BLANC, *Mont*, in *Geography*, a lofty mountain of Savoy, in the duchy of Faucigny, being part of the ancient "Alpes Penninæ." See ALPS. This is reckoned the most elevated mountain of the ancient continent, its height above the level of the sea being, according to the calculations of M. de Luc, 15,304, English feet; or, according to the measurement of Sir George Shuckburgh, 15,662 feet. This accurate observer informs us (*Phil. Trans. vol. lxxvii. p. 595*), that the height of Vesuvius, estimated by Saussure at 3900 feet, placed upon mount *Ætna*, elevated, according to Sir George, 10,954 feet, would not be equal to the height of Mont Blanc, which he supposes to be the most elevated point of Europe, Asia, and Africa. This mountain, observed from the "Col de Balme," and the vale of "Chamouny," is particularly distinguished from other mountains by a mantle of snow, which clothes its summit and sides, almost without the intervention of the least rock to break the glare of the "white" appearance, from which its name is derived. Those who have seen it from the valley of Aost observe, that on that side it does not appear to be covered with a mantle of snow, and that it exceeds the Schreckhorn in ruggedness and horror. See SCHRECKHORN. "Those who are totally unacquainted with Alpine scenes," says Mr. Coxe, (*Swiss. vol. ii. p. 5.*) "may, perhaps, conceive a faint idea of this gigantic mountain, on being informed, that the mantle of snow, which appears to cover its top and sides, exceeds an altitude of 4000 feet perpendicular, and 6000 feet in an horizontal direction from the *dôme de Gouté*, to the summit; and that the height of the snow and ice, estimated from the source of the Arveron, at the bottom of the glacier of Montenvert, to the summit of Mont Blanc, cannot be less than 12,000 perpendicular feet, or near three times as high as Snowdon in North Wales. The highest point of this mountain appears like a compressed hemisphere, and is called from its form "La Boffe du Dromedaire;" from that point it gradually sinks, presenting a kind of concave surface of snow, in the midst of which is a small pyramid of ice; it then rises into a second hemisphere, called by some "Little Mont Blanc," but, more properly, by others "Le Dôme du Milieu," or the "Middle Dôme;" thence it descends into another concave surface terminating in a point, indiscriminately styled by the natives "Aiguille de Gouté," "Point de Gouté," and "Dôme de Gouté;" from this dome it ends abruptly, and loses itself arid the mountains that bound the vale of Chamouny. Five gorges extend into this vale, and are separated from one another by forests, corn-fields, and meadows; so that large tracts of ice are blended with cultivation, and perpetually succeed each

other in the most singular and striking vicissitude. These glaciers, which lie chiefly in the hollows of the mountains, and are some leagues in length, unite at the foot of Mont Blanc.

Of the various attempts that have been made to reach the summit of Mont Blanc, the first was that of M. Couteran, and three guides of Chamouney, Michael Paccard, Victor Tassay, and Maria Coutet. On the 13th of July, 1776, they set off from the priory, about 11 in the evening; passed between the glaciers of Bosson and Tacona; and after spending above 14 hours in mounting rugged and dangerous ascents, and in crossing several valleys of ice, and large plains of snow, found themselves on the top next to Mont Blanc. But though at first sight it appeared to be scarcely a league distant, they soon perceived that it seemed, on account of the clearness of the air, the whiteness of the snow, and its great height, to be much nearer than it really was, and that it would require at least four hours more to reach the summit, even if it were practicable. As the day was far advanced, and the vapours near the summit of the mountain began to gather into clouds, they relinquished their enterprize; and returned to Chamouney, not without personal danger in leaping over chasms of ice, after a journey of 22 hours, with this satisfaction, that they had approached nearer to Mont Blanc than any former adventurers. The summit which they had attained is, according to Sir George Shackburgh, more than 13,000 feet above the Mediterranean. After some subsequent but unsuccessful attempts, M. Bourrit, accompanied by six guides, departed from Bionafay, and began to "scale (as he terms it) the rampart" of Mont Blanc, when he suddenly found himself so exceedingly affected by the intense cold that he was unable to proceed. Maria Coutet, and Francis Guidet, two of his guides, proceeded to the dome of Gouté, which is about 9400 feet in an horizontal direction from the summit; but the approach of night obliged them to return. On the 4th of September 1785, Maria Coutet and James Balmat advanced beyond the dome of Gouté, towards the summit, but a violent storm of hail and wind compelled them to abandon the enterprize. On the 13th of this month Messrs. Saussure and Bourrit, attended by twelve guides, well provided with barometers, thermometers, and other necessary instruments, left Bionafay, and arrived at a hut, which was constructed by their orders, at "Pierre Ronde," 7808 feet above the level of the sea; and on the next morning they pursued their journey to the dome of Gouté; but a heavy fall of snow prevented their progress. Saussure says, that the mercury in the barometer sunk $1\frac{1}{2}$ inches, and that he reached an elevation of 8256 English feet. In July 1786, James Balmat, one of six guides of Chamouney, being separated from his companions, who failed in another attempt, passed the night on a spot above the "Dome of Gouté," elevated more than 12,000 feet above the level of the sea. On his return, however, to Chamouney, he was seized with a very severe indisposition, the effect of extreme fatigue, and of the intense cold; but being attended by Dr. Paccard, a physician of the place, he offered, as an expression of gratitude for his attendance, to conduct him to the summit of Mont Blanc. Accordingly, on the 7th of August, these two daring adventurers sallied forth from Chamouney, and reached the mountain of "La Côte," which overhangs the upper part of the glacier of Bosson. Here they passed the night, and at three on the next morning they pursued their route over the ice, ascended the "Dôme of Gouté," passed under the "Middle-Dôme," and turning to the east, at the last pyramid of rock, continued along the ridge which is seen from Geneva, and which lies on the left of the summit. Here cold and fatigue discouraged Dr. Paccard; but being animated by his companion, he deter-

mined to advance, struggling with a very violent and piercing wind, till at length they attained the summit which no one had visited before. Here they remained about half an hour, when they found the cold so intense, that their provision was frozen in their pockets, the ink congealed in their inkhorns, and the mercury in Fahrenheit's thermometer sunk to $18\frac{1}{2}$ degrees. They spent 15 hours in ascending; but found great difficulty in their descent, their light being much debilitated by the reflection of the snow. On their return to Chamouney at eight in the morning, their faces were excoriated, their lips much swelled, and Dr. Paccard was almost blind. These adventurers prepared the way for the observations and discoveries of future naturalists, and particularly of Saussure, whose indefatigable zeal would not allow him to rest, till he had reached the top of Mont Blanc, and made those experiments, which have served in a very considerable degree to elucidate the theory of the atmosphere.

Having arrived at Chamouney, a village at the base of the mountain, M. de Saussure was detained by continual rains for four weeks; after which, he set out on the 1st of August 1787, accompanied by a servant and 18 guides, who carried the philosophical instruments and the tents, and other apparatus necessary for the intended experiments. Although the distance from the priory of Chamouney to the summit of the mountain is little more than two leagues, or about $6\frac{3}{4}$ miles, in a straight line, it requires nevertheless 18 hours to gain the summit, on account of the difficulties of the road, as well as the necessary circuits. In the evening, they arrived at a hut constructed for them on the top of the mountain of "La Côte," about a mile perpendicularly above the village. Their second day's journey was attended with many difficulties, owing to the wide, deep, and irregular chasms intersecting the ice-valley on the side of the hill, which can only be crossed by means of bridges naturally formed of snow, and often very slender; extended, as it were, over an abyss. In this perilous valley, they were obliged to pursue a winding road, so that they were three hours in crossing it, though in a straight line its breadth is not above three-quarters of a mile. At length, however, they reached the chain of rocks that border on the perpetual snows which cover Mont Blanc, and then mounted, in a serpentine direction, to a valley filled with snow, and running from north to south, to the foot of the highest pinnacle. The surface of the snow in this valley has numerous fissures; penetrating to a great depth, and considerably broad; presenting to view, by their broken sides, the successive horizontal layers of snow, which are annually formed. In this situation the guides wished to pass the night; but Saussure, observing that the loftiest of these rocks is at least 1400 yards perpendicularly lower than the summit of the mountain, wished to proceed, and at length prevailed with the guides to accompany him. At four in the afternoon, they arrived at the second of the three plains of snow, which they had to pass; but as the day was far advanced, and they were apprehensive of exposing themselves to the "Avalanches," which are frequently tumbling from the summit of the mountain, they determined to proceed no farther. Here they encamped at the height of 9312 feet above the priory of Chamouney, or 12,762 feet above the level of the sea. For this purpose, they dug a deep hole in the snow, of sufficient width to contain the whole company, and covered its top with the tent-cloth. In this situation the barometer had fallen to 17 inches, 10 lines $\frac{3}{2}$; and they all felt the effects of the rarefied air. Seven or eight hours' walk, which they had just performed, had not in the least affected these robust and hardy men; but they had scarcely raised five or six shovels of snow, in forming their intended habitation, before they were under a necessity

of desisting from labour and of taking breath at very short intervals. M. de Saussure himself, though accustomed to the atmosphere of mountains, and finding himself, as he says, much better in it than in the air of plains, now felt exhausted with fatigue, only by observing his meteorological instruments. This uncomfortable sensation was heightened by an acute thirst, and water could not be procured, except by melting snow: for the water which they had seen during their ascent, would by this time be congealed; and the small ch.iling-fish which they had taken with them, very slowly supplied 20 people languishing with thirst. From the middle of this snowy plain, not far below the top of Mont Blanc, the snow exhibited the most dazzling brightness, and formed a singular contrast with the sky, which, in these elevated regions, appears almost black. No living creature was seen here, nor the least trace of vegetation. The moon shone with the brightest splendour in the midst of a sky as black as ebony. Jupiter, rayed like the sun, arose from behind the mountain in the east; and the light of these luminaries was reflected from the white plain, or rather basin, in which they were situated and by their dazzling lustre, eclipsed every star, except those of the first and second magnitude. Whilst they were composing themselves to sleep within their tent, incommoded by heat and vitiated air, they were soon alarmed by the noise of an immense mass of snow, or "Avalanche," which fell from the top of the mountain, and covered part of the slope over which they were to climb the next day. The next morning they departed at seven for the third and last plain; turning to the left in their way to the highest rock, which is on the east part of the summit, they found the ascent in some places so steep, that the guides were obliged to hew out their footsteps with hatches. Their progress was slow, and it took them two hours to climb a hill about 1590 feet high. Having arrived at this last rock, they turned to the west, and climbed the last ascent, about 900 feet high, and inclining about 28 or 29 degrees. Here the air was so rarefied, that Saussure could not take 15 or 16 steps without stopping for breath; and at intervals he found himself faint, so that he was under the necessity of sitting down, until, with the return of respiration, his strength was revived. On his arrival to the summit, at 11 o'clock, a slight vapour, suspended in the inferior regions of the air, prevented him from beholding the lower and more distant objects; such as the plains of France and Lombardy; but he had the less reason for regretting this loss, as he was agreeably surpris'd by a most distinct and comprehensive view of all those elevated summits, with the organization of which he had so long desired to be acquainted. He thought himself dreaming, when he saw beneath his feet many majestic peaks, especially "Aiguilles," "Le Midi," "L'Argentiere," and "Le Géant," the bases of which he had found it so difficult to ascend. He seized in his mind their mutual proportion and connection, their form and structure; and a single glance removed doubts, and afforded information much more satisfactorily, than whole years of previous study. During this time, his guides pitched his tent, and made preparations for his experiments; but in attempting to dispose his instruments for this purpose, he was obliged, almost at every instant, to desist, and wholly to occupy himself about the means of respiration. Considering that the barometer stood at only 16 inches, 1 line, or 17.145 inches English, and that the air, consequently, possessed little more than half the density of that on the plains, it is manifest that the deficiency was to be supplied by more frequent inspirations. This frequency, of course, accelerated the circulation of the blood, more especially as the arteries, on the surface of the body, were no longer actuated from without by the pressure which they usually experience.

When M. de Saussure remained perfectly quiet, he only felt rather uncomfortable, with a slight disposition to be sick; but in any exertion, or when he fixed his attention for a few successive moments, and particularly when, by stooping, he compressed his chest, the necessity recurred of resting himself, and respiring for two or three minutes. His guides also experienced similar sensations. They felt no appetite, and had no inclination to take wine or brandy, having found that strong liquors increased the above indisposition; without doubt, by quickening the circulation of the blood. Nothing but fresh water was coveted and relished, and yet both time and exertion were required to light the fire, without which it was impossible to obtain any. In this situation Saussure and his companions continued 4½ hours, and in their descent they found fewer difficulties than they expected. They arrived the next morning at the valley of Chamouny, without the least accident; and as they had taken the precaution to wear veils of crape, their faces were not excoriated, nor their sight debilitated.

M. de Saussure has given an ample detail of his observations on the summit of Mont Blanc, in the 4th volume of his "Voyages dans les Alpes;" and a translation of this account by professor Martyn, of Cambridge, forms an appendix to his sketch of a tour through Switzerland. We shall here select a few particulars. We learn from this narrative, that the summit of the mountain is a ridge, nearly horizontal, lying east and west; the slope at each extremity inclining from 28 to 30 degrees, the south side between 15 and 20, and the north about 45 or 50. This ridge is so narrow as scarcely to allow two people to walk abreast, especially at the west end, where it resembles the roof of a house: it is wholly covered with snow; nor is any bare rock to be seen within 150 yards of the top. The surface of the snow is fealy, and in some places covered with an icy crust, under which the snow is dusty, and without consistence. The highest rocks are all granites; those on the east side are mixed with steatites; those on the south and west contain a large quantity of schist, and a little lapis corneus. Some of them, especially those on the east, which are about 150 yards below the summit, seem to have been lately shivered with lightning. M. de Saussure saw no animal on the mountain, except two flies, a grey phænax, and a "Myrtillus," which he supposes must have been driven there by the wind. At the elevation of 11,202 feet above the sea, he observed the "Silene Acaulis," or moss camp on, in flower; and still higher, on the most elevated rocks, the "Lichen Sulphureus," and "Lichen Rupestris" of Hoffman. He has given us the height of the barometer on the top of the mountain: viz. Aug. 3. at noon, 16 inches 0 line, and 1½ of a line, French measure, *i. e.* 16.181 English; and Reaumur's thermometer was 2.3 below the freezing point, or 27 of Fahrenheit. M. Sennelier, at the same time, observed, at Geneva, the barometer 27 inches 2 ⅞ lines, or 29.020 inches English, and the thermometer 22.6 above freezing, or 82 of Fahrenheit. From these data he makes the height of Mont Blanc 2218 toises, or 14,180 English feet, according to M. de Luc's rule, and 2272 toises, or 14,525 English feet, according to M. Trembley's. To these heights 13 toises, or 83 feet, the height of M. Sennelier's room above the lake of Geneva, must be added, to give the height of the mountain above the level of the lake 14,253 feet, according to M. de Luc, and 14,608 feet, according to M. Trembley. Sir George Shuckburgh made the height of Mont Blanc, by trigonometrical measurement, 14,429 feet above the lake, which is almost the mean between the other two. The result of the observations made at Chamouny, cotemporary with these on Mont Blanc, agrees still more nearly with Sir George's measurement. The general mean result makes the summit of Mont

Blanc 2450 toises, or 15,673 English feet, or nearly three English miles above the level of the sea. By M. de Saussure's experiments with the hygrometer, the air on the top of Mont Blanc contained six times less humidity than that of Geneva, and to the extreme dryness of it he attributes the burning thirst which he and his companions experienced. But the result of his experiments seems very different from the system of meteorology published by M. de Luc. See *HYGROMETER*. It requires half an hour to boil water on the top of this mountain; whereas 15 or 16 minutes are sufficient at Geneva, and 14 or 15 by the sea-side. Water boiled at 68.993 degrees of a thermometer, which rises to 85 with the barometer 27 French inches high. By experiments with the electrometer, M. de Saussure found, that the electricity of the air on the summit of the mountain was positive. The wind on the summit was north, and very piercing; but southward of the ridge the temperature of the air was agreeable. The experiments with lime-water, and with the caustic alkali, shewed that the air was mixed with atmospheric acid, or fixed air.

The difficulty of respiration, experienced by M. de Saussure and his companions, has been ascribed by some to fatigue, and not to the rarefaction of the air; but his observations prove, that the latter was the cause both of the difficulty of breathing and the quickness of the pulse. This, indeed, was so considerable, that the pulse of one of the guides, after continuing four hours on the summit, was 98, of the servant 112, and of M. de Saussure himself 100 in a minute; whereas at Chamouny they were 49, 60, and 72 respectively. M. de Saussure's observations confute an opinion, which is very common, with respect to the change of the senses of smelling and taste supposed to take place on high mountains. He tried the experiment on different mountains, and both the taste and smell of bread, wine, meat, and fruit, appeared to him and to his attendants not at all different. As to sound becoming weaker, this circumstance is not to be attributed to any impaired state of the organ of hearing, but to the rarefied air, which both reflects less and vibrates less. Besides, on an insulated summit there are no echoes nor solid objects to repel the sound. These concurring causes rendered the sounds on the top of Mont Blanc remarkably feeble; the report of a discharged pistol being equal in strength only to that of a small Chinese cracker let off in a room.

Soon after M. de Saussure's expedition, Mr. Beaufoy, an English gentleman, succeeded in an attempt to ascend Mont Blanc; but it was attended with peculiar difficulty, arising from the enlargement of the chasms in the ice. An account of this enterprise was communicated to the Royal Society in 1787.

BLANC, Mont, gives denomination to a department formed of Savoy. It is bounded on the north by the departments of Leman and Ain; on the east by Piedmont; on the south by Piedmont and the departments of Upper Alps and of Here; and on the west by those of Here and of Ann. Its superficies is about 1,254,796 square acres, or 640,427 hectares; and its population about 283,106 individuals. It is divided into four communal districts; *viz.* Chambery, its capital, Annecy, Moutiers, and St. Jean de Maurienne.

BLANC-en-Berry, Le, a town of France, and principal place of a district, in the department of the Indre, containing 3850 inhabitants. The population of the canton amounts to 10,622; and its territory comprehends 387½ kilometres and 10 communes; six leagues W. of Argenton.

BLANC-Courfier Herald, created by patent on the revival of the most honourable military order of the Bath, 1725, "to attend the first and principal companion of the order for the time being." He enjoys all rights, privileges, and

immunities as any other herald; and his office is annexed, united, and perpetually consolidated with the office of genealogist of the said order. See *GENEALOGIST of the Bath*.

BLANCA, in *Geography*, a small island in the West Indies, north of Margarita, in the province of Andalusia, low and uninhabited; having savannahs of long grass, plenty of guanas, and some trees of lignum vitæ: but chiefly remarkable for its turtle fishery. N. lat. 11° 25'. W. long. 64° 10'.

BLANCA, or *BLANCHE*, an island in the gulph of Mexico, near the coast. N. lat. 25°. W. long. 62° 14'.—Also, a river in the province of Chiapa, in the Audience of Mexico, in New Spain. Its water, though clear, is said to have a petrifying quality.

BLANCARD, STEPHEN, in *Biography*, was son of Nicholas Blancard of Leyden, by whom he was initiated into the knowledge of philosophy and medicine. At a proper age he went to Brada, and thence to Francker, where he took his degree of doctor in medicine about the year 1678. We soon after find him settled at Amsterdã, where he dedicated his time to the practice of his art, but principally to writing or compiling a great variety of anatomical and medical works, of which the most valuable, Haller says, is his "Anatomia practica rationalis, s. variorum cadaverum morbis denatorum anatomica inspectio," published 1688, 12mo. But he has, even in this work, introduced many observations taken from other writers, without acknowledging it. The cases here described are 200 in number, and, in general, curious and deserving notice. Geollicke, however, not only accuses him of plagiarism, and of mutilating and spoiling the observations taken from other anatomists, but he blames him for publishing so many of his works in the Dutch, his native language, which cannot fail, in the end, he says, of being highly injurious to the profession of medicine, by enabling persons to practise who have not previously received a liberal education. This is, however, now done pretty generally all over Europe, and necessarily at the least in this country, where there are so many persons practising in every branch of medicine who are incapable of reading any other language than their own, the law here authorizing any persons who may chuse it to practise medicine, without examination, excepting physicians and surgeons residing in the neighbourhood of London, or of the two universities. We shall only mention one other of this writer's multifarious productions, his "Lexicon Medicum," containing explanations of all the terms used in medicine, surgery, and anatomy, first published in 1679, 8vo. This has passed through numerous editions, and lately, in 1777, by the care of Jac. Frãd. Hænsliam, is increased to nearly treble its original bulk, making two large volumes. 8vo.

Blancard's works were collected and published at Leyden, under the title of "Opera omnia theoretica et practica," in 1 vol. 4to. 1701. Haerl. Bib. Med. Chirurg. Anat. Botan. Eloy. Dict. Hist.

BLANCARDS, a name given to certain linen cloths thus called, because the thread used to weave them, has been half-blanchèd or bleached before it was used. They are manufactured in Normandy, particularly in the places which are in the district, or under the jurisdiction of Pont-Audemer, Bernay, and Lisieux.

BLANCAT, St. in *Geography*, a town of France, in the department of the Upper Garonne; 4 leagues W.N.W. of St. Gaudens.

BLANCH, a cape on the French coast, N. W. of Calais, almost opposite to Dover, on the English coast.

BLANCH, or *White Island*, one of the large islands on the coast of France, lying along the shore of the projecting coast to the N. E. of Morlaix.

BLANCH fermé, or *BLANK farm*, in *Law*, a *white farm*, that is, where the rent was to be paid in silver, not in cattle.

In ancient times, the crown-rents were many times reserved to be paid in "libris albis" called *blanche fermes*: in which case the buyer was holden *dealbare firmam*; viz. his base money or coin, worse than standard, was melted down in the exchequer, and reduced to the fineness of standard silver: or instead thereof he paid to the king 12d. in the pound, by way of addition. In Scotland, this kind of small payment is called "blanch holding," or "redius albae firmæ."

BLANCH-Lyon Pursuivant of Arms. This officer took his title from the arms and supporters of the Mowbrays', dukes of Norfolk (being ruby, a lion rampant, pearl.) Thomas Howard, duke of Norfolk, instituted the office of blanch-lyon poursuivant 29 Hen. VIII. and he attended at the funeral of queen Jane. Blanch-lyon was also a name to an officer of the crown in the reign of Edward IV.

BLANCH Rofs Pursuivant of Arms, was a poursuivant created by Edward IV. and to denominated from the distinguished badge of the house of York.

BLANCH-Singlier Pursuivant of Arms. This office was instituted by Richard duke of Gloucester during the reign of his brother Edward IV. in allusion to his badge or cognizance being a white bear.

BLANCHARD, WILLIAM, in *Biography*, an advocate in the parliament of Paris, was admitted to the bar in 1674, and much employed. Notwithstanding his professional labour, he found leisure for literary researches, and in 1687, published a chronological table of the ordinances of the French kings of the third race; which was republished, with improvements, under the title of "A Chronological Compilation, containing a collection of the ordinances, edicts, declarations, and letters patent of the kings of France, relative to public justice, police, and the finances, from the year 987 to the present time," 2 vols. fol. 1715. The work abounds with accurate researches; and a supplement to it was preparing by the author, when he died in 1724. Moreri.

BLANCHARD, JACQUES or JAMES, a painter of history and portrait, was born at Paris in 1600, and having been instructed in the first principles of painting in his own country, he travelled into Italy, where he studied for some time at Rome and Venice, and acquired, from particular attention to the works of Titian and of the Venetian school, distinguished excellence in the art of colouring, so as to have obtained the flattering appellation of the "French Titian." He was employed a considerable time at Turin by the dukes of Savoy, and afterwards painted several pieces at Lyons. Upon his return to Paris he was much engaged, and by his descent of the Holy Spirit, and a St. Andrew kneeling, gained high reputation. Colouring was his peculiar excellence, and he was distinguished for his judicious management of lights and shades. His principal works, besides those already mentioned, are a gallery at the hôtel de Bourbon, of subjects from the heathen mythology, and the bacchanals in the saloon of M. Morin, with some pieces at Versailles and Trianon. To Blanchard is ascribed the good taste for colouring which obtained in France. He is said to have etched several plates from his own compositions. He died at Paris in 1658, and left a son *Gabriel*, who was also a painter of eminence. D'Argeville. Strutt. Pukington.

BLANCHE, in *Ornithology*. Scopoli describes a kind of tern, or *hirondine de mer*, under this name, in his additions to Buffon's History of Birds. The plumage is entirely white; with the legs and bill black. It inhabits the Cape of Good Hope, and may be placed in the Indian and southern seas. Latham calls this bird *Sterna alba*.

BLANCHE-Carte. See **CARTE**.

BLANCHE-Criffe, or **BLANCHE Coiffe,** in *Ornithology*, is the

corvus cayanus of Gmelin and Latham, in Buffon's History of Birds. It is likewise called in the same work *geay de Cayenne*, and by Latham the *Cayenne jay*.

BLANCHE-Raie, synonymous with *étourneau des terres magellaniques*, names given in Buffon's History of Birds to the Linnæan *sturnus milibaris*, a native of Falkland island.

BLANCHE, Fr. for a minim, in *Musick*, or a white note with a tail to it. See **MUSICAL Characters**, and **TIME-TABLE**.

BLANCHERS, a name given to mechanics employed in blanching, i. e. the art or manner of bleaching or whitening.

BLANCHET, THOMAS, in *Biography*, a painter of history, perspective, and portrait, was born at Paris in 1617, and first manifested a genius for sculpture; but on account of the weakness of his constitution he was advised to direct his attention to painting. Accordingly, having practised for some time at Paris, he travelled for further improvement into Italy. By the counsel and assistance of Poussin and Andrea Sacchi, he applied to history painting; and on his return to Paris, he painted several pieces, particularly a picture at Notre Dame, much admired. At Lyons, where he afterwards settled, he became director of an academical school. During his absence from Paris, he was admitted, in 1676, into the academy of painting. Blanchet designed well, and understood the principles of perspective and architecture. His composition was rich, and his colouring natural; and though he was not always correct, his deficiency in this respect is imputed more to the fire of his genius and the rapidity of his execution, than to want of skill. His master-piece was the ceiling of the great hall in the hôtel de ville at Lyons, which was unfortunately consumed by fire; and the accident is said to have affected him so deeply, as nearly to have cost him his life. The magistrates of Lyons rewarded him with a pension, and with apartments in the hôtel de ville. His character was amiable, and his conversation lively and interesting, so that his company was much sought and valued. He died at Lyons in 1689. Some few of his pieces have been engraved. D'Argeville. Pukington.

BLANCHET, in *Ichthyology*, the familiar French name of a sort of salmon that inhabits the American seas; *salmo fetens* of Linnæus.

BLANCHET, in *Zoology*, *P'Amphibène blanchet*, a kind of amphibæna known among the French naturalists of the present day by this name. The species is described as being of a white colour, without any spots; the body as consisting of 230 annulations, and the tail of 16: on the head are six large scales, and about the vent eight very small tubercles. The length is 18 inches, exclusive of the tail, which measures an inch and an half. This is a native of South America, where it feeds on ants and other insects.—Bosc, from whom the above detail is copied, we are convinced, can mean no other than the *amphibæna alba* of Linnæus, when he describes this species. The Linnæan character states the number of rings on the body of this kind at 223, in which particular alone the two descriptions seem to be at variance; and the inconstancy of that character is too well known to justify the opinion of their being distinct, for that reason only.

BLANCHING, in *Gardening*, is the art of rendering the leaves and stems of various sorts of plants, as endive (cichorium), celery (apium), &c. white, tender, and esculent. It consists in producing a kind of vegetable debility or disease, by depriving them of the stimulant effects or influence of light, and is accomplished either by earthing them well up, or completely covering them, when perfectly dry, by boards, tiles, or other similar means, as will be more fully

fully explained in treating of the different plants that require this sort of management.

BLANCHING also denotes the operation of covering iron plates with a thin coat of crut of tin. See LATTEN.

BLANCHING of copper for sale, in imitation of silver; or mixing blanch'd copper with silver, or exposing the same to sale; or any malleable composition or mixture of metals, or minerals heavier than silver, and which looks, and touches, and wears like gold, but is manifestly worse than standard, is made felony, 8 and 9 W. III. &c. 26.

BLANCHING of wax. See WAX.

BLANCHING, in *Coinage*, the operation of preparing the pieces before striking, to give them the requisite lustre and brightness.

The blanching, as now practised, is performed by heating or heating the pieces in a kind of pan or shovel, with a wood-fire, in manner of a reverberatory furnace, so that the flame passes over the shovel. The pieces being sufficiently heated, and cooled again, are put successively to boil in two copper pans, wherein are aqua fortis, common salt, and tartar of Montpellier; when they have been well-drained of this first water in a copper sieve, they throw sand and fresh water over them; and when dry, they are all well rubbed.

The ancient method of blanching was, by putting the pieces, after heating, in a large vessel of common water; and some ounces of aqua fortis, but in different proportions for gold and silver.—The method is now disused, partly by reason of its expensiveness, and partly because it diminishes the weight of the metal.

BLANC-JAUNE, in *Ichthyology*. *Salmo niloticus*, of Linnæus, a fish of the salmon tribe found in the Nile, is called blanc-jaune by some French authors.

BLANCKAMERE, in *Geography*, a town of Brabant, 2 miles S. of Breda.

BLANCKENBERG, BLANKENBURG, or BLAKENBERG, a town of Germany, in the circle of Upper Saxony, and county of Schwartzburg-Rudolstadt, seated on the Rinne, 4 miles S.W. of Rudolstadt.

BLANC-NEZ, in *Zoology*. Under this name the Linnæan *Simia petaurifla* is described, both in Buffon's Natural History, by M. Allamand, and Sonnini, and in the history of Apes, published recently in Paris by Audebert. The prevailing colour of this animal is a very dark olive; the visage is black, with the exception of the nose, a remarkable snowy white spot of a triangular form being situated on the latter, which gives the creature a very singular appearance. The appellation of *blanc-nez* or *Guenon blanc-nez*, is very well applied, and might be rendered into English with much propriety, the white-nose monkey, if that name had not been previously assigned to another species by Mr. Pennant and Dr. Shaw. In the Zoology of the last writer we are informed, that the distinguishing character of his white-nose monkey (*Simia nidiitans*, Linn.) is the tip of the nose, which is milk-white, while the face itself is black. Dr. Shaw observes, however, shortly after, that the white-nose, in this species, is not absolutely peculiar, but is found in another; alluding, as we imagine, to his vaunting monkey, which answers to that description. The last mentioned animal he considers as the *Simia petaurifla* of Linnæus, and *blanc-nez* of Allamand's edition of Buffon's quadrupeds, as Gmelin states them; and so far the countenance of the French naturalists appears in favour of his opinion. But, perhaps, it will admit of some doubt how far we may be authorized in believing still further with Dr. Shaw, that the *Guenon blanc-nez* of Allamand, and Sonnini, in Buffon's Natural History, and *Guenon à nez blanc proëminent* of the Supplement of that work, are of the same species. Dr. Shaw thinks the first of these must be the female, and the other

the male. Virey, and likewise Audebert, are persuaded that they are certainly distinct species. *Guenon blanc-nez*, they consider as the Linnæan; *Simia petaurifla*, and *Guenon à nez blanc proëminent*, as *Simia nidiitans* of the same author.

BLANCO, in *Geography*, the name of a cape of Africa, on the north coast of the kingdom of Tunis, called the "White Promontory;" or, with the same meaning by the inhabitants, "Ras-el-abcaâ;" and supposed to be the "Promontorium candidum" of Pliny; and the "Promontorium pulchrum" of Liyy, where Scipio landed in his first African expedition. N. lat. 37° 9'. E. long. 10° 18'.—Also, a small point to S. E. of cape Corso, in the island of Corsica.—Also, a cape on the western coast of Africa, in Negro-land; first discovered by the Portuguese in the year 1441. N. lat. 20° 55' 30". W. long. 17° 10'. high water 9^h 45'.—Also, a cape on the western coast of the territory of Tschesmê in Asiatic Turkey, opposite to the southern point of the island of Scio. N. lat. 38° 20'. E. long. 25° 9'.—Also, a cape of South America, on the coast of Brazil, between cape Roque on the north, and cape St. Augustine on the south. S. lat. 6° 50'. W. long. 35° 33'.—Also, a cape of South America, on the eastern coast of Patagonia, north of port Desfado. S. lat. 47° 20'. W. long. 64° 42'.—Also, the north-western point of the bay of Salinas, on the coast of Nicaragua. N. W. from Panama-bay. N. lat. 9° 20'. W. long. 85° 48'.—Also, a cape on the north-west coast of America in New Albion, southward of the mouth of the river called "the river of the west," between cape Gregory and point St. George, and at a further distance between cape Foulweather and Mendocino. N. lat. 43° 20'. W. long. 128° 20'.—Also, a promontory of Peru, in South America, on the coast of the South sea, 120 miles S. W. of Guayaquil. S. lat. 5° 45'. W. long. 83°.

BLANCO, an island on the south-eastern part of the peninsula of Yucatan in New Spain. N. lat. 21°. W. long. 88° 5'. See BLANCA.

BLANDA, in *Entomology*. a species of BUPRESTIS, that inhabits South America. The wing-cases are attenuated, serrated, and furrowed; colour brassy-green, with the furrows coppery. Fabricius.

BLANDA, a species of TENTHREDO, found in England. The colour is black; abdomen rufous in the middle; posterior thighs marked with a white spot. Fabricius, &c.

BLANDA, in *Ancient Geography*, a town of Hispania Taragonensis, mentioned by Mela, Ptolemy, and Pliny, situate on the coast of the Laetani, south of Garunda.—Also, a town of Ita'y, in the country of the Brutii, according to Pliny and Mela, but called "Blandz," by Livy, and placed by him in Lucania.

BLANDFORD, commonly called *Blandford forum*, in *Geography*, is a market town of Dorsetshire, England. It is seated on the eastern banks of the Stour, and on the great post road from London to Exeter, Cornwall, &c. In the Dome-day book no less than nine parishes or parishes are included under the name of Blandford or Blandford, of which this is the most considerable, and was stiled a borough in some ancient records, though it does not appear to have been represented in parliament more than twice; once in the reign of Edward I. and again during the reign of Edward III. James the first granted it a charter, and made it a free borough with certain corporate privileges and immunities. The town is governed by a bailiff and six capital burgeses; a part of whom is invested with the power of determining suits not exceeding 10l.

Here is a small manufactory of shirt and waistcoat buttons, and another of thread, but the principal trade of the town depends upon its neighbourhood, and the passage of travellers. The town has been destroyed several times by fire.

In Camden's time it was mostly burnt by accident, but was soon rebuilt in an improved manner. The years 1676, 1713, and 1731 are recorded as particularly calamitous to this town, and in the latter year nearly the whole of it was destroyed. The church, town-hall, alms-house, free-school, and all the houses, but forty, were consumed. Many lives were lost, and the distressing calamity was greatly augmented by the small-pox, which raged in above sixty families. The computed damage was valued at 100,000*l.* but the distress, terror, and misery that prevailed at the time, and resulted from the direful catastrophe, far exceed all calculation, and defy the powers of verbal description. The town has since been rebuilt, and its appearance much improved by some respectable houses, a new church, town-hall, &c. The latter is a neat building composed with Portland stone, and constructed on columns of the Doric order. Within the building is a pump which was erected by John Bland, who having been a considerable sufferer by the last fire, had this pump constructed to supply the town with water, and thereby to prevent another similar disaster. The new church, built in the Grecian style of architecture, consists of a body, two aisles, a chancel, and a tower. Its interior is very neatly ornamented, and contains several handsome marble monuments.

The charitable donations to Blandford are numerous and valuable, and are appropriated to endow an alms house, to apprentice and clothe the poor boys, to erect and support a charity school, two free-schools, and for other benevolent purposes. Blandford is 104 miles W.S.W. from London, and contains 408 houses, with 2526 inhabitants: at the east end of the town are the remains of a handsome old building, called "Damory court," which has been possessed by many noble and distinguished personages.

Blandford is the birth-place of many celebrated characters: among whom the following are the most distinguished: *George Ryves*, who was warden of New College, Oxford, in 1599, and vice-chancellor, in 1601; *Bruno Ryves*, author of the *Mercurius Rusticus*, a singular book, recording many of the events of the civil wars. He also assisted in publishing the Polyglot Bible, was dean of Chichester and Windsor, and died at the latter place in 1677, aged 81 years; *William Wake*, archbishop of Canterbury, &c. was born here in the year 1657, and died at Lambeth in 1736; *Thomas Creech*, the translator of *Lucretius*, and other ancient classical authors, was born here in 1659; *Christopher Pitt*, another translator, dates his birth at Blandford, where he was buried in 1748.

About one mile south of Blandford-Forum is Blandford St. Mary, a village noted in the annals of literature as the birth-place of *Browne Willis*, the celebrated antiquary and topographer (see *WILLIS*). At the distance of one mile west of this town is *Brianstone-house*, the elegant and commodious mansion of *Edward Berkeley Portman*, esq. This house was erected from the designs of *James Wyatt*, who has displayed much judgment and taste in the disposition of the apartments, the arrangement of the offices, and in the two principal façades. The river *Stour* winding in a broad sheet through the grounds, with the plantations and distant fences, combine to render this a charming and delightful residence. *Hutchins's History of Dorsetshire*, second edition, fol. 1796.

BLANDFORD, a township of America, in Lunenburg county in Mahon bay, Nova Scotia, settled by a few families.—Also, a township in Hampshire county, Massachusetts, west of Connecticut river; about 25 miles S.W. of Northampton, and 116 W. of Boston; containing 1778 inhabitants.—Also, a town in Prince George county, Virginia, about 4 miles N.E. from Petersburg, and within its jurisdiction. It contains 200 houses, and 1200 inhabitants, and is pleasantly situated on a plain, on

the eastern branch of Appamattox river. There are many large houses, and three tobacco warehouses, which receive annually 6 or 7000*000* shreds. It is a thriving place; and as the marshes in its vicinity are drained, the air of this town, and also that of Petersburg, are much improved.

BLANDINA, in *Zoology*, one of the Fabrician species of *PAPILIO*, in the *Triphala* section; the wings of which are centrated, black, and marked with white spots; at the base of the anterior pair a blue streak, and another along the margin of the posterior ones. The rare insect inhabits India. *Vid. D. nov. Inf. Ind. Olf.* There is another species of the *Papilio* genus, that bears the same name, that ought by no means to be confounded with the above mentioned insect. (This is also described by *Fabricius* in his "*Entomologia Systematica*," in 14 section "*Satyræ*;" the wings of this kind are centrated, the colour brown, with a nervous ocellated band; posterior pair beneath rufous with a cinereous stripe. This is *papilio ligæ* of *Scopoli*, *albiops* of *Lepèr*, and *mela* of the *Vienna Catalogue*. It inhabits several parts of Europe, but has not been hitherto discovered in Great Britain. The same specific name again occurs in *Cramer's Papiliones*, a strong variety of the *Gmelinian papilio melicerta*, being so named by that author.

BLANDRATA, *GEORGE*, in *Biography*, a physician and divine of the 16th century, was born in the marquessate of Saluzzè in Italy, and practised physic in Poland and Transylvania; but upon his return to Italy, he was obliged by the inquisition to fly, on account of his religious opinions, from Pavia to Geneva, where he declared himself a Catholic. Here, however, his sentiments, which then inclined to Arianism, excited the suspicions of Calvin, which obliged him first to return to Poland, and afterwards, in 1563, to remove to Transylvania; where *Sigismund*, at that time sovereign of the country, appointed him his physician. After the death of *Sigismund* he sustained the same office to *Stephen* and *Christopher Bator*, and to the former when he obtained the crown of Poland. By his credit and influence the doctrine of *Socinus*, which *Blandrata* seems to have now adopted, made its way from Poland to Transylvania; and it was by his means that *Faulus Socinus* was brought thither from Basil in 1578, to second his arguments and efforts in counteraffecting *Francis Davides*, who zealously opposed the custom of offering up prayers and divine worship to *Jesus Christ*. It is said, that *Blandrata*, either through natural levity, or under the influence of an avaricious disposition, abandoned the interests of the Unitarians, and he is accused by *Socinus* with inclining towards the *Jesuits*, who had obtained credit and influence at the court of king *Stephen*. His wealth, however, tempted his nephew to strangle him in his bed, at some period, not ascertained, between the years 1585 and 1592; and this unfortunate termination of his life has been charitably interpreted, both by the orthodox and heterodox, as a divine judgment. Of his character as a writer the theologians of Geneva express a contemptuous opinion; and his conduct seems to have been chargeable with a degree of unsteadiness and duplicity, which has been partly attributed to the persecuting spirit of the times in which he lived. *Gen. Dict. Moss. Eccl. Hist.* vol. iv. p. 513, 525. *Toulmin's Life of Socinus*, p. 6, &c.

BLANÈS, or **BLANDA**, in *Geography*, a sea-port town of Spain, in Catalonia, on the Mediterranean, 34 miles N.E. of Barcelona. N. lat. 41° 42'. E. long. 2° 45'.

BLANFORD, a township of America, in the West Riding of York county, Upper Canada, on the Thames, opposite to Oxford.

BLANGIS, or **BLANCY**, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Neufchâtel. The population of the town includes 1749 persons, and that of the canton 12,879. The territory

territory comprehends $24\frac{1}{2}$ kilometres, and 31 communes: 14 miles N.N.E. of Neufchatel, and 20 miles E. of Dieppe.

BLANGY, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Pont l'Évêque; the place contains 771 persons, and the canton 10,531. The extent of the territory includes 140 kilometres, and 23 communes; 8 leagues E. of Caen, and $1\frac{1}{2}$ league S. E. of Pont l'Évêque.—Also, a town of France, in the department of the Côtes de Calais, and chief place of a canton, in the district of Montreuil, 2 leagues N.E. of Hesdin.

BLANK, or BLANC, in a general sense, signifies WHITE; and BLANCUS, or BLANCA, is more particularly used for a kind of white or silver money, of base alloy, coined by Henry V. in those parts of France then subject to England, valued at 8d. sterling. They were forbidden by his successor to be current in this realm, 2 Henry VI. c. 9. In some ancient charters they were called “solidi blanki, or white shillings.”

BLANK also denotes a small copper coin, formerly current in France, at the rate of five deniers Tournois.

They had also great blanks or pieces of three blanks, and others of six in resp. et whereof the single sort were called little blanks; but of late they are all become only moines of account.

BLANK, or *Blank ticket*, in *Lotteries*, that to which no prize is allotted. The French have a game, under the denomination *blaque*, answering to our lottery.

BLANK, in *Coinage*, a plate, or piece of gold, or silver, cut and shaped for a coin, but not yet stamped. See COINING.

BLANK-bar, in *Law*, is used for the same with what we call a “common bar,” and is the name of a “plea in bar,” which, in an action of trespass, is put in to oblige the plaintiff to assign the certain place where the trespass was committed. 2 Cro. 554.

BLANKS, in judicial proceedings, certain void spaces sometimes left by mistake. A *blank* (if something material be omitted) in a declaration, abates the same; 4 Ed. IV. 14. 20 H. VI. 18. and such a blank is a good cause of demurrer. Blanks in the imparlance-roll aided “after verdict” for the plaintiff. Hob. 76.

BLANK-verse. See VERSE and RHYME.

BLANK-point. See POINT-blank.

BLANKENBERG, in *Geography*, a sea-port town and fortresses of Flanders, situate near the sea-coast, between Ostend on the S.W. and Cadzand island to the N. E. N. lat. $51^{\circ} 18'$. E. long. $3^{\circ} 24'$.—Also, a small town of Germany, seated on a mountain, in a prefecture of the same name, in the circle of Westphalia, and duchy of Berg, 20 miles S. E. of Cologne.

BLANKENBURG, a principality of Germany, in the circle of Lower Saxony, belonging, since the year 1731, to the reigning house of Brunswick-Wolfenbützel, for which he holds a seat at the diet of the empire, and pays 12 rix-dollars a month. This principality lies partly on and partly near the Hartz mountain, and is about 20 miles long and about 8 wide. The northern part, without the Hartz, consists of very good corn-land, but that which lies on the Hartz abounds in woods, quarries of marble, and mines of iron ore. A considerable part of the country is watered by the Bode. The capital town is of the same name; in which are held the courts of judicature and the consistory, with the superintendance of the principality. Near the town, on an eminence, is the ducal palace. It is 7 miles distant from Halberstadt.

BLANKENHAYN, a small town in the circle of Upper Saxony, and principality of Altenburg, belonging to a lordship of the same name, which is a fief of the electorate of Mentz; 17 miles E. S. E. of Erfurt.

BLANKENHEIM, a small town in Germany, and capital of a county of the same name, in the circle of Westphalia, and archbishopric of Treves. The prince, resident here, pays 64 florins a month, and 72 rix-dollars, and $54\frac{1}{2}$ kreutzers to the imperial chamber; 36 miles N.N.E. of Treves. In the French arrangement it is the principal place of a canton in the district of Prüm, and department of Sarre. The population of the place includes 500 persons, and the canton 3936. Its territory comprehends 19 communes.

BLANKENSEE, a lake of Germany in the circle of Upper Saxony, and middle mark of Brandenburg, 6 miles E. of Belitz.

BLANKENSTEIN, a town of Germany in a prefecture of the same name, in the circle of Westphalia, and county of Mark, seated on an eminence near the Rhur, 19 miles E.N.E. of Duffeldorp.

BLANKET, in *Commerce*, a warm woolly sort of stuff, light and loose woven; chiefly used in bedding. The manufacture of blankets is principally confined to Witney in Oxfordshire, where it is advanced to that height, that no other place comes near it. Some attribute a great part of the excellency of the Witney blankets to the absterfive nitrous water of the river Windrush, wherewith they are scoured; others think they rather owe it to a peculiar way of loose spinning, which the people have about that place. Be this as it will, the place has engrossed almost the whole trade of the nation for this commodity; inasmuch that the wool fit for it centres here, from the farthest parts of the kingdom. Plott. Hist. Oxf. chap. ix. § 163.

Blankets are made of felt wool, i. e. wool from off sheepskins, which they divide into several sorts.

Of the head wool, and bay wool, they make blankets of twelve, eleven, and ten quarters broad; of the ordinary and middle sort, blankets of eight and seven quarters broad; of the best tail wool, blankets of six quarters broad, commonly called cuts, serving for seamen's hammocks. See HYKES.

BLANKET, *tossing in a*, a ludicrous kind of punishment, of which we find mention in the ancients under the denomination *sagatio*. Martial describes it graphically enough. “Ibis ab excussu, missus ad astra, sago.”

A late writer represents it as one of Otho's imperial delights. But this is turning the tables; that emperor's diversion, as related by Suetonius, was not to be the subject, but the agent in the affair; it being his practice to stroll out in dark nights, and where he met with a helpless or drunken man, to give him the discipline of the blanket.

BLANKOF, JOHN TEUNISZ, in *Biography*, a Flemish painter, was born at Alkmaar in 1628. After having spent some years in receiving instruction from Arent Tierling, Peter Scheyenburg, and Cæsar van Everdingen, he went to Rome, where he diligently copied the works of the best masters, and was admitted into the society of Flemish painters, called Bentvogels, by whom he was distinguished by the appellation of Jan Maat, signifying, in Dutch, mate or companion, and under which appellation, he is most generally known. His subjects were landscapes with views of rivers, or sea-shores, havens, or ports, which he executed with a light free pencil; and in the representations of storms and calms, he particularly excelled. Those of his pictures that are principally commended, are the Italian sea-ports, with vessels lying before them. And his most capital performance is a view of the sea-shore with the waves retiring at ebb-tide; which Houbraken describes as admirably beautiful and natural. His imagination was lively, and his execution rapid. He died in 1670. Pilkington.

BLANQUEFORT, in *Geography*, a town of France,

in the department of the Gironde, and chief place of a canton, in the district of Bourdeaux, five miles north of Bourdeaux. The place contains 2003, and the canton 9304 inhabitants. The territory comprehends 272½ kilometres, and 9 communes.

BLANQUILLE, in *Commerce*, a small silver coin, equivalent to about 11½*d.* sterling, current in Morocco, and on the coasts of Barbary.

BLANZAC, in *Geography*, a town of France, in the department of the Charente, and chief place of a canton, in the district of Angouleme, 4 leagues S.S.W. of Angouleme. The place contains 546, and the canton 10,440 inhabitants. The territory includes 242½ kilometres, and 20 communes.—Also, a town of France, in the department of the Gard, and chief place of a canton, in the district of Uzès, 3 miles S. S. W. of Uzès.

BLAPS, in *Entomology*, one of the Fabrician genera of *coleopterous* insects, the palpi of which are clavated, and four in number; jaws straight and bifid; lip membranaceous and cleft; and the antennæ moniliform at the tip. Fabricius includes in this genus some of the *tenebriones* of Linnæus, such as *tenebrio gages* and *mortifaga*. Gmelin adopts the genus only as a subdivision of *Pimelia*, in the Syst. Nat. See PIMELIA.

BLAPSIGONIA, compounded of *βλαπτεω*, *I hurt*, and *γυν*, *brood* or *issue*, a kind of disease, or defect in bees, when they neglect or fail to produce young, being wholly employed in making honey.

BLARE, in *Commerce*, a small copper coin, containing a little mixture of silver, struck at Bern, and valued at much the same with the RATZE in other places.

BLARINGHEM, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Hazebrouck, 2 leagues S. E. of St. Omer.

BLARNEY, a small market town of the county of Cork, and province of Munster, Ireland, situated on a river of the same name, about 4 miles W. of the city of Cork. In the reign of queen Elizabeth, its castle was reckoned one of the strongest fortresses in Munster, and it has often proved very troublesome to the inhabitants of Cork. It belonged formerly to the earls of Clancarty, but at present is the property of Mr. Jeffries, whose father built the town, and established several manufactures, of which Mr. A. Young has given a detail in the account of his tour through Ireland. These establishments, however, as too generally happens in like cases, have not been successful, and Blarney is not at present the flourishing town, which Mr. Young's account would lead us to expect. A paper-mill, a stamping-mill, a bleach-green, and one or two cotton manufactories still exist; and many stockings made in the neighbourhood are sold at the weekly market and in Cork, but all may be considered as on the decline. The castle and the grounds about it have been considerably improved, and the country around, as well as the park, is well watered. There is a stone at one of the corners of the top of the castle, which is shewn to strangers, on account of a saying, that any person who has kissed it is privileged to lie and flatter. The origin of this saying, which is often referred to, and from which *Blarney* has become a vulgar synonym for flattery, the writer has not been able to discover. In the castle there is an original painting of Charles 12th of Sweden, at full length, drawn in the dress mentioned by Voltaire, brought over by one of the family who had been envoy to that monarch. The adjoining country is mostly under corn and pasture; the soil is a yellowish clay, and is mostly manured with lime-stone, of which there is a vein that supplies large quantities. Smith's Cork. Young.

BLAS, Str. a cape on the coast of the North Pacific ocean,
Vol. IV.

near which, to the S. E., stands the town of Compostella, in the province of Galicia, in New Spain. N. lat. 21° 30'. W. long. 105° 12'. See BLAISE.

BLAS, a term, in the Helmontian philosophy, denoting the local and alterative motion of the fluids; from whose influence proceed changes of weather, seasons, storms, and the like.

In imitation of this *blas stellarum*, the same author framed another in animals, either natural, whereby each *vifcus* is framed according to the model of its particular; or voluntary, which is directed to motion by the will.

BLASCON, in *Ancient Geography*, an island of Gaul, mentioned by Pliny, situate at the mouth of the Rhone.

BLASE, Str., in *Geography*, a town of Germany, in the archduchy of Austria, 8 miles S.W. of Steyr.

BLASENDORF, or BALASFALVA, a town of Transylvania, in the district of Weissenbourg, the residence of the bishop of Walachia.

BLASIA, from Blasio Biagi, an Italian monk, in *Botany*. Lin. Gen. n. 1199. Mich. Gen. t. 7. Clafs, *Cryptogamia Alge*. Species, 1. *B. pusilla*. Lin. Spec. 1605. Hudf. Angl. 519. Dill. t. 31. f. 7. Pl. dan. t. 45. The dwarf blasia grows on the sides of ditches and brooks, and in moist shady places in a sandy soil, in many parts of Europe; with us on Honnslow heath, and also near Manchester and Halifax. It flowers in the beginning of May.

BLASII ZELLA, in *Geography*, a small town of Germany, in the circle of Upper Saxony, and principality of Gotha, separated in 1640 from the bailiwick of Reinhardsbunn, and added to that of Schwarznot-wald, and famous for its foundery of fire-arms; 16 miles S. of Gotha.

BLASIMONT, a town of France, in the department of the Gironde, and chief place of a canton, in the district of La Réole, 7 leagues E. of Blanout, or 3½ N. of La Réole.

BLASIUS, GERARD, in *Biography*, son of Leonard, physician at Amsterdam, who received pupils into his house, to instruct them in the knowledge of medicine, particularly in the anatomy of brute animals, of which he dissected a great variety. It was this which probably inclined Gerard to this branch of study, and gave birth to several of his works; such as his "Zootomie, seu Anatomies variorum Animalium," published 1676; "Observata anatomica, in homine, simia, equo, vitulo, testudine, echino, glire, serpente, ardea, variisque animalibus aliis," Lugduni, 1674, &c.

After making some progress under his father, he went, for further improvement, to Copenhagen, and at length to Leyden, where he commenced doctor in medicine, about the year 1646. He then returned to Amsterdam, where he acquired so much credit and reputation for his skill in his profession, that in 1660 he was made professor in medicine in the schools of that city, and soon after physician to the hospital.

Besides a variety of original works, Blasius published new editions of parts of the works of Primerose, Th. Bartholine, Licetus, Bellini, Borelli, and Willis, to most of which he gave notes and additional observations, containing such discoveries on the subjects treated of, as had been made since those works had been originally published. Of his original works, besides those mentioned above, we shall notice his "Oratio de noviter inventis," Amst. 1659, 4to. "Observationes medicæ rariores, accedit triplicis monstri historia," Amst. 1667, 8vo. in six books, containing accounts of the dissection of numerous morbid bodies, in one of which, the spleen, and in another the gal-bladder, were found to be misplaced; in one two stomachs were found, in another three testicles. "Anatome animalium terrestrium variorum volatilium, aquatilium, serpentum, insectorum, ovorumque structura"

structuram naturalem proponens." Amst. 1601, 4to. The greater part of this work is collected from Severinus, Harvey, Malpighi, Willis, Bartholine, and other writers and journals. The work has, however, its utility, by bringing into a small compass a great number of curious facts, and observations, which were only before to be found by recurring to a variety of publications. In a letter published in the third century of Th. Bartholine's epistles, Blasius claims the discovery of the ductus salivaris, which he says he first shewed to Steno, then a young man. This has not, however, prevented the discovery from being attributed to Steno, the duct taking his name. For the titles of the rest of the works composed or edited by Blasius, see Haller. Bib. Anat. Med. et Chirurg. and Eloy's Dict. Hist.

BLASKET SOUND, in *Geography*, lies on the west coast of Ireland, between the Great Blasket island and Dunmore-head, on the mainland of the county of Kerry. In this sound there is ten fathom water, and in the summer time and moderate weather a vessel may stop off the east end of the Great Blasket; but the ground will not hold well in blowing weather. In passing through this sound, it is necessary to attend to a pretty strong tide, and to a rock not far from Dunmore point, which is covered at high water.

BLASKETS, BLASQUETS, or *Ferriter* islands, a cluster of islands on the west coast of the county of Kerry, Ireland, being the most westerly land in the European part of the British empire. They are five in number, besides several rocks, some of which are always above water, and others are covered by high tides. Their islands were given by the earl of Desmond to the family of Ferriter, from which one of their names is taken; but at present they belong to the earl of Cork and Orrery. The largest, called *Innismore*, i. e. the Great Island, and more commonly the *Great Blasket*, was visited by Dr. Smith, who found it inhabited by five or six families, and speaks in high terms of the salubrity of its air. Ruins of churches, and cells or hermitages, are found in some of the others, but when Dr. Smith was there, they were not inhabited. The small rocks are frequented by sea-fowl, the feathers of which are collected by the people of the neighbouring coast. The hawks which are found here are remarkably good, and were formerly in much esteem. Amongst other sea fowl the *stormy petrel*, (*procellaria*, Linn.) is common here. The Greater Blasket is 9 leagues S.W. by W. from Louphed, the north point of the Shannon, and 5 leagues north of the Skeligs. The whole cluster lie between $10^{\circ} 17'$, and $10^{\circ} 31'$ W. longitude, and between $51^{\circ} 58'$, and $52^{\circ} 3'$ north latitude. Smith's Kerry. McKenzie.

BLASPHEMY, *bl sphemia*, or *blasphemium*, in *Middle Age Writers*, denotes simply the blaming or condemning of a person or thing. The word is Greek, βλασφημία, from βλαπτω, *lelo*. Among the Greeks, to *blaspheme*, was to use words of evil omen, or that portended something ill, which the ancients were careful to avoid, substituting in lieu of them other words of softer and gentler import, sometimes the very reverse of the proper ones.

BLASPHEMY is more peculiarly restrained to evil or reproachful words spoken of the Deity. Augustin says, "Jam vulgo blasphemia non accipitur nisi mala verba de Deo dicere."

According to Lindwood, blasphemy is an injury offered to God by denying that which is due and belonging to him; or attributing to him what is not agreeable to his nature.

By the Mosaic law, blasphemy was punished with death. Levit. chap. xxiv. ver. 13—16. As also by the civil law. Novel. 77. In Spain, Naples, France and Italy,

the pains of death are not now inflicted. In the empire, either amputation, or death, is made the punishment of this crime.

By the canon law, blasphemy was punished only by a solemn penance, and by custom, either by a pecuniary or corporal punishment. By the English laws, blasphemies against God, and religion, as denying his being, or providence, and all contumelious reproaches of Jesus Christ, &c. to which may be also referred all profane scoffing at the holy scripture, or exposing it to contempt and ridicule, are offences by the common law, and punishable by fine, imprisonment, and pillory. 1 Hawk. P. C. And by the statute law, he that denies any one of the persons of the Trinity to be God, or asserts there are more Gods than one, or, having been educated in, and having made profession of the Christian religion, denies, by writing, printing, teaching, or advised speaking, Christianity to be true, or the holy scriptures to be of divine authority, for the first offence is rendered incapable of any office or place of trust; and for the second, adjudged incapable of bringing any action, being guardian, executor, legatee, or purchaser of lands, and to be imprisoned for three years without bail. 9 and 10 W. III. c. 32. To give room, however, for repentance, if, within four months after the first conviction, the delinquent will in open court publicly renounce his error, he is discharged for that once from all disabilities.

According to the law of Scotland, the punishment of blasphemy is death. The first species thereof consists in railing at or cursing God, and here the single act constitutes the crime. The second consists in denying the existence of the Supreme Being, or any of the persons of the Trinity; and therein obstinately persevering to the last. For reiterated denial does not fully constitute the crime, because the stat. of Charles II. 1661, admits of repentance before conviction as a complete expiation.

This statute of 1661, is ratified by a statute of king William, whereby the calling in question the existence of God, or of any of the persons of the Trinity, or the authority of Scripture, or the Divine Providence, is made penal. For the first offence, imprisonment till satisfaction given by public repentance in sackcloth. For the second, a fine of a year's valued rent of the real estate, and twentieth part of the personal estate: and the trial in both these cases is competent to inferior judges. The punishment of the third offence is death, to be tried only by the justices.

BLASPHEMY against the *Holy Ghost*. Divines are not agreed with respect to the nature of the crime thus denominated, Matthew, xii. 31. Mark, iii. 28, 29. Luke, xii. 10. and the grounds of the extreme guilt ascribed to it. On this subject it may be observed in general, that from our Saviour's expression this sin appears to consist, and to be completed, not in our thoughts, nor in our works, but in our words. Nor, indeed, is the epithet "blasphemous," or any synonymous term, ever joined in scripture, as is common in modern use, with doctrines, thoughts, and opinions. It is never applied but to words and speeches. A "blasphemous opinion," or "blasphemous doctrine," are phrases, which, however familiar to us, are as unsuitable to the scripture idiom, as a "railing opinion," or "slanderous doctrine," is to ours. It may be also observed, that this blasphemy is not of the constructive kind, but direct, manifest, and malignant. It is mentioned as comprehended under the same genus with abuse against man, and contradistinguished only by the object: and it is further explained by being called "speaking against," in both cases. The expressions are, in effect, the same in all the gospels, where

is mentioned, and imply such an opposition as is both intentional and malevolent. This could not have been the case with respect to all who disbelieved the mission of Jesus, and even decried his miracles; many of whom, we have reason to think, were afterwards converted by the apostles.

The learned Grotius, in order to mollify the severity of the sentence denounced against this sin, suggests, that what our Lord expresses absolutely, must be understood comparatively; and that he only designed to intimate, that it is very difficult to obtain the pardon of this sin, but not that it will admit of no forgiveness. But our Saviour here says expressly of this sin, whatever it was, both negatively, that it shall never be forgiven, and affirmatively, that the person guilty of it shall be obnoxious to eternal judgment, confirming the whole with an asseveration. Dr. Waterland (see his *Serm.* vol. ii. N^o 9. p. 177—183.) seems to incline to Grotius's opinion; alleging that ἀβυσσῶν signifies only exceedingly difficult. Dr. Hammond comments upon the words with observing, that this sin shall not be pardoned, but upon a particular repentance; but this is true of every sin as well as of the blasphemy against the Holy Ghost. Some have made this crime consist in final impenitency, because that is unpardonable; but it is not easy to assign a reason why this should be called the sin against the Holy Ghost. Others have represented it as, in its specific nature, a wilful and obstinate opposition to the truth; others again as a malicious opposition to the truth, on the part of those who know and are convinced that it is the truth; whilst some have supposed it to consist in a renunciation of the truth for fear of suffering, which made Francis Spira think that he had committed this sin. Mr. Wakefield, in his *Notes on the Translation of the Gospel of St. Matthew*, p. 178, is of opinion, that what is meant by the blasphemy of the Spirit appears from the context to be perversely resisting and belying with contumacy, against plain and satisfactory evidence, the operation and interference of the holy spirit of God; and he thinks, that those men who reject the Christian revelation, without contemplating its claims with diligence, candour, and exactness, upon a precipitate presumption of its falsehood; and those, who refuse their assent to that degree of moral evidence, of which alone these subjects are capable, and which they would think sufficiently satisfactory in other cases, and in the ordinary occurrences of life, are as much guilty of the sin of blasphemy in our times, as those cavilling and hypocritical Pharisees were in the days of Christ.

Dr. Tillotson (vol. i. *serm.* xvii.) maintains, that this sin, of which the Pharisees were guilty, consisted in maliciously attributing the miraculous operations which Christ performed by the power of the Holy Ghost to the devil. This sense is adopted by bishop Pearce, in his *Commentary on the four Evangelists*, vol. i. p. 85. But Dr. Whitby, with greater probability, refers it to the dispensation of the Holy Ghost, which commenced after our Lord's resurrection and ascension; and those were guilty of the crime, who persisted in their unbelief, and blasphemed the Holy Ghost, representing him as an evil spirit. The crime was unpardonable, because it implied a wilful opposition to the last and most powerful evidence which God would vouchsafe to mankind, and precluded the possibility of a recovery to faith and repentance. Whitby's *Fourth Appendix to the Gospel of St. Matthew*, in his *Paraphrase*, vol. i. p. 289.

Of this sin, it is said, it shall not be forgiven, either in this world or in that which is to come. With regard to the meaning of this expression, it is observed both by Lightfoot (*Hor. Heb.*) and by Grotius (in *loc.*), that through a fond

imagination of the final happiness of all the seed of Abraham, the Jews supposed, there were some sins that had not been forgiven here, which would be expiated by death, and be forgiven after it; and that our Lord designed by this expression to assure them, that there was no forgiveness for those who should be guilty of this sin, either before or after death, and that their expectations of forgiveness then would prove no other than a deceitful dream. Dr. Whitby, however, has clearly shewn, that this was used as a proverbial expression, and that it only signified, "a thing should never be," when it was said, "It shall not be, either in this world, or in the world to come." Others, however, among whom we may reckon bishop Pearce and Mr. Wakefield, have thought that the expressions of "this world," and "the world to come," denote the Jewish and the Christian dispensations. Ὁ αἰὼν, and ὁ νεὺν αἰὼν, say these writers, signify in the New Testament the Jewish age or dispensation, which continued till the annihilation of the Jewish polity, civil and ecclesiastical, by the destruction of Jerusalem under Titus; and ὁ μελλῶν αἰὼν, or the future age, denote the Christian dispensation. Bishop Pearce adds, that under the Jewish law, there was no forgiveness for wilful and presumptuous sins; concerning which he refers to *Numb.* xv. 30, 31. xxxv. 31. *Lev.* xx. 10. and *1 Sam.* ii. 25. With regard to the age to come, or the Christian dispensation, the bishop observes, that no forgiveness could be expected for such sinners as the Pharisees were; because, when they blasphemed the Spirit of God, by which Jesus wrought his miracles, they rejected the only means of forgiveness, which was the merit of his death applied to men by faith, and which under Christianity was the only sacrifice that could atone for such a sin; in this sense, as things then stood with them, their sin was an unpardonable one. But, he adds, it is not to be concluded from hence, that, if they repented of this blasphemy, they could not obtain forgiveness. Mr. Wakefield observes, that the unreserved affirmation in *Matt.* xiii. 32. must be interpreted, as well as the preceding verse, with considerable qualification. Οὐκ ἀφεθήσεται, "will not be forgiven him," must signify, says this writer, "will not readily be forgiven—will not be esteemed a common and venial fault," agreeably to the eastern mode of expression, which constantly requires such limitation. Accordingly he thus gives the general sense of this verse. "Offences of the most heinous nature, even reproach and injustice against the anointed prophet of God, may more readily find pardon, than contumacious blasphemy of the Holy Spirit." This aggravated sin, the result of obstinacy, depravity, and malice in the extreme, will have no title to forgiveness, even from the clemency and mercy of the Christian revelation, a revelation of pardon and peace, in the fullest sense, and to the whole race of man. See *Heb.* vi. 4—7. Nevertheless, "will not any sins be pardoned on sincere repentance, and steadfast purposes of amendment, under that consoling dispensation, which breathes out life; but reconciliation and forgiveness—nothing but favour, mercy, and peace, from God our Father, and our Lord Jesus Christ?"

BLASQUES ISLAND, in *Geography*, lies on the west coast of Newfoundland, in about 42° 30' N. lat.

BLASS-ENT, in *Ornithology*. The common wild duck is called by this name in the vicinity of the lake of Constance.

BLASSENTE, (*Frisch. av.*) a name synonymous with *anas Penelope* of Linnæus, and common *swigron* of English writers.

BLAST, *status*, in the *Military Art*, a sudden compression of the air, caused by the discharge of the bullet out of a great gun. The blast sometimes throws down part of the embrasures of the wall.

B L A S T.

BLAST is also applied, in a more general sense, to any forcible stream of wind, or air, excited by the mouth, bellows, or the like.

BLAST, in *Agriculture*, a disease in grain, trees, &c. See BLIGHT.

The sugar-cane in the West Indies is subject to a disease called the blast, and said to be occasioned by the *aphis* of Linnæus, which is distinguished into two kinds, the black and the yellow; and of these the latter is the most destructive. It consists of myriads of little insects, invisible to the naked eye, whose proper food is the juice of the cane, in search of which they wound the tender blades, and consequently destroy the vessels. Hence the circulation being impeded, the growth of the plant is checked, until it withers and dies in proportion to the degree of the ravage. It is frequently affirmed, says Mr. Bryant Edwards (*Hist. West Indies*, vol. ii. p. 215.) that the blast never attacks those plantations where colonies have been introduced of that wonderful little animal, the carnivorous ant, or "formica omnivora" of Linnæus, called in Jamaica the "raffles ant," from its being supposed to have been introduced there by one Thomas Raffles from the Havannah, about the year 1762. These minute and busy creatures soon clear a sugar plantation of rats; and their natural food seems to consist of all kinds of insects and animalcules.

Fire BLAST. See BLIGHT.

BLASTS, among *Miners*. See DAMPS. See MINES, and MINING.

BLAST, the term used at iron founderies to denote the column of air introduced into the furnace for the purpose of combustion. Its velocity is occasioned by the impelling power of the blowing machine forcing the whole contents of the air-pump through one or two small apertures called nose-pipes; and, according to the absolute power of the engine, air of various densities will be produced, so that density and velocity are always intimately connected, and mutually implied.

The well-known combustibility of iron, and the indispensable necessity of exciting combustion by the introduction of large quantities of condensed air into the furnace, in contact with ore in various states of maturity as to separation, into contact with iron existing in all the modifications of quality as to carbonation, and into contact with an immense body of ignited fuel, render this subject the most important in the major scale of our manufactures. Unfortunately for art, as well as for science, few practical deductions can be brought forward to establish any one theory of blast; one common principle only is acknowledged, that all reduction in the furnace is in consequence of the combustion excited by the column of air introduced.

To take a proper view of this interesting subject, it will be necessary to submit it to the following divisions.

1st. Combustion, as excited in this particular branch of manufacture.

2d. The nature of the fuel submitted to combustion.

3d. The density of the air.

4th. The quantity.

5th. The properties which follow as a consequence of density and quality.

1st. Combustion in the blast furnace consists chiefly in the rapid reduction of a given quantity of solid fuel, and its accompanying portion of ore, in the shortest possible time. That furnace, and that blast, which can, in a given time, reduce the greatest quantity of fuel, all things else being alike, will always manufacture the greatest quantity of iron. In common, before the introduction of the blast, the furnace is previously filled with alternate strata of coke, iron-stone,

and limestone, heated by simple atmospheric pressure to a bright red or white heat, and the iron stone to a melting heat. This temperature is soon increased throughout the furnace, after the blast is applied. The blowing orifices or tuyeres of the furnace exhibit the fuel increasing in whiteness, and the iron-stone rapidly dissolving before the blast, of a blackish colour. At this period, the lava which flows from the furnace, in consequence of the reduction of the ore and lime-stone, is considerably charged with iron, and is of a black, blackish brown, or greenish brown colour. These appearances will continue for twelve, twenty-four, or thirty-six hours, according to the mode of treatment in bringing forward the furnace after blowing. The tuyere (if a bright tuyere furnace) will appear like a blaze of uncommonly pure light, at times very offensive to the eye; it soon, however, becomes accustomed to it, and can with facility discern the individual masses of coke, as they are forced away, with the rapidity of lightning, before the irresistible force of the air. The concrete ore and lime-stone are no longer visible; but a fine metallic spray is constantly descending, and, forced from the fuel, precipitates itself to the bottom of the furnace. The scoria formed by the fusion and union of the lime-stone, with the immetallie parts of the ore, is carried before the blast in a similar manner and form, but easily distinguishable from the fluid metal by its buoyancy, want of velocity when impelled, and by its dull colour. In this state, the furnace is deemed in excellent smelting order. The iron is generally revived with little loss; and the colour and purity of the cinder or lava sufficiently indicate the perfection of the separation. When at any time the brightness of the tuyere fails, and becomes dull white or reddish white, then a change is indicated; the iron-stone and lime-stone will again appear in the solid unseparated state, and the change of colour in the cinder infallibly betokens an irregularity in the movements of the furnace. These appearances are so general, as scarcely to admit of an individual exception, and are sufficient to warrant the following explanation.

At the introduction of the blast, the interior of the furnace at the tuyere was simply a mixture of ignited masses of coles and iron-stone, the latter partly semifused, but the greatest part merely heated to a bright red heat. In the descent through the furnace, in contact with ignited coke, the particles of metal in the ore may, by parting with the oxygen, have received a disposition to become revived. The increased temperature creates an additional tendency, by establishing a greater force of affinity betwixt the fuel and the iron. But the metal approaching to its proper state, meeting the current of blast, is immediately subject to a partial combustion. The portion thus oxydated conveys to the lava in proportion to its quantity and oxygenation, the colour already mentioned.

As soon as the continuation of the blast conveys a higher temperature to the superior regions of the furnace, the appearance of the solid matter at the tuyere ceases. The fusion and separation of the metal from the ore are effected in situations more remote from the blast, or chief source of decomposition in a temperature more suited to the nature and existence of the metal. The iron, once formed into a fluid, and its fluidity preserved, its descent to the blast is attended with little or no injury to its carbonation.

To understand this distinctly, it will be necessary to state two curious facts relative to cast iron in a fluid state; and but for the existence of these properties, the manufacture of the metal in open furnaces or vessels would be totally impracticable. 1st. Cast iron, while kept fluid, never decomposes atmospheric air, and never itself becomes oxydated. 2d. The degree of carbonation passed upon the metal at the

moment it enters into complete fusion, continues without diminution or augmentation throughout the whole operation of the furnace; or, in other words, cast iron neither receives nor loses carbon whilst it preserves its fluidity. The first fact explains the reason why the iron is preserved from combustion, when it descends opposite to the current of blast. The second is a proof that the carbonaceous matter is conveyed to the iron in the furnace by a species of cementation previous to fusion; and that after this point, cast iron will not take up any addition of carbon.

To preserve and establish the relation of cementation and fusion in the furnace ensures uniform products. Combustion in this presents us with a gradation of temperature, diminishing from the tuyere upwards through thirty or forty feet of ignited matter. The inferior temperature towards the top of the furnace heats the materials to redness; an affinity is here commenced betwixt the carbonaceous matter and the oxygen of the ore; the latter is gradually removed, and a second affinity is instituted betwixt the de-oxygenated particles of metal and the carbon: this, as the ore descends to higher temperatures, is rapidly increased, and by and by the saturation of the coaly principle is complete. As the saturation of carbon always increases the fusibility of iron, the metal of the furnace enters into fusion at a comparatively low temperature, and speedily precipitates, through the high temperatures in the neighbourhood of the blast, to the general reservoir below.

It is not, therefore, necessary to suppose, that the great volume of air thrown into the furnace, and the great temperature of course excited, are necessary to the manufacture of the iron, so far as it regards quality; this, is more than probable, may be injured by it, and even the economy of the manufacture itself. Quantity, however, is in general secured; but this is more the effect of mechanical reduction, than of any necessary operation of the blast upon the ore and materials above.

The quicker the body of coles can be reduced, which occupy that part of the furnace between the point of separation and the tuyere, the greater will be the reduction of the whole, and the greater the quantity of manufactured metal. To this point the whole force of the blast is directed; here the chief part of the decomposition of the atmospheric air takes place; and here the destruction of the intervening coles is effected, and that always in proportion to the quantity of air poured upon their highly ignited surfaces.

If we assume, with a blast of a certain density, any two points in the furnace, the one as the point of decomposition, and the other of separation and fluidity of the metal, suppose the former at the tuyere, and the other at the lower end of the bushes at A, (See *description of BLAST furnace*;) then it must be allowed probable, that a change taking place in the density, or even in the quantity of the blast, that change will affect not only the points themselves, but also their relative distances. The point of separation may be brought nearer (and perhaps injuriously so) to the level of the blast, the elevation of which is supposed to remain the same. The contrary may with equal truth be inferred; that if the point of separation is carried to a more elevated situation by a change or increase of temperature, the ore may enter into fusion before it has remained sufficiently long in contact with the ignited fuel, and thereby both the quality and quantity may be injured.

2d. Since pit-coal coke became the staple fuel at the blast furnace, the density and quantity of air deemed necessary to ensure combustion and quantity, have been yearly increasing. The various qualities as to hardness or softness, purity and effect, have given rise to a multitude of opinions, which are the most appropriate quantity and density of air for respec-

tive qualities of coles. The blast of the furnace, in consequence, has at different places varied from $1\frac{1}{2}$ to 4lb. of expansive force upon the square inch of the air vessel. Most of the English works are blown with air not exceeding 2lb. upon the square inch, as being the most proper medium of density, and beyond which the materials would be over-blown. English coal, in general, is soft in its fossil state, but rich in carbon, and free from mixture. In Scotland, where the coal is found in dense strata, and forms heavy cok, the blast is used from 2 lb. to 4 lb. per inch. Those who have adopted dense blasts declare, that quantity of iron is incompatible with a column of air inferior to the measure of their standard. Either the prejudice is very general, or there really must exist a direct analogy between the nature of the blast and the density of the coal.

The operations of the charcoal pig manufactory were conducted with blasts of a trifling density, seldom exceeding $1\frac{1}{2}$ lb. upon the inch, and often under this. Dense blast, it was believed, over-ran the furnace, most probably by exciting too great a temperature, and frequently had a tendency to discharge the materials from the furnace top. There never yet have been any direct experiments made to ascertain upon what this variety of pit-coal depends; whether exclusively from its density, or from containing the carbonaceous matter in more purity or greater disengagement. Perhaps both are necessary to be taken into account, before any satisfactory explanation can be given of the facts now stated and generally admitted.

3d. The density of a column of air depends upon the power of the blowing machine, and the proportion of the area of the steam cylinder to that of the blowing cylinder. Tables of the powers of steam engines, and the diameters of cylinders requisite to condense air from $1\frac{1}{2}$ lb. to 4 lb. upon the circular inch, will be found under the article BLOWING MACHINE. It will appear evident from these tables, that steam cylinders of the same diameter, and working at the same power, when employed to raise air of various densities, do not discharge the same quantity of atmospheric air in any given time. The larger the area of the blowing cylinder, the number of strokes being the same, the greater will be the quantity of air discharged into the furnace. The reverse is the case with blasts progressively more dense; so that any part of an engine's power may be employed, not in raising the true principle of combustion—air, but in condensing a comparatively small body of air, so as to give it additional velocity.

To fix the point, or maximum, of the most profitable density, has hitherto been unattainable. The circumstances deemed intimately connected with coal, render it necessary to accommodate the blast to the combustibility of the fuel: were this not the case, it would be difficult to overturn the following reasoning, and to exhibit an instance where it might not be found generally applicable. Combustion in the furnace will be excited in proportion to the quantity of air introduced. A blowing machine, that with the same power of steam cylinder threw into the furnace double the quantity of air, though of an inferior density, would reduce a greater quantity of combustible matter than one oppositely constructed; or, in other words, 5000 feet of air per minute entering a furnace would produce greater effects than 3000 feet, although the latter were compressed into nearly half the bulk of the former.

The most plausible theory of blast is to fix upon the lowest density at which the air can be forced into the furnace, and then proportion the diameter of the air pump to the power of the steam end. Suppose that this could be effected at half the density usually employed, then that part of the engine's

engine's power used formerly to compress the air to 3 or 4 lb. would now be employed in a blowing cylinder of larger diameter, raising per minute, or indeed per stroke, from 100 to 200 cubic feet of air. Opposed to this there stand two formidable objections, resulting from the necessity of using blow-pipes or nozles of increased diameters, from which to discharge the additional quantity of air, making up in area what is wanting in velocity to discharge the air in a given time. The first is a re-action of the air, so powerful as to issue back from the tuyere with a velocity little short of that at which it enters. This, with nose-pipes of 2, 2½, and from that to 3 inches, is scarcely felt when the blast is soft, and may be entirely obviated by a judicious arrangement of the tuyere iron and nose-pipe; but with pipes from 3 to 4 and 4½ inches diameter, the recoil increases as the squares of the diameters of the blowpipes, and even in dense blasts the recoil increases with the diameter of the discharging pipe. It is therefore probable, that to blow with a nosepipe 4 or 5 inches diameter, so as to have no recoil, a velocity or density of air would be requisite beyond any thing yet in use.

Those who advocate for the use of a soft blast, either upon the plea of their materials, or as being the most advantageous method of using any given mechanical power, frequently feel the full effects of the recoil of a considerable portion of the whole blast. But to obviate this, and to gain the advantage of the whole air, the blowpipe is enclosed in a moveable frame or building, which is made air-tight at every cast, and completely prevents the return of the smallest portion of it. The combustion at these furnaces is carried on with equal effect, and the resulting products in iron equal in point of quantity and quality to those where blasts of double density are used.

Again, at other furnaces, where a soft blast had been originally preferred, the plan of forcing back the recoiled air, in order to make up in quantity what was now deemed to be deficient in density or velocity, has been in vain attempted. The tuyere irons have become immediately heated, and burnt back with violence. The materials would not admit of the tuyeres being raised sufficiently high to prevent the cinder from flowing back into the bag, which connects the large and small pipes, and destroying it. Even in more than one instance, the entire tuyere side of a furnace has been lost in endeavouring to establish this plan of blowing, where either the materials would not answer, or from some misconception in the mode of operating. Where a furnace works uniformly with a dark or honey-combed tuyere, this mode of blowing may be attended with the greatest success. In all new erections, however, the blast ought to possess of itself sufficient velocity not only to enter the furnace, but to ascend through the materials, without admitting of any important recoil.

The second objection, arising as a consequence of the want of velocity, and of being obliged to use pipes of a larger diameter to carry in the full complement of air, arises from a belief that a large pipe never makes the metal of a good quality. This deduction is perhaps not altogether correct; but it seems highly probable, that in the use of a comparatively loose blast, only a small portion of the air passes through the furnace without decomposition. The point of separation may by this means be changed, or perhaps be raised too high for the preservation of the metal, immediately previous to separation. As the increased temperature prevails upwards, the affinity between the particles of metal in the iron-stone, and the carbon of the fuel, may be earlier established, and no ultimate evil consequence, in point of reasoning, ought to ensue. It appears from numerous observations, that the quantity of iron-stone, which a given

weight of cokes smelts, and to the metal of which is conveyed the carbonaceous principle, is considerably dependent upon the diameter of the blowpipe. Supposing the ore of equal richness, the smaller the pipe, the greater burden will the coke carry, and the cheaper will the iron be made per ton, so far as materials are concerned. On the contrary, with large pipes, whatever the density of the air may be, the quantity of coals necessary to manufacture an equal quality of pig iron will be increased, and the cost of the iron is also enhanced. As an equivalent for this, however, the quantity is considerably increased with nearly the same amount of labour; so that it remains a question with the manufacturer, whether the additional cost of coal is compensated by the extra produce of metal he is enabled to bring to market.

4th. The quantity of air discharged into the furnace, under the appellation of blast, depends upon the number of strokes or cylinders which the engine makes per minute, and on the area and diameter of the air pump. This is independent of every consideration of density and increase of power in the steam cylinder, so long as the blowing or air cylinder remains the same, and the engine performs the same discharges; the measure of atmospheric air, which enters the furnace, will remain the same. The rapid improvements, which of late years have been made in the blowing machine, have increased the quantity from 1000 to 4000 feet per minute per furnace; and the quantity or produce in iron has been also considerably increased. We by no means, however, find that the increased manufacture of iron has been in the exact ratio of the quantity of blast thrown into the furnace. Many instances of late years have been noticed during the transition from the old to the improved modes of blowing, wherein the proportion has had little or no similarity.

Fifteen hundred feet of atmospheric air in one minute was found in most situations equal to the manufacture of twenty tons of melting iron; in the same situations, 3000 feet in the same time has never exceeded thirty tons per week; and in one particular trial for two weeks, the discharge of 6000 feet, being the whole produce in air of the engine, the produce in iron never exceeded 36½ tons. In the last case, the quality of the iron was irregular, and the quantity of cokes for each ton of metal thus produced was considerably increased, although the iron was of inferior carbonation.

Without recurrence to the diameter of the air cylinder, and the particular movements of the engine, the same facts have been frequently deduced from the diameters of the nose-pipes. We have frequently seen air discharged under a pressure of 2½ lb. upon each square inch, but with a pipe of 2½ inches diameter, reduce materials, and manufacture good melting iron to the extent of 20, 22, and 25 tons per week; and in the same furnace, and with the same materials, the air discharged by 2 pipes, each 2½ inches, under a pressure of 3 lb. upon each square inch, the produce never exceeded 30 tons of metal of an equal quality, but more frequently 25 to 28 tons. One observation still more direct, and made with a blast of a density equal to 2½ lb. per inch, and discharged by one pipe of 2½ inches diameter, frequently manufactured 22 tons fine melting iron weekly; another pipe was added to the opposite tuyere of the same diameter, and the quantity of metal weekly was never increased beyond 32 tons, and upon an average of six months only 27 tons. These are curious facts relative to the nature and effects of blast, and exhibit the investigation of its principles as a matter of singular importance in the economy of the manufacture.

One remark was made relative to the burden of ore in the last stated fact, that with the small pipe a given weight of cokes smelted and carbonated the metal in 3 cwt. of iron-stone;

stone; but after the two pipes were added, the weight of iron-stone to produce an equal quality of iron, was reduced to $2\frac{3}{4}$, and afterwards to $2\frac{1}{2}$; producing in the first instance per charge $1\frac{1}{2}$ cwt. of iron upon an average, but latterly not above 1 cwt. and 1 lb. of iron of equal qualities. Another observation, in the same case, with every attention paid as to velocity, quantity, and temperature of air, may be adduced as of equal importance, though somewhat different in its mode of application.

Under a pressure of 2 lbs. a $3\frac{1}{2}$ pipe was found upon the average of 18 weeks to manufacture 20 : 12 : 0 : 0 tons; a $3\frac{1}{2}$ inch pipe, 20 : 5. Upon an average of 11 weeks, and a $4\frac{1}{4}$ pipe, 22 : 5. Their respective areas, and iron produced, will stand in opposition thus :

$3\frac{1}{2}$ pipe,	area	10.6625	quantity of metal	20.12
$3\frac{1}{2}$	-	12.25	-	20.5
$4\frac{1}{4}$	-	18.0625	-	22.17

It is but fair to state that the effects of combustion, so far as it related to the reduction of a quantity of fuel, was not in the same unequal proportion as the quantity of metal to the measure of the air. The quantity of reduction was with the

$3\frac{1}{2}$ pipe	equal to	25
$3\frac{1}{2}$	-	31
$4\frac{1}{4}$	-	38

But the capacity of the fuel to carbonate the original quantity of iron, diminished in nearly the same ratio as the combustion increased; so that the same measure by weight which carbonated 140 lbs. of iron with the $3\frac{1}{2}$ pipe, was unable to carbonate more than from 96 to 100 lb. of the same quality with the $4\frac{1}{4}$ pipe. This observation was made previous to the one last mentioned, and reasoning upon the subject led to the practice detailed in that experiment. It will appear therefore conclusive, that the same body of blast may, with greater advantage and economy, be introduced through two pipes than through one, and this for two reasons. The reduction is equal, and the quantity of fuel reduced, smelts and carbonates a larger portion of metal per charge; but it will appear from both cases equally conclusive, that the capacity of the fuel to convey carbonation is in the ratio of the smallness of the pipe, or the reduction of the quantity of air.

This is in unison with what was stated under the particular "Combustion;" that a large volume of air, so far as it related to the institution of affinity between the coaly principle of the fuel, was probably more hurtful to the carbonation than otherwise; but that in so far as it hastened the completion of the affinities, the reduction of quantity, and above all increase of produce, though merely as an agent destroying the superfluous fuel, it may be considered as giving the manufacturer a superiority over his process by means, the extent of which he never could formerly command.

Tradition has, though rather imperfectly, conveyed to us some facts which our forefathers seemed to have understood and practised with better effect than their posterity. In operating with charcoal furnaces, and a blast proportioned to the scanty means then in use for the purpose of producing forge pigs, the whole air was conveyed into the furnace by means of a pipe 2, or at most $2\frac{1}{2}$ inches diameter; but when grey metal was wanted, the same body of air was divided and introduced by two pipes, whose joint capacity was equal to the former.

It appears therefore an inquiry of some importance to those embarked in iron founderies, to ascertain how far this tendency of the fuel to increase the carbonaceous principle proceeds in the ratio of the diminution of the blowpipe. If general observation confirmed the particulars here stated, the effects of

carbonation might be greatly increased, and the quantity perhaps little reduced, by introducing the same quantity of air by means of four, six, or eight small pipes, whose conjoint areas should be equal to the original column of blast.

5. From quantity and density of air, there may and do result peculiar properties of blast, which may affect the operations of the furnace, and which once fully understood may help to explain the facts hitherto unaccounted for, and which we before noticed. Facts resulting from accurate observation would prove an invaluable source of information upon this subject; and it is with regret that we can furnish no perfect aerological table of the different temperatures of air under different densities or degrees of compression. The following, we believe, contains the only collection of temperatures hitherto noted; and as it relates to only one degree of compression, the satisfaction it affords must be only partial.

