and corollas shorter than the angular calyx; a native of Austria, near Vienna, even in the suburbs; flowers in April, and perfects its seed in June; introduced, in 1776, by M. Thouin. 3. *A. septentrionalis*, arctia of Haller, tooth-leaved *A.* with leaves lanceolate, toothed, and smooth, and perianths angular, and shorter than the corollas: a native of Lapland, Sweden, Denmark, Switzerland, Germany, Russia, in mountainous situations; cultivated, by Mr. Miller, in 1755. 4. *A. villosa*, arctia of Hall, sedum of Clus. Chamæjalme alpina of Bauhin, hairy *A.* with leaves hairy and perianths shaggy; common in the Swiss Alps, Jura, &c. in the mountains of Austria and Carniola, in the Pyrenées, &c. introduced, in 1768, by professor de Saussure. 5. *A. laetea*, *A. obtusifolia* of Allion, arctia of Hall, sedum alpinum, &c. of Bauhin and Ray, grass leaved *A.* with leaves lanceolate and smooth, and umbel many times larger than the involucre; a native of the mountains of Switzerland, Austria, and Carniola, flowering, like the foregoing, in July and August. 6. *A. carnea*, arctia of Hall, sedum alpinum of Col. awl-leaved *A.* with leaves awl-shaped and smooth, and umbel equalling the involucre: a native of the Alps and Pyrenées, and introduced in 1768, by professor de Saussure. 7. *A. filiformis*, with leaves ovate-toothed, petioled, rays of the umbel capillary, and corollas exceeding the bell-shaped calyx; a native of Siberia. 8. *A. brevifolia* of Gmelin, with leaves lanceolate, petioled, and hispid, and peduncles four times longer than the involucre. This Willdenow ranks as a variety of the next species. 9. *A. obtusifolia*, with leaves smooth and lanceolate, calyxes angular, pubescent, and less than the corolla, and the folioles of the involucre very short (*G.*) or with leaves lanceolate, narrow at the base and smooth, and the perianths angular and pubescent. It is found on the high mountains of Switzerland, Italy, and Styria. 10. *A. odoratissima*, with leaves triquetrous and ciliated, and perianths shaggy (*G.*) or with leaves triquetrous, lanceolate, and ciliated, the rays of the umbel short, and the perianths angular, and shorter than the corolla; found in the high mountains of Cappadocia. 11. *A. pauciflora*, with leaves setaceous-linear, and smooth, two peduncles of the length of the stalk, and segments of the corolla emarginated.

Gmel.

Gmel. 12. *A. chamajafme*, *A. villosa* of Jacq, chameejafme of Bauhin, *sedum alpinum*, &c. of Cluf. with leaves lanceolate and narrow at the base, ciliate at the margin, and with shaggy perianths. It is found in the high mountains of Aultria. Willd.

Culture. These plants being low, and having small flowers, without any great appearance, are preserved only in botanic gardens. All, except the first, require a shady situation. The seeds should be sown soon after they are ripe; if permitted to scatter they will grow of themselves; the annual sorts perish as soon as the seeds are ripe, but the others, by being merely kept clear from weeds, will live in an open border for several years. Martyn's Miller.

ANDROSACE. See ARETIA.

ANDROSACE, in *Natural History*, a name given by some naturalists to the TUBULARIA ACETABULUM of Linnæus; this species is variously described by authors; it is corallina (androface) tubulosa simplex pelta terminali radiata of Pallas, androfaces cotyledon foliosum marinum of Lobel, androfaces peræ innascens of C. Bauh. pin. herba marina androfaces of Bess. mus. acetabulum marinum of Tournefort, plantula lapidea scutulata, and callophilophorum Matthioli of Donat. adr. Besides this Brown describes a variety, in which the target is not radiated. Vide Jamaica, p. 74. The Linnæan specific character is, the stems filiform and terminating in a calcareous target or cup, which is striated and radiated. Gmelin. This kind inhabits the Mediterranean and American seas, growing upon shells, stones, &c. it is white, soft, and fragile when dry: the tubes are simple, about the thickness of a straw, and two inches in length. Gmelin. This substance, reduced into powder, has been used in France for destroying worms and for dropsies. Dr. Lewis observes, that it does not promise to be of use in either of these intentions, or to differ from the coralline, which has been used as a vermifuge with little success. The dried androface, when held in the flame of a candle, yields repeatedly for several times a dazzling brightness, which is a phenomenon exhibited also by the coralline.

ANDROSÆMUM, in *Botany*. See HYPERICUM.

ANDROSCOGGIN, or AMARISCOGIN *River*, in *Geography*, a river of America, in the district of Maine, may be called the chief western branch of the Kennebeck. Its sources are north of Lake Umbagog, and it pursues a southerly course till it approaches near the White Mountains, from which it receives Moose and Peabody rivers; afterward turning to the east and south-east it passes within two miles of the sea coast, and again turning north, and running over Pejapstkaeg falls into Merry-Meeting Bay, where it joins the Kennebeck, 20 miles from the sea. The lands near this river are good.

ANDROSIA, in *Ancient Geography*, a town of Asia Minor, assigned by Ptolemy to the Troceni.

ANDROTOMY, or ANDRATOMY, from *ανω*, man, and *τομω*, I cut, the anatomy or dissection of human bodies. It is thus called in opposition to *zootomy*, which is used to denote that of brutes.

Anatomy is the genus, and comprehends all dissections in general, whether of men, beasts, or plants; and androtomy and zootomy are the species.

ANDROUET DU CERCEAU, JAMES, in *Biography*, a celebrated French architect, was born at Orleans, or, as some say, at Paris. He was sent for acquiring perfection in his art to Italy, where he was chiefly struck by the triumphal arch at Pola in Istria, to which there is a visible reference in the style of his works. Upon his return, though he was a steady Calvinist, he was made architect to Henry III. who employed him, in 1578, in the construction of the pont neuf at

VOL. II.

Paris. Henry IV. employed him in enlarging the Tuilleries, and continuing the great gallery that connects it with the Louvre. But persecution obliged him to quit his country in 1585; and the place of his retreat, and the time of his death are not known. He left two sons, one of whom was eminent in his father's profession. He was one of the principal improvers of architecture in France, and he published several books on the art; as his "Architecture," in 1560, comprehending designs of all the parts and ornaments of buildings; "Lessons in Perspective," in 1576; "The most excellent Edifices in France," in 1576 and 1607, 2 vols. folio, being a description of 30 royal palaces and other buildings, with figures; "Architecture of Country-houses and Mansions," 1582; and "Roman Edifices, or a Collection of Remains of Antiquity, drawn on the spot."

ANDRUM, in *Physiology*, a local disease, epidemical among the people of Malabar, being a peculiar species of *hydrocele*, or watery tumour of the *scrotum*. The andrum, in the language of the country, is also called *perical*; sometimes paraphrastically *andu wajaku*, q. d. a popular water rupture. Its origin is derived from the vicious quality of the country waters, impregnated with corrosive muriatic salts, the source of most other diseases that affect the Malabarians. Its signs, or symptoms, are an erysipelas of the *scrotum*, returning every new moon, by which the lymphatics being eroded, pour a ferrous saline humour into the cavity of the *scrotum*. The andrum is incurable; those once seized with it have it for life; but it is not dangerous, nor very troublesome, to those used to it; though sometimes it degenerates into a *hydrofarcocoele*. The means of prevention is by a heap of sand fetched from a river of the province Mangatti, and strewed in the wells. This is practised by the rich. As to the cure, they have only a palliative one, which is by incision, or tapping and drawing off the water from the *scrotum*, once in a month or two.

ANDRUSA, in *Geography*, a town of European Turkey in the Morea, 20 miles north-east of Navarin.

ANDRY, NICHOLAS, in *Biography*, born at Lyons in 1658, was made doctor in medicine at Rheims in 1693, having quitted the study of theology, in which he had been engaged several years. In 1697 he was admitted into the faculty of physic at Paris. In 1701 he was made professor of medicine there, and the following year censor or examiner of intended publications in that science. He died in 1742, aged 84 years. He was a considerable contributor to most of the medical and philosophical journals of the time, and in 1702, one of the editors of the "Journal des Savans." He wrote also a variety of other works, of which the principal are, "Cleon and Eudoxe," 2 vols. 12mo. Paris; in which he strenuously insists on the subordination of the surgeon to the physician. "Acrum et ingeniosum scriptum," Haller says. "De la Generation des vers dans le Corps Humain," 12mo. Paris. This was afterwards augmented to two volumes. At the end is an engraving of a tape-worm, of an enormous length, that had been voided entire by one of his patients. "Orthopedie, ou l'Art de prevenir et de corriger, dans les enfans, les difformites du Corps," two vols. 12mo. Paris, 1741; that is, the art of preventing or redressing any defects or deformities in the bodies of children. This is directed to be effected by regimen, exercise, and by various mechanical contrivances, and contains the germ, at the least, of every thing known on the subject at this time. The author composed this work, he says, as a supplement to the Callipædia, the art of getting handsome children, by Quillet; and the Pædotrophia, the art of rearing and nursing children, by

L I

Scævola

Scævola da St. Martha, two beautiful and well known poems, of which he gives an analysis in the preface to this work. The Orthopædia was soon translated into our language, as well as into those of most of the countries in Europe, and still retains its popularity. For the titles of numerous other productions by this writer, see Eloy's Dict. Histor. de la Médecine.

ANDRYALA, eriophorus of Vaillant, in *Botany*, a genus of the *Syngenesia polygamia aequalis* class and order, of the natural order of *composita semistrobilata*, and *cichoraceæ* of Jussieu. Its characters are, that the common calyx is many-parted, short, rounded, and villose; the scales are very many, subequal, and subulate (in a double row, G.); the compound corolla is imbricate and uniform; the corollules are hermaphrodite, numerous, and equal, each ligulate, linear, truncate, and five-toothed; the stamina have five filaments, capillary, and very short, anther cylindrical, and tubulose; the pistillum is an ovate germ, style filiform, of the length of the stamina, stigmas two, and reflex; no pericarpium, calyx converging and globose; the seeds are solitary and ovate, the down capillary, of the length of the calyx, (sessile, G.); the receptacle is villose and flattish, (alveolate and hairy, G.) Martyn enumerates six, and Gmelin eight species. 1. *A. integrifolia*, sonchus lanatus of Dalech. and Bauh. *S. villosus luteus* major of Bauh. and Parkins. hieracium villosum of Ray, hoary *A.* with lower leaves runcinate or notched, and upper ovate-oblong and tomentose. It is about a foot and a half in height; the flowers are in small clusters at the top of the stalk, yellow, and resembling those of fow-thistle; flowers in July, and its seeds ripen in September. There is a variety β . *A. sinuata*, which has the lower leaves indented and woolly, but those on the stem are entire; it seldom rises more than a foot high, and supports a few yellow flowers at top. These are annual plants, growing naturally in the South of France, Spain, Italy, and Sicily; and cultivated in the Chelsea garden in 1711. 2. *A. cheiranthifolia*, *A. glandulosa* of La Marek, *A. tomentosa* of Scop. various-leaved *A.* with leaves runcinate, upper ones lanceolate and entire, down glanduliferous. It is perennial, three feet high, and full of milk. A native of the island of Madeira, and introduced by Mr. F. Masson, who observed it there in 1777. 3. *A. pinnatifida*, with leaves tomentose and pinnatifid, and calyces tomentose and hairy, hairs rather stiff. There are two varieties: α . tooth-leaved *A.* with leaves pinnatifid, and pinnae distant and toothed; a native of Madeira; and β . wing-leaved *A.* with leaves deeply pinnatifid, and pinnae short and entire. A native of the Canary islands; found by Mr. F. Masson; flowering in July and August, and introduced in 1778. 4. *A. crithmifolia*, samphire-leaved *A.* with leaves pinnate, linear, and tomentose. A native of Madeira, found by Mr. F. Masson; flowering from June to August, and introduced in 1778. This and the last species are biennials. 5. *A. ragulina*, downy *A.* with leaves lanceolate, undivided, denticulate, acute, and tomentose, and solitary flowers. As it is very hoary it makes a pretty appearance intermixed with others, whose leaves are green; but it will not live abroad except in a dry soil and warm situation. It has been received from Spain, from the Cape, and from Algiers. Linnæus says, that it is a native of the islands of the Archipelago. This species has leaves stiffer, more acute, and more acutely toothed than the other species. 6. *A. lanata*, hieracium montanum tomentosum of Dill. Hall. and Mill. woolly *A.* with leaves oblong-ovate, slightly toothed and woolly, and peduncles branching; biennial according to Miller, but according to others perennial; flowering in June, and ripening its seeds in August; the whole plant is white. A native of the south of Europe; culti-

vated in 1732 by Dr. Sherard. 7. *A. nigricans*, with lower leaves lyre-shaped pinnate, peduncles ramose, and down blackish above. Poir. voy. cu Barb. 8. *A. uniflora*, with leaves smooth, entire, dentated, oblong-acute, with a single-flowered stalk. Schrank flor. bav.