TABLE of 30 observations made in summer upon various temperatures of air before and during the act of compression, compared with the thermometer in the shade. The air thus ascertained, was received into a magazine containing 2500 cubical feet, free from moisture or damp entirely.

Temperature of the air at the lower valves of the blowing cylinder.	Temperature of the air at the upper valves of the blowing cylinder.	Temperature of the air surrounding the receiving vessel.	Temperature of the air within the receiving vessel.	Thermometer in the shade at the time of making the observations.	Increased diff. of temp. between the included air, and average of the two first columns.	Increased diff. between the included air and the temp. of the external air in the shade.

There can arise no doubt but that heat is extricated by compression from atmospheric air; and that it is further probable, that the quantity of heat disengaged is in proportion to its condensation. If, therefore, we are allowed to reason upon this subject, we should state the following as a considerable approximation towards truth. It is universally believed and felt, that combustion in the blast furnace in June, July, and August, is considerably diminished, as a consequence of the increased temperature of the air. The metal, in these months, is frequently debased in point of carbonation, and diminished nearly one-half in point of quantity. We shall suppose that this takes place at a temperature of 100, which has been proved to exist under a pressure of 2½ pounds. The reverse of this happens in the cool season of the year, and particularly in the winter months. The furnace then yields the largest quantity of iron, and in the most profitable manner. This, with the same probability, takes place at a temperature of 50 found in the table.

It would therefore appear to result from these, that two-thirds, or one-half of the iron only, is manufactured at a temperature of 100, than in winter at 50. The difference between these degrees of temperature amounts to 50, and most probably in combustion affects the operation as sensibly

as the human frame is affected by a transition of temperature equal or similar. It is not necessary now to state the difference between summer and the denser air of our winter, the circumstances of evaporation and aqueous solution; these shall be particularly attended to in the general process of manufacturing iron. The great difference of temperature arising simply from compression seems to us adequate to explain many phenomena regarding the blast furnace. Our knowledge, however, upon this subject, can only be forwarded by a general collection of facts well ascertained, shewing what are the various degrees of heat made sensible by the compression of the blowing machine under every density; what the difference in temperature, the densities being alike, when the air is received over water, in the air-vault, or in the regulating cylinder. From these it might most probably result, that the higher the density of the air, the greater would be the degree of heat manifested; and it might also follow, that in the ratio of this density, or temperature, when the air was received over water, so would be the evaporation or quantity of water suspended in the air, and of course discharged into the furnace.

This article may be concluded by the following remarks:—That all iron works are not alike affected by the heat of the summer months. Many iron works preserve the quality of the iron, though at the expense of fuel, and with loss of quantity; but at other places no extra quantity of fuel will compensate, either as to quality or quantity, for the want of cool air. Neither situation nor density of blast will explain this curious circumstance; for with blasts of equal density and quantity, works situated not 50 feet above the level of the sea have been found to manufacture a greater quantity of soft iron in summer, than at a similar work, not ten miles distant, situated at least 250 feet higher. At both of these works the air is received over water; and no material alteration in the use of that air is or can possibly be applied. The causes of this difference must be sought for in the nature of the coal and iron-stone used at both works, the investigation of which, however interesting, would prove a most laborious undertaking.

BLAST Furnace, a large conical or quadrangular building used at iron works for smelting iron-stones and ores.

BLAST Furnace, Description of.

Plate (Chemistry) II. fig. 1. represents a blast furnace, and part of the blowing machine constructed upon what at one time was the general plan at iron works.

A, the regulating cylinder, eight feet in diameter, and eight feet high. B, the floating piston loaded with weights proportioned to the power of the machine. C, the valve by which the air is passed from the pumping cylinder into the regulator; its length 26 inches, and breadth 11 inches. D, the aperture by which the blast is forced into the furnace. Diameter of this range of pipes 18 inches. The wider these pipes can be with convenience used, the less is the friction, and the more powerful are the effects of the blast. E, the blowing or pumping cylinder, six feet diameter, and nine feet high; travel of the piston in this cylinder from 5 to 7 feet per stroke. F, the blowing piston, and a view of one of the valves, of which there are sometimes two, and sometimes four, distributed over the surface of the piston. The area of each is proportioned to the number of valves, commonly they are 12—16. G, a pile of solid stone building, on which the regulating cylinder rests, and to which the flanch and stils of the blowing cylinder are attached. H, the safety valve, or cock, by the simple turning of which the blast may be admitted to or shut from the furnace, and passed off by a collateral tube on the opposite side. I, the tuyere by

by which the blast enters the furnace. The termination of the tapered pipe, which approaches the tuyere, receives small pipes of various diameters from two to four inches, called nose-pipes. These are applied at pleasure, as the furnace may be deemed to require an alteration in the volume or density of the blast. K, the bottom of the hearth, two feet square. L, the top of the hearth, two feet six inches square. KL, the height of the hearth, six feet six inches. L, is the bottom of the boshes, which here terminate of the same size as the top of the hearth, only the former are round, and the latter square. M, the top of the boshes, twelve feet diameter, and eight feet of perpendicular height. N, the furnace top, at which the materials are introduced, or, as it is commonly called, charged; three feet diameter. MN, the internal cavity of the furnace from the top of the boshes upwards, 30 feet high. NK, total height of the interior of the furnace, or working part, $44\frac{1}{2}$ feet. OO, the lining. This is done in the nicest manner with fine bricks, from twelve to fourteen inches long, three inches thick, and tapered to suit the circle of the cone. PP, a vacancy which is left all round the outside of the first lining; three inches broad. This is sometimes filled with coke dust, but more often with sand firmly compressed. This space is allowed for any expansion which might take place, either by an increased volume of the furnace itself in heating, or by the pressure and weight of the materials when descending to the furnace bottom. QQ, the second lining, similar to the first. The object of this is to guard against the entrance of the flame into the mass of common building, by rents which may take place in the first lining OO. R, a cast-iron lintel, on which the bottom of the arches is supported, eight feet and a half long, and ten inches square. RS, the rise of the tuyere arch, fourteen feet high on the outside, and eighteen feet wide. VV, the extremes of the hearth ten feet square. This and the boshing stones, are commonly made from a coarse gritted sand stone, whose fracture presents large rounded grains of quartz connected by means of a cement less pure.

Fig. 7. represents the foundation of the hearth, and a full view of the manner in which the false bottom is constructed.

AA, the bottom stones of the hearth. B, a stratum of bedding sand. CC, passages by which the vapour generated from the damps is passed off. DD, pillars of brick. The letters in the horizontal view of the same figure correspond to similar letters in the dotted elevation.

Fig. 8. AA, horizontal section of the diameter of the boshes; the lining and vacancy for stuffing at M. C, view of the top of the hearth at L.

Fig. 9. Vertical side section of the hearth and boshes, showing the tympan and dam-stones, and the tympan and dam-plates. a, the tympan stone; b, the tympan-plate, which is wedged firmly to the side walls of the hearth; c, dam-stone, which occupies the whole breadth at the bottom of the hearth, excepting about six inches, which, when the furnace is at work, is filled every cast with a strong binding sand. This stone is surmounted by an iron plate of a considerable thickness, and a peculiar shape, d; and from this it is called the dam-plate. The top of the dam-stone, or rather the notch of the dam-plate, is from four to eight inches under the level of the tuyere hole. The space under the tympan plate, for five or six inches down, is rammed every cast full of strong loamy earth, and sometimes even with fine clay. This is called the tympan stopping.

The square of the base of this furnace is 38 feet. The extreme height, from the false bottom to the top of the crater, measures 55 feet,

BLAST Furnaces, Construction of.

These furnaces are sometimes built of an external quadrangular form, entirely of sand stone, and lined, in contact with the fire, of the same materials; sometimes they are built conical, entirely of bricks, or with sand stone on the outside, and linings of both common and fine bricks within.

One great desideratum in the construction of furnaces, is to counteract the effects of a powerful expansion, which always take place, to a greater or less extent, after heating, and the introduction of the blast, and which has frequently proved fatal to the existence of the entire fabric.

In the general style of building, all are agreed that the pillars, which support the arches, and of course the whole fabric, ought to be done in the most substantial manner. But beyond the arches, a variety of methods has been adopted to ensure a complete fabric, free from large openings or rents after a few weeks blowing.

Some iron-masters are of opinion, that the same degree of firm building, that is bestowed upon the pillars, ought to be continued to the top, with the addition of binders of flat iron pressing with their edges against the body of the building, or with four screwed bars, still passing through the external building, and forming one square binder, if the shape of the furnace is quadrangular. Another species of binder is used for square piles, made of cast iron of a prodigious strength and weight. The individual pieces forming this binder, have, at their extremities, mortises, which mutually receive each other, with a considerable extra space for the expansion, which is invariably experienced afterwards. Other iron-masters, again, prefer rearing a substantial shell of building, and filling the interior space towards the linings, either with dry bricks, or stones loosely laid together. When the mass of building becomes thoroughly heated by the kindling of the fire, and the introduction of the blast, the interior of the furnace expands considerably, and the action is supposed to be merely confined to the wedging together of the loose parts of the building. By the time that this is effected, the expansion is supposed to have ceased, and the exterior shell of the furnace is preserved entire. Others, equally anxious to form a perfect building, have given an octagonal form to that part of the furnace above the arches, that the binding might be more happily effected. Some have assumed this form, with the addition of semi-circular recesses in the sides of the octagon; their convexes being strongly arched to resist the powerful pressure expected from within.

Still more determined to defy the all-powerful effects of expansion, others have hollowed furnaces from the solid rock, forty to fifty feet high, and lined these immense perforations with fine bricks in the usual form.

Where such a variety of form and of method exists in effecting the same purpose, and where the instances of experiment have been very numerous, every mode of construction can boast of a solitary instance of complete success, excepting in the case of the rock, which was only once attempted, and which, after the introduction of the blast, opened from four to six inches from top to bottom.

There are so many circumstances to be taken into the account, besides the mere form of the building, that unless these are all equally guarded against, the chances are in favour of the furnace opening considerably. If the building is constructed of sand stone, and if this material is carried from the quarry as it is wanted by the workmen, an immense proportion of water is thus introduced, which by a little foresight might have been avoided. Sand stones of common density as to fracture, contain, when taken immediately from the quarry,

from 8 to 10 per cent. of water, and coarser-gritted stones from 10 to 12. Taking the average 10 per cent., then in a furnace of equal dimensions to the drawing in *Plate II. fig. 6.* the sand stone of which will weigh upwards of 1200 tons, there will be introduced 120 tons of moisture. This quantity is always considerably increased by the portion of water necessary to reduce the lime to mortar, and frequently augmented by the moist state of the weather during building.

The evaporation of this immense body of water is the source of all the mischief which takes place in the shell of the blast furnace; nor is it much to be wondered at, where every precaution is not used to bring the heat forward in the most gradual manner, preserving the clearness of the vents, and allowing the moisture insensibly to pass away?

In situations where bricks can be obtained, the moisture of the sand stone is avoided, but the great extra quantity of lime, which is necessary to build with bricks, introduces through the medium of the mortar an almost equal quantity of water, as with sand stone. This has been obviated in part by using soft clay in the interior of the walls; but as clay seldom binds to any great extent, the general push of the furnace must be trusted to good binders from without.

In the construction of all blast furnaces, a complete vent-age ought to be preserved by means of narrow flues, or passages proceeding horizontally from the middle of the solid shell, or within two feet and a half of the interior to the outside. These ought to be connected with a circular channel, or gutter, of the same dimensions, proceeding round the circumference of the furnace; so that if any one vent were choked in the general expansion, the moisture conducted by it might easily vent itself among the other openings. The vents cannot well be too numerous; and as they seldom exceed four inches square, the building cannot be materially weakened by them.

In addition to the horizontal channel of communication, some builders carry up in the main building of the furnace four, six, or even eight perpendicular flues, which communicate with it and the openings that proceed horizontally to meet the external air. See *Plate VIII. figs. 1, 2, 3, 4.*

Either of these methods may be considered as just precautions to insure the existence of the furnace, but adopting them in the fullest and most complete manner, is not always accompanied with similar success. If circumstances formerly noticed concur in occasioning an extra degree of expansion, the pressure of the lining against the common building of the furnace often deranges the systematic order of the vents, pushes the bricks into contact with each other, and smothers for a little while, though to gain more fatal elastic effects, the increasing volume of the vapour.

After such a diversity of opinion upon a subject of such general importance, wherein each respective class of votaries can boast of complete success from its peculiar plan, it may be difficult to point out one more generally attended with good effects than another. The following, however, may deserve the serious consideration of the manufacturer of pig-iron.

Of whatever materials the furnace is constructed, let them possess no more moisture than is sufficient for their proper building. The thickness of the common building not to exceed, at its greatest breadth, $6\frac{1}{2}$, or 7 feet. In the middle of the wall, a space of four or six inches ought to be left clear all the way to the furnace top. Into this vacancy should be introduced small fragments of sand-stone, about the size of an egg and under. When the expansion, proceeding from the fire building of the interior, causes the bricks immediately in

contact to push outwards, the masses of sand-stone are immediately reduced in size, and filling the interstices occasioned by their former angular shape, actually occupy much less room; and now present to the flame or fire, should it be inclined to penetrate so far, a solid vertical stratum of sand, after having secured the expansion of the furnace to the extent of some inches. The effects of the pressure are thus diverted from the shell of the building, and lost in the pulverization of the fragments of sand stone.

The advantages resulting from this plan may be nearly doubled, by using a double lining of fire bricks, as represented in *Plate VIII. fig. 3.* betwixt each of which, and the common building, a similar vacancy should be left; but filled with sharp sand, containing no more moisture than serves to compact it into a firm body. As this moisture becomes gradually expelled in the slow heating or annealing of the furnace, the sand occupies less bulk, or, which is the same in effect, is then susceptible of a greater degree of compression when the general expansion of the furnace comes on. It is evident that the force is here also diverted against the sand in place of acting immediately, with a tendency to enlarge the circumference of the building.

Over and above all these precautions, the annealing or drying of the furnace in a progressive and regular manner ought to be carefully attended to and continued for two or three months at least. Many are blown much earlier, from an anxiety to get to work, and make returns for the great capital necessarily expended in these undertakings.

The same variety of opinions exists in the trade relative to the determined figure and dimensions of the blast furnace, as subsist, with regard to the best mode of building. Its height has, at different times, varied from 20 to 70 feet; and its diameter, at the boshes, or widest part, from 8 to 15 feet. It will be easy to trace the source of this indefinite mode of construction, and the uncertainty which must necessarily pervade operations of so much risk and importance.

At the time when charcoal of wood was the common, and indeed, the only fuel used in the blast furnace, the volume and extent of the blast were proportioned to the very imperfect state of the blowing machinery. Long experience had taught the manufacturer what were the proper size and dimensions of his furnace. Many of them were from 12 to 18 feet high, and some of them, where a good water wheel blast existed, reached as far as 28 feet in height.

When pitcoal was introduced into the blast furnace, in the state of coke, to produce similar effects to the charcoal of wood, it was soon found, that in furnaces of equal capacity and height the same effects could not be produced. The ore required to remain in contact with the ignited fuel for a longer space of time, in order, unquestionably, to produce, by attenuated contact, what was deficient in temperature, for the saturation of the ore with coaly matter. This would immediately suggest an increase of the height of the blast-furnace; and if beneficial effects once resulted from a step of this nature, it became a matter of difficulty to say where the progression of height would stop.

Hence, in a few years, arose furnaces of 40, 50, 60, and 70 feet in height. Of the last dimensions, one was erected in Wales. The size of the artificial crater was such, that the strength of the blast was scarcely sufficient to keep the existence of flame visible at the furnace top. After in vain endeavouring to ignite the immense body of materials contained in its vast capacity, the height of the furnace was reduced 30 feet by cutting a hole in its side, narrowing the mouth, and throwing in the materials at the height of 40, in place of 70, feet from the furnace bottom. This was at-
tended

tended with success, and the operations of the furnace proceeded with their usual facility.

After the application of steam-engines to raise and condense air, the quantity and strength of the blast became more a mechanical property in the hands of the manufacturer. It was soon discovered that an increased volume of air, by exciting a much higher temperature throughout the furnace, constituted the immediate action of those affinities, which the tall furnace accomplished by a long attenuated contact, and that iron equally carbonated and fitted for the purpose of melting, could be produced by 30 hours contact, as in four days.

The consequence of these gradual discoveries was a general predilection in favour of small furnaces, and at present the bias of the manufacturer seems inclined to this extreme.—Where the maximum will be found it is difficult to conjecture, for the ground which the manufacturer now occupies is materially altered from what it was when smelting with coke was first introduced. The perfection to which the blowing machine has attained, forms a striking contrast to the feeble and diminished effects of the bellows in the infancy of the trade. So far as the necessary affinity is increased, and more instantaneously produced in high temperatures, than in those inferior, the manufacturer is differently circumstanced, and commands an extent of means unknown to him in former times. That this superiority will produce equivalent effects in the modification of the blast-furnace, requires but little demonstration. Two facts illustrative of this may, however, be mentioned. Cast steel has of late years been formed directly from bar-iron, by a process which only requires an hour or two to complete, and with small quantities of matter the same may be performed in a few minutes. This is effected by presenting the carbonaceous matter to the iron at a melting temperature. In the usual mode of cementation, blistered steel, by a more attenuated contact and inferior temperature, requires six or seven days to complete, what is here produced in two hours. The difference of temperature in the two operations is equal to 60° or 70° of Wedgewood. The first operation will be considerably shortened, if the cast steel is required to hold much carbon; but if this requisite is necessary in the blistered steel, the length of the cementation must necessarily be protracted. Again, a piece of malleable iron may, by presenting it with a proper dose of carbon, at a high temperature, be converted, in a few minutes, into a mass of the richest carburated cast-iron, which, in a temperature inferior, would have required several months.

The same facts will apply, in part, to the manufacture of pig-iron in the blast-furnace; but an unanimity of opinion and action on this subject is precluded, as well by the prejudices of individuals, as from circumstances arising out of the nature of the materials operated upon in different places.

A furnace has lately been tried at Muirkirk in Scotland, only eight feet diameter across the boshes, in place of its former dimensions, which were ten feet, and 40 feet high. It was soon found, that with the same volume of blast which was formerly applied to the ten feet furnace, very inferior effects were now produced. The combustion apparently was carried to too great an extent, and the materials, owing to this circumstance, entered into fusion before the iron had imbibed a sufficient dose of the coaly principle from the fuel. Another great evil which resulted from this diminution of diameter, was a friction, or retardation of the descent of the materials upon the lining of the furnace. This evil was increased and the materials made more buoyant, by the usual volume of air elevating itself in a cone not much more than

half its former area. The consequences were, that the whole mixture of coke, iron-stone, and lime-stone, would have frequently hung for an hour together, or until the blast had cut all the hearth and boshes clear of materials, a slip would have then ensued, and brought with it a large proportion of newly introduced matter. The introduction of this into the fusing point before being properly heated, and long before any affinity had been established betwixt the particles of metal and the carbon of the furnace, invariably changed the quality of the metal, and caused frequent and sudden alterations from grey to white iron.

Upon the subject of height and width of blast furnaces, it may be finally remarked, that the average height in Britain may be taken at forty feet from the upper surface of the hearth bottom, eleven feet diameter at the greatest width or boshings, and three feet and a half for the diameter of the tunnel-head, or furnace-mouth.

If the proportions of height and diameter in the dimensions of the blast-furnace have given rise to a multiplicity of opinions, the internal structure and shape of the cavity have been no less an ample field for speculation and prejudice. At one time this was conceived so essential to the success of iron-making, that any particular furnace that had made a fortunate run of quantity and quality, was copied with the greatest accuracy of design. The fortunate iron-master ingeniously attributed to the mechanism of his own construction the rich and superior harvest he had reaped in metal, and saw, or fancied he saw, in the curvature of a line, or in the inclination of a slope, the talisman of his good fortune. By prolonging the one, or depressing the other, he immediately inferred that still superior effects would be produced, and that by obtaining the perfection of art in the mere fabrication of structure, every thing that was great and powerful would ensue. This rage continued for many years, and gave rise to an endless variety of shapes, many of which, in their eventual success, had only the merit of originality to boast.

In the establishment of this important and national manufacture, the great fluctuation of opinion as to structure seems to have been the prelude to a subsidence into approved forms, founded upon general principles; and though we may now smile at the indispensable forms which our predecessors, or even contemporaries, annexed to the blast-furnace, yet these alterations of shape and structure lay the strongest claim to our respect and gratitude. The path is now opened, and the ground already beat; from the labours of those who have already gone before us, result the happiest effects; we proceed towards our object, free from the interruption which inexperience always entails; and we may now, by the direct application of principle, proceed with facility what may still be deemed desiderata in this important branch.

The varieties of shape which custom and experiment, from time to time, had annexed to the blast-furnace, may be classed under four distinct kinds. *Plate VII. and VIII.* The following description, characterizing the resulting properties and dimensions in the form of each class, will be necessary for comprehending the subject thoroughly.

Plate VII. fig. 1. is the vertical section of the blast-furnace cut across the top of the boshes; the internal shape entirely conical; the external figure a quadrangular pyramid. The construction of this furnace is truly singular; and from this alone great advantages were expected to result. The originality of the principle consists in the double square, or throat. One immediately above the hearth, not represented in this figure, but similar to the square in *Plate IX. fig. 1. B.* and another half way up the cone, four feet in diameter; see *A.*

B L A S T.

B, the top of the boshes, 12 feet in diameter.

C, an inferior diameter of 10 feet, previous to the formation of the throat at A.

D, the top of the second row of boshes, of the same diameter as B.

E, the furnace mouth, or termination of the second cone, four feet diameter, and proportioned to A.

F, funnel top for carrying off the flame occasioned by the blast, so as not to interfere with the workmen in filling the furnace.

The dimensions, as to height, are as follow :

From B to C	height	-	-	-	-	12 feet	
C to A	ditto	-	-	-	-	6	
A to D	ditto	-	-	-	-	6	
D to E	ditto	-	-	-	-	13	
Height of the hearth, and first row of boshings,							
not shewn in the figure, but being the same							
as <i>fig. 1. Plate IX.</i> measure							15
Height of the bottom stones, packing, and							
false bottoms,							4
						56 feet	

Total height of this furnace from the foundation

GG, fire brick lining.

hh, space left for packing.

II, the common building either of sand-stone, or of bricks.

Fig. 2. plan and section of the same furnace taken across the boshes at B.

AAAA, square of the common building 29 feet upon the side, bound byBBBBBBBB, eight cast-iron binders; the number or sets of these requisite, being proportioned, both in strength and dimensions, to the height of the furnace. In common, a full binder is applied every six feet in the height.

The concentric circles represent the various diameters of the interior of the furnace, and are connected each by dotted lines, with their respective places in the elevation.

The reasoning which we believe led to the construction of this furnace, proceeded from a firm belief that the boshes and throat or square of a blast-furnace were of the greatest importance on two accounts. First, because they supported the weight of the materials; and secondly, because they concentrated the heat. These acting conjointly, permitted the least possible quantity of materials to pass, till they dropt away in a state of semi-fusion, or complete separation. In furnaces, however, the cones of which were 30 feet high and upwards, this was conceived impossible to take place for any length of time, to any considerable extent. The height and gravitating pressure of the materials were more than sufficient to counteract the most favourable construction of boshes; and as this could not admit of diminution, the suspension of the materials, and the concentration of the heat must be effected by some other means. This, at one time, was believed to have been completely effected by the scheme of an additional square, and an extra set of boshes; and there is little doubt but that, by converting perpendicular to lateral pressure, the suspension of the materials was reduced at least to one half of its former intensity.

It was not doubted but that the procefs of smelting and separation would commence, in part, at A; that what escaped fusion and separation in that quarter, would be easily resolved below; and that the procefs of combustion intensely at work in two different places at once, would greatly facilitate the general reduction, and add greatly to the produce in iron of the furnace. These sanguine expectations were unfortunately never realized, the solitary instance of one furnace only being constructed in defence of this theory, and

that only for a very temporary endurance, is the best proof of the inutility of the plan.

Fig. 3. is the elevated section of a blast-furnace, of which several were built, and from which it was at one time conceived that the greatest advantages were derived. The numerous minute gradations of diameter exhibited in the construction of this furnace, were at one time held in high estimation by many iron-makers; and a plan of the present furnace circulated from the domains of the lucky projector, with as much care and consciousness of rich acquisition, as an antiquary would remove from Heracleum or Egypt, the precious remains of antiquated obscurity.

It will be extremely easy to trace to its source this particular bias to form, so universally believed in at one time, but now consigned to that oblivion which experience has taught us it deserved at a much earlier period.

It often happens, that when repairing or re-lining a blast-furnace, the manufacturer avails himself of the time thus obtained, to overhaul and repair his engine and blowing machine. The former movements of the machinery may have discovered to him many errors both in movement and construction, which the constant requisite motion rendered impracticable for him sooner to remove. In this way, considerable improvements on the engine and blowing apparatus are frequently made; and when again in motion, may, by increasing the length and number of the strokes in a given time, or by conferring a higher additional working power on the steam piston, increase at the same time both the volume and density of the blast. If the produce of the furnace is increased, which it is highly probable will be the case, then the superior effects are attributed to a few unimportant circles and lines added to the interior of the cone, the acuteness and proportion of which do not survive the blowing of the furnace three days.

In like manner, if a work entirely new, commence operations with a greater advantage of blowing power, and with something original in the shape of the furnace, the consequent effects of the former are industriously attributed to the fortunate construction of the latter, and the grand essential blast is entirely overlooked, and its next important associates coal and iron-stone.

The dimensions of the present furnace are as follow :

Diameter of the cone at A	-	-	-	3 feet
ditto at B	-	-	-	4
ditto at C	-	-	-	8½
ditto at D	-	-	-	9½
ditto at E	-	-	-	10
ditto at F	-	-	-	11
ditto at G	-	-	-	10
From G to F, the distance in height measures				
				1 foot
Increase of diameter				1 foot
F to E, the distance is	-	-	-	12
Diminution of diameter				1 foot
E to D, the distance is	-	-	-	1½
Diminution of diameter				6 inches
D to C, the distance is	-	-	-	6
Diminution of diameter				1 foot
C to B, the distance is	-	-	-	2
Diminution of diameter				4½
B to A, the distance is	-	-	-	4½
Diminution of diameter				1
Height of the hearth and boshes not represented in the plate				
				13
Total height of the cavity of the furnace				
or place occupied by the materials				40 feet
The former descriptions will suffice and apply to this plate,				

B L A S T.

plate, with equal propriety as to the former, regarding the lining, packing, common building, &c.

Fig. 4. is a plan and section of the same furnace at F in the elevation.

The inner circles represent the various diameters of the interior of the cone, the letters in each corresponding. The two external circles describe the packing and lining; and the circle N exhibits the circumference of the common building of the furnace, which, at this particular section, is 26 feet in diameter.

Plate VIII. fig. 1. is the elevation of the interior of a furnace of a plain construction, and at one time very prevalent at founderies. This fashion was deemed to possess its peculiar merits, and still maintains its form unaltered at some iron-works where the regular tapering cone is not yet admitted. Its inferiority, as to height, is amply made up by an enlarged capacity arising from its diameter.

Diameter at the mouth of the cone	A	-	3 feet
ditto - at	B	-	11
ditto at the boshes	C	-	12
Height from C to B	-	-	12 feet
from B to A	-	-	14
Height of the boshings and hearth not represented in the figure	-	-	11
Total height of that part of the furnace occupied by the materials	-	-	37 feet

FF, represents a view of the vertical method of carrying off the moisture and steam from the mass of building, by means of vents. The number of upright flues vary from four to eight, and have regular communications by means of horizontal openings with the external air, GG. They are generally carried up parallel to the lining, and incline with the general diminution of the cone. The former, or vertical openings, are six inches square, and the horizontal communications four inches square.

Fig. 2. is a plan and section of fig. 1. in which are represented the lining, the vacancy for packing, and eight vents or openings corresponding to those in the elevation. The letters in each figure correspond, and the two dotted circles are meant to shew, that occasionally all the vents communicate with each other by means of a horizontal gutter or channel, carried quite round the building. This precaution is used lest any of the tubes were to fill up and choke the free circulation of the vapour, that its appropriate quantity may get easily discharged amongst the other openings.

Fig. 3. is an elevated section of a furnace, the interior shape of which has now almost become universal. The regular and uniform descent of the materials which follows, as a consequence of the gradual enlargement of the cone, fully justifies the general partiality in favour of this shape.

Diameter at the mouth, or opening	A	-	3 feet
Diameter at the top of the boshes	B	-	10
The height from B to A	-	-	31½
Height of the hearth and boshes not seen in the plate	-	-	11½
Total height of this furnace	-	-	43 feet.

This form of furnace is not only constructed with a double lining of fire bricks CCCC, and two openings for introducing sand for packing *bbbb*, but has also an opening DD, from top to bottom, about the centre of the common building. From this, in all directions, proceed small vents, which communicate at a short distance with the open air, as may be seen along the sides of the building.

Fig. 4. is a plan and section of fig. 3. cut across at B.

B, diameter over at the boshes 10 feet.

CCCC, the two circles of fire brick-lining, as seen in the elevation.

bbbb, spaces for receiving packing.

DD, circular vent, or general gutter, from which ramify the horizontal openings.

These are repeated at intervals of four feet in the height, as may be seen in the elevation. In building, DD is filled with fragments of soft sand-stone, which are easily reduced in the expansion of the furnace, and tend, by diverting its real pressure, to preserve the body of the building entire.

A similar want of unanimity of opinion subsists among iron-makers, relative to the general construction of the boshes, their particular height, and most beneficial range. Some contend for flat, others for boshes more vertical, while others again conceive the exertions of those equally successful, who adopt the mean of the two extremes. At different places, and to every possible range, have been attributed the most important consequences in the subsequent process.

Plate IX. fig. 1. represents boshes of the steepest construction.

Diameter at A	-	-	10 feet
Perpendicular height from B to A	-	-	8
Square at	B	-	2½

The opinion relative to this form is, that at first blowing, the boshes are productive of a very proper degree of suspension of the materials; but as the pressure of the descent bears in every direction upon the under or bottom part next the square at B, it becomes increased so much, that the weight of the incumbent materials early begin to press too much towards the bottom of the hearth, counteract the regular precipitation which should take place, and impede the ascent and full effect of the blast.

Fig. 4. is a section of boshes approaching to, or indeed may be considered as the opposite extreme. Here the reverse of the fact attributable to No 1. takes place. The pressure of the descending material is equally distributed over the very flat inclination of the boshes, and there is no more weight deemed to be on the square at A than is equal to a full column of the materials of similar dimensions, left by the direct tendency which the strength of the blast to keep them in a state of partial buoyancy. To counteract these advantages in part, very serious defects are here also imputed. If circumstances unite to increase the tear and wear at A in any uncommon ratio, either by *scouring*, or from a deficiency in the quality of the stone or bricks, the whole of the upper part of the hearth at BB is immediately exposed, and, though composed of a superior quality of sand, will soon follow the direction of the descending current. A pressure of materials then takes place, equal to the whole of the increased space, while the effect of the blast to bear them up is considerably diminished by the enlargement of the original diameter. It will be seen from the plate that the weakness of flat boshes at the top is ill calculated to withstand any accumulating pressure, and that by confining their part of the process to the hearth, the latter must soon, by a similar widening, be entirely destroyed.

Those who wish to steer clear of extremes, or profit by the more adventurous spirit of their neighbours, more generally adopt a mode of boshing that occupies the mean of the two former extremes. This is represented by fig. 3.

Diameter of the boshes at A	-	-	10 feet
Perpendicular height from B to A	-	-	5
Diameter of the square B	-	-	2½

In general, the boshes of blast furnaces are made of the same sand stone with the hearths, but of late fire bricks have been introduced with a considerable indication of advantage and

and permanency. When bricks are used, it is found of utility to make the whole part of the building solid, back as far as the external square of the hearth, so that if the boshes fail in part as to displace one layer of bricks, another surface, equally fresh and entire as the former, presents itself to the action of the fire.

Fig. 2. Ground plan of the top of the boshings of *fig. 1.* A A and B correspond to the same letters in the elevation. The dotted square C describes the form and dimensions of that part of the hearth immediately above the tuyere, as seen in the elevation CC. The large dotted square DD is the external size of the hearth, as seen also in the elevation DD.

Fig. 5. Ground plan of the square and boshings of *fig. 4.*

While we prosecute the detail and history of the construction of the blast furnace, the same diversity of plans formerly noticed comes under review, in every department of the erection. The importance of the hearth is admitted by every class of reasoners upon this subject; and to devise a form better calculated for smelting than another, has been an object of general concern with the manufacturer. Much as may be deemed to depend upon its form and construction, infinitely more benefit is derived from a proper quality of stone, to resist for a given length of time the powerful effects of a continued and unremitting blast. To both of these important desiderata much of the manufacturer's attention has been from time to time directed.

The first singularity that strikes us forcibly in the figure of the hearth, is, that in place of being circular, like the upper parts of the furnace, it is constructed of a square funnel-form, with angles as acute as represented in *Plate IX.*

fig. 1. This narrowing form is continued on three sides of the square to the bottom of the hearth, where it generally measures from 22 inches to 24 inches. The top of the hearth, at B or A, *fig. 1.* and 4. or as it is commonly called the square, is never less than 30 inches, nor more than 33. The height of the hearth from E to B, *Plate IX. fig. 1,* 7 feet, and none are made higher. From C to B, *fig. 3,* 6½ feet, which is now reckoned the most advantageous height; and from C to A, *fig. 4,* the hearth measures 6 feet, under which height there are no hearths ever attempted.

The structure of a hearth, properly speaking, consists of three solid sides only, the fourth, or front, is filled up by the tym, or key-stone. *Plate IX. fig. 1.* The block E. is generally in one piece, and from four to five feet long, according to the height of the hearth. It descends towards the bottom till within two feet or two feet four inches, and then leaves an opening of similar dimensions, as to height, into the centre of the hearth or funnel, as at letter F.

As the square form in which the hearth is finished cannot last a day after the blast is introduced, and is even frequently destroyed in the act of annealing, or heating, it cannot be essentially necessary to the making of iron. The hearths of all furnaces when blown out, are entirely round, or if wasted more upon the tuyere sides, oval. The general usage of the square must have been derived from long acquired habit, or perhaps from the conveniency of working and finishing those immense blocks of stone which are still deemed necessary to the perfection of a hearth. The interior of charcoal of wood furnaces was at one time entirely square from top to bottom, so that in the progress of the trade, from smelting with wood to the use of pit-coal, although the general shape of the furnace has been altered, the square figure of the hearth has been retained.

Whatever may have been the utility of this general pre-

dilection in favour of established forms, the advantages hitherto supposed to be derived from this source are now by many doubted, and all those nice speculations relative to the precise dimensions and figure of boshes and squares, threatened with total annihilation. This innovation is not confined to figure alone, but extends to dimensions, and to the nature and bulk of the material necessary for the construction of hearths.

Fig. 1. Plate X. is the section of a hearth and boshings, constructed upon an enlarged principle as to size.

Diameter of the boshes at A	-	-	10 feet
Diameter of the hearth at B	-	-	4
Diameter of the hearth at C	-	-	3

These enlarged dimensions, in place of being square as formerly constructed, are now entirely round, excepting where the tym stone forms the key to the front of the hearth, as may be seen in *Plate X. fig. 2.* where the external circle A A represents the diameter of the boshes, B, the termination of them, or the top of the hearth, and the form at C, a plan of the inside figure of the hearth across the bottom of the hearth at C, *fig. 1.* same plate.

The difficulty of always obtaining a sand-stone well calculated to stand the violent effects of the blast, the frequent great expence incurred, the immense loss of time sustained in cutting out old and putting in new hearths, and afterwards annealing them, has induced more masters to speculate upon the use of bricks of shapes larger than the common forms, made from good fire clay. No permanent advantage has hitherto been derived from this scheme, although it is abundantly obvious, that a successful experiment of this kind would lessen the expence of a hearth greatly, and save at least half the time now required to replace an old one.

Neither have any uncommon advantages resulted from the hearths laid down in *Plate IX. fig. 6.* and in *Plate X. fig. 1, 2,* and 3. While some approve, more are ready to condemn a measure, which has for its object the enlargement of a space before blowing, which too speedily becomes so afterwards. There cannot, however, be any objection to the circular, in place of the square form, unless a little additional workmanship is sustained as such. The matter rests with experience, accompanied by accurate observation, to prove the sanguine hopes of the projectors, or falsify the prophetic forebodings of those who now condemn the measure. The amount of our progress hitherto, in the making of pig-iron, is ascertained with certainty; to assign limits to its ultimate bounds would be presumption. Of one fact, however, we may rest assured, that the perfection of the steam engine, and the consequent command of blast, has alone done more for the manufacture of this article, than all those nice shades of distinction as to furnace taken collectively, which relieve each other in a successive train of minute gradation from one extreme to the other; to all, or to most of which, the most wonderful effects have been from time to time ascribed.

One subject of considerable importance still remains to be discussed, relative to the construction of the blast furnace; namely, the absolute and relative heights of the tuyeres, the dam-stone, and tym.

On the subject of tuyeres, the general opinion is, that the nearer the cinder the blast is introduced, the greater is the effect as to the absolute quantity of reduction. But this may be productive of consequences more than sufficient to counterbalance the doubtful advantage of accelerated reduction, either by blowing the cinder from off the surface of the iron, and de-carbonating it, or by the cinder rushing back through the blow-pipe at any stop of the blowing machine, and destroying the leather bag which connects the blow-pipe with the main laying pipes. This never happens

happens but a considerable portion of time is sacrificed, besides the expence of the bag.

In common, the surface of the tuyere plate is laid eight inches above the cinder, or, which is the same thing, above the level of the dam-stone. Some blow at a distance of four inches, others at six and eight, and some again as high as twelve and fourteen inches. However, under some circumstances, the height of the tuyere is determined by the nature of the materials. In these cases, if the tuyere is only raised one inch above its proper height, the bottom of the furnace lumps up immediately, and will invariably rise in the same progressive manner in which the tuyere is heightened.

Plate X. fig. 1. represents the relative proportions of height betwixt the dam, tuyere, and tym, in ordinary cases.

G, the dam, or notch of the dam plate, 17 inches above the level of the bottom at H.

I, the centre of the tuyere $26\frac{1}{2}$ inches from the surface of the bottom, and $9\frac{1}{2}$ inches above the level of the dam.

K, the bottom of the tym plate, 23 inches from the bottom of the furnace, and 6 inches above the level of the dam.

At iron-works where different opinions exist as to the proper or working height of the dam, very different relative heights ensue, regarding the tym and tuyere. The former should always regulate the other two. The height of it is seldom used less than 16 inches, nor more than 28 above the bottom.

Considerable advantages result from placing the tuyere, as to its horizontal position, at a judicious distance from the front or back wall. This is, as in the case of height often regulated by the nature of the materials. If the furnace, owing to this circumstance, tends to work cold and languid behind, with a propensity to lump at the back wall, the blow-pipe ought to be directed as near to the extremity of the hearth backwards as it is possible to get in the tuyere iron; *Fig. 4. Plate X. letter a*; but where the operations of the furnaces proceed with ease and facility, the centre of the tuyere should more generally approach the centre of the hearth, as at *b*.

Of late years a new mode of blowing has been introduced, which, from its great prevalency and good effects, seems to bid fair to come into general use. Furnaces till lately were only erected with one arch, or tuyere side, and the blast or column of air introduced by means of one blow-pipe; now most of the new furnaces are built with double tuyeres, with two sets of main conducting pipes, and the blast introduced by means of two pipes in place of one.

The general effects and supposed properties of this mode of blowing are attended to under the article blast.

In the mean time, the proper height and distance of the tuyeres, and their relative position to each other, have been subject to endless disputation. *Fig. 4. Plate X. a and b* shew how, in common cases, the tuyeres are placed to each other in their horizontal range: *a* is placed with its centre three inches from the extremity or back wall of the furnace, and *b* at the distance of nine inches from its centre. That there should be a difference of distance in their horizontal position none are inclined to dispute; but that this should take place in their vertical situation, is by some contended; while others insist that the difference ought never to be less than four inches. *Fig. 6. Plate IX. ee.*

Some less fastidious assert, and with many evidences of sound reasoning on their side, that if the blast is introduced into the furnace, and at a proper distance, to keep the back wall clear, those nice distinctions as to inches go for nothing,

in a region where an instantaneous increase of volume must destroy all repulsion or mechanical contact. This philosophical reason is flatly denied, and the contrary minutely and gravely asserted, that were two pipes placed every way immediately opposite to each other, the action of the opposite columns would retard the velocity of the air, and diminish the real elevated quantity in the furnace, by locking up in mutual opposition a portion of their respective quantities in the laying pipes. There might be some foundation for this conjecture, were the respective nozles or blow-pipes brought into actual contact, or inserted into each other; but to those who consider, that in most furnaces there is never less than four feet of distance between nozle and nozle, and the most of the intervening space filled with a column of semifused materials, ignited to the highest pitch of whiteness, this supposition will appear to rest upon very unsatisfactory grounds.

A less scrupulous class of observers and reasoners upon this subject even go the length to assert, that the tuyeres ought to be put in direct opposition, and that this, so far from being detrimental, would be found to possess unqualified advantages. This it is said would result from a certain degree of coolness which the extremity of each column of air confers upon its opposite tuyere iron, and prevent the same from heating and burning. To whatever cause it is attributable, the fact stands in many instances unquestioned, that not half the tuyeres are lost or burnt out, with the double blast, that was formerly destroyed, where the single blast was in use.

Fig. 7. Plate X. represents a tuyere iron, 16 inches wide, and 12 inches high at the wide end, 18 inches long and narrowing at the other end to 4 inches wide, and $4\frac{1}{2}$ inches in height. *Fig. 6.* is a plan of the under surface of the tuyere iron. *Fig. 5.* represents the size and dimensions of the tuyere plate, which when bedded receives upon its surface the tuyere iron, *fig. 7.* This plate is first laid upon a bed of fire clay, with its narrow end towards the hearth, and inclined to rise a little. The tuyere is then introduced upon its surface, height and distance being attended to in the disposition of the plate, and the space betwixt its surface, and the sand-stone of the furnace, rammed very perfectly with balls of good fire-clay mixed with small fragments of fire bricks. When about to blow, the nose or inner end of the tuyere is covered with a very plastic clay, to prevent it from heating and burning away. This is always carefully attended to, and the blast put off at any time to replace it. Should it be neglected at any time, the iron would inflame with such rapidity, that an opening would be instantly made, by which the cokes and ignited matter of the furnace would be recoiled with the greatest violence imaginable.

Fig. 2. Plate XIII. The dam-stone. This is actually the dam, or barrier, which prevents the fluid contents of the furnace from advancing, and making their escape into the sand of the casting hole. It is generally made from the same stone as the hearth, but is found still more difficult to stand for any length of time the action of the fluid iron, than the hearth to resist the ravages of the blast.

Fig. 3. dam plate. This is laid against the dam stone with a bed of fire clay interposing, and closes the front of the furnace. Its form is double, so that by turning it serves the purpose twice. It often fails, owing to the constant current of lava passing over the curvature *a*, and deepening it, till the iron flows over along with the cinder.

Fig. 4. the tym plate. This embraces the under end of the tym stone, and the sides of the hearth for three feet up. The thickness at bottom, called the heel, or cod, is preserved from the action of the fire by a strong stopping of clay.

This is replaced at least every cast, and prevents the flame and heated materials of the furnace from being blown forward.

Plate IX. *fig. 4.* is a ground plan of the arch pillars, hearth, tuyeres, and vents of a blast furnace.

A, the hearth, or particular spot where the fluid metal is collected.

B, the dam-stone.

c, the fall, or opening, by which the metal is discharged. After the cast it is filled with sand, which soon hardens and presents a very close texture to the fluid metal within. At the following cast it is cut carefully down, till the bar penetrates to the quick. A circular incision is then made, and the metal flows out of the orifice in a connected round stream, into the runner or channel made in the sand.

d d d d, four vents or openings which communicate with the false bottoms. *Plate I. fig. 2.* These serve to convey the damp from the furnace bottom, and by being run out into the external air, two in the front of the hearth, and one at each tuyere, indicate by their temperature, and the quantity of steam or vapour which they emit, the real state of the bottom below.

D D, the two pillars which support the front arch; they, at the same time, serve as abutments to one leg of each of the tuyere arches. The arch at the front is 15 feet wide and 15 feet high, and inclines to the centre of the furnace, in the same manner as the side walls of the pillars approach.

E, main or back pillar built entirely solid.

FF, vent holes six inches square, carried up from the foundation, and brought forward to meet the open air every four or five feet.

G G G G G, tops of the pillars covered with cast iron plates, for receiving three large cast iron lintels, 10 feet long, and 10 inches square. These serve to give solidity to the arch, and support the lining and boshes of the furnace. *Fig. 8, 9,* different forms of tuyere pipes.

BLAST-Furnace.—*History of its Origin and Progress.*

In detailing the progressive history of the blast furnaces, it is necessary to premise, that in this country it has undergone a revolution, of which we meet with no similar instance in other countries.

The most natural and abundant fuel which presents itself to mankind in their progress toward civilization, is that furnished by the numerous and extensive forests, which generally occupy the surface of a wide and uncultivated country. These, in the history of all nations, have been early appointed to domestic uses, and to the comfort of individuals. As a country became more populous, and the spirit of civilization increased, other advantages resulted from the general use of wood as fuel. The amelioration of climate, and the clearing of large tracts of land, making it subservient to the purposes of agriculture, were not the smallest benefits thus derived. As the progress of knowledge began to devise and establish regular manufactories, to supply the wants of the thriving community, the same sources of combustion were opened to the manufacturer and the artizan. These, as they became successful, were only preludes to other establishments more extensive, more lucrative, and entailing wants more difficult to supply. Among others the smelting of metals was no doubt of early origin, and equally dependent upon the woodland counties, in the immediate neighbourhood of the ores. In this class we can trace no metallurgical operation so hostile to the existence of wood, as an extensive manufacture of iron. If this manufacture, owing to the great and unexampled prosperity of the country, in place of remaining stationary, or exhibiting symptoms

of decline, arising from a want of consumption of the article, has increased in capital, in extent, and riches beyond all precedent, wood, the base of the manipulation itself, depending only upon a stock rapidly declining, the existence of which was frequently incompatible with the views and interest of the landed proprietor, must soon have been annihilated, and the art of making iron lost to the community.

In this singular situation was Great Britain placed from the reign of Charles II. to the middle of the last century. The increasing manufactures, commerce and general prosperity of the country called loud for an additional supply of articles fabricated from iron, while wood, the foundation of the whole art, was rapidly declining in point of quantity, without the most distant prospect of ever being again renewed. Pit coal had been long before the latter period suggested as a substitute, but prejudice, interred views of established capitalists, and above all, a want of command of mechanical power, had prevented any successful operation from being established in this new department of iron making. No sooner, however, were these barriers to improvement broken through, and a change of fuel in the blast furnace found to be attended with profitable effects, than the languishing state of the trade began to revive, and improvements succeeded each other, with a facility new and astonishing. In fifty years the revolution was complete whether the consideration regards the increase of the manufacture, the general use of pit coal in the blast furnace, or the almost total annihilation of the charcoal mode of making iron.

It is uncertain at what period the manufacture of iron commenced in Britain. It is probable, that the working of the tin mines of Cornwall, by the Phenicians, would introduce into the country a class of men skilled in all the then known metallic ores, capable of appreciating their true value, by converting the riches of an unexplored country, either to their own immediate necessities, or to the conveniences of the unskilful inhabitants. The invasion of England by the Danes, and their consequent establishment, would most likely add to the former stock of knowledge, in the art of mining and fusing iron ores. Whatever truth there may be in this conjecture, the fact stands unquestioned, that in several counties in England large heaps of scoria are found with an accumulation of soil sufficient to bear large trees. These have been from time immemorial called "Dane's cinders." So early as 1620, Dudley remarks, that large oaks were then found in a state of decay upon the tops of some of these hills of scoria. It is not, however, probable, that these cinders were the product of the blast furnace. At a period so remote as that, wherein these heaps of scoria must have been accumulated, the labours of the iron maker were chiefly directed to the fabrication of small portions of malleable iron in *foot blasts* and *bloomeries*. The art of moulding and casting in iron was either totally unknown, or so very rude, as to excite no interest in favour of prosecuting this fine branch of art. If pig or cast iron was at all formed, it was merely of the most infusible nature, for being speedily converted into malleable iron. It was not till long afterwards, when improvements had taken place in the rude machinery of the times, and a division of labour seemed to be productive of many advantages, that different furnaces existed: one for the making of pig iron, and another for the conversion of it into malleable iron. This first gave rise to the blast furnace, which, properly speaking, was an improvement resulting from the knowledge of the advantages derived from a division of labour. After the appropriation of the blast furnace to the exclusive manufacture of pig iron, the manufacturer would soon discover, that the products of

his furnace were frequently different from each other. Experience and observation would soon enable him to decide, from whence this had its origin. A small additional quantity of fuel, beyond that he formerly used for forge-pig-iron, he found, would confer a degree of fusibility upon the metal that immediately pointed out the practicability of casting it into shape. Moulding from thence would most likely ensue, and become equally an appendage to the blast furnace as was the bar-iron forge. As this new manufacture became familiar to the proprietor, he would immediately find his interest in dividing the product of his blast furnace into grey melting iron or into forge pigs, as the exigencies of his moulding shop, or forge required.

If credit could be given to the "Metallum Martis" of Dudley, in the 12th year of James, anno 1615, there were at that period not less than 300 blast furnaces for smelting iron-ore with charcoal, each of which had fuel, upon an average, for 40 weeks per annum. The average produce in pig-iron at each furnace of 15 tons per week, or 600 tons per annum, make, the total yearly quantity 180,000 tons, being a greater quantity than has ever since been manufactured in Britain.

However much this quantity may be exaggerated, yet it is highly probable, that even at this early period, the iron business in general, and the particular operations of the blast furnace, had obtained an eminent rank in the manufactures of the country. The progress of agriculture, and the increase of population under the reign of the peaceable James, had taught the husbandman and the proprietor the value of cultivated fields. The great consumption of wood for the navy and iron-works had greatly exhausted the principal forests of supply; tracts of country became cleared, and as the spirit of cultivation increased, the annual quantity of fuel for the manufacturing of iron diminished.

It is probable that Mr. Dudley, in estimating the quantities produced from each furnace, formed his average from the winter and spring months, when water was plentiful, and he seems not to have made sufficient allowance for the occasional stoppages in summer, during the time of cutting and collecting the wood for the ensuing wet season. If, therefore, in place of making 600 tons yearly, the furnaces of these days are supposed to have made each, upon an average, five tons per week, or making a little allowance, 250 tons yearly, which is surely nearer the truth, this still leaves an annual amount of manufactured pig-iron equal to 75,000 tons, which, exclusive of the operations of the forge, forms a very respectable staple at that early period of the history of our manufactures.

Pit coal had been long known before this period, and wrought at Newcastle prior to the year 1272. Annually vast quantities of it were exported to Holland and the Low Countries, for the use of the smithy, and other manufactures requiring an intense and continued heat. Yet in England prejudices ran so strong against its application to the manufacture of cast-iron, that the projectors of this original undertaking met with every obstacle which the narrow unenlightened minds of the established manufacturers could devise.

James granted several patents for the exclusive right of manufacturing iron with pit-coal. None of the projectors, however, were successful, till the year 1619, when Dudley succeeded in making coke pig-iron in a blast furnace, though only at the sparing rate of *three tons per week*. At this period many of the iron works were at a stand for want of wood, and the consequence was an advance upon the price of iron: this rendered it a lucrative business to those manufacturers whose supply of wood was still undiminished, and of course made them hostile to any innovation, whereby the present price of iron was likely to meet with a reduction.

This period of prejudice, so unfavourable to innovation in the iron business, was followed by one more general and more calamitous for the nation: amidst the distraction occasioned by civil war, neither innovation nor improvement could be expected. Patents, however, were granted to some during the common-wealth, for the exclusive manufacture in the new way, in one of which, it was at the time believed, that Cromwell was a partner: these partly shared the same fate with the first inventor, and none succeeded in establishing a manufactory either of extent or certainty. In 1663, we find Dudley applying for his last patent, and setting forth, that at one time he was capable of producing seven tons of coke pig-iron weekly, with an improved furnace 27 feet square, and bellows, which one man could work for an hour without being much tired.

It was not, till impelled by necessity, arising from the rapid decline of the annual growth of timber, that pit-coal became an object of universal estimation. When improvements on machinery had attained a pitch of certainty, and experience had taught the mechanic the manifold advantages of the steam engine; the adventurous manufacturer found he possessed an extent of means to which he was formerly a stranger. Small furnaces, supplied with air from leathern bellows, blown by oxen, horse, or human labour, became exploded, and an increase of size took place, together with an increase of the column of blast necessary to excite combustion.

At this eventful era in the history of the blast furnace, when the ameliorating hand of agriculture was progressively sweeping before it, what remained of the once immense tracts of woodland dedicated to the supply of the blast furnace; when the general improvement in machinery, and the introduction of the steam engine threatened to give new life and impulse to manufactures in general, the iron business seemed dwindling into insignificance and contempt. The demand of the country increased for the manufactured article, particularly bar-iron, while every year saw a gradual but steady diminution of the annual quantity. Recourse to foreign markets was had for a supply of that article, of which this country once was the greatest exporter, and the immense annual importations from Russia and Sweden may date their origin from that period. The flourishing and extensive detail of Dudley no longer existed, and the 300 blast furnaces of his day were now diminished to 59 in all; the total amount of whose annual produce was 17,350 tons, or nearly 300 tons to each furnace.

LIST of the Blast Furnaces in England and Wales immediately before the introduction of pit-coal, as a substitute for the charcoal of wood; the particular counties in which they were situated; the collective quantity of iron manufactured in each county, and the produce of each particular blast furnace.

Tons. cwt. qr.
Annual average for each furnace 294 1 1

By this statement it is evident, that the manufacture of pig-iron had diminished during one hundred to one hundred and thirty years preceding, upwards of 50,000 tons annually. Fortunately for the existence of the trade, the application of good going, and what, at that time, would be reckoned powerful, steam engines, about the year 1750, for raising and compressing air, were introduced at some places where abundance of materials was found without water for turning machinery. The manufacturer now found that his produce could be increased by enlarging the diameter of his steam cylinder, or perfecting the vacuum under the piston; and it was soon discovered, that these increased effects alone were requisite to the formation of pig-iron, in profitable quantity from the coke of pit-coal; nor is it to be wondered that this secret remained so long a mystery. The small quantity of air that was formerly requisite to ignite a charcoal furnace, whether from the great inflammability of the fuel, or the smallness of its capacity, was constantly before the eyes of the manufacturer. He had more often felt the effects of over-blowing, than under-blowing his furnace; and it is highly probable, that pit-coal, being deemed every way inferior,

B L A S T.

inferior, an unusual timidity would precede any movement that might have for its object the enlargement of the column of air or the increase of its density.

This, however, once done away, there seemed no end to the quantity of air that a coke blast furnace could with propriety receive before any bad consequences ensued. Density, however, was found inimical to quantity, and the same law was at last discovered to hold good regarding pit-coal as with wood, that the softer qualities could be over-blown, while the more dense and compact strata remained undiminished before a heavier blast.

The celebrated foundry of Carron was begun about the year 1760, and as was the custom of the times, the operation of blowing was performed by large bellows moved by means of a water-wheel. Pit-coal was the staple fuel in view, but the scanty supply of air, and its want of density, seldom permitted the produce of the furnace to exceed 10 or 12 tons weekly, and frequently in summer, the quantity was reduced even below this. The company collected immense quantities of charcoal wood, and found their blast much better calculated for the operation of smelting with it, than the unflammable pit-coal obtained in their neighbourhood. Experience, however, gradually unfolded means of adopting machinery, more calculated to the nature of the coal fuel, more powerful wheels were constructed, the bellows was abandoned, and in their place large iron cylinders were introduced blowing both up and down. A larger column of air of triple or quadruple density was obtained, and effects equivalent to these great improvements followed at the blast furnaces. The same furnaces that formerly yielded 10 and 12 tons weekly, now sometimes produced 40 tons in the same space, and on the average in one year not less than 1500 tons of metal.

From the period (1750 to 1760) that pit-coal coke was applied as a substitute for wood charcoal in the blast furnace, the iron trade began immediately to revive, and its progress in England and Wales, in a period of 30 years, was truly astonishing. The general use of pit-coal, most unquestionably, occasioned an earlier relinquishment of many of the charcoal works, than would have otherwise been the case, but the collective manufacture had so much increased, as to render this an object of trifling importance.

The following is a correct statement of the annual manufacture of pig-iron in England and Wales in the year 1788:

Charcoal Blast Furnaces.	No. of Furnaces.	Tons at each.	Total in each County.
Gloucestershire	4	650	2600
Monmouthshire	3	700	2100
Glamorganshire	3	600	1800
Carmarthenshire	1	400	400
Merioneth	1	400	400
Shropshire	3	600	1800
Derbyshire	1	300	300
Yorkshire	1	600	600
Westmoreland	1	400	400
Cumberland	1	300	300
Lancashire	3	700	2100
Suffex	2	150	300
Total of charcoal furnaces	24		13100
Average produce from each furnace		545	16 2
Former average produce		294	1 1
		251	15 1

Increased produce per furnace, from the year 1750 to 1788, attributable entirely to the general improvement of machinery, and the introduction of the steam engine, 251 tons, 15 cwt. 1 qr.

	Tons
About the year 1750 the annual quantity of charcoal pig-iron manufactured in England and Wales amounted to	17350
In 1788 the same was	13100

Decrease in charcoal iron betwixt 1750 and 1788 4250

attributable chiefly to the decrease of wood, but also in part owing to the use of pit-coal as a substitute in the furnace.

Coke Pig Blast Furnaces in 1788.	No. of Furnaces.	Tons at each.	Total in each County.
Shropshire	21	1100	23100
Staffordshire	6	750	4500

Total quantity of pig-iron made in England and Wales } 77 61300

Annual quantity manufactured immediately preceding the introduction of pit-coal for furnace fuel } 59 17350

Annual increase in 30 years } 26 50950

The period of 1788 or 1790 may be called a new era in the manufacturing of pig-iron. The double power engine of Mr. Watt had now become more general, and was yearly

B L A S T.

yearly finding its way into blast furnace works. The regular and increased effects of this very powerful machine were soon felt in most of the iron counties. The produce of the furnaces in metal greatly increased as to quantity, and as they became more prosperous, stimulated others to engage in similar undertakings. New works were yearly projected, and several blowing furnaces annually added to the former list: so that in eight years the manufacture of pig-iron had nearly doubled itself.

The following table is a curious illustration of this fact. It was drawn up as an authentic document of the returns made from all the blast furnace proprietors in Britain, of the number of their furnaces, and the annual quantity of pig-iron manufactured at their respective founderies. These returns were made at a time when it was in the contemplation of the legislature to impose a tax upon pig-iron, and are copied from Dr. M'Nab's letter to the chairman of the committee of the house of commons upon the subject of the coal trade.

B L A S T.

The demand for iron articles of all kinds in this country not only continued unabated after the period of 1796, but kept increasing in a greater ratio than formerly; so that in the short space of five years, situations were occupied for nearly 50 additional furnaces, or additions made to established works of that extent. Betwixt 1801 and 1802, it was ascertained that the following new furnaces were either building or actually in blast, in England, Wales and Scotland.

Total of new Blast Furnaces 22 25

Blowing and building in Great Britain; the produce of which, supposing them all to have gone to work at the rate of 1000 tons per annum, from each furnace, would amount to, from 47 furnaces, 47,000 tons,
 Manufactured at, and previous } 121 furnaces, 125,079
 to 1796, in } 168 furnaces, 172,079 tons

The respective proportions of this astonishing produce in pig iron manufactured in England and Wales, and in Scotland, will stand thus:

In recapitulating the interesting facts which will result from a review of the gigantic progress of this manufactory, the regular progressive quantity made at a furnace is remarkable, or, which is the same, a diminution of the number of furnaces to perform the same quantity of labour.

Dudley represents, that in his day, 1620, there existed, in England and Wales alone, 300 blast furnaces, for the sole making of pig-iron, to each of these have been assigned the yearly produce of 250 tons.

At a period considerably after this, and before the use of pit-coal was found profitable in the furnace, 59 furnaces produced yearly 17,350 tons of charcoal iron, or each furnace average, 294

In 1788, there still existed in England 24 charcoal furnaces, which yearly manufactured 13,100 tons of metal, or from each furnace, on an average, 545

At the same period, in England and Wales, 53 blast furnaces, at which coke was used, manufactured yearly 48,100 tons, which upon an average was nearly, from each furnace, 907

The same year in Scotland, 8 furnaces produced 7000 tons of iron, or from each furnace, 875

In 1796, the number of furnaces in England and Wales amounted to 104, and yielded 108,993 tons of metal, which from each furnace was equal to 1048

The same year, in Scotland, 17 furnaces manufactured 16,086 tons of pig-iron, which is from each furnace, 946

These are by no means sufficient data to form an accurate opinion of the real progress or improvement of our blowing machinery in Britain. In the collection of furnaces in 1796, a number of charcoal blasts were included, which, from their general small produce, blowing only four, six, or nine months a year, reduces the average considerably on the whole. It may now be safely asserted, that the average produce in iron at pit-coal blast furnaces in England and Wales, is at melting iron works, 1200 tons

Do. at forge pig works, 2000

This bears a very striking contrast to the early exertions of the manufacturers in the sixteenth and seventeenth centuries, and exhibits a wonderful example of the general and rapid improvement of machinery in the last 50 years. With the improvements of machinery, the advancement of the manufacture of iron in general, and particularly of coke pig-iron, has kept equal pace. Nor have we sacrificed quality to quantity, but the reverse; for the melting pig-iron of our time is much more calculated for every variety of casting, than iron, equally saturated with the coal principle, made with wood charcoal.

By comparing the value of a ton of pig-iron at different periods for the last 200 years, a pretty accurate opinion may be formed of the increased price of labour at iron works, and of the increased value of an object of universal utility in all our arts and manufactures.

About

B L A S T.

About the year 1620, charcoal pig-iron sold for 6l. per ton.	-
1788, ditto for melting, -	8l.
1798, ditto - - - - -	9l. 10s.
Coke pig-iron, when first invented by Dudley, } was sold at - - - - - }	4l.
In 1788, it sold for - - - - -	5l. 10s.
1798, ditto - - - - -	7l. 10s.
1802, melting iron was - - - - -	8l. 10s.
And smooth-faced N ^o 1. sold at - - - - -	9l. 10s.

One thing is here worthy of remark, that in a period of 170 years one ton of coke pig-iron rose in value only 30s. i.e. betwixt 1620 and 1788; but that in the short period of 14 years following 1788, an advance of 4l. per ton took place. One thing only may be offered in extenuation of this immense rise, that part of it was owing to the misunderstanding that took place betwixt this country and some of the Baltic powers, which was no sooner adjusted than pig-iron fell in price. The article still, however, maintains itself at 8l. 10s. per ton, being double the rise in point of value in fourteen years that took place in the one hundred and seventy preceding the commencement of that period.

To point out proper channels, whereby to account for the annual consumption of such an immense quantity of raw materials, would prove a satisfactory source of information. The endless detail into which the foundery trade has now branched itself, the almost universal fabrication which it embraces, and the extensive diffusion of the scites of manufactories themselves, preclude the possibility of obtaining this with strict accuracy. The following statement, however, will tend to throw some light upon the subject.

It is reckoned, that the bar iron forged in Britain manufactured annually from pig-iron 40,000 tons of finished bars, which at the rate of 35 cwt. of pigs for every ton of iron bar produced, will account for - - - - -	70,000
Consumed yearly in the erection of new furnaces, forges, machinery, &c. - - - - -	5,000
Purchased by the board of ordnance in the state of cannons, mortars, carronades, shot, and shells, &c. on an average of 1794, 5, 6, 10,935	
Waste in melting from the pig, boring, &c. - - - - -	1,300
	12,235
Purchased by the navy board in the state of ballist, &c. - - - - -	2,664
India Company's annual supply in guns, shot, shells, carcasses, &c. - - - - -	5,000
Waste melting, boring, &c. - - - - -	700
	5,700
Merchant guns, carronades, shot, &c. for arming trading vessels, 10,000	
Waste in melting and boring, 1,000	
	11,000
Ballast for Merchantmen and India men, - - - - -	5,000
	Tons 111,599

For the difference betwixt this and the total manufacture, recourse must be had to the large exportation to Ireland, and to the numerous and extensive casting founderies of London, Liverpool, Manchester, Birmingham, Workington, Newcastle, Edinburgh, Glasgow, &c. none of which melt under 2000 tons yearly, and many of them from 4 to 5000 tons of melting pig-iron.

We shall now leave this interesting subject with some ge-

neral observations upon the origin and progress of the pig-iron manufacture, and its early use in the fabrication of castings.

It appears from Dudley, that towards the close of the reign of queen Elizabeth, blast furnaces had been constructed of size, and with machinery sufficient to produce upwards of two tons of charcoal iron per day. Such great products in iron were most probably confined to situations where there was abundance of water, and where water-wheels and bellows of a considerable magnitude were used. The more common modes of operation were confined to furnaces of an inferior size, which were supplied with air by means of hand-bellows, excited by cattle, or the labour of men. At the same period England enjoyed a considerable export trade, arising from her superior manufacture of iron guns, mortars, &c. As pit-coal had not been applied in any branch to the manufacturing of iron, it is probable, that these articles would be cast from the large blast furnaces; the flame of wood possessing but feeble effects compared to that of pit-coal, would render the application of the reverberating furnace, if then known, of no use in the casting of guns and mortars.

The non-application of pit-coal in every department of the melting foundery, would greatly retard the perfection, or even improvement of the art of moulding, and casting smaller and more general articles. The want of it, as the smelting fuel in the blast furnace, was long severely felt by the general backward state of the art of moulding and casting in this country, and allowed other nations with fewer advantages to get the start of us. It is highly probable, that long before the period formerly alluded to, the application of pit-coal had been speculated upon, either as an auxiliary, or as a substitute in every branch of the iron business. Its well known inflammability and tendency to form a cinder, and the general decay of wood, would furnish ample grounds for what, to many at the time, would be considered as idle and visionary speculations. The advantages arising from the trade, as it was then situated, had been rigidly ascertained, and fully appreciated by the established manufacturers. The business, in point of extent, seemed only limited by the supply of wood. New erections, for want of a proper supply of materials, became impracticable; those already engaged were more anxious to preserve their supply, however much circumscribed, than listen to innovation, which, by substituting pit-coal for the charcoal of wood, would likely give to the speculatist a great superiority in the market. It is also highly probable, that many of the iron works then established were at a considerable distance from pit-coal, the general introduction of which would prove fatal to their interests.

In this view of the subject, the adventurer with capital had every thing to hope, the established manufacturer every thing to fear, by change. Under these circumstances, the discovery, or rather the assertion of the practicability of making iron with pit-coal, was announced by Simon Sturtevant, esq. in the year 1612, who, upon application, was favoured with a patent from king James, for the exclusive manufacture of iron with pit-coal, in all its branches, for the long period of thirty-one years. In return, the said Simon Sturtevant bound himself to publish a faithful account of his discoveries, which afterwards appeared in quarto, under the title of his "Metallica." It is uncertain to what causes his failure was at the time attributed, but in the execution of his discoveries upon a large scale, he had found difficulties amounting to utter impracticability; for in the year following, he was obliged to make a surrender of his letters of monopoly.

The second adventurer in this unexplored path we find to have been John Ravenson, esq. who, like Sturtevant, was successful in obtaining a patent for the new manufacture; but, like him also, was inadequate to the completion of it upon a profitable scale. Ravenson was also enjoined to publish his discoveries under the title of his "Metallica," which was printed for Thomas Thorp, anno 1613. Several other adventurers stepped forth, all of whom had the mortification of resigning their patents, without having contributed to the success of their arduous undertaking.

In 1619, Dudley obtained his patent, and declared, that although he made only at the rate of three tons per week, he made it with profit.

This discovery was perfected at his father's works at Pen-fent, in Worcestershire. This gentleman's success in the various manufactures of iron with pit-coal, had united not only all the proprietors in the charcoal iron trade, but many new adventurers, who wished to share in the emoluments, or to acquire part of the fame of the new discovery. Their interest was sufficient to limit the duration of Dudley's patent from 31 to 14 years. During the greatest part of this period, according to his own statement, he continued to make pig and bar iron, and various castings; all of which he sold much lower than the charcoal manufacturers. In the article of castings he must have had greatly the start of the charcoal founderies, as the quality of melting coke pig-iron is far superior to that of charcoal, particularly that made in this country for the general purposes of casting. Nor was the superior genius of Dudley always an object of passive indifference in the narrow estimation of the new adventurers and the established manufacturers. The envy occasioned by his uncommon success, produced at last a spirit of combination, which terminated in a hostile attack upon his devoted works. His improved bellows, furnace, forge, &c. all fell a prey to a lawless handitti, betwixt whom and its furious leaders no shades of distinction were visible, but those of avarice, ignorance, and the most contemptible prejudice.

To evade the mode of operation discovered by Dudley, or to introduce the making of coke pig-iron with greater advantages, a new plan was adopted by captain Buck, major Wildman, and others, in the forest of Dean, where they erected large air-furnaces, into which they introduced clay pots resembling those used at glass houses, filled with the necessary preparations of ore and charcoal. The furnaces were heated with the flame of pit-coal; and it is probable, that by tapping the pots below, it was expected that the separated metal would flow out. This rude process of assaying on a large scale, was in the end found utterly impracticable; the heat was inadequate to perfect separation; the pots cracked; and, in a short time, the process was abandoned altogether.

The misfortunes which befel the sanguine, but unfortunate Dudley, were an irreparable loss to the perfection of the coke pig process. The hostile rivalships he had to encounter in consequence of the new ground he had occupied [as a manufacturer, together with a zealous attachment to the royal cause during the civil war which followed his discovery, completely prevented his improvements from attaining a pitch of permanency and general utility. The refusal of a new patent after the restoration, prevented him from again entering the laborious paths of discovery and improvement, although it appears, that his former application to the perfecting of this branch of manufacture had not been unsuccessful, for in place of three tons of coke pig weekly, in his petition praying for a renewal of his ancient rights, he states, that he could now manufacture seven tons by means of a large furnace, and an improved bellows.

No greater pitch of improvement took place for nearly one hundred years after this period. The practicability of the manufacture was discovered; but the mode of obtaining quantity, to ensure in general a profitable return, depended upon other circumstances than the proportioning of the raw materials together. Had machinery received the same improvements in the time of Dudley, it is more than probable that the rapid progress of the coke pig trade would have dated its origin from that period. But this great era in the history of our manufactures was reserved for a much later date; and in the improvements of the steam engine, we see new life and existence conferred upon every species of art that can be made subject to motion or mechanical control.

Blast Furnace Works, are large and expensive buildings for the manufacturing of pig iron. An erection upon the smallest scale must consist of a furnace, casting-house, bridge-house, and blowing engine. The latter is sometimes, though seldom, worked by means of a water wheel. The most universal mode of blowing is by means of a steam engine. See *BLOWING Machine*.

There is no general plan laid down for building a blast furnace work. The singular situation which should be occupied, to insure every conveniency, renders this dependent upon the nature of the ground.

It is always reckoned a great advantage to place the blowing machine at as short a distance as possible from the furnace or furnaces, that the air may have the least possible travel in the conducting pipes. When this cannot be conveniently effected, the diameter of the pipes ought to be made sufficiently large to admit of the blast passing without any material friction.

The usual appendages to blast furnaces are mines of coal, iron-stone, and lime-stone. And these form no inconsiderable portion of the whole expence.

In situations where blast furnace building materials are at a moderate price, and when no uncommon difficulty occurs in the progress of the general operations, 15000*l.* of sunk capital may be deemed requisite for one furnace; and for every furnace after this, 10,000*l.* may be added.

This great capital for many years kept the trade in the hands of a few; but of late, since capitalists have become more common, the number and extent of the blast furnace erections have become truly astonishing.

The following descriptions of plates illustrative of the plan and arrangement of blast furnace works will convey a tolerable idea of the nature of these buildings.

Plate XI. Blast Furnace Works, represents the ground plan of an entire fabric, consisting of

- A Steam-engine for blowing two furnaces.
- 2 Blast furnaces.
- 2 Bridge-houses.
- 1 Casting house.
- 1 Boiler-house.
- 2 Boilers.
- 1 Chimney for boiler flues.
- A, Engine-house, 40 feet long, 18 feet wide.
- B, Pedestal for steam cylinder: 7 feet square at base, and 4 feet at top.
- C, Pedestal for blowing, or air cylinder. Base 10 feet square, top 7 feet square. These are generally built of solid hewn stone, and bedded with the greatest accuracy. From centre to centre of the two pedestals is 24 feet, which is also the distance betwixt centre and centre of the steam and air cylinders.
- D, Door or opening through the lever wall. This wall at bottom is built 5½ feet thick, but is occasionally reduced

in point of thickness to $3\frac{1}{2}$ feet at top, as may be seen at the corresponding letter in the section.

F, Door or opening from the engine into the boiler-house. An opening above this serves to conduct the steam pipe from the boiler to the steam apparatus at the cylinder.

E, Door or opening for carrying through the blast pipes from the top and bottom of the air cylinder to the water receiver below.

G, The boiler-house, 40 feet by 30 within the walls. As this is excavated from the solid hill to the depth of 30 feet, it is requisite to have the walls uncommonly strong. Those in the plan are 6 feet thick at bottom, and are reduced at three different heights in thickness, as represented by the interior lines.

HH, Two boiler-seats for boilers, 18 feet long, 9 $\frac{1}{2}$ feet high, and 7 feet wide.

II, Fire-places, 6 feet square.

KK, Dead plates before the bars or grates.

LL, Openings where the furnace doors are hung.

MM, Semi-circular openings formed beyond the dotted line or termination of the boiler, in which the flame from the grates rises to enter the iron flue or tube, which is placed in the centre of the boiler.

N, Chimney, 2 $\frac{1}{2}$ feet square within, and 50 feet in total height; from the bottom of the flue 42, and 8 feet from the foundation.

OO, Coal pits for containing small coals for the engine's supply. These are 8 feet by 6 at bottom, and widen gradually as they approach the surface of the coke yard. The coals are there emptied from the cart into the receivers, and the engine-man easily supplies his wants from the small openings which communicate with O into the boiler-house.

PP, Bridge-houses for containing coals, iron-sloae, and lime-stone, for filling the furnace. Measurement within 42 by 40 feet.

QQ, Doors or entrances from the coke yard into the bridge-houses.

RR, Openings from the bridge-house, which is here connected with the furnace, by means of an arch and parapet walls. This is more fully seen in the elevation section P. Along this bridge the materials are carried or wheeled into the mouth of the furnace.

SS, Two blast furnaces, 34 feet square in the base.

T, Casting-house 102 feet long by 48 in width from the front wall or arch of the furnace, or 88 feet wide from the front wall of the engine and bridge-houses, and 24 feet high in the side walls.

W, Water receiver for receiving and equalizing the column of blast. Length 40 feet, and breadth 18 feet.

V, The space in which the equivalent column of water rises, 3 feet wide. The exterior line denotes the inverted iron chest; the interior lines, the different basements formed by the stone work laid upon the chest to prevent it from rising when the engine is at work.

Y, Termination of the blast conduct pipes from the air cylinder into the iron receiver, 2 feet 6 inches diameter.

Z, Position for the horizontal range of pipes to branch off, which are meant to convey the blast to the opposite tuyeres, *aa*, betwixt the back wall of the furnace, and the bridge-house.

bb, The two tuyere sides next the water pressur. From Y proceeds a straight pipe along the centre line *b*, for conveying the blast to that side of the furnace.

cc, Front arches, under which the furnace workmen perform all the labour of tapping, casting, and cleaning the furnace.

dd, The spaces included within these dotted lines are called pig beds. They are kept constantly filled with sand, and in them the operation of moulding and running the pig metal is constantly performed.

Plate XII. Blast Furnace Works.

Elevated section of the ground plan, *Plate XI.* through N F B D C E and X.

A, Inside of the blast engine-house.

B, Steam cylinder pedestal.

C, Blowing or air cylinder pedestal. Both of these are built upon 4 or 6 inch planking, laid upon strong logs, which are again supported upon the solid stone buildings, *a a*, running from the lower wall along the side wall of the engine-house, to the wall perpendicular to E. The binding down bolts that pass through the flanges of the cylinders are strongly keyed upon the under side of the logs, and are at all times easily accessible.

D, The lever wall and opening of communication betwixt the steam and blowing end of the engine-house.

F, Door or opening into the casting house and water regulators.

E, Door to the boiler-house.

G, The boiler-house.

H, One of the boiler seats.

I, One of the boilers, 18 feet long, by 9 $\frac{1}{2}$ wide, by 7 high.

K, Man-hole door for entering the boiler.

L, Thorough arch in the foundation of the chimney.

M, Throat, or opening into the chimney, for the passage of the flame and smoke.

O, Coal pit for containing fuel for the engine.

P, Arched passage of communication betwixt the bridge-house and furnace mouth. The opening in the bridge-house is more distinctly seen at R, *Plate XI.*

S, Side view of one of the blast furnaces, as connected with its corresponding bridge-house.

W, Water vault, or cistern, for receiving the inverted chest. In rocky foundations this is cut out of the rock, but in soft ground the excavation is made and lined with well jointed mason work, puddled behind with clay to prevent the loss of water.

T, Casting-house and roof.

b, The tuyere arch.

c, The fow, or lintel of cast-iron, 12 inches square.

d, The orifice at which the blast enters, called the tuyere.

e, Spring beams of the engine-house, A. These are composed of two logs 14 inches square. The main gudgeon, seat, and beam rest upon these.

f, Stay logs for the steam cylinder.

g, Ditto, for the blowing cylinder.

Description of Plate XIII. Blast Furnace Works.

Cross section and elevation of *Plate XI.* through S Y S.

SS, Section of two blast furnaces, and their situation as connected with the blowing apparatus.

Y, The branch pipe for communicating the air to the inside tuyeres of the furnace. This pipe has another branch of communication behind, which connects it to the blast pipes which descend from the blowing cylinder at A, and to the double column of pipes which are carried round behind the furnace to the opposite tuyeres.

C C, View of the pipes which convey the air to the opposite tuyere, where double blasts are in use.

D, Front wall of engine and bridge-houses.

X, Iron chest inverted in the water receiver, and connected with the blast pipes.

VV, Opening all round for the water to ascend, as it becomes expressed from the chest by the impelling force of the blast.

O, Logs on which the chest is inverted, to preserve it from the floor of the water receiver, from 12 inches to 18 of space.

Description of *Plate XIV. Blast Furnace Works.*

Ground plan of an extensive blast furnace foundery, consisting of four furnaces and two blast engines. The peculiar construction of this plan is, that only one furnace may be erected at a time, and afterwards the whole number; still preserving that regularity and uniformity of design which will at any time make the blowing machinery of one part subservient to the whole, in case of accidents, stoppages for repairs, &c.

A, Engine-house, with cylinder, pedestals, lever wall, openings, &c.

BB, Two boiler-seats and boilers.

CC, Water regulators for the blast, which conveniently communicates, by means of pipes, with the blowing cylinders, placed upon the pedestals behind A, I.

DD, &c. Centre line of the whole blast pipes. This extensive column may be so arranged, as to enable the furnaces to be blown each with two tuyeres; and the blast of one engine made to pass through the whole. The general communication is effected by carrying the chief column either behind the furnaces, or, as in the plate, through the main pillar of the furnace, by means of an arched opening 3 feet wide.

E, Ground plan of the hearth, squares, and pillars of four blast furnaces.

FFFF, Bridge-houses for materials, and filling or charging the furnace.

GGGG, Openings into the furnace top.

H, Casting-house.

I, Second blast-engine, upon the same plan as A. Each of these two engines ought to be calculated to blow two furnaces, and occasionally, when any thing goes wrong with one, the blast of the other could be easily distributed for a time among all the furnaces.

BLASTED, in *Antiquity*, something struck with a *blast*.

Among the Romans, places blasted with lightning were to be consecrated to Jupiter, under the name of *bidentalía*, and *putealia*. It was also a ceremonial of religion to burn blasted bodies in the fire.

BLASTING of *stones*, in *Agriculture*, the operation of tearing asunder large stones or rocks, which are in the way of the plough or other instruments employed in breaking up ground, by means of gun-powder. The method of performing this business is by boring a large hole, eight, ten, twelve, or more inches deep, according to the nature and size of the stone or rock to be blasted, by means of a chisel for the purpose, and then introducing a sufficient quantity of gun-powder, and afterwards carefully ramming the hole up with small fragments of stone or other solid materials, only leaving a very small aperture, by placing a steel pricker of sufficient length and suitable dimensions, with a handle at the top, at first into the powder, and frequently turning it round while the hole is ramming up. After the hole is quite filled, by forcing the hard materials in with a proper instrument, the pricker is withdrawn, and the aperture left by it filled to the top with gun-powder, and then a match of tow, straw, or other light inflammable material laid to it, and set on fire.

It is observed by Mr. Headrick, in the second volume of "Communications to the Board of Agriculture," that in order to perform this operation properly some experience is necessary, and that a skilful workman can frequently rend stones into three equal pieces, without causing the fragments to fly about. This, he says, depends upon the depth and

position of the bore. It is also remarked, that a small portion of quick-lime, in fine powder, is found to increase the force, and consequently to diminish the expence of blasting stones. On these grounds the following is offered as a substitute for gun-powder, which is now become very expensive, though, as is freely confessed, without any experience of its effects. Supposing *fig. 1, Plate III. (Agriculture)* to be a large stone to be blasted or rent; *ab*, a bore sent down into it in the usual manner. This bore being then well cleaned out and dried, is to be filled from *b* to *c* with the purest quicklime, or such as swells most in slaking. That it may be perfectly quick it should be taken red hot from the kiln, or the small furnace where it has been burnt; being then rammed in hard with the jumper or punch *a c*, the upper part of the bore is to be crammed with rotten rock in the ordinary way. The pricker being removed leaves the aperture at *b*, *a b*, a small pipe of copper, of less diameter than the needle or pricker, having an orifice about the dimensions of the straw, used to convey the fire down to the gunpowder, with a funnel *d* to receive water, is introduced into the aperture. Perhaps a straw or small reed stuck in the lower part of the funnel, among tallow or bees wax, might serve the purpose of a copper pipe. Things being thus prepared, pour water into the funnel *d*; and if the pipe be not too high, so as to prevent the air from escaping from the aperture, left by the pricker, it will descend and cause the lime to flake in the bore *c b*. Every one knows how irresistibly the purest quick lime attracts water, and with what prodigious force it expands in slaking into three or four times its former bulk. From these data it is therefore inferred, that the slaking of lime, in such circumstances, would burst or rend the stone *f* in pieces; but the success of such an experiment, it is observed, must depend entirely upon using lime of the utmost purity, and having it very hot, and perfectly caustic when it is put in.

It is further remarked that if the bore *c b* were filled with water, and the aperture afterwards rammed up, the water being made to freeze by cold, would rend the stone; for when water passes from a fluid to a solid form, it expands with irresistible force, though frost cannot be depended upon in this climate.

BLASTOLOGY, from *βλαστος*, *bud*, and *λῆνω*, *I gather*; the regular and stated pruning of vines.

BLATNA, in *Geography*, a town of Bohemia in the circle of Prachalitz, near which is an inland lake, which is the source of the river Uflava.

BLATTA, in *Middle Age Writers*, denotes a purple in the wool or silk, dyed with the liquor of the blatta.

This was otherwise denominated *blatta serica*, or *blatto sericum*: whence also *blattarius*, used in ancient writers for a dyer in purple.

BLATTA, in *Entomology*, a genus of *hymenopterous* insects, called in England *cock-roaches*, or *black beetles*. The head is infested; antennæ setaceous; feelers unequal and filiform; wing-cases and wings smooth, the former somewhat coriaceous; thorax flattish, orbicular, and margined; legs formed for running; abdomen terminating in two articulated appendages above the tail.

The blattæ, considered in a collective point of view, are a very troublesome race of insects. Certain kinds, that are happily for us still peculiar only to the hotter parts of the world, are so formidable both in respect of number and talents for doing mischief, that they are really considered as a pest to society in those countries which they infest. These noxious creatures enter houses and commit various depredations on the furniture, devour provisions of every kind, tear or gnaw holes in clothes, torment the inhabitants with their bite, and otherwise do considerable injury. The sort of blatta most abundant in England

England was originally a native of the eastern parts of the globe, or, as some suppose, of America, from whence it was long since imported into Europe, and is now completely naturalized to our climate. This is the *blatta orientalis* of systematic writers. Another creature of this kind, *blatta Americana*, was also introduced with the raw sugars brought some years ago to Europe from America.

All the known species of *cock-roaches*, whether in the larva, pupa, or perfect winged state, secrete themselves in the day-time, and wander about during the night in search of food. In allusion to this circumstance, the ancients called them lucifugæ, insects that shun the light. The common cock-roach will eat almost any sort of provision, preferring, however, bread, meal, sugar, and stale meat, either of which it is observed to devour with the greatest eagerness. Except in being completely destitute of wings and wing-cafes the larva resembles the perfect insect, and in the pupa state nothing more than the rudiments of the wings are perceptible. In the dark they are remarkably active and brisk in all their motions, and on the least disturbance, or the return of light, retreat again to their lurking places with timidity and precipitation. They can fly swiftly, but they seldom use their wings for this purpose; even when most closely pursued they are known to trust rather to their legs, with which they are able to run with no small celerity. The fumes of charcoal, we are told, may be employed with success in destroying these unwelcome inmates.

The following species of the *blatta* genus, are described by Linnæus, Fabricius, Gmelin, &c. viz. *gigantea*, *maderæ*, *ægyptiaca*, *occidentalis*, *surinamensis*, *americana*, *australasie*, *erythrocephala*, *capensis*, *indica*, *nivea*, *irrorata*, *viridis*, *brasiliensis*, *petiveriana*, *orientalis*, *cincla*, *picta*, *variegata*, *lapponica*, *germanica*, *ruficollis*, *maculata*, *marginata*, *oblongata*, *nitidula*, *fusca*, *densa*, *chlorotica*, *latissima*, *aterrima*, *perispicillaris*, *asiatica*, *schæfferi*, *sylvestris*, *pennsylvanica*, *livida*, *rufa*, *grisea*, *minutissima*, *aptera*, *punctulata*, *ocellata*.

Blatta, according to some writers, was also used for a particular kind of kermes, or chermes; or, according to others, for "the purple-worm," by which the *coccus cacti*, or cochineal insect was most likely meant. But both of these acceptations are suspicious. We know that the word *blatta* was anciently used for a kind of moth, whose fat was reputed excellent for the ears. This luit was called the book-worm moth. See BOOK-WORM.

BLATTA Americana of Catesby is of the *Silpha* genus with modern entomologists. Gmelin speaks of it under the name of *Silpha americana*.

BLATTA byzantina, in *Physiology* and *Pharmacy*, the *operculum*, or lid of a turbinated shell, whose fish yields a purple dye.

The *blatta* differs from the lid of the *buccinum* or *purpura*, in figure; the first being oblong, the latter round; but in the shops they are ordinarily confounded, and sold for each other. The *blatta byzantina* is also confounded by apothecaries with the *unguis odoratus*, from which it ought to be distinguished, as belonging to another kind of shell-fish.

Dr. Lister takes the *blatta byzantina* to have succeeded the *unguis odoratus*, and to have been brought into the shops in its place. In Dioscorides's time, the belt was brought from the Red Sea, viz. the palest and fattest; the blacker and less, from Babylon, or the Persian gulf: but it seems, latter times took up with those found about Constantinople; whence the present shop *blatta* had its name.