Culture. All these plants may be propagated from seeds, sowing those of the hardy sort in Spring, where they are to remain. They require no other attention but to be thinned and kept free from weeds; the 2d, 3d, 4th, and 5th require the protection of a green-house, in which they will flower all the Summer, often perfecting their seeds, by which they may be propagated. The perennial sorts may be propagated by their creeping roots.

ANDRYALA. See LEONTODON.

ANDUC *Island*, in *Geography*, one of the group called the Maldives, on the east side, in N. lat. 6° 25'. E. long. 73° 40'.

ANDUJAR, or ANDUXAR, a town of Spain, with a castle, situate on the Guadalquivir, in the confines of Jaen and Cordova, and built near the spot on which stood Illurgis, or Illiturgis, called by the Romans Forum Julium, and now Andujar el Viejo. Its principal commodity is silk. The adjacent country abounds with wine, oil, honey, and various sorts of fruit and also game. It is 10 leagues east of Cordova, and 9 west of Jaen.

ANDUINNA, in *Entomology*, a species of PAPIPIO (Nymph. Phal.) found in Russia. The wings are dentated, fulvous, with black spots; under side of the posterior wings white, with two brown bands, and dotted behind with black. Fabricius and Gmelin.

ANDUZE, in *Geography*, a town of France, in the department of the Gard, and chief place of a canton, in the district of Alais, carries on a considerable trade in ferges and other woollen stuffs; eight leagues north-west of Nismes, and two fourth-west of Alais.

ANECDOTES, АНЕДОТА, a term used by some authors for the title of *Secret Histories*; but it more properly denotes a relation of detached and interesting particulars. It is now often used for a biographical incident or minute passage of private life.

The word is Greek, *anecdota*, q. d. *things not yet known*, or *hitherto kept secret*.

Procopius gives this title to a book which he published against Justinian and his wife Theodora; and he seems to be the only person among the ancients, who has represented princes such they are in their domestic relation. Varillas has published anecdotes of the house of Medicis. We have had repeated attempts for arranging anecdotes under different heads; a "Dictionnaire d'Anecdotes," in two volumes, was published at Paris in 1767; and a similar work was published by Mr. D'Israeli in 1793, entitled, "Dissertation on Anecdotes."

ANECDOTES is also an appellation given to such works of the ancients as have not yet been published.

In which sense M. Muratori gives the name *Anecdota Græca* to several writings of the Greek fathers, found in the libraries, and first published by him. F. Martene has given a *Thesaurus Anecdotarum Novus*, in folio. five vols.

ANE'E, otherwise called *asiée*, in *Commerce*, denotes a corn-measure, used in some provinces of France, particularly in Languedoc and Maconnois.

The anee is not so properly a measure as the denomination or assemblage of a certain number of other measures. The anee at Lyons consists of six *bichets*, equal to one *septier* and three bushels Paris measure. At Macon the anee is somewhat more.

ANÉE is also used for a quantity of wine supposed to be

an afs's load, and is fixed to eighty English quarts wine measure.

ANEGADA, in *Geography*, one of the Virgin Isles, in the West Indies, and dependent upon Virgin Gorda. It is about six leagues long, and so low as to be almost covered with water at high tides. On the south side is Treasure Point. N. lat. $18^{\circ} 35'$. W. long. 63°

ANEGADA Bay lies on the eastern coast of South America, and is formed by the mouth of the river Saucés, which falls into the South Atlantic ocean on the east, in S. lat. $39^{\circ} 45'$, and W. long. $62^{\circ} 30'$.

ANEIO, a town of Italy, in the kingdom of Naples and province of Otranto, eight miles south-west of Brindisi.

ANEL, DOMINIC, in *Biography*, physician to the court of Savoy, published, in 1707, in 8vo. "L'art de fucer les plaies sans se servir de la bouche de l'Homme, &c." Among the instruments by which this was performed was a kind of syphon, "metuendæ magnitudinis," of a fearful size, Haller says. But his principal work, and which is still respected, is his "Nouvelle Methode de guerir les fistules lachrymales," published at Turin, in 4to. 1713. He here describes a sound and a fine flexible tube, by which he was enabled to open the lachrymal duct, and by means of a syringe to wash away the sores, and finally heal the passage. This work gave rise to numerous controversial pieces, in some of which his method is censured, or the honour of the invention of it denied him. But the academy of surgery, at Paris, declared his method to be equally new and ingenious; and it has certainly led the way to all the improvements that have been since made in the method of treating this very troublesome complaint. Haller Bib. Chirurg. Eloy. Dict. Hist.

ANELE, or ANIL, in *Commerce*, the same with indigo. 23 Eliz. c. 9.

ANELLA, in *Entomology*, a species of PHALÆNA, of the tineæ tribe. The anterior wings are grey, with an obsolete brown stripe, and two central, sub-ocellated spots. Fabricius. This species inhabits Austria, is large, and has a ferruginous abdomen.

ANEMIUS furnus, among *Chemists*, a wind-furnace, used to make fierce fires for melting, &c. The word is formed of *νεμος*, wind.

ANEMO-CHORD, a name given to the Æolian harp. An instrument of this kind was constructed by John James Schnell, who was born at Wehingen, in the duchy of Württemberg, in 1740, and having passed through several stages of mechanical employment, became at length musical instrument-maker to the Countess of Artois at Paris. The founding of a harp, hung by accident in a passage admitting a breeze, suggested to him the idea of that instrument, which, in 1789, he first exposed to sale by the name of anemochorde.

ANEMOMACHIA, from *νεμος*, wind, and *μαχη*, fight, in some *Ancient Writers*, denotes a whirlwind, or hurricane. In which sense, we sometimes also meet with *anemozale*, *anemotaxis*, &c.

ANEMOMETER, compounded of *νεμος*, wind, and *μετρον*, measure, in *Mechanics*, a machine wherewith to measure the force and velocity of the wind. The anemometer is variously contrived. The first of the kind seems to have been invented by Wolfius in 1708, and first published in his "Aerometry" in 1709, and also in the "Acta Eruditorum" of the same year; afterwards in his "Mathematical Dictionary," and also in his *Elementa Matheos*, vol. ii p. 319. In the Philosophical Transactions we have one described, in which the wind being supposed to blow directly against a flat side or board, which moves along the graduated limb of a quadrant, the number of degrees it advances shews the comparative force of the wind.

This machine is moved by means of sails, A, B, C, K, (Plate IX. *Pneumatics*, fig. 69.) like those of a wind mill, which raise a weight L, that, still the higher it goes, receding farther from the centre of motion, by sliding along a hollow arm K M, fitted on to the axis of the sails, becomes heavier and heavier, and presses more and more on the arm, till being a counterpoise to the force of the wind on the sails, it stops the motion thereof. An index then, M N, fitted upon the same axis at right angles with the arm, by its rising or falling, points out the strength of the wind, on a plane divided like a dial-plate into degrees.

It is objected to this machine, however, that it requires a considerable wind to make it work. Leutmannus has contrived another, the sails of which are horizontal, and are more easily driven about, and will turn what way soever the wind blows.

In the Philosophical Transactions for the year 1766, Mr. A. Brice describes a method which has been successfully practised by himself, of measuring the velocity of the wind by means of that of the shadow of clouds passing over the surface of the earth.

Mr. d'Ons en Bray invented a new anemometer, which of itself expresses on paper not only the several winds that have blown during the space of twenty-four hours, and at what hour each began and ended, but also the different strength and velocities of each. Vide Mem. Acad. Scienc. an. 1734, p. 169. For other instruments of this kind, and their use, see WIND-Gage.

ANEMONE, formed from *ανεμος*, the wind, because the flower is not supposed to open, except the wind blows, or because it grows in situations much exposed to the wind, anemone and pulsatilla of Tourn. anemonoides, anemone-ranunculus, hepatica of Dill. anemonoides of Vaill. *wind-flower*, in *Botany*, a genus of the *polyandria polyginta* class and order, of the natural order of *multiflora*, and *ranunculacea* of Jussieu; its characters are, that it has no calyx; that the corolla has petals in two or three rows, three in a row somewhat oblong; the stamina have numerous filaments, capillary, half the length of the corolla; anthers twin and erect; the pistillum has numerous germs in a head, styles acuminate, and stigmas obtuse; no pericarpium; receptacle globular or oblong, hollowed, and dotted; the seeds very many, acuminate, retaining the style. Obs. Hepatica of Dill. has a three-leaved perianthium, remote from the flower; an involucre. Pulsatilla of Tourn. has a leafy, multifid involucre, with the seeds tailed and hairy. Anemonoides and hepatica of Dill. have naked seeds, without a feathered tail. Martyn enumerates 28, Gmelin and Willdenow 29 species.

* *Hepatica*, with a subcalyculate flower. 1. *A. hepatica*, hepatica, with leaves three-lobed, quite entire. The flower lies a year complete in all its parts within the bud; the seeds are oblong-ovate, involved in a silky substance, and many of them abortive; the plant is a mild allringent and corroborant; and formerly used with these intentions, in an infusion like tea, or in powder given to the quantity of half a spoonful at a time; but it is now expunged from the dispensaries, and its use does not extend beyond that of gargarisms; it is found wild in Sweden abundantly, in Denmark, Switzerland, France, Spain, Italy, and other parts of Europe, in woods and among bushes, with blue, red, and white flowers, single: cultivated here, in 1596, by Gerard. There are many varieties of hepatica, which are common in gardens, as single and double blue, single and double red or peach-coloured, single and double white, single and double variegated red and white, single and double violet-coloured, and with striped leaves. Parkinson mentions a white, with red stamens. These are some of the chief ornaments of the Spring; the

A N E M O N E.

flowers are plentifully produced in February and March, before the green leaves appear, and make a very beautiful figure in the borders of the pleasure-garden, especially the double sorts, which commonly continue a fortnight longer in flower than the single ones, and the flowers are much fairer.