The name *blatta* seems to have been given to this *operculum* from the colour; as being of a dark hair-colour, as the

common *blatta orientalis*, or common *cock-roach*, so frequent in London, is.

The *blatta byzantina*, when exhibited internally, renders the body soluble, softens the spleen, and dissolves peccant humours. When used externally, by way of fumigation, it restores epileptic patients, and women labouring under a strangulation of the *uterus*. In other disorders its effects are the same with those of most testaceous substances.

BLATTARIA, in *Botany*. See *CELSIA*, *LYTHRUM*, *PENTAPETES*, and *VERBASCUM*.

BLATTERIÆ, *AFFINIS*. See *LYSIMACHIA*.

BLATTINUS, in *Entomology*, a species of *staphylinus* that inhabits Austria; the colour is black; thorax broad; wing cafes and the legs testaceous and glossy. Shranck. Inf.

BLATUM-BULGIUM, in *Ancient Geography*, a promontory of Britain, mentioned in Antonine's Itinerary, concerning the situation of which antiquarians have entertained different opinions. Camden, Gale, Baxter, and some others, have fixed it at Boulness, on the south coast of Solway firth, at the end of Severus's wall; yet Mr. Horsley assigns its situation at Middleby in Annadale. Here, as at the most remote limit of the province of Britain, Antonine commences his second route. A military way led from *Blatum-Bulgium* to *Luguvallium*, or *Carlisle*.

BLAU, in *Geography*, a river of Germany, in the circle of Swabia, which rises near the foot of a hill in the *Blautopfe*, as it is called, and runs into the Danube at *Ulm*.

BLAUBEUREN, a town of Germany, in the circle of Swabia and duchy of Wirtemberg, in a small district of the same name, seated on the river *Blau*, 7 miles W. of *Ulm*.

BLAUDRUSELUS, in *Zoology*, (*olaffen* isl.) *phoca cristata* of Erxleben and Gmelin, and *hooded seal* of Pennant.

BLAUENTHAL, in *Geography*, a town of Germany, in the circle of Upper Saxony.

BLAUER-Bock, in *Zoology*, one of the names given by authors to the blue antelope, *antelope leucophaea*. Vide *KOLBE VORGEB*.

BLAVET, in *Biography*, a celebrated performer on the German flute, the first, perhaps, who greatly distinguished himself by that instrument after it superseded the common flute, and became in general use. He was born at Besançon, and coming to Paris in 1723, soon acquired a great reputation. The prince of Carignan, who knew his merit, enlisted him in his service; gave him an apartment in his hotel, and a pension. He was afterwards appointed superintendent of the comte de Clermont's band, and remained in that nobleman's service to the end of his life.

To his admirable talents, *Blavet* joined the respectable virtues of society; his manners and conduct were blameless, his temper tranquil, and his probity scrupulous. He married at eighteen, and lived upwards of fifty years with his wife in uninterrupted harmony and affection. We are always glad when to great professional abilities, such an estimable character can be joined.

Blavet's excellence on the German flute had been heard of all over Europe, before the character of *Weideman* was established in England, or that of *Quantz* in Germany.

About the end of 1765 he was attacked with the stone, which was a malady then more dangerous than it became afterwards, by the skill, experience, and success of eminent surgeons; but determining too soon, like our poor countryman, *Dr. Worgan*, to submit to the operation, he died under it in 1768, leaving behind him the esteem and regret of all who knew him.

BLAVET, in *Geography*, a river of France, which runs into the sea opposite *Belle Isle*. This forms a good harbour and spacious road.

BLAUFELCHEN, in *Ichthyology*, the name under which *Salmo Wartmanni* of Bloch and Gmelin is described by Wartmann Besch. Berl. Naturf. Fr. 3. p. 184.

BLAVIGNAC, in *Geography*, a town of France, in the department of the Lozère, and chief place of a canton in the district of St. Chely d'Apcher; 6 miles south of St. Chely.

BLAUKOEFIGE ROTHE AMSEL *Frisch*, one of the synonymous names of *lanius minor*, Gmel.

BLAUMEISE, in *Ornithology* (*Frisch*, Hist. of Birds), the blue titmouse of English writers, and *parus caruleus* of Linnæus.

BLAUSLUYS, in *Geography*, a town of Holland, 2 leagues west of Gertnefsdenburg.

BLAUSPECHT, in *Ornithology*, the name of the common nut-hatch; *sitta Europæa* in *Frisch*. Hist. of Birds.

BLAYE, **BLAVIA**, or **BLAVUTUM**, in *Geography*, a sea-port town of France, in the department of the Gironde, and chief place of a district of the same name seated on the Gironde, or Garonne, near its conflux with the Dordogne. Its citadel is situate on a high rock, and it is defended by a fort constructed on an island in the river, which is here 1900 toises wide; and on the other side of the river, in the country of Mendoc, is another fort. All ships that are going up the river to Bourdeaux, deposit their arms and cannon at Blaye, before they pass the river, and take them up on their return. The town contains 3580, and the canton 13,819, inhabitants. The territory comprehends 160 kilometres, and 14 communes. It is distant 20 miles north from Bourdeaux. N. lat. 45° 9'. W. long. 0° 45'.

BLAYMARD, or **BLEYMARD**, a town of France, in the department of Lozère, and chief place of a canton, in the district of Mende. The place contains 546, and the canton 11,802, inhabitants. Its territory comprehends 347½ kilometres, and 11 communes; 3¼ leagues east of Mende.

BLAZE, in the *Manege*. See **STAR**.

BLAZEGNIES, in *Geography*. See **MALPLAQUET**.

BLAZEY BAY, a bay in the English channel, on the south coast of Cornwall, between Fowey and Deadman point.

BLAZING STAR. See **COMET**.

BLAZON, or **BLASON**, in *Heraldry*. To *emblazon* is a term signifying the description of things borne in coat-armour, in such manner as they ought to be represented, according to the rules of heraldry. To *blazon*, originally signified the blowing or winding of an horn by the heralds, at justs and tournaments, when they proclaimed and recorded the achievements of the combatants.

BLEA, in *Vegetables*, is that part of a tree, which lies immediately under the bark, and between that and the hard wood, and is the first progress of the alteration of the bark into wood by the natural growth and strengthening of the fibres. See **BOTANY**.

While the blea remains yet soft, and retains something of the nature of bark, it may maintain a feeble vegetation; but when it is grown absolutely hard and woody, it can contribute nothing to the growth of the tree. The vegetation of the young branches of trees is the most lively and vigorous, and the only one that goes as far as the flowers and fruit, because these branches are little else but bark.

BLEACHING. The art of bleaching consists in removing the coloured matters intermixed with vegetable and animal substances in their natural state, or such as they have subsequently imbibed by accident, or some artificial process. Edward Huffey Delaval, esq. F.R.S. has shewn, by a number of accurate experiments on the cause of the permanent colours of opaque bodies, published in the second volume of

the second edition of the Memoirs of the Literary and Philosophical Society of Manchester, "that when the colouring matter of plants is extracted from them, the solid fibrous parts, thus divested of their covering, display that whiteness which is their distinguishing character. White paper and linen are formed of such fibrous vegetable matter, which is bleached by dissolving and detaching the heterogeneous coloured particles." He further observes, "it appears that the earth, which forms the solid substance of plants, is white; that it is separable from the colouring matter by several means; that whenever it is either pure and unmixed, or diffused through transparent colourless media, it exhibits its whiteness, and is the only vegetable matter which is endued with a reflective power; that the colours of vegetables are produced by the light reflected from this white matter, and transmitted from thence through the coloured coat or covering, which is formed on its surface by the colouring particles; that whenever the colouring matter is either discharged or divided by solution into particles, too minute to exhibit any colour, the solid earthy substance is exposed to view, and displays that whiteness, which, as before noticed, is its distinguishing character."

He states that in all those animal matters which do exhibit colours, the colouring particles are endued with the same properties, and are regulated by the same laws, which prevail in vegetable substances.

A reference to the original paper can only do justice to the observations of this excellent philosopher, confirmed by numberless experiments; but what is already said will be sufficient to give an idea of the nature of the process of bleaching, and that it depends on the removal of the matter interposed betwixt the air and this white substance.

The national importance of bleaching is so great, that it comprehends nearly the whole of the cotton and linen manufacture, and goes to an extent beyond most other arts.

Its operation in these branches may be considered under two points; viz. 1st, the separation of extraneous substances from linen and cotton, which is effected by steeping, fermentation, or weak alkaline leys; 2d, the separation of the constituent or inherent colouring matters of those substances, which is effected by different modes, and by various modifications of each method, as exposure to the air, light, the use of alkaline leys, soap, oxygenated muriatic acid, combinations of oxygenated muriatic acid with other matters, sulphuric acid, hepar sulphuris, &c.

To impress upon the mind the nature of the bleaching business, it will be proper first to describe the vessels used in the sundry operations of steeping, boiling, bucking, washing, souring, &c. then proceed to shew the management of each process, with some observations on its effects; and, lastly, how to make or procure the articles necessarily employed in this art, and the method of ascertaining the qualities of each, adding some observations on the theory of the operations.

BLEACHING of goods, particularly cotton manufactures.

1st, On Steeping.

The vessels generally used in bleaching are made of such wood as will not communicate any colour to the liquors they are to contain, and therefore deal or fir wood is preferable to most others. The vessels employed for steeping the goods when received from the loom are usually of the form A, fig. 1. Plate I. Bleaching. The goods when received from the weaver contain not only the natural colouring matter of the cotton, which is of an oily nature, and which prevents the cloth from easily imbibing water, but also a substance called sowins, being a paste made of flour and water, used during the weaving, and applied with brushes upon the warp, in order to give a firmness to the threads by glueing

BLEACHING.

or passing together the loose fibres of the threads, and thus allowing them to pass more freely through the reed and harness. To remove this substance, and to open the fibres of the cotton, so as to give full effect to the subsequent operations, it is proper to steep the goods in a vessel of the above form in lukewarm water, till a gentle fermentation takes place, which will usually be effected in 24 hours. The cloth should then be taken out, and well washed in a current of clear water, which will thus separate a considerable quantity of filth without the expence of using alkaline leys; and the cloth is then ready to be boiled or bucked as may be preferred by the bleacher.

2d, On Boiling.

For boiling, a copper vessel is to be preferred, and the goods prepared, as above mentioned, by steeping and washing, are put into the vessel containing hot water only, or warm alkaline ley; a winch is placed over the vessel, and the piece goods attached to the ends of each other, are, when put in motion by the handle of the winch, dragged or rolled over it till the whole are passed; the winch is then turned with a retrograde motion, and the cloth gradually thus returned back, in order that every part of each piece may be thoroughly impregnated with the liquor, which is raised to and kept at a boiling heat, as long as it appears to extract any colouring matter from the cloth; the goods are then taken out and well washed in water.

Fig. 1. Plate IV. shews a section of the boiling pan A, of copper, set in brickwork B; the winch C, with its handle D; E, uprights of wood, on which the winch turns; F, a cock to empty the pan; G, the fire-place; H, the ash-hole.

The use of this process depends upon the properties which alkaline salts have of uniting with the oily and resinous matters which are either attached to or are a constituent part of vegetable fibres, and which contain their colouring particles, forming with them a saponaceous matter, soluble in water, and by that means easily extricated from the cloth.

3d, On Bucking.

As this is one of the most general operations in bleaching, it will be necessary to describe it more particularly. *Fig. 1. Plate I.* under the word *bucking*, shews at A the form of the bucking tub or kier, in which the goods are to be laid; B is an iron boiler, in which the alkaline salts, as pot-ashes or pearl-ashes, are to be dissolved in boiling water; C is the fire-place, in which a fire is constantly kept up; D is the ash-hole; E, a cock through which the boiling ley is let out upon the goods closely placed together in the bucking tub, A. A sufficient quantity of boiling ley is let into the bucking tub, till all the goods in the tub are thoroughly impregnated with it; the ley liquor is then allowed to pass by a cock at H into an iron vessel placed in the ground at F, and from thence raised by the pump G into the iron boiler B, and thence returned hot again upon the cloth. This operation is continued for several hours, till the ley, by the separation of the colouring matter in the cloth, acquires a colour almost black, a very offensive smell, and nearly the consistence of molasses or treacle. The cloth is then taken out, well washed from its impurities, and, in the old mode of bleaching, it is then laid upon the ground to be whitened by exposure to the atmosphere, but, in the new mode of bleaching, is submitted to the action of the oxygenated muriatic acid, to procure a similar whiteness. It may be proper here to notice, that the old and new methods of bleaching are yet much the same as formerly, only in the substitution of the use of the oxygenated muriatic acid in those parts of the process, where a long exposure to the atmosphere was formerly employed after the alkaline leys.

The operation of bucking acts on a similar principle to that of boiling, but in a much more forcible manner, as a greater quantity of ashes is added in proportion to the water made use of, and more heat is received and retained in the large bulk of cloth placed in the bucking tub, which expands the fibres of the cotton, and admits the more powerful action of the alkali, as is easily demonstrated by observing the very dark colour of the alkaline leys which have been used in bucking, in comparison with those which have been employed in boiling goods. To those persons who wish for a full and minute account of the absorption and power of heat, we recommend a perusal of count Rumford's interesting essays on the subject of heat.

The black alkaline ley which remains after bucking should be preserved, as it will answer, after evaporating and calcining, as hereafter mentioned, to form again fresh alkaline salts of good quality. With a view to preserve as much of the ley as possible, it will be advisable to wring it out into a tub from the cloth or yarn, after it is bucked, by the method shewn in *Plate IV. fig. 3.* where R R are two strong posts, fixed firm in the ground, S T two wringing hooks, upon which the cloth U is twisted, to force out the liquor, by W, a winch handle, which turns the hook round on the post R. The two hooks are kept at a proper distance from each other, one by a collar at X, the other by an iron pin at Y, which runs through a hole in the square part belonging to the hook T, which square has several holes in it to bring this hook nearer to the hook S when required.

4th, Souring.

This process consists in immersing, for the space of twelve hours, or more, the yarn or cotton in a mixture of water and sulphuric acid (vitriolic acid), well incorporated; the proper strength of which mixture is about the acidity of lemon juice, and is usually directed by the taste. The four kettle should be made of lead, of a form which can be heated; the heat of the liquor should not be greater than the hand can bear with ease. This four kettle should be half sunk within the ground, as shewn in *Plate IV. fig. 2.* where M is a section of the souring vessel; N, the level of the ground; O, the brickwork; P, the fire-place, which is a half circle, or arch, without any grate; I I I, a space filled with dry ashes, betwixt the lower part of the four vessel and the brick-work, in order to preserve the heat of the liquor in that part of the vessel below the surface of the ground; K, a brick hearth, on which part of the fire is made; L, a cast iron plate, bending in the form of the four kettle, which is intended to prevent the fire placed on the floor at P K, from acting upon the lead of the four vessel; Q, the space betwixt the vessel and brick-work, through which the smoke goes to the chimney.

The construction of this apparatus is upon the same principle as the warm vats made use of by the blue dyers, the intent not being to make the liquor boil, but to keep it at a degree of heat which the hand can long and easily bear. There are no grate or bars necessary in this fire-place as the coals will burn with sufficient rapidity without them.

The goods may be put into this acid liquor either in a wet or dry state. The best plan is to immerse the goods in the evening in the acid liquor cold, let them remain covered with it all night, then in the morning make a fire and bring the liquor to a blood heat, in which state having a winch over the vessel, similar to that represented at C, *fig. 1.* give the goods a few turns over it, that every part of them may be exposed to the action of the liquor. The goods may then be lapped round the winch to drain a little, to prevent an unnecessary waste of the acid liquor, and afterwards carried to the wash-wheel, or river, to be well washed from

BLEACHING.

the acid, so that the cloth may be perfectly tasteless to the tongue. It is a remarkable circumstance, that cloth may remain immersed a very considerable time in a strong acid liquor without rotting, but that if exposed to the air or heat of a stove, if a very small portion of acidity remains in the cloth, it becomes so concentrated by heat, as to damage the cloth immediately; therefore too much attention cannot be paid to this point.

The use of the acid liquor above-mentioned is to dissolve any earthy or metallic matters inherent in the cloth, or which may have been communicated to it accidentally, or which it may have derived from the impurity of the alkaline salts used in the bucking or boiling.

A considerable quantity of the acid liquor may be preferred by passing the goods which have been soured through a tub of clean cold water, previous to washing them, and replenishing the four kettle with this acidulated liquor, rather than water only.

5th, *Washing.*

After every operation in which acids or alkaline substances are used in bleaching, it is necessary that the goods should be well washed in clear water; it is therefore of the greatest consequence that the water of a bleach ground should be pure, and in considerable quantities, such, for instance, as is perfectly transparent, will not curdle with soap, nor yield any degree of blackness with powdered gall nuts, or, which is a more accurate test, with a tincture of galls by infusion in spirits of wine.

Various methods have been invented for the purpose of washing out the impurities of the articles to be bleached; such as cleansing them in a large current of water by shaking them with the hand in the stream, beating them on blocks of wood with a flat paddle, or hand brush, beating them on a large flat stone with long wooden levers, flatted underneath, passing them over winches placed above vessels of water, or rivers, as *fig. 1. and 3. Plate II.* passing them betwixt plain or fluted rollers, as *fig. 5. and 6.* putting them under falling mills, or fulling stocks, as *fig. 7.* or within wash-wheels, as *fig. 1. and 2.* and by many other modes, few of which are equal, and perhaps none superior, to those of which engravings are here given, for doing the business simply, effectually, and with ease to the workmen; the latter point of which is of consequence to be attended to, as it will be universally found in every mechanical employment, that if the least additional labour or care is required from the workmen, however great the effects produced, prejudice or indolence will prevent their doing justice to the invention. Under these circumstances, the wash-wheel represented in *Plate II. fig. 1, 3, 4,* is the best machine for general use, and the least liable to occasion damage to the goods. The front of the wash-wheel represented at *A, fig. 1.* is supposed to be eight feet diameter, exclusive of the buckets *B,* shewn by dotted lines on its periphery, which give it motion from the water falling into them. This wheel is divided within into four parts or quarters, by the strong arms projecting from the shafts *D,* to the outer circle; in each of these separate quarters or boxes, represented by dotted lines, one or more pieces of goods which require washing, are put loosely folded together through one of the holes *C,* of 14 inches diameter.

Fig. 2. shews the back part of the said wash-wheel, which is made of solid planks, excepting a grate of slender iron bars marked *R,* which encircles the wheel underneath the separation boards or bottoms of the buckets; the use of this grating is to admit within the wheel a current of clear water from the pipe *Q.* When an equal number of piece goods have been introduced into each of the four divisions of the wheel by the holes, *C,* &c. above mentioned, a current of clear water

is permitted to run through a cock from the pipe *Q,* against the grating *R,* which allows it to flow freely through into the boxes, or those parts of the wheel which contain the goods; a valve is then opened from the trough *P,* communicating with a large reservoir or stream of water, a sufficient quantity of which is let into the outside buckets from the valve, to give the proper motion to the wash-wheel containing the goods. In every revolution of the wheel, the goods in each quarter of it are thrown twice, by the simple motion of the wheel, with great force against the arms which form the four divisions of it; viz. once in going down, and once in rising up. The ear can distinguish by the firmness of the found when the wheel moves with proper velocity; and a greater or less quantity of water is allowed to act upon the buckets till that is attained, which usually is when the wheel makes 15 or 16 revolutions in a minute. During the whole time the wheel is in motion, the stream of clear water from the pipe *Q* flows upon the goods within the wheel in every direction; and the dirty water, produced from thus washing the goods, runs out of the wheels from a number of holes bored through the wood-work near the axle, and a few made in the front near the outer circle of the wheel. *Fig. 4.* shews an end view of the wash-wheel, about thirty inches wide, with the manner that the bucket-work is made.

It has been found to answer equally well to make use of a greater number of wash-wheels of a smaller size, as six feet diameter and two feet wide, of which several may be put in motion at once by a large water-wheel, horses, or a steam engine.

The goods, when taken out of the wash-wheel, are to be unfolded, and taken to the river to be streamed, or may be washed from any impurities which may remain in the folds by means of a winch *N,* *fig. 1. and 3. Plate II.* where six pieces of cloth are represented in the action of washing in a large wooden hack divided into six partitions, to prevent the pieces of goods entangling with each other. *Fig. 1.* is a side view of the operation, where the dotted lines represent the partitions which separate the goods; *I,* a trundle wheel, which being put in motion by the cogs, *H,* of the wash-wheel, turns the winch on its axle, which winch may at any time be detached from it by the handle *M* drawing the catch *K* from the hook, as is shewn in the top view *fig. 3.* where also is explained, at the letters *OOOOO,* the manner in which each piece of goods is kept in its proper place on the winch, by the partitions above mentioned, and by angular slips of wood nailed to the back and partitions.

To assist the drying of the goods after washing, they are usually passed betwixt two small rollers, commonly called squeezers, represented at *fig. 5,* where *G* is a solid wooden frame, containing two wooden rollers, each from 10 to 16 inches long, on an iron axis, which rollers receive a proper pressure by means of the two screws *T* acting on an iron bar *V,* which rests on the two ends of the axis of the top roller, as shewn by the dotted lines. In proportion as the screws press the iron bar upon the axle of the top roller, it brings that roller closer in contact with the bottom roller, and occasions more water to be pressed out of the cloth, which is passed betwixt them loosely drawn together, something like a rope, and the goods therefore require less time in the subsequent drying. In this plate the squeezers are connected with the wash-wheel above mentioned by a square iron socket, which, as is shewn at *F,* slides occasionally upon the squares of both axes. *Fig. 4.* shews at *S* the buckets of the wash-wheel, on which the water falls to give it motion; *H,* the cogs round its axle, which work the trundle wheel *I.*

Fig. 6. Plate II. shews two views of another machine used for cleansing cotton goods, consisting of two fluted or grooved

BLEACHING.

grooved rollers, in the section of which *a* represents the hills, or bottom timbers; *b b*, the two supports or side pieces; *c*, one of the upright pieces in which the axles of the rollers are placed; *d d*, the two cross pieces to secure the frame work below; *e e*, the two rollers with grooved channels which fit to each other; *h*, one of the levers, which, from a point *i*, shewn by dotted lines, presses on the round end of the axle of the top roller, more or less, according as the weight *k* is placed on the lever further from or nearer to the axis of the roller.

In the geometrical elevation of the same machine, *ee* shews a front view of the two rollers; *f g*, the winch to turn it, with a hollow wood handle upon the iron work; *l*, the axis of the upper roller projecting beyond the side timber, so as to admit one of the levers *b* above mentioned to press upon it.

The wet goods, by being passed backwards and forwards through these fluted rollers, which are constructed at a much less expence than wash-wheels, are considerably cleaned, but not so perfectly as by the wash-wheels above mentioned.

Fig. 7. Plate II. explains another mode of cleansing goods, and is applicable to cotton, linen, or woollen goods, but more generally to the two last, as, without great care in its management, it is very apt to tear or damage cotton goods. This machinery is usually termed falling stocks, or falling hammers. *N^o 1.* is the axle of the water-wheel, in which are fixed tappets at 2, to raise alternately the levers 3, 4, furnished with large wooden mallets or hammer heads 6, 8, channelled at the lower part as at 8. These lever hammers or fallers, work from a pin fixed in the upright at 7; 9 is a strong piece of timber hollowed out at 10, to receive the goods to be cleansed; 11, a piece of timber fixed a-slant to keep the fallers in their proper place, and direct their motion; 12, a chain fastened to each faller, serving by means of the hook 13, to suspend the faller whilst the goods are put in or taken out of the cavity 10.

When the goods to be cleansed are placed in a loose bundle in this cavity, the hammers are let down upon them, and put in motion alternately by the tappets 2, in rotation, which raise the levers to a certain height, and then quitting them, the hammer heads by their great weight, fall with great force on the goods in the cavity below them; and a current of clear water being admitted upon the goods from a cock above them, the dirty water runs out at a hole in the bottom of the cavity. The falling of the hammers gives a slow circular motion to the goods in the cavity, so as to expose the several parts in rotation to the action of the hammers.

Having noticed the vessels made use of in bleaching, and the general nature of the several operations, we shall now proceed to mention the origin of the several improvements made in this art, and their application to practice.

Under the operation of steeping, we have shewn the method of removing the colouring matters not natural to the vegetable, but acquired in the manufacture, and which may probably be best done by water alone, though sometimes some of the old leys, which have been previously used to other cloth, are employed to this purpose. After the steeping, and indeed after every application of bleaching agents, it should be laid down as a general rule, that the cloth or goods be carefully washed in cold water.

In the old method of bleaching, alkalies, such as pearl or pot-ashes, were, after steeping, applied by bucking or boiling, with alternate exposure to the atmosphere.

Alkalies acting so important a part, it is necessary to describe the bleachers' mode of using them, which consists in dissolving them in clean water, and thus forming what is

termed an alk-ley. To which the more intelligent bleacher, if he does not make use of American pot-ash, or that of a similar quality, adds $\frac{1}{4}$ of quicklime, whereby the ashes are rendered caustic, and their power materially augmented. But in order that no inconvenience may arise from causticity, after mixture, the whole is allowed to settle, and from the pure liquor thereof the work is afterwards supplied; the bleacher, in drawing it off, reducing it by the addition of water to the different strengths which the goods may require.

The ley being prepared, the bleacher proceeds to apply it to the cloth by bucking or by boiling.

In bucking, the alkaline ley is put into the boiler before described, near to and below which is the wooden vessel called a kier, in which the goods are loosely and regularly arranged. After this, a fire is put under the boiler, and beginning whilst the ley is yet cold, it is made to circulate through the cloth in the kier, from which it runs into the iron vessel placed in the ground, from this it is pumped up into the boiler, and again returned upon the cloth in the kier; and this circulation is maintained, and the heat at the same time increased, until the ley be so far concentrated by evaporation, as at last to remain almost wholly in the cloth. This is generally the operation of a day, and the cloth is allowed afterwards to remain thus impregnated with the concentrated ley until next morning.

In boiling in alkaline leys, the mode of which has been before described, the operation is continued from one hour to five or six hours, but it is more tedious and less effectual than bucking, where much business is to be done.

After bucking or boiling, the goods were, by the old bleaching process, exposed for at least a week to the air, before they were again submitted to the action of alkaline leys, and this process alternately repeated many times, till the goods were perfectly white, and the goods at last soured and washed off.

To explain the *old method of bleaching* more particularly, we shall add the following process for bleaching linen cloth.

Steep your raw linen cloth in a wood vessel all night, then change the water, and add fresh till you perceive the water to be no longer discoloured by it; rinse, wring, and lay it on the ground, and water it if you have opportunity. When it has thus lain on the grass three or four days, and is dry, take hold of each piece one after the other by the selvedge, and draw the cloth to you, still holding it in the most even manner you can, until you get the further end, with the corners of which further end you tie the cloth very loosely in the middle of the folds, and so lay it in the bucking tub, with the two selvedges upwards.

Thus proceed till you have placed as much cloth in your tub as will cover the bottom of it, taking care not to pack the cloth so close but that your ley may penetrate every part equally. When you have laid the first range of cloth in your tub, pour upon it as much milk-warm ley as will sufficiently soak through all parts of your cloth. Then lay another range in the same manner upon the first, and pour on more ley till that be soaked as the other was, and continue so to do till your bucking tub be full of cloth.

That done, you must begin to buck for twelve hours together, the remainder of your ley having been put in the pan with a slow fire underneath. For the first five hours the ley should not be of a boiling heat; you must from time to time allow some of the ley to run out of the pan upon the cloth in the bucking tub; then increase your fire gradually and slowly, so as in four hours more to bring it to a boil, continuing to put on the ley, and draw it off your cloth in small quantities at a time. When your ley begins to boil, you must let it boil on for three hours, during the whole

time.

BLEACHING.

time pumping your ley up to the boiler from the reservoir, into which it runs from the cloth, and returning it boiling hot upon the cloth, so that the hot ley may act powerfully and equally upon every part thereof.

After each bucking your cloth must be laid upon the grafs in the bleach-field for some days. The bucking, and exposure on the ground, must be repeated about ten times successively, according to the nature of your cloth; it should then be dried up, soured, and washed well in clean water; if the water is rather warm, the better.

Your two first buckings ought to be from a strong caustic ley of pot-ashes; but afterwards you should abate of that strength, lest it should injure your cloth. Mild ley, or pearl-ash, should be used for the latter buckings, as the cloth becomes nearer white.

This was the management during the summer months; but for four months in winter bleaching was suspended, the operations being periodically interrupted, and the capital of the manufacturers or proprietors of the goods locked up. Even during the bleaching months, their property was long in preparing for sale; as cotton goods, which required from four to six applications or repetitions of alkaline leys, consumed so many weeks in bleaching, whilst linens, which could not be bleached by less than from twelve to twenty applications, could not be brought in a marketable state to the proprietor hardly in six months.

Such was the state of bleaching till Mr. Scheele, a Swede and eminent chemist, discovered the properties of oxygenated muriatic acid, procured by mixing manganese with marine acid, in rendering vegetable matter white; and M. Berthollet, the celebrated French chemist, improved this operation, and actually applied its powers in bleaching cotton goods by interposing its action between the different alkaline operations instead of the tedious exposure of the goods to an uncertain atmosphere; the same effect being produced by immersion of the cloth in this acid, as by laying the goods upon the grafs in the bleach-field, exposed to air and light.

Discovery of and Variations in the Mode of procuring the Oxygenated Muriatic Acid.

By the addition of vitriolic acid to common salt, an elastic aeriform fluid, or muriatic gas, is disengaged, from which with water a marine acid is produced. The mineral substance manganese, or what the modern chemists call oxyd of manganese, contains what was formerly denominated vital air, pure air, or dephlogisticated air, but now named oxygen. Manganese yields oxygen, when marine acid is added to it, and submitted to distillation; the liquor produced by the contact of this oxygen with water, is the oxygenated marine or muriatic acid discovered by Mr. Scheele, about the year 1774, when he observed and applied its effects in rendering colourless vegetable substances of various kinds, more as a matter of curiosity than use.

M. Berthollet, in the year 1786, improved the process of its preparation, applied its power to bleaching or destroying the vegetable colours natural to cloth, the result of which experiments he gave to the world in the year 1789; but, without derogating from the merit of this excellent chemist, it is justice to state, that, previous to any publication by M. Berthollet, Mr. Scheele communicated to M. Kirwan the properties of the dephlogisticated marine acid in whitening vegetable substances, and Mr. Kirwan, then residing in Newman-street, London, suggested to Mr. C. Taylor, the present secretary to the Society of Arts, &c. the probability of its use in bleaching; and a whole piece of callico, in the state received from the loom, was, in the spring of 1788, actually bleached white, printed in permanent co-

lours, and produced in the Manchester market ready for sale, having undergone all these operations in less than 48 hours, by the joint efforts of Mr. Cooper, Mr. Baker, and Mr. Taylor, which is perhaps the first entire piece, either in France or England, that fully ascertained the real merits of the new mode of bleaching, and a certainty that it might be generally useful in commerce. This experiment was immediately followed by the establishment of a large bleaching concern by Mr. Cooper, Mr. Baker, and Mr. Horridge, at Raikes, near Bolton, in Lancashire, and before any considerable bleaching work was actually at work in France.

The ingenious Mr. Watt we believe to be the first person who simplified the process of preparing the oxygenated muriatic acid, by means of a mixture of common salt and manganese, previous to the addition of the vitriolic acid. Soon afterwards the operations of the bleacher were further facilitated by the substitution of large and commodious stills of lead, instead of glass vessels, and both these improvements have since been in general use.

We shall now proceed to mark the various treatment of the oxygenated muriatic acid when obtained, and the different means which have been adopted to fit it for application in bleaching.

It having been found in the earlier stages of distillation, that common marine acid was produced instead of the dephlogisticated or oxygenated muriatic acid; and from the violence of the ebullition, that manganese itself was sometimes thrown over from the still, M. Berthollet had recourse to an intermediate vessel, containing water, to absorb the marine acid gas, and stop other impurities which might contaminate the oxygenated muriatic gas in its passage through this vessel to the receiver.

It will here be necessary to discriminate the various modes in which the oxygenated muriatic gas has been treated, after passing the intermediate vessel last mentioned.

Mr. Scheele seems generally to have operated with the acid in the state of gas; but M. Berthollet sought to condense it in water, with which he filled his receiver, or wooden vessel, and which water he kept agitated during the distillation, to accelerate the solution or combination of the gas.

The oxygenated muriatic acid, thus prepared, was drawn from the receiver into kiers, or large wooden vessels, where its strength was regulated by the addition of water; after which, the goods to be bleached were immersed therein from six to twelve hours, but most frequently during the night; and though these periods may seem short, they were sufficient to allow the cloth to become more white than could be done by as many days' exposure to the atmosphere and a summer's sun, and were then ready for a fresh application of the alkaline leys.

Such was the bleaching liquor of M. Berthollet; but it was found in practice yet defective, as the volatility of the gas occasioned its speedy separation from the aqueous solution; a decomposition even by light alone in glass vessels took place; a rapid loss in the strength of the liquor when exposed; and much danger to the health of the workmen from its suffocating quality; at the same time, that in extracting the natural colours of the cloth, it also tended to discharge the colours dyed in the yarn, and were along with the gray cotton an imperfection which precluded its use in an infinite variety of British manufactures.

Similar circumstances probably led some bleachers resident at Javelle, in France, to add a solution of caustic alkali to the water in the receiver, and by this means to remedy many of the defects complained of.

But M. Berthollet continued to recommend his process, considering such substance as impairing the bleaching powers;

BLEACHING.

an idea that was generally maintained by the chemists, but contradicted by the bleachers, whose experience taught them, that though the acid thus combined whitened with somewhat less rapidity, yet it was not eventually in an inferior extent; and the advantages of preserving the colours dyed in the yarn, compelled them to have recourse to the expensive addition of pot-ashes, in preference to M. Berthollet's mode.

Here we shall observe, that, according to the doctrine of the modern chemists, the oxygenated muriatic acid bleaches in consequence of yielding to the colouring matter of the cloth that oxygen which, in the distillation, the acid absorbed from the manganese; or, in the language of Stahl and Becher, that the dephlogisticated marine acid absorbed the colouring matter from the cloth, and was restored to its original state of common marine acid, by regaining that phlogiston which it had, in its preparation, yielded to the manganese.

In the mixture of an alkali with the acid, we have noticed that the bad consequences arising from its volatility have been corrected, and the requisite protection afforded to dyed colours, yet still that its power of whitening cloth was not diminished, nor much more time taken up by the operation; yet, in part from deference to M. Berthollet's opinion, and in part owing to the expense of the alkali, other means to produce the effect were attempted.

One of the first of these, practised by the bleachers of cotton-hose, at Nottingham, was to receive the dephlogisticated muriatic gas into a small air-tight chamber, in the upper part of which the goods were suspended from a frame, whilst at some distance below was water, sometimes impregnated with ley of pot-ash, and sometimes with lime-water, or water mixed with lime. The gas was introduced betwixt the fluid and the goods, amongst which it ascended and mixed; at the same time, by occasionally immersing the goods in the fluid below, it was sought to modify the action of the acid. This was effected by means of a pole, or long lever, connected with the frame on which the goods were suspended, the centre of which pole moved on a swivel fixed in a hole in the partition, occasionally stopped with clay, and enabled a person to let the goods down into the fluid, not always however without inconvenience, which occasioned it the name of the *Bedlam Process*.

Respecting the above process it must be observed, that the acid is much more powerful or active in the state of gas than in any other way; and though the occasional immersion of the goods into the fluid below, corrected in some degree its violent effects, yet the dyed colours disappeared more rapidly in this than in any other process, and the fabric itself was sometimes injured.

The next process attempted by the bleachers, was to put into the receiver, filled with water, a quantity of pulverized lime, then the goods themselves, and the whole agitated during the admission of the gas; the consequence of which was, that the goods thus mixed with lime were partially coated with it; and this coating being unequal, the action of the acid upon it was irregular, leaving at the same time the parts uncoated to receive the whole action of the bleaching powers; hence inequality of bleaching ensued, and an insurmountable difficulty in preserving the dyed colours of the goods to be bleached.

Having noticed the imperfections of the two last processes, we shall observe that lime-water, or a pure chemical solution of lime in water, has been sometimes substituted instead of a solution of alkalies in the receiver, but was not, when used in that manner, found to answer so well as the alkaline solution.

That lime-water could produce no valuable effect beyond what was derived from M. Berthollet's mode, or from simple water, must be evident, when it is considered that water can dissolve no more than $\frac{1}{75}$ th part of its weight of lime, a quantity wholly insignificant in neutralizing the oxygenated muriatic acid for the purpose of the bleacher; nor could pulverized lime, merely thrown into the water of the receiver, serve a better purpose, since, from its being specifically heavier than the water, all beyond the quantity in chemical solution subsided and remained nearly useless at the bottom of the receiver.

It has been already mentioned, in noticing the application of alkaline leys in bleaching, that the more intelligent bleachers, in preparing their ash-leys, made use of quicklime to augment the power of the alkali, when such alkali was in a mild state, or, in other words, combined with fixed air, or, as it is now termed, carbonic acid; the attraction of caustic lime for the carbonic acid being stronger than that of ashes. Hence, on caustic lime being thrown into mild ash-ley, the carbonic acid, by which the ashes were rendered mild, abandons the alkali to combine with the lime, leaving the ashes in their caustic state.

But, although the attraction of carbonic acid is stronger for lime than for alkali, the contrary is the case with the oxygenated muriatic acid, as it abandons lime to combine with ashes, leaving the lime to precipitate.

This observation is made in order to guard the ignorant bleacher from mistakes, who, from having mixed lime with his ash-ley in the receiver, in the preparation of the oxygenated marine acid, may suppose it acts in a similar manner; but not a particle of lime is acted upon by the acid, whilst ashes remain to combine with it; the only effect of the lime there, being to abstract from the ashes any fixed air they may contain, and so dispose the alkali to absorb more of the oxygenated muriatic acid.

Besides the processes above mentioned, the bleachers attempted to unite the oxygenated muriatic acid with clay; but as the clay has scarcely any affinity with it, the liquor thus made was little, if at all, superior to that of M. Berthollet.

Such were the attempts made from the year 1786; and the oxygenated muriatic acid combined with pot-ash was in general use by the bleacher until 1798, when Mr. Tennant, of Glasgow, by a well conducted series of experiments, formed what may not improperly be called a new era in bleaching.

Mr. Tennant, having seen so long a period elapse without any material improvement in bleaching, and the alkali, though an expensive ingredient, regarded by the bleacher as an indispensable article to unite with the oxygenated muriatic acid in the receiver, made some trials with the earths stromtites and barytes, and with success. Their solubility in water enabled him to combine them with a sufficient quantity of oxygenated muriatic acid to serve the purpose: but the scarcity of stromtites, and the difficulty of separating barytes from the vitriolic acid, with which it is usually found in combination, rendered these discoveries rather objects of curiosity than use.

Mr. Tennant had previously made experiments to combine the oxygenated muriatic acid with lime and lime-water, in the modes above-mentioned, but found they were not adequate to the purposes intended; the lime in general remaining at the bottom of the receiver uncombined with the gas, which was the necessary consequence of the lime being specifically heavier than the water, and the gas much lighter; the water, by its interposition betwixt the two substances which ought to be combined, namely the oxygenated muriatic gas and the lime, preventing their union. To bring the pulverized lime into contact with the gas as quickly as

BLEACHING.

it entered the receiver, became then the object of his attention; and for this purpose he found it was necessary to keep the lime floating, or diffused through the fluid, which he succeeded in accomplishing by two different methods; one of which was by increasing the specific gravity of the water in the receiver, by the addition of common salt, and thus retarding the lime from subsiding; the other mode was by constant agitation of the lime in the water in the receiver, to keep the lime diffused through the fluid, during the time the oxygenated muriatic gas was introduced; and by this means he succeeded in uniting and retaining a much greater quantity of gas with the mixture, than by any method heretofore used, and without the addition of any ashes or alkaline substances.

A very material advantage was gained by this discovery; namely, that it uniformly afforded security to the dyed colours in a superior degree to the alkaline ley.

It is well known, that in the alkali of commerce, such as pot-ash or pearl-ash, a large and very irregular proportion of neutral salts is intermixed, which are soluble along with the alkali in water, thereby so far contaminating the ley, that the bleacher is always uncertain what quantity of pure and active alkali it contains. In bucking or boiling cotton goods, the detriment from these neutral salts is not so great, as a repetition of the process may compensate for those admixtures in the ley; but in the bleaching liquor formed by the mixture of the oxygenated muriatic gas with such ley, if there is a deficiency of alkali, the uncombined oxymuriatic acid immediately attacks the dyed colours of the goods, and discharges them, and thus considerable damage frequently occurs before the real origin of the evil is ascertained and corrected. The bleacher is kept in a constant state of alarm respecting the quality of the ashes he makes use of, besides the great cost of their purchase. In using lime for the same purpose, the expence is a mere trifle; what is not combined with the oxymuriatic acid precipitates, after the agitation is over, leaving a pure liquor free from all uncombined acid.

Simple as the combination of the lime with the oxygenated muriatic acid may now appear, yet it was a long time attempted in vain; but this, perhaps, will not be such a matter of surprize, when we reflect that the French chemists, whose opinions were regarded generally as law by the common bleachers, and whose treatises on the subject of bleaching were almost the only accounts published, considered lime as no farther useful in bleaching, than in absorbing the carbonic acid or fixed air usually combined with alkalies or ashes; and thus rendering the alkaline ley more disposed to unite with the oxygenated muriatic gas, when exposed to its contact in the receiver, to form, as it is called, the liquor de Javelle; or when intended for use as a mere alkaline ley, to render its action more powerful on the oily particles in the vegetable fibre, on a similar principle to the formation of soap.

An excellent treatise on the subject of bleaching, in the English language, viz. "The Report on Experiments made by order of the right honourable the trustees of the linen and hempen manufactures to ascertain the comparative merits of specimens of oxygenated muriatic bleaching liquors," published at Dublin in the year 1791, in claim of a bounty offered by the trustees, appears to convey no further knowledge of the use of lime in bleaching at that time than in promoting the separation of the carbonic acid from the leys, whether they were afterwards to be used alone, or in the preparation of the oxygenated muriatic acid. Mr. Rose's experiments in this report contain, however, much useful information, which we shall further notice.

The simplicity of Mr. Tennant's invention of retaining a greater quantity of the oxygenated muriatic gas, by agitation of a sufficiency of lime in the water of the receiver, should be no derogation to its real merit. In substituting lime for pot-ash, an article, not only of foreign produce, but expensive, he has benefited this country, to an extent almost beyond conception; it having been proved upon oath, that by the use of Mr. Tennant's process, the consumption of ashes at a single bleaching-green has been reduced three thousand pounds sterling in value in one year. A patent for Mr. Tennant's invention was granted him in the year 1798; but as frequently happens in patent causes, on a late trial of its validity, some circumstances arose from which the jury thought themselves justified in reversing the patent; we have therefore with considerable pains collected for the public benefit an account of his process, and the most approved mode of putting it in practice, either on a small or an extensive scale, as will be seen by a reference to *Plate I.* of *Bleaching* hereafter described.

Mr. Tennant's method of using calcareous earth for neutralizing the muriatic acid gas, and forming the oxy-muriat of lime employed in bleaching is as follows; viz.—In a receiver capable of containing one hundred and forty gallons wine measure, dissolve thirty pounds of common salt, which appear useful only in giving an additional degree of specific gravity to the water, and by that means making it easier to keep the lime to be afterwards added, in suspension; when this salt is dissolved, add sixty pounds of finely powdered quicklime, and into the retort of the apparatus put thirty pounds of powdered manganese, mixed up with thirty pounds of common salt, upon which pour thirty pounds of sulphuric acid (oil of vitriol), previously diluted with its bulk of water, and the usual precaution of luting the vessel being taken, proceed to distillation. When the gas begins to appear, the agitation of the lime and water in the receiver must commence, which should be continued by means of a wooden paddle or rake, or similar contrivance, without intermission, until the materials in the retort, after heat being employed as usual, will not yield any more oxygenated muriatic acid gas. Then the whole should be allowed to remain at rest for two or three hours, when the clear liquor in the receiver, may be drawn off for use, and mixed with water in such proportions as may be found necessary, previous to the immersion of the goods to be bleached.

The principal point of attention in preparing this oxygenated muriat of lime is, to obtain a complete diffusion of the lime through the mixture, or a mechanical suspension of it in the water during the operation, so that every particle of the lime may, by agitation, be exposed to the action of the gas, instead of merely its upper surface, as had been formerly practised. By the present means, the oxygenated muriatic acid gas is absorbed with ease, and meets with a sufficient quantity of lime to produce a strong solution of oxygenated muriat of lime, without any uncombined oxygenated muriatic acid; a thing which could not be otherwise effected. The addition of the common salt in the receiver may even be omitted, without prejudice, if the agitation of the lime be well managed.

Plate I. fig. 2. of *Bleaching*, shews a longitudinal section of a method, which has been practised in Ireland for distillation of the oxygenated muriatic acid, and the formation of the oxygenated muriat of lime. *a*, the ash-hole; *b*, the fire under the iron pot or vessel; *c*, the aperture through which it is supplied with coals; *d*, the entrance to the ash-hole, which may be provided with a stopper of burnt clay, or earthen ware, to regulate the draught of the fire, by means of the handle shewn by dotted lines; *e*, a cast-iron pot or vessel,

BLEACHING.

vessel, nearly filled with water, in which the leaden retort is placed; *f*, a tripod of iron, on which the retort stands; *g g*, the leaden retort, from which the gas is to be distilled; *b*, a tunnel of bent lead, through which the oil of vitriol (sulphuric acid) is to be introduced into the retort; *i*, a leaden cover, fitted and luted to the neck of the retort, having three apertures, viz. for the introduction of the tunnel, the rod of the agitator, and the tube of the condenser; *k*, the agitator, formed of a rod of iron coated with lead, having some arms at its lower end to stir the materials within the retort. At the part where the rod passes through the cover, a leaden collar or cap is soldered, to prevent the agitator from descending too low; these two parts are made in a conical form, to fit exactly, and thus prevent the escape of the gas; *l*, a leaden tube or pipe, of three inches bore, to conduct the gas into the tubulated reservoir; *m*, the leaden reservoir, formed upon the principle of Wolfe's apparatus; the tube, *k*, descends by the first aperture, *m*, to the bottom of the reservoir, which is about two thirds full of water. The small portion of sulphuric acid, which rises in distillation, unites with this water; the oxygenated muriatic acid, which traverses this water, passes by the pipe, *n*, into the receiver or condenser, *o o*, which is a wooden vessel, in the middle of which is placed an agitator, *p*, the arms of which raking up the lime cause it to combine with the gas, in proportion as it arises in bubbles from the lower extremity of the leaden pipe, *n*.

The projections of wood, *q q q q*, fixed to the staves within the tub, counteract the rotatory motion of the arms of the agitator, and thus assist the combination of the gas with the lime and water. The cover of this tub is fixed close upon the edge of it at *r*; the cover having a groove in it to unite them tighter together; *s*, a cock to draw off the liquor, when sufficiently impregnated for use; *t*, a wooden handle to give motion to the agitator. The joints may be luted with clay, to prevent the escape of the gas.

Fig. 3, and 4, shew Mr. Tennant's improved machinery for preparing the oxy-muriat of lime. The outline, *A*, (*Pl. 1.*) is the still, made of lead, of a circular form, having a double flange at the top, which is filled with water, to prevent the gas from escaping in that direction. *B*, the leaden cover of the still, having a flange on the under side, which goes into the double flange of the still, and having a double flange on the upper side, which is filled with water; the inner part of this double flange consists of a short tube, which goes quite through the cover, opening by this means a communication with the still, and allowing the gas to escape through the long leaden pipe inserted into it, and from thence into the receiver, as explained at *fig. 4*, where there is a section of the still, furnace, and receiver; *a*, the still; *b*, an iron pan in which the still is placed on an iron stand; this pan is then nearly filled with water; *c*, the fire-place; *d*, the furnace door; *e*, the ash-hole; *f*, double flange filled with water; *g*, the cover, with flanges on the upper side filled with water. *D*, the receiver, made of wood, and lined with lead; *i*, a double flange filled with water, the interior pipe communicating with the inside of the receiver, and bent horizontally as at *k*, from whence the gas issues into the receiver; *l, l*, two short pipes inserted in the top of the receiver, through which the rods of the agitators have a free motion; *m, m*, a stopper in the top of the receiver, closed when the receiver is at work, but sufficiently large, if removed, to admit a person into the inside to repair or cleanse it, when necessary; *n, n*, two paddles, or agitators, generally of a square form, and of a similar construction to the head of a churn staff; *o, o*, the rods of the agitators attached by iron pins to the lever, *q*, which lever has slits at

the place of junction, to allow the rods to rise and fall perpendicularly; *p*, the fulcrum or support of the lever; *q*, the lever, which, by a proper motion communicated to it, alternately raises and depresses the agitators in the receiver; *r*, a rod connecting the lever *q*, with the lever *s*, which last lever is put in motion by the wheel *E*; *t*, a balance weight placed at the other end of the lever; the beam supporting the fulcrum of the lever being near the letter *s*. *E*, the wheel to be put in motion by water, or in any other way, having a crank, *u*, communicating by an upright shaft with the lever *s*.

It will be found that the flanges, filled with water, preclude the necessity of the application of any lute, and occasion the operation to be conducted in a cleaner, cheaper, and more expeditious mode, than formerly employed.

To describe the proportions of the several articles used in the process of bleaching, would carry us far beyond the bounds which can be allotted in the present publication; we shall, therefore, give the following short but clear account of the mode we recommend to be practised, to procure the most perfect and durable white on cotton goods, after their being taken from the weaver; which is, first, to wet them thoroughly in cold water; then to allow them to steep in cold, or lukewarm water, from 12 to 36 hours, according as they are of a strong or thin fabric; then to wash them well in clean cold water; afterwards to buck or boil them in a caustic alkaline ley; then to wash the goods well in clean water, and afterwards immerse them in diluted oxymuriate of lime; and wash them, repeating the operations of the alkaline leys, and the oxymuriate of lime, till the goods are perfectly white; then to pass the goods through the diluted sulphuric acid liquor, washing them well afterwards; lastly, to pass them through a weak ley of pearl-ashes, or of soap, and again through clean water, before drying and finishing them; which finishing of the goods consists in starching, blueing, rolling, or callendering them as fashion directs, or the particular market for which they are intended, may require.

It is to be remarked, that the immersion of the goods in the vitriolic fours, and also in pearl-ash, or soap liquor, is necessary at the end of the process, to prevent a brown hue which the cloths that are bleached white from the oxygenated muriatic acid, without such precaution, are apt to revert to.

By experiments made at Rouen on cotton thread, with a view to ascertain whether the old or new mode of bleaching was more prejudicial to the fabric, it was proved that the cotton thread bleached in the new mode bore, without breaking, considerably more weight than that bleached in the old method, and was less injured in texture.

In the report on experiments, made by order of the trustees of the linen and hempen manufactures at Dublin, in the year 1791, with a view to ascertain the comparative merits of several specimens of bleaching liquors sent for their examination, the following mode of bleaching appeared to be the best for linens, and though executed on a small scale, will convey the principal necessary information.

May 11th, 1791. The linen was steeped, in the state received from the loom, in to water of a heat sufficient to bear the hand, and left in the vessel.

May 16th. The linen was washed out of the liquor, in which a pretty strong fermentation was observed to have taken place.

May 17th. Finished making a mother-ley, which was made in the following manner: three pounds and a half of lime were slaked, and mixed with ten gallons of water; fourteen pounds of Danzig pearl-ash were dissolved in some of this water; then mixed the whole; when it had settled, it

BLEACHING.

was filtered through a coarse cloth, and the residuum washed repeatedly in four gallons of water, to obtain the whole strength of the alkali; the whole fourteen gallons being then carefully mixed, the ley proved, by very accurate weighing, to contain twelve ounces of caustic alkaline salt to the gallon. From this, a ley was made from the work, by adding six parts of water to one of the mother ley; thus each gallon of the working ley contained one ounce, five drachms, and forty-three grains of caustic alkali.

The boiler being charged with this ley, the linen, which had been spittle washed, was steeped in it cold for one hour; then brought up by a very gentle heat to a simmering boil, which was continued for three hours; the cloth was then well washed out, and left in steep for that night.

May 18th. Washed out the above linen in fresh water; hung it on cards in the open air, watering it several times in the day.

May 19th. Finding the cloth not so well cleared as could be wished, the boiler was again charged with one of mother-ley, to four of water, which made the strength two ounces, three drachms, twelve grains of caustic alkali to the gallon. In this was boiled another piece of linen which had been spittle washed as the others; and after it was boiled, it was well washed out.

May 20th. Steeped the whole of the linens for six hours in the liquid prepared with the oxymuriatic acid of the several claimants; afterwards washed them well out, and left them steeping in cold water all night.

May 21st. Washed out all the above linens, and when dry, boiled the whole parcel as before in one of the mother-leys, to five of water, containing two ounces of caustic alkaline salt to the gallon; washed them well out of the ley, and left them to steep in pure water till Monday morning, the 23d instant.

May 24th. Steeped the linens for the second time in the oxygenated muriatic acid for six hours; then washed them out, and left them to steep all night in cold water.

May 25th. Having charged the copper with a ley made from one of mother-ley, to six of water, containing one ounce, five drachms, and forty-three grains of caustic alkaline salt to the gallon, the linens were boiled in this for the third time, with a very gentle simmering heat for three hours; they were then washed out, and left to steep.

May 27th. Steeped all the linens for the third time six hours in oxygenated muriatic acid as before; washed them out, and left them in water all night.

May 28th. Immersed all the linens which had been steeped yesterday in the oxygenated muriatic acid, in a weak vitriolic acid for four hours; then washed them out, and left them steeping in cold water.

May 29th. Washed and dried the linen cloth which had been soured yesterday.

June 1st. Boiled all the linen which had been soured in a strong lather of soap.

June 2d. Soured and washed out all the linen which had been boiled in a soap lather yesterday. This operation finished that experiment, in which the above linens were first steeped in water; then boiled in caustic alkaline ley, and steeped in oxygenated muriatic acid alternately four times; then soured in vitriolic acid, soaped and soured again.

The above experiments were made, with various others, by Mr. John Arbuthnot, and Mr. John Clarke; and on the trials of the different specimens of the oxygenated muriatic acid, the preference was given to that prepared by Mr. Robert Roe, of Bing's End, on the principle of the javelle liquor mentioned by Mr. Bartholles, by adding a solution of alkali in water in the receiver. Mr. Roe's best prepara-

tion, of which was made by adding thirty-eight pounds of quicklime to 114lb. of pearl-ash, which made a caustic ley of about nine pounds weight per gallon; he found caustic ley more susceptible of imbibing the gas and retaining it, than mild ley of equal strength.

From the different experiments made to bleach various articles at the above time, the following inferences may be deduced, viz. that allowing cotton or linen, when raw from the loom, to ferment, by steeping in warm water a considerable time before boiling the cloth in an alkaline ley, is of considerable service.

That cloth or yarn is not injured by steeping for six hours together in oxygenated muriatic acid.

That strong alkaline leys answer better than weak ones, at the commencement of using the leys.

That the white colour of bleached cloth can be better judged of wet than when dry.

That very minute attention in excluding light and air is not absolutely necessary in bleaching with oxygenated muriatic acid.

That purging or clearing yarn or cloth in an alkaline ley, previous to steeping in oxygenated muriatic acid, is absolutely necessary.

That the bleaching liquids made from oxygenated muriatic acid, in which alkaline salt is blended in the composition, require the cloth to be frequently steeped in vitriolic acid; and that the oxygenated muriatic acid made with water only, make more frequent boilings of the cloth in alkaline leys necessary.

That the loss of the cloth in weight, when bleached by the new method, is only one fourth, but by the old method one third.

That steeping in warm water is infinitely better to extract the sown and dirt from the raw cloths, than boiling them with soap or ley immediately as they come from the loom.

The liquors of the oxygenated muriatic acid, and also those made from the vitriolic acid, may be repeatedly used without detriment, till the whole strength is exhausted.

The cloth or linen, in the acid bleaching liquors, should be moved in the liquor every hour, that every part may be equally cleared.

It is difficult to ascertain the strength of the leys proper for use in bleaching cotton or linen, as the alkalies or ashes differ so greatly in purity, and the admixture generally found in them of neutral salts prevents the hydrometer from being a regular test. The common allowance for bleaching linens in Ireland, is stated by Mr. Higgins, in his ingenious memoir in the Transactions of the Dublin Society, to be for sixty gallons of water, six pounds of barilla, or four pounds of pot-ash at the least, and most bleachers use more than this.

To discover adulterated pot-ash, Mr. Higgins recommends the following method. The specimen of ashes being first weighed, is digested for a few minutes on a sand-bath, in twice its weight of water, in a heat of about 212 degrees, and instantly stirred. It is then removed from the sand-bath, and before it is cooled to the temperature of the atmosphere, it must be filtered through paper. When all the liquor has passed through the filter, a small quantity of cold water is gradually poured upon the saline residuum or the filter, in order to wash through the whole of the alkali. The undissolved salt sulphate of pot-ash (vitriolated tartar,) remaining on the filter, is afterwards dried and weighed, to ascertain the quantity.

To determine whether any common salt is suspended in the liquor which has been filtered, evaporate the clear solution a little on a sand-bath, and set it in a cold place for 24 hours.

BLEACHING.

hours; at the end of which time, any common salt it contains will be found crystallized in regular cubes at the bottom of the vessel; pour off the clear liquor, and repeat the process, till no more cubic crystals are produced. If it is desired to be very accurate in the analysis, before the common salt (muriate of soda) thus procured is weighed, some muriatic acid may be poured upon it, in order to take up any of the pure pot-ash which may have adhered during its crystallization. The muriatic acid, with such of the alkali as it has dissolved, may be then drained off and thrown away, and the muriate of soda dried and weighed.

The sum of the impurities being then subtracted from the weight of the specimen, the quantity of the pure pot-ash is ascertained.

To shew what quantity of mere alkali is contained in 100lb. avoirdupois of several different alkaline salts examined by Mr. Kirwan, we shall add the following table, published by him in the Irish Transactions, in 1789.

One hundred Pounds.	Mineral Alkali.
Crystallized soda - yielded	20lbs.
Sweet Barilla - - -	24
Mealy's cunnamara kelp - - -	3.437
Do. desulphurated by fixed air - - -	4.457
Strangford kelp - - -	1.25
One hundred Pounds.	Vegetable Alkali.
Dantzic pearl-ash - yielded	63.33lbs.
Clarke's refined ash - - -	26.875
Cassup - - -	19.76
Common raw Irish weed-ash - - -	1.666
Do. slightly calcined - - -	4.666

It is much to be regretted that, considering the immense quantities of pure marine alkali which could be procured at a cheap rate from the East Indies, so little attention should be paid by the East India company to an article which would be so profitable a branch of commerce to them, and prevent a considerable sum being paid to other nations. The mineral alkali procured from the East Indies, is much purer than what is obtained from Barilla; and a preparation exactly similar in appearance and quality to the Alicante Barilla, may be made with great advantage to the manufacturer, from a mixture of the East India mineral alkali with the common Scotch kelp, for the purposes of the bleacher, the soap-maker, or the Turkey-red dyer. To shew the importance of this object, the following table of the imports into Great Britain are annexed for seven years.

	Barilla.	Pot-Ashes.	Pearl-Ashes.
1796	86.723 cwt.	62.829 cwt.	45.290 cwt.
1797	51.185	57.826	36.674
1798	123.990	81.482	60.691
1799	146.163	77.246	51.792
1800	179.629	135.40	45.161
1801	63.210	90.523	54.835
1802	151.796	48.054	64.288

When it is considered that 20 pounds of the mineral alkali brought from India in a powdery state, as it usually is, will, by mere solution in water, yield 100lbs. of the crystallized soda fold in the shops, it will be seen, that the purchase of the mineral alkali from the East India company, will be an object well deserving the attention of the bleachers and soap-boilers; and far preferable to the use of Spanish kelp or Barilla.

Mr. Kirwan, by means of muriatic acid, precipitated the colouring matter from an alkaline ley, saturated with the colouring matter of linen yarn, and found it to possess the following properties. When suffered to dry for some time on a filter, it assumed a dark green colour, and felt somewhat

clammy, like moist clay. His observations in the Irish Transactions for 1789, are as follow:

"I took, says he, a small portion of it, and added to it 60 times its weight of boiling water, but not a particle of it was dissolved. The remainder I dried in a sand-heat; it then assumed a shining black colour; became more brittle, but internally remained of a greenish yellow, and weighed one ounce and a half."

"By treating eight quarts more of the saturated ley in the same manner, I obtained a further quantity of the greenish deposit, on which I made the following experiments:

1st. Having digested a portion of it in rectified spirits of wine, it communicated to it a reddish hue, and was, in a great measure, dissolved, but by the effusion of distilled water, the solution became milky, and a white deposit was gradually formed; the black matter dissolved in the same manner.

2d. Neither the green nor the black matter was soluble in oil of turpentine or linseed oil, by a long continued digestion.

3d. The black matter being placed on a red-hot iron, burned with a yellow flame and black smoke, leaving a coal residuum.

4th. The green matter being put into the vitriolic, marine and nitrous acids, communicated a brownish tinge to the two former, and a greenish to the latter, but did not seem at all diminished.

"Hence, it appears, that the matter extracted by alkalies from linen yarn, is a peculiar sort of resin, different from pure resins only by its insolubility in essential oils, and in this respect resembling lacs. I now proceeded to examine the powers of the different alkalies on this substance, eight grains of it being digested in a solution of crystallized mineral alkali, saturated in the temperature of 62°, instantly communicated to the solution a dark brown colour; two measures (each of which would contain eleven pennyweights of water), did not entirely dissolve this substance. Two measures of the mild vegetable alkali dissolved the whole."

"One measure of caustic mineral alkali, whose specific gravity was 1.053, dissolved nearly the whole, leaving only a white residuum."

"One measure of caustic vegetable alkali, whose specific gravity was 1.039, dissolved the whole."

"One measure of liver of sulphur, whose specific gravity was 1.170, dissolved the whole."

"One measure of caustic volatile alkali dissolved also a portion of this matter."

The colouring matter of cotton is much more soluble in alkali, than that of linen: hence the greater facility with which cotton is bleached.

The theory of bleaching vegetable matter, as we have before observed to have been described by Mr. Delaval, depends on removing the colouring matters, whether natural or accidental, which cover their solid fibrous parts, which are the only parts endued with a reflective power.

Raw cotton or linen, boiled in a diluted solution of caustic alkali, gives to the liquor a deep brown colour, and destroys its causticity; and fresh portions of clear ley applied a second or third time, will produce a similar effect, but in an inferior degree. If the cotton or linen be now plunged into the oxymuriatic acid, and allowed to remain a short time, they will become white; and if they are then plunged into an alkaline ley, the liquor will again become brown, and lose its causticity.

On saturating either the first or last of the alkaline solutions with an acid, a similar precipitate is obtained from each, of a dark coloured matter, almost insoluble in water, but soluble in caustic alkali.

Hence

BLEACHING.

Hence it appears, that after raw cotton or linen has been acted upon by alkalies for two or three times, they have no further effect upon it, till the cloth comes in contact with oxygen or pure air, either by immersion in the oxygenated muriatic acid, or by exposure to the atmosphere; and it is on account of the speedy action of the acid, in comparison with that of the atmosphere, that the new mode of bleaching is now generally adopted.

M. Berthollet, and the modern chemists suppose, that the colouring matter of linen is composed principally of carbon and hydrogen; and they conclude, that linen, bleached by the oxymuriatic acid, becomes yellow on this principle, that when the oxymuriatic acid renders linen white, a quantity of oxygen has combined with the colouring particles; but that this oxygen gradually enters into a combination with the hydrogen, and forms water which passes off; that then the carbon becomes predominant, and the linen, in consequence, assumes a yellow colour.

The old chemists, on the principles of Stahl, would say, that a part of the dephlogisticated marine acid, (oxymuriatic acid,) after the cloth had been acted upon by the alkali, absorbed such phlogistic colouring matter from the cloth, as the alkali had no affinity for; and thus became diluted common marine acid, which has a great attraction to cotton or linen, and, if exposed to a moderate heat, will act upon the texture of the cloth, and render it of a yellow colour.

We notice this circumstance in two different points of view, that the bleacher may be aware of the necessity of applying, in either case, a weak ley of pearl-ash, ultimately after the use of the muriatic acid, to prevent this yellowness from occurring; and also that the reader may comprehend the reasoning of Home, and other persons who have written upon the subject of bleaching, previously to Mr. Scheele's discovery.

To recover the pure alkali from the black coloured leys, which have been used in bleaching, and to render them equally proper for the same purpose, has been for a considerable time a material object in the neighbourhood of Manchester, and practised with great success.

To effect this, the black or brown strong leys, which have been left after bucking linen, or cotton yarn, or goods, or saved after wringing them, is put into an oblong flat shallow iron pan, made of plate iron, rivetted together. (See *Plate IV. fig. 4, 5.*) Under this pan a fire is made, and the old leys gradually evaporated, till they become of a consistence nearly resembling tar; the matter is then put into casks, and carried to the reverberatory furnace, *Plate IV. fig. 6, 7.* where it is laded or poured into the cavity or bed within the furnace; the fire being then made, acts powerfully on the alkaline mass; gradually dries the water left amongst it; then acts on the colouring matter the ley has abstracted from the cloth, which is partly dissipated in a black, offensive smoke, and partly destroyed by combustion; the calcination of the ashes is assisted from time to time, by raking them up with a long iron rod, in order to expose fresh surfaces to the flame; the heat is continued and increased till the inflammable matter amongst the alkali is dissipated, and the ashes brought to a perfect fluid state; they are then let out by an aperture in the side of the furnace, into an old iron pot put into the ground, and when cold, broken into small pieces for use, being frequently in a purer state than when first imported.

Fig. 4. Plate IV. is a section of the evaporating pan for the waste leys, where A represents a flat iron pan, of an oblong square form, about six inches deep, and of a size proportionate to the quantity of leys to be evaporated; B, the fire-place; C, the ash-hole; D, the flue in which the fire

acts under the pan; E, the chimney for the smoke; F, the brick work.

Fig. 5. Plate IV. is a bird's eye view of the same evaporating pan, which is made of plates of beaten iron rivetted together, as shewn in the plan; the fire-place underneath it is marked by dotted lines at B, and the chimney flue at E.

Fig. 6. Plate IV. represents a longitudinal section of the reverberatory furnace used in the preparation of ashes, or solid alkaline salts from the old leys after evaporation, to a proper consistence; *a* the brick work; *b*, the ash-hole; *c*, a channel, or passage under the furnace, to admit a free current of air; *d*, the fire-grate; *e*, the fire-place; *f*, the inner part of the furnace; *g*, the bed of fire proof brick, on which the matter is calcined; *h*, the alkaline ley to be calcined; *i*, a door through which the ley is introduced by an iron ladle into the furnace, and through which door the matter, during calcination, is stirred from time to time; *k*, the passage for the smoke, or chimney, which chimney should be from 20 to 30 feet high; *l*, the upper part of the furnace, arched like an oven; *m*, the separation wall between the fire and matter to be fluxed or calcined.

Fig. 7. Plate IV. represents the upper plan of the furnace, of which *fig. 6.* is a section; *a*, the outer walls; *b*, the ash-hole and draught-hole; *c*, the iron grate of the fire-place; *d*, the basin in which the leys are calcined; *m*, the door through which fossil coal is thrown into the fire-place; *n*, an iron tube through which the ashes in fusion flow out of the furnace when sufficiently calcined; *o*, an iron pot into which the melted ashes flow, and where they are suffered to cool; *p*, a wall of fire-brick between the fire-place and basin, over which wall the fire passes; *r*, the steps leading down to the ash-hole.

It is necessary to remark, that all the interior part of the reverberatory furnace should be made of Welsh brick, or such as will withstand the action of a strong fire; the whole building should be well bound together by iron bars, or cramps. If so constructed, it will last for several years; and when it then wants repair, the ashes, which will be found accumulated in the interstices of the brick-work, will defray the expence of such repairs.

Having shewn the methods generally used in bleaching linen and cotton, we shall notice a process lately discovered by Mr. W. Higgins of Dublin, for using the sulphuret of lime, as a substitute for pot-ash in bleaching. The sulphuret is prepared in the manner following, viz. sulphur or brimstone in fine powder, four pounds; lime well flaked and sifted, twenty pounds; water sixteen gallons; these are all to be well mixed, and boiled for about half an hour in an iron vessel, stirring them briskly from time to time. Soon after the agitation of boiling is over, the solution of sulphuret of lime clears, and may be drawn off free from the precipitate, which is considerable, and which rests upon the bottom of the boiler. The liquor, in this state, is nearly of the colour of small beer, but not quite so transparent.

Sixteen gallons of water are afterwards to be poured upon the remaining precipitate in the boiler, in order to separate the whole of the sulphuret from it; the matter is then well agitated, and must, when settled, be drawn off, and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which reduce the liquor to a proper standard for steeping the cloth.

Though either lime or sulphur, separately, is very little soluble in water, yet this sulphuret of lime is highly soluble.

This preparation has been applied, in the following manner, to the bleaching of linen in Ireland.

BLEACHING.

The linen, as it comes from the loom, is charged with the weaver's paste or dressing, to discharge which, the linen must be steeped in water for about 43 hours, and afterwards taken out and well washed; in order to separate the resinous matter inherent in the vegetable fibre, the linen must then be steeped in the cold solution of sulphuret of lime (prepared as above), for about 12 or 18 hours; then taken out and well washed; when dry, it is to be steeped in the oxy-muriate of lime, prepared by Mr. Tennant's process, for 12 or 14 hours, and then washed and dried. This process is to be repeated by six alternate immersions in each liquor, which are sufficient to whiten the linen.

Though we must confess, that we have some doubts respecting the application of sulphuret of lime to supersede the use of ashes, in bleaching goods intended to remain perfectly white, yet we think it incumbent upon us to state, that for goods previously bleached for dyeing, it possesses advantages over those where alkalies have been used, and which has been actually proved above 30 years ago, by the practice of Mr. Peter Henry Otterfen, communicated by him to the late Mr. John Wilson, of Aisworth, near Manchester. Mr. Wilson's memory deserves every mark of respect from the cotton manufacturers of England, for his numerous improvements in the bleaching, dyeing, and finishing of cotton goods.

For the use of private families, where the linen is dirtied by perspiration or grease, it will be of great service towards rendering it white, to steep it for some time in a clear liquor, made by mixing one quart of quicklime in ten gallons of water, letting the mixture stand 24 hours, and then using the clear water drawn from the lime. After the linen has been steeped in this liquor, it should be washed as usual, but will require much less soap to be used.

Cotton goods, after bleaching, were formerly dried in the open air, on frames or tenter-rails, or on rails in covered buildings, or in large rooms or stoves heated for the purpose, all which modes were attended with great delay and disadvantages.

These difficulties were removed in 1797 by an apparatus, simple in its construction, easily managed, and of singular use in facilitating the process of the bleacher. For this useful invention the public are indebted to John Burns, esq. of Paisley.

By this discovery the bleacher can erect a drying machine, equally useful at all seasons, and in all weathers, at less than one-tenth of the expence of former constructions, for doing business to the same extent. There is no risk of damage from wind or rain, less chance of injury from servants, owing to the simple manner in which the goods are prepared. They receive a fine gloss during the process of drying, the colour is as well preserved as if dried in the open air, and they cannot be injured by the heat.

A contrivance so obviously beneficial and complete, was soon introduced into general practice in the west of Scotland; and so undoubted were the claims of the above gentleman on the originality of invention, that the bleachers in the neighbourhood presented him with a handsome donation of silver plate, suitably inscribed, in testimony of their sense of his merit, and as some reward for communicating his plan to the public.

We are more particular in noticing this circumstance, as some other persons have subsequently taken out a patent for the same principle, with a little variation in the construction of the machine, but which alteration has not been found to answer the purpose as expected. We shall therefore now more particularly describe Mr. Burns's apparatus for drying.

Fig. 1. Plate III. A is the boiler or steam vessel; B, the

safety valve; C, the hollow leaden pipe which conveys the steam from the boiler to the rollers; D, a brass cock hollowed to receive the pivot of the roller, represented in *fig. 2*, one of which cocks is fixed to the pipe under each roller, and by opening which the steam is admitted into the roller; E represents twelve rollers placed upon the cocks, one of which, next to D, has the cloth upon it in the operation of drying; FFF, the wood frame in which the machinery is placed; GGG, the supporters of the leaden steam-pipe, and of the trough H H, which trough is 15 inches broad at top, to receive the water formed by the condensed steam as it drops from the bottom of the rollers, E, and to conduct it to I, a small pipe extending from the trough, H, to the funnel, K, which funnel has its lower pipe reaching to within eight inches of the bottom of the boiler, to prevent the steam from issuing out at its mouth, and which funnel keeps the boiler supplied with water to its proper height, or skews when any is wanted, as the steam would arise through it if water should be wanting in the boiler.

Fig. 2. Plate III. shews one of the rollers separate from the frame. It is usually five feet long, one foot in diameter, and made of double tinned sheet iron, and hollow in the middle, for containing the steam; *a* is the lower pivot of the roller, which is an open tube at the end for receiving the steam conveyed through it from the cock. This pivot rises a foot within the roller, at the under part of the roller; at *d* is a small hole for allowing the condensed steam to drop into the trough placed below it as above-mentioned; *b*, the other pivot or axis of the roller, which is fastened to the top bar of the frame by a latch, as represented in *fig. 1*; *c*, a row of teeth fixed into a small slip of tinned sheet iron, soldered to the roller, and thereby elevated to prevent the teeth from tearing the cloth.

Fig. 3. Plate III. a machine about three feet in height, for the purpose of lapping the cloth upon the rollers. A, the box in which the cloth is first laid; B, the farthest wooden roller, over which the cloth passes from A, and from thence under the wooden roller C, to the tin roller D, on which it is lapped by turning it with the handle E; F, the cloth passing under the roller C, to the tin roller D, on which, when it is lapped, it is ready to be carried and placed in the drying machine; G, a weight hung from the projection in the frame at H, over the roller B, to keep the cloth sufficiently tight as it passes from the box A, over that roller to be lapped on the drying roller D.

Fig. 4. Plate III. shews another method of lapping the cloth on the tin roller, previous to its being dried. A, a perpendicular frame, in the front of which is placed the tin roller B, with a handle for turning it at C; the cloth D extends from the roller B over the wooden roller E, in a frame F to G, where its other end is attached by a wire run across it to some wrapper or linen cloth, fastened to a board H, fixed below the roller B. LL are upright posts fixed to the outer side of the bottom frame KK, having wooden pegs NN in them, on the side nearest the tin roller B. Rails or rods are laid across from these to similar pegs opposite, to prevent the cloth touching the ground when it is adjusting in the beginning of the operation, and the number of these posts necessary, therefore, are in proportion to the length of the cloth.

At the commencement of lapping the cloth on the tin roller B, the frame F, moveable on small rollers II, running in grooves on the frame KK, is drawn so far back, that when the cloth is fastened to the wrapper G, one half of the piece reaches to the roller F, the other half passed over that roller, reaches to the tin roller B, to which it is then to be fastened. On turning the handle C, the cloth is gradually lapped round

BLEACHING.

the roller B, the moveable frame F being drawn forward by the cloth; for as the cloth is lapped on the roller B, the frame F is drawn towards it betwixt the uprights LL, and by means of a projecting wood forming an inclined plane fixed at M, on each side, near the top of the frame F, the rails O are raised off the pegs NN, and carried forward on the part M of the frame F, without impeding its progress to the tin roller B, till the wrapper G, to which the cloth is fastened, passes over the roller, and the wire at G, which attaches it to the cloth, is withdrawn, leaving the whole of the cloth to be dried on the tin roller B, which roller is then taken out and placed in the drying frame.

To ascertain the strength of the oxygenated muriatic acid used by the bleachers in France, Mons. Desferoizilles made use of a solution of indigo in the vitriolic acid, for which purpose he takes one part of finely pulverized Guatimala indigo, and eight parts of concentrated vitriolic acid, which mixture should be put in a glass vessel, and kept of a gentle heat by standing near the fire or in warm water all night, and repeatedly stirred with a glass rod or tube. When the solution is complete, it is diluted with a thousand parts of water. One measure of this solution is put into a graduated tube of glass, and oxygenated liquor is added, until the colour of the indigo is completely destroyed, and the strength of the oxygenated liquor is ascertained by its power in discharging the colour.

Mr. Rose has recommended a method which is better adapted for general use; which is, "to have small measures properly proportioned to each other, and when the liquid is strong, to prevent waste of the indigo liquor prepared as above, and a tedious repetition of measures, let a small measure of the liquor to be tried be put into a measure containing 24 of the same measures of water (it then becomes diluted to a twenty-fifth part); to a measure of this diluted liquor add as many measures of the blue test as it will discharge, which multiplied by 25, gives its whole strength. It will be proper to have a measure of five for the sake of dispatch, in adding the blue test liquor. It is necessary that the experimenter should sit low enough to view his measures horizontally, in order that they may not be overfilled, otherwise he may be deceived.

Great care should be taken in the choice of the indigo and the vitriolic acid employed, for unless the indigo is of the Guatimala kind, or best East India, and the vitriolic acid highly concentrated and pure, the colour produced will be a greenish brown, instead of a bright blue.

Mr. Chaptal has employed the oxygenated muriatic acid to the purpose of bleaching paper, both by applying it to the rags before worked down, and to the pulp or paste; he also restored the white to prints discoloured by time, by immersing them in the oxygenated muriatic acid liquor, or exposing them to the action of its vapour. And several patents have been granted in this kingdom for bleaching pulp or paper, amongst which Messrs. Clement and George Taylor, of Maidstone, in Kent, have obtained one for bleaching the pulp, by inclosing it with a liquor of oxygenated murate of pot-ash, in a vessel resembling a churn, eight feet diameter at the great end, three feet four inches diameter at the little end, and two feet ten inches in the clear. This vessel revolves upon an axis at each end, and the pulp, by this motion, and projecting parts within the vessel, is constantly exposing fresh surfaces to the liquor, till the whole pulp is sufficiently whitened.

Mr. Bigg, of Iping, in Sussex, has since obtained a patent for bleaching paper, and restoring to whiteness damaged or mildewed paper, by exposing in close wooden vessels paper, in quantities of six or eight sheets together, on wooden frames

placed at small distances from each other, to the action of oxygenated muriatic gas, and after the paper is taken out, pressed, and dried, previous to its being sized, wetting it in a solution of alum water.

Another method he proposes, is by wetting and soaking the paper in oxygenated muriatic acid liquor, till it is properly bleached; after which it should be well pressed and dried, and wet out in the alum water, as in the other process.

A patent has likewise been granted to Mr. Elias Carpenter, of Bermondsey, London, for a method of bleaching paper in the water leaf or sheet, and sizing it without drying; he uses for this purpose a stout deal box or case, which must be carefully closed, and capable of confining water or steam within this. The paper to be bleached is to be hung on strips of glass, about 15 inches long, placed in grooves within the box, about four sheets on each strip; the paper is taken for this purpose when pressed in the packs in its wet state, and when the box is filled and closed, it is exposed to the action of oxygenated muriatic gas for eight or ten hours, and when sufficiently bleached, sized with a preparation made from one hundred weight of pieces of skins boiled in water and strained, then fourteen pounds of alum, seven pounds of white vitriol, and one pound of gum arabic added; these ingredients will make size enough for about 50 reams of foolscap paper; the paper when sized and pressed, is finished in the usual way. To prevent the noxious qualities of the gas to the workmen, he directs a solution of pot-ash in water to be placed at the bottom of the bleaching box, to absorb the elastic vapours which would otherwise affect them on opening the box.

Mr. Tennant of Glasgow, subsequent to the patent granted him for his bleaching liquid, has obtained a patent for preparing the oxygenated muriate of lime in a dry form, by which means bleachers may be cheaply and conveniently supplied with it by him, and save much of the trouble, expence, and hazard which attend the preparation of the former bleaching liquor.

To bleach silk from its natural gummy state, whether in skain or manufactured, it should be put into a thin linen bag, and thrown into a vessel of boiling water in which good white soap has been dissolved; the silk should boil two or three hours in this liquor, and the bag of silk frequently pressed with a stick, and turned, so that the gummy matter may separate from it, and rise to the surface of the liquor, from whence it should be skimmed off, and thrown away; the bag should then be taken out, and if it contains silk goods, they should be well washed in clean cold water, to prepare them for printing or dyeing; but if the bag contains silk in the skain, after it has been well washed in clean water, beaten, and slightly wrung, it may be put the second time into the copper vessel, filled with cold water mixed with soap, and a little indigo blue, if you wish it tinged a little of the blueish hue.

The silk, when taken out of the second water, should be wrung hard with a wooden peg, to press out all the liquor; then shaken, to separate the threads; then suspended on poles, in a close room or stove where sulphur is burnt, which improves the whiteness of the silk.

Woollen cloths or stuffs may be bleached and made white by soap and water; by the vapour of sulphur; or by chalk, indigo, and sulphuric vapour. In the best case, after the stuffs have been cleaned at the fulling mill, they are again worked in warmish soap and water, to render them whiter, and afterwards washed in clear water and dried; in this state they are fit for dyeing any light colours.

To destroy or remove the reddish hue arising from boiling printed cottons in madder decoctions, which prevents the

printed colours appearing to advantage, the goods are usually boiled for some time in bran and water, and then exposed to the air, by laying them on the grass, and throwing upon them clear water from time to time. Mr. Grimshaw, in the year 1796, obtained a patent for clearing printed goods coming from the madder copper, by using the grains after brewing malt liquors, instead of bran; the plan he recommends is, that the grains should be previously sour, and that three or four bushels thereof, more or less, according to the colour of the cloth, should be put into a copper of hot water, containing 200 gallons or upwards, and four or five pieces of the printed cotton goods then immersed therein, and worked over a winch backwards and forwards, for ten or fifteen minutes; the pieces are then taken out of the copper, and well washed in clear water, and laid straight upon the ground for two or three days, till the parts which should be white become clear. The same liquor, with the addition of a few grains, will serve to clear other printed goods, till the whole number wanted to be cleared have been completed; a sufficient quantity of clear water being added to replenish what has been absorbed by the goods, or evaporated in boiling. After either of the operations above-mentioned, the immersion of the printed goods in dilute oxygenated acid, will answer the purpose of the exposure to the air.

BLEACHING of Books, Prints, and Paper. See BOOKS, &c. and BLEACHING; *supra*.

BLEACHING of Hair. See HAIR.

BLEACHING of Wax. See WAX.

BLEAK, in *Ichthyology*, the English name of *CYPRINUS ALBURNUS*, a species distinguished from the other fishes of its genus by having twenty rays in the anal fin.

The bleak is a very abundant fish in many of the English rivers, and in those of the northern countries of Europe in general. The flesh is in some esteem; but it is chiefly taken for the sake of the beautiful silvery scales, which artists make use of in the manufactory of artificial pearl. The credit of this invention is claimed by the French; and it is said that they have arrived at such a degree of perfection in this art, that, independent of the plain silvery hue of the beads in common, they can vary the colour to blue, green, or any other vivid tint they may desire. The process is very short; the scales are scraped off, washed, and then reduced to a fine powder; this is diluted with water, and introduced into a thin bubble of glass, where it forms an internal coating; the cavity is then filled with wax, through which a hole is bored, and the bead is finished.

Gmelin speaks of this species being from four to ten inches in length; but these do not commonly exceed six inches. This fish is infested in the summer-time with a creature of the vermes tribe, that lives in the intestines, and which oftentimes increases to such a vast size as to occasion the death of the bleak. Fishes so infested rise to the surface of the water, where they leap and tumble about in the greatest agonies, and in that state are well known to the fishermen by the name of mad bleaks. The white bait taken in the Thames at Blackwall and Greenwich, in the month of July, is believed to be the fry of this species. Vide *Donov. Brit. Fishes*, pl. 18.

BLEB, a small blister, or bubble.

Naturalists have observed small purple blebs on all the plants of the *hypericum* kind. *Phil. Trans.* N° 224. Thick pieces of glass, fit for large optic glasses, are rarely to be had without blebs. *Ibid.* N° 4.

BLECHINGLEY, or **BLETCHINGLEY**, in *Geography*, an ancient but small borough town of Surrey, in England; has had the privilege of returning members to parliament from time immemorial. The right of voting is vested in burghage tenure;

and the lord of the manor's bailiff was the returning officer till 1723, when, by a resolution of the house of commons, he was deprived of that office; and the borough has now the singularity of sending two members to parliament, without a mayor, constable, or any other legal returning officer. Sir Robert Clayton is the proprietor of the borough, and has consequently the power of appointing the representatives. The town occupies the summit and side of a hill, and commands some fine and extensive prospects into Kent, Hampshire, &c. Here was formerly a castle, which is nearly obliterated, and its site is overgrown with coppice wood. An almshouse and free school are the only charitable foundations of this place. The church is large and handsome; but its spire was destroyed by lightning in 1606, at which time the bells were melted by the electric fire. Fuller's earth and a species of iron-stone are obtained in the vicinity of this town. Blechingley is 21 miles south from London. The town and suburbs within the parish, contain 186 houses, and 1344 inhabitants.

BLECHNUM, in *Botany*. *Lin. gen. n.* 1175. *Reich.* 1292. *Schreb.* 1627. Class *Cryptogamia Filices*, or ferns. *Gen. Char.* Fructifications disposed in two lines, approaching to the rib of the frond, and parallel.

Species, 1. *B. occidentale*, South American B. "Fronds pinnate; pinnae lanceolate, opposite, emarginate at the base." This species rises by a simple undivided stalk to the height of 13 or 18 inches; leaves long and narrow; many pinnae, with two small auricles at the base. A native of the West India islands, and the continent of South America. Introduced here about 1777. 2. *B. orientale*, Chinese B. "Fronds pinnate; pinnae linear, alternate." Frond three feet long; stipe covered at the base before, with large grey bristles; the anterior side scored with three longitudinal grooves; leaflets linear-lanceolate, sessile, entire, streaked at an acute angle, the length of the finger. Found in China by Osbeck, and also in the Society isles. 3. *B. australe*, Cape B. "Fronds pinnate; pinnae sub-fessile, cordate-lanceolate, quite entire, the lowest opposite." Stipes a foot long, green; fronds entire, about the edge rugged; the barren ones with broader pinnae, truncate at the base; the fertile, with lanceolate pinnae, heart-shaped at the base; having two lines of fructification, longitudinal, and distant both from the edge and rib. A native of the cape of Good Hope. Introduced here, in 1774, by Mr. F. Masson. 4. *B. virginicum*, Virginian B. "Fronds pinnate; pinnae multilid." Having the stature of polypodium filix mas or male fern; frond smooth; pinnae lanceolate, sessile, semipinnatifid, acute; divisions obtuse, quite entire. A native of Virginia and Carolina. Cultivated, in 1774, by Dr. John Fothergill. 5. *B. japonicum*, Japanese B. "Frond bipinnatifid; pinnules ovate, obtuse, serrated." Stipe convex at the back and smooth, before flat and streaked; the whole smooth, flexuose, equal; pinnae oblong, acute, pinnatifid; the lower subpetioled, the upper sessile; differing from the *orientale* in having an erect frond and blunt pinnules. A native of Japan. 6. *B. radicans*, rooted-leaved B. "Fronds bipinnate; pinnae lanceolate, crenulated; the lines of fructification interrupted." Frond rooting; pinnae sessile, slightly concurrent at the base, ferrate with a very fine callus, acuminate, more veined beneath; the line of fructification is next the nerve, but interrupted as it were by long points. A native of Virginia and Madeira, where it was observed by Kœnig. Introduced, in 1779, by Mr. F. Masson.

Propagation and Culture. The fourth species alone will abide the open air in England; the first must be kept in the bark stove; the rest require only the protection of the dry stove, or conservatory; they are increased by parting the roots. Martyn.

BLED SOE LICK, in *Geography*, lies in the state of Tennessee, in America, 32 miles from Big Salt Lick garrison, and 36 from Nashville.