*** *Pulsatilla*, with the peduncle involucred, and the seeds tailed. 2. *A. patens*, *pulsatilla patens* of Mill. *pulsatilla polyanthes violacea*, *anemones folio* of Breyn. and Helw. woolly-leaved *A.* with peduncles involucred, and leaves digitate and multifid. The corolla is white, villose underneath, and the stamens yellow; a native of Siberia, about Tobolski, and also of lower Lusatia; cultivated here in 1759 by Mr. Miller. 3. *A. sulphurea*, with peduncle involucred, leaves triply-pinnate, hairy, flat, acutely gashed, and seeds tail'd. 4. *A. helenifolia*, with biternate shaggy leaves, or with biternate leaves, tripartite folioles, triid lacinie, foliose involucre, and woolly seeds, with a very short permanent style, Willd. It is distinguished from the *A. alpina*, which it resembles, by its leaves and seeds; and grows wild about Aigle, &c. in Switzerland, Mont Baldo, M. Cenis, &c. 5. *A. vernalis*, *pulsatilla vernalis* of Miller, with peduncle involucred, leaves pinnate, folioles tripartite, obtuse and smooth, and erect flowers, Willd. The flower is red without, and white within, and blows earlier than our pasque-flowers. It grows in the woods, bordering on the mountains, in barren lands, in Sweden, Germany, and the high Alps of Switzerland. 6. *A. cernua*, with peduncle involucred, leaves pinnate, and flowers nodding. It differs from the last species in the nodding of the flowers, and in the leaves having more pinnæ finely cut. Thunberg found it near Jedo, in Japan, flowering early in Spring. 7. *A. pulsatilla*, *pulsatilla folio crassiore et majore flore* of Bauhin. Park. Mor. Ger. Helw. Camer. and Ray, *pulsatilla vulgaris* of Miller, *A. pratensis* of Sibth. and Wither. pasque-flower, with peduncle involucred, petals straight, and leaves bipinnate. It grows wild on open hills in dry soils, in Sweden, Denmark, Switzerland, France, Italy, Germany, Carniola, Siberia, &c. and in England on chalky downs, as Gogmagog hills, near Cambridge; Barnack heath, near Stamford, in the neighbourhood of Pontefract, near Chelbury in Oxfordshire, Lexham, Bury, Newmarket, &c. It is perennial, and flowers in April and May. It has the Italian name *pulsatilla*, from the downy seed being beaten about by the wind. The plant is acrid, and will raise blisters; the distilled water will vomit; and it cannot be given with safety in disorders of the lungs. The juice of the petals stains paper green. Goats and sheep eat it; but horses, cows, and swine refuse it. There is a variety with double, and another with white flowers. 8. *A. pratensis*, *pulsatilla pratensis* of Miller, *flore minore nigricante* of Bauh. and Helw. *p. vulgaris*, *faturatiore flore* of Clauf. *p. flore minore* of Ger. *p. flore clauso obsoleto*, *petalis reflexis* of Helw. *p. foliis decompositis pinnatis*, *flore pendulo*, *limbo reflexo* of Hort. Cliff. &c. Meadow *A.* with peduncle involucred, petals reflex at the tip, and leaves bipinnate. It is very common in the barren stony fields of Oeland and Scania, also in Denmark, Piedmont, and in Germany, where it grows in the open fields and flowers in May. It was first cultivated in England by Mr. Miller in 1731, and in our gardens it very much resembles the *A. pulsatilla*, which would prove a good substitute to it; the principal distinctions between these species, as they grow naturally, are taken from the flower, which in this species is more pendulous, of a darker colour, and has the apices of the petals reflexed: the stem is also said to be less hairy and shorter than that of the *pulsatilla*; to which may be added, that the leaves of the *pratensis* are somewhat tomentose, while those of the *pulsatilla* are of a

bright green. All the anemones have a considerable degree of acrimony; but this (says Dr. Lewis) seems to possess the greatest share. In its recent state the plant has scarcely any smell; but its taste is extremely acrid, and when chewed, corrodes the tongue and fauces; and the dried plant likewise retains a considerable share of acrimony. The root is milder than the other parts. The liquor, obtained by distilling the plant with water, is strongly impregnated with its virtues; and the remaining extract is considerably active. It also appears from some experiments to contain a camphoraceous matter, which was obtained in the form of crystals, of an unctuous taste, and very inflammable. This plant, as well as others of great activity, has been received into the *Materia Medica* of the Edinburgh pharmacopœia, upon the authority of Baron Stoerck, who recommends it as an effectual remedy for most of the chronic diseases affecting the eye, particularly amaurosis, cataract, and opacity of the cornea, proceeding from various causes. He likewise found it of great use in venereal nodes, nocturnal pains, ulcers, caries, indurated glands, suppressed menses, serpiginous eruptions, melancholy and palsy. Six cases of amaurosis, three of cataract, and seven of affections of the cornea, we are told, were either entirely cured, or greatly relieved, by this remedy. The sensible operation of the medicine was nausea and vomiting, particularly when the distilled water was used; and increased flow of urine; and sometimes gripes and looseness with increased pain at first in the affected part. The dose of the distilled water to adults is about half an ounce, twice or thrice a day; of the extract, reduced to powder with the addition of sugar, five or six grains. Many German physicians have tried the effects of this medicine in diseases of the eyes, with success; but several others, among whom is Bergius, bear testimony to its inefficacy in these diseases, though they increased the dose beyond that directed by Stoerck. Notwithstanding this, says Dr. Cullen, (*Mat. Med.* vol. ii. p. 216.) "I would still recommend it to the attention of my countrymen, and particularly to a repetition of trials in that disease, so frequently otherwise incurable, the amaurosis. The negative exception of Bergius, and others, is not sufficient to discourage all trials, considering that the disease may depend upon different causes; some of which may yield to remedies, though others do not." Every part of the plant, except its root, is ordered for medicinal use, and was prepared by Baron Stoerck for that purpose into an extract, or distilled water, and an infusion; but the first form seems to have been preferred, and was given from seven grains to three or four times that quantity, twice or thrice a day. The fluid preparations of the plant are likewise recommended for external use in ulcers and disorders of the skin. The manner of preparing the extract is given in the Edinburgh pharmacopœia. Murray's *Mat. Med.* vol. iii. p. 93.—101. Lewis's *Mat. Med.* p. 525. Woodville's *Med. Bot.* vol. iii. p. 400—403.

9. *A. alpina*, *pulsatilla flore albo* of Bauh. and Lob. *alpina A.* with stem-leaves ternate, connate, superdecompound, multifid, and seeds shaggy tailed. Willdenow mentions as a variety, *A. alpina alba major* of Bauh. and Burf. This species grows wild on the Alps, Jura, and in Austria, and was cultivated here by Mr. Miller in 1731. 10. *A. apiifolia*, *pulsatilla lutea* of Camer. and Gesn. *p. tertia alpina* of Dalech. *A. sylvestris tertia* of Cluf. with stem-leaves ternate, connate, superdecompound, multifid, very slender, extremely hairy underneath. It has no smell, and is a native of the Leon-tine Alps. It is doubted whether it be a distinct species from the last.

*** *Anemones* with a leafy stem, and tailed seeds. 11. *A. coronaria*, *pulsatilla foliis decompositis ternatis* of Hort. Cliff.

ANEMONE.

Cliff. *A. tenuifolia*, simplici flore of Bauh. narrow-leaved garden A. with radical leaves ternate-decompound and involucre leafy, or with radical leaves ternate-decompound, mucronated teeth, leafy involucre and woolly seeds; according to Willdenow, who reckons as varieties *A. tenuifolia* multiplex rubra of Bauh. and *A. angustifolia* multiplex, mutata florum facie quotannis nova of Miller. This species grows naturally in the Levant, particularly in the islands of the Archipelago, where the borders of the fields are covered with it of all colours; but the flowers are single and have been rendered double by culture. It was cultivated in France long before it was known in Holland or England: in our gardens, however, it was found in 1596. Parkinson, in 1629, says, that some reckoned 30 sorts with single flowers; and of those with double flowers he gives 12 varieties. Ray enumerates near 300 varieties of this and the broad-leaved sort. The catalogues of our modern seedsmen have usually about 150 or 200. The principal colours in anemones, according to Mr. Miller, are white, red, blue, and purple; and in some these are curiously intermixed; but the most prevailing colours amongst our English raised anemones are white and red; though we have received from France a great variety of blues and purples, which are very fine flowers. The plain colours in the modern catalogues are red, crimson, rose-coloured, purple, lilac, clear and pale blue, ash-coloured and white. The principal variegated ones are red and white striped, rose and white, blue and white, red, white, and purple; but there are innumerable shades of these and the other colours. A double anemone, in order to be fine, should have a strong upright stem, about nine inches high; the flower from two to near three inches in diameter, the outer petals firm, horizontal, except turning up a little at the end, and the smaller petals within these should lie over each other gracefully, so as to form an elegant whole. The plain colours should be brilliant and striking; the variegated ones should be clear and distinct. 12. *A. hortensis*, pulsatilla foliis digitatis of Hort. Cliff. broad-leaved garden A. or hard-leaved A. or star A. with leaves digitate and seeds woolly; or, according to Willd. with radical leaves digitate, laciniae trifid, stem leaves ternate, lanceolate, connate, and subdivided, and woolly seeds. It is found wild, with single flowers, in Italy, Provence, and Germany. There are several varieties of this with single and double flowers; it was cultivated here by Gerard in 1597. 13. *A. palmata*, pulsatilla foliis palmatis of Hort. Cliff. *A. latifolia* flava of Bauh. or *A. hortensis latifolia* of Clus. with leaves heart-shaped and sublobate, and calyx six leaved and coloured. This species connects the hepaticas with the anemones by its six-parted calyx. It was found by Clusius in Portugal, near the Tagus.

*** *Anemoneides*, with a naked flower, and tailless seeds. 14. *A. sibirica*, with stem one-flowered, involucre leafy, and obtuse; found by Gmelin in Siberia. 15. *A. sylvestris*, large white-flowered wood A. with naked peduncle and seeds roundish, shaggy and awnless; or with a stem two-flowered and leafy, leaves tripartite, laciniae trifid and dentated, seeds roundish and woolly, and permanent stigma, according to Willdenow, who mentions as a variety, *A. sylvestris alba* minor of Bauhin, &c.; a native of many parts of Germany, found also in Sweden, Alsace, and Siberia; flowering in May, and ripening its seeds in June. 16. *A. fragifera*, with peduncle naked, seeds roundish, woolly, awnless, gashes of the leaves acute, and lanceolate; a native of Carinthia. 17. *A. virginiana*, virginian A. with peduncles alternate, very long, fruit cylindrical, and seeds shaggy and awnless; or according to Willd. with many flowered leafy stem, tripartite leaves, laciniae trifid acuminate and dentated, acute petals, shaggy seeds, and very short per-

manent style; a native of North America, cultivated here in 1722, and flowering in May and June. 18. *A. decapetala*, ten-petalled A., with stem one-flowered, flower ten petalled, leaves ternate, lobate and radical; a native of Brazil. 19. *A. pennsylvanica*, pennsylvanian A. with stem dichotomous, leaves sessile, stem-clasping, the lowest ternate, trifid, and gashed; resembling the dichotoma, a native of Canada and Pennsylvania, and cultivated here in 1766 by Mr. J. Gordon. 20. *A. dichotoma*, with stem dichotomous, leaves sessile, all opposite, stem-clasping, trifid and gashed. It flowers about Midsummer, and ripens its seeds; a native of Canada and Siberia, and sent growing into Sweden by David de Gorter, physician to the emperors of Russia, in 1760. 21. *A. trifolia*, with leaves ternate, ovate, entire, ferrate; and stem one-flowered; a native of France, Carniola, and Siberia, growing in woods and flowering at the end of April. 22. *A. quinquefolia*, ranunculus nemorum, &c. of Pluk. with leaves quinate, oval and ferrate, and stem one-flowered; a native of Virginia and Canada. 23. *A. nemorosa*, wood A. ranunculus sylvarum of Clus. *A. nemorum alba* of Ray and Ger. with seeds acute, leaflets gashed, and stem one-flowered. This grows in woods, among bushes and in hedges, in most parts of Europe, and sometimes in pastures. In many of our woods the ground is almost covered with the flowers in March, April, and May. In fine clear weather, the blossoms are expanded and face the sun; but in the evening and wet weather, they are closed and hang down. It is perennial, and flowers in April. This plant is acrid, and in some degree poisonous. Linnæus says, that cattle brought from open to woody pastures, and eating this plant, have been affected with the bloody flux, and have made bloody urine. Goats and sheep eat it; but horses, cows, and swine refuse it. It is now disused in medicine; but Chomel says, that the leaves bruised with the flowers, and applied twice a day to the head, have in a little while healed the tinea; and it is also said that a blister prepared of these when recent serves to remove intermittent fevers, but it should be cautiously used. This plant may be employed as a dye, because Dr. Stokes says that the paper in which dried specimens are preserved is stained brown. This plant is sometimes found with yellow dots on the under surface of the leaves, and has been mistaken for a polypodium. Some have supposed these dots the work of an insect, but without sufficient proof. Mr. Relhan ascribes this appearance to the *Æcidium fuscum*; but Dr. Pulteney (in Linn. Transf. vol. ii. p. 305.) has rendered it probable, that they are formed by a minute species of lycoperdon, allied to the lycoperdon epiphyllum of Linnæus; though as they may be discovered in their younger state under the outer cuticle of the leaf, it is not evident how the seeds could be introduced. The plants thus affected are in a feeble or morbid state, of a yellow green, and do not bear flowers. When the flowers become double, the wood anemone is cultivated by the gardeners; if pains were taken with it, it might be much improved. 24. *A. apennina*, ranunculus nemorosus, flore purpureo cæruleo of Park. Ray, Mentz, and Clus. blue mountain A. with scape involucred and one-flowered, involucre three-leaved petiolate and foliaceous, seeds tailless, and petals lanceolate and numerous. Smith. It bears some affinity in its foliage to the preceding, but the root is thicker, the petals much narrower; more than twice as many, and of a light pleasant purplish blue; it is perennial and flowers in April; it grows in woods and shady places; a native of the Apennines, near Rome, and of some few places in England, as Lord Spencer's park at Wimbledon, near Harrow on the Hill, a wood near Luton Hoe in Bedfordshire, and near Berkhamstead in Herts.