BLEEDA, or **BLIDA**, in *Geography*, a town of Africa, in the kingdom of Algiers, and province of Titeri, is situate in the interior of the country, over-against the mouth of the Ma-Saffran, at five leagues distance, under the shade of a ridge of mountains, forming a part of mount Atlas. It is about a mile in circuit, encompassed by a wall chiefly of mud perforated by horns, and tolerably populous, but without much trade; some of the houses are flat-roofed, and others tiled; it is well-watered, as a branch of an adjacent rivulet may be conducted through every house and garden, and it is surrounded by very fruitful gardens and plantations. As Bleeda and Medea (see **MEDEA**) lie nearly in the same meridian, and are situated at a proper distance from the Hamam Mereega, the Aquæ Calidæ Colonia of the ancients, and as their modern and ancient names resemble one another, Dr. Shaw supposes that we may take one for the Bida Colonia, and the other for the Lamida of Ptolemy. That part of mount Atlas which lies between these towns, and reaches as far as mount Jurjura, is inhabited by numerous clans of Kabyles; few of which, from their rugged situation, have been made tributary to the Algerines. The Beni Sala and Haleel overlook Bleeda, and the rich plains of Mettijah; whilst the Beni Selim and Halefa sometimes descend into the pasture ground, near the banks of the Bishbeh, or river of fenmel, of which a great quantity grows on its banks. Shaw's Travels, p. 36.

BLEEDING, or **BLOOD-LETTING**, in *Medicine*, a species of evacuation frequently resorted to, as a principal remedy in inflammatory affections, such as pleurisy, peripneumony, phrenitis, quinsy, enteritis, acute rheumatism, &c.; and in disorders accompanied with plethora, such as mania, apoplexy, &c. See these diseases separately. In all these cases, the earlier this remedy is employed the better, and especially in those inflammatory disorders, such as phrenitis and peripneumony, where, from the great vascularity of the part, the progress of the inflammatory action is extremely rapid, and the injury done to organs so essential to life, often becomes irreparable.

Nor is the *timing* of this remedy the only circumstance that requires attention. Other circumstances of equal moment are to be attended to; viz. *the quantity of evacuation, and the suddenness with which it is effected*. The quantity must be regulated by the degree and seat of inflammatory action, and the age and constitution of the patient. The appearances of the blood, when drawn (see **BLOOD**), are commonly regarded as a good criterion for regulating the repetition of the lancet, and the quantity to be taken away each time; but the state of the pulse affords a much better guide; and venesection will often be found necessary in cases where the buffy coat or fizy appearance of the blood is not present in any considerable degree.

The impression produced upon the system is very different, according as the blood is drawn from a large or a small orifice; i. e. according as it is evacuated suddenly or slowly. The former method is to be practised in all violent inflammations of parts essential to life; such as the brain, the lungs, the stomach, &c; for thus the increased action of the vascular system is subdued almost on the onset; a momentary deliquium is induced (a state the opposite to that in which the morbid condition consisted) from which the most beneficial consequences result.

Provided equal quantities of blood be drawn in equal times, it matters not whether it be taken from the *right* or the *left* arm; in other words, supposing, in the case of pleu-

rify, the seat of the pain and inflammation to be in the *right* side, those symptoms will be as speedily removed by taking away in the whole thirty ounces of blood at three different times from the left arm, as they would be, if the same quantity were taken away from the *right* arm, in the same number of times, and from orifices equally large; because in both cases there is the same quantity abstracted from the whole mass of blood, and consequently from the quantity circulating through the lungs, and their investing membranes; whence the *general* and *local* effects in both cases are ultimately the same. Hence the futility of the doctrine of *Revulsion*, about which such warm disputes were at one time carried on.

Hitherto we have merely hinted at the *general effects* produced upon the system by blood-letting. It will now be expected that we should specify what they are. The first and most obvious effect is upon the heart and arteries. The blood is to them a stimulus; consequently, by withdrawing a quantity of that fluid from them, we withdraw a proportionate quantity of stimulus, and bring down their action so much nearer to their natural standard. The absorbents participate in this change; whence a less impeded exhalation takes place. At the same time a diminution of the animal heat succeeds. But the cerebral system and the vascular system are so intimately connected, that the one cannot be materially affected without producing a corresponding effect upon the other. This is proved by the deliquium and convulsions which succeed to sudden and profuse hæmorrhages. Thus it appears that the beneficial effects of blood-letting, in the disorders to which it is applicable, are not owing merely to the abstraction of a quantity of the circulating mass, and consequent abatement of activity in the sanguiferous vessels; but also to the abstraction of a quantity of the superfluous *Animal Heat*, and to the impressions at the same time made upon the lymphatic vessels, and finally upon the system of brain and nerves.

From this view of a remedy so powerful and so extensive in its operation, it is easy to perceive what mischievous and even dangerous consequences must result from its abuse. Being the most speedily debilitating of all remedies, it is obvious that what is termed *general bleeding* ought never to be resorted to, but in cases where the pulse denotes an increased degree of strength, as well as excessive activity. It has been from attending merely to its increased activity, and the accompanying accumulation of heat, without a due estimation of the strength of the pulse in fevers and other disorders supposed to be inflammatory, that so much abuse has been committed in the employment of the lancet. See **FEVER**; under which article, the propriety and impropriety of blood-letting will be fully considered, with remarks on the practice of Fernelius, Botallus, Sydenham, Pringle, and other celebrated physicians, who pushed this remedy to an extravagant length.

Although *general bleeding* be only admissible under the conditions above mentioned, yet *topical bleeding* may be sometimes employed with good effect in cases of partial inflammation, existing in states of the body where vigour in the system at large is wanting; especially when the vessels belonging to some organ essential to life, are obstructed, overloaded, or inflamed.

Bleeding was formerly employed for the purpose of *preventing* plethoric and inflammatory conditions of the body. Hence many of the old writers recommend it to persons in health, both in spring and autumn, to pregnant women, &c.; but this practice is very properly discontinued, and other modes of counteracting a tendency to over-repletion are adopted in its place; such as a vegetable diet, regular exercise, occasional purging, and the like.

BLEEDING.

BLEEDING, or BLOOD-LETTING, in Surgery, is the artificial extraction of blood from an **ARTERY** or **VEIN**, for medicinal purposes. The operation of cutting an artery is named **ARTERIOTOMY**; that of opening a vein is called **VENESECTIO**, or **PHLEBOTOMY**.

The instrument used in this country for bleeding the human subject, is denominated a **LANCEET**; though a *phlebotome*, or *fleam*, was formerly employed, and is still very commonly used by farriers in England, and even by the best surgeons in Germany, &c. See the *Plate of Surgical Instruments*. The lancet, on these occasions, is used single; but where the intention is to puncture numerous small blood vessels at the same instant, rather than any one considerable vein or branch of an artery, surgeons have recourse to an instrument containing many lancets, which is known by the name of **SCARIFICATOR**.

Leeches are often applied to a part of the body requiring the local evacuation of blood; and in this case, as well as in scarifying, the operation is termed *local* bleeding, in contradistinction to *general* blood-letting by the lancet.

Some nations, especially those which have scarcely emerged from a state of barbarism, are accustomed to draw blood by making one or more incisions or punctures at random, with a knife, a stone, a tooth, or a needle. See **ACUPUNCTURE**, **PHLEBOTOMY**, **ARTERIOTOMY**, **LLECHES**, and **CUPPING**.

The art of bleeding may be traced back to the remotest antiquity, and seems to have been common among the Egyptians, Assyrians, Scythians, &c. at a time when anatomy had never been cultivated. The Greeks boast that Podalirius, the son of Esculapius, was the first who practised bleeding, soon after the siege of Troy; but the fact itself is related by only one author (Steph. Byzan. in voce *Syrna*), who lived too long afterwards to be credited implicitly. It is therefore much more likely, that bleeding had been performed previously to the time alluded to. Pliny, indeed, supposes that physicians first learnt this operation from having observed the hippopotamus draw blood by pushing sharp reeds into its body (Hist. Nat. lib. viii. cap. 26.); but this is a very improbable thing, as there is very little analogy between the artificial opening of a vein with a lancet, and the random wounding of an animal by friction against a broken reed.

We shall, however, not enlarge on the history of this practice, but proceed to describe the common modes of opening a *vein* in several parts of the body, after which we shall treat of **ARTERIOTOMY**.

When we resolve to perform venesection, we must, besides the instruments required for that operation, have in readiness one or two well-rolled blood-letting bandages, or tapes, from four to eight feet in length, and of two fingers breadth, with pins, or else needles and thread. Those bandages are, by foreigners, reckoned the best, which have narrow straps at their ends.

In general, venesection is practised at the bend of the elbow, or upon the foot. When the patient is to be bled at the arm, we place him, with his face towards the light, upon a chair of a moderate height; draw his shirt as high as is necessary above the elbow; let him extend his arm to a certain degree, but not too much; after which, the surgeon, in order that the veins may become turgid by checking the circulation, applies a bandage (which is often made of fine red cloth), of the breadth of three or four fingers, twice round the arm above the elbow, with the ends of which, after having previously drawn them moderately tight, he ties a bow with a single knot, at the posterior part of the arm. Whether this bandage has been properly applied, we

know by the circumstance, that the veins become elevated and tumid, whilst the pulsation of the artery at the wrist is distinctly perceptible.

We then choose a vein in the bend of the elbow, which must be done with caution. The upper is the cephalic vein, and this a beginner ought, if possible, always to choose, as little or no danger is to be apprehended from opening it; but it is very seldom to be seen or felt, and commonly is too small. The median vein is most easily seen and felt; but generally the tendon of the biceps muscle is situated under or at the side of it, which we must take great care not to puncture. The inner vein of the arm, or the basilic (which in the right arm is by some termed the hepatic vein, and in the left the splenic), is indeed commonly very easy to be seen, and still more easy to be felt; sometimes, however, it is also very small, or lies so close upon the artery as to render it hazardous to open it.

Some recommend blood-letting upon the back of the hand, although this is an inconvenient place, and, in certain cases, not very safe for the operation. But if it is to be performed, we tie the red bandage two fingers breadth above the wrist, round the fore-arm; and, in order to raise the vein, let the patient then hold his hand in warm water. The most common vein upon the hand is the cephalic of the thumb, which lies between the bones of the carpus; with which the thumb and the fore-finger are joined. But the vena salvatella of the middle finger, which lies between the two metacarpal bones with which the middle and the ring fingers are joined, is at present but very rarely opened, and only when no other is to be seen; especially as it does not discharge much blood, is difficult to be tied, and, if cut quite through, forms a thrombus.

In bleeding these veins, the patient must be placed in a somewhat oblique position against the light; so that when the hand is half closed, and laid upon the edge of the vessel, the fingers are directed towards the light, in order that the instrument may throw no shade upon the place of the vein where we intend to open it.

Bleeding at the foot is generally performed upon the vena saphæna, which lies upon the first metatarsal bone, connected with the great toe, running along it and the tarsus, over the inner ankle. Where it lies close upon the ankle, it is inconvenient to open, and we must be very careful lest we cut through it and injure the periosteum, or even thrust the fleam or lancet into the bone itself. If possible, it will be better to open it one, two, or three fingers' breadths farther from the ankle towards the great toe. We may also open a branch far forwards, almost close upon the great toe; and here we are required often to open it with pregnant women who have swelled legs.

The other pretty safe vein upon the foot is the cephalica pedis, that lies between the two tendons which extend the great and the second toes; only we must be cautious not to injure the tendon lying beside it. The other veins situated upon the back of the foot should never be opened, but in cases of extreme necessity; for the operation is attended with danger, on account of the contiguous tendons; besides, they do not discharge a sufficient quantity of blood, and they almost always form a thrombus, which a beginner should be careful to avoid.

When we bleed at the foot, the patient should first place the limb in a pail of warm water, in order that the vessels may be seen and felt; and it is also necessary with small veins to apply the red bandage, which, however, in order that the purpose of checking the flow of the blood may be attained, and no inconvenience occasioned, must be applied in the middle of the calf, especially with lean persons, in

BLEEDING.

the same manner as on the arm; but the bow and its knot must not lie upon the tibia.

On the arm, therefore, we choose either the cephalic or the median vein, and, if the tendon lying below it should occasion hesitation, the basilic, especially if this lies more convenient and superficial. When the surgeon, then, has brought his eye to the proper distance from the vein, he wets the point of his middle finger, presses gently with this finger upon the vein at the places where he thinks he can best open it, and accurately marks the place with which he was satisfied in trying by the feel; after which he suffers the arm to fall down again into the patient's lap. In the same manner he chooses a vein upon the hand.

For blood-letting at the right foot, the patient is placed upon a chair of a moderate height, in the most enlightened part of the room, with his face directed towards the window, and his feet immersed in a vessel filled with warm water, so that the water covers all the veins of the whole foot. When therefore the foot is warm, and the veins sufficiently tumid, the surgeon lays hold of the foot with his left hand, and places it with the middle of the sole upon the edge of the vessel which is the most remote from the body, in such a manner, however, that the foot is not extended, but forms a right angle with the leg. With the middle finger of the right hand he examines those veins which lie the most elevated, and makes, according to the rules before laid down, a scientific selection; but he must always first direct his attention to the vena saphæna.

The most convenient attitude for the surgeon is when he kneels down with one knee; as in this position the eye is near to the vein, the position is firm, and can be better supported for the requisite length of time. If any other vein besides the saphæna be chosen, the patient is directed to move his toes, whilst we are examining the vein, in order that we may feel how near a tendon may be situated below it; and here the caution should be observed, not to make all the fingers wet, for the warm water diminishes the sense of touch, and consequently renders it indistinct. We therefore use at first only one hand, because, in case of a failure, or from some other cause, we may be under the necessity of taking also the other foot.

The vein may be opened either longitudinally, that is to say, in the direction of its course, or we open it rather obliquely or transversely. The first is the safest, easiest, and most convenient method; but it is admissible only with large veins, and when we foresee that during the operation they will not slip or twist, as it were, out of the way of the instrument. Commonly the veins are opened somewhat obliquely, and in this manner we may generally open the veins on the arm, and in most cases upon the foot. But when the veins are too small, there is reason to apprehend that we may not hit them, or that they will not discharge a sufficient quantity of blood; and when their situation requires it, as is the case with the cephalic of the foot (where it lies over the tendon that elevates the great toe), the orifice must be made quite transversely.

When therefore we have properly examined the vein with the moist finger, we hold the phlebotomy in readiness (if we use this instrument); that is to say, we draw up the spring, take it in the right hand, so that the thumb lies upon the slider, the fore-finger upon the bridge, and the middle finger upon the presser, exactly over its spring, and the ring finger upon the round part of the bottom plate. With the fore-finger and thumb of the left hand, which are moistened with a little saliva, we move the iron as high up in the groove as we think it necessary to make the orifice deep; and place the box (after having again elevated the arm, or

taken the foot or hand out of the water, and supported them, in the manner above described, upon the margin of the vessel) in such a manner upon the skin, that the iron has exactly the proper direction toward the place where the orifice is to be made, and then, by a gentle pressure with the middle finger, let the spring fly loose.

If a person should be so fat as to render bleeding impracticable, and with such it is at least very difficult to do it on the foot, we may in some measure attain our purpose, if we direct the patient, as he gets out of bed, to hold his foot or hand in warm water; after which the veins will generally become sufficiently perceptible to the eye or touch of an experienced surgeon.

But though the phlebotomy is used for blood-letting, especially in Germany, it is however an universally acknowledged truth, that the lancet is the safest and best instrument for the purpose. We run less hazard with it of doing damage, and the surgeon is always able, according as the circumstances require, to make the orifice either small or large. When therefore we let blood with the lancet, we place it so that the handle forms a somewhat acute angle with the blade. The surgeon next lays hold of the limb upon which he is to perform the operation, supports the right arm, with his left hand; and at the same time presses with the left thumb upon the vein, about two fingers' breadth below the place which is chosen for the orifice: he then takes the lancet between the thumb and fore-finger of the right hand, so that something more of the blade is uncovered than he thinks necessary to introduce. At the same time he lets his hand rest upon the middle, ring, and little finger, which must be placed as conveniently as possible below the vein that is to be opened. He then pushes the point of his lancet carefully through the skin and integuments into the vein, and carries the instrument in an oblique direction a little forwards, till the orifice is sufficiently large. But, during the introduction of the lancet, the operator must hold the point as steady and even as possible, in order that it may not penetrate into the subjacent parts. Should he, however, not be able to depend sufficiently upon the steadiness of his hand, he will do well to leave no more of the point of the lancet uncovered than is to penetrate into the vein. The Surgeon having withdrawn his right hand, at the same time removes the thumb of his left hand from the vein, in order that the blood may flow out freely.

If the blood will not flow properly, notwithstanding the vein has been properly hit, either the orifice is too small, or fat perhaps gets into the orifice of the integuments and stops it. The fat is to be pressed back, by stroking with a wet and warm sponge, or by means of an instrument. The impediment, indeed, may lie in the motion of the part; when, for example, the arm is bent obliquely, or the foot is placed in the water, the orifice of the vein may easily be displaced, and some of it be closed by the sound part of the skin. But, finally, the circumstance may also be occasioned by the viscid consistence of the blood. To this latter cause it is often to be attributed, after the first few minutes; on which account it will be proper to wipe the arm, over the orifice of the vein, with a sponge filled with warm water, and let the hand rest in a somewhat higher situation than the orifice, upon a stick, which the patient may also turn round, or press firmly with his fingers.

When a sufficient quantity of blood has flowed from the vein (for example, in the arm), and we are to tie it up, we take the sponge, moistened with warm water, in the right hand, the bandage in the left, and the linen compress between the thumb and middle finger of the same hand; we hold against the vein with the sponge, and with the left hand

remove

B L E E D I N G.

remove the red bandage and hang it over the chair, or the shoulder of the patient. The assistant takes away the vessel into which the blood has been received, and the operator now with a moderate pressure draws the sponge from the vein towards the hand in a right line with the orifice that has been made; and it will be proper, whilst he brings the lips of the wound together with the thumb of his left hand from the side, to repeat the wiping with the sponge once more, in order completely to remove the blood that may have been left in the orifice.

When the surgeon now sees the vein well closed, he lays upon it the compress, with the fingers of his right hand, whilst he draws it towards the thumb of the left hand upon the skin; and when the middle of it is upon the orifice, he presses it down with the fore and middle fingers of the right hand, and immediately changes these for the thumb of the left hand. With the right hand he washes the blood from the limb, by means of the sponge; after which, he lays the sponge aside. He then takes the bandage out of his left hand, lays hold of it with the fore and middle fingers of the right hand at the inner part of its head, and the thumb upon the outer, and places it upon the compress in such a manner that the fingers of the left hand make way for it, whilst the two fingers of the right hand continue the pressure in their place. But, immediately after, these are again changed for the left, fore, and middle fingers, which now press at the same time upon the one turn of the bandage and the compress. The right hand carries the bandage cross-ways round the arm, whilst the fore fingers of the two hands always alternate, till the last, when both ends of the bandage are either sewed, tied, or pinned together.

Notwithstanding we have given these very precise directions, a young surgeon will learn better by seeing the operation performed by a skilful hand, than by any verbal instructions.

Tying the vein upon the thumb is performed in the following manner:—Pressing with the compress, which here must be pretty narrow and thick, is like that performed on other veins; and therefore, whilst we hold it fast upon the wound of the vein with the two fore fingers of the left hand, we let the bandage, (which is rolled upon one head, an inch in breadth, four feet in length from the end to the place where it touches the compress), hang about half a foot down over the back of the hand, obliquely from the wrist outwards; carry the head of the bandage, after pressing it over the compress with two fingers of the left hand, through between the thumb and the fore-finger, over the palm of the hand; and, proceeding over the back of the hand, cover the end of the bandage; then go round the wrist, again over the back of the hand, under the thumb, and now round the ball of the thumb; again over the turn that has just been made across the back of the hand; and after having once more carried it half round the wrist, pin both ends together on the back of the hand. We may also apply this bandage with varied turns. In a similar manner, with turns round the little finger, and circular turns round the wrist, the bandage is applied, when the vena salvatella is opened.

With the veins of the foot, the common bandaging is made by the STAPES, which, however, sometimes requires a peculiar method, that every one will easily be able to adapt according to circumstances. The bandage may be applied somewhat tighter than upon the arm: however, on account of the injurious consequences, which may even be attended with danger, the bandage must not be drawn too tight; but it will be better some hours after to examine it again, and if necessary, draw it somewhat tighter. Upon

the whole, it is to be recommended, if possible, in all blood-letting operations, especially in arteriotomy, that the surgeon should see the patient again some hours after; as he may obviate several small inconveniences, which afterwards frequently occasion unpleasant complaints.

Venesection is more rarely performed upon the frontal vein, the veins under the tongue, and upon the neck. For the frontal vein, when it requires to be opened, we apply a bandage, or a garter or cloth, round the neck, lay the middle of the bandage upon the back of the neck, carry both extremities over the throat, and round again to the back of the neck, where an assistant takes one end in each hand. This the patient may also perform himself; only then the middle of the bandage must be applied to the throat, the two ends carried round the neck till they meet at the throat again; there the patient holds them with both his hands, and according to circumstances, draws the bandage tighter, or relaxes it, so as still to retain sufficient space for respiration. A still more convenient mode of distending the veins of the neck, &c. is to pass the bandage over the sides of the neck, and under the opposite arm-pits, so as not to press upon the trachea, which may impede respiration; then hold the swelled vein down with the thumb or finger of your left hand, a little below the part allotted for the operation. The incision is to be made, when the vein is sufficiently tumid, with a lancet.

In order that the blood may not run down upon the face, we press a card bent crooked under the orifice upon the skin, and thereby conduct the blood into a vessel. After a sufficient quantity of blood has been discharged, we remove the bandage from the neck, when the bleeding generally ceases immediately, and the orifice is secured with sticking plaster, or, if it should be necessary, with a compress and DISCRIMEN bandage.

When we have to open a sublingual vein, we must promote the efflux of the blood, as in bleeding at the forehead by the application of a cloth under the arms and across the sides of the neck. The orifice is made with the lancet, and the incision is continued till it seems large enough. In order more conveniently to get at it, we hold back the tongue with a wooden fork, or spatula. We may draw a silk thread through the wound, in order to clear it from the blood which here easily coagulates, and at the same time to prevent the lips of the wound from adhering together, and consequently to obviate whatever might impede the flow of the blood. When its flow must be stopped, we take off the bandage, and let the patient hold some spirit of wine, or common brandy, in his mouth. If the blood flows more copiously, we may dispense with the thread, and immediately remove the bandage from the neck; also, when it is to be stopped, apply a little alum or agaric to the wound, and press it down for a time; or apply Lampe's compressory, described in L. Val. Heur. Koehler Anleitung zum Verbande, &c. Leipzig, 1796, 8vo. Tab. VI. fig. 5.

To bleed at the external jugular vein, the bandage is likewise applied round the neck; against the clavicle, and upon the vein that is to be opened, a thick compress is placed, and the bandage drawn somewhat together. The thumb is placed upon the compress which lies upon the vein and the fore-finger over it, in order to secure it and to stretch the skin; we then take a pretty large lancet, and with it open the vein in the ordinary manner; only with this difference, that we must introduce it deeper, and make the external orifice larger. To catch the blood, we make use of a card, as in bleeding at the forehead. When a sufficient quantity of blood has been drawn, we remove the bandage; after which, the lips of the wound generally close sponta-

BLEEDING.

neously. But should a bandage be necessary, we may secure a compress upon it by means of two circular turns round the neck. As this bandage, on account of the pressure upon the trachea and vessels, &c. of the neck, is always very troublesome; and also the pressure, as it never must be strong, is frequently insufficient; we may most conveniently use the instrument invented by Mr. Chabert for compressing the veins of the neck. In want of it, we must let an assistant close the orifice by pressure with his finger, till the danger of hæmorrhage is over.

Some moisten the compresses with brandy, vinegar, &c. and thereby, on account of the irritation, occasion some inconvenience at the orifice of the vein, in which sometimes inflammation, and even a suppuration, is excited. It is better to apply the compress dry, or to stick upon it a piece of gold-beater's skin, whereby the lips of the wound, if they have been well brought together, are retained in that state, so that the bursting open of the vein is more effectually prevented.

Easy and insignificant as some young surgeons think the operation of phlebotomy, it nevertheless often requires the greatest accuracy, and is on that account one of the most delicate operations. To a true surgeon, therefore, it is always of importance, and the more so as his honour and reputation are endangered by committing an error in it. Frequently the faults which the patient commits during and after the operation, such as incautious motion of the limb whilst the operation is performing, violent exertion of it, drawing on boots, &c. after blood-letting at the feet, are ascribed to the negligence or ignorance of the surgeon. Inasmuch also as no operation occurs so frequently as this, and as it so very often endangers the life of a man, or at least an error committed may give rise to such danger; the surgeon must well consider the symptoms which occur in it, and may superinduce more important consequences dangerous to health, in order that he may timely obviate or remove them.

Sometimes there arises, as the most common bad consequence of blood-letting, an inflammation of the external integuments, and of the subjacent cellular substance. Sometimes it is chronic, but little painful, suppurates slowly, and produces a circumscribed abscess. Sometimes it is more diffused, and has the appearance of an erysipelatous inflammation: sometimes it is violent and acute, and resembles a phlegmon. This generally occurs when the instrument is a bad one, and rather tears than cuts; when the patient is of a very irritable habit, and much disposed to inflammation; when the requisite precautions for healing the wound by the first intention are neglected, and the arm is suffered to be moved: when the wound is externally rubbed, pressed, &c. The nature of this inflammation cannot be mistaken, and it must be treated like a common wound.

It may sometimes happen, that when the wound of the vein does not soon close, an inflammation of the vein takes place, which however varies with respect to its violence, its extension, and progress. In a milder degree, this inflammation is followed merely by a slight swelling of the vein, and an adhesion of its sides. A violent inflammation induces suppuration. The common method of treatment is the antiphlogistic. As the internal membrane of the veins is continued to the heart, and as inflammations in such membranes spread easily and rapidly, where they are not prevented by an adhesion of the sides of the vein, it is in most cases advisable to produce such an adhesion by the application of external pressure at some distance above the orifice. If, as may very easily happen, such an inflamed vein should pass into suppuration, it would (if known) then be necessary

to cut open the vein, in order to prevent the pus from mixing with the circulating fluids.

When a vein has been cut entirely through, the pain is not greater than common, nor does the patient experience any inconvenience whilst the blood is flowing; but a greater or less quantity of it descends under the vein into the adipose membrane, remains there inclosed, and during the first twenty-four hours occasions a tension. The external orifice of the skin may be displaced from the orifice of the vein, likewise, when the orifice of the integuments is smaller than that of the vein; when the patient moves the arm too much, in consequence of which some blood is indeed discharged from the wound, but more penetrates between the vein and the skin into the cellular texture; and when the operation has been absurdly performed where two veins anastomose; from all these causes an effusion of blood may take place, in consequence of which the part acquires a bluish black colour, and sometimes an ecchymoma, sometimes a sugillation, and at other times a thrombus is produced. Although the appearance frequently seems to indicate greater danger than really exists, the speedy application of remedies is nevertheless necessary.

In the first case, cataplasms, with warm vinegar, wine, and other spirituous or discutient remedies, are serviceable. When such extravasated blood is not again taken up, or when the vessels are inadequate to its re-absorption, on account of its great quantity, an abscess is generally formed, which must be treated according to the rules of art, and the spirituous remedies laid aside. See ABSCESS. In the sugillation, we must endeavour to remove the obstacles that may impede the circulation of the blood: these are either external ones, such as a too tight bandage; by loosening which the complaint is removed; or they are internal ones, and occasioned by a contraction of the vessels. In a recent sugillation, we may combine the resolvent means above-mentioned with mild astringents; and when the stagnating blood has been again dissolved and removed, we at last apply cold, discutient, and spirituous remedies.

When an aponeurotic part (for example, the fascia of the fore-arm) is wounded, the patient sometimes experiences a more violent pain than usual, especially when he moves the limb; and this he feels presently after the blood-letting has been performed. A compress, moistened with cold Goulard's water, &c. is of service, whilst at the same time the bandage is left applied for three or four days, and the limb kept completely at rest, and wetted many times a day with such remedies. When this is neglected, there very often takes place a serious inflammation, which must be treated according to the antiphlogistic plan. Repose of the limb, which is to be kept in a bent position, and relaxation of the inflamed parts by means of warm emollient applications, are absolutely necessary. As soon as the inflammation abates, it is proper every day to attempt moving the joints, in order to prevent a stiffness. But if the tension and inflammatory symptoms run very high, it may even be requisite to divide the fascia completely.

When a nerve is injured, the patient experiences a still more violent pain, which extends itself throughout the whole limb, and the patient is also apt to faint; the muscles of the affected part contract, and the blood sometimes does not flow so freely as usual, although the vein has been well opened. The orifice of the vein does not become violently inflamed, and the pain continues. In order to prevent inflammation and other symptoms, a larger quantity of blood must be let run out, the limb must at least for some days be left completely at rest, and we must take care that the muscles of the part remain as much relaxed as possible. Moreover,

BLEEDING.

over, we must treat the patient antiphlogistically, prescribe a spare diet, and also, if the case should require it, administer opiates and laxatives. For lesions of the nerves, the application of warm spirit of turpentine is commended; but it would probably be useful only in case the nerve should lie above, but hardly when under, the vein. Over the orifice we apply some lint and a mild plaster, and over this and the whole limb, emollient and discutient cataplasms, with which anodyne remedies are mixed.

If, notwithstanding this treatment, the symptoms should become more violent, the lips of the wound acquire a hardness, and become more inflamed, affected with pain and tumour, with a full and quick pulse, blood must be drawn by leeches, or at another place by venesection. Instead of the warm emollient fomentations and cataplasms, which are recommended in such cases, Mr. B. Bell extols, from his own experience, cooling astringent remedies. Preparations of lead he has found most serviceable. The parts which suffer the most may be covered alternately with cloths wetted with a solution of saccharum Saturni, and with pledgits spread with ceratum Saturni. The fever must also be particularly attended to, and the above mentioned cooling treatment continued. When the pains are so violent, that they entirely deprive the patient of sleep and rest, we must use antimony and opium; but in order that the opium may prove serviceable, it is administered always in considerable doses. The limb must be also kept continually at rest, and in a horizontal posture.

But frequently the first affection is neglected, or improper remedies are employed, so that opium, and all the remedies that have been mentioned, have not the smallest effect. This is particularly to be supposed, when the nerve is cut in such a manner, that only a part of its fibres still remains entire, and these are preternaturally stretched; in which case the whole body suffers, and the most violent convulsive affections take place, which indicate the most imminent danger. The only remedy under these circumstances is the division of the nerve by a transverse incision above the inflamed part, that is to say, higher than the orifice of the vein. As the nerve certainly lies within the breadth of the orifice of the vein, the incision needs not be long, and it must penetrate only down to the fascia of the fore-arm, for all its cutaneous branches always lie on the outside of this fascia.

Mr. Benjamin Bell has given very extraordinary directions on this subject, which have (most unaccountably) been transcribed by many surgeons in France and Germany: he directs, among other things, an extensive transverse incision to be made through the original wound, and even down to the bone! which Mr. Abernethy has very properly reprobated as "dangerous and unnecessary."

When the branch of an artery has been wounded, the patient does not feel more pain than usual; but the surgeon immediately concludes from the colour and spouting of the blood what fault he has committed. See ANEURISM.

In venesection, a bone may also be injured, chiefly with lean persons, who generally have very thin veins, especially on the feet; which though they are very visible, lie, however, so close upon the bones and tendons, that the instrument passes through and injures the subjacent bone. In most cases, this only occasions a pain which the patient feels during the operation, and no bad consequences ensue. Frequently the surgeon himself would not know it, did he not find, on examining the instrument, that the point is entirely wanting, or at least bent round, and its edge spoiled. This, however, applies only to the case where none of the iron is left in it; but when this happens the case is worse. We may know, that it has taken place from the cutting blade being wanting, or in

part broken off; from the pain which the patient feels, and which is generally of a pulsating kind; from the divided stream of the blood; from the feel with the fingers, when they are stroked over the orifice of the vein, and from the rebounding which the surgeon feels in the fingers at the stroke. If it is not seated very firmly, the stream of blood generally drives it out, if we draw the orifice gently asunder with two fingers. But when it is more firmly seated, we must endeavour to draw it out with a fine pair of forceps as cautiously as possible, that it may not break in extracting, and the point remain sticking in the bone. When it has been successfully extracted, we must endeavour to prevent the symptoms, such as inflammation, tumour, &c. by moistening the compress and the bandages with a discutient lotion, and afterwards also keep the bandages moistened with such remedies throughout the day. This accident is only liable to occur in using the phlebotomy.

But the breaking off the blade may also happen with muscular subjects, and this the surgeon can certainly in general prevent, by always inspecting his instruments carefully, and providing them with good blades. The best blades are those which are very sharp and finely polished, and these are generally very thin, and consequently most liable to fly off. Before we use any blade, especially a thin one, we ought always to put it to the following test. We screw the new blade into the phlebotomy, and let it fly two or three times without any object opposed to it. If the blade remains as it should, we are then so much the more secure against its flying off in blood-letting, because it has a resistance opposed to it. This precaution should never be neglected, and the loss of a few blades should not be regarded, in order to secure ourselves against the danger to which we are exposed if we neglect it. These observations and precautions will scarcely be wanted for *English* surgeons, who have laid aside that instrument.

Sometimes a lymphatic vessel is wounded; in which case the patient experiences no extraordinary pain, nor does the surgeon foresee the injury that is still to arise, and consequently cannot be immediately discovered. After the bandaging, the vein heals up, no inflammation is left behind, but there daily flows out of the orifice of the skin a quantity of clear pellucid lymph, which continually keeps the dressings wet. This circumstance often gives the surgeon much trouble. Here we may apply with advantage, Goulard's saturnine water, or a solution of alum, or mere cold water. The cure is best completed by means of dry lint, applied daily once or twice in the form of a tent. We may also sprinkle pulverized alum, or apply a strong pressure upon the vessel; and sometimes we may use the lapis infernalis with advantage. Mr. Jaeger, however, thinks (*Fünfzig. chirurg. prakt. Cantelen. &c. Frankf. a. M. 1788, p. 3.*) that the cure may most speedily be effected by immediately promoting suppuration.

It may happen, that in letting blood at the arm a lymphatic vessel becomes inflamed; in which case we feel upon examination, a hard absorbent vessel both above and below the wound of the vein, which last, however, is not yet healed, but generally uninflamed: if the affected limb is used, the pains become more violent, and sometimes extend themselves into the axilla, where also the glands swell; generally the fore arm likewise swells and becomes painful, and at last abscesses take place in different parts. Besides keeping the affected arm at rest, we must cover the wound with an emollient ointment, and apply to the hard vessels and tumours, cataplasms of emollient, discutient, and anodyne remedies, upon which they are generally discussed. When abscesses have already been formed, they must be opened and healed, according to the rules of the art. See ABSCESS.

BLEEDING.

The most common symptom consequent upon blood-letting is fainting, which, however, is in most cases unattended with danger, especially when it does not arise from a too copious evacuation of blood. It may often be prevented, by keeping the patient engaged in conversation, by letting him take a spoonful of vinegar, or a glass of cold water into his mouth, or sprinkling him and washing his hands and face with it. But if it nevertheless supervenes, we must immediately place the patient in a horizontal position, throw open the chamber window, and apply strong stimulating substances, such as volatile alkali, to his nostrils; and when he has come to himself, we may give him a glass of wine, provided it be not contra-indicated by his ill state of health.

With persons who always faint whenever they are bled, and who on this account, however necessary the operation may be for them, always dread it, the best method of preventing their fainting, is to lay them immediately in a horizontal position, with the head low, and at the same time frequently to stop the discharge of blood by holding the vein. This caution is particularly to be recommended with pregnant women, as faintings and convulsions in them, if they continue too long, may prove very injurious to the fœtus, or produce abortion.

We have hitherto confined our remarks to the opening of a VEIN: it therefore now remains for us to describe the operation of ARTERIOTOMY, which is the artificial opening of an ARTERY.

This operation was very frequently practised by the ancients; who, perhaps, from having incorrect ideas of the nature of these blood-vessels, were not always aware of the dangerous consequences which follow from this practice, if injudiciously managed. Those who are desirous of reading a full account of the ancient practice in this branch of surgery, may peruse what Oribasius has collected from Galen and Antyllus; to which they may add the observations of Paulus Ægineta, and Prosper Alpinus, the latter of whom describes the operation as it was performed in Egypt.

The supposed advantages of opening an artery, rather than a vein, are 1st, that the blood flows with greater velocity than from a vein; and therefore affords a larger quantity in a given time: 2dly, that it prevents the accumulation of blood in any local inflammation more effectually, because it intercepts the fluid in its passage towards the affected part: 3dly, that its salutary effects more speedily follow, on this account, than from the operation of phlebotomy; and, therefore, it is preferable in cases of a very urgent nature, such as apoplexy and phrenitis, arising from the pressure of blood upon the brain.

But these advantages are speculative, rather than practical, for the following reasons: 1st, No surgeon who is acquainted with the serious consequences of opening a large branch of an artery, and the difficulty of restraining the effusion of blood in many instances, will perform this operation in the same parts of the body, and in the same dauntless manner, as the ancients did. And in opening only very small branches, (suppose of the temporal artery,) it rarely happens that the blood flows rapidly, and never with the same freedom as it does from a large vein: 2dly, That we may sometimes, by this means, intercept the blood as it passes towards an inflamed part is certain, by cutting through the principal artery which conveys the blood; but this advantage is not often obtained, because we dare not divide any considerable ramification, and there are always more arterial branches than one to supply an important organ: 3dly, We admit, that in certain cases, (in ophthalmia, or inflammation of the eyes, for example,) the good effects of blood-letting by arteriotomy near the affected part, is far

more useful than by phlebotomy, in a remote part; but, unfortunately, the surgeon cannot always evacuate a sufficient quantity of blood by this means, on account of the difficulty of finding a suitable branch of an artery, which may be easily as well as safely incised.

Therefore, considering all the disadvantages of this operation, it is now very rarely practised, except in the temples, where the pulsation of a small branch of the artery may be often felt with ease; and there is little or no danger in attempting to divide it. If we do not succeed in our attempts, or do not procure so much blood as is requisite, the operation of phlebotomy may then be had recourse to. It should, however, be mentioned as an undoubted fact, that acute inflammations of the eyes, are more effectually relieved by arteriotomy, (when it properly succeeds,) than by opening a vein in the arm; and that the excretion of four ounces of blood in this way, is as useful as twenty or even thirty ounces taken from the venous system!

As arteriotomy is now scarcely ever performed in any other part of the body besides the temple, we shall content ourselves with describing this operation alone. In that situation, the artery lies near enough upon the cranium to be compressed readily, when we wish to stop the current of blood; though, in general, the blood does not flow so freely, as to cause any difficulty in restraining it by moderate pressure.

The patient being placed in a good light, the operator feels for a pulsating vessel in the temple, nearly opposite the outer angle of the eye. When he has discovered it, he endeavours to trace the direction in which it runs; and then he places the two foremost fingers of his left hand upon the artery, leaving a space of about half an inch between them for the place of the incision. The vessel is so small, in general, that it cannot be opened by an oblique, or a longitudinal puncture, as in bleeding the veins of the arm; but must usually be cut across, by a single stroke of the lancet, or scalpel. A lancet is not so convenient as a small knife for this purpose, because its fine point is apt to be broken; and it will be found best to draw the instrument over the artery, instead of endeavouring to strike it with the point, (which Dr. Butler, Mr. B. Bell, and others, direct to be done,) as in phlebotomy. It may be convenient to make a little impression with the finger-nail, or with ink, on the exact spot we determine upon for the incision, lest we lose our object in operating; for a surgeon cannot always ensure the division or wounding of the artery on his first attempt, especially if the incision be made with timidity, or hesitation.

When a sufficient quantity of blood has flowed, (which it does by a florid and salient stream,) we close the wound; and apply a long bandage over a very firm, thick compress of linen, in which may be included a piece of coin, or some other hard substance. It is a matter of small importance whether or no we first use an adhesive plaister, except when the bleeding is likely to prove troublesome: but the different modes of arresting arterial hæmorrhages, are described under the articles HÆMORRHAGE, LIGATURE, STYPTIC, and ANEURISM.

Frequently it is necessary that the surgeon should make himself acquainted with the state of the blood, and often also it is required of him to pass his opinion upon it. As long as the blood is warm and flows out of the vein, it exhibits a pretty uniform red colour, and has a viscid gluey feel; but when it grows cool, it coagulates into a mass varying in colour and density. After some hours, there gradually exudes from this coagulated mass a fluid, which separates the more solid parts from the sides of the vessel, so that it swims in it. This water is called *serum*, but the coagulated red cake is named *cruor* or *crassamentum*.

BLEEDING.

Good venous blood, exposed to the air, is of a dark red colour: when it cools, it separates a thin and almost colourless serum, and a thick cake, which has no crust of a different colour from the blood below it; and of which the serum forms a proportion, amounting to between the third part and the half. Such blood has no preternatural acrimony, or saline quality; and in it are found all its constituent parts in the proper proportions. From this condition of the healthy blood, we may form a judgment of its preternatural state, if it be materially changed.

When the blood remains so fluid that it will not coagulate, it indicates a deficiency of the gelatinous part, and a great redundancy of serum. Such blood is to be found in many fevers, especially in malignant ones, or when the patient is in a very debilitated condition.

If there be too much serum in the blood, dropsy and other similar diseases are to be apprehended; for such dissolved blood always indicates a weakness of the vessels, and of the muscular fibre.

When the serum is yellow, it indicates an obstructed flow of the bile, and its regurgitation into the mass of the circulating fluids.

When the blood has much serum and little of the red part, the blood is overloaded with mucus, and it indicates that a cachectic disease is impending; especially when the serum has various different colours, and the texture of the crur is very slender.

If the blood has its proper and sufficient redness and fluidity, but at the same time exhibits a greasy pellicle, it indicates a superfluity of oleaginous particles.

When it separates and yields a very compact, tenacious, yellow, or buffy surface, it is too thick; and if the serum be at the same time small in quality, it shews a great degree of vascular action and inflammation. This is a fact very generally admitted.

Finally, it is to be observed, that we need not be alarmed when the thicker part of the blood seems to swim in a milky fluid; for it commonly happens, in drawing blood only a few hours after a meal, when it proceeds from the chylo, which, about this time, is imperfectly mixed with the blood.

We have thrown out these few hints for the attention of practical surgeons; but they are by no means to be regarded as complete, or absolutely incontrovertible. There is a great deal of fallacy in judging from the colour, and other sensible qualities of the blood; and the moderns have, therefore, learnt to give their opinion with diffidence. This subject is considered more at large in a subsequent article. See BLOOD, and its properties.

BLEEDING a Horse, a frequent operation in the *Veterinary Art*, principally intended to diminish the mass of blood, and thereby destroy the too great fulness or over-action of the heart and arteries.

When this operation is intended to affect the general system, the evacuation is usually made from the jugular vein. For the relief of particular parts, the vessels which belong to it, or which are adjacent to it, may be opened; as the vein running down the inside of the fore-arm is commonly opened when it is conceived the shoulder is affected; the necessity of this operation, on account of injuries of this part, is less frequent than is generally imagined; the vein itself in general gives out but little blood, and is very apt to swell after the operation.

Affections of the feet are more frequent, and we have often opened the coronary veins with obvious good effects; by puncturing with a lancet various parts of the coronary ring,

the blood flows copiously, and at length stops of itself without the least ill consequences.

The vein which encircles the coffin bone is also, without much difficulty, opened in inflammations of this part: the blood flows freely, the artery which accompanies it being in general opened along with it. It is necessary in performing this operation, to remove the horn covering the vessels with a drawing knife till the blood flows in sufficient abundance. The horn round the point of section should be thinned considerably, to prevent irritation, and mild resinous dressings should afterwards be laid over the part, to exclude the air, &c.

This operation we have heard condemned by some, as producing ill consequences, and a sore difficult to heal. We have only to remark, after having frequently performed it, we have not met with an instance of these ill effects following it.

The angular veins of the eye are often opened with good effects in inflammations of this part, as also the vessels which are seen passing over the sclerotic coats of the eye, and over the duplicature of the *membrana conjunctiva* on the inside of the eye-lids, both of which admit of easy section with the lancet.

The *temporal* artery also presents itself very conveniently for opening in the horse; and in inflammations of the brain, or its coverings, or where a sudden depletion of the system is desired, it is productive of manifest good effect. If this vessel should bleed too freely, and apprehensions are entertained of the loss of too much blood, it is most easily stopped by pressure, or by a deep incision, which completely severs the vessel; in this case its ends soon retracting, stop the farther effusion of blood.

The veins of the palate are conveniently situated for opening by making a transverse incision in this part with a lancet, and this is often had recourse to in the relaxation of the palate, termed lambers, and with apparently good effect. Some are deterred from the operation, by having experienced a difficulty in stopping the flow of blood; a circumstance that in a few times when we have performed this operation, has not occurred to us.

We shall now briefly state the mode of operating, and the consequences which sometimes follow the opening of the jugular vein in horses.

It is most usual to bleed with the fleam, or the lancet; the former on account of the thickness of the skin of the horse, and the resistance afforded by the hair, is generally had recourse to. It is also next to impossible to drive the blade into the neck so deep as to be injurious, on account of the shoulder to which it is affixed; it is perhaps, on this account, the safest and most certain instrument, especially in the hand of grooms and helpers in stables, as it cannot be much abused. In the structure of it, the back should be particularly attended to, for in general this is too narrow, inasmuch, that the instrument being struck, it sinks into the channel of the vein, the prominent muscles of the neck receive the stroke, and the vein is not opened. To remedy this, which is a very common inconvenience, the back of the fleam should be at least three quarters of an inch broad, in which case the operation very rarely fails.

The lancet is also very convenient in thin skinned horses, and performs the operation very well. It requires, however, on account of the resistance of the skin and hair, to be used rather boldly, as to the length it is presented with, and the force employed, at least when a copious flow of blood is desired.

It is usual to wet the hairs over the part intended to be punctured,

punctured, and then if they are drawn parallel to the direction of the vein, the lancet passing between them, there is less resistance than if they presented themselves transversely to the blade, in which case they must necessarily be divided before the incision can take place.

The jugular vein, after bleeding, often ulcerates, and is attended with the most serious ill consequences, the mischief extending in both directions along the internal surface of the vein, from the point of the incision; the cavity of the vein, or its canal, becomes obliterated, and the irritation occasions a thickening of the cellular membrane surrounding the vein, often to some inches in depth. This, in general, if no external irritation happens, subsides gradually, and disappears without any farther ill consequences, and the vein is totally lost on that side: at other times, an oozing and discharge of thin lymph takes place from the injured part, and a sinus forms, running mostly against the course of the vein up the neck, which, being freely opened, soon heals without farther inconvenience. At other times, considerable abscesses form, which are opened without danger, and the thickening of the cellular membrane gradually subsides, and the part heals. Again, in others, the inflammation and ulceration extend along the course of the vein to the head, forming abscesses, which burst and discharge blood, and the ulceration extending to the head becomes fatal.

As prevention is often much easier than cure, to avoid this accident great care should be taken to use a clean instrument, with a smooth, keen edge, not to strike where the vein has been already opened, where very often is an enlargement, and the vein becomes thinner in that part, and more extended, not to include any thing but the skin in pinning it up, and not to leave the pin remaining in the neck too long, to become cankered and rusty, and thus produce irritation. The pin should be clipped as short as possible, to prevent the horse rubbing it out against the manger, &c.

The wound will in general close of itself after a few minutes, if all pressure upon the vein be removed, and sufficiently firm to stop the escape of the blood, if the lips of the orifice are pressed together, without any pinning, and the horse's head, to render it more certain, should be tied rather high to the rack for a short time; where, however, the orifice is very large, or the veins very tumid, and disposed to bleed, pinning is the surest practice.

Lancets are often made with a spring, suddenly to plunge them into the vein, and are usefully and commodiously employed for this operation, as they do it with great suddenness and effect, more so than the hand or the blow of a blood-tick. The only objection is, that the instrument, from the pressure against the neck required in using it, cannot be so suddenly withdrawn as might be desirable, so that if the horse plunges at the moment he might severely cut himself, which we have seen happen. To prevent the possibility of such an occurrence, the instrument might be provided with a second spring to bring back the lancet to its sheath, or case, immediately after the stroke, which would render this instrument very useful and perfect.

BLEEDING from the nose. See *EPISTAXIS*.

BLEEDING from the lungs. See *HÆMOPTYSIS*.

BLEEDING by measure, is where an account is taken of the quantity as it flows from the vein, in order to put a stop to the flux when the requisite portion is had.

BLEEDING at large, where the flux is continued without regard to the quantity, till such time as some expected effect is perceived. This method is sometimes used in cases of apoplexies, comata, &c.

BLEEDING of a corpse, cruentatio cadaveris, is a phenome-

non said to have frequently happened in the bodies of persons murdered, which, on the touch, or even approach of the murderer, began to bleed at the nose, ears, and other parts; so as formerly to be admitted in England, and still allowed in some other parts, as a sort of detection of the criminal, and proof of the fact. Phil. Trans. N^o 77. p. 3012. But this kind of evidence derives its weight merely from superstition and credulity. Numerous instances of these posthumous hæmorrhages are given by Webster, Lemnius, Libavius, and especially Horstius, who has a discourse express on this point, under the title, "De Cruentatione Cadaverum."

BLEEDING is also applied, in a less proper sense, to a flux of sap out of the wounded vessels of plants, either spontaneously at certain seasons, or by art, and the help of incision.

BLEGNY, NICOLAS, in *Biography*, a bold, and, for a time, successful adventurer in medicine, to which he was not regularly educated. Dionis says, he married a midwife, which probably first suggested the idea of becoming a rupture doctor, and of contriving an elastic bandage for that complaint. In 1676, he published at Paris, "L'art de guerir des hernies," 12mo. which has passed through several editions. He used to cauterize the skin of the groin with aqua fortis, or the muriatic acid; when the wound healed, a firm cicatrix was left, which contributed in preventing the further descent of the gut. This remedy was invented by the prior De Cabeveres. He relates several remarkable cures performed by him: in one case, part of the urinary bladder had slipped into the ring. In 1679 he published, "Histoire anatomique d'un enfant, qui a demeuré vingt cinq ans dans le ventre de sa mere," Paris, 12mo. The fetus was said to be petrified. It had acquired, from its long residence in the abdomen, and from the pressure of the neighbouring viscera, an almost cartilaginous hardness, and retained very little of the human form. About the same time, he commenced the publication of a medical journal, under the title of "Les nouvelles decouvertes, sur toutes les parties de la medicine," of which one number came out every month, and he solicited and obtained assistance from a variety of practitioners; he also contributed considerably to it from his own stock. His name appeared as the editor for the first three years, but was afterwards omitted. Bouet thought the journal deserving of being translated into Latin, and published it at Geneva, in 4to. under the title of "Zodiaci medico-Gallici." He had before this made himself known by a treatise on the venereal disease; "L'Art de guerir les maladies veneriennes expliqué par les principes de la nature, et de la mecanique," 12mo. 2 vols. Paris. This was soon republished, translated into German, English, and other languages. He says, the disease was known to the ancients, and even to Moses. It may be brought on, he thinks, by immoderate venery. He objects to the use of astringent injections in the gonorrhœa, and professes to cure the lues, equally certainly, and more safely, with decoctions of guaiacum and sarsaparilla, than with mercury. He had also published, by order of his sovereign, "Remede Anglois, pour la guerison des sievres," 1682, 12mo. The principal part of this remedy was the Peruvian bark. He had now attained to very high rank in his profession, having been made, in succession, surgeon to the queen, to Philip duke of Orleans, and, in 1687, one of the physicians in ordinary to the king. Soon after he undertook the management of a hospital, for the reception of the sick poor at Pincourt, but for some immoral practices, encouraged in this place, a report of which was made to the king, he was removed from all his appointments,

and confined in prison for eight years. Released at length from his confinement, he went and settled at Avignon, where he continued to the time of his death, about the year 1722, being 70 years of age. Haller. Bib. Chirurg. Anat. et Med. Eloy Dict. Hist.

BLEICHERODE, in *Geography*, a town of Germany, in the circle of Upper Saxony, county of Hohenstein, and lordship of Lora; though small, it is populous and thriving, has some manufactures, and carries on a good trade; 20 miles north of Mulhausen.

BLEIDENSTATT, a town, or large village of Germany, in the circle of the Upper Rhine, and principality of Nassau-Saarbrück-Ufingen, seated on the Aar, 9 miles N.N.W. of Mentz.

BLEISTEIN, or **PLESTAIN**, a town of Germany, in the circle of Bavaria, and principality of Newburg, with an annexed lordship, a fief of the kingdom of Bohemia; 22 miles E. N. E. of Amberg.

BLEKEDE, a small town of Germany, in the circle of Lower Saxony, and principality of Lüneburg-Zell, seated on the Elbe, to which belongs a toll on the river of considerable produce; 20 miles E. N. E. of Lüneburg.

BLEKINGEN, called by the Swedes *Blekingh*, by the Danes *Blegind*, and by the inhabitants *Blegen*, a province of Sweden, bounded on the north by Smoland, on the south and east by the Baltic, and on the west by Scania, Schonen, or Skone, is about 100 English miles in length, and about 26 in breadth. It is a mountainous country, but various parts of it are more pleasant than any other provinces of the kingdom. It abounds with forests of oak, beech, pine, and birch trees, and carries on a considerable trade in pot-ash, tar, tallow, hides, leather, beams, deal-boards, and mats. The inhabitants also employ themselves in fishing and hunting. The shallow soil does not admit of much tillage, but the pastures afford the best cheese in Sweden; the cattle, however, are of a smaller size than those of Schonen. This country has several lakes and six principal rivers, which furnish good salmon. Its islands belonging to this jurisdiction are numerous, and the whole province contains 29 parishes. The clergy are subject to the see of Lund. As to its political division it consists of four barads, or districts, and its principal town is Carlserona, which see.

BLEMISH, in *Horse-dealing*. By this term, among the venders of horses, is understood any appearance by which the horse is disfigured, as broken knees, a blind eye, scars of various kinds, &c. The term blemish, by some, may be extended even to any unsightly natural markings of the horse. These blemishes, however, for the most part, are considered as in no wise of themselves constituting an unsoundness.

BLEMISH, a term in *Hunting*, used when the hounds, or beagles, finding where the chace has been, make a proffer to enter, but return.

BLEMMYES, or **BLEMYES**, among the *Ancient Geographers*, a fabulous sort of people, supposed without heads; having eyes and mouths on their breasts; said to have inhabited part of Ethiopia, on the borders of Egypt.

Some authors imagine that this fable had its origin in a custom which prevailed among this people of depressing their heads between their shoulders, which they forced upwards, so that their necks were very short, and their heads were concealed partly by their shoulders, and partly by their long and thick hair. To this purpose it is alleged, that the Egyptian, or bearded Bacchus, has the head sunk in his breast. We learn from Vopiscus, that some Blemmyan captives, taken prisoners by Probus, in an expedition against

them, about the year of Christ 278, made a very odd appearance at Rome. But at this time they could not be quite unknown at Rome, as some of them had appeared there before, on occasion of Aurelian's triumph. In the time of Dioclesian, the number of the Blemmyes, scattered between the island of Meroe and the Red sea, was very inconsiderable, their disposition was unwarlike, and their weapons rude and offensive; yet, in the public disorders, these barbarians, whom antiquity, shocked with the deformity of their figure, had almost excluded from the human species, presumed to rank themselves among the enemies of Rome. With a view of opposing to the Blemmyes a suitable adversary, Dioclesian, in his attack on the rebellious Egyptians, A. D. 296, persuaded the Nobatæ, or people of Nubia, to remove from their ancient habitations in the deserts of Libya, and resigned to them an extensive but unprofitable territory above Syene, and the cataracts of the Nile, with the stipulation, that they should ever respect and guard the frontier of the empire. We find, however, that at a subsequent period they sent ambassadors to the court of Constantine. The Blemmyes were subdued by Florus, the lieutenant of Marcian, A. D. 450.

Bochart derives the word *Blemmyes* from בְּלִי, which implies a *negation*, and בְּרוּת, *brain*; in which sense, the Blemmyes should have been people without brains. See Strabo, l. xvii. p. 1. 172. Pomponius Mela, l. 1. c. 4. His words, in describing these savages of Ethiopia, are curious; "Intra, si credere libet, vix homines magisque semiferi; Ægipanes, et Blemmyes, et Satyri."

BLENAU, in *Geography*, a town of France, in the department of the Yonne, and chief place of a canton in the district of Joigny, containing 1065 persons; the number of people in the canton amounts to 5976; the territory comprehends 290 kilometres and 9 communes; 2 leagues N.W. of St. Fargeau.

BLENCH, in *Law*, a sort of tenure of land; as to hold land in blench is by payment of a sugar-loaf, a couple of capons, a beaver-hat, &c. if the same be demanded in the name of *blench*, i. e. *nomine albæ firmæ*. See **ALBA FIRMA**.

BLENDE, in *Mineralogy*, called also black-jack, or pseudo-galenæ, the native sulphuret of zinc. See **ZINC**, *ores of*.

BLEND-metal-iron, a coarse sort of iron from the Staffordshire mines, used for making nails and heavy ware; in some places also for horse-shoes.

BLEND-water, a distemper incident to black-cattle, which comes several ways. 1. From blood. 2. From the yellows, which is a ringleader of all diseases. And 3. From the change of ground: for being hard, it is apt to breed this evil, which if not remedied in six days, will be past help.

BLENHEIM, in *Geography*, a village of Germany, in the circle of Bavaria, and principality of Newburg, 2 miles N. E. of Hockstedt, famous for a victory obtained there by the English and their allies over the French and Bavarians, August 13th 1704. For an account of the battle, see **HOCKSTEDT**.

BLENHEIM, a new town of America, in the state of New York, in Schoharie county, incorporated in 1797.

BLENNA, or **BLENA** (βληνα) in *Medicine*, a term used by Hippocrates, and subsequent medical writers, to denote a phlegm or mucus excreted from the nostrils. This sort of excretion occurs not unfrequently in acute diseases, and is generally a favourable symptom.

BLENNIUS, in *Ichthyology*, a Linnæan genus of jugular fishes.

Steph. Byz. to have derived its name from one of the companions of Cadmus.

BLIEGG, in *Ichthyology*, a name given by the Germans to the fish we call the *bleak*. See BLEAK, and ALBURNUS.

BLIESCASTEL, in *Geography*, a town of France, in the department of Sarre, and chief place of a canton, in the district of Sarrebruck; containing 1278 inhabitants; the population of the canton includes 10,084 persons; and the territory has 30 communes.

BLIESNA SALENSI, a harbour on the coast of Lapland, between the river Kola and Kilduyn island.

BLIGH's *Cap*, a name given by captain Cook, on account of its shape, to an island in the southern Pacific ocean, near Kerguelen's land, before called by Kerguelen "the island of Rendezvous." It is a high round rock accessible only to birds. S. lat. $48^{\circ} 29'$. E. long. $68^{\circ} 40'$.

BLIGHT, in *Agriculture*, a general name for various distempers incident to corn and fruit-trees.

It affects them variously, the whole plant sometimes perishing by it, and sometimes only the leaves and blossoms, which will be scorched and shrivelled up, the rest remaining green and flourishing. Some have supposed, that blights are produced by easterly winds, which bring vast quantities of insects' eggs along with them from distant places. These being lodged upon the surface of the leaves and flowers of fruit-trees, cause them to shrivel up and perish.

Mr. Knight, however, observes, that blights are produced by a variety of causes; by insects, by an excess of heat or cold, of drought or moisture; for these necessarily derange and destroy the delicate organization of the blossoms; but he believes the common opinion, that they arise from some latent noxious quality in the air, or from lightning, to be totally unfounded. The term blight is very frequently used by the gardener and farmer, he remarks, without any definite idea being annexed to it. If the leaves of their trees be eaten by the caterpillar, or contracted by the aphid; if the blossoms fall from the ravages of insects, or without any apparent cause, the trees are equally blighted, and if an east wind happen to have blown, the insects, or at least their eggs, whatever be their size, are supposed to have been brought by it. See APHIS.

The true cause of blights seems to be, continued dry easterly winds for several days together, without the intervention of showers, or any morning dew, by which the perspiration in the tender blossom is stopped; and if it so happen that there is a long continuance of the same weather, it equally affects the tender leaves, whereby their colour is changed, and they wither and decay.

The best remedy, perhaps, is gently to wash and sprinkle over the tree, &c. from time to time, with common water; and if the young shoots seem to be much infected, let them be washed with a woollen cloth, so as to clear them, if possible, from this glutinous matter, that their respiration and perspiration may not be obstructed. This operation ought to be performed early in the day, that the moisture may be exhaled before the cold of the night comes on; nor should it be done when the sun shines very hot. Mr. Forsyth recommends their being washed well with urine and soap-suds, as soon as possible after the disease appears.

Another cause of blights in the spring, is said to be sharp, hoary frosts, which are often succeeded by hot sun-shine in the day-time. This is the most sudden and certain destroyer of fruit that is known. The chief remedy to be depended upon in this case is, that of protecting the fruit-trees during the night-time with nets. This mode, where regularly and correctly performed, has been found highly beneficial.

But, in order to cure this disease, some have advised the burning of wet litter on the windward side of the plants, in order that the smoke of it may be carried to them by the wind, which they suppose will stifle and destroy the insects, and thereby cure the mischief. Others direct the use of tobacco-dust, or the washing of the trees with water in which tobacco-stalks have been infused for twelve hours, which they say will destroy those insects, and recover the plants. Pepper-dust, scattered over the blossoms of fruit-trees, &c. has been recommended as very useful in this case; and there are some who advise the pulling off the leaves that are affected.

What is termed the blight is frequently, however, no more than a debility, or distemper in trees. Mr. Forsyth observes, that "this is the case when trees, against the same wall, and enjoying the same advantages in every respect, differ greatly in their health and vigour, the weak ones appearing to be continually blighted, while the others remain in a flourishing condition. This very great difference, in such circumstances, can be attributed only to the different constitutions of the trees, proceeding from want of proper nourishment, or from some bad qualities in the soil; some distemper in the stock, buds, or scions; or from some mismanagement in the pruning, &c. all of which are productive of distempers in trees, of which they are, with difficulty, cured. If the fault be in the soil, it must, he says, be dug out, and fresh mould put in its place; or, the trees must be taken up, and others, better adapted to the soil, planted in their room. It will be found absolutely necessary always to endeavour to suit the particular sorts of fruit to the nature of the soil; for it is in vain to expect all sorts of fruit to be good in the same soil. If the weakness of the tree proceed from an in-bred distemper, it will be advisable to remove it at once, and after renewing the earth, to plant another in its place." But if the weakness is brought on by ill management in the pruning, which is frequently the case, he would advise more attention to the method of pruning and training.

Besides this, "there is another sort of blight that sometimes happens pretty late in the spring, as in April or May, which is very destructive to fruit-trees in orchards, and open plantations, and against which we know of no effectual remedy. This is what is called a *fire-blast*, which, in a few hours, hath not only destroyed the fruit and leaves, but often parts of trees; and sometimes entire trees have been killed by it." This, Mr. Forsyth observes, "is generally thought to be occasioned by certain transparent flying vapours, which may sometimes take such form, as to converge the sun's rays in the manner of a burning-glass, so as to scorch the plants they fall upon; and this, in a greater or less degree, in proportion to their convergency. As this generally happens in close plantations, where the vapours from the earth, and the perspiration from the trees, are pent in for want of a free circulation of air to disperse them, it points out to us the only way, yet known, of guarding against this enemy to fruits; namely, to make choice of a clear healthy situation for kitchen-gardens, orchards, &c. and to plant the trees at such a distance, as to give free admission to the air, that it may dispel those vapours before they are formed into such volumes as to occasion these blasts." But blasts may also be occasioned by the reflection of the sun's rays from hollow clouds, which sometimes act as burning mirrors, and occasion excessive heat. Against this there is no remedy yet discovered.

Mr. Marshall, in the Rural Economy of midland counties, observes, that it is well known that this disease is most injurious

jurious to grain crops in wet seasons; hence, principally, the scarcity and advanced price of wheat after such seasons. It is also remarked to affect the north side of fields, much more than the south, and that the effect is governed by the state of ripeness; consequently, a few days of forwardness may be sufficient to prevent the effect. It is evident, that the forward wheats are least liable to be blighted; for, having passed some certain stage of maturation, they become invulnerable to the attack of this mischievous enemy; at least, no obvious injury is incurred. It is also observable, that no perceptible blight takes place while a dry season continues. The only guard a farmer has against the attack of this secret enemy appears to be that of sowing early.

BLIGHT of corn is called SMUT.

BLIGNY-SUR OUCHES, in *Geography*, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Beaune, 3 leagues N.W. of Beaune, containing 1169 inhabitants; the canton contains 6598; and comprehends 26½ kilometres, and 23 communes.

BLIKOOSKOL, a small island in the Frozen sea. N. lat. 71° 30'. E. long. 125° 14'.

BLIND. See BLINDNESS.

BLIND, *Pore*, or *Pur*, denotes only a great degree of short-sightedness. Phil. Trans. N° 37. p. 731.

BLIND, is also used for occult, or imperceptible. Hence blind rampart, *cæcum vallum*, among the ancients, was that beset with sharp stakes, concealed by grafs or leaves growing over them.

BLIND testimonies, *cæca testimonia*, those given by absent persons in writing.

BLIND is also used in speaking of bodies without apertures.

Hence.

BLIND wall, *cæcus paries*, that without windows. In a like sense we meet with *blind chamber*, *cæcum cubiculum*.

BLIND is also used in speaking of vessels which are not perforated. In this sense the chemists say a blind alembic. A tube is said to be blind, when it is closed a-top. Some anatomists also call the third cavity of the ear *cæcum*, as having no issue; but it is more usually denominated labyrinth, which see.

BLIND harbour, or *Murderer's bay* of Tasman, in *Geography*, a deep bay at the N.W. part of the southern island of New Zealand, having two small islands near the bottom of it on the west side; 6 leagues to the east of cape Farewell.

BLIND, in the *Military Art*, signifies generally every material which serves to cover and protect the besiegers from the fire of the enemy; as wool-packs, sand bags, earth-baskets, &c. Blinds sometimes consist only of canvas stretched, so as to intercept the view of the garrison from the walls. Sometimes they are planks erected, and in this case are more properly called mantlets. They are also occasionally constructed with a number of baskets or barrels.

More particularly taken, blinds denote wooden frames of four pieces, either round or flat. Two of them are six feet long, and pointed at the extremities; the others, about three or four feet in length, serve as spars, to fasten the two former together. These blinds are fixed upright in the ground against the sides of the saps, to hinder the earth from falling in, and to fasten fascines upon the upper part. They are likewise of use in covering the saps, and supporting a roof of fascines to secure the troops from stones and grenades.

Blinds, of another sort are commonly made of osiers, or branches interwoven and laid across between two rows of

stakes, about the height of a man, and four or five feet asunder.

Blinds are of essential service at the heads of trenches, or saps, when they are extended in front towards the glacis; and when, from the superior elevation of the enemy's works, he may overlook, and pour his fire in upon the besiegers. They are also indispensable, in case the nature of the ground should oblige the approaches to be carried on in a straight direction, and the workmen and the guard to be necessarily exposed to the batteries of the garrison. But in this case, the saps can only be carried on in the night, as the loss of men would otherwise prove extremely serious.

BLIND is also sometimes used for ORILLON.

BLIND granado, that which does not light or take fire.

BLIND faith. See FAITH.

BLIND gut. See CÆCUM.

BLIND worm. See SLOW-worm.

BLINDING, a species of corporal punishment anciently inflicted on thieves, adulterers, perjurers, and others; and from which the ancient Christians were not exempt. Sometimes lime in vinegar, or barely scalding vinegar, was poured into the eyes, till their balls were consumed; sometimes a rope was twisted round the head till the eyes started out. Solin. Polyhiit. c. 4. Lamprid. in Alex. Sev. c. 17. Val. Max. lib. vi. c. 5. Lactant. de Mort. Perfec. c. 36.

In the middle age, they changed total blindness for a great darkness, or diminution of sight, which they produced by holding a red hot iron dish or basin before the eyes, till their humours were dried, and their coats shrivelled up.

The inhabitants of the city Apollonia executed it on their watch whom they found asleep. Democritus, according to Plutarch, Cicero, and A. Gellius, put out his own eyes, that he might be less disturbed in his mental contemplations, when thus freed from the distraction of the objects of sight. Herodot. lib. vi. c. 92. Aul. Gell. Noct. Att. lib. x. c. 71. Cicero Tusc. Qu. 5.

BLINDING, *obscatio*, in the *Black Art*, denotes a species of necromancy, whereby a visible body may be concealed, or hidden by an invisible power. See NECROMANCY.

BLINDING of a *casemate*, signifies erecting a battery against it, in order to dismount its cannon and render them useless.

BLINDNESS, in *Surgery*, the privation or want of sight. This defect may arise from a variety of causes, existing either in the organ of sight, or in the circumstances necessary to produce vision. See OPTICS and EYE. Blindness will be complete, when the light is wholly excluded; or partial, when it is admitted into the eye so imperfectly as to convey only a confused perception of visible objects. Blindness may again be distinguished into periodical or permanent, transient or perpetual, natural or accidental, &c.; but these distinctions do not serve to communicate any idea of the causes of blindness, which are to be slightly mentioned in the present article. For a more particular account of the causes and remedies of blindness, the reader will consult the articles which give an account of the doctrine of vision, and the diseases of the eye.

The ordinary causes of blindness are as follow:

1. In the eyelids and muscles. By a cohesion of the eyelids; by an elongation of the upper eye-lid; by a paralytic state, which disables the patient from raising it sufficiently; by an irregular or defective action in the muscles which are attached to the eye-ball.

2. In the membranes of the eye. By their opacity, so as to exclude the rays of light; by their exquisite sensibility, so as to render vision intolerable; by their blood-vessels assuming a morbid action, and effusing a fluid (suppose pus, for example) into any of the cavities of the eye.

BLINDNESS.

3. *In the humours of the eye.* By their defective quantity; by the turbid state, or imperfectly transparent condition, of the humours; by the loss of any one of them, through accident or violence; by an altered figure of the crystalline lens.

4. *In the brain or optic nerve.* By compression, producing pally or *GUTTA SERENA* (which see); by a state of debility or inertness in the visual organ, so as to require an uncommonly strong light; by too great sensibility in the optic nerve, enduring but a very feeble impression from the light, and transmitting only a confused perception of visible objects to the mind; by some unknown change in the nervous power, causing depraved vision, and exciting imaginary scenes, which no person can observe besides the patient himself.

It has been generally supposed, that blind persons have not any idea of visible objects, though they can distinguish them by the touch: thus the gentleman couched by Mr. Chefelden, though he knew the colours asunder in a good light during his blind state; yet when he saw them after couching, the faint ideas he had of them before, were not sufficient for him to know them by afterwards. *Phil. Transf.* N^o 403. p. 447.

It was even a considerable time before he could remember which was the cat and which the dog, though often informed, without feeling them. Add, that he had no idea of distance; but thought all the objects he saw touched his eyes, as what he felt did his skin.

But a case is recorded by Mr. Ware in the *Philosophical Transactions* (read to the society June 11th, 1801), which does not accord with Mr. Chefelden's observation on this subject. It was the case of a young gentleman, who (by a surgical operation) recovered his sight when seven years of age; after having been deprived of it by cataracts, before he was a year old. Mr. Ware gives the following account of the facts in question: "I performed the operation on the left eye, on the 29th of December last, in the presence of Mr. Chamberlayne, F.A.S. Dr. Bradley, of Baliol college, Oxford, and Mr. Platt, surgeon, in London. It is not necessary, in this place, to enter into a description of the operation. It will be sufficient to say, that the child, during its performance, neither uttered an exclamation, nor made the smallest motion, either with his head or hands. The eye was immediately bound up, and no inquiries made on that day with regard to his sight. On the 30th, I found that he had experienced a slight sickness on the preceding evening, but had made no complaint of pain, either in his head or eye. On the 31st, as soon as I entered his chamber, the mother, with much joy, informed me that her child could see.— About an hour before my visit, he was standing near the fire, with a handkerchief tied loosely over his eyes, when he told her that under the handkerchief, which had slipped upward, he could distinguish the table by the side of which she was sitting: it was about a yard and a half from him; and he observed that it was covered with a green cloth (which was really the case), and that it was a little farther off than he was able to reach. No further questions were asked him at that time; as his mother was much alarmed, lest the use thus made of his eye might have been premature and injurious. Upon examination, I found that it was not more inflamed than the other eye; and the opacity in the pupil did not appear to be much diminished. Desirous, however, to ascertain whether he was able to distinguish objects, I held a letter before him, at the distance of about twelve inches, when he told me, after a short hesitation, that it was a piece of paper; that it was square, which he knew by its corners; and that it was longer in one direction than it was in the

other. On being desired to point to the corners, he did it with great precision, and readily carried his finger in the line of its longest diameter. I then shewed him a small oblong band-box covered with red leather, which he said was red and square, and pointed at once to its four corners. After this, I placed before him an oval silver box, which he said had a shining appearance; and, presently afterwards, that it was round, because it had not corners. The observation, however, which appeared to me most remarkable, was that which related to a white stone mug; which he first called a white basin, but, soon after, recollecting himself, said it was a mug, because it had a handle. These experiments did not give him any pain; and they were made in the presence of his mother, and of Mr. Woodford, a clerk in his majesty's treasury. I held the objects at different distances from his eye, and inquired very particularly if he was sensible of any difference in their situation; which he always said he was, informing me, on every change, whether they were brought nearer to, or carried further from him. I again inquired, both of his mother and himself, whether he had ever, before this time, distinguished by sight any sort of object; and I was assured by both that he never had on any occasion; and that when he wished to discover colours, which he could only do when they were very strong, he had always been obliged to hold the coloured object close to his eye, and a little on one side, to avoid the projection of the nose. No further experiments were made on that day. On the 1st of January, I found that his eye continued quite free both from pain and inflammation, and that he felt no uneasiness on the approach of light. I shewed him a table knife; which at first he called a spoon, but soon rectified the mistake, giving it the right name, and distinguishing the blade from the handle, by pointing to each as he was desired. He afterwards called a yellow pocket-book by its name, taking notice of the silver lock in the cover. I held my hand before him; which he knew, but could not at first tell the number of my fingers, nor distinguish one of them from another. I then held up his own hand, and desired him to remark the difference between his thumb and fingers; after which he readily pointed out the distinctions in mine also. Dark-coloured and smooth objects, were more agreeable to him than those which were bright and rough. On the 3d of January, he saw, from the drawing room window, a dancing-bear in the street; and distinguished a number of boys that were standing round him, noticing particularly a bundle of cloths which one of them had on his head. On the same evening, I placed him before a looking-glass, and held up his hand: after a little time he smiled and said he saw the shadow of his hand, as well as that of his head. He could not then distinguish his features; but, on the following day, his mother having again placed him before the glass, he pointed to his eyes, nose, and mouth, and seemed much gratified with the sight.

Having thus stated the principal observations that were made by Master W. I shall now make a brief comparison between this statement, and that which is given in the XXXVth volume of the *Philosophical Transactions*, of M. Chefelden's patient, who was supposed to be born blind, and obtained his sight when he was between thirteen and fourteen years old.

It should be observed, that though Master W. was six years younger than Mr. Chefelden's patient, he was remarkably intelligent, and gave the most direct and satisfactory answers to every question that was put to him. Both of them, also, if not born blind, lost their sight so very early, that, as Mr. Chefelden expresses it, "they had not any recollection of having ever seen."

BLINDNESS.

My first remark is, that, contrary to the experience of Mr. Cheselden's patient, who is slated "to have been so far from making any judgment of distance, that he thought all objects touched his eyes, as what he felt did his skin," Master W. distinguished, as soon as he was able to see, a table, a yard and a half from him; and proved that he had some accuracy in his idea of distance, by saying, that it was a little further off than his hand could reach. This observation, so contrary to the account we have received of Mr. Cheselden's patient, would have surpris'd me much more than it did, if I had not previously, in some similar instances, had reason to suspect that children, from whom cataracts had been extract'd, had a notion of distance the first moment they were enabled to see. In the instance particularly of a young gentleman from Ireland, fourteen years old, from each of whose eyes I extract'd a cataract, in the year 1794, in the presence of Dr. Hamilton, physician to the London hospital, and who, before the operation, assur'd me, as did his friends, that he never had seen the figure of any object, Dr. Hamilton and myself were much astonish'd by the facility with which, on the first experiment, he took hold of my hand at different distances, mentioning whether it was brought nearer to, or carried further from him, and conveying his hand to mine in a circular direction, that we might be the better satisfied of the accuracy with which he did it. In this case, however, and in others of a like nature, although the patients had certainly been blind from early infancy, I could not satisfy myself that they had not, before this period, enjoyed a sufficient degree of sight to impress the image of visible objects on their minds, and to give them ideas which could not afterwards be entirely obliterated. In the instance of Master W. however, no suspicion of this kind could occur; since, in addition to the declaration of himself and his mother, it was proved by the testimony of the surgeon who examined his eyes in the country, that the cataracts were fully formed before he was a year old. And I beg leave to add further, that on making inquiries of two children, between seven and eight years of age, now under my care, both of whom have been blind from birth, and on whom no operation has yet been performed, I find that the knowledge they have of colours, limited as it is, is sufficient to enable them to tell whether coloured objects be brought nearer to, or carried further from them; for instance, whether they are at the distance of two inches or four inches from their eyes; nor have either of them the slightest suspicion, as is related of Mr. Cheselden's patient, that coloured objects, when held before them, touch their eyes.

But the judgment which Master W. formed of the different distances of objects, was not the only instance in which he differed from Mr. Cheselden's patient; who, we are inform'd, "did not know the figure of any thing, nor any one thing from another, however different in shape and magnitude;" for Master W. knew and describ'd a letter, not only as white, but also as square, because it had corners; and an oval silver box, not only as shining, but also as round, because it had not corners: he likewise knew, and call'd by its name, a white stone mug, on the first day he obtain'd his sight, distinguishing it from a basin, because it had a handle. These experiments were made in the presence of two respectable persons, as well as myself; and they were several times repeated, to convince us that we could not be mistaken in them. I mention the circumstance, however, with much diffidence, being aware that the observations not only differ from those that are related of Mr. Cheselden's patient, but appear, on the first statement, to oppose a principle in optics, which I believe is commonly and justly admitted, that the senses of sight and feeling have no other connection than that

which is formed by experience; and, therefore, that the ideas derived from feeling can have no power to direct the judgment, with respect either to the distance or form of visible objects. It should be recollected, however, that persons who have cataracts in their eyes, are not, in strictness of speech, blind, though they are deprived of all useful sight. The instances I have adduc'd prove, that the knowledge they have of colours is sufficient to give them some idea of distance, even in their darkest state. When, therefore, their sight is cleared by the removal of the opaque crystalline, which intercepts the light, and the colour of objects is thereby made to appear stronger, will it be difficult, or unphilosophical, to conceive that their ideas of distance will be strengthened, and so far extended as to give them a knowledge, even of the outline and figure of those objects with the colour of which they were previously acquainted?"

The miseries of blindness are feelingly describ'd both by Homer and Milton, in the following impressive passages. The venerable father of epic poetry, who is said, in the person of Demodocus the Phœacian bard, to have describ'd his own situation, proceeds thus:

"Τὸν πρῶτον Μῆσος ἔφιλῆσσε, δῖος δ' ἀγαθὸν τε, κακὸν τε,
Ὅτ' ἄσπετον μὲν ἄμερσσε, δῖος δ' ἦναι ἄσπιδον."

Odyss. l. 9. v. 63, 64.

"Dear to the muse, who gave his days to flow
With mighty blessings mix'd with mighty woe,
In clouds and darkness quench'd his visual ray,
Yet gave him pow'r to raise the lofty lay." POPE.

In similar strains does Milton bewail his calamity, in his address to light:—

"Taught by the heav'nly muse to venture down
The dark descent, and up to re-ascend,
Though hard and rare; thee I revisit safe,
And feel thy sov'reign vital lamp; but thou
Revisit'lt not these eyes, that roll in vain
To find thy piercing ray, and find no dawn;
So thick a drop serene hath quench'd their orbs,
Or dim suffusion veil'd. Yet not the more
Cease I to wander, where the muses haunt
Clear spring, or shady grove, or sunny hill,
Smit with the love of sacred song: but chief
Thee, Sion, and the flow'ry brooks beneath,
That wash thy hallow'd feet, and warbling flow,
Nightly I visit; nor sometimes forget
Those other two, equal'd with me in fate,
So were I equal'd with them in renown,
Blind Thamyras and blind Mæonides,
And Tiresias and Phœneus prophets old:
Then feed on thoughts, that voluntary move
Harmonious numbers: as the wakeful bird
Sings darkling, and in shadiest covert hid
Tunes her nocturnal note. Thus with the year
Seasons return; but not to me returns
Day, or the sweet approach of ev'n or morn,
Or sight of vernal bloom, or summer's rose,
Or flocks, or herds, or human face divine:
But cloud instead, and ever during dark,
Surrounds me, from the cheerful ways of men
Cut off, and for the book of knowledge fair
Presented with an universal blank
Of nature's works to me expung'd and ras'd,
And wisdom at once entrance quite shut out."

Paradise Lost, b. iii.

Thus also does he deplore, in the most affecting accents, the misfortune of blindness in his "Sampson Agonistes:—

—————"But chief of all,

O loss of sight, of thee I must complain!

BLINDNESS.

Blind among enemies, O worse than chains,
 Dungeon, or beggary, decrepid age.
 Light, the prime work of God, to me is extinct,
 And all her various objects of delight
 Annul'd, which might in part my grief have eas'd,
 Inferior to the vilest now become
 Of man or worm. The vilest here excel me :
 They creep, yet see ; I dark in light expos'd
 To daily fraud, contempt, abuse, and wrong,
 Within doors, or without, still as a fool,
 In power of others, never in my own ;
 Scarce half I seem to live, dead more than half.
 O dark, dark, dark, amid the blaze of noon,
 Irrecoverably dark, total eclipse
 Without all hope of day !
 O first created beam, and thou great word,
 Let there be light, and light was over all ;
 Why am I thus bereav'd thy prime decree ?
 The sun to me is dark,
 And silent, as the moon
 When she deserts the night,
 Hid in her vacant interlunar cave.
 Since light so necessary is to life,
 And almost life itself, if it be true
 That light is in the soul,
 She all in every part ; why was the sight
 To such a tender ball as th' eye confin'd ?
 So obvious, and so easy to be quench'd ?
 And not, as feeling, throughout all parts diffus'd,
 That she might look at will through ev'ry pore ?
 Then had I not been thus exil'd from light,
 As in the land of darknes, yet in light
 To live a life half dead, a living death :
 And buried ; but yet more miserable !
 Myself the sepulchre, a moving grave ;
 Bury'd, yet not exempt
 By privilege of death and burial
 From worst of other evils, pains, and wrongs,
 But made hereby obnoxious more
 To all the miseries of life."

The degree in which the calamity of blindness is felt and lamented by those to whom it occurs, may be also partly guessed at by the extasies into which persons have fallen on their recovery from it.

Mr. Boyle mentions a gentleman, who, having been blind, and brought to sight at eighteen, was very near going distracted with the joy. See a remarkable case of this kind, Tatler, N^o 55. vol. i. Boyle's Works abr. tom. i. p. 4.

We find various recompences for blindness, or substitutes for the use of the eyes, in the wonderful sagacity of many blind persons recited by Zaharius in his "Oculus Artificialis," and others. In some, the defect has been supplied by a most excellent gift of remembering what they had seen; in others, by a delicate nose, or the sense of smelling; in others, by an exquisite touch, or a sense of feeling, which they have had in such perfection, that, as it has been said of some, they learned to hear with their eyes; as it may be said of these, that they taught themselves to see with their hands.

Some have been enabled to perform all sorts of curious and subtle works in the nicest and most dextrous manner. Aldrovandus speaks of a sculptor who became blind at twenty years of age, and yet ten years after made a perfect marble statue of Cosmo II. de Medicis: and another of clay like Urban VIII. Bartholin tells us of a blind sculptor in Denmark, who distinguished perfectly well, by mere

touch, not only all kinds of wood, but all the colours; and F. Grimaldi gives an instance of the like kind; besides the blind organist living in Paris, who is said to have done the same.

The most extraordinary of all is a blind guide, who, according to the report of good writers, used to conduct the merchants through the sands and deserts of Arabia. James Bernouilli contrived a method of teaching blind persons to write. Leo Afr. Desc. Afr. lib. vi. p. 246. Casaub. Treat. of Enthuf. chap. ii. p. 45. Fonten. Elog. des Acad. p. 114.

An instance no less extraordinary is mentioned by Dr. Bew in the "Transactions of the Manchester Society." It is that of a person, whose name is John Metcalf, a native of the neighbourhood of Manchester, who became blind at so early an age as to be altogether unconscious of light and its various effects. His employment in the younger period of his life was that of a waggoner, and occasionally as a guide in intricate roads during the night, or when the common tracks were covered with snow. Afterwards he became a projector and surveyor of high-ways in difficult and mountainous parts; and in this capacity, with the assistance merely of a long staff, he traverses the roads, ascends precipices, explores valleys, and investigates their several extents, forms, and situations, so as to answer his purpose in the best manner. His plans are designed, and his estimates formed, with such ability and accuracy, that he has been employed in altering most of the roads over the Peak in Derbyshire, particularly those in the vicinity of Buxton, and in constructing a new one between Wilmslow and Congleton, so as to form a communication between the great London road, without being obliged to pass over the mountain.

Although blind persons have occasion, in a variety of respects, to deplore their infelicity, their misery is in a considerable degree alleviated by advantages peculiar to themselves. They are capable of a more fixed and steady attention to the objects of their mental contemplation, than those who are distracted by the view of a variety of external scenes. Their want of sight naturally leads them to avail themselves of their other organs of corporeal sensation, and with this view to cultivate and improve them as much as possible. Accordingly they derive relief and assistance from the quickness of their hearing, the acuteness of their smell, and the sensibility of their touch, which persons who see are apt to disregard; and many instances have occurred, that seem to verify the opinion of Rocheller;

"That if one sense should be suppress'd,

It but retires into the rest."

To this purpose we may observe, that Democritus is said to have put out his eyes, that he might think more intently.

Many contrivances have also been devised by the ingenious for supplying the want of sight, and for facilitating those analytical or mechanical operations, which would otherwise perplex the most vigorous mind and the most retentive memory. By means of these they have become eminent proficient in various departments of science. Indeed, there are few sciences in which, with or without mechanical helps, the blind have not distinguished themselves. The case of professor Saunderson at Cambridge is well known. His attainments and performances in the languages, and also as a learner and teacher in the abstract mathematics, in philosophy, and in music, have been truly astonishing; and the account of them appears to be almost incredible, if it were not amply attested and confirmed by many other instances of a similar kind, both in ancient and modern times. Cicero mentions it as a fact scarcely credible, with respect to his master in philosophy, Diodotus, that "he exercised himself

BLINDNESS.

in it with greater assiduity after he became blind; and, which he thought next to impossible to be performed without sight, that he professed geometry, and described his diagrams so accurately to his scholars, as to enable them to draw every line in its proper direction." Jerom relates a more remarkable instance of Didymus in Alexandria, who, "though blind from his infancy, and therefore ignorant of the letters, appeared so great a miracle to the world, as not only to learn logic, but geometry also to perfection, which seems (he adds) the most of any thing to require the help of sight." Professor Saunderson, who was deprived of his sight by the small pox, when he was only twelve months old, seems to have acquired most of his ideas by the sense of feeling; and though he could not distinguish colours by that sense, which, after repeated trials, he said was pretending to impossibilities, yet he was able with the greatest exactness to discriminate the minutest difference of rough and smooth in a surface, or the least defect of polish. In a set of Roman medals he could distinguish the genuine from the false, though they had been counterfeited in such a manner, as to deceive a connoisseur, who judged of them by the eye. His sense of feeling was so acute, that he could perceive the least variation in the state of the air; and it is said, that in a garden where observations were made on the sun, he took notice of every cloud that interrupted the observation, almost as justly as those who could see it. He could tell when any thing was held near his face, or when he passed by a tree at no great distance, provided the air was calm, and there was little or no wind: this he did by the different pulse of air upon his face. He possessed a sensibility of hearing to such a degree, that he could distinguish even the fifth part of a note; and by the quickness of this sense he not only discriminated persons with whom he had once conversed so long as to fix in his memory the sound of their voice, but he could judge of the size of a room into which he was introduced, and of his distance from the wall; and if he had ever walked over a pavement in courts, piazzas, &c. which reflected a sound, and was afterwards conducted thither again, he could exactly tell in what part of the walk he was placed, merely by the note which it sounded. See SAUNDERSON.

Sculpture and painting are arts which, one would imagine, are of very difficult and almost impracticable attainment to blind persons; and yet instances occur, which shew that they are not excluded from the pleasing creative and extensive regions of fancy. We have known cases in which the form and features of the face have been delineated wholly by the touch, and in which it has been moulded with the utmost exactness. De Piles (*Cours de Peint.* p. 329.) mentions a blind sculptor, who thus took the likeness of the duke de Bracciano in a dark cellar, and made a marble statue of king Charles I. with great justness and elegance. However unaccountable it may appear to the abstract philosophers, yet nothing is more certain in fact, than that a blind man may, by the inspiration of the muses, or rather by the efforts of a cultivated genius, exhibit in poetry the most natural images and animated descriptions even of visible objects, without deservedly incurring the charge of plagiarism. We need not recur to Homer and Milton for attestations to this fact; they had probably been long acquainted with the visible world before they had lost their sight; and their descriptions might be animated with all the rapture and enthusiasm which originally fired their bosoms, when the grand and delightful objects delineated by them were immediately beheld. We are furnished with instances in which a similar energy and transport of description, at least in a very considerable degree, have been exhibited by

those on whose minds visible objects were never impressed, or have been entirely obliterated. Dr. Blacklock affords a surprising instance of this kind; who, though he had lost his sight before he was six months old, not only made himself master of various languages, Greek, Latin, Italian, and French, but acquired the reputation of an excellent poet, whose performances abound with appropriate images and animated descriptions. See BLACKLOCK.

Another instance, which deserves being recorded, is that of Dr. Henry Moyes in our own country, who, though blind from his infancy, by the ardour and assiduity of his application, and by the energy of native genius, not only made incredible advances in mechanical operations, in music, and in the languages, but acquired an extensive acquaintance with geometry, optics, algebra, astronomy, chemistry, and all other branches of natural philosophy. From the account of Dr. Moyes, who occasionally read lectures on philosophical chemistry at Manchester, delivered to the Manchester society by Dr. Bew, it appears, that mechanical exercises were the favorite employment of his infant years; and that at a very early age he was so well acquainted with the use of edge-tools, as to be able to construct little wind-mills, and even a loom. By the sound, and the different voices of the persons that were present, he was directed in his judgment of the dimensions of the room in which they were assembled; and in this respect he determined with such a degree of accuracy, as seldom to be mistaken. His memory was singularly retentive; so that he was capable of recognizing a person on his first speaking, though he had not been in company with him for two years. He determined with surprising exactness the stature of those with whom he conversed, by the direction of their voices; and he made tolerable conjectures concerning their dispositions, by the manner in which they conducted their conversation. His eyes, though he never recollected his having seen, were not totally insensible to intense light; but the rays refracted through a prism, when sufficiently vivid, produced distinguishable effects upon them. The red produced a disagreeable sensation, which he compared to the touch of a saw. As the colours declined in violence, the harshness lessened, until the green afforded a sensation that was highly pleasing to him, and which he described as conveying an idea similar to that which he gained by running his hand over smooth polished surfaces. Such surfaces, meandering streams, and gentle declivities, were the figures by which he expressed his ideas of beauty; rugged rocks, irregular points, and boisterous elements furnished him with expressions for terror and disgust. He excelled in the charms of conversation; was happy in his allusions to visual objects; and discoursed on the nature, composition, and beauty of colours, with pertinence and precision. This instance, and some others which have occurred, seem to furnish a presumption, that the feeling or touch of blind persons may be so improved, as to enable them to perceive that texture and disposition of coloured surfaces by which some rays of light are reflected and others absorbed, and in this manner to distinguish colours. But the fact is still undecided; and farther trials are necessary, in order to set aside high authorities to the contrary, and absolutely to decide it. Dr. Reid, in his "Inquiry into the Human Mind on the Principles of Common Sense" (ch. vi. § 2.), deduces evidence from acknowledged facts, as well as reasoning, in order to shew, that there is very little of the knowledge acquired by sight, that may not be communicated to a man born blind. One who never saw the light may be learned and knowing in every science, even in optics; and may make discoveries in every branch of philosophy. He may understand as much as

BLINDNESS.

another man, not only of the order, distances, and motions of the heavenly bodies, but of the nature of light, and of the laws of the reflection and refraction of its rays. He may understand distinctly, how those laws produce the phenomena of the rainbow, the prism, the camera obscura, and the magic lanthorn, and all the powers of the microscope and telescope. Nevertheless, as to the appearances of colour, a blind man must be more at a loss, because he has no perception that resembles it; though, by a kind of analogy, he may supply even this defect. To those who see, a scarlet colour signifies an unknown quality in bodies, that exhibits to the eye an appearance which they have often observed, and which they well know; but to a blind man, it denotes an unknown quality that exhibits an appearance, with which he is unacquainted. But he can conceive the eye to be variously affected by different colours, as the nose is by different smells, or the ear by different sounds; thus, he can conceive scarlet to differ from blue, as the sound of a trumpet does from that of a drum; or, as the smell of an orange differs from that of an apple. It is impossible to know whether scarlet colour has the same appearance to me which it has to another man; and if its appearances to different persons differed as much as colour does from sound, they might never be able to discover this difference. Hence it is plain, that a blind man might talk for a long time about colours distinctly and pertinently; and if you were to examine him in the dark about the nature, composition, and beauty of them, he might be able to answer, so as not to betray his defect. After all, as a blind man has never had any sensation of light and colour, his knowledge concerning them, however extensive and accurate, must be the result of previous instruction; it must depend on the force of genius, or on the strength of memory; and his language concerning coloured objects must be like that of a parrot, without any precision of meaning, and without any corresponding ideas. On this disputed subject the reader may derive information from Diderot's "Lettre sur les Aveugles a l'usage de ceux qui voyent," or "A letter concerning the Blind for the use of those who see," in his "Works," vol. ii.; and they also may consult Chefelden's "Anatomy," and Locke's "Essay on the human understanding."

With regard to the scientific and practical departments of music, every age has supplied numerous instances of blind persons who have attained to great excellence. They will occur among the articles of musical biography in the course of this work.

Of the contrivances that have been devised for the assistance of the blind, we have already mentioned those of professor Saunderson, and of Mr. Grenville, under the article *Palpable ARITHMETIC*. We shall here subjoin, from a letter addressed by Dr. Moyes to the editor of the "Encyclopædia Britannica," an account of the palpable notation generally used by him for twenty years, for the purpose of assisting his memory in numerical computations. With this view he made use of a square piece of mahogany, a foot broad and an inch thick, represented by ABCD (*Plate I. Algebra, fig. 3.*); he divided each of the sides AB, BC, CD, DA, into 24 equal parts; joined each pair of opposite divisions by a groove cut in the board of sufficient depth to be felt with the finger; and perforated the board at each intersection with an instrument $\frac{1}{16}$ th of an inch in diameter. Having thus divided the surface of the board into 576 small squares, perforated at each of their angles, he fitted to the holes in the board three sets of pegs or pins, resembling those in the plate, *figs. 4, 5, 6*, in such a manner, that when fixed in them they kept their position, and required some force to turn them round. The head of each peg belonging to the first

set is a right-angled triangle, about $\frac{1}{16}$ th of an inch thick; the head of each peg belonging to the second set differs from the former merely in having a small notch in its sloping side or hypotenuse; and the head of each peg of the third set is a square, the breadth of which should be equal to the base of the triangle of the other two. These pegs should be kept in a case consisting of three boxes or cells, each cell being allotted to a set; and the case must be placed close by the board before the commencement of every operation. Each set should consist of 60 or 70 pegs, at least when employed in long calculations; and when the work is finished, they should be collected from the board, and carefully restored to their respective boxes. When a peg of the first set is fixed into the board, it will acquire four different values, according to its position with respect to the calculator. When its sloping side is turned towards the left, it denotes *unit*, or the first digit; when turned upwards, or from the calculator, it denotes 2, or the second digit; when turned to the right, it represents 3; and when turned downwards, or towards the calculator, it denotes 4. The number 5 is denoted by a peg of the second set, having its sloping side turned to the left; 6, by the same turned upwards; 7, by the same turned to the right; and 8, by the same turned directly down, or towards the body of the calculator. The figure 9 is expressed by a peg of the third set, when its edges are directed to right and left; and the same peg expresses the cypher 0, when its edges are directed up and down. By these different pegs the relative values of the ten digits may therefore be distinctly expressed with facility; and by a sufficient number of each set the steps and result of the longest calculation may be clearly represented to the sense of feeling. For an example, let it be required to express the year of the Christian æra 1788. Take a peg of the first set, and fix it in the board, with its sloping side turned towards the left, which represents 1; take a peg of the second set, and fix it in the next hole in the same groove, proceeding as usual from left to right, with its sloping side turned to the right, and this expresses 7; take again a peg of the same set, and fix it in the next hole with its sloping side turned downwards, and this will represent 8; and lastly, take another peg of the same set, and place it in the next hole in the same position which will denote 8; and thus the whole will express the number required. In order to express a vulgar fraction, the numerator is placed in the groove immediately above, and the denominator in that immediately below the groove in which the integers stand; and in decimal arithmetic an empty hole in the integer groove represents the comma, or decimal point. By similar breaks are also denoted pounds, shillings, pence, &c.; and by the same expedient, the divisor and quotient in division are separated from the dividend. "This notation," says the ingenious inventor, "which supplies me completely with coefficients and indices in algebra and fluxions, seems much superior to any of the kind hitherto made public in the west of Europe. That invented and described by Mr. Grenville, having no less than ten sets of pegs, is by much too complicated for general practice; and that which we owe to the celebrated Saunderson is apt to puzzle and embarrass the calculator, as the pegs representing the numerical digits can seldom or never be in the same straight line."

It redounds very much to the honour of modern times, that the public attention has been directed to the improvement of the condition of blind persons; and that institutions have been formed in different countries for providing them with suitable employment, tending not only to alleviate their calamity, but to render them useful. The first regular and

BLINDNESS.

systematic plan for this purpose was proposed by M. Haüy in an "Essay on the education of the Blind," printed at Paris in the year 1766, under the patronage of the Academy of Sciences. An English translation of this essay is annexed to "Dr. Blacklock's Poems," printed at Edinburgh in 1793, 4to. The object of this plan is to teach the blind reading, by the assistance of books, in which the letters are rendered palpable by their elevation above the surface of the paper; and by these means to instruct them, not only in the liberal arts and sciences, but likewise in the principles of mechanical operations, such as spinning, knitting, book-binding, &c. so that those who are in easy circumstances may be capable of amuling employment, and those of the lower ranks of life, and such as have no genius for literary improvement, may nevertheless, become respectable, useful, and independent members of society, in the situation of common artificers. By these palpable characters, they are taught to read, to write, and to print; and they are likewise instructed, according to their several talents and stations, in geometry, algebra, geography, and every branch of natural philosophy. The institution encourages and cherishes a taste for the fine arts; it teaches the blind to read music with their fingers, as others do with their eyes; and it does this with so much success, that though they cannot at once feel the notes and perform them upon an instrument, yet they are capable of acquiring any lesson with as much exactness and rapidity, as those who enjoy all the advantages of sight. Of this curious and interesting essay, now before us, we shall give such an account as may serve to gratify those of our readers, who are concerned in the support of plans, somewhat resembling that which it describes, in our own country. The author, after stating the object of his plan, and obviating the scruples of those who demur against allowing its general utility, in the two first chapters, proceeds, in the third chapter, to illustrate the method of reading, as adapted to the practice of the blind. This method consists, as we have already observed, in the use of typographical characters, whose elevation above the surface of the paper renders them obvious to the touch, without the intervention of sight. From the perception of typographical characters, the transition is not difficult to that of written characters; i. e. of characters not written with ink, but formed by impressions made upon strong paper with an iron pen, whose point is not slit. The characters, thus produced, are distinctly separated and inverted; and they are marked on the side of the paper contrary to that which is read, and in such a manner that the position and order of the letters may appear right and in relief when the page is turned. The blind may thus be able to form and decypher musical characters, mathematical diagrams, and all the necessary processes of arithmetic and geography, as well as those that are printed and written. In the fourth chapter the author replies to several objections that are urged against the method of reading he has proposed. The fifth and sixth chapters contain an account of the art of printing, as it is practised by the blind, for their peculiar use, and also as it is performed for the use of those who see. In the process of printing, the blind compositor has a box for every alphabetical character in use; on the outside of these boxes are palpably marked the peculiar character belonging to each; these are filled with types, which he selects and sets as they are wanted, but in a contrary position to that in which they are read. When the types have been arranged and fixed, a page of very strong paper is moistened, so as to be capable of receiving and retaining impressions, and laid upon the types; and then by the operation of the press, or by the easy strokes of a small hammer frequently repeated over the surface, the impression of the type is made to rise on the opposite side of the paper; and it continues, when

dry, not only obvious to the sight but to the touch, and is not easily effaced. On the upper side of the paper the letters appear in their proper position; and by their sensible elevation above the common surface, the blind may easily read them with their fingers. The seventh chapter explains the method of teaching the blind to write; which we have already noticed. The eighth chapter shews how they are taught arithmetic; for this purpose they are provided with a board pierced with different lines of square holes, proper for receiving moveable figures, and bars for separating the different parts of an operation. To render this board more useful, a case is added, composed of four rows of little boxes, which contain all the figures proper for calculation, and which are placed at the right hand of the blind person while he operates. In order to obtain characters for expressing all the possible fractions, 10 simple denominators are cast, in the order of the figures 0, 1, 2, &c. to 9 inclusively, and likewise 10 simple numerators in the same order, moveable, so as to be adapted at the head of the denominators. By means of this combination, the blind are able to express any fraction. The ninth chapter treats of geography, and in teaching it, M. Weissenbourg and Mad. Paradis marked the circumference of countries by a tenacious and viscid matter, and covered the different parts of their maps with a kind of sand mixed with galls, in various modes; and distinguished the order of towns by grains of glass, of a greater or less size. M. Haüy satisfies himself with marking the limits of the maps, for the use of the blind, by small iron wire rounded; and it is always a difference, either in the form or size of every part of a map, which assists his pupils in distinguishing the one from the other. For the purpose of teaching music, the subject of the tenth chapter, musical characters are cast; and these are so numerous, as to represent upon paper, by elevations on its surface, all the possible varieties that occur. The eleventh chapter contains an account of the mechanic arts, in which the blind are employed, and of the method in which they are formed for such occupations. Accordingly they have been successfully employed in spinning, in making pack-thread of the thread they have spun, in weaving girths with this pack-thread, in making nets, in sewing, in binding books, &c. In the twelfth chapter we have a view of the proper mode of instructing the blind, together with a parallel between their education and that of the deaf and dumb. This operation, it is said, is easy in itself, and requires in a matter more courage than knowledge. "By the aid," says M. Haüy, "of our books in relief, every one can teach them to read. Upon the musical works found in our press, every professor of that art may give them lessons. With an iron pen, with plates and moveable characters, executed according to our models, the first master in writing may teach them that art, and arithmetic." The thirteenth chapter contains a brief account of the elementary books of languages, mathematics, and history, which should compose the library of the blind person. The essay terminates with an historical summary of the rise, progress, and actual state of the institution for blind children. The success of this institution has fully answered the expectation of its founder, and amply compensated the expense bestowed upon it by the liberal and well disposed. We are happy to add, that institutions of a similar kind have been established in our own country; and to render our particular tribute of respect to the founders and supporters of the "School for the Indigent Blind," instituted in London in 1799. It is now situated in St. George's-fields, but will speedily be removed to Gray's Inn-lane, as soon as the necessary buildings for its accommodation are erected. The object, with a view to which this school was founded, is unquestionably one of the most important and interesting kind

BLINDNESS.

that can excite compassion, or demand encouragement. It provides instruction for the indigent blind, in a trade, by which they may be able to provide, either wholly or in part, for their own subsistence; and thus, instead of being altogether a burden to the community, they will be of some service to it; and instead of being depressed and cheerless themselves, under a sense of their total dependence, and for want of regular employment, habits of industry will relieve their spirits, and produce the most beneficial effects on their state and character. The children of this institution, amounting in the present year (1804) to 32, are completely clothed, boarded, lodged, and instructed, gratis. The articles at present manufactured in the school are shoemakers' thread, fine and coarse thread, window sash-line, and cloaths' line (of a peculiar construction, and made on a machine adapted to the use of blind persons), by the females; and window and sash-line, cloaths' line, hampers, and wicker baskets, by the males. The success that has crowned the efforts of the friends of this institution, since its first establishment, affords sufficient evidence of the degree in which the situation and faculties of the blind are capable of improvement; and a view of it in its present prosperous state, must be gratifying to persons of humane and compassionate feelings. Here they will not find the scholars sitting in listless indolence, which is commonly the case with the blind, or brooding in silence over their own defects, and their inferiority to the rest of mankind; but they will behold a number of individuals, of a class hitherto considered as doomed to a life of sorrow and discontent, and to be provided for merely in alms-houses, or by donations of charity, not less animated in their amusements, during the hours of recreation, and far more cheerfully attentive to their work in those of employment, than persons possessed of sight. This important and useful institution is under the direction of a president, eight vice-presidents, a treasurer, and a committee of 24 members. A subscription of one guinea annually, or of not less than 20 guineas at once, or within one year, constitutes a member.

To this article we shall subjoin the following directions given by Mr. Thicknesse, for teaching the blind to write:

“Let any common joiner make a flat board, about 14 inches long, and 12 wide; in the middle of which let a place be sunk, deep enough, when lined with cloth, to hold only two or three sheets of fool's-cap paper, which must quite fill up the space: over this must be fixed a very thin false frame, which is to cover all but the paper, and fastened on by four little pins, fixed in the lower board: and across the lower frame, just over the paper, must be a little slider, an inch and a half broad, to slip down into several recesses made in the upper frame, at a proper distance for the lines, which should be near an inch asunder; and this ruler, on which the writer is to rest his fourth and little finger, must be made full of little notches, at a quarter of an inch distant from each other; and these notches will inform the writer, by his little finger dropping from notch to notch, how to avoid running one letter into another. When he comes to the end of the line, he must move his slider down to the next groove, which may easily be so contrived with a spring to give warning that it is properly removed to the second line, and so on.”

BLINDNESS, in the *Veterinary Art*, a disease very frequently happening to horses. The eye of the horse is subject to various diseases which may occasion blindness, as the *catarrh*, the *gutta serena*, opacity of the cornea or its coverings, &c.

The disorder, however, generally inducing blindness among horses is the *catarrh*, and the inflammation of the external parts of the globe of the eye, which precedes the obscuration of

the crystalline, is termed blindness, as though the disease was really confirmed; and horses so affected are considered as such, and denominated blind, though at this period of the disease the sight is only rendered imperfect.

This destructive disorder, in general commences with an inflammation of the outer coats of the eye, as the *membrana conjunctiva*, or *cornea*, or both together, and extending gradually to the interior, inflames and destroys the transparency of the crystalline, and obstructs the admission of light.

These attacks of inflammation not unfrequently disappear for a time, or, at least, become much less distinguishable, and then return again, observing something like regular periods of accession and remission; and from hence the disease has been termed by some the *moon blindness*; and these changes were considered as under the influence of this planet, and corresponding with the periods of its change: there are, however, other causes more powerful in their influence, to which these changes in this disorder may, with more appearance of truth, be attributed, as improper exposure to excessive cold, or drafts of air; to a close, low, over-heated stable, or sudden alternations from the one to the other; violent exercise and sweating; then washing with cold water, leaving the hair drenched with it; acrid volatile salts rising from the dung; over-feeding with too hot, dry, and stimulating food, and all causes inducing an increased action of the heart and arteries, naturally tend to induce a recurrence of this complaint.

As this disease is one of the most interesting in the veterinary art, and the most necessary to be well understood, as well by professional men, as by dealers and possessors of horses, we shall describe at some length the appearances by which it is known to exist, and the means that have hitherto been employed, as far as they have come to our knowledge, for the removal of it. Those who may desire to be acquainted respecting the information possessed by the ancients of this complaint, and their practices for its cure, may be referred to the writings of Aëtyus and Vegetius: the latter, in his elegant work *de arte Veterinaria*, lib. 2: cap. xvi. *de suffusione oculorum*, has divided this disorder into three kinds, under the titles *stenochoriafis*, *protophoriasis*, *hypochoriafis*; by his definitions, however, of these three kinds, it appears that he only meant the different stages of the formation of the cataract, from the first inflammation of the eye, to the crystalline becoming perfectly opaque and bursting its capsule; rushing to the anterior chamber of the eye, and resting, like a white opaque ball, against the cornea; occasioning a total loss of sight, and which he compares to the yolk of an egg bursting from its situation in the centre of the egg, and to which it can never be again reduced. He considers the cause of this complaint to be the rupture of the membrane containing the sight; by excessive heat, or more certainly from the fatigue of a long journey, or the neglected injury of the eye, from the inattention of the master. His *hypochoriafis*, which appears to be the first stage of this disorder, he says, descends from the head; and often shews itself in one eye, and then migrates to the other, and is attended with a flow of water or tears. His treatment, in this case, is to bleed often from the eye-brow, or rather the eye-lids, and from the temples; to foment frequently with warm water in which rue and fennel seeds have been boiled; to anoint the eye “*cum collyrio opopanato et opobalsamato*.” He also recommends applying the actual cautery to the temples above the veins. This author, in another chapter, recommends, in this complaint, that you should inspect the nostril on the same side with the morbid eye, and you will find

BLINDNESS.

find a small opening, through which, by inserting a pipe, you may fill the eye with wine, and relieve the disorder; a remarkable proof of the minute and accurate observation of the ancients. The existence of such an opening (for it is, in reality the opening of the lacrymal duct that is alluded to), is not known to many who profess to practise on the diseases of horses at this day.

Ablyrtus, a Greek writer, who lived about the reign of Constantine the Great, and prior to Vegetius, recommends, in this disorder, and which he calls *αλωμα*, that the ear should be pierced with an awl, and a piece of white hellebore should be inserted in the perforation for its relief.

The following we venture to give as a more natural and true description of the appearances of the eye, during the presence of this complaint, than what has before been exhibited; though, no doubt, subject to many omissions and imperfections, which future observations may lead us to rectify.

The earliest indication of this disease is exhibited by the external transparent parts of the ball of the eye becoming obscured, assuming a blackish glassy hue; sometimes blue or brown, or a dull white, and streaked with blood, according to the degree of inflammation or distension of the blood-vessels; admitting, according to their capacity, the different parts of the blood which are not transparent; and this inflammation, it may be remarked, takes place more frequently in young horses of five or six years old, than in those of a more advanced age, and the upper half of the *cornea* generally appears more obscured than the lower; this, however, may be a deception, arising merely from the point of vision, the observer being placed below the eye, and seeing directly through the lower part, and more obliquely through the upper. The blood-vessels also may be observed increased in number and size, passing over the opaque white surface of the sclerotica, to the *cornea* and *conjunctiva*; for it has not, as far as we know, been ever ascertained from actual dissection or experiment, whether it is the *cornea* that is inflamed, or the *conjunctiva*, or both; nor is it absolutely necessary for the treatment, that this should be known.

The eye and eye-lids feel hotter to the hand than usual; and often times there is a deposit of a white matter resembling pus, in the bottom of the anterior chamber of the eye, which, perhaps, proceeds from the vessels of the ciliary fringe, or uvea, which are large in the horse.

After this opacity of the *cornea* has existed some time, the eye of itself, or still more certainly, if antiphlogistic means are used, returns to its natural brilliancy, and the disorder seems removed; a few weeks or months may elapse before its return; and if these remedies are had recourse to very early, the disorder may even be permanently removed; it very frequently, however, returns, and again disappears, and this several times before the inflammation of the crystalline, and the destruction of sight take place. In other subjects, one uninterrupted course of inflammation, without any interval takes place, till the cataract is fully formed.

When this morbid process begins in the crystalline, the inflammation of the exterior parts of the eye often disappears, and they assume their usual brightness, and afford us an opportunity of distinctly observing the changes which take place in the lens.

And with respect to the cataract itself, or this opacity of the lens, we may remark that the whole crystalline shall assume this milky appearance at once, or a small speck only near the centre shall be seen, which often remains for years, without the least perceivable increase, and without producing blindness, or any sensible detriment to the ani-

mal; again, in other cases, no speck is observable but whitish lines which reflect the light, stretching like rays from the centre of the lens to its circumference; and sometimes the capsule containing it is said to be only affected.

The cataract, as it is called, being fully formed, the complete opacity of the lens being established, and light no longer admitted, the iris begins to lose its properties, nearly closing up the opening of the pupil; from its relaxation, the whole eye becomes diminished, and apparently sunk in the head; and the capsule, especially in draft horses, bursts, and the lens is forced from its situation, and falls to the anterior chamber of the eye, resembling, as we have before observed, an opaque white ball.

As perfect clearness and distinctness in all parts of the eye, with a due contraction of the pupils, are the most certain indications of its goodness, so the slightest dulness or opacity in the external coats, or diminution of the pupil, should lead the purchaser to be cautious; for it cannot be too often observed, that this opacity, after it has been of some standing, is almost certain destruction to the eye; and there are no remedies at this time known that can prevent its fatal termination, though numerous attempts and experiments have been instituted with this view; and the operation for the cataract is useless in the horse; for if it succeeds, the vision is still so imperfect, that blindness itself is preferable.

Though various useful offices can be found for horses that have lost their sight; yet it is of importance, for most of the purposes to which they are applied, that it should be preserved. We cannot recommend with too much force, the necessity of an early recurrence to the prescribed remedies for destroying the inflammation; for, at its very commencement, it has probably only the characters of common inflammation, and might be entirely and effectually subdued as in other parts; but neglected, this disorder soon assumes its peculiar properties, arising, perhaps, from the particular structure and functions of the parts affected, and in a short time becomes perfectly beyond the reach of any remedy; for though, no doubt, there are a few insulated instances where this disorder has been removed, yet, as the termination of the generality of cases is of an opposite nature, it would be unwarrantable to make a conclusion from such cases of the general possibility of cure in this complaint.

Where the inflammation has not yet received the specific properties above described, the following remedies will frequently remove it; and in more confirmed cases, we shall mention the means that have been unsuccessfully employed to remove it, that we may shew the insufficiency of such attempts, and promote farther experiment and research respecting it.

In the commencement of this complaint, the use of abstinence from heating food, or hard exercise; exposure to stables of cooler temperature, and well aired, not from partial drafts, but their loftiness only; exclusion of too much light, or the light altogether; diluent drinks, and purgatives; such may be employed to the general system. To the part itself, washes of cold water, or ice and water, or litharge water, or with a small portion of opium dissolved in it; others think more favourably of stimulating, or caustic washes, as weak solutions of vitriolated zinc, very dilute acids, and even spirits and water.

Blisters applied to the cheek, or over the masseter muscle, produce an irritation which is very successful in removing this inflammation, and, in particular, the insertion of a seton or two in the muscular parts surrounding the eye, care being taken that the fascia over the muscle is divided, otherwise

otherwise there is no suppuration; these will tend, as we have experienced, powerfully to carry off an attack of this disorder. Firing with a hot iron has also been employed with the same view, on the surrounding skin; and likewise blood-letting from the jugular vein, or from the temporal artery, or locally from the vessels proceeding from the inner canthus, or anterior angle of the orbit; as also the vessels passing over the sclerotic coat, which become very much enlarged and visible in this disease, as well as those in the lining of the lids.

Mr. Coleman, the very ingenious professor of the veterinary college, secured up the vessels of the scleroticæ with a hot iron, forming an entire circle round the ball of the eye, at some distance from the cornea, to prevent all access of blood to this part, and so endeavoured, mechanically, to put a stop to the inflammation; it was found, however, insufficient to destroy the disorder, and we believe that any hope of relief from this mode of treatment has since been abandoned; and for this reason, perhaps, this experiment has proved insufficient, that when communication is stopped from the exterior vessels, there are others whose trunks are short of these, which supply the substance of the cornea; and others again, out of our reach, on the inside of the cornea; but above all, the habit in the parts to diseasè, and the disposition in the system to generate it, are not overcome, and the morbid tendency is not thereby destroyed.

The farriers, who practise medicine, in treating this complaint, often remove the lacrymal gland, which they call the haw, from its supposed resemblance to this fruit; and as this part partakes of the inflammation, and is much swelled, they mistake it for the source of the disorder. The removal of it, which is easily done, by drawing it out with a hook, and cutting it off, occasions a copious discharge of blood, which, in slight attacks, relieves the eye, and encourages them in this practice; but from our own personal experience we have learned, that in cases of any duration, it is totally inadequate to the removal of the complaint, and the eye must obviously suffer from the loss of a part that is necessary to its well-being: and means less injurious to the eye may be equally well employed with as much success, such as we have before pointed out.

An infusion of the *polygonum hydropiper* injected into the nostril, so as slightly to inflame the membranes, produces very good effects in this complaint.

It has been observed, that in the human eye, long continued inflammations of the exterior coats rarely produce cataracts, as they do in the horse; and the reason that has been assigned for this is, that the same blood-vessels which supply the *tunica conjunctiva* and *cornea*, also supply the lens and the humours of the eye, which they say is not the case with the human, as these parts are supplied from the eyelids and integuments; there is, however, in the horse, a singular propensity to inflammatory complaints, and to this disposition, perhaps, it is rather to be attributed.

In the inflammation of the cornea, which is attended with a black, glossy appearance of this part, there is seldom any increased discharge of tears from the eye and nose; but in the other kinds which we have before enumerated, there is, in general, a considerable increase of this secretion. When blood-streaks, or blotches appear, it is probable that the vessels are ruptured, and that this blood is really in a state of extravasation.

BLINK of the ice, in *Sea Language*, denotes that bright, white appearance produced by the ice near the horizon, and perceptible, in approaching the ice, long before it is itself seen. This phenomenon has been often remarked by ma-

riners, and is particularly mentioned in Phipps's (lord Mulgrave's) voyage to the North Pole, p. 70.

BLINKS, in *Botany*. See MONTIA.

BLINKS, among *Ancient Sportsmen*, denoted boughs broken down from trees, and thrown in the way where deer are likely to pass, to hinder their running, or rather to mark which way a deer runs, in order to guide the hunter.

BLINKING of beer, in Lincolnshire, signifies letting the wort stand for some time in the vat, till it hath acquired some degree of acidity, in order to dispose it to fine, and be the sooner ready for drinking.

BLISSOM, among *Husbandmen*, corruptly called *blissom*, is the act of a ram, when coupling with an ewe.

BLISTER, in *Pharma y*. Blisters are raised on the surface of the body for medicinal purposes, by applying, for a number of hours, some of the most active of the animal or vegetable stimulants. Of these, by far the most convenient, and that which is almost universally employed, is the *cantharis*, or *Spanish fly*, (*MELÖE Vesicatorius*.) These insects are found in Spain, Italy, and the south of Europe; they have a longish body, beautifully brilliant with green and gold. They are gathered, by shaking the trees which they frequent, and are killed by the vapour of spirit of wine burnt beneath them, or by the fumes of vinegar, after which they are dried in a stove. In this state they are brought over without further preparation.

Cantharides possess so much acrimony, that in reducing them to powder, the face should be covered with a mask, to prevent the troublesome sneezing and excoriation of the fauces, from the finer dust flying about. Taken internally, in an overdose, they inflame the whole intestinal canal, in a greater or less degree; and they have a peculiar tendency to irritate the urinary organs. Applied to the skin, they first inflame the part, but often, with scarcely any attending pain; after which they produce a very copious blister of clear, yellowish serum beneath the cuticle, which rises in a large bag. This insect appears to possess this vesicating property in a much larger degree, in proportion to the pain excited, than any other stimulant; and hence its peculiar utility in producing this serous discharge with the least possible inconvenience to the patient. It is not exactly known in what part of the insect the vesicating property resides, or whether it does not equally belong to every part. It is not easily destroyed, or impaired by long keeping, if the insect be unbruised, and preserved in a dry place.

For blistering the skin, the cantharides are first finely powdered, and then incorporated, with some labour, with a simple mixture of wax and resin melted together, to which some add a little vinegar, and allowed to grow nearly cold before the flies are added. This is a necessary precaution, since it is certainly known that a considerable heat impairs the blistering property. The plaster, thus made, should be of such a consistence, as readily to soften with a moderate heat. When used, it is generally spread uniformly upon leather, of the requisite size and shape, by the assistance of an iron spatula, warmed scarcely more than the hand can bear.

To increase the effect, some apothecaries sprinkle the plaster with powdered cantharides, after it is spread on the leather, but this is not necessary, where the plaster itself is good; and the powder is apt, after vesication, to lodge on the tender cutis, and produce much needless irritation. As the blistering plaster adheres very loosely to the skin, it is useful in applying it to children, to maniacal persons, and wherever it is in danger of being too soon pulled off, to surround the blister with a margin of strong adhesive plaster.

The plaster of cantharides seldom fails to produce a large blister, in ten or twelve hours; but its operation continues sometimes longer, so that it may be conveniently suffered to remain for twenty-four hours, the large cuticular bags being punctured to let out the fluid. When the plaster is taken off, and the serum mostly discharged, the blistered part should be dressed with spermaceti, or some other mild ointment, unless it be intended to keep up the serous discharge by stimulating applications.

The pain produced by the action of cantharides varies greatly, according to the part affected, the thickness of the skin, and the general irritability of the constitution, and in particular of the surface of the body. Most frequently the pain is very slight, often amounting to no more than a sense of heat on the part. When very acute, it is of great service to remove the plaster, when it has been on about two hours, to anoint the part with oil or cream; and about an hour or two after, to replace the blistering plaster, which will then often proceed to vesicate without much further irritation.

The operation of cantharides is much affected by the thickness of the skin beneath; and hence the scalp resists vesication more than the softer skin of the abdomen; and particularly by the heat of the body, so that the plaster should be stronger, and its consistence softer, when applied to an unusually cold surface.

Sometimes, though rarely, the symptoms of strangury produced by this active medicine, follow even its external application.

A more active vesicatory is supposed to be made by adding other stimulating substances to the cantharides plaster. In the Paris Pharmacopœia, euphorbium (the most acrid of all the medicinal gums) is added in equal quantity with the cantharides: in the Edinburgh, verdegriis, mustard, and black pepper are used.

It is often of advantage to keep up a discharge from a blistered part for a considerable time. It then becomes gradually purulent. For this purpose, a milder form of cantharides is highly useful, and a softer consistence is given to it. This may be done by mixing a small portion of the flies in powder, with any simple ointment; but this is liable to act unequally, and the entire particles of the fly sometimes create trouble, by lodging upon the tender cutis. To remedy this, the London college use a watery infusion of cantharides, mixed with a stimulating resin ointment, melted, and continued over a slow fire, till all the water is evaporated, leaving a small portion of extractive matter of the flies, equally diffused through the ointment, and strongly increasing its stimulating power.

A few other substances have been occasionally used to produce vesication. One of these is the inner bark of the *Mezereon*, (*ДАРЪНЕ Mezereum*) and of another plant of the same genus, the *Thimelœa Laureola*, or *Spurge Laurel*, (*ДАРЪНЕ Laureola*) both shrubby plants, well known in gardens. The use of the latter (which will equally apply to the mezereon) is thus directed in the Paris Pharmacopœia. Small twigs of the plant, about the size of a pen, and smooth, are selected, and cut transversely into portions of the requisite length. These are steeped in milk-warm water, or in vinegar, for about half an hour, to loosen the bark, which is then peeled off with a pen-knife, and the wood is thrown away. This bark is applied to the skin to be blistered, previously rubbed with vinegar.

In twenty-four hours a perfect vesication is produced, with little pain, and without the possibility of those symptoms of strangury, which now and then attend the use of cantharides.

BLISTERED, *bullatus*, in *Botany*, is applied to the

surface of a leaf, which rises high above the veins, so as to appear like blisters.

BLISTERING of *horses*, in the *Veterinary Art*, a remedy much in use for promoting the removal of a great variety of disorders; more especially, however, in reducing morbid enlargements of bone, or morbid thickenings of any of the softer parts, where its utility is principally obvious.

The vesication of the skin of the horses is attended with some remarkable circumstances, in which it differs from the human, especially in the greater irritability of the skin; for the cuticle of the horse is raised by a blister of less strength, than is required in raising the human cuticle; whence, perhaps, it may be inferred, that its sensation also is more acute. It is probable that the skins of animals covered with hair are, in general, more irritable than naked skinned animals; the spirits of turpentine producing a most painful irritation, both in the horse and the dog, when applied to the skin, but not so in the human.

Irritants, however, of the skin, without any blistering, or vesication, may be had recourse to with very great advantage, in the veterinary art, as they can, without injury to the parts, be very frequently renewed, and with the happiest effects.

The mildest applications of this description, are the animal and vegetable oils; as hog's-lard, and the oil expressed from linseed, or olives: where more irritation is thought requisite, the addition of the essential oil of origanum, or the spirits of turpentine, will readily afford it.

Lard alone, rubbed on the skin of the horse, we have often observed to produce a sensible irritation and increased warmth in the part, so susceptible is this part in these animals; and may serve as a basis from which we may proceed to the higher degrees of stimulus, firing the skin with the actual cautery, in lines more or less close, being the highest degree of irritation to which we can or ought to proceed.

That irritation which is produced by the cantharides, is, of all others, we believe, the most useful in its effects. It should be applied, mixed with lard, or olive-oil; to which it is usual to add the dried juice of the euphorbium; as, however, it is ever desirable to avoid unnecessary complication in the remedies we prescribe, by which our effects are rendered more certain, and the inductions more easy and clear, so we proposed to try this medicine by itself, to ascertain its precise effects; and being mixed with olive-oil, it was applied to the skin of the leg of the horse: no distinct vesication of the part followed, but it produced a considerable heat, and formed a brown scab, with very little discharge of serum; but, on the contrary, was particularly dry and irritating to the horse. We have since omitted it in the blister, and, we believe, without the smallest detriment to its operation; for the cantharides, when they act properly, and are not applied too strong, produce a plentiful vesication, and a copious discharge of thick serum, almost of the consistence of honey.

We have found also the pyro-ligneous acid, or the acid obtained by the distillation of wood, in close vessels, and properly concentrated, a cutaneous irritant, of very useful qualities. After the skin has been simply wetted with it, it slightly inflames it; and the cuticle, after two or three days, comes away dry, bringing with it any foulness of the skin, for the removal of which it is most particularly serviceable.

We have known some, from motives of economy, omit the cantharides in their blister, and use, instead of it, vitriolic acid. It, in general, as far as we have seen, forms a dry, black scab, and is by no means so agreeable in its effects as the former.

It is a common habit with farriers practising medicine, to mix corrosive sublimate with their blister; and, where it may be desirable to destroy the skin, this should be used, but not otherwise; for it is no vesicatory, but a most violent caustic, soon destroying any living matter with which it comes in contact; and we have seen, from the ignorant use of it, the most deplorable effects, by its bringing off extensive sloughings of the skin, and even penetrating to the parts beneath, and so injuring them, as ever after to render the horse unserviceable.

There is an effect produced by the cantharides on the skin of the horse, which, as far as we know, has not met with much attention; though it is very remarkable, and not analogous to its effects on the human skin: it is that prodigious thickening of the integuments, after the operation of the blister, which sometimes does not subside for many weeks, being a great disfigurement: a blister, therefore, if one could be devised not producing these effects, would be a desirable thing in the veterinary Pharmacopœia. This effect, we should, however, remark, is not constant.

BLITAS, LAs, in *Geography*, a cluster of small islands in Nicaragua lake, in Spanish North America.

BLITH. See BLUTH.

BLITHE, a river of England, which runs into the Trent, 4 miles N. E. of Litchfield.

BLITUM, from βλεπον, *abjiciendum, fit only to be thrown away*, in *Botany*. Lin. Gen. n. 14. Schreb. 18. Juss. 86. Chenopodio-Morus, Boerh. Morocarpus, Rupp. Eng. *Blite*. Fr. *Blète*. Class and Order, *Monandria Digenia*. Nat. Ord. *Holoracea. Atriplices*, Juss. Gen. Char. *Cal.* perianth three-parted, spreading, permanent; divisions ovate, equal, two more gaping than the other. *Cor.* none. *Stam.* filaments setaceous, longer than the calyx, within the middle division, erect; anther twin. *Pist.* germ ovate, acuminate; styles two, erect, gaping, the length of the stamen; stigmas simple. *Per.* capsule very thin, rather the crust of the seed, ovate, a little compressed, contained within the calyx now become a berry. *Seed* single, globular, compressed, the size of a capsule.

Ess. Char. *Cal.* trifold. *Pet.* none. *Seed* one, with a berried calyx.

Species 1. *B. capitatum*, berry-headed straw-berry blite, Lin. Spec. 6. Reich. 11. Hal. helv. n. 1571. Morocarpus capitatus. Scop. Carn. n. 3. Atriplex. Bauh. pin. 119. n. 7. Prodr. 58. n. 2. Ger. emac. 326. n. 8. Park. 748. f. 1. Mor. hist. 2. 606. f. 5. t. 32. f. 11. Raii hist. 197. n. 5, 7. "Heads spiked terminal." An annual plant, with leaves resembling those of Spinach, and stalk rising, in gardens, about 2½ feet high; but in a wild state, upright and only about a foot high; flowers on the upper part issuing in small heads at every joint, and terminated by a cluster of the same; when the flowers are past, these heads swell to the size of wood-strawberries, and when ripe have the same appearance, full of a purple juice, which stains the hands, and formerly much used in cookery, for colouring puddings, &c. seed black when ripe: commonly called straw-berry blite, straw-berry spinach, or bloody spinach, and by some, berry-bearing orach. A native of Switzerland, the Grisons, Austria, the Tyrol, Spain, and Portugal; cultivated by Parkinson, in 1633. 2. *B. virgatum*, slender-branched straw-berry blite. Lin. spec. 7. Reich. 12. Gmel. sib. 3. 16. Atriplex. Bauh. pin. 119. n. 6. Mor. t. 32. f. 10. Raii hist. 197. n. 6. "Heads scattered, lateral." Scidom growing more than one foot high, with smaller leaves than the former; flowers produced from the axils, almost the whole length of the stalk; small, and collected into little heads, smaller than the first, and not so deeply coloured, but of the same shape. A native of the south of France, Spain, Italy,

and Tartary. 3. *B. tataricum*. Mill. Dict. n. 3. *B. fragiferum maximum polyspermum*. Amm. ruth. "Leaves triangular, sharply toothed; heads simple, lateral." Rising near three feet high; flowers axillary, in small heads; fruits of the same shape and colour with those of the first, but smaller; differing from it in the shape and indentures of the leaves; and in having leaves placed between the fruits the whole length of the stalk, not terminated by heads, as the first, but having leaves above the heads. Probably a variety of the second sort. The seeds were sent to Mr. Miller by Dr. Amman, professor of botany at Petersburg. 4. *B. chenopodioides*. Linn. Syst. Reich. 12. Mant. 170. "Heads in whorls, juiceless." A low plant, resembling chenopodium. A native of Tartary; now in Sweden. Probably only a variety; and in reality the four sorts seem to be but one.

Propagation and Culture. All are annual plants, which drop their seeds, that will produce plentifully the following spring; or if the seeds of any one of them be sown in March or April, upon a bed of common earth, in an open situation, the plants will come up in a month or six weeks, and remaining in the same place, will require no other care besides being kept from weeds, and thinned out to the distance of six or eight inches apart; and in July the plants will begin to shew their berries, which will make a pretty appearance. By many they are transplanted into the borders of the flower garden, and by others planted in pots, so as to be ready for removal into the court-yard, or for being placed upon low walls for ornament. When these plants are designed to be removed, they should be transplanted before they shoot up their flower-stems, for they will not bear transplanting afterwards; and when planted in pots, they must be watered in dry weather; and, as the flower-stems advance, they should be supported by sticks. Martyn.

BLITUM. See ACHYRANTHES, AMARANTHUS, CHENOPodium, and GUNNERA.

BLOATED *fish* or *herring*, in our *Statutes*, are those which are half dried. Vide Stat. ann. 18 Car. II. c. 2.

Bloated herrings are made by steeping them in a peculiar brine, and then hanging them in a chimney to dry.

BLOATING, in *Medicine*. See LEUCOPHLEGMATIA, and OEDEMA.

BLOCH, MARK ELEAZAR, in *Biography*, a Jewish physician at Berlin, and a celebrated ichthyologist, was born at Anspach in Franconia. His parents were in a condition so obscure and destitute that they were scarcely able to maintain him during his infancy, and much less to procure for him any suitable means of education. At the age of 19 he understood neither German nor Latin; and as he had read only a few Rabbinical books, he spoke a kind of Franconian gibberish, intermixed with the Jewish jargon. About this time, however, he was taken into the house of a surgeon at Hamburg, who was a Jew, and employed by him in the instruction of his children; and in this situation he acquired a competent knowledge of the German language. The savings of his scanty salary enabled him to procure assistance in the study of Latin. Having also gained some knowledge of surgery, he repaired to Berlin, where his relations lived, with a view of prosecuting the study of anatomy. After struggling with various difficulties, he was admitted as doctor in the university of Franckfort, and returned to Berlin for the exercise of his profession. Here he became acquainted with M. Martini, who recommended him to be elected a member of the Society of the Friends of Nature. In order to promote the objects of this institution, he undertook a natural history of the murena, a fish caught, as it was supposed, only in the lakes of Pomerania. He also began to form a cabinet of natural history; and having made a considerable collection

of aquatic animals from all parts of the globe, he determined to write a natural history of fishes; and in this design he was encouraged and aided by obtaining possession of the original MSS. of Father Plamier, who had made three voyages to America, and brought with him many objects highly interesting to the natural historian. M. Bloch first published, in German, four numbers of an "Economical Natural History of Fishes, particularly those in the states of Prussia, with figures from original drawings;" Berlin, 1781 and 1782, large 4to. In the following years appeared an "Economical Natural History of the Fishes of Germany," in 3 volumes, consisting of 108 plates, and including the three numbers already mentioned. He afterwards published, in 9 volumes, "The Natural History of foreign Fishes;" so that his whole work was comprehended in 12 volumes, and contained 432 plates. The last appeared in 1795. He also, at his own expence, procured a French translation of his work, by C. Laveaux, then at Berlin, which he published under the title of "Histoire general et particuliere des Poissons;" Berlin, 1785—1788, in 6 vols. folio, with 216 plates. In order to defray the expence of this work, his only son, a young man distinguished by his talents, undertook a tour through France and England for the purpose of procuring subscriptions; and in the prosecution of his journey died at Paris, in 1787. This loss, and the embarrassment of his circumstances, preyed upon the spirits of this ingenious naturalist, and sunk him into the deepest affliction. However, he still continued to employ himself in his favourite work, the history of fishes, and having completed it, undertook a journey to Paris. He died at Carlsbad in Bohemia, August 6th, 1799. Besides the above voluminous works, M. Bloch published many memoirs on subjects of natural history, in the transactions of different societies. That on the murena, in the Memoirs of the Friends of Nature, has been already mentioned; he also communicated, in the same Memoirs, "Observations on the regular depressions in vitriform stones;" "On the worms in the intestines and lungs of birds;" "An Essay towards the natural history of the worms which live in other animals;" "On worms of the bladder;" "Description of the bullard, and some kinds of birds found in marshes;" "On the oil of herrings;" "On the vulgar opinion that the organ of generation in the ray and shark is double;" "On the myxina glutinosa of Linnæus," &c.

BLOCK, DANIEL, an eminent portrait-painter, was born at Stertin, in Pomerania, in 1580, and educated for his profession under Jacob Scherer. As a painter of portraits, he gained great reputation, and had the honour of painting the portraits of Christian IV. king of Denmark, and of Gustavus Adolphus, king of Sweden. His merit recommended him to the prince of Mecklenburg, in whose service he was retained for 44 years, and for whom he painted the portraits of his whole family, at full length, as large as life, and in the antique habit. By the agreeable manner of his colouring, and the easy attitudes of his figures, he obtained so much employment, as to enable him, before the decline of his life, to amass a large fortune; of which, however, he was unfortunately deprived by a plundering party, preserving, with great difficulty, his own life. He died in 1661. Pilkington.

BLOCK, JACOB ROGER, was born at Gouda, where he acquired the art of painting, particularly in reference to perspective and architecture, which he principally cultivated. Having spent several years in Italy, where he imbibed that taste of grandeur and elegance in his compositions, by which he was advanced in the public esteem above all his contemporaries, he returned to his own country, and was appointed state-painter to the archduke Leopold, whom he attended in all his campaigns; but whilst he was passing a small rivulet,

over a bridge of planks to view the fortifications of St. Vinox in Flanders, his horse slipped, and he was unfortunately drowned. Whilst he lived at Gouda, he was visited by Reubens, who, having examined his works, testified to his honour, that he had not seen any painter in the Netherlands, who could stand in competition with him for the subjects he painted. The time of his birth and death are not ascertained. Pilkington.

BLOCK, BENJAMIN, son of Daniel Block, was born at Lubeck in 1631, and, with a view of improving himself in colouring and design, resided for some time at Rome, Venice, and Florence. Having thus acquired a good taste, and a pleasing tone of colouring, he was introduced to the court of Saxony, where he painted several portraits of the elector and prime nobility; and he also painted several altar-pieces for the churches and convents of Hungary, which are much commended. His capital performance is the portrait of Kircher the Jesuit, which, even at Rome, was exceedingly admired. The time of his death is not ascertained. Pilkington.

BLOCK is used for a piece of marble as it comes out of the quarry, before it has assumed any form from the hand of a workman.

BLOCK, in the *Mechanic Arts*, a large piece of solid wood, whereon to fasten work, or to fashion it; strength and stability being the requisite properties.

In this sense we say a chopping block; a sugar-finer's block; a smith's block, on which his anvil is fastened; an executioner's block, on which the criminal's head is laid to be struck off.

BLOCK, *Mounting*. See ANABATHRA.

BLOCK, among *Cutters of Wood*, is a form made of pear-tree, box, or other hard and close grained wood, free from knots, on which they cut their figures in relieve, with knives, chisels, &c. The like are in use for card-making; and from the same first arose the modern art of printing. Phil. Trans. N^o 310. p. 2398.

BLOCK, among *Bowlers*, the mark which is aimed at, being a small sized bowl laid on the green for this purpose; it is called also the *jack*.

BLOCK, in *Falconry*, denotes the perch whereon a bird of prey is kept. This is to be covered with cloth.

BLOCK *Island*, in *Geography*, called by the Indians "Manisses," lies about 21 miles S. S. W. of Newport, in Newport county, and state of Rhode Island. It was erected into a township, named "New Shoreham," in 1672. This island is 7 miles in length, and its extreme breadth is 4 miles. It has 714 inhabitants. It is famous for cattle and sheep, butter and cheese; and round its coasts are caught considerable quantities of cod-fish. The southern part of it is in N. lat. 41° 8'.

BLOCK, in *Naval Architecture*, denotes an eight square, or round part below the heeling of the main and fore top-masts.

BLOCKS are short pieces laid under a mast to raise it from the ground.

BLOCKS are also pieces of wood belonging to ships, in which the shivers, or sheaves, of pulleys are placed, and whereon the running ropes go. Accordingly they possess the properties and powers of pulleys, and they have from one to eight sheaves. The blocks in general use are the single block, the double block, the treble block, and the four-fold block; but when heavy weights or bodies are to be raised or moved, blocks with a greater number of sheaves are applied, the increasing power being as two to one for every sheave moving with the object. See PULLEY.

Blocks differing from the common shape are the bee-block, the cheek-block, the long-tackle-block, the main-sheet-block, the monkey-block, the nine-pin-block, the rack-block, the

B L O C K.

shoe-block, the shoulder-block, the sifter-block; the snatch-block, the strap-bound-block, the viol-block, and the warping-block. The principal parts of blocks are their shells, sheaves, and pins, which are of various sizes and powers, according to the effect which they are to produce. The dimensions of the shells, and the thickness and number of the sheaves, are proportioned to the size of the ropes working in them, and the powers required. The sheaves turn abreast of each other in the shell, on one axis or pin, or one above another, on separate pins. The shell is made of elm or ash, and hollowed between the cheeks, with one or more sheave-holes to receive the sheave or sheaves. On the outside of the cheeks of blocks that are to be strapped, one score is cut towards the ends, in which part of the strap is buried; if they are double-strapped, they have two scores. A hole is bored through the centre to admit the pin; which, passing through both sides of the shell, forms the axis for the sheaves. The sheave is a solid cylindrical wheel, and round its circumference is a groove, one-third of the thickness of the sheave deep, in which the rope works. It is commonly made of lignum vitæ; but for laborious purposes, it is coated in the middle with metal, or else made of cast metal; if the sheave is iron, it is coated with brass, and if of brass, with the hardest bell metal. The hole in the centre is somewhat larger than the pin. The pin is made of lignum vitæ, cocus, greenheart, which is a wood imported from the West Indies, or iron, and it is the axis on which the sheaves turn.

The proportions for single, double, treble, four-fold blocks are as follow; viz. the length is eight times the breadth of the sheave-hole, which is one-sixteenth of an inch more than the thickness of the sheave; and this is one-tenth more than the diameter of the rope for which it is intended, and the diameter of the sheave is five times the thickness. The breadth of the block is six times the thickness of the sheave, and the thickness about one half the length. Flat thin blocks are three-eighths of the length thick; but all blocks, having more than one sheave, are increased in thickness more than in the above proportion by the additional number of sheave-holes, and middle-parts or partitions; the thickness of each partition being one-sixth less than the breadth of the sheave-hole. These dimensions are variable, according to the uses for which blocks are intended. Very large and four-fold blocks are formed of separate pieces, as the cheeks; partitions, &c.; and when thus made, they are denominated "made-blocks." The shells of blocks are first sawed to their length, breadth, and thickness; and the corners or angles are taken off. The workman then gauges the size of the sheave-hole in the middle, one sixteenth larger than the thickness of the sheave, and one-third the thickness longer than the diameter, for a single-sheaved block. In blocks of two sheaves, the partition is kept in the middle, and is one-sixth less than the sheave-hole; each sheave-hole is gauged equally on each side, and so for all blocks with a greater number of sheaves. The blocks are then jammed up edgewise with wedges in a clave, and the sheave-holes are made in this manner: the length and breadth are first gouged out, and holes are bored half way through the block, along the part gouged out, with an augre of the size of the sheave-hole; then the sheave-hole is gouged and bored on the opposite side in the same manner, so as to meet the opposite holes. Blocks from 10 inches and upwards have one hole bored at each end, and cut through with a chissel; and the wood is sawed out with a rib-saw. All blocks have the sheave-holes cleared through by chissels, and by burrs at the corners. Blocks that are to have iron straps, should have the strap fitted on before the wood is cut out of the middle. The hole for the pin is bored through the middle of the block, one-tenth less than the diameter of the pin. The outsides and edges of the shell are next rounded off by

the stock-shave, and neatly finished by the spoke-shave. In the royal navy, blocks are left thick upon the edges of the cheeks; but in the merchant ships, the edges are sometimes thinned off to a small square, and sometimes rounded off. The scores for the straps are gouged out along the outsides of the cheeks, and taper in depth from nothing at the pin to half the thickness of the strap at the ends of the block, for a single score, and the same on each side of the pin for a double score. The scores are gouged down, across the breast of the block, to half the size of the strap, in order to allow for the serving. After the score is cut, the sheaves are fitted; they are one-tenth thicker than the diameter of the rope intended for running on them, and five times that thickness in diameter. The hole for the pin should be bored through the centre by a bitt fixed in the mandrel of a turning lathe, or with a stock and bitt, and reamed with an augre one sixteenth larger than the diameter of the pin, that it may easily turn; they are then put in a lathe and turned smooth, and the outer circumference hollowed one-third of its thickness, that the rope may embrace it closely. The diameter of the pin is the thickness of the sheave, and is turned in a lathe, except its head, which is left eight square, to prevent its turning in the block, and is driven through the holes in the block and sheaves. After the sheaves are fitted, the inside of the sheave-hole, at the arse of the block, is gouged hollow, to admit the rope, and correspond with the sheave; and a small neat chamfer is taken off the edges.

Blocks, Bee, are made of elm, in length seven-ninths the length of the bee, in depth two inches for every foot of length, and in thickness seven-eighths of the depth. A block of this kind is trimmed square, chamfered on the outside edges, and fitted with a sheave in one end; and in the other end is cut a hole, to be fitted with a sheave, in case the other should fail. The sheave-hole is $\frac{3}{4}$ ths of the length of the block, and $\frac{1}{4}$ th the length of the sheave-hole in breadth, and half the length of the sheave-hole within the end. Bee-blocks are bolted to the outer ends of bowsprits, under the bees, and the bolts serve like the axis or pin for the sheaves to work upon; the fore-top-mast stay reeves through the sheave-hole at the fore-mast end of the starboard bee-block, and the fore-top-mast preventer, or spring-stay, through the sheave-hole at the after-end of the larboard bee-block.

Blocks, Brail, in rigging the mizen-yard, are strapped together in one strap, and lie over the yard, and seize together underneath; the throat-blocks next the cleats to the mast; the middle-blocks in the middle between the throat-block and peek; the peek-blocks about three or four feet within the cleats at the peek.

Blocks, Bunt-line, are lashed in rigging the lower-yards, like the leech-line blocks in the middle between them and the slings of the yard. These, in rigging the top-fail yards, are spliced round the strap of the top-fail-tye-block upon the yard.

Block, Cat, is employed to draw the anchor up at the cat-head. See CAT-HEADS.

Blocks, Cheek, or half-blocks, are made of elm-plank; the length being twice and a half the depth of the top-mast head; the breadth is seven-eighths of the depth of the top-mast head, and the thickness half that depth. The depth of each tenon, and thickness of the cheek, when the sheave-hole is cut, is each three-eighths of the whole thickness, so that the remaining two-eighths are the sheave-hole. The three tenons are each two inches square, one in the middle, and one at each end; and the length of the holes is more than the breadth of the block, by the thickness of the sheave. The back of the block is divided into three parts, and one-third on each side is bearded down to one-third the thickness of the cheek on each edge. Pins of iron are made for fasten-

B L O C K.

fastening them to the top-mast head, and for durability the sheave-holes are coppered. Check-blocks are bolted to the thwart-ship sides of top-mast heads, close up under the cap, the bolts serve as the pin or axis for the sheaves to work on; the jib-stay and haliards, and fore-top-mast stays, sail-stay, and haliards reeve through the check-blocks at the fore-topmast-head, and the main-topmast-stay sail haliards, and middle-stay, sail-stay, and haliards reeve through the check-blocks, at the main-topmast head.

Blocks, Clue-garnet, serve to draw the clues, or lower corners of the courses up to the yards, and are fastened to the clues of those sails. In rigging the lower-yards, these lash through the eyes upon the yard; the blocks hanging underneath, four feet without the middle cleats on each side. See *Clue-garnet*.

Blocks, Clue-line, in rigging the sprit-sail yard, are strapped with two eyes, and are lashed through those eyes round the yard, three feet without the slings; the lashing to be upon the yard. In rigging the sprit-sail top-sail yard, these blocks are strapped with two eyes, and are lashed through those eyes round the yard, about two feet without the slings. The clue-line blocks, in rigging the top-sail yards, are strapped with two lashing eyes, and lash upon the yard three feet without the slings; the blocks hanging underneath the yard through which the clue-line reeves, and is strapped with a knot, and leads down upon the deck. In rigging the top-gallant yards, these blocks are strapped with two lashing eyes, and lash upon the yard three feet without the slings. The blocks hang under the yard, through which is reeved the clue-line, which is stopt with a knot. The leading part leads down the mast, and into the lower shrouds. Some sloops and light-rigged vessels have no clue-line blocks; they lower the yard.

Blocks, D, are lumps of oak in the shape of the letter D, from twelve to sixteen inches long, and eight or ten inches wide. They are thirded and bearded on the back, and the edges beaded. A sheave-hole is cut through the middle fore and aft. It is bolted to the ship's side, in the channels, to reeve the lifts, &c.

Blocks, De-p-sea-line, are the same as a wooden snatch-block (which see,) only smaller; generally from nine to eleven inches long.

Block, Derrick, in rigging the mizen-yard, is strapped with eyes, that go round the yard, and lash underneath, between the slings and the outer yard-arm or peck; the other block is cross-seized into the strap, has an eye spliced in each end, and lies upon the mizen cap, and seizes or hangs through the eyes under the cap, or upon the upper side of it.

Block, Fists, is hung in a notch at the end of the davit, and serves to haul up the flukes of the anchor to the ship's bow.

Blocks, Girt-line, in rigging the fore-mast, and main and mizen masts, are lashed round the mast head, above the stop of the cap, one to hang on each side. The girt-lines that reeve through them lead down upon deck, for hoisting the rigging-tops, and cross-trees, and the persons employed to place the rigging over the mast-head.

Blocks, Leech line, in rigging the lower yards, are lashed round the yard, and through the eye of the strap, ten feet within the cleats on each yard-arm; the blocks hang on the fore-part of the yard.

Blocks, Lift, in rigging the lower yards, are spliced into the strap of the top-sail-sheet blocks; the lifts reeve through the block in the span round the mast head, between that and the top-mast, then lead down abreast the shrouds, and reeve through a block fastened to the side, and are there belayed. In rigging the top-sail-yards, the lift-blocks are strapped with an eye to the side of the yard arm. The lift

reeves through the lower sheave in the fister block in the top-mast shrouds, and through the block on the yard-arm. The standing part hooks to a becket round the top-mast-cup, and the leading part leads down the side of the mast, and belays to the dead-eyes in the lower shrouds.

Block, Long-tackle, resembles two single-blocks joined together endways, one being two-thirds less than the other. The shell is made of ash, or elm, two-thirds longer than the proportion for a single block. These blocks are used for tackles, and are made according to the size of the rope, as other single blocks. They are used in the Royal Navy and East India service as yard-tackles; but in the merchant service as loading tackles.

Blocks, Made, have the shell formed of several pieces of elm-plank, suited to the thickness of the cheeks, sheave-holes, and middle parts, and are strongly bolted together with three bolts at each end, driven through and clenched on a ring at the points. These blocks have flatter cheeks and more square edges than other treble and four-fold blocks. Of this sort are large treble and four-fold blocks, for heaving down ships, or other heavy purchases. Smaller made blocks, of modern invention, are formed of two pieces, joining in the middle; the pin working on patent rollers, let into the inside of the cheeks, which are bolted or rivetted together at the ends. These blocks are thought too complex for the Royal Navy, and are not so easily remedied in case of failure.

Block, Main-sheet, is used for the sheet-tackle of the main-sail-booms of small vessels, and is single or double; the sheet or fall being always belayed round the pin. The shell is made of ash or elm, one half longer than the proportion for single or double blocks; the additional length is tapered, and a hole bored through between the sheaves and the end, to admit the strap; the length of the pin is the length of the block, and is similar to a belaying pin, for which purpose it is sometimes used.

Blocks, Monkey, are sometimes used on the lower yards of small merchant ships, to lead (into the mast or down upon deck) the running rigging belonging to the sails. The shells are made of ash or elm; some are only small single blocks, attached by a strap and iron swivel to iron-traps that embrace and nail to the yard, the block turning to lead the small running-ropes in any direction; others are nearly eight-square, with a roller working in the middle, the same as a sheave, with a wooden saddle beneath, to fit and nail to the yard.

Blocks, Nine-pin, are used to lead the running-ropes in an horizontal direction. The shells, made of ash or elm, resemble the form of a nine-pin, though flattened on the sides; their lengths are generally confined to the place in which they are fixed, and this is for the most part under the cross-pieces of the fore-castle and quarter-deck bitts. The breadth of the block, sheave, &c. is governed by the rope, and tapers at the ends to three-eighths of the breadth of the middle; the pin at each end, serving as a vertical axis, is two-thirds of the bigness of the end. The thickness is five-eighths of the breadth. These blocks may be turned in a lathe, and flattened afterwards with a spoke-shave.

Block, Quarter. See *Thick and thin Block*.

Blocks, Rack, are a range of small single blocks, made from one solid, by the same proportions as single blocks, with ends, in form of a dove's tail, for the lashing, by which they are fastened athwart the bowsprit, to lead in the running ropes. They are seldom used.

Blocks, Shoe, are two single blocks, cut in a solid piece, transversely to each other. They serve for legs and falls of the hunt-lines, but are seldom used.

Block, Shoulder, is a large single block, left nearly square at the lower end, or arse of the block, and cut sloping

B L O C K.

in the direction of the sheave. Shoulder-blocks are used on the lower yard-arms, to lead in the top-fail sheets; and, on the top-fail-yards, to lead in the topgallant-sheets; and by means of the shoulder, are kept upright, and prevent the sheets from jamming between the block and the yard: they are also used at the outer end of the boomkins, to lead in the fore-tacks.

Blocks, Sister, are made of ash, similar to two single blocks, and are turned out of a solid piece, about twenty inches long, one above the other; between the blocks is a score for a middle seizing: a round head is turned at each end, and hollowed underneath, to contain the end-seizings; along the sides, through which the pins are driven, is a groove, large enough to receive part of the topmast-flroud, in which it is seized. In these blocks reeve the lifts, and reef-tackle-pendants, of the top-fail-yards.

Blocks, Slab-line, in rigging the lower-yards, are strapped with a short lashing-eye, that seizes to the span of the quarter-blocks underneath the yard.

Blocks, Snatch, are proportioned by the rope, as a single block, leaving twice the length for the score and lashing; they taper from the sheave to the lashing end, to half the breadth and thickness at the sheave; one side of the shell is cut across above the sheave, large enough to admit the rope or fail. In the Royal Navy, snatch-blocks are iron-bound, terminating at the small end with a swivel hook, or an eye, large enough to receive several turns of lashing; that part of the strap, over the notch in the side, lifts up with a hinge, and is confined down, when the rope is in the block, by a small iron hook, or latch, that hooks in the eye of a toggle-bolt, and that secures the upper end of the strap; the hinged part of the strap goes over the bolt, with a hole in the end; the strap is let into the block its thickness, and is confined by the pin and nails; they are used for heavy purchases, and where a warp, or hawser, is brought to the capstern. Snatch-blocks, not iron-bound, have a large hole bored through the tapering end of the shell, for the lashing. They are used for the main and fore sheet blocks of square-rigged vessels.

Block, Spring, a new kind of block, invented by Francis Hopkinson, esq. of Philadelphia, and designed to assist a vessel in sailing, by increasing the acting spring of her rigging. It is proposed to apply it to all such parts of the rigging as will admit of it with safety and convenience, and where its operation will be most advantageous; but particularly to the sheet ropes, and, if practicable, to the dead-eyes, in lieu of what are called the chains. A, (see *Plate of Ship*) is a block made in the usual manner, having a ring, or eye, B, at one end. C, is a spiral spring, linked at one end to the hook DE, and at the other to the ring F, which is to be annexed by a staple to the timber-head, or by some other means to the place where it is to be applied. The spring C must be of well-tempered steel, and proportioned in strength to the service it is to perform. Within the cavity or pipe, formed by the spiral spring, there must be a chain of suitable strength, called a check-chain (represented separate at G), connected by the links to the hook DE and ring F. When the spring is not in action, this chain is slack; but when the spiral spring is extended, by the force of the wind, as far as it can be without danger of injury, the check-chain must then begin to bear, to prevent its farther extension, and, if strong enough, will be an effectual security against failure.

Fig. 2. represents part of the gun-wale of a sloop, with the spring-blocks in action, one of them hooked to a staple in the timber-head, and the other to the corner of the jib.

The inventor of this machine apprehends, that a vessel thus furnished will be less liable to heel; and that she will

receive the impulses of the wind to better advantage, and sail with a more lively and equable motion than if rigged in the common way. *Transactions of the American Philosophical Society, vol. III. art. 40.*

Blocks, Strap-bound, are single blocks, with a shoulder left on each side, at the upper part, to admit the strap through, a little above the pin. These blocks are used at the clues of the square-sails, for the clue-garnets or clue-lines, and under the yards; the shoulder preserves the strap from chafing.

Block, Thick and thin, or Quarter, is a double block, with one sheave thicker than the other, and is used to lead down the top-fail-sheets and clue-lines. In the merchant service they are used single, thick and thin. In rigging the lower yards, they are strapped with a long and short leg, with a lashing eye spliced in the ends, and lash to the yard within the cleats, in the middle of the yard, the block hanging downwards. The long leg comes up the aft-side, and meets the short leg on the fore-side, and there lashes through the eyes. Although these are used for the top-fail sheets, and intended for the clue-lines, a single block would be cheaper and better; as the thin sheave is seldom used for the clue line, it being found rather to impede than to facilitate. Small ships, in the merchant service, have a double block lashed in the middle of the yard, as the quarter block through which the sheets reeve, and lead down on opposite sides. Large ships, in the merchant service, have a single block lashed on each side of the middle of the yard, and the sheets reeve on their respective sides, and lead down by the mast. A quarter block, in rigging the cross-jack-yard, is strapped with a double strap, with an eye in each of the four ends, and is lashed upon the yard in the middle between the cleats.

Block, Top. See **TOP-ROPE.**

Blocks, Top-Gallant-Sheet, in rigging top-fail yards, are strapped with two lashing-eyes, and lash upon the yard, close within the clue-line-blocks on each side.

Blocks, Top-fail-Sheet, in rigging the lower yards, are put over the yard-arms, strapped with an eye of the size of the yard-arm.

Blocks, Tricing, for the yard-tackles, are strapped with a short lashing-eye, that seizes round the yard about one third of the length within the arm cleats; the blocks hanging under the yard.

Blocks, Tye, in rigging the top-fail-yards, lash at the topmast-head close up to the rigging, under the collar of the stay, as the lower ones; and the blocks on the yards lash under the fore-part of the yard, as the lower ones, and reeve with a double tye, in large ships, and with a single tye, like the lower, in small ones. The standing parts of the double tyes clinch round the mast-head, then reeve through the double block upon the yard, and up again, and reeve through the block on each side of the mast-head. The blocks are then spliced in their lower ends, and connected by their haliards to a single block, that is strapped with a long strap, with a hook and thimble, that hooks to a swivel-eye-bolt in the channel on each side; the leading-part comes in through a block lashed on each side; the foremost ones abaft the forecable, and the after ones on the quarter-deck.

Block, Voyol or Viol, is a large single-sheaved-block; the length is ten times the thickness of the sheave-hole, which is three-eighths more than the thickness of the sheave; the thickness of the sheave is one-tenth more than the diameter of the viol, and the diameter of the sheave is seven times the thickness. The breadth of the block should be eight times the thickness of the sheave, and the thickness two-sevenths of the length. This block is double scored,

BLOCKS.

the sheave is coated with brags, and the pin is iron, and nearly as thick as the sheave. It is used in heaving up the anchor. The viol passes round the jeer-capstern, and through the block, which is lashed to the main-mast; and the cable is fastened in a temporary manner to the viol in several places. It is seldom used except in the largest ships of the Royal Navy.

Block, *Warping*, is made of elm or ash board, shaped like the body of a bellows; the sides or cheeks are 8½ inches broad in the middle, and tapered to 2 inches broad at the ends; the back, or longest cheek, is 16 inches long, and ½ths of an inch thick, with a hole bored through the upper end to receive a leathern strap; the upper cheek is 12 inches long, and ½ths of an inch thick, except the lower end, which is 1⅓ inch thick, and forms the sheave-hole. The sheave is, 1½ inch thick, and 7¼ inches in diameter, made of lignum vitæ, coated with brags; it is let into the cheeks one-eighth of an inch, to prevent the yarn from getting between the sheave and the cheeks. The cheeks are fastened together at the lower end with three screws and nuts; and the pin, which is iron, is seven inches long, driven through the middle of the block, with a shoulder on the upper side, and clinched at the point on the lower side of the shell; the upper part of the pin is tapered small, and a wooden handle rivetted upon it. The cheeks have a broad chamfer round the outer edges; the inside edges, and inside of the block above the sheave, are lined with thin iron neatly screwed on, to prevent the block from wearing. This block is finished in a neater manner than blocks in general, and is seldom used but by rope-makers, to warp off the yarn into hauls for tarring.

Blocks, *single, double, or treble, in Rope-making*, are strapped with a hook and thimble, and reeved with a rope, called the tackle-fall, which is used to stretch the yarn to its full extent, before the press is put on, by a capstern, or crab, at the lower end of the rope-walk. The fall is then belayed, until every yarn is hove through the strands and brought down, so that the rope may not exceed the circumference intended. For other blocks, see **BULLS'-eyes, DEAD-eyes, and EUPHROES.** See *Plates of Ships.*

Blocks, *Strapping of.* A seventeen-inch block has a five-inch rope strap, and every inch in length above or under, to a twelve-inch block, has half an inch more or less sized rope allowed for the strap; a 11-inch block has a 3-inch strap; a 10 and a 9-inch block, 2½ inches; an 8 and 7-inch block, 2 inches; a 6-inch block, 1½ inch; a 5 inch block, 1 inch; and a 4-inch block, ¾ of an inch. The score round iron-bound blocks is taken out to the size of the iron-strap, sufficient to bury it, except at the pin. Iron straps are from ¼ of an inch to 1 inch in thickness, and nearly three times the thickness in width; the thickness of these should correspond to the strain which they are to resist. The cat-block must have a strong strap and large iron hook, which hooks the ring of the anchor in catting. The top-block should have a stout iron binding, with a strong short hook. Top tackle blocks have strong iron bindings, the upper block with a tackle-hook, and the lower block with a swivel-hook. The swivel, in iron-bound blocks, serves to turn it occasionally, in order to untwist the parts of the rope that form the tackle, as the mechanical power is greatly reduced thereby.

In rigging, the whole length of all the different sizes of block-strapping is got upon the stretch, and hove out tight for worming and serving; it is then wormed and served, and cut into shorter lengths, to suit the different blocks. The strapping of jeer-blocks is wormed, parcelled, and served; strapping of 4 inches diameter, and above, is wormed and served; and all under 4 inches is only served with spun yarn;

except the sprit-fail brace, bunt-line, and leech-line blocks, that are lashed under the tops, which are only served with spun-yarn over the splice, and the tail left half a fathom in length. Jeer-blocks are double scored, and the double and treble blocks are strapped with a double strap, thus: it is spliced together at the ends, and, when doubled, to be the size of the block and circumference of the yard; it is then doubled, and the block seized in the bight, with a long and short leg; the splice lying in the arse of the block.

The scores of all blocks are to be well-tarred, and the pin and sheave examined, before the strap is put on. The block is set well into the strap with wedges, thus: the four parts are frapped together with rope-yarn under the block, with a chock between, and the wedges are set between the breast of the block and chock. Then the strap is nippeded, with a heaver, round the block; the wedges, chock, and frapping, taken away, and the block hung upon the flake-head, or post, and the strap well seized together, close under the block, with nine under and eight riding turns, every turn strained tight round by a heaver, and crossed each way with two turns.

Jeer-blocks, for the mast-heads, are strapped with long eyes, to receive many turns of the lashing; and the block is seized into the strap as before, as are all seizing blocks, in proportion to their sizes. The straps are cut agreeable to the following table.

A TABLE of the Dimensions of Straps for Lashing and Seizing Blocks.

Size of the Blocks.	Circumf. of the Straps.	Length of the Straps.	
		Feet.	Inches.
17	5	7	4
16	4½	6	8
15	4	6	0
14	3½	5	4
13	3½	4	11
12	3½	4	6
11	3	4	2
10	3	3	9
9	2½	3	4
8	2½	3	0
7	2½	2	9
6	2	2	6
5	1½	1	9
4	0¾	1	6

Blocks, strapped with eyes or thimbles spliced in the ends, are seized tight into the bight, and the legs left long enough to lash through the eyes, round a mast, yard, &c. as the top-fail clue lines, clue-garnets, and sprit-fail clue lines, &c.

Blocks strapped with a thimble, or hook and thimble, have the strap spliced together at the ends. The block is fixed in one bight, for the splice to lay on the arse of the block, and the thimble in the other bight; the seizing is put on, between the block and thimble, with eight under and six riding turns, according to the size of the block, each turn strained tight by a heaver; the turns double crossed, and the end stopt with a wall-knot crowned.

Blocks strapped with double tails, are fixed in the strap, similar to blocks with eye-straps: and those with a single tail are spliced in, and served with spun yarn over the splice.

Girtline blocks are strapped in the house, and the girtlines reeved. See *Elements and Practice of Rigging, &c.* vol. i.

BLOCKADE.

Block-and-Block, in *Sea-Language*, denotes the situation of a tackle, when the effect is destroyed by the blocks meeting together.

Block-wood, is a name sometimes given in our laws to logwood. 23 Eliz. c. 9.

BLOCKADE, in the *Military Art*, signifies the method adopted in cutting off all communication between a town which it is intended to reduce by famine, and the neighbouring country. It is effected by posting troops on all the passages and avenues leading to and from the place; preventing any supplies of provisions or reinforcements from being thrown in by the enemy, and thus, in course of time, starving the garrison into a surrender. A blockade differs from a regular siege, inasmuch as there are no trenches or attacks. Blockades are principally formed by the cavalry. The term probably owes its origin to the German expression *blockus*, or *blockhaufe*, a *bulwark*, or *house of wood*; or to the Gaulish *bloca*, a *barricade*; though others derive it from the Latin *baculare*, signifying to *stop a passage*.

The word is sometimes used in speaking of the commencement of a siege, when detachments are sent forward to seize the principal avenues, and occupy the ground on which the besiegers intend to fix their quarters.

To *raise a blockade* is to force the troops, which keep the place blocked up, from their posts.

The only method of reducing fortresses in the more remote ages of antiquity, was by blockade. The town was completely invested by a wall of masonry constructed around it, and furnished at certain distances with redoubts and places of arms; or the besiegers contented themselves in surrounding it with a deep ditch and intrenchment, well pallisaded, to prevent the garrison from making sorties, or any succour or provisions from being introduced by the adversary without. In this situation the investing army tranquilly waited until famine brought about what at that period art and force were unable to accomplish. From hence proceeds the extreme length of those sieges chiefly spoken of in the more early pages of profane history; that of Troy, which lasted ten years; that of Azotus, by Phamærichus, which continued twenty-nine; and that of Babylon, by Cyrus, who, according to Xenophon (*Cyrop.*), would have been much longer detained before its walls, if a lucky surprize had not rendered him master of the place. See **BABYLON**.

The ancient Greeks, on foreseeing that the siege of a fortress would prove a work of time, often changed it into a blockade. They environed the town with a fosse and rampart against the attempts of the garrison, and drew another ditch round it towards the country, to oppose such troops as might advance to succour the place. The besiegers established their camp between the two lines, and thus, in process of time, starved their adversaries into a capitulation.

In the instance of the blockade of Platæa, carried on during the third year of the Peloponnesian war, the works constructed by the Lacedæmonians were of a more complex nature. They consisted in two walls of solid masonry, built at the distance of sixteen feet from each other, of a reasonable thickness, and covered in at top by a kind of roof or platform. The intervening space formed a suite of apartments, in which the troops, destined to carry on the blockade, were lodged during the winter. Each of these walls was furnished with a parapet and battlements, and, at the distance of every ten of these last, was erected a turret with a flat roof, of the breadth of the whole terrace, and capable of making resistance at the same time against an enemy from within or without. The only method of communication between the different chambers, was by traversing these towers.

The approach to the walls on either side was defended by a deep ditch, the earth of which had been used in constructing the rampart. During the night, guards were kept on the several towers; centinels were established at different posts round the whole extent of the circumvallation; and a corps de reserve of three hundred men remained always under arms, ready to march on the first signal wherever there might be occasion for their services.

This is the most remarkable instance of a blockade we meet with in the Grecian history. Notwithstanding, however, all the precautions above related, and the seeming impracticability of flight, the intrepid garrison of Platæa, found means to elude the vigilance of their besiegers, and by a well concerted sortie, about one half of them effected an escape across the formidable works of the Peloponnesians, and reached Athens in safety. The event is related in a very interesting and circumstantial manner by Thucydides in his second book. The Romans first imitated, and finally surpassed the Greeks in this as well as in every other branch of scientific warfare. As early as the siege of Agrigentum, in the first Punic war, we find them dividing their forces, and forming two encampments to block up the place on both sides; connecting these encampments by lines of circumvallation, and braving within these defences every effort made to relieve the town by the enemy from without. But these lines were equally badly guarded against a sortie with those of Platæa. The Carthaginian garrison, imitating the former example, succeeded in a like manner in forcing a passage by night over the intrenchments of the besiegers. (*Polyb. lib. i. c. 17.*) The famous blockade of Lilybæum, during the same war, which lasted for nearly ten years, is a remarkable instance of Roman perseverance in military undertakings, although, the place being open to receiving supplies from the sea, the assiduity of the besiegers was not attended with such complete success as it deserved. By degrees, however, the Romans improved in the art of reducing fortresses by blockade. Syracuse, which the abilities of Archimedes rendered impregnable by open force, had been thus reduced by Marcellus, but for the treachery of a townsman, which in a great measure abridged his labour; and all the military science and manœuvre of the formidable Hannibal was in vain exerted for the preservation of Capua, during the twelve months the siege lasted. (*Polyb. Livy.*)

The works constructed by Scipio Æmilianus for the reduction of Numantia, exceeded in magnitude all which had been raised on any former occasion, and besides surpassing them in strength, embraced a much greater extent of ground, than the intrenchments of the Lacedæmonians before Platæa. Numantia was eighty-four stadia, or nearly a league in circuit. Scipio, after having invested it, drew a circle inclosing twice the area of the circumference of the town; and this work being completed, he threw up his lines of circumvallation and contravallation at a reasonable distance from each other. Each of these fortifications was composed of a rampart eight feet thick, and ten in height, defended by sharp pallisades, and flanked with turrets at a hundred feet distant from each other. We can hardly comprehend or credit the immense labour of such a circumvallation; but nothing can be better attested than these facts. (*Appian. de Bell. Hisp.*)

Among the numerous exploits of Cornelius Sylla, the blockade of Præneste, during his civil war with the party of Marius in Italy, is not to be reckoned the least. The inflexible assiduity, with which it was kept up during a long period of time, and preferred unbroken against the bloody and almost unintermitted attacks of several hostile armies, superior in number to his own, conveys the highest idea of

BLOCKADE.

his martial abilities. It was, however, under the auspices of Julius Cæsar, that this branch of military science attained its highest point of perfection among the Romans; and whether we consult the annals of ancient or modern warfare, we find no example to equal the talents displayed by that unrivalled general, in the formation of his immense works before Alesia, and at Dyrrhachium, which have deservedly excited the wonder and admiration of posterity.

In the former instance, he undertook the arduous task of blocking up an army of 80,000 Gauls, doubly superior in number to his own forces; commanded by a general of the greatest military knowledge, Vercingetorix, and entrenched under the walls of a fortified city, situated itself on an almost inaccessible mountain. Cæsar's line of contravallation, extending nearly eleven miles, was composed of a ditch fifteen feet broad, and as many deep, defended by a rampart twelve feet in height, furnished with a parapet, and fortified all round by turrets, at the regular distance of eighty feet. The front of the rampart, looking towards the town, was protected by a pallisade of sharp stakes and boughs of trees, interlaced, cut sharp, and pointing outwards. Before the fosse were planted five different rows of *cippi*, or large branches sharpened at the ends, fixed in trenches five feet in depth, and so strongly interwoven, as not to be removed or plucked up, without infinite labour. In front of these were arranged eight other rows of *lilia*, or pits, three feet deep, disposed in the form of a quincunx, ruck thick with strong sharp stakes, and covered over with bushes to deceive the enemy. Before these again were scattered up and down numerous stakes of a foot in length, fastened in the earth, and headed with barbed iron hooks, called by the Romans *stimuli*. Farther advanced than these last, at 400 paces distance from the rampart, Cæsar drew another ditch, twenty feet broad and deep, to keep the garrison at a distance, and prevent them from annoying his soldiers while employed on the contravallation. Not contented with such immense labours, he constructed the like fortifications towards the country, for the purpose of frustrating any attempts the expected Gaulish succours might make for the relief of their besieged countrymen. Between the lines, a space of nearly half a mile in breadth, was disposed the investing army, and their principal encampment was pitched in the most convenient situation for communicating with every part of the circumvallation. Behind these defences did Cæsar baffle the utmost efforts of a new army of 250,000 Gauls, sent to extricate Vercingetorix; and, after a series of the most brilliant achievements ever recorded, obliged the town of Alesia, and the army inclosed within its walls, to surrender at discretion. Cæs. de Bel. Gal. lib. vii.

No less famous in history, though not productive of equal success, were the celebrated lines at Dyrrhachium, carried over a tract of fifteen miles, and within which, Cæsar flattered himself, to surround, and compel to a capitulation, an army exceeding his own in strength, and commanded by the great Pompey. But in this instance the conqueror of Gaul had to do with Romans, and the enterprise proved too vast for his strength. Pompey, by a sudden and well-directed effort, broke through the blockade, when it was on the very point of being completed; and had he briskly followed up the advantage, might, according to Cæsar's own confession, have converted his adversaries' hopes of success into total defeat. Cæs. de Bel. Civ. lib. iii.

The works thrown up by Augustus at Perusia, and the entrenchments within, which Stilico at Pæsula enclosed, and destroyed an inundation of 400,000 Goths, are proofs that in after ages the Romans retained a remembrance of the means by which Cæsar had triumphed at Alesia, and were

still capable of practising them for the extermination of their numerous enemies. App. de Bel. Civ. Zozim. Prosp. Marc. Chron.

In modern warfare, there are two ways of forming blockades. The first, and most simple, consists in fortifying and occupying different positions at a small distance from the place, principally upon all the highways and avenues, and along the banks of rivers, both above and below the town. These posts are guarded by distinct corps of infantry and cavalry, who take care to keep up an easy communication with one another, and to prevent all supplies of provisions from being conveyed into the fortrefs blockaded. This, by degrees, reduces the garrison to great necessity, causes them to desert, and frequently occasions such murmurings and mutinies among the inhabitants, as to force the governor to a premature capitulation. Such a species of blockade is extremely tedious; for it is almost impossible to prevent provisions from being sometimes introduced in small quantities, and reviving the courage and patience of the besieged. But it is of advantage, after having thus for some time invested a town at a distance, to convert the operations into a regular siege, as the garrison are then generally unprovided with the materials necessary for protracting their defence.

The second kind of blockade is much closer and nearer. It is effected by means of lines of circumvallation and contravallation, between which the army lies encamped, and is adopted only in particular cases. If, for example, after the loss of a battle, the enemy should retire into a town which is well known not to be over-abundantly supplied with provisions, and, it is presumed, must be obliged to surrender in a few days. But as it would be the height of imprudence in a beaten general to expose the remains of his army to certain ruin, by shutting them up in a place so ill-circumstanced, (a fault, nevertheless, committed by marshal Wurmser in 1796, after the loss of the battles of Bassano and Roveredo, and which all the importance attached by the imperialists to the preservation of Mantua can hardly excuse,) this kind of blockade is seldom put in practice.

It is rarely a fortrefs is reduced to surrender, by the mere process of blockading; but sieges are often greatly accelerated by it, on account of that scarcity of necessaries, whether for the subsistence or defence of the garrison, which, in a greater or less degree, is its never failing consequence.