It

It is a very ornamental plant, suitable to the flower-garden or plantation, and loves a light loamy soil. 25. *A. ranunculoides*, *A. nemorum* lutea of Ger. *ranunculus nemorosus luteus* of Bauhin, yellow wood *A.* with seape involucred subbiflorous, involucre three-leaved subsessile and foliaceous, tailless seeds, and petals elliptic and by fives, Smith; or with acute seeds, leaflets gashed, petals roundish, and stem mostly one-flowered. It differs from the *A. nemorosa* or wood *A.* in having a yellow corolla, two petals alternately outer, and two inner, and one having one side within and the other side without the next petal, whereas that has three outer and three inner petals; it differs also in the peduncles being accompanied with two leaflets, the latter of which is furnished with three at the base. This is perennial and flowers in April; grows wild in Sweden, Denmark, Switzerland, France, Germany, Austria, Carniola, Italy, and Siberia; and with us in shady places and hedges, near King's Langley, Herts, and near Wrotham, in Kent. 26. *A. narcissiflora*, *ranunculus montanus*, &c. of Bauh. narcissus-flowered *A.* with flowers umbelld (involucred Willd.), and seeds oval-depressed and naked (radical leaves palmated and gashed dentated, Willd.) This grows wild on the mountains of France, Switzerland, Austria, Silesia, Siberia, and Cappadocia: introduced here in 1773 by John, earl of Bute. 27. *A. fasciculata*, *ranunculus orientalis*, &c. of Tourn. with flowers umbelld, collected, and leaves multifid. This was first observed by Tournefort, in the Levant, and is found on the mountains about the lake Baikal. Linnæus doubts whether it be a distinct species; Haller thinks it is only a variety of the last species, and Willdenow says, that it differs only in having shorter peduncles. 28. *A. thalicroides*, *ranunculus nemorosus, aquilegiæ foliis*, &c. of Pluk. meadow rue-leaved *A.* with flowers umbelld, stem-leaves simple, and verticillate; and radical leaves ternate. It grows wild in Virginia and Canada, and was cultivated here in 1768 by Mr. Miller. 29. *A. Halleri*, with leaves shaggy and pinnate, the pinnæ acutely lobated, and the involucre multifid, Gmelin from Allion. flor. pedcm., or with involucred peduncle, pinnated leaves, leaflets tripartite, acuminate, and villose, and flower somewhat erect, Willd.; a native of the Alps of Piedmont, &c. Willdenow has omitted the fragifera, fasciculata and sulphurea, and inserted the following species, viz. *A. triternata*, with leaves ternated, leaflets cuneated and slightly cut, and multifid involucre; a native of Brasil, and described by Vahl. *A. reflexa*, with stem subbiflorous, stem-leaves by threes and ternated, leaflets subtrifid, at the tip dentated, and petals lanceolate, obtuse, and reflex; a native of Siberia, and very much resembling *A. ranunculoides*. *A. umbellata*, *ranunculus orientalis napelli folio lanuginoso flore albo* of Tourn. with flowers umbellate and involucred, radical leaves tripartite, and lacinix trifid and entire; a native of Cappadocia.

Culture. The plants of this genus are mostly hardy perennials, and may be increased both by seeds and by the roots. The *Hepaticas* are some of the chief beauties of the Spring; they produce flowers in February and March, before the green leaves appear; and the double sorts especially make a very handsome figure, continue a fortnight longer in flower than the single ones, and afford much fairer flowers. The single sorts are easily propagated by seeds, which they produce every year. The best season for sowing them is the beginning of August, and they should be sown in boxes or pots of light earth, exposed only to the morning sun till October, and then removed to the full sun during the whole Winter. In March, when the plants begin to appear, they should be removed to a shady situation, and frequently watered in dry weather. In August they will be fit to be

transplanted; for this purpose a border should be prepared facing the east, of good fresh loamy earth, in which the plants should be set at about six inches distance every way, and the earth should be closed firmly to the roots, to prevent their being injured by the worms; in the following Spring they will shew their flowers, but it will be an interval of three years before the flowers are strong, and you are able to judge of their goodness. If at this time any double flowers, or any of a different colour from the rest should appear, they should be transplanted into the borders of the flower-garden, where they should continue at least two years before they are taken up or parted. The double flowers, which never produce seeds, are propagated by parting their roots in March when they are in flower. The soil in which they delight is strong and loamy, in an eastern situation exposed to the morning sun.

The *pulsatillas* (2—10.) may be propagated by seeds, in boxes or pots filled with light sandy earth, and exposed to the morning sun till ten, and secured from it in the heat of the day, and in dry weather often refreshed with water. The seeds are best sown in July and August soon after they are ripe. The pots should remain in a shady situation till October, and then exposed to the full sun during the Winter. About the beginning of March, when the plants appear, they should only have the forenoon sun, be refreshed with water in dry weather, and kept free from weeds. When the leaves are decayed, which occurs usually in July, all the roots should be carefully taken up, and immediately planted in beds of light, fresh, sandy earth, about three or four inches asunder, and covered to the depth of about three inches with the same light earth. In the following Spring most of these plants will produce flowers, but they will be larger and fairer in the succeeding years, when the roots are larger.

The *garden anemones* (11, 12.) are natives of the east, from whence their roots were originally brought; but culture has so improved them, that they are become the chief ornaments to our gardens in the Spring. To prepare the soil for these plants, take a quantity of fresh, light, sandy loam, or hazel-earth, from a common or dry pasture, not dug above ten inches deep; mix this with a third part its quantity of rotten cow-dung, and lay it up in a heap; turn this over at least once a month, for eight or ten months, and every time pick out the stones and break the clods. After this mixture has been twelve months made, it will be fit for use.

The beds of this earth must be prepared in September, and should be made six or eight inches deep, in a wet soil; but in a dry one three inches will be sufficient; lay this compost at least $2\frac{1}{2}$ feet thick, with about four or five inches of rotten neat's dung, or the rotten dung of an old melon or cucumber bed at the bottom; in a wet soil let the beds be rounded, so that the water may run off; but in a dry soil let them be nearer to a level: three weeks after the compost has been laid in, stir it about six inches deep with a spade, and then with a stick draw lines each way of the bed, at six inches distance, so that the whole may be in squares; then make a hole three inches deep in the centre of each square, and plant a root in each; and when all are planted, rake the earth of the whole bed smooth, so as to cover the roots two inches thick. The season of planting these roots for forward flowers is the latter end of September, and for those of a middle season is October: this is best done at a time when there are gentle rains. Some roots should also be saved to be planted after Christmas, for fear of accidents to the former from very hard weather. These usually flower three weeks after those planted in Autumn.

ANEMONE.

In the beginning of April the early planted roots will begin to flower, and they will keep in flower near a month, if the weather prove favourable, and they are properly shaded with mats, laid over hoops in the greatest heat of the day: the second, and last planted ones, will follow these; and, in the whole, there will be at least two months fine flowering.

Toward the beginning of June the first planted roots will lose all their leaves, and they must be then taken up and washed clean, and laid to dry on mats in the shade; after which they are to be put up in paper bags, and hung up till the time of planting them comes on again. The later planted ones are to be taken up also as soon as their leaves decay, and not suffered to remain to make new shoots, for then it is too late to remove them.

They are propagated two ways, either by dividing the roots or by sowing. The roots are to be divided as soon as they are taken up out of the ground: they will succeed if broken into as many parts as there are eyes or buds in them; but they flower most strongly, if not parted too small.

The way, by sowing, is this: choose first some good kinds of single anemones, called by the gardeners *poppy anemones*; plant these early, and they will produce ripe seeds three weeks after the flower first blows. This must be carefully gathered, and in August it should be sowed in pots or tubs, or a very well prepared bed of light earth, rubbing it between the hands with a little dry sand, to prevent several of the seeds from clinging together, and spreading them as even as possible all over the bed; after this a light hair-brush should be drawn many times over the surface of the bed, to pull asunder any lumps of seed that may yet have fallen together; observing not to brush off the seed, and as much as possible not to brush it into heaps. When this is done, some light earth, about a quarter of an inch deep, should be sifted over the bed. If the weather be hot, the bed must be at times covered with mats laid hollow, and gently watered.

In about ten weeks after sowing, the plants will appear, if the season has been favourable, and they are to be carefully defended from the hard frosts by proper covering, and from the heat of the sun afterwards by a moveable reed-fence. As the Spring advances, if the weather be dry, they must be gently watered, and when their green leaves decay, there must be a quarter of an inch more earth sifted over them, and the like again at Michaelmas; and the bed must be kept clear from weeds, and the following Spring they will flower.

The single or poppy anemones will flower most part of the Winter and Spring, when the seasons are favourable, and in a warm situation; and they require little culture, for it will be sufficient to take up the roots every other year, and when they are taken up, they should be planted again very early in the Autumn, or else they will not flower till the Spring. There are some fine blue colours among these single anemones, which, with the scarlets and reds, form a beautiful mixture of colours; and as these begin to flower in January or February, when the weather is cold, they will continue for a long time in beauty, provided that the frost is not too severe. The seeds of these are ripe by the middle or end of May, and must be gathered daily as they ripen, otherwise they will soon be blown away by the winds.

The roots of *wood anemone* (23, 24, &c.) may be taken up when the leaves decay, and transplanted into wildernesses, where they will thrive, and in the Spring have a good effect in covering the ground with their leaves and flowers. The *blue anemone* (24.) flowers at the same time with the foregoing, and intermixed with it, makes a fine variety. Double flowers of both these sorts have been obtained from seeds.

This, and most of the other wild anemones, may be propagated by offsets from the root, which they put out plentifully, and they will grow in moist soils and situations. *Virginian anemone* (17.) and some others, produce plenty of seeds, and may be readily increased also that way. Martyn's Miller.

ANEMONE pumilla. See DRYAS.

ANEMONE, in *Natural History*, a species of HYDRA in Gmelin's arrangement, but which should with more propriety be referred to the ACTINIÆ of Linnæus, as Ellis had placed it with other analogous species before. The body is fleshy and flat, the disk sub-hexagonal, and surrounded with numerous tentacula. It is found in the West Indian seas.

ANEMONE is likewise the trivial name given by some to the ACTINIÆ of Linnæus in general; hence the French author Dicuemarre calls the *actinia rufa* of Linn. *Anemone de la première espece*, *actinia crassicornis*, *anemone de la seconde espece*, &c. &c.

The singular reproductive properties of this kind of vermes is now sufficiently ascertained, yet it appears that we were in a considerable degree indebted to the accurate observations and experiments of M. Dicquemarre, in the first instance, for the interesting discovery. This author conjectures that it is owing to the gelatinous texture of those creatures that they possess the wonderful faculty of reproduction. He observes, that their limbs budded out successively after several amputations; nay, some of them were dissected through the body; and the basis, together with that part of the stump which was left, survived, projected new limbs, and the animal moved and eat bits of muscles, which are its usual nourishment. They appeared to bear a considerable degree of heat, and to live in a vacuum, at least in a very rare air; and they require for a very considerable time no other food than what they find disseminated in sea water.