The blocking up of towns by corps principally of cavalry, posted in the neighbouring places of strength, is more convenient than any other method; because the troops forming the investiture, are not so fatigued as they would be in occupying open positions, and unfortified villages. In the latter case, it is necessary to be always on the alert, not only against the garrison, who, by a well directed sortie, may interrupt the communication, and cut off some of the detachments; but, against the enemy from without, who, by secretly marching a strong force, may surprise, beat up one of the besieger's quarters, and introduce a convoy, or reinforcement into the town. On account of these inconveniences, it is essentially necessary to ascertain the quantity of provisions and stores contained in the magazines of a place blockaded, in order to compute how long it may hold out, and to have an army in the field sufficiently strong to protect and cover the blockade. For, should the enemy succeed in surprising and cutting off one detachment, its defeat might occasion the successive destruction, or capture of all the others, before they could assemble in competent force to repulse the collected attacks of an enterprising and vigorous adversary. (Fouquieres, Mem. chap. lxxxii. p. 377.)

It is chiefly, since the contest for the imperial succession

BLOCKADE.

in 1740, that the expedient of blockading fortresses of the most formidable strength, has been preferred to the less tedious, but more destructive plan of carrying them by a regular siege. In the latter case, every outwork belonging to the place must be taken, or battered down inch by inch, with an immense loss to the besieging army, and frequently at the hazard of its being so reduced in numbers, as not to be capable of undertaking any action of moment during the remainder of the campaign. On the other hand a blockade, well kept up, must, sooner or later, reduce the garrison to the last extremity for want of provisions, or ammunition. The number of troops engaged in the enterprise is comparatively small. The loss of men, necessarily considerable in the frequent and bloody attacks on the fortifications of a well defended place, is entirely avoided; and the major part of an army is still at liberty to continue its advances into the heart of the enemy's country, and to follow up a previous success, without the tedious process of stopping to reduce every strong hold in its way. The inconveniences which might otherwise result from leaving a hostile garrison in the rear, are, in a great measure, obviated, if the blockade is kept up with proper alacrity and closeness. The enemy within the town have nothing to do to attend to procuring provisions for themselves, without troubling the convoys destined for the main army of their besiegers; and by this means, the operations of a campaign, so far from being retarded, are frequently accelerated, by having recourse to a blockade. Had the allied powers, instead of mouldering away their armies before the walls of Mayence and Valenciennes, and afterwards completing their ruin, by the impotent and bloody attempts upon Dunkirk and Maubeuge, adopted this method during the summer of the year 1793, they possibly might have made greater impression on the territory of the French republic. Had, on the contrary, the generals Jourdan and Pichegru endeavoured, in 1794, to carry Landrecy, Valenciennes, Condé, and Luxembourg, by regular sieges, instead of contenting themselves with leaving those fortresses in a state of blockade, it is very evident that the successes of the French, during the latter part of that memorable campaign, would have been by no means so rapid and important as they actually turned out.

When the directory formed, in 1796, the resolution of invading Germany, their armies made no attempt to attack in front the towns of Mannheim, or Mayence, but proceeded to effect a passage over the Rhine, at a distance from those places; and, instead of consuming their time, and wasting their strength in long and tedious sieges, they advanced rapidly into Suabia and Franconia. They wished to become masters of Ehrenbreitstein, Mayence, Mannheim, and Philippsburg, by the same method by which, in 1794, they had recovered the towns of Landrecy, Quefnoy, Valenciennes, and Condé, and to achieve, by a single manœuvre, that which would, in former times, have been the result of two or three successive campaigns. Pursuant to this system, they forbore to undertake any siege, and ventured to leave fortified places at a great distance behind them. Their generals foresaw, that by carrying the war away from these towns, they should, by force, detach the enemy from them; and judged that if they could obtain and keep possession of the country situated beyond these fortresses, they would, in the end, fall into their hands perfectly undamaged, and without having cost them either blood or treasure. They proposed to acquire the fortified places, by making themselves masters of the surrounding country; as formerly these countries were secured by getting possession of the

fortified places. These had hitherto been the means of conquest; they now meant to make them its result. This method, by which the French acquired so great a number of fortified towns in 1794, met not with the same success in 1796; but their failure did not arise from the strong places which they left behind them; and as these had not impeded the progress of Jourdan and Moreau, neither were they the causes of their first disasters. If the troops of the republic had been victorious at Amberg, or at Wurtzburg, the fortresses of Ehrenbreitstein, Mannheim, Mayence, and Philippsburg, would, no doubt, have ultimately fallen, as Luxembourg did in 1795. *Hist. of the Camp. of 1796, Lond. 1796, 8vo.*

As a proof of the little danger attending this method of carrying on war, we shall only add, that the garrisons of Philippsburg and Mayence remained so closely blockaded by a small part of the French forces, as not to be capable of affording the archduke any essential assistance in cutting off the retreat of the invaders, notwithstanding the rapid and disorderly manner in which more particularly that of Jourdan was conducted. During the same year, Buonaparte, although the reduction of Mantua was the principal object of the campaign in Italy, did not for a moment discontinue his other operations in the field. On the contrary, this did not hinder him from carrying his arms into the middle states of that beautiful country; from laying Parma and Modena under contribution; obliging the pope and duke of Tuscany to agree to a neutrality; forcing the English from Leghorn, and fighting the imperialists almost incessantly, on every point of a very extended line, to the destruction of no less than four of their armies successively detached against him.

Notwithstanding the tardy proceedings of a blockade are far from being congenial to French vivacity, yet, where the strength, or peculiarly inaccessible situation of a fortress, have precluded all hopes of success from a coup de main, they have often had recourse to this means. That they are possessed of sufficient perseverance on these occasions, the three blockades of Luxembourg, Mantua, and Ehrenbreitstein, in 1795, 1796, and 1798, are convincing proofs.

The most famous blockades which, during the last century, have distinguished the military history of Europe, are the following: That of Prague by the Austrians in 1742, is renowned for the gallant defence made by the French forces under the marshals Bellisle and Broglio, for the space of five months, during which time they were driven to the last necessity for want of provisions; and for the daring retreat by which the former of these generals preserved the remains of his army from falling into the hands of the enemy. The late war has produced several remarkable instances. The two already mentioned of Luxembourg and Ehrenbreitstein reflect equal honour on the besiegers, whom no obstacle could deter from continuing, with invincible patience, their plan of reduction; and the garrisons, whose resistance was in the highest degree meritorious.

In 1796, public attention was every where engrossed by the blockade of Mantua, which gave occasion for the utmost exertion of that military talent by which the first consul of France has so eminently distinguished himself, and for the veteran marshal Wurmser to add fresh laurels to those he had already acquired, and draw even from his conqueror a flattering acknowledgement of the ability he had displayed in its defence. The different exploits of these generals; the entire destruction of four imperial armies, in vain attempts to relieve the place; the bloody battles of Castiglione, Roveredo, Arcole, and Rivoli, the result of those attempts; and the conquest of all Italy by the French,

French, the consequence of its fall, secures to the blockade of Mantua everlasting fame.

The conduct of general Massena, when blocked up in 1800 within the walls of Genoa, may justly be compared with the most glorious actions of the war. Surrounded on all sides by enemies; cut off from every hope of succour by land or sea, and almost destitute of provisions or ammunition, he maintained, for sixty days, a post the Austrians had flattered themselves to reduce by famine in six; destroyed immense numbers of them in his different attacks on their posts; and having defended the place to the last extremity, obtained a negotiation (for Massena would not suffer the word capitulation to be inserted in the treaty), equally honourable to himself, and advantageous to his country. It was advantageous, inasmuch as it obliged the enemy to divide and scatter their forces, entangle themselves among the defiles of the Apennines, and, besides losing a number of men before Genoa, drew them to such a distance from what the French government intended to make the principal seat of action during the campaign, as enabled the first consul to pass the great St. Bernard unopposed, occupy the plains of Piedmont, throw himself in the rear of general Melas, and, by the battle of Marengo, extinguish at once the hopes of the Austrians in Italy.

BLOCK-battery, in the *Military Art*, denotes a wooden battery on four wheels, moveable from place to place, whereby to fire *en barbe*, or over the parapet; sometimes also used in galleries and casemates, where room is wanted.

Block-brush, a term used in *Heraldry*, to express a bundle or bunch of knee-helm, or bastard myrtle, formerly used by butchers to clean the surface of their chopping-blocks, which forms a part of the armorial ensigns assigned to the company of butchers of London.

Block-carriage, in the *Artillery*, denotes a carriage used for conveying mortars and their beds from one place to another.

Block-house, in the *Military Art*, a kind of wooden fort or battery, either mounted on rollers, or on a vessel, and serving either on the water, or in some counter-scarps and counter-approaches. The name is sometimes also given to a brick or stone fort, built on a bridge, or the brink of a river, serving not only for its defence, but for the command of the river, both above and below. Such was that noted *block-house* anciently on the bridge of Dresden, since demolished on enlarging the bridge.

Block-printing. See **PRINTING**.

BLOCKING, in *Middle Age Writers*, denotes a kind of burial used for persons dying excommunicated.

Blockings, circular, in *Architecture*, are bases to the dome, represented in the *Plate of Archit.* (title *Basilic*) QQQ; which, by their apparent solidity, seem to strengthen the dome, and at the same time taking from its height, add a peculiar gracefulness to its appearance.

Blockings, square, are represented at S (title *Basilic*), in *Plate of Archit.* These, when enriched with base and cap, obtain the appellation of **PEDESTALS**.

Blocking-course. See **COURSE**.

BLOCKLAND, ANTHONY DE MONTFORT, in *Biography*, a painter of history and portrait, was born of a noble family at Montfort, in 1532, and acquired his art in the school of Francis Floris, whose manner he always followed. By endeavouring principally to imitate the taste of the Roman school in design and composition, he became a distinguished artist. He well understood the principles of perspective, and he disposed his figures with judgment and accuracy. The style of his colouring was agreeable, and

his pencil mellow. He designed every object after nature, and gave to the contours of his figures considerable elegance. His genius was best adapted to grand compositions, of which he designed many, both at Delft and Utrecht. Several of his works, particularly a Venus, and the history of Joseph and his brethren, are in so good a taste, that they seem to have been painted by a master educated in the school of Florence. Pilkington.

BLOCKLEY, in *Geography*, a township in Philadelphia, in the county of Pennsylvania.

BLOCKY, among *Jewellers*, a name given to a diamond when its sides are too upright, by its table and collet being larger than they ought to be.

BLOEMAERT, ABRAHAM, in *Biography*, the most distinguished of a family of Dutch artists, was the son of Cornelius, an architect, engineer, and excellent statuary of Dordrecht, who, during the troubles of the Low Countries, removed to Utrecht. He was born at Gorcum in 1567; and resided chiefly at Utrecht, where he probably died, A. D. 1647. In his youth, he diligently copied the designs of Francis Floris; but the excellence to which he attained was chiefly owing to his own genius, which enabled him to acquire a style of painting peculiar to himself. He painted history pieces, sacred and profane, landscapes, and animals; but though he possessed a facility of invention, and a free-spirited touch, and well understood the chiaro-scuro, his taste and style are said to have too much of the Flemish, and he is charged with having indulged his own fancy, and deviating from nature in his figures. The historical picture of the death of Niobe and her children, gained him great reputation; the figures in the composition being as large as life. Some slight, masterly etchings are attributed to this artist, which are executed in a manner imitating drawings with a pen, from his own compositions. He also published some spirited chiaro-scuros, the outlines of which, contrary to the usual custom, were not cut on blocks of wood, but etched upon copper. Of this kind are two large prints by him, representing Moses and Aaron, both sitting figures. He left four sons, all artists. His son *Frederic* worked chiefly from his father's designs, and imitated his style in his etchings and chiaro-scuros. He also, conjointly with his father, made a large drawing book, consisting of figures, animals, landscapes, &c. *Henry* and *Adrian*, were both painters; and they are also mentioned as engravers: the most eminent, as a painter, was the latter.

Cornelius, the most distinguished as an engraver, was Abraham's youngest son, and born at Utrecht, in 1603. Devoting himself wholly to the art of engraving, he first studied under Crispin de Pass, and then went to Rome, where he died, at a very advanced age. The manner of engraving adopted by this artist was original, and the source of that style, in which the best French masters excelled, or those of them who worked merely with the graver. He covered the lights upon his distances, and the other parts of his plates which required tinting, with great care; whereas, before his time, the lights on the distant hills, trees, buildings, or figures, had been left quite clear; and by so many white spots, scattered in various parts of the same design, the harmony was destroyed, the subject confused, and the principal figures prevented from relieving with any striking effect. By this judicious improvement, Bloemaert gave to his prints a more clear and finished appearance, than all the laboured neatness even of Jerom Wierix had been able to produce. He drew correctly; but as he executed entirely with the graver, the extremities of his figures are heavy; and his heads are not always beautiful or expressive. In the mechanical part of the work few have excelled him,

either as to clearness, or freedom of execution. His great fault, however, is want of variety. The naked parts of his figures, the draperies, and the back ground, are equally neat, and engraven precisely in the same manner. Hence the effect is flat, and the flesh, for want of distinction, appears cold and silvery.

His works, which are numerous, are justly held in high estimation, and cannot be easily procured. The following are particularly noticed, and the first impressions of some of them are very rare: the "Chastity of Joseph," from Blanchart; the "Adoration of the Shepherds," from Raphael; the same subject from Pietro de Cortona; the "Holy Family" of the "Spectacles," as it is called, from Joseph's holding a pair of spectacles in his hand, from Annibale Caracci; another "Holy Family," from Parmegiano; the "Virgin and Child," the child sleeping, from Guido; "St. Luke painting the Virgin and Child," from Raphael; "St. Peter raising Tabitha from the Dead," from Guercino; "St. Marguerita" leaning on a pedestal, and setting her foot upon the dragon, after Annibale Caracci; the "Four Fathers of the Church," from his father A. Bloemaert; "Christ appearing to St. Ignatius," from the same; "Meleager presenting the boar's head to Atalanta," from Rubens; several "prints for a missal," after Ciro Ferri and others; a set of small prints of "Rustics, &c." from his father; "Heads" from the same; &c. &c. Pilkington and Strutt.

BLOEMEN, JOHN FRANCIS VAN, a painter of landscapes, called by the Italians, from the delicate manner in which he painted his distances, "Horizonti," or "Orizonti," was born at Antwerp in 1656; and as he studied at Rome, and always resided in some part of Italy, he is generally considered as an Italian artist. His works have been very much admired in every part of Italy, and bought at very high prices by the best judges. His first manner resembled that of Vander Cable; but he afterwards made nature his model, and more particularly the views about Tivoli, the subjects of many of his landscapes, in which he represents, with extraordinary truth and beauty, the mists arising from the agitated surface of the river below. His pictures are generally well designed, and well handled; and those of his best time are now considered as an ornament to the most select cabinets in Europe. A very capital picture of this excellent artist, in which the figures were inserted by Sebastian Conca, is in the collection of the earl of Moira. By this artist we have five small etchings, probably done for his amusement. They are "perspective views," apparently near Rome. Pilkington and Strutt.

BLOEMEN, PETER VAN, brother of the preceding, was born at Antwerp, and after living several years with his brother at Rome, and studying the works of the greatest masters, returned to his native city, where, in 1699, he was appointed director of the academy. The subjects of his pictures are the marchings of squadrons of cavalry, encampments, artillery, battles, Italian fairs, markets, and festivals, in which he manifests correctness of design and drawing, and an elegance in the manner of dressing his figures. His horses are designed in an admirable style, and in his battles they exhibit great spirit, graceful attitudes, and an expression full of life and nature. His landscapes are enriched with elegant architecture, with basso-relievos, and mutilated statues, in a noble taste; and they are rendered the more agreeable by a good tone of colour, animals of different kinds, and excellent figures. His best works are admired in all parts of Europe, and afford high prices; but some of them are too laboured, and less valuable. Pilkington.

BLOEMEN, NORBERT VAN, brother of the preceding, was born at Antwerp in 1672, and being allured by the reputation of his brothers to visit Italy, he there devoted all his hours to study. He principally painted conversations and portraits; but the colouring of his pictures is too glaring, and wants more truth and nature. Pilkington.

BLOIS, in *Geography*, lat. *Blesie*, a city of France, was, before the revolution, the capital of "Le Blaisois," the see of a bishop, suffragan to the archbishop of Paris, and formerly the residence of the kings of France; but is now the capital of the department of the Loir and Cher, and divided into east and west Blois, the former containing 5,400 inhabitants, and its canton 12,885, and the latter 7912, and its canton 11,862: the whole territory comprehends 237½ kilometres, and each canton has eight communes. Blois is seated in a pleasant country, on a small eminence near the river Loir, over which is a handsome stone bridge. The castle is the principal ornament of the city, and has, on the first view, the appearance of two distinct buildings, which are joined by a passage cut out of a rock. That part of the castle, which was built by the duke of Orleans, instead of that which he demolished in 1632, is a superb, but unfinished edifice. The court before it, where the church of St. Saviour is situated, is very large, and was formerly used for tournaments. The adjoining gardens are magnificent and beautiful. On every gate of the city is exhibited an image of the Virgin Mary, who is thought to have delivered the inhabitants from the plague in 1631. In this castle, famous as the birth-place of Louis XII., are shewn the chambers where the duke of Guise, and his brother the cardinal, were murdered by order of Henry III., December 23, 1587. The church of St. Solenne is the cathedral, which is a beautiful structure. The front of the Jesuits' college is decorated with the Doric, Ionic, and Corinthian orders of architecture. About three quarters of a mile from the city, water in great abundance descends through the clefts of a rock, in a large aqueduct, by which it is conveyed to a reservoir near the walls, and it is then distributed by leaden pipes to the several parts of the city. The trade of Blois consists chiefly of wine and brandy; though it has manufactures of ferges and ticken. Several kings have kept their courts at Blois, and the French language is spoken in the greatest perfection by its inhabitants. N. lat. 47° 35' 20". E. long. 1° 20' 10".

BLOIS, PETER OF, *Petrus Blesensis*, in *Biography*, an eminent writer of the 12th century, was born about the year 1120 at Blois in France, whence he derived his name; and as his parents were opulent, he enjoyed all the necessary means of a learned education. In his youth he studied in the university of Paris, where he manifested a strong inclination to poetry, and in his more advanced life, he applied with peculiar ardour to the study of rhetoric. At Bononia, in Italy, whither he removed from Paris, he acquired eminence by his knowledge of the civil and canon laws; and he appears also, by his writings, to have cultivated an acquaintance with medicine, and with various branches of the mathematics. But the principal object of his attention, and in which he is said to have particularly excelled, was theology, or the scholastic theology of the times, which consisted in vain attempts to prove and explain the numerous absurd opinions, which prevailed in the church, by the subtleties of Aristotelian logic. To him some have ascribed the first use of the term "transubstantiation," which was soon after adopted in the church of Rome. Being appointed preceptor to William II. king of Sicily, A.D. 1167, he obtained the custody of the privy-seal, and, next to the archbishop of Palermo, the prime minister, he had the greatest influence in all affairs. However, his power

power soon terminated; for, upon the banishment of the archbishop, A. D. 1168, he left the court of Sicily, and returned into France. From France he was invited into England, by Henry II. who employed him as his private secretary, made him archdeacon of Bath, and gave him some other benefices. After having spent a few years at court, he conceived a disgust at that mode of life, and retired into the family of Richard, archbishop of Canterbury, who made him his chancellor, about A. D. 1176. After the death of this prelate, A. D. 1183, he acted as secretary and chancellor to archbishop Baldwin, his successor; and was deputed by him on an embassy to Rome, A. D. 1187, in order to plead his cause before pope Urban III. in the famous controversy between him and the monks of Canterbury, about the church of Hackington. When Baldwin departed into the Holy Land, A. D. 1190, he was involved in various troubles in his old age, the causes of which are not distinctly known, and died about the end of the 12th century. From his works, which may be justly reckoned among the most valuable monuments of the age in which he flourished, and some of which may even now be read with profit, he appears to have been a man of approved integrity and piety, as well as of a lively inventive genius, and uncommon erudition. He is said to have dictated letters in Latin to three different scribes, on different subjects, and to have written a letter in the same language himself, at the same time. His printed works consist of 183 letters, which he collected together at the desire of Henry II.; of 65 sermons, delivered on various occasions; and of 17 tracts on different subjects; "Opera P. Blesens. Paris, edit. A. D. 1667," fol.; and afterwards printed in the *Bibliotheca Patrum*, tom. 24. *Cave Hist. Lit.* vol. ii. p. 333. Henry's *Hist.* vol. vi. p. 147, &c.

BLOKZYL, in *Geography*, a town and fort of Overijssel, situated at the mouth of the Steenwyk, or Old Aa, where it enters the Zuyder sea, with a harbour capable of containing 200 vessels; defended by six bastions, and erected by the Dutch, at the commencement of their republic, to defend them from the invasions of the Spaniards. N. lat. 52° 45'. E. long. 5° 45'.

BLOMARY, or **BLOOMARY**, the first forge in an iron-work, through which the metal passes after it is melted out of the ore. (See *IRON*.) They are also called *blomary-hearths*.

BLOMBERG, in *Geography*, a town of Germany, in the circle of Westphalia, and county of Lippe, which obtained its first privileges, in the beginning of the 14th century, from count Simon I.; 8 miles S. E. of Lemgow.

BLOMESHOLM, a manor of Sweden, in the district of Bohus, about 3 Swedish miles from Stromstadt, in which is a very ancient monument, consisting of large stones, set up perpendicularly, and arranged in the form of a ship.

BLONAI, a barony and castle of Switzerland, near Vevay, and about 1½ mile from the lake of Geneva.

BLOND, **LE**, **CHRISTOPHER**, in *Biography*, a painter, was born in 1670, but little noticed in the more early part of his life. He became known at Rome in 1716, and established his reputation in Italy, as a good painter of portrait in miniature. At Amsterdam he distinguished himself by painting small portraits, for bracelets, rings, and snuff-boxes, first in water colours, with a very lively and natural colouring, and afterwards in oil. From the Low Countries he came over to England, and projected a new manufactory for impressing colours on paper with copper-plates, which promised to be advantageous, but in the end proved detrimental to himself and his associates, to which his own dissolute life and manners very much contributed. His scheme was to copy the most

capital pictures in England, of the greatest masters, so as to give his prints the appearance of paintings in oil. Many of his prints were well executed, are still extant, and are held in estimation. It is said, however, that he was not the original inventor of this method of managing colours; but that he took it from Lastman, and others, who with equal capacities and more discreet conduct, had undertaken it before him, but failed of success. Pilkington.

BLONDEL, **DAVID**, a French protestant minister, eminent for his acquaintance with ecclesiastical and civil history, was a native of Chalons in Champagne, admitted minister in 1614, and settled at Houdan near Paris. His first work in favour of the Protestants was printed at Sedan in 1619, under the title of "Modeste Declaration, &c." or, "A Modest Declaration of the sincerity and truth of the reformed churches in France:" and intended as a reply to the invectives of the party of the bishop of Luçon, afterwards cardinal Richelieu. This work established his reputation among the Protestants, and occasioned his being much employed in their synods. He was not distinguished as a preacher; and his style, as a writer, was perplexed, and incumbered with parentheses; but his judgment was penetrating, his memory tenacious, and his erudition extensive. As an honorary professor, with a pension, to which office he was appointed by the synod of Charenton in 1645, he had opportunity to devote his time to literature; but though he undertook to refute Baronius's annals, it does not appear that he did much besides writing a few notes in his own copy of the work. His works were "Explications on the Eucharist;" a treatise concerning "The Primacy of the church;" "Pseudo-Isidorus et Turrianus vapulantes," against the Decretal epistles; a "Treatise on the Sibyls," disproving the truth of their oracles, and refuting the ancient practice of praying for the dead; and a treatise "De Episcopis et Presbyteris." By his treatise against the story of pope Joan, which he rejected as fabulous, he offended some Protestants, who did not wish to be deprived of this topic of satire against the Romish church. Among Blondel's works on civil history, we may reckon his "Genealogy of the kings of France against Chifflet," written in Latin, and printed at Amsterdam in 1654, 2 vols. fol. which is said to have been undertaken at the desire of chancellor Seguier; and his piece "De formula regnante Christo." On the death of Gerard Vossius, he was chosen to succeed him as professor of history in the schola illustris of Amsterdam, and took possession of his office in 1650; but his assiduity in the prosecution of his studies and change of air, occasioned the loss of his sight, after which, it is said, that he dictated his work intitled "Genealogy, &c." At Amsterdam his situation was rendered uneasy by a charge of Arminianism; and he died in 1655. *Gen. Dict.*

BLONDEL, **FRANCIS**, an eminent mathematician and military engineer, was born in 1617, at Ribemont in Picardy. In 1652, he was travelling governor to the young count of Brienne, and after a tour of three years he published an account of it in Latin. After his return he was advanced to considerable posts both in the army and navy, and he was employed in various negotiations with foreign princes. In 1659, being deputed by Louis XIV. as his envoy-extraordinary to Constantinople, he visited Egypt; and at the termination of his embassy, he was appointed counsellor of state, tutor in mathematics and belles-lettres to the dauphin, and one of the mathematical professors at the royal college. In 1655, he began to display his talents for architecture, when the court employed him to construct a bridge over the Charente at the town of Saintes. In 1669, he became member of the Academy of Sciences; and in 1670 he was honoured

honoured with letters patent from the king for the superintendance of all the public works in Paris. To him were intrusted the repair and decorations of the gates of St. Antony and St. Bernard; and the gate of St. Denis, one of the most finished pieces of French architecture, was designed and erected by himself. In the office of director and professor of the Academy of Architecture, established in 1671, he gave "A Course of Architecture," which was published in large folio, in 1698, and which was long considered as a standard book. In 1675, he presented to the king his treatises "On the art of throwing bombs," printed in 1685, 4to. and "On a new method of fortification," which procured for him the rank of marshal de camp. His other works were "Notes on the architecture of Savoy;" the "Resolution of four principal problems of architecture," Paris, 1676, fol.; "A Course of mathematics," Paris, 1683, 4to.; the "History of the Roman calendar," Paris, 1682, 4to.; and a "Comparison between Pindar and Horace." He also communicated several ingenious pieces to the Royal Academy of Sciences, which are inserted in their Memoires, particularly for the year 1666. He died at Paris, Feb. 1. 1686. Gen Dict.

BLONDEL, FRANCIS, was admitted doctor in medicine at Paris, the place of his birth, in 1632. As he had acquired considerable reputation as a scholar, he was engaged, on the death of Chartier, to assist in completing his magnificent edition of the works of Hippocrates and Galen, three volumes of which were left unfinished. He was an avowed opponent to the admission of antimony, and of all chemical preparations, into the practice of medicine, coinciding in that respect with his cotemporary and coadjutor, Guy Patin. In 1658, he was made dean of the faculty of medicine, which office he held the following year. In 1660, he published "Statuta facultatis medicine," Paris, 12mo.; and in 1665, an epistle to Alliot, "De cura carcinomatis, absque ferro et igne," 4to. Alliot used for the purpose a medicine prepared from the arsenicum rubrum, dissolved in aqua fortis, and precipitated with the acetum saturni. The precipitate was then washed by repeated affusions of warm water, and its causticity further mitigated by burning spirits of wine, in which it was immersed, until the powder became perfectly insipid. Blondel died Sept. 5th, 1682. Haller. Bib. Chirurg. et Med. Eloy Dict. Hist.

BLONDEL, FRANCIS, born at Liege in 1613, studied medicine at Cologne, and was for some time physician to the elector of Treves. On the death of that prince, in 1652, he went to Aix, and was appointed physician and superintendant of the baths in that city. In 1662, he published "Lettre de Francis Blondel a Jaques Didier, touchant les eaux minerales chaudes d'Aix, et de Borset, et les cures qui se font faites par son usage," Brux. 12mo.; and in 1671, "Thermarum aquigranensium, et porcetianarum descriptio," which was reprinted in 1688, in 4to. with engravings, and considerable additions. He died in 1703, much regretted by the inhabitants of Aix, having, by his writings, so recommended the waters, as considerably to increase the resort of patients there. Eloy. Dict. Hist.

BLONDEL, JAMES AUGUSTUS, of a French family, but born in England, and admitted licentiate of the college of physicians in London, about the year 1720; published, in 1727, "The strength of imagination in pregnant women examined, and the opinion that marks and deformities in children arise from thence, demonstrated to be a vulgar error," 12mo. Though Dr. B. had not put his name to this work, yet his neighbour and colleague Dr. Turner, discovering that he was the writer, and considering it as an attack upon what he had said on the subject, in the 12th chapter of his treatise on the diseases

of the skin, in which he gives numerous instances of marks and deformities in the bodies of children, impressed on them by the disturbed imaginations of the parents, thought himself called upon to explain and to defend what he had there advanced. He therefore, in an appendix to his treatise on gleans, published the following year, gave some additional observations on the subject, in further proof of the influence of the affections of the mother over the fœtus in utero. To this Dr. Blondel replied, in 1729, and with much humour, as well as argument, shewed the absurdity and fallacy of the opinion maintained by his antagonist; who, if he insisted on his point, must admit that animals, and even plants, are under the influence of the same affections; their fœtuses being frequently produced equally defective and monstrous as those of the human species. The answer is entitled, "The power of the mother's imagination over the fœtus examined, in answer to Dr. Daniel Turner's book, entitled, 'A Defence of the 12th chapter of his treatise, de morbis cutaneis.'" This drew a more serious reply from Dr. Turner, addressed immediately to his opponent, under the title of "The force of the mother's imagination upon the fœtus in utero still farther considered, in the way of a reply to Dr. Blondel's last book, by, &c." 1730, 8vo. But though the doctor supports himself with the authority of Schenckius, Hildanus, Horstius, and many other collectors of wonderful and extraordinary stories, the good sense of his antagonist prevailed, and he has the merit of having contributed very largely towards removing the prejudices on this subject, which had prevailed for ages, and, with them, the solicitude and anxiety which never failed to torment the minds of such women as had the misfortune, while pregnant, to see or hear any thing, strongly affecting their imaginations, lest their offspring should be born with some defect or deformity. It is now pretty generally known, that no such consequences follow, and that the few cases in which children are produced defective, with redundant parts, or in any way distorted, happen indifferently, where the mother has or has not, in the course of her pregnancy, received some shock or alarm. The power of the imagination in marking, distorting, or deforming the fœtus in utero is vanished, with the witches, ghosts, and hobgoblins, formerly equally objects of distress and terror. Haller. Bib. Chir. et Med. Pract. Eloy. Dict. Hist.

There is another writer of the name mentioned by bibliographers.

BLONDEL, JACQUES, surgeon of Lille in Flanders. He translated the Chirurgia militaris of Nicolas Godin, under the title of "La Chirurgie militaire, tres utile a tous ceux qui veulent suivre un camp, en tems de guerre, pareillement a tous autres en condition pestilente ou dysenterique, ecrite en Latin, par Nic. Godin," Anvers, 1558, 8vo.

BLONDEL, JOHN FRANCIS, was born at Rouen in 1705; and was known, not only as architect to the king, member of the Academy of Architecture, and royal professor of the art at the Louvre, but by several useful publications; as "A Discourse on Architecture," 12mo.; "A Treatise on the decoration of buildings," 1738, 2 vols. 4to.; "A Course of Architecture," 6 vols. 8vo. 1771—1773. The two last were published in 1777, 3 years after his death. M. de Bastide also published, in 1774, a posthumous work of Blondel, entitled, "L'homme du monde éclairé, par les Arts," 8vo. 2 vols. Blondel was the author of the articles relating to architecture in the Encyclopedie. He died Jan. 9, 1774. Encycl.

BLONDIN, PETER, a native of Picardy, born Dec. 18th 1682, was a disciple of Tournefort, by whose advice he travelled over Picardy, Normandy, and the Isle of France, to improve himself in botany. In the course of his excursion, he

discovered upwards of an hundred and twenty plants, which had not been before described, and several others, which had been supposed peculiar to America. In 1708, he was admitted doctor in medicine at Rheims; and, in 1712, he was received into the French academy, in quality of eleve of M. Reneaume, an honour he did not long enjoy, being cut off in the following year, by an inflammation of the lungs. M. Fontenelle, who spoke his funeral eulogium, attributed to him a small work, published in his life-time, in which he had made some corrections in Tournefort's arrangement of certain species of plants; he also says, he left some curious memoirs on the subject of botany, intended for publication, and which were prevented being printed by his premature death. But his name does not appear in Haller's Bib. Botan. nor in the catalogue of botanical works contained in the splendid library of sir Joseph Banks, lately published by Dr. Dryander. Eloy Dict. Hist.

BLONDVAURY, in *Geography*, a town of France, in the department of the Charente, 5 leagues east of Confolens.

BLONDUS, or BIONDI, MICHAEL ANGELO, in *Biography*, was born at Venice, May 4th 1497. After studying under Augustin Niphus, a celebrated teacher of that time, he settled at Naples. He was a voluminous writer. The titles of the most distinguished of his works follow. "Epitome ex libris Hippocratis de nova et prisca arte medendi deque diebus decretoriis," Romæ, 1528, 1545, 8vo.; "Libellus de morbis puerorum," Venetiis, 1539, 8vo.; "De partibus icthi sectis citissime sanandis, et medicamento aquæ, nuper invento. In plurimorum opinionem de origine morbi Gallici, deque ligni Indici ancipiti proprietate," Venetiis, 1542, 8vo. For wounds made with a cutting instrument, and recently inflicted, he recommends the application of simple water, as a most valuable and useful remedy. He does not admit that the venereal disease was a new complaint, originating in the West Indies, but believes it to have been known to Hippocrates, and other ancient physicians, and described in their writings. He had used the *lignum sanctum* in his attempts to cure the disease, but ineffectually; the disease returning, he says, after discontinuing the medicine, with increased violence. He placed his principal dependence on mercury, but does not give the rationale, or method of using it. This work is inserted by Conrad Gesner in his "Collectio scriptorum optimorum de chirurgia," 1555, fol. For the titles of the remainder of his works, see Eloy's Dict. Histor. Med. Astruc. de Morb. Vener. Haller. Bib. Med. Pract. et Botan.

BLONSK, in *Geography*, a district of Poland, belonging to the territory of Warsaw, in the palatinate of Czerk, or Masovia.

BLOOD, is the nutritive fluid of animals. In the human subject it circulates through the arteries and veins (see CIRCULATION), being of a scarlet colour in the former, and of a purple colour in the latter; it is of considerable consistence; of a slightly saline taste, and peculiar smell; its specific gravity is estimated at 1.0527. When blood is drawn into a basin, it first congeals into a tremulous, jelly-like mass; and then spontaneously separates into a solid, heavier substance termed the crassamentum, cruor, or the clot of the blood, and a supernatant pale liquor called the serum. If the crassamentum of the blood be washed with water, all the red colour may be washed out of it, and a firm whitish substance will remain. This substance, which did exist in a state of subtle fluidity, so as to be capable of permeating the minute vessels of the body, and which thus spontaneously concretes, has been, therefore, called the coagulating lymph of the blood. If the blood be stirred with a wisp,

this substance concretes in a fibrous form round about it, and it was in consequence formerly termed the fibrous part of the blood. By this latter denomination, it is also now generally known and described. Thus it appears, that there are three parts readily distinguishable in the blood; the serum; the fibrous part or basis of the crassamentum; and the colouring matter; to the more particular consideration of these we now proceed.

Of the Serum.

The Serum of the blood is of a light greenish yellow colour, and its mean specific gravity is estimated at 1.0287. If it be heated to about 165° of Fahrenheit's thermometer, the fluid serum becomes converted into a tremulous solid substance; which being cut in pieces and compressed, there can be squeezed out of it a muddy and somewhat glutinous fluid, which is termed the serosity of the blood. If the remainder be boiled, part of it will be found to be insoluble; and this has all the properties of albumen, or that insoluble matter which is contained in the white of the egg; for an account of which, see the article ALBUMEN. That part of the serum which is dissolved in boiling water, becomes a jelly, if the water be evaporated to a certain degree, and it be suffered to become cold. It is again soluble, if more water be added. This modification of animal matter is now termed gelatine, and to that article the reader is referred for a more full account of its properties. The serosity of the blood appears to contain animal mucilage, but no accurate chemical examination has as yet been made of it. The serum of the blood turns the syrup of violets green; which effect is owing to soda, that is contained in it. If coagulated serum be heated in a silver vessel, the silver becomes blackened by being converted into a sulphuret; in consequence of the serum containing sulphur. If the salts of the serum be dissolved in boiling water, and afterwards crystallized, they are found to be carbonat of soda, muriat of soda, phosphate of soda, and phosphate of lime.

Of the fibrous Matter of the Blood.

This matter spontaneously concretes in open and in close vessels, in the temperature of the animal, or in a much lower degree of temperature, though with some little variation as to the time in which the coagulation happens. Dilution of albumen by water prevents its coagulation, even by those chemical agents which suddenly and firmly coagulate it in its natural state, such as heat, spirit, and acids. No dilution of the blood by water has hitherto prevented even the spontaneous coagulation of its fibrous part. The basis of the crassamentum, or fibrous part of the blood, is found to be a whitish solid elastic substance, of greater specific gravity than the serum. This substance, which is insoluble in water or alcohol, and which resembles the muscular fibres in its chemical properties, has been denominated by the French chemists fibrine, or fibrina, to which article the reader is referred for a more particular account of it. It is tight however here to remark, that chemical analysis ultimately converts all animal substances into azot, hydrogen, and carbon; and that the proportion of the former is greater in the fibrous part of the blood than in albumen, or perhaps in any other animal compound.

Of the colouring Matter of the Blood.

The colouring matter of the blood has an attraction to water and dissolves in it, forming a transparent red liquor. This attraction is perceived in macerating flesh in water; for the colouring part, which is specifically heavier than any other part of the blood, and readily sinks in the serum, yet rises up and becomes dissolved in the water. The watery solution of this part of the blood turns the syrup of violets green, and contains both soda and albumen. If the red

part of the blood be incinerated by fire, it is found to contain much iron, which Fourcroy and Vauquelin discovered was combined with phosphoric acid in the state of subphosphate of iron; and this is the only part of the blood which is found in analysis to contain any of that metal. Fourcroy examined the blood of the fetus, and found that the colouring matter was darker and more abundant than in the adult subject. He also found that the blood of the fetus contained no fibrine, but much more gelatine than in the adult.

The colouring matter of the blood is found, by examination with the microscope, to be composed of very minute globular particles. They were particularly attended to by Leeuwenhoeck, and afterwards examined and described by others, chiefly by Senac, Hewson, and Fontana. They are so small as scarcely to admit of an accurate examination in this climate by the common microscope. This assertion will probably be readily admitted, if it be granted that they do not exceed a 200,000th part of an inch in diameter; yet such dimensions may be stated as the average estimate of their size, drawn from the accounts of various observers. Haller says, that he saw them as large as peas by the solar microscope, and it was by the aid of that instrument that we are enabled to give the following account of them. A drop of blood, much diluted with water, was put upon a micrometer or piece of glass, ruled by a diamond in squares of $\frac{1}{32}$ th of an inch, and put before the lens of the solar microscope. The squares were magnified upon the screen to eight inches diameter. The globules of the blood were seen undulating to and fro in vast numbers; they all appeared exactly of the same size; and a few which were separated from the rest were attentively examined. These had all the appearance of globules; they were circular in their disk, and were regularly illumined on one side, and shaded on the other, with the prismatic colours arranged in the middle or greatest convexity; the violet being next to the light, and the red next to the shade. On varying the focal distance of the lens, indeed, an alteration of appearance took place, some shading appeared in the middle just in the manner represented by Fontana. Upon again varying the position of the lens, the globules appeared as at first. This shadowy appearance, in the middle probably led Mr. Hewson to suppose that they contained a central solid particle. It is, however, generally admitted, that the colouring particles of the blood are spherical; and if their size be calculated from the preceding account, they will be found to be less in diameter than the 200,000th part of an inch.

If, for instance, the square of $\frac{1}{32}$ th of an inch be magnified to a square of eight inches, and the globules appear $\frac{1}{32}$ th of an inch in diameter, then 64 may be placed in a line on one side of the square, and $64 \times 64 = 4096$, is the number that will stand within that surface. Now, this square is but $\frac{1}{32}$ th of an inch, magnified on the screen to a square of 8 inches; then, multiply 4096 by 50, and it gives 204,800, as the number of these globules which would stand in the square of one inch.

The preceding account of the blood imperfect as it is, yet affords us much satisfactory information. We perceive that there are contained in the blood, in a state of subtle fluidity, the materials of which the body is constructed, and which are capable of becoming solid fibres of various degrees of solubility. We find in it also that aqueous liquor which fills all the interstices of the solid parts. It is true, that we find in the animal body many substances which do not exist formally in the blood, and which are new compounds of matter made out of that fluid; and for an account of which the reader is referred to glandular secretion.

With respect to that change which the animal matter undergoes from a fluid to a solid state, and which is called coagulation, but little is satisfactorily known. It seems to have been a problem amongst chemists. Scheele attributed it to the agency of caloric; Fourcroy, to that of oxygen; and Dr. Thomson has of late accounted for it, without supposing the addition of any other substance to the coagulated matter. With reference to the last opinion, it should be observed, that in coagulation, a change in the chemical properties of the coagulated substance takes place, which implies, that a chemical alteration has also taken place; and that even if the theory were true with respect to albumen, it will not account for the coagulation of the fibrine of the blood. Where chemistry fails to explain phenomena incident to living bodies, it is fair to inquire if life may not have some share in their production.

Mr. Hunter thought that the coagulation of the blood depended on its living powers, and supported his opinion by many ingenious arguments. To remove any objection which might be made to a fluid or unorganized substance being alive, he adverts to what happens with respect to the yolk and white of the egg, which, in consequence apparently of their possessing a principle of life, are preserved from putrefaction during incubation, and which resist the effects of heat and cold in a degree and manner similar to the lower kinds of animals. His chief arguments in evidence of the coagulation of the blood depending upon life are, that in some cases where death has been caused by lightning, or by violent fatigue in running, as in animals who are hunted to death, or by blows on the stomach, the irritability of the muscles has been destroyed, and the blood has remained fluid, and never coagulated. Mr. Hunter also mentions, that he mixed infusions of bitter vegetables, which are generally considered as tonics, with blood, and these did not retard its coagulation, but that a solution of opium had that effect. As a prosecution of this hint, the writer of the present article caused blood to be much diluted with water, and infusions of noxious vegetables to be stirred into it; yet in these experiments the fibrine still coagulated, and that in a sudden manner.

The vegetable infusions were those of opium, tobacco, and the atropa belladonna. It may be proper to relate the particulars of one of these experiments, in order to give a general idea of the whole. Eight ounces of blood were drawn from the arm into ten pints of water of 95° of Fahrenheit's thermometer, containing a strong infusion of the atropa belladonna. It was stirred with a glass rod; the two fluids appeared transparent and homogeneous. In eight minutes, the temperature being 93°, a considerable quantity of flocculent coagulum at once suddenly formed, and no additional coagulation afterwards took place. The thermometer was attentively observed, but no change was remarked in it during this coagulation. The gentleman who performed these experiments, wishing to repeat them with some variety in the mode of conducting them, observed, however, that heat was given out during the coagulation of the blood, as will be seen in the following experiment.

Ten ounces of blood were drawn into a wooden bowl, in which a thermometer was held. The temperature of the blood, while flowing from the vein, was 93°. In six minutes the thermometer had sunk to 89°, and coagulation commenced on the surface; on elevating the bulb of the thermometer to the coagulum on the surface, the quicksilver rose to 90 and $\frac{1}{2}$; on depressing it to the bottom of the bowl, it sunk to 89. This was repeated twice with nearly the same result, and on the third trial the quicksilver rose to 91°; and on depressing it again, it was perceived that the blood was coagulated

coagulated throughout. After this, the quicksilver regularly continued to descend, and was no longer influenced by changing the situation of the bulb of the thermometer.

With respect to the use of the red particles, Boerhaave supposed, that they might tend to keep the dissimilar parts of the blood incorporated, as shot agitated in a mixture of sand and water would prevent the subsidence of the former from the latter. It seems, however, no improbable opinion, that this is the matter which has the very peculiar properties of forcibly attracting oxygen gas, even through the medium of the blood vessels, and combining with it, and becoming in consequence of a scarlet colour, yet, of holding it so loosely as to part with it in the round of the circulation to carbon and probably to hydrogen, and thus contributing to the production of animal heat. The writer of the present article is of this opinion, because he has exposed the red parts of the blood to air containing oxygen gas, and always found the oxygen gas diminished in proportion to the quantity of blood which had acquired a scarlet colour by exposure to it. On the contrary, he has exposed the serum of the blood to similar kinds of air, and never perceived any abstraction of oxygen gas by that fluid. Thus probably we discover the principles of nutrition of the body and the cause of its heat. For a further account of the effects of respiration on the blood and its consequences, see LUNGS, *function of*.

Haller's elements of physiology may be consulted for an account of all that had been done respecting the investigation of the nature of the blood till his time; the works of Mr. Hewson and Mr. Hunter may be referred to for additional information on this subject; the works of Fontana, for microscopical observations; and for novel chemical experiments, the writings of Fourcroy, Vauquelin, &c. in the *Annales de Chimie*, and those of Deyeux and Parmentier in the *Journal de Physique*, and Dr. Thomson's excellent summary contained in his *System of Chemistry*.

BLOOD, *transfusion of*. See TRANSFUSION.

BLOOD, *injecting liquors into it*. See INJECTION.

BLOOD, *spitting of*. See HEMOPTYSIS.

BLOOD, *cooling of*. Lord Bacon has suggested that the prosecution of experiments on this subject might possibly lead to the means of prolonging life. But this great philosopher appears to have entertained erroneous notions respecting the animal economy, on this and some other points. Nothing accurate was known, in those days, on the subject of animal heat. If the blood were cooled below a certain standard, disease and death, and not longevity, would be the consequence. However, when the quantity of animal heat exceeds what is natural, the excess is carried off by an increased evaporation from the surface of the body, in other words, by perspiration. And in this way, or by the direct application of water of a low temperature to the skin, the blood, as well as every other part of the body, may be said to be cooled, and disease prevented or removed. But this is not what Lord Bacon meant in his proposal for cooling the blood.

BLOOD, *Depuration of*. See SECRETION.

BLOOD, *Flux of*, is called an HÆMORRHAGE. The periodical ones of women, MENSES. Those after child-birth, LOCHIA. That ordinarily happening on the first coition is by some called and considered as the test of virginity.

BLOOD, *staunching of*. See STYPTIC.

BLOOD, *vomiting of*. See HEMATEMESIS.

BLOOD, *Circulation of the*. See CIRCULATION.

BLOOD, *morbid alterations of*. The alterations which the blood undergoes in various diseases are such as claim the attentive observation of physicians. But, in order to form

a just conception of them, it is necessary previously to consider what are the component parts of this vital fluid, and their relative proportions, in the natural and healthy state.

By the accurate analyses of modern chemists it has been proved, that, besides water, and various saline matters (such as soda, phosphates of lime, of soda, and of ammonia, and muriates of soda and ammonia), the blood consists of what is termed fibrin, albumen (coagulable lymph), and a colouring principle, viz. oxyd of iron combined with phosphoric acid. These several materials constitute the fluid called blood, which, in its natural state, is kept in constant motion, under a temperature of 98° or 100° (in some animals the temperature is rather higher) of Fahrenheit's thermometer. A large proportion of fibrin, some albumen, and the colouring matter, constitute the cruor, or crassamentum; while the serum is composed of water, with a large proportion of albumen, and the saline substances above mentioned.

Now, it is probable, that considerable alterations take place in the relative proportions of these ingredients, whenever the living body, whether of man or brute, becomes long or violently disturbed in its action, and especially (as Mr. Hewson has shewn) whenever the energy of the vascular action is much increased. But in accounting for any remarkable alterations in the blood, there are several other circumstances, besides that of vascular action, which require to be noticed; and particularly the circumstances connected with respiration, such as the temperature, and purity or impurity of the surrounding air, its greater or less degree of humidity, &c. These, by their chemical agency, must have a considerable influence in the production of the various morbid alterations which take place.

Many variations, however, in regard to the relative proportion of the constituent parts of the blood, and other chemical changes in its qualities, which in all probability frequently take place, are not obvious to the senses, in some diseases, whilst in others they are very conspicuous: for instance, in pleurisy, peripneumony, acute rheumatism, &c. In these disorders, the blood drawn from the veins, and suffered to stand in the cup until it is cold, becomes covered with a tough buff-coloured coat, or size, and is usually called *inflamed*, or *inflammatory blood*. This size is formed (says Mr. Hewson) by the coagulable lymph (which consists of albumen and a portion of fibrin) being fixed or coagulated, after the red particles have subsided. The blood in these cases does not appear to be thicker, but on the contrary thinner than natural. It is slower in coagulating than healthy blood. The coagulation is owing to the action of the air. Perhaps in pleurisy, acute rheumatism, and other disorders belonging to the phlegmatic of notological writers, some chemical change is produced in the fibrous matter of the blood (see Fourcroy, *Connoissances Chimiques*, article *Sang*), whereby it is preternaturally softened or liquefied; or there may be an over-proportion of albumen, and that of an altered quality. Whatever be the real chemical difference, we cannot think with Mr. Hewson, that it is wholly occasioned by the increased force or energy of vascular action, since it sometimes occurs in cases where the action of the heart and arteries is not more vigorous than natural, and even where their action appears to be below the natural standard. Thus a size has been sometimes observed upon the blood drawn from patients affected with typhus (Parmentier and Deyeux in Fourcroy, as above referred to), and even on the blood taken from scorbutic patients. (Ibid.) And Mr. Hewson himself remarks, that it is a common occurrence in pregnant women. Increased energy of vascular action is doubtless a principal cause of the changes observ-

B L O O D.

able in fizy blood; but much is also to be ascribed, in this business, to the circumstances connected with respiration as before mentioned.

This fizy blood being so constantly seen in pleurisy, peripneumony, acute rheumatism, and other inflammatory diseases, it has been considered as a proof of the existence of inflammatory action in all other cases, wherein it has been observed; and has accordingly been deemed by many practitioners the best and surest test or index when venesection should be repeated or withheld, as also concerning the quantity of blood which should be drawn at each operation. But this is a very wrong mode of proceeding. We have shewn that this appearance (the size or buffy coat of the blood) is not restricted to disorders belonging to the class of phlegmasie, but that it occurs in other instances, where the free and frequent employment of phlebotomy would be useless, or even pernicious. Indeed, we have often found it necessary to repeat the use of the lancet, where this appearance of the blood has been wanting; and to abstain from a repetition of it, where it has been present. In regulating, therefore, the abstraction of blood, it is necessary to attend not only to the appearances of the blood, but more especially to the kind of inflammatory action, to the state of the pulse and respiration, to the degree and seat of the pain, and to the age and constitution of the patient. Further, the term inflammatory blood, as being liable to misconception and abuse, should be discontinued; and the expression *fizy blood*, or *blood with a buffy coat*, should be employed in its place. But if the term *inflamed blood* be improper, that of *putrid blood* is much more so. This was never yet drawn from any living animal, man or brute. Putridity is easily known. The smell affords an obvious test; but the chemical products obtained from animal substances in a state of putrefaction, are the surest tests. Yet those expert chemists, Messrs. Parmentier and Deyeux, could trace no marks of putridity in the blood taken from patients labouring under the worst forms of typhus, or what are commonly called putrid fevers. Such blood did not yield, by distillation in a water bath, any volatile alkali; nor in a moderate temperature did it run into putrefaction sooner than the blood of a healthy person. The blood in these cases, however, has its peculiar appearances; which, until we arrive at something more certain in regard to the cause thereof, we should be content to call *typhus-fever blood*. In like manner, the dark-coloured blood of scorbutic patients (which some ascribe to a deficiency of oxygen, and we would add of albumen also,) we should be content to call *scorbutic blood*, until we have better data to proceed upon. Again, it is conjectured that the pale colour and dilute quality of the blood, in chlorotic and dropical patients, may be owing to a deficiency of the colouring matter (iron) of the blood, as well as an under-proportion of the fibrous and albuminous matter. But we know not of any experiments by which this has been demonstrated. Hence we must for the present be content to name such blood *chlorotic* and *hydroptic blood*; taking care at the same time to have it understood, that in using these terms, it is by no means intended to convey the idea, that such a state of the blood is the cause of chlorosis or dropsy, but merely the concomitant of those disorders. Whoever wishes to investigate the subject of the morbid appearances of the blood more fully, should consult the writings of Hewson and John Hunter; and for what relates to the chemical part of the inquiry, Fourcroy.

BLOOD, *Uses of the*, are either in the animal œconomy (see BLOOD *Supra*, and LUNGS,) or in medicine, religion, diet, arts, manufactures, &c.

BLOOD, *mechanical and commercial uses of the*, are chiefly in agriculture, where it is found an excellent manure for fruit-trees; among lapidaries; in the manufacture of sugar, &c.; in building, boards are sometimes rubbed with blood to turn them brown. Some also pretend it has anciently been used in the mortar of old walls. Blood is the basis of that noble colour called by painters *Prussian Blue*. See PRUSSIC ACID.

BLOOD, *eating of*. This practice appears to have been prohibited to Noah (Gen. ix. 3, 4), which prohibition was renewed by Moses (Lev. xvii. 10—14.), and observed by the Jews, principally with a view to the use of sacrifices in divine worship, and as a token of respect to the altar, at which the blood of every victim was presented before God. The prohibition was repeated by the apostles at the council of Jerusalem (Acts, xv. 28, 29.), confirmed and defended by all the fathers except St. Augustin, and the universal practice both of the eastern and western churches till his time; and in many churches, even of the West, much longer, as low as the middle of the 10th, some say the 11th and even the 12th century. The practice of the primitive Christians seems to intimate that they understood the apostolical prohibition to be absolute and perpetual, as they abstained from the use of blood for many centuries. When they were charged with meeting in the night, and drinking blood, by way of binding one another to secrecy, in some immoral practices, Tertullian replies to this charge, that it was well known that no Christian would eat blood at all; inasmuch, that it was usual with heathens, when they wanted to know whether any person was a Christian, to set blood-puddings before him as a very sufficient test. Moreover, blood is not eaten by Christians in any part of the East, or by the Greeks, or Russians, who are of the Greek church, to this day; and it has been alleged, that the use of blood was not introduced into this western part of the world till a very late period. When the Pomeranians were converted to Christianity, in 1120, they were particularly enjoined to abstain from blood, as a badge of their profession. It was not allowed to be eaten in the West in the time of Bede, or a century afterwards; and blood was not eaten in any part of Swisserland, till Calvin introduced the practice from some other place. Dr. Lardner, however, says (*ubi infra*), that little regard was paid to these regulations of the apostolical decree by the Latin Christians, from the end of the fourth century.

The question is, whether the apostolical precept to abstain from blood, should be considered as only temporary and occasional, a sort of accommodation to the weakness of the Jewish converts; or perpetual, founded on moral principles, and consequently still obligatory. The former opinion seems the more probable, and is the most generally received. For the prohibition in the law of Moses, two reasons have been assigned; one is, that the blood was appointed to make atonement on the altar for offence against the law. The prohibition, according to this reason of it, must be restricted to Jews and others circumcised after the manner of Moses; for no other persons could offer sacrifices, or be cut off for transgressing the Levitical laws, but such as were of that people. The other reason is thus expressed: "It is the life of all flesh; the blood of it is for the life thereof." (Lev. xvii. 14.); that is, as some have interpreted the passage, it is the nourishment of the animal, and not fit for your nourishment; and because it was not fit for food, and was useless and offensive, therefore it was to be poured out upon the earth, or covered with dust, that is, buried in the earth; and this order is frequently repeated. Lev. xvii. 13. Deut. xii. 16. 24. xv. 23. Hence we may account for the conduct

duct of David, when his three warriors brought him water from the well of Bethlehem, at the extreme hazard of their lives (1 Chron. xi. 18.); considering the water as if it were their blood, which they hazarded to obtain it, he refused to drink it; and there being no rule or reason for offering such water upon the altar, he did what seemed to be next to offering it; "he poured it out before the Lord." The Jewish ordinance answered two obvious ends; it served, with other regulations and restrictions, to keep the Jewish people separate from other nations; and it also promoted their bodily health and vigour. But there is no foundation, either in the reason of the thing, or in the prohibition, to support the opinion of those who imagine the eating of blood to be an immoral thing; if this had been the case, God would not have permitted the Israelites (Deut. xiv. 21.) to tell a creature that died in his blood to an alien or stranger, that he might eat it. If, therefore, the eating of blood cannot be reckoned an immorality, the prohibition in the apostolical decree cannot be binding upon all men in all times, but only at some seasons, when the circumstances of things render forbearance or abstinence expedient. Accordingly, if blood be thought disagreeable and unwholesome, as food, the use of it may be avoided for the sake of health; but we are not obliged to abstain from it upon a religious account, or in virtue of this decree, which would be no better than superstition. It has been supposed, by some approved writers, and especially by Dr. Lardner, that this was only a temporary provision, designed to prevent giving offence to the believing Jews, and to facilitate civil converse and religious communion between believing Jews and Gentiles. Dr. Lardner also supposes that the decree is not to be understood as a precept or commandment, but as delivering advice and counsel concerning some matters of prudence and expedience, considering the circumstances of things and persons in that time. It has been farther urged as an argument against the perpetuity of the apostolical decree, that the apostle Paul never quotes, or alludes to it in his writings.

On the other hand it has been argued, that the prohibition to eat blood, given to Noah, seems to be obligatory on all his posterity: and as it accompanied the first express grant of animal food, it seems to be reserved, by way of acknowledgment to God, as the giver of life, and of the food which supports it. This respect paid to blood, which is shed when animals are killed for food, and which is the most apparent vehicle of life, may also be intended to inculcate a respect for life, as the most valuable gift of God, and to warn us not to deprive any animal of it, and much less man, without necessity. It has also been pleaded, as an additional argument for abstaining from blood, that it is not a wholesome aliment, especially in hot countries, promoting leprous and scorbutic disorders. The advocates of this opinion farther argue, that blood is prohibited because it tends to make men savage; that the prohibition is joined with that of fornication, which is an immorality in the common sense of the term, but which Dr. Lardner understands as denoting marriage with heathens, from which the apostle Paul so earnestly dissuades the Christians at Corinth: and that God has enjoined abstinence from blood on all Christians, in order to manifest his supreme dominion over all their enjoyments. Helden, de Jure Gentium, &c. l. vii. c. 1. Shuckford's Conn. vol. i. p. 93, &c. Lardner's Remarks on Dr. Ward's Dissertations in works, vol. xi. p. 329, &c. Priestley's Institutes, vol. ii. p. 439, &c.

Blood, *religious uses of*. Among the ancients, blood was used for the sealing and ratifying of covenants and alliances, which was done by the contracting parties drinking

a little of each other's blood; for appeasing the manes of the dead, in order to which blood was offered on their tombs, as part of the funeral ceremony. Thus we read, that twelve youths were sacrificed at the funeral of Patroclus: and eight at that of Pallas. Homer. Il. φ. ver. 27. Virgil. Æn. lib. x. ver. 518.

The blood of victims was the portion of the gods, both among Jews and Heathens; and accordingly was poured or sprinkled on the altars, in oblation to them.

Some have asserted, that the Romans offered human blood to appease their deities, which is denied by others.

The priests made another use of blood, viz. for divination: the streaming of blood from the earth, fire, and the like was held a prodigy, or omen of evil.

The Roman priests were not unacquainted with the use of blood in miracles; they had their fluxes of blood from images, ready to serve a turn; witness that said to have streamed from the statue of Minerva at Modena, before the battle at that place. But in this their successors have gone beyond them. How many relations in ecclesiastical writers of Madonas, crucifixes, and wafers bleeding! At least the liquefaction of the blood of St. Januarius, at Naples, repeated annually for so many ages, seems to transcend by far all the frauds of the Grecian or Roman priesthood. But the chemists are got into the secret, and we find M. Neumann at Berlin performed the miracle of the liquefaction of dried blood, with all the circumstances of the Neapolitan experiment. See JANUARIUS.

BLOOD, in the *Romish Church*, is used in speaking of the wine in the eucharist; which they suppose miraculously converted, by the priest's consecration, into the real blood of Christ. See TRANSUBSTANTIATION, &c.

BLOOD, is also used abusively for the sap of plants; as having much the same office, in the vegetable, as the other in the animal œconomy. In a sense not unlike this, wine is sometimes also denominated the *blood of the grape*.

BLOOD is also applied, in *Pharmacy*, to certain vegetable juices, tears, &c. as dragon's blood gum. Dragon's blood, *sanguis draconis*, is also used by the Arabs for the juice of the anchusa.

BLOOD, *satyrion*, a ruddy liquor produced from the roots of *satyrium*, baked with bread; and liquefied, as it were, into blood, by a long digestion.

BLOOD, in *Chemistry* and *Alchemy*, is a denomination given to several artificial compositions, chiefly on account of their red colour.

BLOOD is more peculiarly used by the alchemists for the tincture of a thing. In which sense we meet with *blood of mercury*, denoting the tincture of it; dragon's blood, denoting the tincture of antimony.

BLOOD, *Dragon's*. See DRAGON'S BLOOD.

BLOOD is also used, in *Middle Age Writers*, for supreme jurisdiction, exercised by the lord of the fee, in cases where blood is spilt. This is also called "judgment of blood," "justice of blood," sometimes "cognizance of blood."

BLOOD, *avenger of*, among the Jews, was the next of kin to the person murdered, who was to prosecute the murderer. Ecclesiastical judges retire when judgment is to be given in cases of blood, because the church is supposed to abhor blood: it condemns no person to death; and its members become irregular, or disabled from their functions, by the effusion of blood.

BLOOD of *Christ*, is the denomination of a military order instituted at Mantua, in 1698, by Vinc. Gonzangua IV. Its device was "Domine probasti me;" or, "Nilhil hoc triste recepto." Herment speaks of this order, and observes that it took its name from some drops of the blood of Christ

said to have been preserved in the cathedral church of Mantua. The number of knights was restrained to twenty, besides the grand-master; the office whereof was annexed to himself and his successors.

BLOOD, in *Farricry*, denotes a distemper in cattle's backs, which makes them in going draw their heads aside, or after them; the cure is by slitting the length of two joints under the tail, and thus letting the beast bleed plentifully. If he bleed too much, the farriers knit his tail next the body, and then bind salt and nettles bruised on the part.

BLOOD-running itch, is a species of itch in a horse, proceeding from an inflammation of the blood by over-heating, hard riding, or other fore labour; which getting between the skin and flesh, makes the beast rub and bite himself; and if let alone, sometimes turns to a grievous mange, highly infectious to all nigh him.

BLOOD, field of, in Syriac *aceldama*, was a field purchased by the Jews, with the thirty pieces of silver which had been given to Judas for betraying his master, and which he had restored. It still serves for a burial-ground, in which all pilgrims, who die in their pilgrimage at Jerusalem, are interred. See *ACELDAMA*.

BLOOD-flower, in *Botany*. See *HÆMANTHUS*.

BLOOD-hound. See *HOUND*.

BLOOD-letting. See *BLEEDING*.

BLOOD, precious, in *Ecclesiastical History*, a denomination given to a reformed congregation of Bernardine nuns at Paris, first established under that name in 1661.

BLOOD, Princes of the, in France, are those descended from the blood royal.

BLOOD-spotten, in *Surgery*, a distemper of the eyes, wherein the blood-vessels are greatly distended, so as to make the eyes appear red. See *OPHTHALMIA*.

BLOOD-stone. See *HÆMATITES*.

BLOOD of sulphur, *sanguis sulphuris*, is a preparation of liver of sulphur, ground with the oil of tartar *per deliquium*, then digested with dulcified spirit of nitre. It is reputed a good pectoral and diuretic, but rarely prescribed.

BLOOD-vessels, in *Anatomy*, usually include only the veins and arteries; though, in a larger sense, all the vessels in the body, as the nerves, lymphatics, &c. to the very hair, may be comprehended under the denomination. See *ARTERY*, and *VEIN*.

BLOOD-snake. See *Blood-SNAKE*.

BLOOD-wite, in *Ancient Law Writers*, signifies blood, and a customary amercement paid as a composition for the shedding or drawing of blood.

The word is also written *blodwite*, *blodwita*, *blodwyta*, *blodwüt*, *blodwüt*, *bloudwüt*, and *bluidweit*; and is formed from the ancient Saxon *blud*, *blood*, and *wite*, or *wite*, a *fine* or *penalty*.

The word also denotes an exemption from this penalty, granted by the king to certain persons and communities, as a special favour. Thus, king Henry II. granted to all tenants within the honour of Wallingford—"Ut quieti sint de hidagio et blodwite et bredwite."

BLOOD-wood. See *HÆMATOXYLON*.

BLOOD-wort or *Bloody Dock*, in *Botany*. See *RUMEX*.

BLOOD, Corruption of, in *Law*. See *CORRUPTION of Blood*.

BLOOD, inheritable, denotes such a regular descent as gives a person legal right to inherit the estate of an ancestor. See *ATTAINDER*, *ESCHEAT*, *INHERITANCE*, &c.

BLOOD, Restitution in. See *CORRUPTION of blood*, and *PARDON*.

BLOOD, Royal, is applied to the regular descendants of the royal family. See *ROYAL Family*.

BLOOD, whole and half; a kinsman of the whole blood

is he that is derived from the same pair of ancestors; whereas a person of half blood descends from either of them singly, by a second marriage. Blackst. Com. vol. ii. p. 227. See *DESCENT*.

BLOODY CRIME, *Sanguineum Crimen*, in *Writers of the Middle and Barbarous Age*, that which is punished with the blood or life of the offender.

BLOODY Flux, in *Medicine*. See *DYSENTERY*.

BLOODY Hand, in *Law*, one of the four kinds of trespasses in the king's forest, by which the offender being taken with his hands or other part bloody, is judged to have killed the deer, though he be not found either hunting or chasing. In Scotland, in such crimes, they say, taken in the fact, or with the red hand. See *BACKBEROND*.

BLOODY-beel Cock. See *HEELER*.

BLOODY Island, in *Geography*, an island in the harbour of Port Mahon, in the island of Minorca.

BLOODY Point, a cape on the south-west coast of the island of St. Christopher's. N. lat. 17° 24'. W. long. 62° 41'.

BLOODY Bay, a bay on the north side of the island of Egnont, or New Guernsey.

BLOODY-Farland Point, a remarkable head-land on the northern coast of the county of Donegal, Ireland, nearly opposite to Tory island. N. lat. 55° 9' 30". W. long. 8° 11'. M^cKenzie. Beaufort.

BLOODY Rains. See *RAIN*.

BLOODY Sweat. Many instances of this are recorded, in which it has been owing to bodily disorder, or extreme mental agitation and agony. See particularly Aristotle's Hist. Animal. lib. iii. cap. 19. apud Oper. tom. ii. Thuanus Hist. Temp. &c. lib. ii. apud Oper. tom. i. Melanges d'Histoire et de Literature, &c. par M. V. Marville, tom. iii. p. 149. Acta Physico-Med. Norimbergæ, vol. i. p. 84. and vol. viii. p. 428. See *AGONY*.

BLOODY Urine, in *Medicine*. See *HÆMATURIA*, and *URINE*.

BLOOM, in the *Iron works*, a term used by the miners for a four-square mass of hammered iron, about two feet long, and three quarters of a hundred weight, made from part of a sow of cast iron. The bloom, however, is not yet become iron fit for the smith's use, but must undergo many hammerings, and be first made what they call the *ancony*; which see.

BLOOM, half, a round mass of metal, which comes out of the fiery of an *iron work*. See *BLOMERY*.

BLOOMS, in *Sea Language*, hot burning winds, blowing from the land to the sea.

BLOOMFIELD, in *Geography*, a township of America, in Ontario county, New York. By the state census of 1726, 151 of the inhabitants were electors.

BLOOMING VALE, a tract of land, in the township of Manlius, and state of New York, or Butternut creek.

BLOSSOM, in a general sense, denotes the flower of any plant. See *FLOWER*. In a more proper sense, the word is restrained to the flowers of trees, which they put forth in the spring, as the forerunners of their fruit, otherwise called their *bloom*. The office of the blossom is partly to protect, and partly to draw nourishment to the embryo fruit, or seed. Phil. Trans. N° 399. p. 329.

BLOSSOM, in *Botany*, denotes one of the parts of a flower. See *COROLLA*.

BLOSSOM is also used in the *Manège*, for the colour of a horse, which has his hair white, but intermixed all over with sorrel and bay hairs, called also *peach-coloured*.

Horses of this colour generally are hard and insensible, both in the mouth and the flank; so that they are little valued; besides they are apt to turn blind.

BLOSSOM, in respect of sheep. See *BLISSOM*.

BLOT L'ÉGLISE, or *Blot à Roche*, in *Geography*, a town of France, in the department of the Allier, 10 miles W. of Gannat.

BLOTTED China Ware, a name given by some to a sort of china that is loaded with colours in an irregular manner. This pleases some people, but it is a defective sort of ware, the large blotches of colours having been only laid on to cover the blemishes or faults in the first baking.

BLOTNO, in *Geography*, a town of Lithuania, in the palatinate of Wilna, on the river Rawie, 16 miles N. of Lida. N. lat. 54° 5'. E. long. 25° 34'.

BLOTTING PAPER, a species of paper, made without size or stiffening, serving to imbibe the wet ink in books of account, and prevent its setting off, or blotting the opposite page.

BLOTTING-book, a sort of minute book, or memorandum book, used by some merchants for making imperfect entries in a present hurry, which are to be copied out fairer and fuller at sight into the journal.

BLOUNT, THOMAS, in *Biography*, a learned English writer, was born at Bordesley, in Worcestershire, in 1619; and, without the advantage of an university education, made a considerable progress in literature. By profession he was a barrister of the Inner Temple. Upon the breaking out of the popish plot in the reign of Charles II., he was much alarmed on account of his being a zealous Roman Catholic, and seized with a palsy, which terminated in his death, in 1679. His works were numerous, and are as follow: viz. "The Academy of Eloquence;" "Glossographica, or a dictionary interpreting such hard words, Hebrew, Greek, Latin, Italian, &c. introduced into the English tongue," 1656, 8vo; "The Lamps of the Law, and the Light of the Gospel, &c.;" "Boscobel, or the History of his Majesty's Escape after the battle of Worcester," 1660, 8vo; the second part was printed in 1681, 8vo; "The Catholic Almanac for 1661, 62, 63, &c.;" "Booker refuted," or Animadversions on Bocker's Ephemeris, 1665, 4to.; "A Law Dictionary," 1671, fol.; "Animadversions upon sir Richard Baker's Chronicle, &c." 1672, 8vo; "A World of Errors discovered in the New World of Words, &c." 1673, fol.; "Fragmenta Antiquitatis, ancient tenures of lands, &c." 1679. Biog. Dict.

BLOUNT, SIR HENRY, was born at the seat of his father sir Thomas Pope Blount, at Tittenhanger, in Hertfordshire, in 1602; and having completed his education at Trinity college, Oxford, he commenced the study of the law at Gray's Inn. Being resolved to travel, he set out on his tour in 1634, and visited the Turkish dominions in Europe, and also several parts of Egypt. After a long stay at Grand Cairo, he returned to England, in 1636, and published an account of his travels under the title of "A Voyage into the Levant, &c." Lond. 1636, 4to. which had a rapid sale, though it was not held in high estimation by the most competent judges. Charles I. appointed him one of the band of pensioners; and, on his father's death, in 1638, he succeeded to the family seat at Blount's hall in Staffordshire, and a considerable estate. In the civil war he joined the royal party; but abandoning the royal cause, he was well received in London by persons in power. In 1651, he became one of the committee for reforming the practice of the law; and he was very zealous against tythes, and for the reduction of the stipends of all parish ministers to an equal and moderate provision. His general knowledge recommended him to the office of one of the commissioners for advancing the trade and navigation of the commonwealth. His brother's death, in 1654, made way for his succession to the Hertfordshire estate. At the Restoration he was

favourably received by the king; and in 1661 he served the office of high-sheriff for the county of Herts. From this time, till his death in 1682, he lived as a retired English gentleman; but he seems to have acquired from his travels an inclination to freedom of opinion, and to have adopted several singular and paradoxical notions. Six comedies, entitled "Court Comedies" and published under the name of John Lilly, have been ascribed to him. Biog. Brit.

BLOUNT, SIR THOMAS POPE, eldest son of the preceding, was born at Upper Holloway, near London, in 1649, and educated under the immediate inspection of his father. Having established an early reputation for learning and worth, he was created a baronet by Charles II. in 1679. He represented first the borough of St. Alban's, and afterwards the county of Herts, and was always esteemed as a friend of liberty, and a true patron of literature. Of his erudition he gave evidence in his learned work, entitled, "Censura Celebrorum Authorum," printed at London, in 1690, folio, and reprinted at Geneva in 1694 and 1710, 4to. This work is an accurate and useful compilation, containing an account of the characters and writings of both ancient and modern authors. His work "De Re Poetica," published in 1694, 4to. is a similar compilation, comprehending an account of ancient and modern poets. His "Natural History," printed 1693, 12mo. is a kind of common-place book, containing observations, many of which are uncommon, selected from the best modern writers. Of his talents as an original writer, we have a specimen in his "Essays on several subjects," 8vo. in which he discusses many curious points; such as the influence of the priesthood; the regard due to the ancients; the variety of opinions; the uncertainty of human knowledge; the effects of custom and education, &c. He died at Tittenhanger in 1697, and left a numerous family. Biog. Brit.

BLOUNT, CHARLES, brother of the preceding, was born at Upper Holloway in 1654, and possessed distinguished talents, which were assiduously cultivated by his father, who assumed the direction of his studies. As he was the favourite of his father, he encouraged his marrying and settling in an independent estate at the early age of eighteen years. If we except a little treatise, published without his name, and entitled "Mr. Dryden vindicated, &c." his literary career commenced in 1678 or 1679, with the publication of his "Anima Muodi, or an historical narration of the opinions of the ancients concerning man's soul after this life, according to unenlightened nature;" in the composition of which he is said to have been assisted by his father. This work contained free opinions, which gave great offence; and though it had been previously licensed, was suppressed by order of Compton, bishop of London; and during his absence burned by some officious zealot. Several answers to it were written; and it was particularly animadverted upon in the second volume of Nichols's Conference with a Theist. In the same year Mr. Blount published some extracts from Hobbes's Leviathan, in a single sheet, entitled "Mr. Hobbes's last Words and dying Legacy;" and intended to expose, probably, the political principles of this writer. To these, his ardent zeal for liberty rendered him peculiarly adverse; and his zealous attachment to this cause was soon after manifested in a pamphlet, under the signature of "Junius Brutus;" designed to alarm the nation with regard to a popish plot, and the prospect of a popish successor to the crown. In 1680 he published his translation of "the Two First Books of Philostratus, concerning the life of Apollonius Tyanæus, with philological notes on each chapter," fol. which, being considered as a dangerous attempt to reproach and injure the Christian religion, was immediately suppressed, so that

few copies of it could be obtained. This was followed, in the same year, by a work entitled "Great is Diana of the Ephesians, or the Original of Idolatry, together with the political institutions of the Gentiles' Sacrifices;" which, though professedly written against the impositions of the Heathen priests, was thought to be aimed at the Christian priesthood, and indirectly against all revelation. The author was now considered as the head of the Deistical sect, and he is charged with having taken great pains, by conversation and correspondence, to propagate and defend his opinions. In a letter to Dr. Sydenham, however, he acknowledged, that in point of practice, Deism was less satisfactory than the Christian scheme. The clamour occasioned by his former publications made him somewhat more cautious and reserved; and accordingly he studiously concealed his being the author of a treatise, entitled "Religio Laici," published in 1683, and laid, by Dr. Leland, in his Deistical writers, vol. i. p. 37. to be little more than a translation of Lord Herbert's work, under the same title; and he also abandoned the design which he had formed of writing a life of Mahomet. From this time he seems to have changed the objects of his study; for in 1684 he published "Janua Scientiarum; or an Introduction to Geography, Chronology, Government, History, Philosophy, and all genteel sorts of learning;" 8vo. which was intended to assist young persons at an early age in the acquisition of principles of philosophy and science, without pursuing the tedious course that had been usually prescribed to them in schools.

Mr. Blount was one of those who cordially concurred in the revolution; and in a letter addressed to W. Leveson Gower concerning corporations, and inserted in the "Oracles of Reason," he expresses his wish, that those counsellors of the late king, who had injured the independence of parliament, might be punished, justly considering the purity of representation as the essence of a free constitution. About this time he wrote his treatise entitled "A Just Vindication of Learning, and of the Liberty of the Press;" which is esteemed one of his best performances, and a summary of all the principal arguments that can be urged upon this topic. In his zeal for the cause of king William, he wrote a pamphlet in 1693, intended to prove the right of William and Mary to the crown, on the ground of conquest; and in explanation of this design, so dissonant, one would imagine, with his principles, and no less obnoxious than ill-founded, he declares that he wrote "with an especial regard to such as have hitherto refused the oath, and yet allow of the title of conquest, when consequent to a just war." By this performance he gave such offence, that, on a complaint being brought before the house of commons against this pamphlet, entitled "William and queen Mary Conquerors," it was ordered to be burnt by the hands of the common hangman; and in the same censure was involved a pastoral letter of bishop Burnet, in which the same notion was advanced, probably with the same views.

Mr. Blount, having lost his wife, became ardently enamoured of her sister, a lady of great beauty and merit, who seemed disposed to return his affection; but as the ecclesiastical laws opposed their union, he drew up a case strongly argued, and referred it to certain divines, who of course gave their opinions against his wishes. As the lady refused to comply, after such a determination, Mr. Blount sunk into despair, and at length shot himself through the head.

After this act of phrensy, he languished for some days, receiving no nourishment but from the hands of the object of his affection, till at last death released him, August 1693. Many of his private letters and some small tracts were published, together with a preface, by Gildon, in 1693, before the author's death, in a work entitled "The Oracles of

Reason;" which was afterwards re-printed, with some additional pieces, after his decease, in 1695, in a collection of "The Miscellaneous Works of Charles Blount, esq." by the same Mr. Gildon, who prefixed to it an account of the life and death of the author. The learning of Mr. Blount is unquestionable, and he seems to have possessed a strong and ardent mind; but his early dislike of superstition precipitated him into some very considerable errors, and inclined him to believe all revealed religion to be priestcraft, because he perceived that some priests had converted religion to their own secular advantage. His sentiments on the subject of religion were divulged in his writings without disguise, and sufficiently warrant our referring him to the class of deists; but the charge of atheism alledged against him by some foreign divines, is certainly unfounded. See an account of Mr. Blount's writings by Dr. Leland, in the fourth letter of his View of the Deistical Writers, vol. i. By this author we are informed that Mr. Gildon, who published the "Oracles of Reason," and communicated them to the world, was afterwards, upon mature consideration, convinced of his error, and in 1705 published his retractation in a book, entitled "The Deist's Manual." The greatest part of this book is intended to vindicate the doctrines of the existence and attributes of God, his providence and government of the world, the immortality of the soul, and a future state. And his avowed reason was, because many of the deists, with whom he was well acquainted, did really deny those great principles, which lie at the foundation of all religion, or at least, represented them as doubtful and uncertain. And their not admitting natural religion in its just extent, formed some of their principal prejudices against the Christian revelation. Biog. Brit.

BLOUNT, in *Geography*, a new county of the State of Tennessee, in America, bounded southerly by lands retained by the Indians. It contains 5526 inhabitants, of whom 339 are slaves.

BLOUNTSVILLE, a town of America, in North Carolina, on the post-road from Halifax to Plymouth, 49 miles from Plymouth, and 55 from Williamstown.

BLOW, in a general sense, denotes a stroke given either with the hand, a weapon, or instrument. The effect of a blow is estimated like the force of percussion, and accordingly it is expressed by the velocity of the body multiplied by its weight.

In *Fencing*, blows differ from thrusts, as the former are given by striking, the latter by pushing. We say to give, to return, to parry a *blow*. (See PARRYING.) Blows on the sword make a kind of pursuit, called BEATING.

BLOW, *blind*, *idus orbis* or *cæcus*, is that which does not appear, or is not attended with effusion of blood; in contradistinction from that followed by a wound, discolouring, *tumour*, or the like, called *idus apertus* or *apparens*, an open *blow*.

In the ancient laws, we find blows for remembrance, given to make persons remember some transaction, and enable them to become better witnesses of it in future times.

BLOW, *military*, *alapa militaris*, that given with the sword on the neck or shoulder of a candidate for knighthood, in the ceremony of dubbing him. The custom seems to have taken its rise from the ancient ceremony of manumission.

In giving the blow, the prince used this form: "esto bonus miles;" upon which the party rose a complete knight, and qualified to bear arms in his own right. Sometimes a double or even triple blow was given, called *trina percussio*.

BLOW, DR. JOHN, in *Biography*, born at North Collingham, in Nottinghamshire, was one of the first set of children of the chapel royal after the restoration, that was brought up under captain Cook. He likewise received instructions

from Hingeston, domestic organist to Oliver Cromwell, and Dr. Christ. Gibbons. In 1673, he was sworn one of the gentlemen of the chapel; and in 1674, upon the decease of Humphrey, appointed master of the children. In 1685, he was nominated one of the private music to king James II. and in 1687, he was likewise appointed almoner and master of the choristers in the cathedral church of St. Paul: but, in 1693, he resigned this last place in favour of his scholar Jeremiah Clark.

Blow had his degree of doctor of music conferred on him by the special grace of archbishop Sancroft, without performing an exercise for it in either of the Universities. On the decease of Purcell, in 1695, he was elected organist of St. Margaret's, Westminster; and, in 1699, appointed composer to the chapel of their majesties, king William and queen Mary, at a salary of 40*l.* a year, which afterwards was augmented to 73*l.* A second composer, with the like appointment, was added in 1715, when John Weldon was sworn into that office; at which time it was required that each should produce a new anthem on the first Sunday of his month of waiting.

That Blow was a composer of anthems, while a singing-boy in the chapel royal, appears from Clifford's Collection of the Words of the Services and Anthems used in our collegiate and cathedral churches, 1664; for among the ecclesiastical composers mentioned in this book, amounting to upwards of sixty, are included the names of Pelham Humphrey, John Blow, and Robert Smith, children of his majesty's chapel. Humphrey was born in 1647, and Blow in 1648; so that at the restoration, the first being only thirteen, and the second but twelve, their composing anthems fit for the chapel royal, before they had attained the age of sixteen or seventeen, would now be regarded as wonderful proofs of precocity, if Purcell, soon after, at a more early period of his life, had not produced compositions that were still superior to these.

Dr. Blow died in 1708, at sixty years of age: and though he did not arrive at great longevity, yet, by beginning his career, and mounting to the summit of his profession so early, he enjoyed a prosperous and eventful life. His compositions for the church, and his scholars who arrived at eminence, have rendered his name venerable among the musicians of our country.

Though his church music was never collected in a body, yet, besides the three services and ten full and verse anthems printed by Boyce, in Dr. Tudway's MS. collection, nineteen of his choral productions have been preserved; and in Dr. Aldrich's collection in Christ-church there are five more. The aggregate of which, amounting to upwards of forty different compositions of this elaborate kind, is but a small part of what might be found in the chapel and choir-books of our cathedrals.

Some of his choral productions are doubtless in a very bold and grand style; however, he is unequal, and frequently unhappy, in his attempts at new harmony and modulation; but, as a composer who ranked so high among our most classical masters should not be praised or censured indiscriminately, we shall point out a few instances of his great, and to our conceptions, unwarrantable licentiousness, as a counterpart.

We are as sorry to see, as to say, how confused and inaccurate a harmonist he was; but as it is necessary to speak of an artist so celebrated and honoured by his contemporaries, to dissemble his faults would surpass candour, and incur the censure of ignorance and partiality; for it is as much the duty of an historian to blame as to praise, when justice and integrity require it. Indeed, upon whatever subject a man

writes, he should aspire at nothing so much as speaking truth, if he wishes for the approbation of his conscience, which is not only the most comfortable of all praise, but, luckily, the most within his own power. The abilities of the dead, we can have no interest in depreciating; and if our opinion should be unjust, the mischief will recoil on ourselves; for the dead have more friends than the living, who are ever ready to vindicate such wrongs.

Though there are strokes of pathetic and subjects of fugue in Blow's works that are admirable; yet we have examined no one of them that appears to be wholly unexceptionable, and free from confusion and crudities in the counterpoint. Of the two-part anthem with choruses, "Lord how are they increased," the first movement is very plaintive and expressive; but there are licences in the harmony which look and sound quite barbarous. Indeed, these crudities are so numerous as to throw a doubt on his learning, as well as genius. Whether they are notes of passion, effusions of an unruly spirit, or of ignorance and affectation, we will not venture to determine; but to our ears, they have the full effect of jargon and want of principles.

It does not appear that Purcell, whom he did himself the honour to call his scholar, or Crofts, or Clark, his pupils; ever threw notes about at random, in his manner, or insulted the ear with lawless discords, which no concords can render tolerable.

In an anthem, "Turn thee unto me, O Lord," printed by Henry Playford in the second collection of Divine Harmony, there are so many wanton violations of rule, particularly in the last chorus, that it would be endless to point them out; but they seem such as no rule, authority, or effect, can justify; 7ths resolved on the 8th, ascending and descending; 2ds treated with as little ceremony as 3ds. Indeed, we never saw so slovenly a score in print; and it may, in general, be said of his faults in counterpoint, that there are unaccounted millions of them to be found in his works.

He has been celebrated by Dr. Boyce, for "his success in cultivating an uncommon talent for modulation;" but how so excellent a judge of correct and pure harmony could tolerate his licences, or reconcile them to his monumental character, and the additional praise he has himself bestowed upon him, is as unaccountable as any thing in Blow's compositions, considering the knowledge and known probity of the late worthy editor of Cathedral Music.

Many of his ballads, though only in two parts, are full of crude discords unprepared and unresolved; the cause of which, in some measure, may be ascribed to the *ground-bases*, on which it was now the fashion to write: for melody being scarce, both that and the harmony were frequently injured by this Gothic restraint. But the passing-notes and notes of embellishment of the composers, in general, of this period, were uncouth in melody, and licentious in harmony. Perhaps those of the present times, in less than a century, will be equally unpleasing to the ears of posterity; and yet we fancy that both melody and harmony have received their last polish.

The ballads of Dr. Blow are in general more smooth and natural than his other productions, and, indeed, than any other ballads of his time; there is more melody than in those of Henry Lawes, or any composer of the preceding reign; yet it is not of that graceful kind in which the Italians were now advancing towards perfection, with great rapidity. It is either of a Scots cast, or of a languid kind, that excites no other sensation than fatigue and drowsiness.

His pastoral, "Since the Spring comes on," is, however, as *chantant* as any mongrel mixture of Scots, Irish, French, and English, that has been since compiled.

BLOW-PIPE.

piled. The first movement particularly, seems to have been the model of most of the Vauxhall songs of the last fifty years.

"Fill me a bowl," p. 52, has the same kind of merit.

The collecting of his secular compositions into a folio volume in 1700, under the title of "Amphion Anglicus," was doubtless occasioned by the great success of the "Orpheus Britannicus," a similar collection of Purcell's dramatic and miscellaneous songs, published by his widow, in 1698. But whether Dr. Blow was stimulated to this publication by emulation, envy, or the solicitation of his scholars and friends, by whom there are no less than fifteen encomiastic copies of verses prefixed to the work, the ungrateful public seems to have remained always insensible to these strains of the modern *Amphion*, which were not only incapable of building cities, but even of supporting his own tottering fame.

Some of his innumerable deformities from the *Amphion Anglicus* are added to those of his church music, in the third vol. Gen. Hist. Mus. "Go perjured man," is the best of all his secular productions; but that, which was an imitation of a duet by Carissimi, "Dite, O celi," is overloaded in his "Amphion Anglicus," with a laboured and unmeaning accompaniment. P. 44 and 46 of this collection, contain two of his best ballads, "Sabina has a thousand charms," and "Philander do not think of arms." In these ballads the union of Scots melody with the English, is first conspicuous. The subject of a song, p. 168, "Orithæa's bright eyes," is likewise broad Scots.

BLOWS, in *Common Law*. See BATTERY.

BLOWS, *fly*, the ova of flies deposited on flesh, or other bodies proper for hatching them.

BLOW, in the *Sea Language*: when the wind increases from a moderate breeze, it is said to blow; and, according to the various degrees of strength with which the wind blows, it receives different appellations.

BLOW-PIPE, *Tubus ferruminatorius*, Lat.; *Löthrobr*, *Blasferobr*, Germ.; *Chalumeau*, Fr. A blow-pipe is a wind instrument for the purpose of increasing the heat of a candle or lamp, in the same manner as a pair of bellows is employed for raising the temperature of a common fire or furnace. It is not known at what time or by whom this very useful instrument was invented, but it appears to have been employed by glass-workers, enamellers, and jewellers, long before it was adopted as an article of chemical apparatus. The first intimation of its value to the chemist is to be found in Kunkel's treatise on glass-making.

The common glass-blower's lamp is represented in *Plate X. fig. 1.* (*Chemistry*). *A*, is a wooden table, within the frame of which is fixed a pair of double bellows *B*, that are worked by the foot of the artist; from the nozzle of the bellows proceeds a pipe of lead, or tinned iron, *CC*, which, first rising perpendicularly, is then brought under the top of the table to *D*, where it penetrates the wood, and terminates on its upper surface, in a recurved hollow cone *E*, the apex of which is pierced with a minute round hole. A shoe-lamp, *F*, is placed on the table, so that its wick is somewhat below, and about half an inch distant from the aperture of the pipe; the bellows being then worked, a constant stream of air is thrown upon the wick of the lamp, producing a long conical horizontal flame, *G*, of very considerable intensity. The increased heat of the flame appears to depend, in part, on a more rapid and complete combustion of the oil, and in part, also, on the concentration of the flame, by the action of the blast. The flame, upon examination, will be found to consist of an exterior yellow cone, inclosing another of a lighter yellow colour, at the extremity of which last is the focus of greatest heat.

The shoe-lamp (more distinctly represented in *fig. 2.*) is so called from its resemblance to a shoe. It is made of tinned iron, and consists of two parts; the exterior, *a*, serves to hold the proper lamp, and to retain the oil, which occasionally drops from the wick; the lamp, *b*, has a fixed cover, except at the tip, *c*, where a circular aperture is left for the wick *d*, which consists of a bundle of cotton threads, about an inch in diameter; at *e* is a hinge, by which that part of the lid nearest the wick may be raised, in order to pour in fresh oil, or to renew or raise the wick.

The glass-worker's blow-pipe is, however, not sufficiently portable for the use of the chemist and mineralogist, and it was a happy thought of Swab, the Swedish mineralogist, to substitute the lungs for the bellows. Gahn, Engeström, and Bergman suggested various improvements in the construction of this instrument, which now appears to have attained as great a degree of perfection, as it is perhaps capable of.

The common chemical blow-pipe consists of five parts; (*Chemistry, Plate XI. fig. 3.*) the mouth piece, *a*; a plain tube, *b*; a bulb, *c*; a curved tube, *d*; and a nut, *e*.

The mouth-piece (more distinctly represented by *fig. 5.*) is made of ivory, the rest of the apparatus being of brass, and fits closely into the pipe, *b*, so as to be air-tight; the bulb, *c*, is divided into two hemispheres, which screw into each other, and is designed to collect and condense the moisture of the breath; into the lower hemisphere is fixed the recurved tube, *d* (as represented in *fig. 4.*), in such a manner as to prevent the condensed vapour from escaping out of the bulb; the nut, *e*, is a hollow cylinder sufficiently wide at one end to receive the extremity of the curved tube, and perforated at the other with a small round hole, to allow a passage for the air; each blow-pipe has generally three of these nuts (*fig. 6.*), with apertures of different sizes, the largest of which does not exceed the diameter of the smallest pin.

In using the portable blow-pipe, the only difficulty is to keep up a constant stream of air; which is to be done by performing the function of respiration through the nostrils alone, diverting from time to time a portion of the expiration into the mouth for the supply of the blow-pipe, and forcing it through the tube by the action of the muscles of the cheek. This knack is by some acquired in an instant, while others are a long time in making themselves masters of it. To those who experience any difficulty in the free use of this instrument, the following directions may be of service. First, let the learner accustom himself to breathe freely with the mouth shut; then in making an expiration, let him transfer the air into the mouth, till the cheeks are moderately inflated, and retaining it there, let him discharge the surplus of the expiration through the nostrils, and then make two or three easy inspirations and expirations through the nostrils, without allowing the air in the mouth to escape. When practice has rendered this easy, which may be effected in half an hour, let the nut with the smallest aperture be fixed on the curved tube of the blow-pipe, and introduce the mouth-piece within the lips; then inflate the cheeks by an expiration, and continue breathing easily through the nostrils, till nearly the whole of the air has passed out of the mouth through the tube; then renew the air as before, and, after a few days' practice, the muscles of the mouth will be accustomed to this new mode of exertion, and an uniform uninterrupted stream of air may be kept up for half an hour without any extraordinary fatigue. A wax candle, *f*, having burnt long enough to allow the wick to be turned down, in the manner represented in the plate, the nut of the blow-pipe is to be applied to the arch of the wick, and the air, as it comes through, will bend the flame into a neat horizontal cone, the exterior part of which is yellow, and the interior

BLOWING.

ficer under the denomination of *sufflator*, or *fire-blower*. The Roman mint-men were distinguished by the appellation of blowers of gold, silver, and brass, &c. *fiatores auri, argenti*.

BLOWER, among dealers in horses, a term used for such horses as wheeze much, without wanting wind. See **WHEEZING**.

BLOWING, in *Medicine*. One method of administering medicines is by inflation, or blowing them into the part by a tube; thus it is they sometimes convey powders into the eye, and sometimes up the nose, for the cure of a polypus.

BLOWING, *exsufflatio*, was also a ceremony in the ancient administration of baptism, whereby the catechumen, upon rehearing the renunciation, blew three blasts with his mouth, to signify that he rejected or cast the devil absolutely off.

Something like this is still retained in the Russian church. In the sacramentary of St. Gregory, the priest who administers baptism, is enjoined to blow thrice on the child's face, making the sign of the cross with his hand, and pronouncing the words *exi ab eo Satān*. Justin Martyr, Tertullian, St. Cyril, and St. Augustin speak of this ceremony as used in their times.

BLOWING of a *fire arm*, is when the touch-hole is run or gulled, and become wide, so that the powder will flame out.

BLOWING is also used in speaking of the natural motion or course of the wind.

In the *Sea-Language*, the wind is said to *blow home*, or *blow through*, when it does not cease, or grow less, till it comes past the place where the speaker is. To *blow through* is sometimes also used to denote, that the wind will be so great as to blow afunder the sails. When a wind increases so much that they cannot bear any top sails, they say, they were *blown into their courses*, i. e. they could only have out the sails so called. To express an extraordinary great wind, they sometimes say, it will blow the sail out of the bolt-ropes.

BLOWING is also used in speaking of the force and effect of kindled gunpowder on bodies which happen to be over it. In this sense we say to blow up a house. Engineers at sieges make mines wherewith to blow up walls, bastions, and other defences. Powder-mills are apt to blow up by the iron gudgeons growing hot, and setting fire to the powder dust flying about.

BLOWING, among *Gardeners*, denotes the action of flowers whereby they open and display their leaves. In which sense, blowing amounts to much the same with flowering and blossoming.

BLOWING OF **GLASS**, one of the methods of forming the divers kinds of works in the glass manufacture. It is performed by dipping the end of an iron pontoglio, or blow-pipe, in the melted glass, and blowing through it with the mouth, according to the circumstances of the glass to be blown.

BLOWING of *tin*, a term used by the Cornish miners for the fusion or reduction of tin-ore to the metallic state, after having been roasted to get rid of the sulphur and arsenic.

BLOWING *Machine*, is used in metallurgical operations on a great scale, for the purpose of exciting combustion in furnaces appropriated for the smelting and reducing of ores.

The history and improvement of machinery of this nature have kept pace with the other branches of our national manufacture, and, in many instances, may be justly said to have gone beyond them.

In the smelting of lead and tin ores, the size and powers

of the blowing machine have been less a subject of alteration and improvement, than those used at furnaces and works where iron ore is smelted.

The natural fusibility and easy volatilization of the former metals, in temperatures beyond a bright red heat, have prescribed the size of the furnace, the measure of the blast, and the nature of the fuel.

In the manufacture of copper, air-furnaces are generally used, except where precipitated oxyd of copper is revived in small blast-furnaces, resembling those called cupolas, used at iron founderies.

The construction of a lead smelting machine, or what is commonly called a "Lead Mill," is extremely simple. A water wheel is erected in the middle of a square building. To the shaft of this wheel are attached four small wheels of cast iron, about 18 inches diameter. Four pairs of bellows, two pairs on each side of the shaft, are placed at equal distances, and supported upon a strong framing of wood. As the water wheel shaft revolves, the small wheels are carried round, and alternately, or two and two together, depress the extremity of a lever attached by an iron chain to an equipoised beam, the descent of this lever elevates the opposite end of the beam, to which is also attached, by means of another iron chain, the upper or moveable surface of the bellows. The blast produced in this way is in general soft, much inferior in point of either quantity or density to what is found necessary at iron furnaces. The bellows in common measure 10 feet in length, and 5 or 6 feet across the breach, moving about 30 strokes per minute.

In the manufacture of iron it has always been, particularly since the introduction of pit coal, the unceasing object of the iron-maker to improve his blowing apparatus; for uniformly he has found, that in proportion as he can raise air, and make it enter the furnace, so will his weekly quantity of metal be increased.

In the early history of this interesting manufacture, when charcoal of wood was the matter of fuel made use of, the affinities betwixt the latter and the ore were established with more facility. Small furnaces, called bloomeries, were sufficiently large, and deemed of profitable capacity, if they produced a bloom or two of iron per day, of 90 to 120 lbs. each.

Hand bellows, and what were called fuel blasts, were sufficiently large for the minor operations. After the general introduction of the refinery furnaces, and the division of the manufacture into the making of pig iron, and the refining of this into bar or malleable iron, the advantages of a powerful blast were immediately perceived. Water wheels, working two pairs or more of leather bellows, were found to produce powerful effects, and, in consequence, almost every situation that presented a command of materials and a waterfall, became the seat of an iron-mill.

The simple mode of blowing furnaces by means of a trompe, was at the same time introduced; but in general it was found, that much greater advantage could be derived from the descent of water upon a wheel, either as to density or quantity, than by means of the best constructed trompe.

The use of water wheels and leather bellows continued general throughout the iron business, until the principles and mechanism of the steam engine were established upon unerring grounds. This wonderful invention was soon applied with the happiest effect in many situations rich with mineral treasures, but to which nature had denied the advantage of water sufficient to turn machinery. Cylinders, composed of wood, firmly jointed and looped, were first introduced as a substitute for leather bellows: these were soon after replaced by bored cylinders of cast iron; and with

BLOWING.

with this great discovery and application of the art of caitting, the blowing machine assumed a general and well-proportioned form.

This took place nearly 40 years ago, and continued with a few temporary deviations until the introduction of Bolton and Watt's highly improved engine. The following may serve for an outline of the old blowing steam engine.

A steam cylinder, working with atmospheric pressure from 3 to 7 lbs. upon every square inch of the area of the piston. The diameter of the cylinder for one furnace varied from 25 to 36 inches, and for two furnaces from 36 to 50 inches. Upon the opposite of the main or working beam, sometimes at equal, and sometimes at unequal distances from the centre, was placed the air-pump or blowing cylinder. This was, in common, equal to four or five times the area of the former; and, with the small working power of the steam cylinder, seldom condensed the air beyond $1\frac{1}{2}$ to $1\frac{3}{4}$ lbs. per square inch. The air-pump was commonly constructed open below, as may be seen in *Plate II. fig. 1. (Ch. mistry.)* The plan was sometimes deviated from, and the cylinder inverted. The blowing piston was loaded with weights, and the air expressed by its descent. In this mode of working, the act of the steam piston, descending in vacuo raised the air-pump piston loaded with weights. Upon the return of the stroke, or while the steam piston ascended in the cylinder, this piston loaded with weights sunk the whole length of the stroke, and by means of this loading, proportioned to the powers of the engine, forced the air either into the regulator or the furnace.

Above, or parallel to the air-pump, was placed the regulating cylinder, as may be seen in the plate above mentioned. This had a valve of communication, which opened every stroke the engine made, and admitted the whole discharge of air. The piston of the cylinder, frequently called the fly piston, was loaded with weights, and kept constantly vibrating; so that when any deficiency of pressure arose from the remitting action of the air-pump piston, the blast was comparatively equalized by the pressure of the fly piston upon the included air. The size of this cylinder was generally in the proportion of 9 to 6 of the air-pump.

The chief objections to this mode of blowing, even when in universal use, were founded upon the great inequality of the blast, and a very considerable waste of air that took place at the *snort*, or safety valve, to prevent the fly piston being blown entirely out of the cylinder. The snort was an opening made in the top of the air-pump cylinder, on which rested a heavy iron valve, faced with leather stuffed with wool; this was, by means of an upright iron rod, attached to a lever, which run across the top of the regulating cylinder. As soon as the fly piston arose to a certain height, a block of wood, or other contrivance, lifted the one end of the lever, and along with it the valve, to a certain height, and permitted a quantity of the denser air to escape, sufficient to insure the safety of the piston. Notwithstanding these precautions, many accidents and stops ensued; the breaking of a pin, or the loosing of a key, frequently ejected the piston from its cylinder, though loaded with several tons of weight.

Some iron masters, more ingenious than others, contrived to take the spare or waste air from the snort, to receive it in an inverted chest above water, and blow to its extent smithy and fiery fires. Endeavours of this kind to husband and economise air, raised and condensed at a great expence, were sufficient proofs that a method was still wanting to complete the blowing machine, to render its motions steady and uniform, and to equalize the density of the blast throughout the whole stroke.

This was completely accomplished by inverting large chests, or cylinders, in cisterns of wood, stone, or iron. The space betwixt the inner and outer cisterns was constructed of sufficient capacity to oppose to the expansive force of the blast a column of water of equal or superior resistance.

This invention was called the water blast, water pressure, water regulator, &c. The dimensions differed materially from each other; this circumstance being much regulated by convenience, opinion, and the size of the engine.

Plate XIV. fig. 1. (Chemistry) represents a ground plan of a very capacious water regulator, sunk in the ground, and built of stone and bricks.

A, the inverted chest made of plates of cast iron, 40 feet long, 12 feet wide, and 12 feet high. The square superficies of this chest is equal to 480 feet, and its cubical contents are 5760 feet. Its weight will amount to nearly 30 tons.

B, the opening to which the air-pipe is attached; 2 feet diameter.

CCCC, open space betwixt the inverted chest and stone cistern, for the column of water to ascend; $3\frac{1}{2}$ feet wide.

DDDD, stone or brick-work, of which the great cistern is built. This work requires to be well jointed, as the motion of the water has a great tendency to open the spaces betwixt the stones. This cistern is 47 feet long, 19 feet broad, and 14 feet high; its cubical measurement amounting to 12,500 feet, and capable of containing 93,500 gallons wine measure.

EEEE, an opening of one foot in breadth left in the middle of the building. This is compactly filled with well trod clay, called puddling, and prevents the escape or circulation of water through the building. Beyond this the common building extends to a sufficient thickness to give general security to the whole.

Fig. 2. is a cross section of the water regulator at B, *fig. 1.* The letters in this view correspond with those in the plan.

F, the blast pipe from the cylinder entering the chest, and branching to the two blast furnaces.

GG, large hewn stones, on which the chest is supported about two feet from the bottom of the cistern, at intervals of six feet from each other.

H, loading of hewn stone, which for this cistern requires to be equal in all to 90 tons. If the chest weighs 30, then 60 tons of loading will be requisite. This is supposing that the power of the blowing machine is calculated to press equal to 3 lbs. upon every square inch, which many of them are constructed to perform.

To comprehend distinctly in what manner the water regulator performs its functions, and upon the supposition that the compressing power of the engine is equal to 3 lbs. upon every square inch, we shall suppose the engine at rest, and water introduced into the regulator, till it rise to the level of the dotted line *b*, 5 feet from the lower edge of the chest, and 7 feet in total depth of water. As soon as the engine is set to work, the compression of the air immediately sets the water in motion; every stroke making the water rise in the space CC, and proportionally falling towards GG, in the interior of the chest.

When the inverted chest becomes filled with air, and the condensation has reached the maximum of the power of the blowing machine, the water will be found elevated $3\frac{1}{2}$ feet to *i*, and the gauge will exhibit a depression in the interior of the chest, from *b* to *k*, $3\frac{1}{2}$ feet, making in all 7 feet from *k* to *i*.

At every turn of the engine stroke the water maintained at *i* falls a few inches, and elevates itself above *k* in the interior

BLOWING.

terior of the chest, a similar height. This description takes it for granted, that the spaces CC are equal to the area of the inverted chest; so that every inch of water forced out of the chest adds exactly one inch to the height of the column.

A blowing machine, capable of blowing to purpose two blast furnaces, ought to have the inverted chest of the regulator equal to three or four hundred square feet of area. There cannot arise any error from having this large enough; the want of space and capacity frequently proves a real detriment.

In calculating the proportions and dimensions of water regulators in general, the principle is, to allow the space around the inverted chest equal in point of superficial measurement to the area of the interior of the chest, that the descending column of water may displace no more in the perpendicular ascent, than it is itself absolutely depressed.

If the area or space in which the water rises and falls, is only equal to half the area of the inverted chest, then for every foot of water which is depressed in the bottom of the chest, a column of two feet will be raised and maintained on the outside. On the contrary, if the outside space for water be equal to twice the area, then every foot of water depressed in the chest will only elevate the external column six inches.

It will appear evident from these general facts, that a considerable latitude may at any time be assumed in constructing the water regulator, particularly in old established works, where local circumstances and conveniency confine its situation to one spot.

Where it is not inconvenient to use a high perpendicular column of water, the inverted chest may be increased one half, double, or even triple the superficial measurement of the outside space; so that if the power of the blowing machine is equal to 3 lbs upon the square inch, the water in the chest will be depressed $3\frac{1}{2}$ feet nearly, and raised in the perpendicular column 5 feet 3 inches in the first, 7 feet in the second, and $10\frac{1}{2}$ feet in the last case. This plan to suit former establishments may be adopted with considerable modifications, always keeping in mind, that every foot of area gained upon the surface of the water is a material acquisition to the equalizing powers of the regulator.

One imperfection attends this want of equilibrium on the two spaces for the action and re-action of the water.—Whatever space the waters would fall, at the return of the stroke, supposing the inside and outside columns exactly balanced, would in this case be increased one half, double, or triple.

Again, where situation does not admit of the perpendicular column being raised beyond, or not even to the extent of the depression, that takes place within the inverted chest, and where an additional space cannot be procured for an increase of its diameter, an inverted chest of much less height than common may be used, loaded with a material of great weight, such as iron. The water in that case would distribute itself over the surface of the chest, instead of rising in perpendicular height.

One serious objection, however, is made to chests or cylinders, where the eduction pipe approaches within a short space of the surface of the water: namely, water rising in the pipes, and being conveyed along with the air into the furnace. This may take place in two ways; by an insensible and uniform discharge of water into the furnace, making the blast at the tuyere visible, like the respiration of the human body in a frosty day; or in quantity, threatening utter destruction to the furnace and buildings. The former is occasioned by the air from the eduction pipe, at the com-

mencement of the stroke, impinging violently upon the surface of the water, and raising a portion of it in the state of spray. This is speedily dissolved or entangled in the mass of condensed air before the return of the next stroke, and becomes expressed along with the blast into the furnace. The other hazardous consequence is occasioned chiefly by undulation in the column of water, when the blowing machine is, by derangement or accident, working under its proper power or number of strokes. In these cases, when the pause at the end of the stroke is prolonged, an exhaustion sometimes takes place in the air-pipes, the water rises and is carried in a stream through the blow-pipe into the furnace.

The same casualties may more readily occur, if the surface of the water is upon a level, or nearly so, with the tuyere.

In judicious erections this is most carefully avoided; the surface of water in the inverted chest or cylinder is kept at least 8, 9, and 10 feet under the level of the tuyere, even at the last period of return, when the water has risen to its greatest height within.

This very proper precaution ensures an advantage of much importance. A large space is obtained betwixt the top of the chest and the depressed surface of the water; this becomes a spacious reservoir for the condensed air, and, by generating a considerable portion of elasticity, prevents any violent perturbation upon the water at any period of the stroke. The increased distance betwixt the surface of the water, and the pipe which conducts the air from the cylinder, has a complete tendency to prevent the elevation of the aqueous particles, and always ensures a quantity of air comparatively free from moisture.

Upon the principles formerly noticed, it is possible to construct a blowing apparatus of this nature, wherein there could be little or no visible motion in the perpendicular column of water even with the same engine.

Let us suppose a machine of this nature at work, with an accurately balanced column of water, the fall of which, at the return of the stroke, was equal to 12 inches. It is evident, that if the outside space was enlarged so much over its surface as to contain this foot of water, without adding any perceptible height to the column; that included within the chest would, at the return of the stroke, being fed from a more capacious limb, rise a foot, without any sensible diminution taking place in the perpendicular height of the external fluid. It is equally obvious, in this as in every case with water regulators, that the rise and fall of the inside column of water will remain the same, under every modification and form, while the pace and powers of the engine remain the same.

The application of water regulators to blowing machines was soon followed by an attempt to further improvement, by the introduction of the air-vault; the principle of which was to form a receiver of such capacity, that the elasticity or spring of the condensed air would be sufficient to express and equalize the blast during the return of the stroke.

To effect this, an immense magazine was requisite; to erect which of any metallic substance would have been ruinously expensive, and, if constructed of wood, insufficient for retaining the air. It became therefore requisite to try the experiment upon building, or by excavation from the solid rock. In both these ways has the air-vault been tried, and found to produce an excellent effect, as to equalizing the density of the blast; but it has been conceived with such indifferent consequences as to quantity, that the plan is for the present given up.

BLOWING.

Air-vaults were constructed both at the Clyde and Muirkirk iron works in Scotland, and a constant current of air produced; but nearly one half the quantity lifted by the air-pump escaped through the walls and arches of the building. This was at any time made visible by rubbing soapy water upon the external walls.

At Devon iron works in Scotland, an air-vault was excavated from the solid rock, 72 feet long, 14 feet wide, and 13 feet high; equal to 13,000 feet of cubical measurement. This immense excavation was made comparatively air-tight, by caulking the seams and fissures of the rock, plastering and then covering the whole with alternate layers of pitch and close wove paper.

This was the most perfect experiment ever tried upon the air-vault; and if an opinion is to be formed of the perfection of the apparatus by the quantity of iron at one time manufactured, a very trifling portion of air indeed must have been lost.

It has been frequently noticed in Scotland, that at works where the materials were in any degree similar, 3000 to 3500 cubical feet of air per minute will, in the course of a week, produce from 30 to 35 tons of pig iron, whatever may be the density at which it is thrown into the furnace.

The Devon furnace at one time averaged 33 tons weekly for 9 months running, and consumed of air, per data furnished by Mr. Roebuck in his paper published in Nicholson's Journal, vol. iv. nearly 3400 cubical feet per minute, under a pressure of $2\frac{3}{4}$ lbs. per square inch. Notwithstanding this powerful demonstration, strong prejudices were entertained to its disadvantage; and many believed, that had any other mode of regulator been attached to the blowing machine, abundance of air would have been obtained to have blown two furnaces equally well. That this idea was incorrect, may be easily gathered by calculation from the area of the air-pump, the length of the working stroke, and the number of strokes per minute, all of which are particularly stated by Mr. Roebuck.

For the general construction of an air-vault formed by building, see *Plate XV. (Chemistry.)*

Fig. 1. is a section of the vault constructed under the bridge-house, or place where the materials are proportioned, previously to their being thrown into the furnace. One half a blast furnace outline, is seen as connected in point of situation and blast to the air magazine.

A, the termination of the blast pipes that convey the air from the blowing cylinder into the receiver, 3 feet diameter; the length depends upon the contiguity of the engine to the vault.

B B B B, four vaults, 13 feet wide each, 25 feet deep, and 10, 11, 12, and 13 feet high to the springing of the arches; total height to the crown of the arches, $16\frac{1}{2}$, $17\frac{1}{2}$, $18\frac{1}{2}$, and $19\frac{1}{2}$ feet. These cells communicate with each other by arched openings in the cross-walls, which may be distinctly seen in the ground plan at L.

C C, the education pipes that carry the air to the furnace; 18 inches diameter.

D, end view of the range of laying pipes at the tuyere of the furnace. The dotted lines betwixt D and C are meant to represent the horizontal range of the pipes.

E, part of the outline of a blast furnace to shew its proper situation to the air vault.

F F F F, floor of the respective vaults, composed of a mixture of two parts of boring dust, two of fine riddled lime, and one part of fine roasted iron stone, mixed up into

plaster with water containing a considerable portion of salt.

G G, end walls of bricks or stone, four feet thick.

H H H, lining of brick-work, built in the most accurate manner, with fine riddled mortar, and run every second or third course with mortar made thin and very liquid. These walls are two feet and a half in thickness, are carefully plastered, and afterwards covered with several layers of strong paper and pitch, to prevent the escape of air. The roofs of the vaults are finished in the same manner.

I, door arch into the vaults; entrance obtained by means of a ladder or wooden stairs suspended within.

K, space above the arches, filled with rubbish, to prevent any spring, and to raise the floor to the level of the furnace top.

L, the range of the floor, or acclivity to the furnace mouth.

Fig. 2. is a ground plan of the bridge-house containing the air-vaults, and exhibits one half the ground plan of the furnace through the centre of the tuyere arches.

B B B B, corresponding to the same letters in the elevation.

C C, pipes for taking off the blast into the furnace.

D, corresponding to the same letter in the section.

E, main pillar of the furnace, same as E in the section.

G G G G, and H H H, correspond with the same letters in the elevation.

I, square for receiving the furnace hearth.

K, part of the ground view of the hearth, and the approaching blast pipes.

L L L, openings of the cross arches, which communicate the vaults with each other.

The cubical contents of a vault constructed according to these dimensions, will amount to 20,000 feet.

In general, it may be remarked upon the construction of the blowing machine, that since the period of the introduction of Mr. Watt's engine, the air-pump, or blowing cylinder, has been constructed so as to discharge a cylinder full of air every ascent and descent of the piston. This, instead of travelling 4 to 5 feet per stroke, more generally moves 8 feet; and the number of cylinders per minute are seldom under 24.

Formerly, in the common atmospheric engine, the movement of the piston from top to bottom, and back again, produced only one cylinder full of air from the air-pump, and the number of cylinders discharged per minute seldom exceeded 16. A steam cylinder of 40 to 44 inches diameter, and an air-pump of 6 feet diameter, the piston moving about 5 feet per stroke, were deemed sufficient in the construction of a blowing machine for two blast furnaces. The quantity of air pumped up and thrown into the furnaces by such an engine seldom exceeded 3000 cubical feet per minute. This, and even a larger quantity, is now thrown into one furnace, and the produce by such means increased from 15 to 35 tons weekly.

The first set of tables following are calculated to shew the quantity of air that would be discharged by blowing cylinders of various diameters, the length and number of the strokes being given.

The second set, to shew what diameter of blowing cylinder is requisite, with a given steam power, to raise the air to a certain density per square inch. See *ENGINE, WATER REGULATOR, and REGULATING VAULT.*

BLOWING.

TABLE I. of Blowing Cylinders, their Capacity, Area, and Quantity of Air discharged by a Four-Foot Stroke, &c.

Di- am. of Air in Inch.	Area in Circles in Inch. s.	Area in Square Inches.	Capacity of the Stroke in Cubic Feet.	Air disch'd at the Rate of 5 Cylinders per Minute.	Air discharge at the Rate of 4 Cylinders per Minute.	Air discharged at the Rate of 3 Cylinders per Minute.	Air discharged at the Rate of 2 Cylinders per Minute.	Air discharged at the Rate of 1 Cylinder per Minute.	Air disch'd at the Rate of 1 Cylinder per Minute.

BLOWING.

TABLE II. of Blowing Cylinders, their Area, Capacity, and Quantity of Air, discharged by a Five-Foot Stroke.

Number of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.

BLOWING.

TABLE III. of Blowing Cylinders, their Area, Capacity, and Quantity of Air Discharged by a Six-Foot Stroke.

Diameter in Inches.	Area in square Inches.	Capacity of the Stroke in Cubic Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 25 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 15 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 12 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.

BLOWING.

TABLE IV. of Blowing Cylinders, their Area, Capacity, and Quantity of Air discharged by a Seven-Foot Stroke.

Diameter of Cylinders.	Area in Circular Inches.	Area in Square Inches.	Capacity of Cylinders in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 60 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 70 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 80 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 90 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 100 Cylinders per Minute in Cubical Feet.

BLOWING.

TABLE V. of Blowing Cylinders, their Area, Capacity, and Quantity of Air, discharged by an Eight-Foot Stroke.

Diame- ters of Cylinders	Area in Circular Inches.	Area in Square Inches.	Capacity of the Stroke in Cubical Feet.	Air discharged at the Rate of 10 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 20 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 30 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 40 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 50 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 60 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 70 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 80 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 90 Cylinders per Minute in Cubical Feet.	Air discharged at the Rate of 100 Cylinders per Minute in Cubical Feet.

BLOWING.

TABLE II. of the Powers of Steam Engines working at the Rate of 6 lbs. Avoirdupoise upon every Circular Inch, or 7.639 lb. upon every Square Inch of the Steam Piston applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requisite to raise Air of various Densities from 1½ lb. to 4 lbs. upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. Avoirdupoise upon each Square Inch of the Air Receiver.

Diameter of Steam Cylinder.	Area of Ditto.	Power of the Engine in H.P.	Blow 1 lb. per Circular Inch, or 1.60 lb. per Square Inch.		Blow 2 lb. per Circular Inch, or 2 1/2 lb. per Square Inch.		Blow 3 lb. per Circular Inch, or 3 5/8 lb. per Square Inch.		Blow 4 lb. per Circular Inch, or 4 5/8 lb. per Square Inch.		Blow 5 lb. per Circular Inch, or 5 1/2 lb. per Square Inch.		Blow 6 lb. per Circular Inch, or 6 1/2 lb. per Square Inch.		Blow 7 lb. per Circular Inch, or 7 1/2 lb. per Square Inch.		Blow 8 lb. per Circular Inch, or 8 1/2 lb. per Square Inch.		Blow 9 lb. per Circular Inch, or 9 1/2 lb. per Square Inch.		Blow 10 lb. per Circular Inch, or 10 1/2 lb. per Square Inch.			
			Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.	Area of Blowing Cylinder.	Diam. of Ditto.

BLOWING.

TABLE III. of the Powers of Steam Engines working at the Rate of 7 lbs. Avoirdupoise upon every Circular Inch, or 8.91 lbs. upon every Square Inch of the Steam Piston, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requisite to raise the Air Receiver.

Diameters of Steam Piston	Area of Piston	Power of Piston in H.P.	Blow 1 1/2 lb. per Cir. Inch, or 1.90 lb. per Square Inch.		Blow 2 lb. per Cir. Inch, or 2.27 lb. per Square Inch.		Blow 2 1/2 lb. per Cir. Inch, or 2.80 lb. per Square Inch.		Blow 3 lb. per Cir. Inch, or 3.41 lb. per Square Inch.		Blow 3 1/2 lb. per Cir. Inch, or 4.13 lb. per Square Inch.		Blow 4 lb. per Cir. Inch, or 4.77 lb. per Square Inch.		Blow 4 1/2 lb. per Cir. Inch, or 5.02 lb. per Square Inch.	
			Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto	Area of blowing Cylinder	Diameter of Ditto

BLOWING.

TABLE IV. of the Powers of Steam Engines working at the Rate of 8lbs. Avoirdupoise, upon every Circular Inch, or 10.18 lbs. upon every Square Inch of the Steam Piston, applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requisite to raise Air of various Densities from 1½ lb. to 4 lbs. upon each Circular Inch, or from 1.90 lb. to 5.092 lbs. Avoirdupoise upon each Square Inch of the Air Receiver.

Diameter of Steam Cylind.	Area of Ditto.	Power of the Engine in H.P.	Blast 1½ lb. per Circular Inch, or 1.90 lb. per Square Inch.		Blast 2 lb. per Circular Inch, or 2.54 lb. per Square Inch.		Blast 2½ lb. per Circular Inch, or 3.18 lb. per Square Inch.		Blast 3 lb. per Circular Inch, or 3.81 lb. per Square Inch.		Blast 3½ lb. per Circular Inch, or 4.45 lb. per Square Inch.		Blast 4 lb. per Circular Inch, or 5.09 lb. per Square Inch.		Blast 4½ lb. per Circular Inch, or 5.73 lb. per Square Inch.		Blast 5 lb. per Circular Inch, or 6.37 lb. per Square Inch.

BLOWING.

TABLE VI. of the Powers of Steam Engines working at the Rate of rolbs. Avoirdupoise upon every Circular Inch, or 12.73 lbs. upon every Square Inch of the Steam Piston applicable to Blowing Machinery; and the Areas and Diameters of Blowing Cylinders requisite to raise Air of various Densities from 1½ lb. to 4 lbs. Avoirdupoise upon each Circular Inch, or from 1.90 lb. to 5.09 lbs. upon each Square Inch of the Air Receiver.

Numbers of Steam Cylinders.	Areas of Dittos.	Powers of the Pumps.	Blatt 1 lb. per Circular Inch, or 4.90 lb. per Square Inch.		Blatt 1½ lb. per Circular Inch, or 5.22 lb. per Square Inch.		Blatt 2 lb. per Circular Inch, or 5.54 lb. per Square Inch.		Blatt 2½ lb. per Circular Inch, or 5.86 lb. per Square Inch.		Blatt 3 lb. per Circular Inch, or 6.18 lb. per Square Inch.		Blatt 3½ lb. per Circular Inch, or 6.51 lb. per Square Inch.		Blatt 4 lb. per Circular Inch, or 6.83 lb. per Square Inch.		Blatt 4½ lb. per Circular Inch, or 7.15 lb. per Square Inch.		Blatt 5 lb. per Circular Inch, or 7.47 lb. per Square Inch.

BLOWING of a Flower, among *Florists*, an artificial process in order to bring a flower to display itself with greater perfection and beauty than it would arrive at in the natural way of blowing. The usual method is thus: about April, when the flower stems begin to put forth, or *spindle*, as the gardeners call it, they place by each flower a strait stick four feet long, and tie the spindles to it as they shoot. As soon as the flower-buds appear, they leave only one of the largest on each flower-stem to blossom. About ten days before the flowers open themselves, the round-podded kinds will begin to crack their husks on one side, when the careful gardener, with a fine needle, splits or opens the husk on the side opposite to the natural fracture; and about three or four days before the complete opening of the flower, cuts off with a pair of scissars the points on the top of the flower-pod, and supplies the vacancies or openings on each side of the husk with two small pieces of vellum or oil-cloth, slipped in between the flower-leaves and the inside of the husk; by such means, the blossom will display its parts equally on all sides, and be of a regular figure. Besides this care, when the blossom begins to shew its colours, they use to shade it from the extreme heat of the sun with a trencher-like board, or other device of the like nature, fastened to the stick which supports it; for the flowers as well as fruits, grow larger in the shade, and ripen and decay soonest in the sun.

In *Heraldry*, a fleur de lys is said to be blown, *espanoui*, when its leaves are opened, so that buds appear among the fleurons. The arms of the city of Florence are *argent, a fleur de lys blown, gules*.

BLOWING-snake, in *Zoology*, a name given by the people of Virginia to a species of serpent much resembling the European viper, but considerably larger, and very remarkable for its inflating and extending the surface of its head before it bites. Its wound is very fatal.

BLOWN RED, in the manufacture of porcelain. See **RED**.

BLUBBER, in *Physiology* and *Trade*, the fat which invests the bodies of all large cetaceous fish, serving to furnish an oil.

The blubber is properly the *adeps* of the animal: it lies immediately under the skin, and over the muscular flesh. In the porpoise, it is firm and full of fibres, and invests the body about an inch thick. In the whale, its thickness is ordinarily six inches; but about the under lip, it is found two or three feet thick. The whole quantity yielded by one of these animals ordinarily amounts to forty or fifty, sometimes to eighty or more hundred weight. *Phil. Trans.* N^o 77. p. 2275.

The use of the blubber to the animal seems to be partly to poise the body, and render it equiponderant to the water; partly to keep off the water at some distance from the blood, the immediate contact whereof would be apt to chill it; and partly also for the same use that cloaths serve us, to keep the fish warm, by reflecting or reverberating the hot steams of the body, and so redoubling the heat; since all fat bodies are, by experience, found less sensible of the impression of cold than lean ones.

Its use in trade and manufactures is to furnish train-oil, which it does by boiling down. Formerly this was performed ashore in the countries where the whales were caught; but of late the fishers do not go ashore, they bring the blubber home, stowed in casks, and boil it down there.

BLUBBER-livers. The livers of cod, which having been barrelled, yield spontaneously a considerable quantity of oil, which being skimmed off, the residue are called blubber-livers, to be boiled down for more oil.

BLUBBER, *sea*, a denomination given by our navigators to the *urtica marina*, or sea-nettle. *Phil. Trans.* N^o 349.

BLUDENTZ, in *Geography*. See **PLUDENTZ**.

BLUE, one of the seven primitive colours of the rays of light, into which they are divided, when refracted through a glass prism. See **COLOURS**, and **REFRACTION**.

Anciently blue was the symbol of the sea; for which reason, in the Circensian games, the combatants who represented the sea were clad in blue; and those who had distinguished themselves by any notable exploit at sea, were rewarded with a blue ensign.

Mr. Boyle has given us the following method of making transparent blue, nearly equal to ultramarine. The principal ingredient of this beautiful colour is the *cyonus*, or blue corn-bottle flower, which abounds almost in every corn-field, and may easily be had during four of the summer months. It may be gathered by children about the verges of corn-fields, without doing any damage to the corn. This flower has two blues in it, one of a pale colour in the large outer leaves; and the other of a deeper blue, that lies in the middle of the flower. Both these will do, being separated from the buttons or cases in which they grow; but the deep blue leaves in the middle produce much the best colour; this may be observed by rubbing the leaves while they are fresh upon a piece of writing-paper, so hard as to express the juice which will yield an excellent colour, that by the experience of two or three years has not been found to fade. A sufficient quantity of these middle leaves being procured, let the juice be pressed from them; to which a little alum being added, will give a lasting transparent blue, scarcely inferior in brightness to ultramarine. It is very probable, that if the chives of these flowers were cured in the same manner with saffron, they would produce a much greater body of colour, from which a tincture might be drawn with more ease than when pressed fresh from the field.

Mr. Boyle also recommends another fine blue, produced from the blue leaves of rue beaten in a stone mortar with a wooden pestle, and then put in water for fourteen days or more, washing them every day until they are rotten. These beaten up at last, water and all, until they become a pulp, and then dried in the sun, will make a fine blue for shading.

BLUE Ashes, *Cendres bleues*. See **VERDITER**.

BLUE Lice, is a colour of good brightness, next to Prussian blue; it is also a colour of a body, and flows well from the pencil. See **BLUE**.

BLUE, in *Dyeing*. See **DYEING**, **INDIGO**, and **WOAD**.

BLUE black. See **BLACK**.

BLUE enamel. See **Azure ENAMEL**.

BLUE, *Flanders*, is a colour seldom used but in landscapes as being apt to turn green. The French call it *cendre verte*, or green ashes.

BLUE for painting or joining glass. See **GLASS**.

BLUE Japan. See **JAPANING**.

BLUE Indigo. See **INDIGO**.

BLUE Livers, or *Laemus*. See **LITMUS**.

BLUE, *Painter's*, is made differently according to the different kinds of paintings. In limning, fresco, and miniature, they use indifferently ultramarine, blue ashes, and smalt; these are the natural blues, excepting the last, which is partly natural, partly artificial. See each under its proper head. In oil and miniature they use indigo, blue lice, blue verditer, lapis armenus, smalt, and litmus, also a counterfeit ultramarine. Enamellers and painters of glass have blues peculiar to themselves; each preparing them after his own manner. See **ENAMELLING**, *Painting on GLASS*, and **Neumann's Chem. Works**, by Dr. Lewis.

BLUE, *Prussian*. See PRUSSIC ACID.

BLUE, *Saxon*, a solution of indigo in sulphuric acid. See INDIGO.

For an account of the processes for obtaining blue liquors from oak duct and vitriol, from log wood and verdigrise, from log-wood and blue vitriol, from an essential oil and volatile spirit; see Dr. Lewis's *Commercium Philosophico-Technicum*, ed. 4to, ann. 1773, p. 382. 407. 436.

BLUE, *Stone*, or *Powder*, used in washing of linen, is the same with smalt, either in the lump or powdered.

When the smalt is taken from the pot, it is thrown into a large vessel of cold water: this makes it more tractable and easily powdered. Afterwards, when examined after cooling, it is found to be mixed with a greyish matter resembling ashes, which they call *schel*. This grey matter is separated by washing, and then the blue substance is powdered and sifted through fine sieves, to bring it to what we call *powder-blue*. Phil. Trans. N° 396. See COBALT.

BLUE, *turnsol*, is a blue used in painting on wood, made of the seed of that plant. It is prepared by boiling four ounces of turnsol in a pint and a half of water wherein lime has been slacked. See TURN SOL.

BLUE, *ultramarine*. See LAZULITE.

There is a blue substance, something like what Kentman mentions under the name of *caruleum patavinum*. It was discovered in a peat-moss in Scotland. This earth is at first of a white colour, and only grows blue by being exposed to the air. It has also some resemblance to what Mr. de Costa in his Nat. Hist. of Foss. p. 103, calls *ochria friabilis carulea*. It is described very minutely by Mr. Douglas, who gives an account of his various experiments upon it, and recommends it as a cheap paint in gum water, particularly as it is levigated and prepared by nature. See Phil. Trans. vol. lviii. N° 27. an. 1768.

Many similar specimens of blue earth have been discovered in England and Ireland, and several parts of the continent.

BLUE-ball, a name given in some countries to the *Conewheat*.

BLUE-bottle, in Botany. See CENTAURIA.

BLUE-Cap, in Ichthyology. See BLEW-CAP.

BLUE *John*, the common appellation, among the Derbyshire miners, of FLUOR-SPAR.

BLUE *Mantle Pursuivant of Arms*. This officer is by patent a member of the corporation of heralds. Sir Henry Spelman conjectures, that the title was taken from the colour of the mantle of the French kings. This office is said to have been instituted by Henry V., and probably might be coeval with that of Garter, and erected with reference to that order; but although the catalogues place John Wrexworth and others by this title under the reign of Henry V.; Anthony Wood ascribes the creation of this office to Henry VI, in whose 26th year *Bluemantle Pursuivant* waited on Bruges, Garter king of arms, into France, and also on the bishop of Chichester and others, ambassadors thither. Previous to that date there are not any entries on record relating to this Officer; but from thence to the present time the succession hath been carried on without any interruption.

BLUE Nuns, *filles blues*, those of the order of the Annunciation.

BLUEFIELD'S BAY, in Geography, a bay in the island of Jamaica, lying S.E. of Savannah-la-Mar, and having good anchorage for large vessels. N. lat. 18° 10' 30". W. long. 78°.

BLUEFIELD'S, or *Blewfield's Bay*, a bay on the western

coast of Nicaragua, in New Spain, into which a river of the same name is discharged N. lat. 11° 40'. W. long. 83°.

BLUEHILL, a township of America, in Hancock county and district of Maine, on the west side of Union river, 344 miles N.E. of Bolton, and 13 E. of Penobscot; having 274 inhabitants.

BLUEHILL Bay, a bay of America, formed by Naskeag point on the west, and Mount Desert island on the east and extending northerly to a mountain on the east of Penobscot river, which, from its appearance at sea, is called "Blue-hill." Union river discharges itself into this bay.

BLUE Hills, a range of mountains in New England, the first ridge of which in New Hampshire passes through Rochester, Barrington, and Nottingham.

BLUE Mountains, are mountains of America, in Northampton county, and state of Pennsylvania, extending from S.W. to N.E. and through a small interval across the Delaware. — Also, a range of mountains, which run from S.E. to N.W. through Surry county, in the island of Jamaica. Blue mountain peak is said to rise 7431 feet above the level of the sea; and the precipices are interspersed with beautiful savannahs. — Also a mountain in Russia, part of the Altay mountains. See SINNAI SOPKA.

BLUE Ridge, or *South Mountain*, is the first ridge of the Alleghany mountains in Pennsylvania, Virginia, and North Carolina, distant from 150 to 200 miles from the sea, and, measured from its base, about 400 feet high. Between this and the north mountain is a large fertile vale. The Passage of the Potomack river through this ridge is one of the most stupendous scenes in nature. See ALLEGHANY Mountains, and POTOMACK RIVER.

BLUE Lick, lie on the main branch of the Licking river in Kentucky, and are situated about 8 miles westerly from the Upper Blue Licks. Both of them are on the N.E. side of the river; and the latter is about 5 miles N.E. of Millers.

BLUE Spring, lies between Big Barren and Little Barren river, southern branches of Green river, in Mercer's county, Kentucky, about 22 miles south-westerly from Sulphur spring, and 13 south of Craig's fort, on the north side of Green river.

BLUE Stone Creek, a small western branch of the Great Kanaway.

BLUE-water river, a river of America, that rises among the southern branches of Duck river, and empties into the Tennessee. It is scended by boats.

BLUENESS, that quality which denominates a body blue, depending on such a size and texture of the parts that compose the surface of a body, as dispose them to reflect the blue or azure rays of light, and those only, to the eye.

With respect to the blueness of the sky, M. de la Hire, after Leonardo da Vinci, observes, that any black body viewed through a thin white one, gives the sensation of blue; and this he assigns as the reason of the blueness of the sky, the immense depth of which being wholly devoid of light, is viewed through the air illuminated and watered by the sun. For the same reason, he adds, it is that foot mixed with white makes a blue; for white bodies, being always a little transparent, and mixing themselves with a black behind, give the perception of blue. From the same principle he accounts for the blueness of the veins on the surface of the skin, though the blood they are filled with be a deep red; for red he observes, unless viewed in a clear, strong light, appears a dark brown, bordering on black: being then in a kind of obscurity in the veins, it must have the effect of a black; and this, viewed through the membrane of the vein and the white skin, will produce the perception of blueness.

In the same way did many of the early writers account for the phenomenon of a blue sky; such as Fromondus, Funceius, Otto Guericke, and many others: their opinion long prevailed, and has been adopted by some in more modern times, especially by Wolffius and Muschenbroek. But in the explanation of this phenomenon, sir Isaac Newton observes that all the vapours, when they begin to condense and coalesce into natural particles, become first of such a bigness as to reflect the azure rays, before they can constitute clouds of any other colour. This, therefore, being the first colour which they begin to reflect, must be that of the finest and most transparent skies, in which the vapours are not arrived to a grossness sufficient to reflect other colours.

M. Bouguer, without having recourse to the vapours diffused through the atmosphere, in order to account for the reflection of the blue-making rays, ascribes it to the constitution of the air itself, whereby these fainter-coloured rays are capable of making their way through any considerable tract of it. And he accounts for those blue shadows, which were first observed by M. Buffon in the year 1742, by the aerial colour of the atmosphere, which enlightens these shadows, and in which the blue rays prevail; whilst the red rays are not reflected so soon, but pass on to the remoter regions of the atmosphere. The abbé Mazeas, in a Memoir of the society of Berlin, for the year 1752, accounts for the phenomenon of blue shadows by the diminution of light; having observed that, of two shadows which were cast upon a white wall from an opaque body illuminated by the moon, and by a candle at the same time, that which was enlightened by the candle was reddish, and that which was enlightened by the moon was blue. However, the true cause of this appearance seems to be that assigned by M. Bouguer, which agrees with the solution given of it about the same time by Mr. Melville. But instead of attributing the different colours of the clouds, as sir Isaac Newton does, to the different size of those globules into which the vapours are condensed; Mr. Melville supposes, that the clouds only reflect and transmit the sun's light; and that according to their different altitudes, they may assume all the variety of colours at sun rising and setting, by barely reflecting the sun's incident light, as they receive it through a shorter or longer tract of air: and the change produced in the sun's rays by the quantity of air through which they pass, from white to yellow, from yellow to orange, and lastly to red, may be understood agreeably to this hypothesis, by applying to the atmosphere what sir Isaac Newton says concerning the colour of transparent liquors in general, and that of the infusion of *lignum nephriticum* in particular. Edinb. Ess. vol. ii. p. 77. Bouguer *Traité d'Optique*, p. 366. Newton's *Optics*, p. 228; or Priestley's *Hist. of Vision*, &c. p. 435-445.

BLUFF-HEAD, or *Bluff-headed*, in the *Sea-Language*, is, when a ship has but a broad rake forward on, being built with her stem too straight up.

Bluff-headed ships are opposed to those that are sharp-headed. They are shorter, less masted, and sail cheaper.

BLUING OF IRON, a method of beautifying that metal sometimes practised; as for mourning buckles, swords, or the like. The manner is thus: take a piece of grind-stone, and whet-stone, and rub hard on the work to take off the black scurf from it; then heat it in the fire, and as it grows hot, the colour changes by degrees, coming first to a light, then to a dark gold colour, and lastly to a blue. Sometimes they grind also indigo and salad-oil together, and rub the mixture on the work with a woollen rag, while it is heating, leaving it to cool of itself.

Among sculptors we also find mention of bluing, a figure of bronze, by which is meant the heating of it, to prepare it for the application of gold leaf, because of the bluish cast it acquires in the operation.

BLUM, JOACHIM CHRISTIAN, in *Biography*, an esteemed German poet, was born at Rathenau, in 1739, and received the early part of his education in his father's house, from a lady, who was the governess of his sisters. At the age of eleven years he lost his father, and became master of a library, of which he availed himself to great advantage. During his residence with his mother and sisters, he amused himself with playing hymns on the harpsichord, and with reading moral authors, and reciting orations, which he did in a manner so affecting as to cause his hearers to shed tears. His mother concluded, that he had an inclination to become a clergyman, and with this view placed him, in 1754, at a school in Brandenburg, where he manifested by his course of reading, and also by his performances, a strong turn for poetry. In 1757, he removed to the gymnasium at Berlin; and giving up all thoughts of the ministerial office, he devoted himself to the study of philosophy and the belles lettres, indulging himself occasionally in his favourite pursuit. From Berlin he proceeded, in 1759, to Frankfort on the Oder, where he studied for some time under Baumgarten, for whom he professed the highest respect; but when this city fell into the hands of the Russians, he retired to the house of his mother; and as his health was in an infirm and declining state, in consequence of an accident which had almost proved fatal to him in his youth, he determined to continue with his mother, and to devote the remainder of his days to the muses in his native place. Here he closed his life, August 28, 1790. His poetical works were "Lyric Poems," and "Idylls," published at various periods after the year 1765. A dramatic piece, in praise of his native town, entitled "Rattenau delivered," was often represented at Berlin with applause, but forbidden in compliance with the request of the Swedish ambassador. Blum's poetry is said to be characterized by softness, simplicity, and correctness, and he ranks among the best poets of Germany. He also published some volumes under the title of "Walks;" two volumes of "Orations;" and a collection of "German Proverbs." His works in general were much read, and approved by persons of the first distinction. The late king of Prussia, Frederick William, honoured him with a very particular token of favour. As Blum's health required his residence in the country, he purchased, in 1787, a small estate, upon which was a mansion in a very ruinous condition; but having in the purchase exhausted almost the whole of his property, he could not repair his house without assistance; and, therefore he addressed a poetical epistle to the king, in which he introduced the following lines:

"O aid thy poet, gracious prince,
And free his breast from care;
All that he asks is competence
His mansion to repair.
Those mould'ring walls, which long have stood
Offensive to the eyes,
A temple then to gratitude,
Shall renovated rise.
His groves, near yonder wand'ring stream,
Whose banks with reeds are crown'd,
Thus consecrated groves shall seem,
And shade the hallow'd ground."

With this address his majesty was so much pleased, that he ordered for him 2000 rix dollars. Blum expressed his gratitude in a second epistle, to which the king returned his best

wishes. Besides the Greek and Latin, he well understood the French, Italian, and English languages; and he had studied with great attention the history of the Christian church. Gen Biog.

BLUMBERG, in *Geography*, a small town of Germany, in the landgravate of Baar.

BLUMENAU, a bailiwick of Germany, in the principality of Calenberg, seated on the Leine.

BLUMENFELD, a town of Germany, in the circle of Swabia, and commandery of Minau, seated on the river Ach; 8 miles N.N.E. of Schaffhausen.

BLUMENSTRAS, J. DEODATUS, in *Biography*, took his degree of doctor in Medicine in Leyden. Returning thence to Russia, his native country, he was soon distinguished by the emperor, who made him archiater, or principal physician to his court. He had also the honour of being appointed the first president of the Royal Academy of Sciences at Petersburg, which had been instituted, Haller says, by his exertions. He died at Moscow at an advanced age, in April 1755, leaving only one publication, which was first printed in the year 1700, 4to. "Medicus Castrensis Exercitui Moscovitarum." Haller Bib. Med. Pract. Eloy. Dict. Hist.

BLUMENTHAL, in *Geography*, a bailiwick of Germany, in the duchy of Bremen.

BLUMLIS ALP, a majestic eminence of the Alps, in the canton of Bern, in Switzerland, terminating the valley of Lauterbrunnen, and having at its feet a large glacier, which stretches towards the valley of Gaster. The Blumlis Alp, and also the feet of the Alpschelenhorn, are covered with black schistus; but the granite is not apparent, except at a considerable height. The sides of the Blumlis Alp, bordering the glacier, are black slate, in which have been found several blemmites, and a fragment of a Cornu Ammonis, a foot in diameter.

BLUNDERBUSS, in the *Military Art*, a short sort of fire arm, with a large bore contrived to carry a number of musket or pistol bullets at once. The blunderbuss is proper to do execution in a crowd, or to make good a narrow passage, as the door of a house, stair case, or the like.

BLUNT, in *Fencing*. To fight with blunts, is to exercise or parade with weapons without points or edges.

BLUNTING the angles of a *battalion*, in the *Military Art*, signifies to retrench the four corners, and turn the square into an octagon. This is done in order to give an opportunity for presenting the pikes, or firing on all sides, and was a military evolution formerly much in use, but now disused.

BLUSHING, a suffusion or redness of the cheeks, excited by a sense of shame, on account of consciousness of some failure or imperfection. See ENCHYMOA.

Blushing is supposed to be produced from a kind of consent or sympathy between several parts of the body, occasioned by the same nerve being extended to them all. Thus the fifth pair of nerves being branched from the brain to the eye, ear, muscles of the lips, cheeks, palate, tongue, and nose; a thing seen or heard, that is shameful, affects the cheeks with blushes, driving the blood into the minute vessels thereof; at the same time that it affects the eye and ear. For the same reason it is, as Dr. Derham observes, that a savoury thing seen or smelt, affects the glands and parts of the mouth; if a thing heard be pleasing, it affects the muscles of the face with laughter; if melancholy, it exerts itself on the glands of the eyes, and occasions weeping, &c. And to the same cause Dr. Willis ascribes the pleasure of kissing.

BLUSTERING *weather* is that where the wind blows

with various degrees of strength, attended with a dark sky, rain, snow, &c.

BLUTEAU, DON RAPHAEL, in *Biography*, a religious theatine, was born of French parents in London in 1638. After having distinguished himself in sacred and profane literature, he visited Portugal and acquired such knowledge of the language as to be able to preach in it with applause. From Portugal he returned to Paris, and was for some time preacher to Henrietta-Maria, queen of England. Upon revisiting Portugal, he obtained an office in the inquisition, and became member of the Royal Academy of History. Of his works, the most esteemed is "A Portuguese and Latin Dictionary," in 8 vols fol. Coimbra 1712—1721, to which he added a Supplement in 2 vols. fol. Lisbon. 1727, 1728. He died at Lisbon in 1734, at the advanced age of 96. Moreri.

BLUTFINK, in *Ornithology*, one of the synonymous names of *loxia pyrrhula*, the common bulfinch. Frisch. Av.

BLYSOOG, in *Geography*, a river of South Wales, which runs into the Tivy, about 3 miles S.S.E. of Cardigan.

BLYTH, in *Geography*, a small market town of Nottinghamshire, in England, has been the seat of a castle and a priory; but these buildings with their endowments and privileges, being entirely demolished at the dissolution, the town also sunk in the general wreck, and has never since been renovated. The whole parish consists now only of 157 houses, with 589 inhabitants. Here are a small market on Wednesdays, and two annual fairs. The church is a large handsome structure, and contains several ancient monuments. Some of the Cressy family built an hospital here, which bears the name of Blyth-spittle.

BLYTH, or *South Blyth*, a small sea-port town of Northumberland, in England, is a place that has obtained its sole consequence since the restoration; for, previous to that period, here were scarcely any houses. In the year 1728, its trade had so much increased that above 200 vessels were entered in the custom house books as sailing from this port. It is considered as a creek to the port of Newcastle, and its principal trade is in coals. Blyth is 14 miles N.E. of Newcastle, and 288 miles N. of London. The township contains 183 houses, and 1170 inhabitants, of whom 234 are employed in trade. Here is a small market on Saturdays. About three miles south of Blyth is Seaton Delaval, a seat belonging to lord Delaval, whose grandfather, sir Francis Blake Delaval, was an able admiral in the beginning of the last century. He was often projecting some improvements in the ports near his seat, and after surmounting great difficulties, constructed one upon a new plan, which now bears his name.

BMI, in *Music*. See GAMUT.

BOA, in *Zoology*, a genus of the SERPENT race distinguished by having plates, or undivided scuta, both on the belly and beneath the tail; the latter of which, unlike the crotali, does not terminate in a rattle.

Such is the Linnæan character of this genus, the species of which are not very numerous. Gmelin enumerates the following kinds in the Systema Naturæ: contortrix, canina, hipnale, constrictor, cenchris, ophryas, enydris, murina, scytale, and hortulana. But in addition to these we are to mention a few other species described by Dr. Patrick Russel in a recent publication on the serpents of India, with the observations of Dr. Shaw upon the newly discovered kinds, and several others lately spoken of by continental writers.

Dr. Russel in the work above cited, has four new species

of boa, called, in the Indian language, *bungarum pamah*, *padain cootoo*, *geedi paragoodo*, or in the young state *cobra monil*, and the *horatta p-m*. These are the species, fasciata, viperina, lineata, and horatta of Dr. Shaw's zoology. Dr. Shaw has likewise increased the number of the boæ by the addition of a fifth species, *crotalus mutus* of Linnæus, which he is induced to remove from the crotali to this genus, because it is not furnished with a genuine rattle like the rest of that tribe.

But the French writers of the present day have regarded the arrangement of the Swedish naturalist in the amphibious class of animals with much less indulgence, their alterations tending to little less than the subversion of his system. The boa genus, as established by Linnæus, is obviously defective, in one point at least, where nature had herself prescribed those characters which ought not to have escaped the discrimination of the naturalist. Nothing, we must admit, can be more improper, if it could have been avoided, than to include in the same natural family both the venomous and inoffensive kinds of serpents; or, in other words, to unite, under one head, those which, having fangs for the conveyance of poison into the wound inflicted with their bite, are highly dangerous, and such as have no fangs for this purpose, and are therefore comparatively harmless. The first innovation upon the Linnæan genera was made by Lacepede, whose method has been followed by others; and lastly, by Latreille, with some improvements, in his Natural History of Reptiles.

Latreille retains among his boæ those only of the Linnæan species which have no venomous fangs; for the reception of the remainder he establishes the new genus SCYTALE. This genus forms an intermediate link between the two Linnæan genera boa, and crotalus; having, in common with both, the abdominal plates, and either plates alone, or plates and scales beneath the tail; the poisonous fangs removing them from the boæ, and the naked tail from the crotali. or snakes that have a rattle at the extremity of that part. The boæ of Latreille contain the following species: *le boa devin* (constrictor, Linn.), *le boa géant* (a species hitherto confounded with the former,) *le boa bejubi* (boa canina, Linn. and Lacepede), *le boa bipnale* (hipnale, Linn.), *le boa cenchris* (cenchris, Linn.), *le boa enhydre* (enydris, Linn.), *le boa ophrie* (ophrias, Linn.), *le boa scytale* (scytale, Gmel. Scheucher), *le boa brodé* (hortulana, Linn.), *le boa ratiore* (Seba, v. 2. pl. 29. 1.), and *le boa turc*, a native of the Grecian islands, described by Olivier in his "Voyage dans l'Empire Ottoman."—Thus the Linnæan *boa constrictrix*, a poisonous species, *le scytale a groin* of this writer, is removed from among the boæ to the genus SCYTALE, together with another species not before described, *le scytale a tête plate*, and the four new species mentioned by Dr. Russel belong unquestionably to the same genus, being all of the venomous kind. We have, therefore, six species of the SCYTALES confounded with the natural family of boa.

The boæ, taken collectively, exceed in magnitude all the other tribe of serpents. The powers of certain species, like their stature, are prodigious. These enormous kinds are principally the inhabitants of the burning regions of Africa, whose fame, in this respect, was celebrated in ages of remote antiquity. History speaks of these tremendous serpents in terms that stagger credibility; but travellers of our own times, who have had the opportunity of observing these creatures in their native haunt, and whose relations deserve every rational degree of credit, afford so much collateral evidence, that we are not allowed to reject the authority of the ancients in many of the most material points. When Valerius Maximus relates, upon the authority of Livy, the contest between an army of Romans under Attilius

Regulus, and an enormous snake, that disputed with them, for a considerable time, the passage across the river Bagdara in Africa, and was at last only overcome, after killing many of the soldiers, by means of the battering machines employed in attacking fortresses, we are inclined to suspect the whole as fabulous. If, however, we reflect at the same time upon the size and power of this monster, the skin of which, when taken off, was 120 feet in length, we need not be astonished at the resistance it was capable of making. Something must be allowed on this occasion for the luxuriance of fancy, or the fictions of the battle between the Phœnicians, and the sacred snake of Mars, would almost shrink from comparison with this surprising adventure.

Ille volubilibus squamos nexibus orbes
Torquet, et immanes saltu sinuatur in arcus:
Ac media plus parte leves erectus in auras
Despicit omne nemus:—

Nec mora: Phœnicas (sive illi tela parabant,
Sive fugam; sive ipse timor prohibebat utrumque).
Occupat; hos morsu, longis complexibus illos;
Hos necat afflatus functi tabe veneni. Ovid.

The serpent mentioned by Livy is believed to have been an overgrown creature of the boa genus, the *constrictor* of Linnæus; a kind which, from the superiority of its size, is emphatically denominated the "King of Serpents." This species, of which we shall speak more largely in another place (vide CONSTRICTOR), is found occasionally in Africa, India, and South America, from 20 to 30 feet in length, and even more; and of a strength so great, as to be able to destroy most of the larger animals by the violence of its pressure only. We have seen the skins of this particular species almost 20 feet in length, and of a bulk proportionate. Among the articles of Natural History, collected in South America for the National Museum at Paris, but intercepted, and sold in this country, there were several specimens; dried skins of this kind are also preserved in the British and Leverian museums, and in most of the public museums on the continent, which at once remove every unreasonable degree of suspicion as to the actual existence of such a monstrous kind of serpent.

If, therefore, according to the ideas of latter writers, the true boæ are destitute of poisonous fangs, nature has more than amply supplied the deficiency by the powers they are endowed with for the destruction of their prey. The elephant, the rhinoceros, the hippopotamus, and the lion, are the only animals that can resist them with success. The stag, the leopard, and even the buffalo, entangled once within the coils of the body of the boa, must fall an easy victim to its voracity. The boæ are, among serpents, what the elephant and the lion are among quadrupeds: like the elephant, they surpass the rest of the serpent race by their size; and, like the lion, excel them in their address, their courage, and their force. They seldom attack their prey by artifice, decoying their unwary adversary, and, by a wound as sudden as insensible, paralyzing its efforts with the deadly torpor of their poison. Confident in their powers, they attack them openly; oppose their strength to the resistance of their enemy with ardent intrepidity; and when they conquer, it is by the manifest superiority of bodily vigour over that of their opponent.—It should be observed, that these traits of character relate only to the largest of the boa genus, of which no more than two species are correctly ascertained, although there is reason to believe the number must be greater. Much confusion prevails among travellers who have described these serpents: they have entered largely into the prodigies of their history, without paying any due regard to the descrip-

tion of the animals themselves, a circumstance that has hitherto involved this matter in obscurity, and leaves us in considerable doubt as to the real number of distinct species already discovered, and mentioned by those travellers. See *CONSTRICTO*, &c.

BOACRÆ, in *Ancient Geography*, a place of Italy, on the Aemilian way, in the route from Rome to Arlito, through Etruria and the Maritime Alps. Anton. Itin.

BOAD, in *Geography*, a town and fort of Hindoostan, in the country of Orissa, near the Mahanuddy river; 55 miles S. E. of Sumpulpour, and 100 west of Cattack. N. lat. 20° 40'. E. long. 84° 16'.

BOADICEA, *BOUDICRA* (Tacitus), or *BUNDUICA* (as she is called by Dion), in *Ancient British History*, a queen of the Iceni, celebrated for her misfortunes, and for her formidable, though unsuccessful, resistance to the Roman power in Britain.

At the time when the revolt, of which Boadicea was the principal mover, took place, the southern part of the island had tranquilly submitted to the government of the Cæsars. Although scarcely 13 years had elapsed since the invasion of Claudius, Britain was already considered an important acquisition. Several flourishing colonies were founded; numerous settlers flocked from the more distant provinces of the empire, and the only expedition which employed the legions, was that undertaken against the sequestered island of Mona, the principal remaining seat of Druidical superstition. But amidst this seeming security, the oppression exercised by individuals excited indignation among the natives. The procurator, Catus Decianus, who, in the absence of the proprætor, possessed the exclusive administration of government, behaved with the most insufferable tyranny; and, according to the confession of Tacitus himself, the great men of the nation were treated as slaves, and deprived injuriously of their estates by this upstart governor. The fear, however, of incurring the imperial resentment, restrained them from expressing their dissatisfaction otherwise than by murmurs, till the decease of Prasutagus, king of the Iceni, brought matters to a crisis. This monarch, by his attachment to the party of the invaders, had merited the title of friend and ally of the Roman people, and by his last will, had bequeathed his estates as a joint inheritance between the emperor Nero and his two daughters. His policy, if intended as such, failed of the desired effect. The procurator, under pretence of carrying the testament into execution, seized on all the possessions of Prasutagus without exception; and as Boadicea dared to murmur against such flagrant injustice, he actually caused herself to be publicly scourged as a slave, and the chastity of her daughters to be violated by his officers.

Such outrages were beyond sufferance. The Iceni to a man rose up in arms, headed by Boadicea in person, who to a masculine spirit joined a gift of natural eloquence calculated to inflame the passions of a barbarous multitude. The Trinobantes, and other neighbouring nations, alike incensed at the extortions of the procurator, followed the example, and an army of 120,000 islanders being rapidly formed, marched directly against Camalodunum, (supposed to have been Maldon,) the nearest Roman colony. As Decianus could only spare a few soldiers to assist the inhabitants in its defence, the place was almost instantly stormed, and, with a temple lately erected to the divinity of Claudius Cæsar, reduced to ashes, all within it being previously massacred. The ninth legion, which had ventured to take the field against the insurgents was next attacked and defeated. The infantry were almost totally destroyed. The commander, Petilius Cerealis, at the head of his cavalry, with

difficulty regained his camp, where he carefully intrenched himself; while Catus Decianus, terrified at the consequences of his infamous conduct, made his escape into Gaul, covered with universal odium.

After such a series of ill-fortune, the only hope of the Romans remained vested in the proprætor Suetonius Paulinus, at this time occupied in exterminating the Druids of Mona. On receiving news of the progress made by Boadicea, he immediately marched, though by a dangerous route, and through the midst of an hostile country, to Augusta (London), already a considerable place, though not yet dignified with the name of a colony. As he judged this post untenable, he retired to unite his scattered forces, accompanied by such of the inhabitants as chose to follow his fortunes; but the women and children, the old and infirm, who were left behind, without any other protection than their sex, their age, or their situation afforded, were indiscriminately sacrificed to the fury of the Britons. Verulamium, another colony, shared the same fate. All foreigners were every where put to the sword, and the cruelties, said by Dion to have been exercised upon some of the sufferers, are shocking beyond description.

The rebellion had now attained its utmost height. Three Roman stations laid in ashes, and the blood profusely poured of 70,000 of her persecutors, had amply revenged the wrongs of Boadicea. The whole eastern part of the island was in possession of her partizans, and her forces in arms had increased to the amazing number of 230,000, when Suetonius, having taken every measure prudence could suggest in his circumstances, prepared to check this torrent in its course. The proprætor, although accused, and perhaps with justice, of pride and excessive cruelty, yet possessed the most splendid military talents. During the last reign he had signalised himself, when commander in Africa, by a complete victory over the rebellious Mauritanians. Nero rewarded his bravery by naming him to the government of Britain. The late reduction of Mona had increased his celebrity; and he appears to have been the only general then in the empire, Corbulo probably excepted, equal to the task of reducing the insurrection raised by Boadicea. His situation was, however, extremely critical. It was in vain that he dispatched instructions to Pænius Posthumus, who commanded the second legion, to march to his assistance. Pænius, in consequence of some difference with his general, or actuated by a secret jealousy, refused to move, in direct disobedience to orders. Thus Suetonius saw his whole force reduced to the fourteenth legion, Gemina, and the Vexillarii of the twentieth, which, added to a few auxiliary cohorts, only amounted to about 10,000 men. With his army, so small as it was, he determined on hazarding a battle, and therefore waited the approach of the Britons on a narrow spot of ground, opening in his front into an extensive plain, while his rear was protected by a thick wood. According to the usual disposition observed by the Roman armies, the legionaries were stationed in the centre, flanked by the light armed and auxiliary cohorts; the wings being composed of cavalry. Suetonius did not tarry long in expectation of the enemy. The Britons soon appeared, covering the plain in immense numbers. Their wives and children, who had accompanied them to become spectators of a victory already considered as certain, were mounded in heaps on waggons, encircling the field in their rear, like an amphitheatre. Boadicea, with her two daughters, drove in a chariot along the ranks, encouraging her troops in animated language. She renewed the detail of Roman injustice: besought vengeance for the wrongs sustained by herself and her family; magnified the importance of the victory she had already gained, and assured her fol-

lowers that their enemies, forsaken by all the gods, would never be able to endure even their shouts of rage. She finished by exhorting them to conquer or die; which, she added, was her own resolution. Suetonius on his side did not neglect to animate his men by a faithful oration, and the acclamation and cheerful countenance with which it was received convinced him that he had every thing to hope from the bravery and discipline of his soldiers.

The Britons came on, uttering loud shouts, menaces, and songs of victory, while the Romans, closely drawn up, awaited the onset in perfect silence and at the requisite distance, made a first discharge of the pila with terrible effect. Preserving the advantage of the ground, they received the attack of the Britons with such firmness, as checked its impetuosity; till, having expended all their javelins, without the dreadful carnage of the enemy, they rushed forward from all parts at once, observing the form of a wedge, the more easily to penetrate such an immense multitude. This charge was seconded by the alms with equal ardour. The first ranks of their opponents were instantly borne down, and heven in pieces; but the rest crowded to surround the Romans, a bloody conflict commenced. The British war-chariots, whenever they succeeded in breaking in among their enemies, occasioned the most sanguinary destruction, ordering his men to direct their blows at the naked bodies of the drivers, by degrees discombed himself of these troublesome invaders. The action was long maintained with fury on both sides, the Britons, though destitute of order or discipline, fighting with great obstinacy and desperation; but, finally, the superior skill, coolness, and bravery of the Romans, bore down every opposition. Prodigious numbers perished beneath the swords of the legions, or by the charges of the cavalry, who trampled all before them; while the crowds that endeavoured to save themselves by flight, met with an insurmountable impediment in their own waggons, which enclosed them in form of a fence. Here the slaughter was terrible, for mercy in the circumstances of Suetonius, would have been in the highest degree imprudent. The Romans, in the heat of their fury, spared neither age nor sex. Even the beasts of burden, struck through with darts, increased the horrors of the scene, and the heaps of dead, which covered the plain, the fields, and the surrounding forests. Upwards of 80,000 Britons are computed to have perished on this occasion; while of the Romans about 400 were killed, and scarcely so many wounded.

Few victories, even in the most flourishing ages of the republic, deserved to be compared with this of Suetonius. Never had any been more decisive. The remaining rebels, terrified at the dreadful chastisement they had received, dispersed into their respective districts, and Boadicea herself perished soon after the battle, either through distress, or, as is the prevailing opinion, she ended her days by poison. P. Posthumus, whose disobedience had prevented the second legion from sharing in the triumph of their countrymen, fell upon his own sword, thus avoiding the punishment and disgrace which awaited his conduct. The vigour with which, though accompanied by acts of the most terrible severity, Suetonius pursued the revolted, restored tranquillity to the whole island before the ensuing spring. The indignities of individuals, and the jealousy of his venerable sovereign, occasioned his subsequent recall from his government; yet the triumphs obtained under his auspices, conferred everlasting honour and renown both on his own name and that of the legion he commanded.

Boadicea is described by Dion Cassius as a woman of large stature, strong and well proportioned in her limbs, of a manly

and stern countenance, harsh, authoritative voice, and possessing beautiful golden hair, which reached down below her waist. That she was possessed of uncommon abilities, or at least had persons of extraordinary talents to assist her, is evident from the rapidity with which she cut off the Roman garrisons one after another; the disposition of her forces, so as entirely to interrupt the communication between the quarters of the legions; the victory she obtained over Cerealis, famous himself for his military knowledge, and the extremities to which she reduced Suetonius, the greatest general of the age. Dion is loud in praise of her eloquence, and puts into her mouth several elaborate orations. We have preferred the authority of Tacitus, reserving, however, such passages of Dion as are most necessary to elucidate the narration. The defeat and death of Boadicea are said to have happened A. D. 61. Tacit. Annal. xiv. c. 31—37. Dion Cassius, Hist. Rom. lib. lxxii. cap. 11—12.

BOADJOOS, in *Geography*, called also *Oron Jaut*, or men of the sea, are a sort of itinerant fishermen in the East Indies, said to come originally from Johore, at the east entrance of the straits of Malacca, though some are of opinion, that they must have come either from China or Japan. They live chiefly in small covered boats, on the coasts of Borneo, Celebes, and the adjacent islands. Others dwell near the sea, on these islands; their houses being raised on posts, at a little distance in the sea, and always at the mouths of rivers. They are Mahometans; and have a language of their own, but no written character. Many Boadjoos are settled on the north-west coast of Borneo, who not only fish but make salt, and trade in small boats along the coast. Some of their boats are from 12 to 15 and 20 tons burden, and carry from 10 to 20 men, and form, in some places, a fleet of a hundred sail. Others of them are about 5, or 6 tons burden, which are managed by women, even in heavy seas. Their method of making salt is as follows; they gather sea-weeds, burn them, make a ley of ashes, filter it, and form a better kind of salt in square pieces, by boiling it in pans made of the bark of the anechon, or cabbage-tree; these pieces of salt are carried to market, and pass as a currency for money. Those that are settled on the north-west coast of Borneo used to supply the market at Balambangan with rice, fowl, and other provisions. Many of them are settled at the mouth of the river of Palan, who employ themselves chiefly in catching small shrimps with hand-nets, which they push through the mud; the shrimps, after being well washed with water, are exposed to a hot sun. They are then beat in a mortar, and made into a kind of paste, called *blanchong*, which has a strong smell, and is much in request all over India. These last Boadjoos may be considered as stationary or fixed, compared with those who live always in their boats, and who, as the monsoon shifts on the islands Borneo and Celebes, shift their situation to leeward, so as to be always under the lee of the land, for the sake of fine weather. Most of those who rove round Celebes, though they change their situation with the monsoon, consider Macassar as their home. Whilst the Boadjoos lie at anchor, in boats managed by their women, they are dextrous in fishing for *tripngs*, i. e. swallows, or sea-slugs, which they take in seven or eight fathoms water. When they see the swallow in clear water, they strike it with an instrument, consisting of four-bearded iron prongs fixed along an almost cylindrical stone, rather smaller at one end than at the other, about 18 inches long; an iron sheet is fixed at the end of the stone, next the point of the prongs. The swallow is dried in the smoke, and sent to the China market. They also dive for it, the best being found in deep water. The black is reputed the best; but there is some of a lighter colour, found only in deep water, which is more valued

valued in China than the black, and sold even for 40 dollars a picol: some of the pieces weigh half a pound. The white, caught in shoal water and on the dry sand, among coral rocks, is the worst; its value being about four or five dollars a picol. The Boadjoos are very useful to the Dutch East India company, in carrying intelligence speedily from place to place. St. vorinus's *Voyages*, vol. ii. p. 240.

BOADODA *Bashaw*, in the *Turkish Military Orders*, an officer of the *janizaries*, whose business it is to walk every day about the principal parts of the city, with a number of janizaries to attend him, to keep order and see that all things are regular, even to the dress. This office is for three months, and from this the person is usually advanced to be a *serub*.

BOÆ, in *Ancient Geography*, a town of Peloponnesus in Laconia, at the extremity of the Bœotian gulf. Diana was particularly worshipped in this place; Apollo and Esculapius had their respective chapels here. At some stadia from this city was a temple of Serapis and Isis. Pausanias.

BOAGRIUS, a river, or rather torrent, of Greece, in the country of the Epicnemidian Locrians, according to Ptolemy. Strabo says, that it watered the town of Thronium.—Also, a town of the same country, situate to the west, on the confines of Phocis.

BOANERGES, i. e. *Sons of Thunder*, in *Scripture History*, a name given by our Lord to the two apostles James and John (Mark, iii. 17.) which some have erroneously supposed to be an appellation of reproach, intimating a fierceness and furiousness of temper; whereas it is much more reasonable to consider it, with others, as a title of honour, prophetically representing the resolution and courage with which they would openly and boldly declare the great truths of the gospel, when they were made fully acquainted with them. How well they deserved this title, sufficiently appears in the sequel of their history. See JAMES, and JOHN.

BOANS, in *Zoology*, a species of RANA, or frog, the body of which is smooth, marked with contiguous spots beneath; and the feet palmated. Gmelin. Two varieties of this kind are described; β , having the upper part of the body blackish lead colour, and γ , with the body inclining to orange. Laurent. Amph. &c.

This kind inhabits America, and differs from *rana arborea*, the tree-frog, to which it is nearly allied, according to Gmelin, in having all the feet webbed, and the body spotted with white. Much confusion prevails respecting the Linnæan species, boans. Dr. Shaw suspects it to be the same as the *rana maxima* of that author, probably in a younger state. He mentions likewise another supposed variety, the *rana virginiana altera* of Seba.

BOAR, the *wild boar* or hog from whence the common hog derives its origin. See SCROFA Sus. The male of the tame hog is also called the boar.

The wild boar is a native of almost all the temperate parts of Europe and Asia, and is also found in the upper parts of Africa. Formerly it was an inhabitant of this country, as appears from the laws of Howel Dda, who permitted his grand huntsman to chase that animal from the middle of November to the beginning of December. (*Leges Wallicæ*, 41.) There are also many places in Wales that retain the name Peanarth, or the Boar's Head, to this day. William the Conqueror punished with the loss of their eyes any that were convicted of killing the wild boar, the stag, or the roebuck. (*Leges Saxon.* 292.) And Fitz-Stephen tells us, that the vast forest, which in his time grew on the north side of London, was the retreat of stags, fallow deer, wild boars,

and lulls. Charles I. turned out wild boars in the New Forest, Hampshire; but these were destroyed in the civil wars. (Pennant.) In France, Germany, Poland, and other countries on the European continent, they are still common, and the hunting of them is a principal amusement among parties of the gentry. Boar-hunting is a favourite diversion also in other more distant parts of the world.

These animals are found in the steppes of the Samara and the Volga, in Russia, on the confines of the river Ural in Daouria, and about the Irtysh. Between the Ural and the Yamba they are very numerous, and are hunted in winter by the Cossacks, not without danger, with dogs, and sometimes killed with carabines, and sometimes with lances. Although they feed solely on the roots of sea-weed and sedge, they grow to such an extraordinary size, that they are frequently found weighing upwards of six hundred pounds; their bacon is nearly four inches thick in fat, though their flesh is in general dry and firm and well-flavoured.

Sonnin thinks it probable (see his *Travels in Upper and Lower Egypt*, p. 348.) that the wild boars of Egypt are not the same with those in Europe. The great difference of climate, and the still greater difference of situation, must have occasioned at least some varieties in the species of these animals. More multiplied in temperate or cold countries, which appear more suitable to their nature, they inhabit the thick recesses of the forests, where they can find abundance of food: They never leave the woods but to pass from one to another, or to ravage the growing crops, and these predatory excursions are undertaken only by night. In general, they retire to the darkest and closest places at the rising of the sun, the brightness and heat of which they seem to dread. The wild boar of Egypt, on the contrary, has no shelter. Continually exposed to the rays of a burning sun, he roams over the hottest sands, where he with difficulty finds a few scattered shrubs, which afford him a scanty subsistence, and scarcely any shade. He is also frequently seen in the deserts of Nitria, which is the resort of a greater number of animals than any other part of the deserts, on account of the sheets of water it contains, and of the plants that grow on their banks. These boars are solitary, though a general want of food sometimes drives them in herds to the environs of the lakes of Natron. As the Mahometans and Copts do not eat the flesh of the wild boar more than that of the hog, and hold both these animals in equal abhorrence, it was impossible, says this writer, to procure a wild boar in Egypt, at least without seeking it in the desert. Upon the whole he concludes, that they are not the same as those of Europe. It is perhaps, he adds, in this sense only that we must understand the passages of Aristotle (*Hist. Nat.* l. viii. c. 24.), and Pliny (*Hist. Nat.* l. viii. c. 33.), who have asserted that there are no wild boars in Africa. Wild boars, says Buffon, are as common in Asia and Africa as in Europe. But he has given an account and a drawing of an African wild boar, which is remarkable for several particular characters; and hence there is reason to believe, that the "hanzire" of Egypt is the same animal as the wild boar of Africa.

Among huntsmen, the wild boar has several names according to its different ages: the first year it is called a pig of the faunder; the second, a hog; the third, a hog-steer; and the fourth, a boar. When leaving the faunder, he is called a singler, or fangler. The wild boar inhabits woods, living on roots, masts, acorns, and other vegetable food. Though gluttons, they do not attack other animals to devour them; but they eat flesh when they meet with it. They have been seen to eat horse-flesh; and the skin of the deer,

deer, and the claws of birds have been found sticking in their stomach, but this may be from necessity. Yet they are fond of blood, since they will eat their own young, or even children in the cradle, according to Buffon. Wild boars (says this writer) do not separate from their mothers until the third year, and till that age are called by the hunters *stock beasts*, or *beasts of company*. They never wander alone till they have acquired sufficient strength to resist the attacks of the wolf. These animals when they have young, form a kind of flocks, and it is upon this alone their safety depends. When attacked, the largest and strongest front the enemy, and by pressing all round against the weaker, force them into the centre. Domestic hogs are also observed to defend themselves in a similar manner. The wild boar is hunted with dogs, or killed by surprise during the night when the moon shines. As he flies slowly, leaves a strong odour behind him, and defends himself against the dogs, and often wounds them dangerously, fine hunting dogs are unnecessary, and would have their nose spoiled, and acquire a habit of moving slowly by hunting him. Mastiffs, with very little training, are sufficient. The oldest boars, which are known by the track of their feet, should alone be hunted: a young boar of three years is difficult to be attacked, because he runs very far without stopping; but the old boars do not run far, allow the dogs to come near, and often stop to repel them. During the day, the boar commonly keeps in his foil, which is the most sequestered part of the woods, and comes out by night in quest of food; and in summer, when the grain is ripe, it is easy to surprise him among the cultivated fields, which he frequents every night.

The boar lives to twenty-five or thirty years, if he escapes accidents. The time of going to rut is in December, and lasts about three weeks. They feed on all sorts of fruits, and on the roots of many plants; the root of fern, in particular, seems a great favourite with them; and when they frequent places near the sea-coast, they will descend to the shores, and demolish shell-fish. Their general places of rest are among the thickest bushes that can be found, and they are not easily put out of them, but will stand the bay a long time. In April and May they sleep more soundly than at any other time of the year, and this is therefore the successful time for taking them in the toils. When a boar is roused out of the thicket, he always goes from it, if possible, the same way by which he came to it; and when he is once up, he will never stop till he comes to some place of greater security. If it happens that a *saunder* of them are found together, when any one breaks away, the rest will follow the same way. When the boar is hunted in the wood where he was bred, he will scarce ever be brought to quit it; he will sometimes make towards the sides, to listen to the noise of the dogs, but retires into the middle again, and usually dies or escapes there. When it happens that a boar runs a-head, he will not be stopped or put out of his way by man or beast, so long as he has strength left. He makes no doubles or crossings, when chased; and when killed, makes no noise, if an old boar; but the fows and pigs will squeak when wounded.

The season for hunting the boar begins in September, and ends in December when they go to rut. If it be a large boar, and one that has lain long at rest, he must be hunted with a great number of dogs, and those such as will keep close to him; and the huntsman, with his spear, should always be riding in among them and charging the boar as often as he can to discourage him. Such a boar as this, with five or six couple of dogs, will run to the first convenient place of shelter, and there stand at bay, and make at them as they attempt to come up with him. There ought

always to be relays also set for the best and staunchest hounds in the kennel; for if they are young eager dogs, they will be apt to seize him, and be killed or spoiled, before the rest come up. The putting of collars with bells about the dogs' neck is a great security for them; for the boar will not so soon strike at them when they have these, but will rather run before them. The huntsmen generally kill the boar with their swords or spears; but great caution is necessary in making the blows, for he is very apt to catch them upon his snout, or tusk, and, if wounded and not killed, he will attack the huntsman in the most furious manner. The places in which the wound is to be given with the spear, are either between the eyes in the middle of the forehead, or in the shoulders; both these places make the wound mortal. When this creature makes at the hunter, his safety consists merely in courage and address; if he flies for it, he is surely overtaken and killed; if the boar comes straight up he is to be received at the point of the spear; but if he makes doubles and windings, he is to be watched very cautiously, for he will attempt getting hold of the spear in his mouth, and if he does so, nothing can save the huntsman but another person's attacking him behind. He will, on this, attack the second person, and the first must then attack him again. Two people will thus have enough to do with him; and were it not for the forks of the boar-spears that make it impossible to press forward upon them, the huntsman, who gives the creature his death's wound, would seldom escape falling a sacrifice to his revenge for it.

The modern way of boar-hunting is generally to dispatch the creature by all the huntsmen striking him at once; but the ancient Roman way was for a person on foot, armed with a spear to keep the creature at bay; and in this case the boar would run of himself upon the spear to come at the huntsman, and push forward till the spear pierced him through.

The hinder claws of a boar are called *guards*. In the corn he is said to *feed*; in the meadows or fallow-fields, to *root*, *worm*, or *fern*; and in a close to *graze*. The boar is farrowed with as many teeth as he will ever have; his teeth increasing only in bigness, not in number. Among these there are four called tusks, the two biggest of which are of no use to him when he strikes, serving only to whet the two lowest, which are his most formidable weapons of defence. As the boar advances in age, he becomes less dangerous, on account of the growth of those tusks, which turn up or take such a curvature, as rather to impede than assist him in wounding his adversary. The Ethiopian boar, or hog, is a still more fierce and dangerous animal than the kind found in Europe. In habits and manners they are pretty much the same, although specifically different; and, like the common boar, is capable of inflicting the most tremendous wounds with its tusks.

The flesh of the boar was esteemed a delicacy among the ancient Romans; a boar served up whole was a dish of state. The boar was sometimes also the military ensign borne by the Roman armies in lieu of the eagle. Certain writers of modern date speak of the flesh being unwholesome, except to those with athletic constitutions.