Dicuemarre endeavours to prove that sea anemones may be made use of for indicating the different changes of temperature in the atmosphere; but certainly without success, as the observations of later naturalists fully demonstrate. His account of this new kind of barometers is thus related. The sea-water, in which the anemones are placed, must be renewed every day, and this must be their only nourishment; and the observations should be made at intervals equally distant from the renewals of the water. If the anemones be shut and contracted, there is reason to apprehend an approaching storm; that is, high winds, and a rough agitated sea. When they are all shut, but not remarkably contracted, they forebode a weather somewhat less boisterous, but still attended with gales and a rough sea. If they appear in the least open, or alternately and frequently opening and closing, they indicate a mean state both of winds and waves. When they are quite open, tolerably fine weather and a smooth sea may be expected. And, lastly, when their bodies are considerably extended, and their limbs divergent, they surely prognosticate fixed, fair weather, and a very calm sea. The glass in which they are deposited may be swung at sea, in the same manner as the compass, so that the rolling of the ship, may agitate the water as little as possible. These animals are viviparous; for several of them brought forth eight, ten, or twelve young ones in the hand.

The account of the species *sociata*, as related by Mr. Ellis, in the Philosophical Transactions, affords still more accurate information concerning this tribe of creatures, their internal organization, economy, &c. than the reports of Dicquemarre. "This compound animal, which is of a tender fleshy substance, consists of many tubular bodies, swelling gently towards the upper part, and ending like a
bulb,

bulb or very small onion; on the top of each is its mouth, surrounded by one or two rows of tentacles, or claws, which when contracted look like circles of beads.

"The lower part of all these bodies has a communication with a firm fleshy wrinkled tube, which sticks fast to the rocks, and sends forth other fleshy tubes, which creep along them in various directions. These are full of different sized of these remarkable animals which rise up irregularly in groups near one another.

"This altho'ng tube, that secures them fast to the rock or fleshy bottom, is worthy of notice. The knobs that we observe are formed into several parts of it by its insinuating itself into the inequalities of the coral rock, or by grasping other pieces of shells, part of which still remain in it, with the fleshy substance grown over them.

"This shews us the instinct of nature, that directs these animals to preserve themselves from the violence of the waves, not unlike the anchoring of muscles, by their fine sicken filaments that end in suckers, or rather like the fleshy basis of the serpula, or worm-shell, the tree oyster, and the slipper barnacle, &c. whose bases conform to the shape of whatever substance they fix themselves to, grasping it fast with their tentaceous claws to withstand the fury of a storm.

"When we view the inside of this animal dissected lengthwise, we find a little tube leading from the mouth to the stomach, from whence there rise eight wrinkled small guts, in a circular order, with a yellowish soft substance in them; these bend over in the form of arches towards the lower part of the bulb, from whence they may be traced downwards to the narrow part of the upright tube, till they come to the fleshy adhering tube, where some of them may be perceived entering into the papilla, or the beginning of an animal of the like kind, most probably to convey it nourishment till it is provided with claws; the remaining part of these slender guts are continued on in the fleshy tube, without doubt for the same purpose of producing and supporting more young ones from the same common parent.

"The many longitudinal fibres that we discover lying parallel to each other, on the inside of the semi-transparent skin, are all inserted in the several claws round the animal's mouth, and are plainly the tendons of the muscles for moving and directing the claws at the will of the animal: these may likewise be traced down to the adhering tube."

Another remarkable creature of this kind is described in Hughes's Natural History of Barbadoes, and which, it is said, was only found in a basin in one particular cave.

"In the middle of the basin," says that author, "there is a fixed stone, or rock, which is always under water. Round its sides, at different depths, seldom exceeding 18 inches, are seen, at all times in the year, issuing out of little holes, certain substances that have the appearance of fine radiated flowers, of a pale yellow, or a bright straw colour, slightly tinged with green, having a circular border of thick-set petals, about the size of, and much resembling those of a single garden-marigold, except that the whole of this seeming flower is narrower at the discus, or setting on of the leaves, than any flower of that kind.

"I have attempted to pluck one of these from the rock, to which they are always fixed, but never could effect it; for as soon as my fingers came within two or three inches of it, it would immediately contract close together its yellow border, and shrink back into the hole of the rock; but if left undisturbed for about four minutes, it would come gradually in sight, expanding, though at first very cautiously, its seeming leaves, till at last it appeared in its former bloom. However, it would again recoil with a surprising

quickness when my hand came within a small distance of it. Having tried the same experiment by attempting to touch it with my cane, and a small slender rod, the effect was the same.

"Though I could not by any means contrive to take or pluck from the rock one of these animals entire, yet I once cut off (with a knife which I had held for a long time out of sight, near the mouth of an hole out of which one of these animals appeared) two of these seeming leaves. These, when out of water, retaining their shape and colour; but being composed of a membrane-like substance, surprisingly thin, it soon shrivelled up and decayed."

The same author further adds, that many people coming to see these creatures, and occasioning some inconvenience to a person through whose grounds they were obliged to pass, he resolved to destroy the objects of their curiosity, and that he might do so effectually, caused all the holes out of which they appeared to be carefully bored and drilled with an iron instrument, so as to crush their bodies to a pulp, and yet they again appeared in a few weeks from the very same places. It has been suspected that this Barbadoes *anemone* may be a species of tubularia rather than actinia.

ANEMONOIDES, in Botany. See ANEMONE.

ANEMONOSPERMOS. See ARCTOTIS and GORTERIA.

ANEMOSCOPE, derived from *ανεμος*, wind, and *σκοπεω*, I consider, is sometimes used for a machine invented to foretel the changes of the wind. For this purpose it should consist of an index moving about a circular plate, like the dial of a clock, on which the 32 points of the compass are drawn instead of the hours. The index, pointing to the divisions in the dial, is turned by an horizontal axis, having a handle-head at its outward extremity. This handle-head is moved by a cog-wheel on a perpendicular axis; on the top of which is fixed a vane, that moves with the course of the wind, and gives motion to the whole machine. The whole contrivance is very simple, and nothing is required in the construction, but that the number of cogs in the wheel and rounds in the trundle-head be equal; because it is necessary, that when the vane moves entirely round, the index of the dial should also make a complete revolution. An anemoscope of this kind is placed in one of the turrets of the Queen's palace. An account of an anemoscope contrived by Mr. Pickering, may be seen in the Phil. Transf. vol. xliii. pl. II. p. 9; and another described by Mr. Martin, in his Philos. Britan., vol. ii. p. 211. See ANEMOMETER and WIND GAGE.

It has been observed, that hygrosopes made of cat's-gut, &c. prove very good anemoscopes; seldom failing, by the turning of the index about, to foretel the shifting of the wind.

The anemoscope used by the ancients seems, by Vitruvius's description of it, to have been intended rather to shew which way the wind actually blew, than to foretel into which quarter it would change.

Otto de Gueric also gave the title anemoscope to a machine invented by him, to foretel the change of the weather, as to fair and rain. It consisted of a wooden little man, who rose and fell in a glass tube, as the atmosphere was more or less heavy.—Accordingly, M. Comiers has shewn, that this anemoscope was only an application of the common BAROMETER. See WIND.

The anemoscope of Væroe is famous. It is made of the bird *lunde*, whose feathers are picked, the skin stripped off, *viscera* taken out, and the skin in this state drawn a-new over the bones; this being hung up in the chimney, is said always to direct its bill to the point from whence the wind

is like to blow. Ephem. Acad. N. C. Dec. 3. An. 9. App. 245.

AN-END, in *Sea-language*, denotes the position of any mast, &c. when erected perpendicularly on the deck. The top-masts are said to be *an-end*, when they are hoisted up to their usual station.

ANET, in *Geography*, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Dreux, near the Eure; eight miles north-north-east of Drenx.

ANETHIFOLIUS, in *Botany*. See PROTEUS.

ANETHUM, derived from *anaethum*, because it runs up quick or straight, a genus of the *pentandria digynia* class and order, and of the natural order of *umbellata* or *umbellifera*: its characters are, that the *calyx* has an umbel universal and partial manifold, the involucre neither universal nor partial, the perianth proper obsolete; the *corolla* universal, uniform, floscules all fertile; proper; five-petals, involute, entire and very short; the stamina have capillary filaments and roundish anthers: the *pyfillum* is a germ inferior, styles approximating, obsolete; stigmas obtuse; no *pericarpium*, fruit subovate, compressed, striated and bipartite; the seeds are two, subovate, margined, convex, and striated on one side, flat on the other. There are three species, 1. *A. graveolens*, *A. hortense* of Bauh. Common dill, "with fruit compressed." Dill differs from fennel, which it most resembles, in having an annual root, a smaller and lower stem, the leaves more glaucous, and of a less pleasant smell, the seeds broader and flatter, surrounded with a membranaceous rim, and of a less pleasant flavour than fennel seeds. This plant grows wild among the corn in Spain and Portugal, and also in Italy on the coast, and near Constantinople; it is annual, and was cultivated here in 1597; the seeds of dill are directed for use by the London and Edinburgh pharmacopœias; they have a moderately warm pungent taste, and an aromatic smell, but not of the most agreeable kind. Water extracts very little of their virtues, either by infusion or digestion for many hours. In boiling, their whole flavour exhales with the watery vapour, and may be collected by distillation. The distilled water, drawn off to the quantity of a gallon from a pound, is occasionally made the basis of carminative draughts or juleps. The simple water arises better than any in the shops. Along with the water arises a considerable portion of essential oil, in taste moderately pungent, and smelling strongly of the dill. Rectified spirit, digested in dill seeds, readily extracts both their smell and taste; but, by distillation, it brings over very little of the flavour, the active part of the seeds remaining in the extract. The seeds and the plant itself were formerly much used in medicine, and, from the time of Dioscorides, have been esteemed for their carminative and hypnotic powers; and they have, therefore, been recommended in flatulent colics, and certain dyspeptic symptoms proceeding from a laxity of the stomach. Forestus speaks highly of their use in allaying vomiting and hiccups. They are also said to be more effectual than the other seeds of this class in promoting the secretion of milk. At this time, however, the seeds of dill are seldom employed, though a simple distilled water from them is directed both by the London and Edinburgh pharmacopœias. Allaine says, that the essential oil, rubbed on the abdomen, is useful in allaying flatulence and colic; and in a clyster, as a carminative. Lewis. Murray. Woodville.

2. *A. segetum*, *A. sylvestre* minus of Bauhin, *feniculum lusitanicum* minus annuum anethi odore of Tourn. "with three stem leaves, and oval fruits." It is annual, and a native of Portugal. 3. *A. faniculum*, common fennel, or finckle, "with gibbous fruits, and stem leaves numerous and deflexed."

It is a native of Germany, Spain, Italy, Madeira, China, &c.; it is biennial, and flowers in July and August, and the seeds ripen in Autumn. Linnæus distinguishes four varieties of fennel, viz. sweet fennel; common fennel, *F. vulgare germanicum* of Bauh. Italian fennel, *F. vulgare italicum* of Bauh.; wild fennel, *F. sylvestre* of Bauh.; Miller enumerates three varieties, viz. *F. vulgare*, or common fennel, *F. dulce*, or sweet fennel, and *F. azoricum*, or azorian fennel, or finchio. The common fennel runs from three to five feet high, blue green, with yellow flowers. It has a strong fleshy root, which penetrates deep into the ground, and will continue for several years; it has sown itself in many places, and appears like a native in England; accordingly it is enumerated among our native plants by Hudson, Withering, Smith, &c.; and is now common on chalk cliffs, as about Marazion in Cornwall, in Sussex, about Gravesend and in other parts of Kent, Nottingham Castle, near Spetchley in Worcestershire, Barwell, and other places in Cambridgeshire, and commonly on the western coasts. The sweet fennel has been supposed to be a variety of the common sort, but it has been cultivated in the same ground with the other and retained its differences; though botanists affirm, that it will return to its primitive form and qualities. The seeds, which are longer, narrower, and of a lighter colour, are generally imported from Germany and Italy, and are reckoned superior to those of our own growth.

Dietetic and medical qualities of fennel. The tender buds of fennel are eaten in salads; the leaves boiled are used as sauce for fish, particularly mackerel, and they are eaten raw with pickled fish. In Spain they put them up with olives and pickled pork. The seeds of sweet fennel are admitted into the materia medica of the London and Edinburgh pharmacopœias, and the root of the common fennel in that of Edinburgh. Sweet fennel seeds are an useful stomachic and carminative, and are sometimes given in powder, from a scruple to a dram; and sometimes candied. Water extracts the virtue of these seeds very imperfectly by infusion, but carries it off totally in evaporation. By distillation, they impregnate water with their flavour; a gallon of water receiving a strong impregnation from a pound of the seeds. A large proportion of essential oil separates in the distillation, and floats on the surface of the aqueous fluid; in colour yellowish, in smell moderately strong and dissolutive, and exactly resembling the fennel, in taste mild and sweetish, like the oil of aniseeds, and like it also congealing, by a slight cold, into a white butyraceous mass. These seeds contain likewise a considerable quantity in gross oil of the expressed kind, which, when freed from the essential oil, manifests no particular smell or taste. This oil is extracted, with the aromatic matter of the fennel, by digestion in rectified spirit, but separates and rises to the surface upon inspissating the filtered tincture. The spirit, gently distilled off, has very little of the flavour of the seeds; the oily matter retains a part both of their taste and smell; but much the greatest part remains concentrated in the extract. The seeds of the common fennel are warmer and more pungent, but less sweet, and of a less grateful flavour than that of the preceding; and there is the same difference in the preparations from them; the spirituous tincture of the sweet fennel is yellowish, but that of the common greenish. The leaves impregnate water by distillation with a grateful flavour, and yield a considerable portion of essential oil. An extract made from them by rectified spirit is no elegant aromatic. The roots, taken up early in the spring, have a pleasant sweetish taste, with a slight aromatic warmth. They are ranked among the aperient roots, and supposed by some to be equivalent in virtue to the celebrated ginseng of the Chinese, from which, however, they

differ in their sensible qualities. They are said to be pectoral and diuretic, but now wholly disregarded. The feniculum of the Latins is supposed to be the *μαραθρον* of the Greeks, by whom it was highly esteemed for promoting the secretion of milk; and this opinion has been confirmed by the experience of some modern authors. The stomatic, carminative, and other effects ascribed to fennel, depending upon their stimulant and aromatic qualities, must be less considerable than those of dill, anise, and caraway, though termed one of the finest greater hot seeds. Lewis. Murray. Woodville. The finocchio, supposed to have been originally brought from the Azores, has been long cultivated in Italy as a salad herb; and it is also cultivated in some few gardens in England.

Culture. Dill is propagated by sowing the seeds in autumn soon after they are ripe, in a light soil, where they are to remain, at the distance of eight or ten inches asunder. When the plants are come up, they should be hoed, and left at the above distance, and kept clear from weeds. When the seeds begin to be formed, those that are intended to be put into the pickle for cucumbers should be cut up, and those intended for seeds left till they are ripe; and then they should be cut, spread upon a cloth to dry, and beat out for use. The best time to sow the seeds of fennel is soon after they are ripe; the plants will come up in the autumn or following spring, and require no other care besides being thinned and cleared from weeds; they will grow in any soil or situation. For the finocchio, good seeds must be procured; and a good spot of light rich earth, neither dry nor very wet, selected, the first crop may be sown about a fortnight in March, which, if it succeeds, will be fit for use in July; and, by sowing it several times, a supply may be had for the table till the frost puts a stop to it. When the ground has been well dug and levelled, a hollow drill must be formed by a line and the seeds thinly scattered in it, about two inches apart; the drills should be 18 inches asunder, that there may be room to clean the ground and earth the plants. The plants will usually come up about three weeks or a month after sowing; and then with a small hoe the weeds should be cut between them, and the plants thinned; and thus successively till they are at the distance of seven or eight inches. The stems of the plants, which rise above the surface of the ground, should be earthed for blanching, about a fortnight or three weeks before they are used, and they will thus be rendered very tender and crisp. The second crop should be sown about three weeks after the first; and these crops should be continued in succession at such intervals till the end of July. In April, May, and June, the soil should be moister than the first; and in July it should be drier and in a warm situation, and the beds at this season should be watered and shaded. In autumn, if sharp frosts should occur, the plants should be covered with peas-baum, or some light covering; and thus they may be preserved for use till the middle of winter. Martyn's Miller.

ANEURIN, in *Biography*, one of the most eminent of the ancient bards of Britain, who was a chieftain of the Otodini, and bore a conspicuous part in the battle of Cattraeth, about A. D. 530, the subject of a noble heroic poem composed by him; and which is printed in the *Archæology of Wales*, with another composition by the same person, entitled *Odes to the Months*. About the year 540, Aneurin is supposed to have lost his territories in the north, in consequence of the growing power of the Saxons; and eventually, some old documents and traditions say, that he took refuge in the famous monastery of Iltutus, in the country of the Silures, where he died, about A. D. 570.

ANEURISM, or ANEURYSM (from *aneuryvω*, dilato), in *Surgery*, a preternatural dilatation of an artery, or a collec-

tion of blood in the cellular membrane, occasioned by the rupture or puncture of an artery. The first case has been called the *true*, or *genuine* aneurism; the second, the *false* or *spurious* aneurism. The true aneurism is again distinguished into the *true circumscribed aneurism*, in which the artery is only dilated in one small part, and the tumour is circumscribed; and the *true diffused aneurism*, when the tumour produced by the dilatation of the artery is of considerable extent, and, as it gradually loses itself in the surrounding parts, its boundaries cannot be accurately defined.

The spurious aneurism is again divided into the *circumscribed spurious aneurism*, in which the blood is collected in a sac in some part of the cellular membrane, forming a distinctly circumscribed tumour; and the *diffused spurious aneurism*, where the blood is effused into the adjacent cavities of the cellular membrane, forming an unequally elongated tumour.

Besides these two principal species of aneurism, a third, the *mixed aneurism* is reckoned; which consists in a combination of the true and false aneurisms with each other. The *first* subdivision of this species occurs when the external membrane of an artery has been injured by puncture, cutting, laceration with the splinter of a bone, or any other accidental cause, whilst the internal membrane remains untouched. The internal membrane, which is unable of itself to resist the impetus of the blood, is protruded through the orifice in the external membrane, so as to form a tumour, partly by laceration, partly by dilatation of the artery, and consequently by a combination of both causes. The *second* subdivision occurs, when the sac of the true aneurism bursts, and the blood, penetrating into the adjacent cellular membrane, surrounds the sac. As the true circumscribed aneurism may be produced wherever arteries exist, and consequently as well in the internal as the external parts of the body; it is divided into the *internal* and *external* true circumscribed aneurism. Of the internal, that of the aorta, and of the external, that in the ham or hollow of the knee, is the most frequent.

The true circumscribed external aneurism may be known when the patient remarks an unusual pulsation in any part of his body; when, upon close examination, he discovers a small pulsating tumour on the part, which disappears on being pressed with the finger, and, as soon as the pressure is removed, returns. It also will often disappear when the artery is strongly compressed at some part above it, and returns again as soon as the pressure is removed.

This tumour is not painful, neither is the external skin discoloured. When it has once been produced, it generally goes on increasing with an uninterrupted progress. The larger it grows, the less the pulsation is perceived, which may at length entirely cease when the tumour has become very large. When the sac is of considerable size, and the pulse under the tumour weak and small, the limb frequently becomes cold, collapsed, pale, weak, or oedematous. The danger is the greatest when the sac bursts, which it does either in such a manner as to leave the external skin, that covers it, entire, in which case the *true* aneurism is changed into the *mixed*; or, the sac bursts, together with the external skin, in which case a violent hæmorrhage ensues, that proves fatal, unless speedy assistance can be procured. The rupture of the sac is sometimes produced by concussion, or any other external cause, and sometimes spontaneously; in which case it may generally be foreseen for some time before it happens, by the place, which before was particularly dilated and elevated, becoming thin, soft, red, or bluish.

The internal true aneurism is only to be discovered by an unusual, constant, and violent pulsation in one part, which cannot be distinctly perceived till the tumour has attained a considerable

ANEURISM.

considerable magnitude; for whilst it is still small, this pulsation is very indistinct. When these tumours have attained to a considerable size, they sometimes at length appear externally, in which case they may easily be ascertained.

It now and then happens, however, that pulsation combined with dilatation does not certainly characterize this disease. (See Deffault's *Obs. Chir. and Medical Communicat.*) We have known the most careful observers deceived both in tumours of the extremities as well as internally, by forming their diagnosis from the pulsation alone. It is therefore necessary in these cases to take all the circumstances into consideration, from the earliest period of the disorder to its complete formation. When a soft tumour lies immediately upon an artery, the pulsation of the vessel may be felt through the tumour; and when the coagula of a real aneurism have become firm, the pulsation may be obscure or imperceptible.

The proximate cause of the true aneurism is indisputably a preternatural debility of the artery in some part, whereby it is rendered unable to resist the impetus of the blood, in consequence of which it yields, and is dilated into a sac. This may happen from a local injury; for example, a bruise; which may particularly be the case in those parts of the body where the artery has but few muscular parts to cover it, and is situated near a bone. Probably a sudden and violent elongation or stretching of the artery may occasion this topical weakness; at least we sometimes see true aneurisms arise after violent stretching of a limb, in fractures, dislocations, violent bodily exertions, convulsions, &c. Sometimes, probably, the cause may consist in a violent and inordinate motion of the blood: the artery may also be deprived of its support, by an abscess in any part of the body, and weakened in such a manner as to be unable to resist the impetus of the blood. In all these, and other similar cases, the aneurism deserves the name of a topical disease. Frequently, however, and perhaps in the majority of cases, the aneurism is the consequence of a general disease of the whole arterial system. According to the experience of Morgagni and others, aneurisms are said to be sometimes produced by the venereal, rheumatic, scorbutic, and other constitutional taints in the system. Sometimes these tumours arise spontaneously, without any occasional cause; frequently several of them are produced at the same time in different external and internal parts: we also find in dissecting the bodies of persons who have been affected with aneurism, that the arterial system is in many parts, nay, even universally, extremely feeble, and easily lacerated. This species of the disease, *DIATHESIS ANEURYSMatica*, is, in the present state of our knowledge, to be considered as altogether incurable, as we cannot determine its cause with certainty.

The false or spurious aneurism consists in a rupture of the artery, the blood being effused through the orifice into the surrounding cellular membrane. As this species, like the true aneurism, may be produced both in internal and external parts, it is likewise subdivided into the *internal* and *external*. The causes by which a preternatural orifice may be made in an artery, are numerous: *e. g.* sudden violent exertion of a limb or of the whole body, the lifting of heavy burdens, violent spasms, vomiting, &c. The most frequent cause, however, is a lesion of the artery by some foreign substance, as by the splinter of a bone; and particularly by the lancet, when blood-letting is performed in an unskilful manner, at the bend of the fore-arm, of which we therefore shall treat more minutely than of the other kinds.

In letting blood at the arm, the artery may be discovered to have been wounded, by the blood being thrown out with unusual force, in an uninterrupted but unequal stream, as it

were by jerks; also by its florid red colour; and, which is the most certain sign, by the blood flowing out in an even stream, with less force, when pressure is applied to the artery above the wound. In these cases the diffusion of the blood forming a spurious aneurism is generally owing to the fault of the surgeon, in attempting to stop the hæmorrhage too suddenly, either by pressing his fingers upon the wound, or by applying a bandage. The aneurism is produced either in consequence of the orifice in the external skin being displaced in such a manner that the blood can no longer be discharged through it, and must consequently diffuse itself in the cellular membrane; or by the pressure, which is hastily applied, being too weak, so as merely to close the orifice in the skin and vein, but not that in the artery, which consequently discharges the blood into the surrounding cellular membrane. The tumour produced in this manner is commonly of a red, bluish, and, finally, of a black colour.

The false diffused aneurism, arising from this cause, increases in size as long as the internal hæmorrhage continues; and if this be not speedily stopped, it produces violent pain and immobility of the limb, nay, at length, inflammation, suppuration, and gangrene. The most recent case of this kind, with which we are acquainted, is related in the sixth volume of the *Medical and Physical Journal*, by Dr. Adams, of Madeira; and in this case a perfect cure was effected, by long continued pressure on the artery, at the superior part of the arm.

The circumscribed spurious aneurism is produced, when the hæmorrhage has at first been stopped by the application of a proper pressure, but the bandages have been removed too early, and before the orifice of the artery has been closed, so that the blood is effused through the wound, still left, or newly torn open, into the surrounding cellular texture; but, on account of the adhesion of the cellular membrane, produced by the pressure previously applied, cannot penetrate into its cavities, and consequently collects itself into a mass, near to the orifice in the artery, dilating the cellular membrane into a sac. Sometimes, however, though rarely, this kind of aneurism is produced immediately after the artery has been wounded; namely, when on account of the smallness of the puncture in the artery, the hæmorrhage takes place so slowly, that the blood first discharged becomes coagulated, so as to stop the apertures through which the succeeding discharge might pass into the cavities of the cellular membrane, and prevent its diffusing itself. Sometimes also the artery is covered with a membrane, aponeurosis, &c. which prevents the diffusion of the blood, and compels it to collect into a mass.

The circumscribed false aneurism consists therefore of a sac, formed out of the cellular texture, and filled with blood, which is situated close to the artery, and communicates with the artery itself by means of the wound in it. In the false aneurism a pulsation can almost always be perceived, and that the more distinctly, the smaller the tumour is. The larger this sac becomes, the more it loses its elasticity, the greater becomes the accumulation of coagulated blood within it, and the weaker consequently becomes the perceptible pulsation, which in very large aneurisms of this kind entirely disappears. At first the tumour is small, and vanishes entirely under the pressure of the finger; but as soon as the pressure is removed it appears again. It vanishes in the same manner, when pressure is applied to the artery above the tumour, and re-appears when that pressure is removed. As soon as coagulated blood has accumulated in the sac, the tumour can no longer be made entirely to disappear by pressure, but it becomes hard. It is without pain, and the integuments that cover it, present the natural appearance. When

ANEURISM.

once produced, it increases with a constant and regular progress, and at last becomes enormously large. The flow of the blood into the limb below the tumour is always impeded, the pulsation of the arteries in it becomes feeble and small, and the limb itself is cold, collapsed, torpid, pale, or oedematous. A cavity of the neighbouring bones frequently takes place. This aneurism may also at length burst, and produce a fatal hæmorrhage, unless speedy assistance can be procured. The part where it bursts previously grows thin, soft, and bluish, or of a gangrenous aspect.

Notwithstanding the great resemblance which exists between the phenomena of the true and those of the false aneurism, they may however in general be easily distinguished from each other, especially after the first period of their existence. The true aneurism yields to the pressure of the finger very quickly, and re-appears as quickly, when the pressure is removed; the false aneurism, on the contrary, yields only in a gradual manner, and appears again in the same manner, as the blood contained in the sac cannot be wholly pressed through the orifice of the artery, nor again be effused, except by slow degrees. Sometimes a whizzing sort of noise may be distinctly heard, when the blood is pressed into the orifice, and again poured through it. The pulsation in the false aneurism is always weaker; and, as the tumour increases in size, diminishes much more rapidly than in the true aneurism, in which, even though it have attained a very considerable size, a strong pulsation can always be felt. The false aneurism becomes sooner hard than the true one, and cannot then be made entirely to disappear by pressure, as coagulated blood is very readily accumulated within it. Moreover, any mistake that may be occasioned by the difficulty of the diagnosis between the two species, cannot often be attended by any bad consequences, as they both require pretty much the same method of treatment. The internal false aneurisms are, on account of the pulsation being much weaker and imperceptible, and vanishing much sooner, than in the true aneurisms, as difficult, nay more difficult to be distinguished than these, though in other respects they excite similar symptoms.

When, in letting blood at the arm, the surgeon discovers, by the signs which we have already mentioned, that an artery has been wounded, he must immediately apply a **TOURNIQUET** to the upper part of the arm, in order first to stop the hæmorrhage, and obtain time for applying his bandages with the requisite care and accuracy. The hæmorrhage from the vein is to be stopped with the common bandage. But, in order permanently to arrest the hæmorrhage and close the wound of the artery, he must apply a compress with great exactness, which must be sufficiently tight entirely to prevent the hæmorrhage, and not easily to be removed from its situation; it ought also to close merely the artery itself, without affecting the lateral branches and the veins, lest a swelling and mortification might ensue from want of circulation. A pledget, or firm compress, is to be applied, the inner surface of which must be somewhat broader than the opening in the vessel, immediately upon the external wound, otherwise the pledget might easily miss the orifice of the artery. All now depends upon this compress being sufficient to stop the wound, its being applied with an uniform pressure, and in such a manner as not to prevent the motion of the blood through the lateral branches and veins. The common bandage used in blood-letting does not answer these purposes so conveniently as by means of Plenks' apparatus, which, however, must be applied with great exactness. (Jof. Jac. Plenks Sammlung von Beobachtungen ueber einige Gegenstände der Wundarzneiwissenschaft. Vienna, 1775. 8. p. 195. Also: Richters Anfangsgruende der Wundarz-

neyk. B. i. § 531. tab. iv. f. 7.) Should a small tumour arise close to the point of the pledget, the apparatus should first be screwed somewhat tighter, as the pressure was possibly not sufficiently strong. If nevertheless the tumour should grow still larger, we may be certain that the compress does not lie upon the wound of the artery; the tourniquet must therefore be immediately applied, and the dressings removed; after which they must be again applied with as great exactness as possible; but first the extravasated blood must be pressed back into the artery, by gently rubbing and squeezing the tumour. If at any subsequent time it should become necessary to remove the apparatus from the limb, the tourniquet must be employed in the same manner.

The apparatus being properly applied, the arm should be suspended, moderately bent, in a sling, and kept as much as possible at rest during the whole course of the cure. Should any swelling appear in the fore-arm, we ought to endeavour to disperse it by diligent friction with spirituous and aromatic remedies. Moreover, the surgeon should daily examine whether the bandages remain firm and unmoved in their situations, and as soon as he discovers any tumour, he should proceed as above recommended. The length of time during which the compress ought to remain in its situation, in order to preclude the possibility of a future hæmorrhage, cannot be accurately determined: if, therefore, we wish to examine whether it may be safely removed, we ought first to apply the tourniquet, and then take off the apparatus: this being done, we should gradually loosen the tourniquet, and carefully observe whether any tumour is produced at the place of the wound. Should no such tumour appear, we need not use these bandages any longer; it will, however, be proper, for security's sake, (as in some instances the wound of the artery has been known to burst open afresh) to apply gentle pressure, by means of a compress, to the artery, immediately after the bandages have been entirely removed, in order to diminish the flow of blood through it, and prevent its bursting. Every other motion of the limb should be avoided for some time after.

When a circumscribed false aneurism has already been produced, we may also in that case employ compression, provided the tumour be still soft, and can be made entirely to disappear by pressure. For, as experience has proved, that the efforts of nature alone may, in such circumstances, sometimes effect a perfect cure of the aneurism, (Repertorium Medicin. u. Chirurg. Abhand. &c. b. i. Leipzig. 1792. 8vo. p. 107.) we have the greater reason to expect a favourable event from the employment of compression. The surgeon ought, therefore, after having applied a tourniquet to the arm, as in the former case, to return the blood into the artery, by means of repeated pressing and stroking of the part, and then apply the compress. But when there is already coagulated blood in the sac, and the tumour can no longer be made to disappear under pressure, compression can be of no use. Should there, however, be but a small quantity of coagulated blood, we may still attempt compression; for it may sometimes succeed, and when it does not, it produces the advantage of compelling the blood to flow with greater force into the lateral branches, by the distention of which a favourable issue of the operation is secured.

Mr. Theden (in Neue Bemerkungen u. Erfahrungen zur Berinherung der Wundarzneik. u. Arzneygelehrsamh. th. i. Berlin. 1792. p. 20. & th. ii. p. 52.) recommends another method for curing aneurisms, which is applicable even where there is already a very considerable quantity of extravasated and coagulated blood. When, in performing the

A N E U R I S M.

the operation of blood-letting, we have wounded an artery, we are to suffer more than the proper quantity of blood, may even so much as to induce syncope, to be discharged, and in the mean time prepare whatever is requisite for bandaging the limb. Three or four compresses, into the lower-molt of which we may introduce a small piece of money, are then to be applied in such a manner as to fill up the cavities in the angle of the elbow, which, till the rest of the bandages are ready, is to be pressed by an assistant so tight upon the orifice of the artery, that no blood can be discharged from it. The bandaging must then be performed spirally, a *linguette* of the thickness of a finger's breadth must be laid upon the trunk of the artery, and inclosed in the bandage. When the hæmorrhage has been stopped in this manner, a quantity of Theden's *aqua traumatica* is to be poured upon the whole of the bandages, so as to wet them through and through. The bandages should not be applied too tight at first, if we intend to soak them with the liquid, as it is well known that moisture causes them to contract and compress the limb with greater force, by which means obstruction, tumour, and pain might be produced. Should we, however, have applied them tight, on account of the hæmorrhage, we must not wet them till after they have become somewhat loose. As our success depends upon the bandage lying equally close in every part, each turn of the bandage ought to cover half of the former, so that no part of the limb remain uncovered, or not inclosed within the bandage; neither ought any one turn of the bandage to be drawn tighter than the rest.

The first bandages may be suffered to remain on the limb for the space of three or four days, unless they should grow loose at an earlier period, as generally happens when there is a large quantity of extravasated blood, and this soon begins to be separated and re-absorbed. In applying the bandages the second time, we proceed in the following manner. The roller is taken off from the fingers, hand, and fore-arm, and these parts are bandaged anew before the bandages and compresses are removed from the joint and humerus. The roller is then applied over the elbow, and upwards to the axilla. The end of the fillet is carried round the neck, in order to prevent the bandages from sliding downwards, and, as an additional security against this accident, the turns of the roller are sewed to each other from the elbow to the arm-pit; the whole is soaked with Theden's vulnerary, and kept continually wet. These dressings may remain in this condition for three or more days, provided the bandage becomes neither too tight nor too loose, and applies to the limb in an uniform manner. If, says Mr. Theden, all these measures are adopted immediately after the accident, the cure may certainly be effected in the space of eight days, only we must examine very attentively whether, at the place where the artery has been wounded, a new tumour or effusion takes place. Should this happen, we must still continue to apply the bandages for some time; but if the blood has been effused from the beginning into the cellular substance, as sometimes happens, the bandages must be worn till the whole has been re-absorbed, and the wound properly cicatrised. The utility of this method of Theden's has been confirmed by several practitioners, especially by the successful cure of a remarkable case, related by Mr. Schmalz. (*Seltene Chirurg. u. Medicinische Vorfälle. Leipzig. 1784. 8vo. p. 59.*)

But when there is a great deal of extravasated blood in the sac, when the tumour is very large, so as not to admit of compression or bandaging, and there is reason to apprehend that the tumour may burst open, an operation must be performed without delay. The tourniquet being applied

to the humerus, the skin which covers the tumour is laid open by an incision, made according to the direction of the artery, and carried across the middle of the tumour, so as to extend from one of its extremities to the other. The sac, which is generally situated immediately under the skin, is opened in the same manner. The whole of the extravasated blood contained in the sac is then taken out, upon which the wounded artery becomes distinctly visible at the bottom, and should be tied. But in order completely to stop the hæmorrhage and prevent its recurrence, the artery must be tied not only above, but also below the orifice. Sometimes the surgeon is obliged to apply even three or more ligatures; for when, in the vicinity of the wound of the artery, between the two principal ligatures, any lateral branches proceed from the trunk of the artery, these must be tied close to the trunk.

Since, after the operation has been performed, every thing depends upon the restoration of the circulation in the limb, by means of the distension of the lateral branches in consequence of the increased impetus of the blood in them; the surgeon must be particularly attentive in performing the operation, not to injure these branches. For this purpose the two ligatures must be applied as near the wound of the artery as can be done with safety, lest any lateral branch should happen to be included between them, whereby it would necessarily be rendered useless. On this account also we must not use a very broad two-edged needle for applying the ligatures. Mr. Desfault used an elastic needle of his own invention. It is needless, after having tied the vessels, to apply another tourniquet or other bandage to the humerus, with a view to prevent the recurrence of the hæmorrhage; for if the ligatures have been skillfully applied this precaution will be superfluous. In cases where the ligatures become loose, and successive hæmorrhages are produced, the method of Mr. Desfault has been recommended. At the third hæmorrhage, which took place on the eleventh day after the operation had been performed on the femoral artery, he first applied new ligatures above and below, secured them properly, and renewed the bandages. But in order to prevent a recurrence of the hæmorrhages, which might have supervened in consequence of the collapse of the artery and the ligatures growing loose, he applied, four days afterwards, over the ligatures, and at the sides of the artery, small flat pieces of soft wood, fifteen lines long and three broad, which were secured by winding them round with several turns of waxed thread, and were made to compress the artery at the sides with more or less force, by introducing under their upper extremity small wedges of the same wood. By this means the impetus of the blood was restrained, and a new effusion prevented. Suppuration took place in the wound, and on the 35th day after the operation, the small pieces of wood fell off, the ligatures having come away some days earlier.

If it can be avoided the surgeon must take care not to include the nerve in the ligature. Sometimes the extravasated blood, which frequently penetrates behind the artery, separates the nerve from the artery; and in this case we may, in order to avoid inclosing it in the ligature, bend the patient's arm, before applying it, and by means of a somewhat crooked probe, introduced into the open space, raise up the artery, and remove it from the bone, and then introduce the needle, to which the thread is attached, close under the artery. We must, however, not raise up the artery with too much force, lest we should tear some of the lateral branches. Moreover, it is always advisable not to draw the ligature tighter than is necessary for stopping the hæmorrhage, lest we should cut through the coats of the vessel,

or cut or press the nerve too forcibly, in case it should happen to be included. Frequently the artery is so much detached from all the neighbouring parts, that the thread may easily be drawn through below it, by means of a common needle with the eye foremost. But when the artery is not detached from the subjacent parts, we must make use of a pointed needle having an eye near its point, taking care always not to puncture the nerve, or any tendinous parts, or to include them in the ligature. The ligature should be secured with a double knot, and the ends of the threads suffered to hang out about two inches long. The tourniquet may then be immediately loosened, in order that we may see whether the ligature be sufficiently tight; after which the wound is to be dressed lightly with lint, and the proper bandages applied; and the patient should be directed to carry his arm in a sling.

The wound is treated after the usual manner till the ligatures have come away. In order to restore the natural heat in the fore-arm, and to disperse the tumour in it, it may frequently be rubbed with spirituous, stimulant, and aromatic applications. M. Pouteau assures us, that no remedy has succeeded so well with him, in restoring the natural warmth and sensibility of the fore-arm, as dry heat applied by means of hot ashes or sand. The remaining debility may, in general, be speedily removed by using the shower-bath, and external tonic applications.

When in consequence of an aneurism in a limb, the neighbouring parts are destroyed, when suppuration or caries have taken place in a high degree, or when the limb remains lifeless after the operation, so as to threaten the production of gangrene, amputation becomes necessary. We ought, however, not to be too hasty in proceeding to this operation, since even in cases where gangrene has seemed to be unavoidable, the limb has still sometimes been preserved; frequently after the lapse of several weeks the pulse has again become perceptible. We shall here subjoin an account of the method employed with success by Dr. Adams. (Med. and Phys. Jour. vol. vi. p. 555.)

On the 4th of February, 1797, a young baronet was bled in the *vena mediana basilica*, and from his having worn a tight flannel sleeve, it was not immediately observed that the blood came also from an artery. The orifice having been closed in the usual manner, bled again in the evening, but was stopped before Dr. Adams could see the patient. On the following morning a considerable extravasation of blood took place. In a few days, however, the gentleman was not thought in need of further attendance, although the arm did not recover its ordinary size. Six weeks afterwards a small circumscribed tumour had arisen in the arm, below the original cicatrix; and, on pressure, a very obscure pulsation might be felt; it was firmly bound by the fascia, and not at all discoloured or painful. The tumour increased suddenly towards the end of March, with the same circumscribed appearance and an evident surrounding extravasation. Strong pressure was now applied by means of a roller to the upper part of the fore-arm, exactly upon the trunk of the artery, so as to lessen its pulsation; but the bandage was kept hollow, except over the artery, by several pieces of cane applied along different parts of the limb. Although this degree of pressure was had recourse to with the view of obliterating the large trunk of the artery, an increase of the swelling took place in about ten days, accompanied with slight pain.

The mechanical pressure on the vessel itself was then augmented, until but little pulsation could be felt in the radial artery. Painful sensations near the wrist, along the lower arm, and under the aneurism, were now complained of as intolerable. The fingers were without sensation, the whole

arm was enlarged, the veins became turgid, and the pulse remained very feeble. This process being persevered in, Dr. Adams had at length the satisfaction to obliterate the main trunk of the brachial artery, and to effect a complete cure. The mass of coagulated blood, however, was discharged by a gangrenous sore at the bend of the arm, about two inches in diameter, which was cicatrized before the end of July, 1797; and in January, 1798, every unpleasant symptom had disappeared. This plan of treatment, by *compression*, was adopted by the author without his having known that it had been several times practised with success, in different parts of the continent, for other cases of aneurism.

The treatment of the true external aneurism is in most respects the same as that of the false. If it be small in size, and not of long standing, external astringent applications, as also ice, have been used with very good effect. In trying such an experiment we may, at the same time, apply a tourniquet to the artery, above the swelling, in order to diminish the quantity and momentum of blood flowing into the sac. Compression has likewise been recommended in this species of aneurism, but only at the commencement. Mr. Bruckner, however, (D. Jull. Chr. Loder Journal fuer die Chirurgie, &c. b. v. ll. 2. Jena 1797. p. 248.) has used it in a case of a very large and old aneurism in the hollow of the knee, in combination with the remedies before mentioned, together with Theden's bandage applied from the toes upwards, and the concurrence of other favourable circumstances, with complete success. When compression is applied, it ought to be to every part of the surface of the tumour, as well as in the course of the artery; and it will act with greater safety and efficacy, if we combine it with Theden's manner of bandaging, as was done by Mr. Bruckner.

When none of these remedies are applicable, we must proceed to the operation, which (if we follow the old mode) is in no essential circumstance different from that performed in cases of false aneurism. It is, however, to be observed, that it is not advisable to cut through the posterior part of the sac, as in that case the ends of the artery easily contract themselves under the flesh; and if the first ligature should grow loose, they cannot easily be tied again. It appears from experience, that the operation has been far more rarely attended with a successful event in the true than in the false aneurism; it being frequently followed by violent pain, fever, swelling, gangrene, and death. Only in those true aneurisms which are small, and originate from external causes, the surgeon is able to operate with expectations of a successful event. Sometimes, however, these aneurisms require amputation to be performed, and that, under the same circumstances by which the operation is indicated in the false aneurism. But as this operation, as well as the application of the ligatures, very frequently miscarries, all the precautions with respect to the application of the ligatures, that have just been mentioned, are here also to be recommended.

Internal aneurisms, both true and false, are incurable: all that we can do is to retard the progress of the disease, by frequent blood-letting, spare diet, and the careful avoiding of every thing by which the blood may be heated, or its motion accelerated. Moreover, it is very advisable to cover the tumour well, as soon as it appears externally, and to defend it against all external violence, by friction, blows, &c. whereby its bursting might be hastened.

To the cure of the diffused false aneurism two things are requisite; namely, to close the wound of the artery, in order to stop the hæmorrhage, and to disperse the extravasated blood. The first is performed by compression with a pledget, and the second by applying bandages to the whole limb, according to Theden's method, and keeping them constantly

A N E U R I S M.

stantly wet, either with Theden's vulnerary, or a solution of sal ammoniac in vinegar and water. But if the extravasation spreads farther, and the hæmorrhage continues, the operation must be performed without delay.

The mixed aneurism, produced by a laceration of the outer and a distension of the inner coat of the artery, is rare, and exhibits no external symptoms by which it can be distinguished from the true aneurism. This, however, makes no difference; for we endeavour to remove it, like a true aneurism, by compression; and when this either does not succeed, or 'cannot be applied, the operation is performed in the same manner as in the true aneurism. The second species of the mixed aneurism is more frequent. This consists at first of a true aneurism, in which the sac, by occasion of violent motion, concussion, a bruise, or even spontaneously, in consequence merely of too great distension, has burst, and produced an effusion of blood, which surrounds the true aneurism. The change of a true into a mixed aneurism may in general be easily discovered. The swelling, which before was circumscribed, suddenly spreads; the strong pulsation, which before was distinctly perceptible in the tumour, suddenly grows weak and indistinct, or even becomes altogether imperceptible; and the tumour, which formerly was soft, suddenly becomes hard to the touch. The mixed aneurism, on account of the continual effusion of blood, and the increase of the false aneurism, generally requires that the operation should be speedily performed. The most common mode of doing this (perhaps not the most eligible) we have already described; but it is a fact worthy of notice, that the Greeks were acquainted with the practice lately recommended, of tying and dividing the trunk of the artery high above the tumour, as will appear from the following extract (*Ætii Tetr. iv. Serm. iv. cap. 10.*) "At vero quod in cubiti cavitate fit aneurisma, hoc modo per chirurgiam agredimur: Primum arteria supernè ab ala ad cubitum per internam brachii parte simplicem sectionem, tribus aut quatuor digitis infra alam, per longitudinem facimus, ubi maxime ad tactum arteria occurrit; atque ea paulatim denudata, deinceps incumbentia corpulentia sensim exoriamus ac separamus, et ipsam arteriam cæco uncino attractam duobus sili vinculis probe adstringimus, medianque inter duo vincula difficamus; et sectionem polline thuris explemus, ac linamentis inditis congruis deligationibus adhibemus." Afterwards we are directed to open the aneurismal tumour at the bend of the elbow, and when the blood has been evacuated, to tie the artery twice, and divide it again. If the ancients had only omitted the latter part of their operation, they would absolutely have left nothing to be discovered by the moderns. What a striking example of the bold manner in which our forefathers have acted without being guided by the lights of anatomy and physiology! But there are two or three passages in Galen, Celsus, and Hippocrates, from which we may suspect that even *Ætius* himself was not the inventor of this operation of tying the trunk of an artery, &c. See also *Paul. Ægin. lib. vi. cap. 37.*

The operation of tying the large trunk of an artery, above the aneurism, seems to have been regarded by *Dr. Wm. Hunter* as "a proposal which a modern surgeon would think of with horror" (*Med. Obs. & Inq. vol. i. p. 335.*); and *Mr. Bromfield* calls it a "most extravagant proposition." (*Chir. Obser. vol. i. p. 306.*) But we are now fully convinced, by the evidence of incontrovertible facts, that this operation "may be done with a fair prospect of preserving the limb." *Mr. Bromfield* relates, that he "once saw an attempt of this kind in a true aneurism, situated in the ham;" on which, however, he makes "no further remark, than that the patient died," and that he believes

"the embarrassments which occurred, as well as accidents in the operation, will deter the operator from making a second attempt." We have reason to suppose that most of the cases of aneurism on record, in which patients recovered, after long enduring compression upon the artery, have in reality been cases where the vessel was totally obliterated by the pressure; although the opinion of surgeons has usually been, that the orifice of the artery had previously coalesced and healed like a common wound, still allowing the blood to circulate as before. Cases are likewise recorded in which a spontaneous cure of aneurism has been effected; and in these we may also conclude, that the vessels were obliterated as completely as they would have been by a ligature in the modern operation.