A remarkable circumstance concerning the wild boar is related by Sommius. In the year 1787, an animal of this kind, of a most extraordinary size, was killed in the neighbourhood of Cognac, in Angoumois, which had many times escaped from the hunters, had received many gunshot wounds, and had cost the lives of several dogs and men each time of attacking him. When this animal was at length slain, several bullets are said to have been found be-

tween his skin and flesh. Had not the above account been given by hunters of distinguished order, and too well acquainted with these animals to have made any mistake, it might have been imagined, that this formidable creature, which had long continued its ravages in the park of Cognac, belonged to a different species. It was of an enormous size, with a very long head, a very sharp or pointed snout, and its mouth was armed with teeth of a very singular form. The hairs of the body were white; those of the head yellowish; the neck marked with a black band in form of a cravat; and the ears large and straight; and what appears surprising, considering its size, it was of uncommon swiftness. For a further history of this animal, see SCROFA.

BOAR, in the *Manege*. A horse is said to *boar* when he shoots out his nose as high as his ears, and tosses in the wind.

BOARD, a piece of timber sawed thin, for the purposes of building. See **TIMBER**.

We say, a deal-board, an oak-board, &c. Boards thicker than ordinary are called *planks*. Boards formed ready for the coopers' use are called *clap-boards*. We have also mill-board, and scale-board, shaved very thin, for cases, hand-boxes, &c. Deal-boards are generally imported into England ready sawed, because they are prepared cheaper abroad, by means of saw mills. Clap-boards are imported from Sweden and Dantzick. Oak-boards chiefly from Sweden and Holland; some from Dantzick. Pipe-boards are brought from Dantzick. We also import white boards for shoe-makers; mill and scale-boards, paste-boards, &c. for divers artificers. Scale-board is a thinner sort, used for the covers of primers, thin boxes, and the like. It is sawed with mills, and imported from Hamburg.

BOARD, *feather-edged, graining, log, post, sound, trail, waste, weather*. See the several adjectives.

BOARD, is also used for a kind of table or bench, whereon several artificers perform their work.

In this sense, we say a work-board, a shop-board, a tailor's-board, &c.

BOARD, is also used for a flat machine, or frame, used in certain games, and the like.

In this sense, we say a draught-board, a chefs-board, a shovel-board, and the like.

BOARDS, in *Book-binding*. See **BOOK-BINDING**.

BOARD, *bureau*, is also used for an office where accounts are taken, payments ordered, and the like.

In this sense, we say the board of works, board of ordnance, board of treasury, and the like.

BOARD of green cloth. See **GREEN-CLOTH**.

BOARD of Controll, was first instituted in 1784, by stat. 24 Geo. III. sess. 2. c. 25. with a view of directing and aiding the East India company, in the executive government of India, and establishing a power of controul in this kingdom. This board was further established and regulated by the stat. 33 Geo. III. c. 52. the operation of which commenced in India on the 1st of February 1794. By the former act six persons were to be nominated by the king, as commissioners for the affairs of India; but by the latter, the number, instead of being limited to six privy-counsellors, is indefinite, depending upon the king's pleasure; of which number the two principal secretaries of state, and the chancellor of the exchequer are to be three; and his majesty, if he pleases, may add to the list two commissioners, not of the privy-council; and the person first named in the king's commission is to be president. The king may give 5000l. a year among such of the commissioners as he pleases; which, together with the salary of the secretary and officers, and other ex-

pences of the board, are to be paid by the India company; the whole not to exceed 16,000l. per annum. The members of this board and their officers are sworn to execute the several powers and trusts reposed in them, without favour or affection, prejudice or malice. The office of a commissioner, or chief secretary, is not to be deemed a new office, to disable them from sitting in parliament; nor is the appointment of a commissioner, not having a salary, or of a chief secretary, to vacate a seat. Three commissioners must be present to form a board. The powers of the board are to superintend, direct, and control all acts, operations, and concerns, which relate to the civil and military government and revenues of the British territorial possessions in India, subject to certain restrictions. They and their officers are to have access to the papers and records of the company, and to be furnished with copies or extracts of such of them as shall be required. They are also to be furnished with copies of all proceedings of general courts, and courts of directors, within eight days, and with copies of all dispatches from abroad, relating to matters of government or revenue, immediately after their arrival. No orders on those subjects are to be sent by the company to India, until approved by the board; and when the commissioners vary or expunge any part of the dispatches proposed by the directors, they are to give their reasons; and all dispatches are to be returned to the court of directors in 14 days. The directors may state their objections to any alterations, and the commissioners are to re-consider them; and if they interfere with what the directors deem matter of commerce, the directors may apply to the king in council to determine betwixt them. But the board is restricted from the appointment of any of the company's servants. If the directors, on being called upon to propose dispatches on any subject relating to government or revenue, shall fail to do so within 14 days, the board may originate their own dispatches on that subject. The board is not to authorize any increase of salaries, or any allowance or gratuity to be granted to persons employed in the company's service, except the same shall be first proposed by the company; and their intention and reasons for such grant are to be certified to both houses of parliament, 30 days before the salary can commence. The directors are to appoint three of their members to be a committee of secrecy, through whom dispatches, relating to government, war, peace, or treaties, may be sent to or received from India. This committee, and their clerks, are to be sworn to secrecy. Orders of directors, concerning the government or revenues of India, once approved by the board, are not subject to revocation by the general court of proprietors. For the further provisions of the acts, appointing the board of controul, see *East India COMPANY*.

BOARD of Ordnance. See **ORDNANCE**.

BOARD of trade and plantation, was established by king William, in the year 1696. Commercial matters had before this time been generally referred to a fluctuating committee of the privy-council; the obvious inconveniences attending this mode of management, induced king Charles II. to erect a special council of trade in the year 1668, which was soon after laid aside; it was renewed again in 1672, but soon discontinued, and the former method of reference to committees of the privy-council revived. In 1696, a regular and permanent board was established, for settling all disputes and regulations relating to commerce and colonies. This board, beside such of our ministers of state, who only attended on extraordinary occasions, consisted of a first lord commissioner, and of seven other commissioners, with an annual salary of one thousand pounds each. This board was abolished in 1780.

BOARD of trade, bureau de commerce, an office in the French polity,

polity, established in 1723, composed of eight persons of experience in commerce and navigation, where all papers and proposals relating to the improvement of trade are examined, and all difficulties which occur in affairs of navigation and commerce, either within or without the realm, are discussed.

BOARD-WAGES, denote a certain annual sum allowed to household servants for maintenance. Board-wages, granted to the menial officers and servants of the crown, commenced in 1629, when the necessities of king Charles obliged him to retrench the expence of his household, by abolishing the greatest part of the daily tables in his palace, which were eighty in number, and substituting this annual allowance in their room.

BOARD, or ABOARD, in the *Sea Language*, is used in speaking of things within a ship or other vessel.

Hence, to go *aboard* signifies to go into the ship; to heave *over-board*, is to throw a thing out of the vessel into the sea; to slip by the *board*, is to slip down by the ship's side; to fall *a-board* of, is to strike or encounter another ship, when one or both are in motion; to keep the land *a-board*, or to keep hold of the land, is to steer near to, or in sight of the land; *board and board*, is when two ships come so near as to touch one another, or when they lie side by side. *Weather-board*, is that side of a ship which is to windward. To *board a ship*, is to enter an enemy's ship in an engagement. See **BOARDING, infra**.

Board denotes the distance run by a ship at one tack; and hence to *make a board*, or as it is otherwise expressed, to *board it up* to a place, is to turn to windward; and to beat sometimes upon one tack, and sometimes upon another; in which it is to be noted, that the farther you stand off to one point of the compass, the better board you will make; and that it is better making *long boards* than short ones, if you have sea-room. A *long board* is when you stand a great way off before you tack or turn; a *short board* is when you stand off a little; a *good board* is when a ship does not go to leeward of her course, or advances much at one tack, and sails upon a straight line. To leave a land on *back-board*, is to leave it a-stern, or behind; the *back-board*, being that which in boats or ships, we lean our backs against. *A-board* main-tack, the order to draw the main-tack; i.e. the lower corner of the main-sail, down to the chees-tree. See **CHESS-tree**.

BOARD, Lar, and Starboard. See **LARBOARD** and **STARBOARD**.

BOARDED Floor. See **FLOOR**.

BOARDING, in *Naval Tactics*, denotes the art of approaching the ship of an enemy so near as to admit of the grapnels, which are fixed on the lower yard-arms, at the forecastle, gang-ways, &c. being thrown into it, for the purpose of securing the vessels together, and of entering her decks, with a detachment of armed men. The method of conducting or of avoiding this kind of attack depends upon the relative situation of the contending ships; and varies, as it is to be performed to windward, to leeward, with the wind at large, or when the ship proposed to be boarded is at anchor.

In the first case, when the enemy's ship keeps her wind under an easy sail, and is overtaken in a chase by those who intend to board her, the vessel of the latter must get on the weather-quarter of the former, within half a pistol shot. She should then begin and continue a brisk action, so that the smoke of the cannon and musquetry of both ships may conceal her manœuvres; and, under the cover of this cloud, she should increase her sail, if she has not way enough, in order to augment her velocity and the rapidity of her move-

ments, that she may more readily lay on board the enemy, on the weather-side, either exactly abreast or a little abaft. This may be easily done, by edging down suddenly upon her, but avoiding being raked by the enemy's fire. By this manœuvre the grapnels will be on board of the adverse ship, before or very soon after she suspects the design of the boarders. In this situation, the vessel proposed to be boarded can recur only to one precarious expedient, which, duly observed by the boarder, will be of little or no avail. For when she braces sharp a-back her head sails, to cause the ship's falling off, and squares those aft, to give her stern-way, the boarder, by performing briskly the same manœuvre, will be as well situated for boarding as before; provided the boarding ship feels the impulse of her sails and helm, which ought to be put a-weather, and kept so till the ship's head-way ceases, when it is to be put a-lee, to assist her in falling off, in order to board the enemy to lee-ward; for the boarder ought to be on the quarter of the other, since at the moment the two ships were right before the wind, she who was directly to windward and wished to board, had only to continue her movement of rotation, and render her velocity equal to that of her adversary, by shortening sail in order not to pass her. If, therefore, the circular motion is kept up by the boarder, which at first caused him to fall off, and now brings him to the wind on the other tack, he will join the enemy to lee-ward; for it is evident that, if this motion of turning be more rapid than that of the ship which wishes to avoid boarding, the boarder will close with her before she can range to the wind on the other tack, since the boarder comes round with greater celerity. However, if the ship which fears boarding was pressed thus closely, she could make no other attempt than to throw once more all her sails to the mast, by bracing them only perpendicular to the keel to give her stern-way, and putting the helm a-weather, to keep her to the wind, as soon as her head-way ceases; observing that, as she is to windward, she may be thus driven on the boarder, who watches for her under her lee. But necessity obliges her to adopt this only expedient; because, if she could go a-stern with sufficient velocity, she might let the boarder pass a-head, veer under his stern, and rake him, if he does not anticipate this manœuvre, and as quickly manœuvre in the same manner, the great velocity with which he comes to the wind, and goes a-head, his sails being still full, reducing him to this state, which may prevent his persisting in the design of boarding. Nevertheless the boarder may attain his purpose, if he throws all his sails a-back at the same time as the ship to windward; because, the attacked ship dropping to leeward, and having stern-way first, approaches the boarder, who has preserved his position on the quarter, and longer kept his luff, by having gone a-stern somewhat later than the weather ship. It should also be observed, that when the two ships are right before the wind, if the vessel which fears boarding moves more quickly to the wind than the one which attacks, she will avoid it, as the retreating ship will be close to the wind before the other, and able to get a-head of her, by making all sail to keep her wind, or to heave in stays, and get upon the other tack. This last movement, however, is disadvantageous; because it will present the stern to a ship, which will avail itself of that situation, and rake her, and this may be more destructive than a well opposed attack by boarding. After all, if the ship that is inclined to board sails better than the other, she will always have it in her power to execute her purpose, if she is as well manœuvred as the ship which endeavours to escape.

In the second case of boarding to leeward, when close to the wind, the boarder should arrive within pistol shot, close in

BOARDING.

the wake, or, at most, to the weather quarter of the ship against which the attack is meditated; taking care to continue steering, so as not to be raked by any of the guns that belong to the quarter on which he stands. In order to come up with his adversary, he must edge away a little, and range round aft, so close upon the enemy's lee-quarter, that his cat-head may almost touch her quarter-gallery. When the ship has shot sufficiently a-head, and is parallel to that of the adversary, the fore-castle being a-breast of the enemy's main-mast, the mizen and mizen stay-sail sheets are to be well hauled out, the helm put hard a-lee, and the head-sheets let fly; then the ship, coming rapidly to the wind, shivers her sails, and closes with the opposing vessel side to side. In executing this manœuvre, which cannot fail to succeed with the advantage of sailing, great attention is necessary; because, if at this moment the weather-ship, which wishes to avoid being boarded, either sets her courses, or lays all these flat a-back which she had set, she may chance to break the grapnels, if the sails of the boarding vessel have not been trimmed like those of the other; for, by making more full if the wind be a little fresh, she will shoot a-head through the water, and drag the boarder with such force as to break the chains or hawsers by which the two ships are confined together. By laying all flat to the mast the boarded vessel is still more likely to succeed, since the sails of one ship will be full, while those of the other are a-back.

This mode of boarding may be avoided, if the boarder does not pay strict attention to his own manœuvres, as well as to those of his adversary; and it may be more readily avoided, if the adversary's vessel braces her head-sails sharp a-back, setting only, if necessary, the fore-sail, at the same instant laying to the mast or shivering, according to the necessity for more or less stern-way, all those which are abaft, and putting the helm hard a-lee. This is to be executed, when the boarder is about a ship's length a stern of the other vessel. The quickness of this evolution, and the rapid veering of the weather-ship, may bring the boarding vessel, which is a little to leeward or a-stern of the other, into the most dangerous situation, if she does not manœuvre in the same manner, and with equal celerity; as the boarder's sails being full, keep up his velocity, and may, before he can veer, engage his bowsprit in the main shrouds of the enemy, who pays short round on her head. Those who wish to board a ship, and to engage the enemy's bowsprit in their main shrouds, need only to get a little to windward of her, and about one or two ship's lengths a-head, according to the estimated celerity of their movements; then brace sharp a-back the head sails, shiver the after-ones, or lay them flat to the mast, with the helm a-lee. This manœuvre, well performed, and covered by a brisk fire, will commonly succeed; but care must be taken not to come round too soon, but to range very close to the adversary; because if the boarding vessel be not sufficiently a-head of him, it might fail in boarding by paying too short round, and its bowsprit get foul of his fore shrouds, which would be very disadvantageous. The design will be frustrated, if the boarding ship being too far a-head, passes under the bowsprit of the enemy, who will thus, however, be exposed to be raked at his head, if he does not manœuvre in the same manner and equal quickness as the boarding vessel, which has the great advantage of priority. In order to engage the bowsprit of the enemy's ship in the rigging of the boarding vessel, this should be ranged very close to the other; because, if this were attempted at only a ship's length large, and to windward of the enemy, he need merely, upon perceiving the design, to put the helm hard a-lee, and heave in stays. If this last method be properly executed, the two ships can

only range very near each other, and exchange their broadsides, and the lee-ship will immediately gain the wind of her adversary. Consequently to execute this manœuvre well, the vessels must be nearly yard-arm and yard-arm.

If the boarder be at a certain distance aft on the weather-quarter, the ship wishing to avoid boarding must heave in stays, as soon as the other vessel is in the act of veering, in order to close with her to leeward. By this manœuvre they will come head to head, so that they may reciprocally fire their broadsides, in passing on opposite directions, and the lee-ship will get to windward.

In the third case, when two ships engage with the wind large, the boarding vessel should keep as close as possible on the lee-quarter of the ship she means to attack by boarding, that she may execute her purpose by coming rapidly to the wind, and being careful not to pass a-head of her opponent. The weather-ship, in order to avoid being boarded, must act according to circumstances, in the manner directed in the last case. A ship may be boarded on the weather-side, by conforming to the instructions relating to boarding to windward. When two vessels are engaged with the wind right aft, the boarder ought to drop a-stern of the enemy, in order to run up close along-side of him, if the boarder has the advantage of sailing; for, as she then advances towards her adversary, the adversary can only endeavour to range rapidly to the wind on the other tack, as soon as the bowsprit of the boarder is a-breast of her stern, and thus gain the wind, in order to be in a situation to extricate herself more easily by a good manœuvre. The boarding vessel should be allowed to come a-breast of the stern of her adversary, before she hauls her wind; because, if this were done sooner, the ship a-stern, at a small distance, would board her perfectly well, even if she sailed with equal celerity, since the boarder would be to windward, would run large longer than the other, would range more slowly to the wind, and continue to stem a-head of the flying ship. This will appear more evident by considering, that the boarder coming from windward preserves his velocity longer, trimming his sails only as the ship comes to the wind, and cuts the course of his adversary with a line less curved than that described by the retreating ship. If, by coming too soon or too fast to the wind, the boarder chose to abandon his design, he might do so by veering a few points on the other tack, and shortening sail; so that the retreating ship will shew her stern, and the boarder can then rake her by passing under her stern.

In attacking a ship closely to leeward, the boarder should keep away a little when abreast of her, and seem to yield under her fire. If the enemy's ship should thus be induced to veer, in order to bring the boarder more under her guns, the latter should heave rapidly to the wind, by putting the helm a-lee, trimming all sharp a-baft, and suppressing the effect of the head sails; which should be done at the instant when the enemy is perceived to be bearing down. The two ships will by the quickness of this manœuvre, and the priority of the movement thus gained on the enemy, soon close, and, with proper attention, the enemy's bowsprit may be entangled in the fore or main rigging of the boarding vessel, which would be a favourable circumstance in the attempt to board. However it may happen that no attempt can be made to board, if the weather-ship, instead of bearing away, plies more and more to leeward; for this faint manœuvre may take the boarder too far off to leeward of the adversary. If the boarder should chance to be a ship's length to leeward, and about the same distance a-head of the enemy's vessel, it may, under cover of a heavy fire, heave in stays; and thus come right athwart the enemy's hawse, rake him fore and aft, and board him, his bowsprit being
right

right over the enemy's gang-way; nor can he possibly avoid a broadside; for if he heave all a-back and make a-stern board, which is his only resource, he may avoid being boarded, but his situation will be very perilous.

In the last case of boarding a ship, which is at anchor, riding head to wind, it must be executed under sail; for if the boarder cannot approach the enemy except by towing a-head, he will never be able to board the latter against his will; because he will be always able to annoy the boats which are laying out the tow-lines. It should not therefore be attempted, unless the boarder be under way. In order to perform it with success, the boarder must be sufficiently to windward to approach the enemy by a little falling off, without exposing his stern to the fire of the latter, which in this situation might be played on with great advantage. If the boarder, then, should be thus to windward, so as to be able to approach the enemy at anchor, he ought to stop his head-way, by taking a-back his mizen top-sail and fore-day-sail; and when about a ship's length from the vessel proposed to be boarded, let go an anchor, and then work, so that, as soon as the mizen top-sail is taken a-back, the mizen close aft, the top-sails clued up, and the fore-topmast stay-sail hauled down, he may come head to wind, and veer away cable, till, by falling off, he comes board and board with his opponent, who is still riding at his moorings, and who at that instant ought to be also raked by the boarder. This is the only method of manœuvring to which the boarding ship can recur; because, as soon as the anchor is gone, the ship acquires stern-way, and when the cable is checked, she runs head to wind, in which she is much assisted by the mizen and mizen top-sail, which impel her stern to leeward, till the wind is right in the direction of the keel; and, as the cable is veered away, till exactly along-side the ship at anchor, her own anchor being right a-head of the vessel she means to board, it follows that, as soon as the boarding ship comes head to wind, she is in a proper situation to throw her grappels, and send her crew on board of the other, if they are the strongest.

The ship at anchor should never wait for the enemy in that situation, which is always disadvantageous, and as there is much greater probability of escape when under way. But if it be necessary for the enemy to continue at anchor, he should take advantage of the boarder's ship letting go her anchor, to cut the cable by which she rides; and by this manœuvre fall athwart, rake the boarder, avoid being boarded, and bring up with the lee anchor. If time allow, two springs should be cast out, one on each side of the cable by which the ship rides, if there have been no previous opportunity for laying out two anchors, and thus guard against surprise, in case the ship which attacks has it in her power to pass on either side of the other; and when the side for which she is determined is perceived, the assailed should heave on the spring which is on the same side she has let go her anchor, if she be a-head, and on the opposite, if she be a-stern, veering out at the same time the other spring and cable, till the assailant be brought right a-breast. Then he may be raked at pleasure, as he has no way of escape. His only course to prevent danger would be having also a spring; and under cover of a brisk fire, veering upon that spring and cable to lay his enemy handsomely on board. But if this precaution should have been neglected, he must cut his cable, and drop on board of the ship to leeward; who on the other hand, has no mode of avoiding being boarded, but by cutting, to get under way, or to run on shore.

It is always easy to board a ship at anchor, when the wind will allow approaching to her under sail; in which case it is most advisable to run her along side, or to bring-to to

windward of the ship intended to be attacked, keeping her exactly to leeward; then to drift on board of her, by trimming the sails in such a manner as to keep as nearly as possible the broadside of the attacking vessel opposite to that of the adverse ship. In this situation the boarder should annoy the enemy with his guns till he can close with him; and by constantly cannonading, his fire may not be so well served as it otherwise might be. If, whilst a vessel is under way, it be proposed to board a vessel that is moored, an anchor should be let go at the time of boarding; for if the attacked ship should at this moment cut her cables to drive on shore, this would prevent the assailant and the assailed running a-ground together. Elements and Practice of Rigging and Seamanship, vol. ii. Boarder's Manœuverer, or Skillful Seaman, &c. translated from the French by Saufeuil, 4to. 1788.

BOARDING-netting, in *Ship Rigging*. See NETTING.

BOARI, in *Geography*, a village of Africa, on the Gold Coast, situated between Sukonda and Sama, where the Dutch had formerly a small factory, which was afterwards removed to Sama.

BOARI LAPPA a name given by the antient Romans to the fruit or rough balls of the common sparine or cleavers. Pliny calls this plant sometimes *lappa*, sometimes *lappago*; and the fruit by the names of *lappe boaria*, or *lappe canina*, and sometimes *canaria*.

BOARINA, BOAROLA, in *Ornithology*, the name of a small bird, described by Aldrovandus and others. This is the fig-eater of Albin and Latham; and *Motacilla Nevois* of Gmelin.

BOARULA, a species of MOTACILLA, called in England the grey wagtail. The colour of this bird is cinereous above, beneath yellow; tail feathers dark, and pale at the edges. This is an European bird, about seven inches and a half in length, and, like the rest of the wagtail tribe, frequents watery places. They are lively, active birds, perpetually flirt the tail, and seldom perch, but rest upon the ground. They feed chiefly upon insects. The nest of this species is made on the ground, and is composed of dried fibres and moss, lined with wool or feather, and usually contains from six to eight eggs, which are of a dirty white, marked with yellow spots. They breed in the north of England, seldom approaching nearer to the southward than Cumberland, till after the month of October. Linn. Donov. Brit. Birds, pl. 40, &c. *Le Bergette*, of Belon; and *la Bergonette jaune*, of Brisson, is of this species.

Obs. A variety of *Motacilla Boarula* inhabits Java. The colour is an olive brown, beneath yellow; lower part of the neck grey; first tail-feather entirely white; inner side and tip of the second and third white.

BOAS, in *Entomology*, a species of SCARABÆUS, that inhabits Sierra Leona. The thorax is retuse, excavated, bidentated; horn of the head recurved and simple. Fabricius.

BOAT, a small vessel, generally without a deck, managed by sails or oars, or drawn by horses upon canals, rivers, or lakes, for the purpose of conveying passengers, goods &c. from one place to another. The form, equipment, and names of boats are different according to the purpose for which they are intended, or to the country where they are built. Hence, boats are made slight or strong, sharp or flat-bottomed, open or decked, plain or ornamented, as they may be designed for swiftness or burden, for deep or shallow water, for sailing in a harbour or at sea, and for convenience or pleasure.

As boats make always a necessary appendage to ships it

BOAT.

will, therefore, be proper to give a brief account of those belonging to the different classes of shipping.

Ships of war, particularly of the line, have usually six boats, and the number decreases with the rate of the ship. The largest is called the *long-boat*, and sometimes the *launch*; and its principal employment is to convey heavy stores to the ship. This boat is generally furnished with a mast and sails, and is occasionally decked, armed, and equipped, for cruising short distances against merchant ships of the enemy, or smugglers, or for impressing seamen, &c. The *barge* is the next less boat, and is particularly appropriated to carry the principal sea officers, as the admiral, captain, &c. to or from the ship; and in consequence of its slender construction, combined with its small breadth, is very unfit for sea. This boat never rows less than ten oars. The *pinnace* is similar to the barge, but smaller, never rows above eight oars, and is used by lieutenants in going ashore, or coming off to the ship. *Cutters* are broader, deeper, and shorter than the former; they are employed on almost all occasions, as for going ashore, carrying stores, provisions, boarding ships at sea, &c. *Jolly-boat* is the smallest boat used in any of the ships in his majesty's service. In *Plate VI* of *Ships* are perspective views of a man of war's long-boat, of a barge, and flat-bottomed boat.

In an East Indianman there are four boats, the *long boat*, *cutter*, *jolly-boat*, and *yarwl*. The first of these is for conveying stores and goods to and from the ship; the second for going ashore; and the others are employed occasionally.

Ships in the West India trade use boats in number and size according to the islands at which they intend to take in their cargo. Four boats generally belong to a ship in the Jamaica trade. The largest, called a *shallop*, will carry from eighteen to twenty hogheads of sugar. The next less in size is usually called a *ten hoghead boat*, from the number of hogheads it carries; these two are left in the country. The next less boat called a *double moses*, or *pinnace*, carries two hogheads a short distance; and the smallest boat is called the *jolly-boat*, and is generally suspended from the taffrail.

Ships in the Windward Island trade, loading at Barbadoes, Martinico, Dominica, &c. generally use a flat launch with skeeds, each about thirty-six feet long, one end being upon the boat's stern, and the other upon the beach, upon which the sugar hogheads are rolled from the beach into the launch. At St. Vincent's, Grenada, and Tobago, a one hoghead moses is used. At Trinidad a launch as flat as can be built is used. At Demerara, Berbice, and Surinam, they generally use sailing craft that will carry from twelve to twenty hogheads.

Ships employed in the whale fishery have six or more boats. These are very narrow in respect to their length, for the purpose of pulling fast; they are strong built, and sharp at both ends.

Smaller vessels of one hundred tons and under, have in general one boat.

Bachot, a fishing boat on the rivers in France; it is provided with a mast, oars, fishing lines, a staff, a pole to fasten their boat on the river when they are fishing, &c.

Balza or *balsa*, a boat, or rather raft, composed of five, seven, or nine logs or trunks of trees, used in South America. This boat is so called from *balza* or *balsa*, the name of the wood of which it is constructed, but which is called *puero* by the Darien Indians. The *balza* is a whitish spongy wood, and so very light that a boy can easily carry a log four yards long and a foot in diameter. The following account of this boat is extracted from the *Relacion Historica del Viage a la America Meridional*, *necho de Orden*, de S. Mag, &c. *Impressa de Orden de Rey en Madrid*, 1748.

The *balzas* are not only adapted to this river (Guayaquil),

but venture to sea, and carry on the trade as far as Payta. Their dimensions are proportionate to their use, or the voyage for which they are intended; some being only for fishing, others for the river trade, bringing fruits, and all sorts of merchandize from Bodega to Guayaquil, and from thence exporting them to Puna, Salto de Tumbez, and Payta; others are yet more commodiously contrived for carrying families, with all their furniture and necessaries, to their plantations or country houses. The *puero* trees, of which they are built, are twelve or thirteen toises long, reckoning five feet to the toise, and two feet, or two and a half diameter, so that the whole breadth of nine logs, of which some of them consist, is between twenty and twenty-four feet; and those of seven or fewer logs are proportionate.

These logs are fastened to each other only by the *bejuco*s or withies, with which the cross logs are also lashed to them, yet so securely as never to give way, if not worn out by long use, though in their voyage to the coast of Tumbez and Payta the sea runs very high; but the negroes neglecting to examine if the *bejuco*s are not too much worn to sustain another voyage, before they put to sea, it too often happens that the lashing breaks, the logs separate, and both cargo and passengers perish: indeed the Indians, being more active, get upon a log and safely work it to the nearest harbour. One of these melancholy instances happened while we were in the jurisdiction of Quito, and are wholly to be imputed to the sordid negligence of the Indians, who seem to have no sensibility of danger.

The thickest log of the *balza* is placed so as to reach farther than the others; at the stern, another log is lashed to this, on each side, and others to these, till the intended number be completed, which is always odd; the large one in the middle being, as it were, the stay and foundation of the others. The larger sort of these vessels usually carry about twenty-five tons, without damaging the cargo in consequence of its being too near the water's edge, for the sea never breaks over them, nor does the water swell between the logs, or ever rise above them, because the whole body of the vehicle accommodates itself to the motion of the water in all weathers.

These rafts work and ply to windward like a keeled vessel, and keep their course before the wind almost as exactly, which is the effect of another contrivance besides the rudder; some large planks, three or four yards long, and half a yard broad called *guares*, are set up vertically at the stern, and also forward between the main logs. By pushing some of these under the water, and taking others a little up, the float sails large, bears up, tacks, or lies to, according as the machine is worked; an invention which has hitherto escaped the acuteness of the most ingenious Europeans; and though the Indians have indeed contrived the instrument, yet they are utter strangers to the principles of mechanics, and the causes of its operations.

Had it been known before in Europe, the loss of many lives in shipwreck might have been prevented, as appears by the following, among many other instances: in the year 1730, the Genouefa ship of war, being lost in the Vivora, the mariners made a *jangada*, or raft, to save their lives, but miscarried by committing themselves to the winds and currents, without any steering; and the frequency of such melancholy events induces me to give a minute explanation of this instrument, from a memoir of Don Jorge Juan, relating to it.

The direction in which a ship moves, when under sail, is in a line perpendicular to the sail, according to the demonstrations of Renau, in his *Theory of Manual Arts*, cap. ii. art. i. Bernouilli, cap. i. art. 4; and Pitot, sect. ii. art. 13. The

re-action being equal, and opposite to the action, the opposition of the water to the motion of the vessel will also be in a direction perpendicular to the sail, from leeward to windward, and the impulse of a longer body exceeding that of a smaller, supposing the motion of both to be equal, it follows that, upon one of the fore guares being thrust under water, the vessel will lie to, and bear up again, if it be taken out; and by a parity of reasoning, an after one being thrust under water will cause the ship to bear up and to lie to, on its being taken out. The way used by the Indians, in managing the balza, is to increase the number of guares to four, five, or six, to keep her to windward; for it is evident that the more there are under water the greater will be the lateral resistance, which is thus increased by the lee-boards used in smaller vessels, and for the same purpose. These guares so effectually answer the end for which they are intended, that, when once the balza is underway, only one need be worked; and by thrusting it down or raising it up a foot or two, the vessel is kept in a right course. *Plate I. of boats*, contains a perspective view of a Balza.

Barge, the second boat in a ship of war, as mentioned above; a vessel employed in carrying merchandize in the river Thames, with one mast. See also the article *BARGE*.

Bum boat, a small boat employed in felling vegetables, &c. to vessels lying at a distance from the shore.

Bunder boat, a boat at Bombay for carrying off pilots to a ship, and taking passengers ashore.

Chalaud, a boat navigated on the river Loire in France; these boats are narrow and low, for the purpose of more easily passing through the locks of canals: they are principally used in carrying wines and other productions, and merchandizes of the provinces, which lie near the Loire and Allier.

Coolie, a boat employed as a wherry at Bombay; it has one mast, with a considerable rake forward, and sails very fast.

Felucca, is a strong passage-boat used in the Mediterranean, having from 10 to 16 banks of oars. The natives of Barbary often employ boats of this sort as cruisers.

Ferry-boats, are used for conveying passengers, goods, horses, cattle, &c. across a river or branch of the sea; and, therefore, are of different dimensions and forms of construction accordingly.

Fishing boats, are of various kinds; those employed in the salmon fishing, which is generally in rivers, or at the sea shore, and commonly called *colles*, are narrow at one end, and broad at the other, for the purpose of making up the net upon it, and from which the net is let into the river or sea. Boats employed in the white fishery, that is, in taking ling, cod, haddocks, &c. are pretty large; some carrying ten tons and upwards, with two masts, with a square or lug-sails, and strong built so as to endure a rough sea; they are usually and unequally sharp at both ends, the sharpest end being the bow. Decked vessels called *snacks* having one mast, or *luggers* with three masts, are employed in this fishery.

Flat-bottomed boat, is so constructed for taking the beach easily, for the greater convenience of landing troops with their baggage, accoutrements, &c.

Flotts, boats of the master ferryman at Paris. The ordinance of that city, made in the year 1672, enjoins them to keep their boats always provided with daves and oars; and to have a sufficient number of boats ready at the places and services appointed by the provost of the merchants and echevins.

Foncts, boats which navigate on the river Seine; they are large, long, and strong; they come from Roan, and from the river Oise, and are commonly used to carry great loads of wood for fuel, also goods, &c.

Gig, a small light boat, usually suspended from the taffrail of a ship.

Holland, Boats of. In almost all the Seven United Provinces there are boats which serve for public carriages, which set out from every city at all hours of the day, and carry passengers very conveniently from one place to another, at a very small expence. They are long, narrow, and covered, and contain about sixty persons; each boat is drawn by one horse, and has only two men to manage it, the one attends the helm, and the other takes care of the rope; the horse is generally rode by a boy. In these boats there is a room which can easily contain six persons; this room, which is called a *roof*, has glass windows, whereas the other openings in the boat are shut with oil cloth in bad weather. A passenger may take a place in this room, or the whole room. Those boats which carry goods from Amsterdam to the Hague, and which leave Amsterdam at eight at night, arrive at the Hague next morning. In those boats, however, designed for passengers only, a person is obliged to change boat several times. From Amsterdam to Haerlem he must change boats half way, because the canal there is cut by a dyke. At Haerlem, the passengers must cross the town to get to the boat that is to carry them to Leyden. At Leyden, he must again cross the town to meet the boat in which he is to go to the Hague. All this can be performed in ten hours and a half; for, at eight o'clock precisely, a boat sets out from Amsterdam to Haerlem, where it arrives about half an hour after ten; at eleven a boat sets out from Haerlem for Leyden, and arrives there at three in the morning; half an hour after three a boat sets out from Leyden, and arrives at the Hague half an hour after six. There is such good order kept, that at the ringing of a bell the boat must set out immediately, without waiting for any passenger. There are few countries where people can travel so conveniently as in Holland.

Ivahab, a boat or canoe of the Society Islands, of which captain Cook gives the following description. The ivahah is used for short excursions at sea. These boats are all of the same figure, but of different sizes, and used for different purposes; their length is from ten to seventy-two feet, but the breadth is by no means in proportion; for those of ten feet are about a foot wide, and those of more than seventy are scarcely two feet. They have the fighting ivahah, the fishing ivahah, and the travelling ivahah, for some of these go from one island to another. The fighting ivahah is by far the longest; and the head and stern are considerably raised above the body, in a semicircular form, particularly the stern, which is sometimes seventeen or eighteen feet high, though the boat itself is scarcely three feet. These never go to sea singly, but are fastened together side by side at the distance of about three feet, by strong poles of wood, which are laid across them, and lashed to the gunwales. Upon these in the fore part, a stage or platform is raised about ten or twelve feet high, and somewhat wider than the boats, which is supported by pillars about six feet long; upon this stage stand the fighting men, whose missile weapons are slings and spears; for, among other singularities in the manners of these people, their bows and arrows are used only for diversion as we throw quoits; below these stages sit the rowers, who receive from them those that are wounded, and furnish fresh men to ascend in their room. Some of these have a platform of bamboos, or other light wood, through their whole length, and considerably broader, by means of which they can carry a great number of men. The fishing ivahahs vary in length from about forty feet to the smallest size, which is about ten feet; all that are of the length of twenty-five feet and upwards, of whatever sort, occasionally carry sail. The travelling ivahah is always double, and furnished with a small neat house, about five or

six feet broad, and six or seven feet long, which is fastened upon the fore part, for the convenience of the principal people, who sit in them by day, and sleep in them at night. The fishing ivahals are sometimes joined together, and have a house on board, but this is not common. Those which are shorter than twenty-five feet, seldom or never carry sail; and though the stern rises about four or five feet, they have a flat head and a board that projects forward about four feet. The ivahals are the only boats used by the inhabitants of Otaheite.

Life-boat, a boat invented by Mr. Henry Greathead of South Shields, for the purpose of preserving the lives of shipwrecked persons. The following circumstance gave rise to this invention:

In September 1789, the ship *Adventure* of Newcastle, was stranded on the *Herd* sand, on the fourth side of Tyremouth haven, in the midst of tremendous breakers; and all the crew dropped from the rigging one by one, in the presence of thousands of spectators, not one of whom could be prevailed upon, by any reward, to venture out to her assistance, in any boat or coble of the common construction.

On this occasion, the gentlemen of South Shields called a meeting of the Inhabitants, at which a committee was appointed, and premiums were offered for plans of a boat which should be the best calculated to brave the dangers of the sea, particularly of broken water.

Many proposals were offered; but the preference was unanimously given to that of Mr. Greathead, who was immediately directed to build a boat at the expence of the committee.

This boat went off on the 30th of January 1790; and so well has it answered, and indeed exceeded, every expectation, in the most tremendous broken sea, that since that time, not fewer than two hundred lives have been saved at the entrance of the Tyne alone, which otherwise must have been lost; and in no instance has it ever failed.

The principle of this boat appears to have been suggested to Mr. Greathead by the following simple fact.—Take a spheroid, and divide it into quarters; each quarter is elliptical, and nearly resembles the half of a wooden bowl, having a curvature with projecting ends; this, thrown into the sea or broken water, cannot be upset, or lie with the bottom upwards.

The length of the boat is thirty feet; the breadth, ten feet; the depth, from the top of the gunwale to the lower part of the keel in midships, three feet three inches; from the gunwale to the platform (within), two feet four inches; from the top of the stems (both ends being similar) to the horizontal line of the bottom of the keel, five feet nine inches. The keel is a plank of three inches thick, of a proportionate breadth in midships, narrowing gradually towards the ends, to the breadth of the stems at the bottom, and forming a great convexity downwards. The stems are segments of a circle, with considerable *rakes*. The bottom section, to the floor-heads, is a curve fore and aft, with the sweep of the keel. The floor timber has a small rise curving from the keel to the floor-heads. A bilge plank is wrought in on each side, next the floor-heads, with a double rabbit or groove, of a similar thickness with the keel; and, on the outside of this, are fixed two bilge-trees, corresponding nearly with the level of the keel. The ends of the bottom section form that fine kind of entrance observable in the lower part of the bow of the fishing boat, called a *coble*, much used in the north. From this part to the top of the stem it is more elliptical, forming a considerable projection. The sides, from the floor-heads to the top of the gunwale, flaunch off on each side, in proportion to

above half the breadth of the floor. The breadth is continued far forwards towards the ends, leaving a sufficient length of straight side at the top. The sheer is regular along the straight side, and more elevated towards the ends. The gunwale fixed to the outside is three inches thick. The sides, from the underpart of the gunwale, along the whole length of the regular sheer, extending twenty-one feet six inches, are cased with layers of cork, to the depth of sixteen inches downwards; and the thickness of this casing of cork being four inches, it projects at the top a little without the gunwale. The cork, on the outside, is secured with thin plates or slips of copper, and the boat is fastened with copper nails. The thwarts, or seats, are five in number, *double-banked*; consequently the boat may be rowed with ten oars. The thwarts are firmly stanchioned. The side oars are short, with iron tholes and rope grommets, so that the rower can pull either way. The boat is steered with an oar at each end; and the steering oar is one third longer than the rowing oar. The platform placed at the bottom, within the boat, is horizontal, the length of the midships, and elevated at the ends, for the convenience of the steerer, to give him a greater power with the oar. The internal part of the boat next the sides, from the under part of the thwarts down to the platform, is cased with cork; the whole quantity of which, affixed to the life-boat, is nearly seven hundred weight. The cork indisputably contributes much to the buoyancy of the boat, is a good defence in going along-side a vessel, and is of principal use in keeping the boat in an erect position in the sea, or rather for giving her a very lively and quick disposition to recover from any sudden *cant* or *lurch*, which she may receive from the stroke of a heavy wave. But, exclusively of the cork, the admirable construction of this boat gives it a decided pre-eminence. The ends being similar, the boat can be rowed either way; and this peculiarity of form alleviates her in rising over the waves. The curvature of the keel and bottom facilitates her movement in turning, and contributes to the ease of the steering, as a single stroke of the steering oar has an immediate effect, the boat moving as it were upon a centre. The fine entrance below is of use in dividing the waves, when rowing against them; and, combined with the convexity of the bottom, and the elliptical form of the stem, admits her to rise with wonderful buoyancy in a high sea, and to launch forward with rapidity, without shipping any water, when a common boat would be in danger of being filled. The flaunching or spreading form of the boat, from her floor-heads to the gunwale, gives her a considerable bearing; and the continuation of the breadth, well forward, is a great support to her in the sea; and it has been found by experience, that boats of this construction are the best sea boats for rowing against turbulent waves. The internal shallowness of the boat from the gunwale down to the platform, the convexity of the form, and the bulk of cork within, leave a very diminished space for the water to occupy; so that the life boat, when filled with water, contains a considerable less quantity than the common boat, and is in no danger either of sinking or overturning. It may be presumed by some, that in cases of high wind, agitated sea, and broken waves, a boat of such a bulk could not prevail against them by the force of oars; but the life-boat from her peculiar form, may be rowed a-head, when the attempt in other boats would fail. Boats of the common form, adapted for speed, are of course put in motion with a small power; but for want of buoyancy and bearing, are over-run by the waves, and sunk, when impelled against them; and boats constructed for burthen meet with too much resistance from the wind and sea, when opposed

BOAT.

to them, and cannot in such cases be rowed from the shore to a ship in distress.

Mr. Greathead gives the following instructions for the management of the life-boat.

The boats, in general, of this description are painted white on the outside; this colour more immediately engaging the eye of the spectator when rising from the hollow of the sea than any other. The bottom of the boat is at first varnished (which will take paint afterwards) for the more minute inspection of purchasers. The oars she is equipped with are made of fir, of the best quality; having found by experience, that a rove ash oar, that will dress clean and light, is too pliant among the breakers; and when made strong and heavy, from rowing double-banked, the purchase being short, sooner exhausts the rower, which makes the fir oar, when made stiff, more preferable.

In the management of the boat she requires twelve men to work her; that is, five men on each side rowing double-banked, with an oar slung over an iron thole, with a grommet (as provided), so as to enable the rower to pull either way, and one man at each end to steer her, and to be ready at the opposite end to take the steer-oar, when wanted. As, from the construction of the boat, she is always in a position to be rowed either way, without turning the boat; when manned, the person who steers her should be well acquainted with the course of the tides, in order to take every possible advantage: the best method, if the direction will admit of it, is to head the sea. The steersman should keep his eye fixed upon the wave or breaker, and encourage the rowers to give way, as the boat rises to it; being then aided by the force of the oars, she launches over it with vast rapidity, without shipping any water. It is necessary to observe that there is often a strong reflux of sea occasioned by the stranded wrecks, which requires both dispatch and care in the people employed, that the boat be not damaged. When the wreck is reached, if the wind blows to the land, the boat will come in shore without any other effort than steering.

The following additional observations and instructions are given by Mr. Hinderswell of Scarborough.

The life-boat at Scarborough is under the direction of a committee. Twenty-four fishermen, composing two crews, are alternately employed to navigate her. A reward, in cases of shipwreck, is paid by the committee to each man actually engaged in the assistance; and it is expected the vessel receiving assistance should contribute to defray this expense. None have hitherto refused.

It is of importance that the command of the boat should be entrusted to some steady experienced person, who is acquainted with the direction of the tides or currents, as much skill may be required in rising them to the most advantage, in going to a ship in distress. It should also be recommended, to keep the head of the boat to the sea, as much as circumstances will admit; and to give her an accelerated velocity to meet the wave, much exertion is necessary in approaching a wreck, on account of the strong reflux of the waves, which is sometimes attended with great danger. In a general way, it is safest to go on the lee quarter; but this depends on the position of the vessel; and the master of the boat should exercise his skill in placing her in the most convenient situation. The boatmen should practise themselves in the use of the boat, that they may be the better acquainted with her movements; and they should at all times be strictly obedient to the directions of the person who is appointed to the command.

Plate II of *Boats* contains a perspective view of the life-boat rising over a heavy surge, and going out to the assistance of a ship, which appears in the horizon in distress. In

the life-boat are ten rowers pulling to get to the ship. At the lower end of the boat, a man is steering her with a long oar towards the ship; and another person is stationed with an oar at the higher end, to steer the boat on her return; both ends of the boat being formed alike, in order to use either at pleasure in going to or coming from the ship. The sheer, or curve of the boat, rising considerably from the middle to the stems, or ends, is clearly distinguished; also the coating of cork secured by slips of copper along the outside of the boat, near the part where the rowers are seated.

As every thing relating to this important invention must be interesting to the public, it is, therefore, presumed the following additional information will not be unacceptable, especially as it contains the strongest evidence of the great utility of this boat.

The life-boat having been submitted to a test of twelve years' experience, during which period Mr. Greathead sacrificed a very considerable portion of his time in furnishing plans, and otherwise rendering the invention as extensively useful as he could; on the 25th of February 1802, he presented a petition to the house of commons, the prayer of which was as follows:

"Your petitioner having been instrumental in saving the lives of so many persons; and the utility of the boat being now established; and your petitioner having derived little or no pecuniary advantage whatever from the invention, his models having been made public; humbly hopes, that this honourable house will take his case into their consideration, and grant your petitioner such reward as to this honourable house shall seem meet, &c."

The petition, having been recommended by his majesty, was referred to the consideration of a committee; from whose report the following is a brief abstract.

"It appeared to your committee to be necessary to direct their inquiries particularly to the three following subjects.

"1st. The utility of the life-boat.

"2dly. The originality of the invention claimed by Mr. Greathead.

"3dly. Whether he had received any and what remuneration.

"And in order to ascertain these facts, your committee proceeded to examine,

"Ralph Hillery, a seaman, who stated, that he had been forty-five years at sea, in the Greenland and coal trade, and has resided always at Shields. About three years ago, he was in the Northumberland life boat, which was presented to North Shields by the duke of Northumberland, the first time she went off, which was to the relief of the sloop Edinburgh. This vessel was seen to go upon the Herd sands, about a mile and a half from shore; she was brought to an anchor before the life-boat got to her, and she continued striking the ground so heavily, that she would not have held together ten minutes longer, had they not got to her; they made her cut her cable, and then took seven men out of her, and brought them on shore. The sea at that time was monstrously high, so high that no other boat whatever could have lived in it.

"He was then asked, whether he had been out in the life-boat on any other occasion? to which he replied, that he had been five times out in her to the relief of different ships; from one ship they saved fifteen men; and in every instance when he, the witness, was in the boat, they saved the whole of the crews of the wrecked ships. Besides the times he has been himself in the boat, he has seen her go off scores of times, and never saw her fail in bringing off such of the crews as stayed by the ships. But many times part of the crews of the vessel wrecked have taken to their own boats,

BOAT.

and have been drowned by the boats' upsetting; whilst the remainder of the crews that continued on board have been saved by the life-boat. And the witness declared his conviction, that no other boat that ever he saw could have gone from the shore and saved the crews, at the times the life-boat went.

"He stated that in the event of the life-boat filling with water, she would continue still upright, and would not founder, as boats of a common construction do. That about two months ago, he saw her come on shore with a ship's crew, besides her own crew, so full of water that it ran over each side; the sea had broken several of her oars; and he believes, that no boat of any other construction could have brought the crew on shore so filled with water.

"Captain William Carter, of the ship Providence of Newcastle, stated, that he had resided at South Shields twenty-five years, and been fifteen years in the coal and Baltic trades; that on the 28th of November 1797, he commanded the Velocity of 59 tons, riding at anchor on Tynemouth bar, amongst the broken water, when the ship Planter was driven on shore by the violence of the gale, about one hundred yards from the Velocity; the life-boat came off and took fifteen persons out of the Planter; and they had scarcely quitted the ship when she went to pieces; they must all otherwise have inevitably perished, as the wreck came on shore almost as soon as the life-boat. He conceived that no boat of a common construction could have given relief at that time. There were several other vessels in the same situation with the Planter, namely, the Gateshead, the Mary, and the Beaver, besides a sloop, whose name the witness does not know. The crew of the Gateshead, being nine in number, took to their own boat, which sunk, and seven of them were lost; the other two saved themselves by ropes thrown from the Mary. After the life-boat had landed the crew of the Planter, she went off successively to the other vessels, and brought the whole of their crews safe on shore, together with the two persons who had escaped from the boat of the Gateshead. He has seen the life-boat go to the assistance of other vessels at different times, and she always succeeded in bringing the crews on shore.

"The witness has several times observed her to come on shore full of water and always safe.

"Captain Gilfred Lawson Reed, an elder brother of the Trinity-house, stated, that he had been bred to the sea, and had been a member of the Trinity-house seventeen years. He had the management of the life-boat at Lowestoffe, particularly last year, where he was requested by the subscribers to make any improvement he thought necessary. She was built exactly upon Mr. Greathead's plan, corresponding with the model before the committee. Having fitted her for service as far as he thought proper, he was requested by a number of the subscribers to launch this life-boat; he took an opportunity, when the sea fell very heavy on the beach, and launched her in the presence of at least two hundred spectators. Twenty-four men jumped into her; and when she first mounted the waves, the spectators with one voice expressed their astonishment. He had given the men orders to cross a shoal, that lay about a mile and a half from the shore upon which the sea broke very heavily; by some mistake one of the plugs was left out of the bottom, and she filled with water before she got to the shoal, which obliged the men to return immediately, and she brought the twenty-four men safe to shore, though when she gained the shore, she was full of water to the gun wale and midships; yet by her sheer one-third of her at each end was out of the water.

"Being asked, wherein he considered the superiority of the life-boat consists over any other boat that has hitherto

been invented? he answered, the curvature of the keel, and the flanking sides, which render it almost impossible to be upset. When this boat was afloat and full of water, the men all went to one side of the boat, in order to try the possibility of upsetting her, which they could not effect.

"Mr. Thomas Henderwell, of Scarborough, ship-owner, stated, that the peculiar nature of the curvature of the keel of this boat is the foundation and basis of its excellence. It regulates, in a great measure, the sheer with elevation towards the ends. This construction spreads and repels the water in every direction, and enables her to ascend and descend with great facility over the breakers. The ends being reduced regularly from the centre to less than one-third proportion of the midships, both ends are lighter than the body section. By means of the curved keel, and the centre of gravity being placed in the centre of the boat, she preserves equilibrium in the midst of the breakers. The internal shallowness of the boat in the body section, occasioned by the convexity of the keel and the sheer at the top, leaves to small a space for the water to occupy, that the boat, though filled with water, is in no danger of sinking or upsetting. The buoyancy of the boat, when filled with water, is also assisted by the cork being placed above the water-line.

"Mr. Samuel Plumb, of Lower Shadwell, described himself to have been bred to the sea, and to have acted in the capacity of master of a ship from 1777 until within these eighteen months; that he had been chiefly employed in the coal and Baltic trades, and had resided at Shields the whole of his life till within the last five years. He is acquainted with the Shields' life-boats; and from every information he had received, Mr. Greathead has been universally considered as the inventor of them.

"He went out in one of them to the relief of a ship, which was wrecked on the coast near the mouth of the Tyne. The first time they reached the wreck, the rope, which they threw from the wreck to the life-boat, broke, and the boat was drifted to the northward by the violence of the wind and strong current of the tide; they then landed, and by two horses dragged the boat along the sand to the southward, and then launched her again through the breakers to the vessel. In the second attempt they succeeded in bringing the crew on shore. The witness never saw any other boat in which he would have ventured to the relief of the crew, or which he thinks could have executed the purpose of saving them.

"Mr. William Masterman of South Shields, ship-owner, was one of the original committee that ordered the life-boat at South Shields in 1789. He corroborated the evidence given by captain William Carter; and stated, that from the situation of his residence, he has seen the performance of the life-boat more frequently than probably any other of the committee at South Shields, and has frequently seen and assisted in the launching of the life-boat from the beach into the sea during a storm. That this is done with the assistance of low wheels, or what may be called rollers, upon which she is dragged to the water's edge, and by means of hands proportioned to the weight of the boat, she can be launched with as much ease as any other boat. He remembers the instance stated by Mr. Samuel Plumb, in which the life boat, being drifted to the northward by a strong tide, was landed, and again launched to the southward opposite to the wreck, and in the face of a very heavy sea. When the Gateshead, Planter, and other ships were wrecked, it was first discovered that the life-boat could act with perfect safety *athwart the sea*; and since that time, the boat has been rowed *athwart sea*, or otherwise, indifferently,

as the object to be relieved required it; and that the goes with the same safety from one object to another, in a broken sea, as an ordinary boat would pass from one ship to another in a smooth sea. He is confident, since the establishment of the life-boat, that there have been at least 300 persons brought on shore from ships in distress, and wrecks off Shields, the greatest part of whom must otherwise have perished. And the witness added, that it was his opinion, founded upon experience and the observations he had been enabled to make, that no sea, however high, could upset or sink the life-boat."

The *originality* of Mr. Greathead's invention is there proved by proper certificates and attestations; and the remuneration that he had received over and above a profit of from ten to fifteen pounds each, upon building a few boats, is stated to be,

From the Literary and Philosophical Society of Newcastle, five guineas.

Royal Humane Society, a medallion.

Corporation of the Trinity House, 100 guineas.

Society of Arts, a gold medallion and 50 guineas.

The vote of parliament, on the 3d of June, in consequence of the foregoing report, was, "That a sum not exceeding 1200 pounds be granted to his majesty, to be paid to Henry Greathead, of South Shields, in the county of Durham, boat builder, as a reward for his invention of the life-boat, whereby many lives have already been saved, and great security is afforded to seamen and property in cases of shipwreck."

The subscribers at Lloyd's, on the 20th of May, voted to Mr. Greathead the sum of 100 guineas, "as an acknowledgement of his talents and exertions in inventing and building a life-boat," and 2000 pounds "for the purpose of encouraging the building of life-boats on different parts of the coasts of these kingdoms."

At the beginning of 1804, Mr. Greathead received a very valuable diamond ring from the emperor of Russia, whose munificence to ingenious men of all countries is well known.

The following extract from the Tyne Mercury of the 20th November 1803, is another proof of the great utility of the life-boat.

The Bee of Shields, John Houston master, having put to sea (21st Nov.) in an easterly wind, had not proceeded far, when it began to blow strong from the south-east, which obliged him a few hours after to put back. In taking Tynemouth bar at the last quarter ebb, in a very heavy sea, she struck the ground, and unshipped her rudder. Being now completely unmanageable, she drifted towards the north side of the bar, and at length drove on the Black Middens. They who have witnessed the tremendous sea which breaks on the north-east part of this harbour, in a south-easterly wind, may form a conception of the dreadful situation in which the crew of the vessel were situated. In the midst of rocks, where the sea runs mountains high, so as frequently to obscure the ship, and where any vessel might be expected immediately to go to pieces; their only refuge from being swept into the gulf, was to climb up into the shrouds, which the captain, with six men and boys, being the whole crew, instantly effected. The dangerous situation in which they were placed, immediately attracted an immense number of spectators from both North and South Shields. The shores in every direction were lined with people who expressed, by their anxious looks, the most sympathetic apprehensions for their safety. The making use of the life-boat was by most people thought impossible; and at all events, the attempt was attended with extreme dan-

ger, owing to the tremendous sea, and the immense rocks which lay where the vessel was stranded. So confident, however, was Mr. Greathead, the inventor, of the life-boat being able to live in any sea, if properly navigated, that he, without hesitation, and with the greatest alertness, volunteered his services to bring off the men from the brig. This intrepid offer operated like electricity among the sailors; and immediately the Northumberland life-boat was launched, and manned with Mr. Greathead and South Shields pilots. In the course of a few minutes they reached the vessel, without much difficulty, and picked off the men from the shrouds shivering with cold, and almost perished by fatigue. One man, in making too much haste to enter the boat, fell into the breakers, but was immediately recovered. When the whole crew was in the boat, they rowed towards the shore, and in less than an hour from the time the boat was launched, did they return in safety to South Shields, without a single accident!

Upon the 1st of August 1777, some trials were made on a boat, or sloop fit for inland navigation, coasting voyages, and short passages by sea, which is not, like ordinary vessels, liable to be upset or sunk by winds, waves, water-spouts, or too heavy a load, contrived and constructed by Monsieur Bernieres, director of the bridges and causeways in France, &c. at the gate of the invalids in Paris, in the presence of the provost of the merchants, of the body of the town, and of a numerous concourse of spectators of all conditions.

These experiments were made in the way of comparison with another common boat of the same place, and of equal size. Both boats had been built ten years, and their exterior forms appeared to be exactly similar. The common boat contained only eight men, who rocked it and made it incline so much to one side, that it presently filled with water, and sunk; so that the men were obliged to save themselves by swimming; a thing common in all vessels of the same kind, either from the imprudence of those who are in them, the strength of the waves or wind, a violent or unexpected shock, their being overloaded, or overpowered any other way.

The same men who had just escaped the boat which sunk, got into the boat of M. Bernieres; rocked and filled it, as they had done the other, with water. But, instead of sinking to the bottom, though brim-full, it bore being rowed about the river, loaded as it was with men and water, without any danger to the people in it.

M. Bernieres carried the trial still farther. He ordered a malt to be erected in this same boat, when filled with water; and to the top of the malt had a rope fastened, and drawn till the end of the malt touched the surface of the river, so that the boat was entirely on one side, a position into which neither winds nor waves could bring her; yet, as soon as the men, who had hauled her into this situation, let go the rope the boat and malt recovered themselves perfectly in less than the quarter of a second; a convincing proof that the boat could neither be sunk nor overturned, and that it afforded the greatest possible security in every way. These experiments appeared to give the greater pleasure to the public, as the advantages of the discovery are not only so sensible, but of the first importance to mankind.

Marnois boats, so called from being employed on the river Marne in France. They are flat, and carry wine, corn, timber, &c. from the province of Champagne.

Norway boat, or yawl, is sharp at both ends, and of various dimensions. This boat, from its construction, is admirably adapted for enduring a high sea, and will often ven-

BOAT.

ture out to a great distance from the land, when some ships can scarcely carry any sail.

Pabie, a boat of the Society islands; it is bow-sided, and sharp-bottomed. The *pabie*, according to captain Cook, is of different sizes, from thirty to sixty feet long, but like the *ivahah*, is very narrow. One that was measured was fifty-one feet long, and only one foot and an half wide at the top; in the widest part it was about three-feet, and this is the general proportion. It does not, however, widen by a gradual swell, but the sides being straight and parallel for a little way below the gunwale, it swells abruptly, and draws to a ridge in the bottom; so that a transverse section of it has somewhat the appearance of the mark upon cards, called a spade, the whole being much wider in proportion to its length. These, like the largest *ivahahs*, are used for fighting, but principally for long voyages. The fighting *pabie*, which is the largest, is fitted with the stage or platform, which is proportionably larger than those of the *ivahah*, as their form enables them to sustain a much greater weight. Those that are used for sailing are double, and those of the middle size are said to be the best sea-boats. They are sometimes out a month together, going from island to island, and sometimes as is credibly reported, they are not unfrequently a fortnight or twenty days at sea, and could keep it longer, if they had more stowage for provisions, and conveniencies to hold fresh water.

When any of these boats carry sail single, they make use of a log of wood which is fastened to the end of two poles that lie across the vessel, and project from six to ten feet, according to the size of the vessel, beyond its side; somewhat like what is used by the flying proa of the Ladrone islands, and called, in the account of lord Anson's voyage, an *Outrigger*; to which the shrouds are fastened.

Some of them have one mast, and others two; they are made of a single stick; and when the length of the canoe is 30 feet, that of the mast is somewhat less than 25 feet; it is fixed to the frame that is above the canoe, and receives a sail of matting about one-third longer than itself; the sail is pointed at the top, square at the bottom, and curved at the side, somewhat resembling what is called a shoulder of mutton sail, and used for boats belonging to men of war; it is placed in a frame of wood, which surrounds it on every side, and has no contrivance either for reefing or furling, so that if either should become necessary, it must be cut away, which, however, in these climates, can seldom happen. To the top of the mast are fastened ornaments of feathers, which are placed inclining obliquely forwards, the shape and position of which will be conceived at once from the figure in the *plate of Boats*.

The oars or paddles that are used with these boats, have a long handle and flat blade, not unlike a baker's peel. Of these, every person in the boat has one, except those that sit under the awning, and they push her forward with them at a good rate. These boats, however, admit so much water at the seams, that one person at least is continually employed in throwing it out. The only thing in which they excel is landing and putting off from the shore in a surf; by their great length, and high sterns, they could land every day, where the English boats could scarcely land at all; they have also the same advantages in putting off by the height of the head.

The exact dimensions of a *pabie*, given from a careful admeasurement, will so very materially contribute to the elucidation of the description subsequently given, as to the manner and particular form in which this class of canoes is built, that they might perhaps enable an European draughtsman, to construct one so nearly resembling them as to

create some difficulty in pointing out the true from that which was fictitious:

	Feet.	Inches.
Extreme length from stem to stern, not reckoning the beading up of either	51	0
Breadth in the clear of the top forward	1	2
Breadth in the midships	1	6
Breadth aft	1	2
—In the bilge forward	2	8
—In the midships	2	11
—Aft	2	9
Depth in the midships	3	4
Height from the ground on which she stood	3	6
Height of the head from the ground without, including that of the figure	4	4
Height of the figure	0	11
Height of the stern from the ground	8	9
Height of the figure	2	0

To illustrate the description of the manner in which these vessels are built, it will be necessary to refer to *fig. 2. Plate II*.

The first stage or keel under *aa*, is formed of a tree hollowed out like a trough, for which the longest trees are chosen that can be procured, so that there are never more than three in the whole length; the next stage under *bb*, is formed of straight planks, about four feet long, fifteen inches broad, and two inches thick; the third stage under *cc*, is like the bottom, made of the trunks hollowed into its bilging form; the last is also cut out of trunks, so that the moulding is of one piece with the upright. To form these parts separately without saw, plane, chissel, or any other iron tool, may well be thought no easy task; but the great difficulty is to join them together.

When all the parts are prepared, the keel is laid upon the blocks; and the planks, being supported by stanchions, are sewed or clamped together with strong thongs of plaiting. These are passed several times through holes that are bored with a gauge or auger of bone, which performs its office with tolerable exactness; and the nicety with which this is done, may be inferred from their being sufficiently water-tight for use without caulking. As the plaiting soon rots in the water, it is renewed at least, once a year, in order to which the vessel is taken entirely to pieces; the head and stern are rude, with respect to the design, but very neatly finished, and polished to the highest degree.

These *pabies* are kept with great care in a kind of house, built on purpose for their reception; the houses are formed of poles set upright in the ground, the tops of which are drawn towards each other, and fastened together with their strongest cord, so as to form a kind of Gothic arch, which is completely thatched quite to the ground, being open only at the ends: they are sometimes fifty or sixty paces long.

Peter-boat, a boat employed in the river Thames in fishing. They in general sail well, and are good sea-boats.

Pleasure-boat, a vessel employed by gentlemen in excursions upon the water, for their amusement. Their size and manner of equipment are very various, being from a few tons burden, to upwards of two or three hundred tons, and having one or more masts.

Post-boats, are boats established on the river Loire in France, for the convenience of the public. They are long in respect to their breadth, and go very fast: There are also some on the Rhone, which go from Lyons to Avignon in 24 hours.

Proa; see that article.

Punt, a sort of flat-bottomed boat, whose floor resembles the platform of a floating stage. It is used by the naval artificers,

artificers, either in caulking, breaming, or repairing the bottom of a ship.

Sampan, a Chinese boat without a keel, appearing almost like a trough; they are made of different dimensions, but are mostly covered. There are passenger sampans, to carry people backward and forward, between the town and ships. These boats are as long as sloops, but broader, almost like a baking trough, and have, at the end, one or more decks, made of bamboo-sticks; the cover, or roof, is also made of bamboo sticks, arched over in the shape of a grater, and may be raised or lowered at pleasure; the sides are made of boards, with little holes, and shutters instead of windows; the boards are fastened on both sides to posts, which have notches like steps on the inside, that the roof may be let down, and rest on them; on both ends of the deck are commonly two little doors, at least there is one at the stern. A fine, white smooth carpet, spread up as far as the boards, makes the floor, which, in the middle, consists of loose boards; but this carpet is only made use of to sleep on. As these boats differ from those of Europeans in shape, they are likewise rowed in a different manner; for two rowers posting themselves at the back end of the sampan, work it forwards very readily by the motion of two oars, and can almost turn the vessel just as they please; the oars, which are covered with a little hollow quadrangular iron, are laid on iron swivels, which are fastened in the side of the sampan. At the iron the oars are pieced, which makes them look a little bent. In common, a rower sits before with a short oar, but this he is forced to lay aside when he comes near the city, on account of the great throng of sampans; and this inconvenience has continued the Chinese in their old way of rowing.

Sampans of *burden* are the largest boats, by which all porcelain, silks, and other commodities, are conveyed from Canton to the European ships. But these boats do not serve for the above-mentioned purposes only, but are used, besides, as houses for whole families, which are born, marry, and die in them. They commonly have, besides, hogs, some chickens and dogs, and some flower-pots, containing Guinea pepper, or some other plants, in these boats.

Duck sampans, are boats in which they feed four or five hundred ducks. They have on both sides a bridge, which may be let down. In the day-time the ducks feed in the river upon herbs and fish; at night their master calls them into his boat; they immediately obey him, and come on board as soon as he lets down his Bridge.

Fishing sampans, are the smallest of all, narrow, like some European fishing boats, and have either a very small deck of straw, or bamboo, or are even without that poor convenience. Bad as these boats are, yet parents, and their naked children, are seen to get their livelihood in them, both summer and winter, by fishing, and picking up what has been thrown overboard from other vessels. For this purpose they tie several hooks to a cord, and throw them out in different places; almost in the same manner as fishermen lay their eel-hooks. They have better or worse fortune, as it happens. There is nothing so filthy but what these people will use as food; and the hogs, which having died are thrown overboard, when they begin to putrefy, float in a few days, and often become the occasion of quarrels, which end in battles. The reason why the Europeans sink the hogs, which die on board their ships, is, that the inhabitants of this place may not fall upon them; for it is said that the Chinese, when they go on board any ships, will give pepper to the hogs, which they think is poison to them, that they may get them again if they should die. It is certain, that numbers of hogs die in possession of the Europeans whilst they stay in China.

Mandarin's sampans are greater or less red-painted boats, ornamented with dragons, and such like figures, or with little flags.

The *Stage-boats*, called in French, bateaux coches, and more commonly coches-d'eau, water coaches, are large covered vessels, which serve, particularly, on the river Seine, for the conveniency of travellers, and for carrying all sorts of merchandizes. The names of them are the passage boat, or water coach of Sens, of Auxerre, of Montereau, and of Fontainebleau, or Valvin.

Tilt-boat, one with a cover, to defend the passengers from rain, &c.

Trawl-boat, a boat employed in a canal in conveying passengers, &c. from one place to another. This mode of travelling, though not expeditious, is indeed very pleasant, and certainly much cheaper than by any land carriage. From Grangemouth to Port Dundas, a distance of nearly 30 miles, the fare is only one shilling, or eighteen pence.

Well-boat, a boat having a well in the bottom, to preserve fish alive.

A *Wherry* is a light sharp boat, used in a river or harbour, for carrying passengers from place to place.

The boats, or wherries, allowed to ply on the Thames about London, are either *skullers*, wrought by a single person with two oars; or *oars*, wrought by two or more persons, with each an oar.

The following are some of the terms used in the management of a boat.

Bale the boat, is to throw out the water which remains in her bottom, or the well-room. See BAILE.

Fend the boat, to save her from beating against the ship's sides.

Man the boat, an order to those appointed to manage her to go on board the boat immediately.

Moor the boat, the order to fasten a boat with two ropes, so as that the one shall counteract the other.

Trim the boat, the order to fit in the boat in such a manner as that she shall float upright in the water, without leaning to either side.

Wind the boat, the order to bring her head the other way.

The *boat's gang*, includes those who are employed for rowing in the boat; such as the cockswain and his gang, to whom the charge of the boat immediately belongs.

A *bold boat* is that which will endure a rough sea well.

To preserve boats from foundering at sea when ships founder. Take any mast, yard, boom, &c. that may be found floating from the ship; the longer the better; make fast to each end of the boom a rope about twice its length; and bend one end of another rope, about ten fathoms long, exactly in the middle of the span, and the other end is to be made fast to the forepart of the boat, so that she may drive stem on to the sea. When this misfortune happens far from land, and the storm ceases, in moderate weather the drift boom may be towed end on to the boat's stern, that they may either row or sail towards land.

Mr. Hutchinson, in his treatise on practical seamanship, gives an account of a boat being preserved by this method, as follows. The Basil, in her passage from the West Indies, took up ten men in a small boat, twelve feet long, which was preserved from foundering after the vessel had foundered, by having a rope fast to a log of wood, as they called it, and tied to the boat's bow, which kept her to drive end on with the head to the waves, and broke their violence so much as to preserve her from filling with water, when one half of them was obliged to lie down in the bottom of the boat, to prevent her being top-heavy. By particular inquiry of the maller

mafter and mate of the *Dasil*, Mr. Hutchinſon was informed, that thoſe people belonged to a ſchooner bound from *Bur-mudas* to the *West Indies*; that it was after a hard gale of wind when they met with the boat, which had two oars for masts, and two blankets ſet upon them for fails, and was ſteering for *Bermudas*, when they were fortunately taken up; and that the log of wood, as it was called, they drove by, was their fore ſquare ſail yard, ſpanned with a rope to each yard-arm, and a rope about ten or twelve fathoms long beat to the middle of the ſpan, and made faſt to the boat's bow, to drive by. The mate of the ſchooner told the maſter of the *Basil*, that they had been ſaved in this manner in a boat once before, by driving to leeward of a maſt, in a hurricane in the *West Indies*.

In order to account for this wonderful effect of the drift-boom, in preventing the broken water from ſwamping the boat, it may be obſerved, ſays Mr. Hutchinſon, that waves never break till their tops are forced forwards by their great velocity beyond the perpendicular of their baſe; then that water falls down forward, and incloſes and compreſſes a quantity of air, which, by the power of its elafiicity, blows this fore part of the waves to pieces, forwards and upwards, in an oblique direction, and makes it appear like froth. They then have no buoyant power to lift a boat; but when they are high, they fill and ſink her. And they break more in ſhoal water than in deep, in proportion as their bottoms or baſe are more obſtructed in their velocity by the ground than their tops; hence, in very ſhoal water, they are continually breaking, ſo that they make nothing but what is called broken water, by which ſhoals may be ſeen and known at a great diſtance in clear weather.

If we endeavour to account for the wonderful effect of ſo ſmall and ſimple a machine, to preſerve ſuch a ſmall boat, deeply laden as ſhe muſt be with ten men, from being filled with water in ſuch a ſtorm; in our opinion it is owing to the boat driving end on by the drift boom, that keeps it always ſwimming on the ſurface, broadſide to the wind; and the waves that are running towards it, within the length of the drift boom, muſt certainly obſtruct the velocity of the upper part of theſe waves, ſo as to leſſen their increaſe in height, and prevent the top from running beyond the perpendicular of the baſe, or bottom of theſe waves, that occaſions their breaking, as has been deſcribed, but ſpend themſelves without breaking. Theſe reaſons we hope will be thought ſufficient to recommend this method to be tried and brought into practice on ſuch dreadful occaſions: and we cannot help thinking, that the ſame method ſhould be tried, when under the dreadful neceſſity of ſaving lives by boats landing on a lee ſhore in a ſtorm, where broken waves run high. The only difference we would recommend in the management, is to proceed with the boat's ſtern to the drift boom, and her head to the ſhore, to be ready to row and ſteer for the beſt apparent landing-place; and if it is a long flat ſhore, as ſoon as the boat ſtrikes the ground, cut or ſlip the drift boom rope, that it may not haul the boat off the ſhore again by the back ſweep of the waves.

Upon landing a boat in a ſurf. Before the boat comes near the ſhore, pour a little oil on the water, which will prevent its breaking, and greatly allay the ſwell, ſo that the boat may approach the ſhore without the dread of being ſwallowed up in the breakers.

Mr. Danzel has lately invented an hydraulic machine for making a ſhip or boat advance during a calm, and even againſt a current.

The mechanism of this machine is very ſimple; it conſiſts of a long pole, to the anterior extremity of which an appa-

ratus, ſhaped like a drawer without back or front, is attached in ſuch a manner, that when puſhed forwards it folds itſelf back under the pole, to which it (as it were) adheres, and preſents to the water the thin cutting ſurface of its three edges, viz. of the bottom and two ſides, which can neither oppoſe to the water a reſiſtance capable of preventing the pole from penetrating farther, or of making the ſhip recede. When the pole, which is puſhed forwards from the veſſel, has attained to its full reach, the drawer, as ſoon as the pole is puſhed back, aſſumes a vertical poſition, and preſents to the water its whole cavity. By theſe means it embraces a column of water, which, without finding means to eſcape, preſſes on a ſurface much larger than that of a common oar, and keeps the drawer immoveable; ſo that thoſe who draw the pole towards them, inſtead of making the veſſel to recede, cauſe it to advance. This machine, which may be multiplied more conveniently than oars, has this viſible advantage over the latter, that it oppoſes to the water a reſiſtance infinitely ſuperior, while the paſſive re-acti-
on of this reſiſtance renders the labour of the mariners leſs labori-
ous and more effectual.

De Chales propoſes the conſtruction of a boat, which, what burden ſoever it bear, ſhall not only move againſt the current, without either fails or oars, but alſo advance ſo much the faſter, as the rapidity of the water is greater. Its make is the ſame with that of the others, excepting only a wheel added to its ſide, with a cord, which winds round a roller as faſt as the wheel turns.

Something of the like kind has alſo been ſince done by M. Pitot. Vide Mem. Acad. R. Scienc. an. 1729. p. 359. and p. 540.

M. de la Hire has given us an examination of the force neceſſary to move boats, both in ſtagnant and running water, either with ropes faſtened to them, or with oars, or with any other machine; wherein he ſhews, that the larger the ſurface of the oars plunged in the water, and the ſmaller that of the boat preſented to the water, is; and again, the longer that part of the oar between the hand and the places where the oar reſts on the boat, and the ſhorter that between this laſt point and the water; the freer will the boat move, and the greater effect will the oar have. See OAR.

Hence it is eaſy to calculate the force of any machine that ſhall be applied to rowing; v. gr. if we know the abſolute force of all the men who row, it muſt be changed into a relative force, according to the proportion of the two parts of the oar; i. e. if the part out of the veſſel be double the other, and all the men together can act with the force of 900 pounds, we compute firſt, that they will exert 300; which 300, multiplied by the ſurface which the veſſel preſents to the water, gives a ſolid water of a certain weight; which weight may be found, and of conſequence the velocity impreſſed on the veſſel by the oars. Or, the velocity of the oars may be found in the ſame manner, by multiplying the 300 pounds by the ſurface of all the parts of the oars plunged in the water. Nor would there be any difficulty in finding firſt the relative forces, then the abſolute ones; the velocities either of the oars, or of the veſſel being given, or the proportion of the two parts of the oar.

Boats ſail more ſlowly and heavily over ſhallow than over deep waters. See an account of experiments for explaining this, in Dr. Franklin's Letter to Sir John Pringle. Experiments, &c. 4to. 5th ed. p. 510.

BOATS, Conſtruction of. In order to illuſtrate this by an example, let it be required to lay down the ſeveral plans of a long boat, the extreme length being 31 feet, and breadth moulded 9 feet.

Draw the straight line PO, *fig. 1. Plat. I. (Slip-building)* equal to 31 feet, the extreme length of the boat, and also to represent the upper edge of the keel. Let \oplus be the station of the midship frame. From the points P, \oplus , and O, draw the lines PT, \oplus M, and OS, perpendicular to PO. Make \oplus M, \oplus N, equal to the upper and lower heights of breadth respectively at the main frame, PT, the height of breadth at the transom, and OS, the height at the stern. Describe the curve TMS, to represent the sheer, or extreme height of the side, which, in a ship, would be called either the upper height of breadth line, or the upper edge of the wale. Through the point N draw a curve parallel to TMS, to represent the breadth of the upper strake of a boat, or lower edge of the wale if in a ship. The dotted line TNS may also be drawn to represent the lower height of breadth.

Set off the rake of the post from P to p , and draw the line p , to represent the aft side of the post; then T p will represent the round up of the transom. Set off the breadth of the post from p to r , and from T to s , and draw the line rs to represent the fore-side of the post, which may either be a curve or a straight line at pleasure. Set up the height of the tuck from p to k . Let kx be the thickness of the transom, and draw the line Z x to represent the fore-side of the transom.

There is given the point S the height of the sheer on the fore-side of the stem; now that side of the stem is to be formed either by sweeps, or some other contrivance. Set off the breadth of the stem, and form the aft side of it.

Set up the dead-rising from \oplus to d , and form the rising line *ris*. Draw the line KL parallel to PO, to represent the lower edge of the keel, and another to represent the thickness of the plank or the rabbet. The rabbet on the post and stem may also be represented; and the stations of the timbers assigned, as \oplus , (1), 1, 2, 3, 4, 5, 6, 7, 8, 9; and \oplus , (A), A, B, C, D, E, F, G, H; and the sheer plan will be completed.

The half-breadth plan is to be formed next; for this purpose the perpendiculars TP, 9, 8, &c. must be produced. Upon M \oplus produced set off the half-breadth from the line KL to R (*fig. 2.*); set off also the half-breadth at the transom from K to b , and describe the extreme half-breadth line bRX , making the fore part of the curve agreeable to the proposed round of the harpin.

We may next proceed to form the timbers in the body plan. Let AB (*fig. 3.*) be the breadth moulded at \oplus . Erect the perpendicular CD in the middle of the line AB, draw the line mn distant therefrom the half thickness of the post, and xy the half thickness of the stem. Then take off the several portions of the perpendiculars \oplus , 1, 2, &c. intercepted between the upper edge of the keel and the rising line in the sheer plan, and set them up from C upon the line CD; through these points draw lines parallel to AC; take off also the several lower heights of the breadth at \oplus , 1, 2, &c. from the sheer plan, and set them up from C upon the middle line in the body plan; and draw lines parallel to AC through these points; then take off the several half-breadths corresponding to each from the floor plan; and set them off on their proper half-breadth lines, from the middle line in the body plan.

Construct the midship frame according to the directions mentioned in that article, the form of which will in some measure determine the form of the rest. For if a mould be made on any side of the middle line to fit the curve part of it, and the rising line, or that marked *bend mould*, (*fig. 4.*) and laid in such a manner that the lower part of it, which is

straight, may be upon the several rising lines, and the upper part just touch the point of the half-breadth in the breadth line corresponding to that rising upon which the mould is placed, a curve may then be drawn by the mould to the rising line. In this manner we may proceed so far as the rising line is parallel to the lower height of the breadth line. Then a hollow mould must be made, the upper end of which is left straight, as that marked *hollow mould* (*fig. 4.*). This is applied in such a manner, that some part of the hollow may touch the side of the keel, and the straight part touch the back of the curve before described by the bend mould; and beginning abaft, the straight part will always come lower on every timber, till we arrive at the midship timber, when it comes to the side of the keel. Having thus formed the timbers, as far as the whole mouldings will serve, the timbers abaft them are next formed. Their half-breadths are determined by the sheer and floor plans, which are the only fixed points through which the curves of these timbers must pass. Some form these after timbers before the whole is moulded, and then make the hollow mould, which will be straighter than the hollow of either of these timbers. It is indifferent which are first formed, or what methods are used: for after the timbers are all formed, though every timber may appear very fair when considered by itself, it is uncertain what the form of the side will be. In order to find which, we must form several ribband and water lines; and if these do not make fair curves, they must be rectified, and the timbers formed from these ribband and water lines. In using the hollow mould when it is applied to the curve of each timber, if the straight part is produced to the middle line, we shall have as many points of intersection as there are timbers; and if the heights above the base be transferred to the corresponding timbers in the sheer plan, a curve passing through these points is called a *rising strait*. This may be formed by fixing a point for the aftermost timber that is whole moulded, and transferring that height to the sheer plan. The curve must pass through this point, and fall in with the rising line somewhere abaft dead-flat; and if the several heights of this line be transferred from the sheer to the middle line in the body plan, these points will regulate what is called the *hauling down* of the hollow mould.

The timbers in the after-body being all formed, those in the fore-body are formed in the same manner, by transferring the several heights of the rising and breadth lines from the sheer to the body plan; the half-breadth corresponding to each height must also be transferred from the floor to the body plan. The same hollow mould will serve both for the fore and after-body; and the level lines, by which the water lines to prove the after-body were formed, may be produced into the fore-body, and by these the water lines to prove the fore-body may be described.

Another method of proving the body is by ribband lines, which are formed by sections of planes inclined to the sheer plan, and intersecting the body plan diagonally, as before observed, of which there may be as many as may be judged necessary. In this, four ribband lines are laid down, marked *diag.* which are drawn in such a manner as to be perpendicular to as many timbers as conveniently may be. After they are drawn in the body plan, the several portions of the diagonal, intercepted between the middle line and each timber, must be transferred to the floor plan. Thus, fix one foot of the compass in the point where the diagonal intersects the middle line in the body plan, extend the other foot to the point where the diagonal intersects the timber, for example, timber 9. Set off the same extent upon the perpendicular representing the plane of timber 9, from the point where it intersects the line KL, on the floor plan; in like manner proceed

with all the other timbers, both in the fore and after-body, and we shall have the points through which the curve must pass. If this should not prove a fair curve, it must be altered, observing to conform to the points, as nearly as the nature of the curve will admit; and, therefore, it may be carried within one point and without another, according as the timbers will allow. For after all the ribband lines are formed, the timbers must, if necessary, be altered by the ribband lines; this is only the reverse of forming these lines; for taking the portions of the several perpendiculars intercepted between the line KL, and the curve of the ribband line in the floor plan, and setting them off upon the diagonal, from the point where it intersects the middle line, we shall have the points in the diagonal through which the curves of the timbers must pass. Thus, the distance between the line KL, and the ribband at timber 3, on the floor plan, when transferred to the body plan, will extend on the diagonal from the middle line to the point where the curve of timber 3 intersects that diagonal. The like may be said of all the other timbers; and if several ribband lines be formed, they may be so contrived that their diagonals in the body plan shall be at such distances, that a point for every timber being given in each diagonal, will be sufficient to determine the form of all the timbers.

In stationing the timbers upon the keel, for a boat, there must be room for two futtocks in the space before, or abaft \oplus ; for which reason the distance between these two timbers will be as much more than that between the other, as the timber is broad. Here it is between \oplus and (A), which contains the distances between \oplus and (1), and the breadth of the timber besides.

The timbers being now formed, and proved by ribband and water lines, proceed then to form the transom, fashion-pieces, &c.; see these articles.

This method of whole moulding will not answer for the long timbers afore and abaft. They are generally canted in the same manner as those for a ship. In order to render this method more complete, we shall here describe the manner of moulding the timbers after they are laid down in the mould loft, by a *rising square*, *bend*, and *hollow mould*.

It was shewn before how to form the timbers by the bend and hollow moulds in the draught. The same method must be used in the loft; but the moulds must be made to their proper scantlings in real feet and inches. Now, when they are set, as before directed, for moulding each timber, let the middle line in the body plan be drawn across the bend mould, and draw a line across the hollow mould at the point where it touches the upper edge of the keel; and let them be marked with the proper name of the timber, as in *fig. 4*. The graduations of the bend mould will therefore be exactly the same as the narrowing of the breadth: Thus, the distance between \oplus and 7 on the bend mould is equal to the difference between the half breadth of timber 7 and that of \oplus . The height of the head of each timber is likewise marked on the bend mould, and also the floor and breadth firmarks. The floor firmark is in that point where a straight edged batten touches the back of the bend mould, the batten being so placed as to touch the lower edge of the keel at the same time. The several risings of the floor, and heights of the cutting-down line are marked on the rising square; and the half-breadth of the keel set off from the side of it.

The moulds being thus prepared, we shall apply them to mould timber 7. The timber being first properly sided to its breadth, lay the bend mould upon it, so as may best answer the round according to the grain of the wood; then lay the rising square to the bottom of the bend mould, so that the line drawn across the bend mould at timber 7 may coincide

with the line representing the middle of the keel upon the rising square; and draw a line upon the timber by the side of the square; or let the line be scored or cut by a tool made for that purpose, called a *raising knife*; this line so raised will be the side of the keel. Then the square must be moved till the side of it comes to 7 on the bend mould, and another line must be raised in by the side of it, to represent the middle of the keel. The other side of the keel must likewise be raised after the same manner, and the point 7 on the rising square be worked on each side of the keel, and a line raised across at these points to represent the upper edge of the keel. From this line the height of the cutting down line at 7 must be set up, and then the rising square may be taken away, and the timber may be raised by the bend mould, both inside and outside, from the head to the floor firmark; or it may be carried lower if necessary. After the firmarks and heads of the timbers are marked, the bend mould may likewise be taken away; and then the hollow mould applied to the back of the sweep in such a manner, that the point 7 upon it may intersect the upper side of the keel, before set off by the rising square; and, when in this position, the timber may be raised by it, which will complete the outside of the timbers. The inside of the timbers may likewise be formed by the hollow mould. The scantling at the keel is given by the cutting down before set off. The mould must be so placed as to touch the sweep of the inside of the timber formed before by the bend mould, and pass through the cutting down point.

The use of the firmarks is to find the true places of the futtocks; for, as they are cut off three or four inches short of the keel, they must be so placed that the futtock and floor firmarks may be compared and coincide. Notwithstanding which, if the timbers are not very carefully trimmed, the head of the futtock may be either within or without its proper half breadth, to prevent which a half breadth staff is made use of.

The half breadth staff may be one inch square, and of any convenient length. Upon one side of it are set off, from one-end, the several half breadths of all the timbers in the after-body; and those of the fore-body, upon the opposite side. On the other two sides are set off the several heights of the sheer; the after-body on one side, and the fore-body on its opposite. Two sides of the staff are marked *half-breadths*, and the other two sides *heights of the sheer*.

The staff being thus prepared, and the floor timbers fastened on the keel and levelled across, the futtocks must next be fastened to the floor timbers; but they must be set first to their proper half breadth and height. The half breadth staff, with the assistance of the ram-line, serves to set them to the half breadth; for as the keel of a boat is generally perpendicular to the horizon, therefore the line, at which the plummet is suspended, and which is moveable on the ram-line, will be perpendicular to the keel, whence we may by it set the timbers perpendicular to the keel, and then set them to their proper half breadths by the staff; and when the two firmarks coincide, the futtock will be at its proper height, and may be nailed to the floor timbers, and also to the breadth ribband; which may be set to the height of the sheer, by a level laid across, taking the height of the sheer by the staff, from the upper side of the keel; by which means we shall discover if the ribband is exactly the height of the sheer; and if not, the true height may be set off by a pair of compasses from the level, and marked on the timbers.

Juvenal (*fat. xv. v. 126—128*,) describes the boats of the ancient Egyptians, as if they were earthen-ware; and it is alleged, that such earthen-ware ships were used on the Nile, and that they were called "*picæ*," painted, because these boats

boats of baked earth were marked with various colours. However, it is much more probable, that the Egyptians formerly, as they have done in more modern times, made use of rafts, which were made to float by empty vessels of earthen-ware fastened under them. The word 'pictæ,' it is suggested, does not denote their being beautified with a variety of colours, but means their being rubbed with some substance that might fill up the pores, so as to prevent the water's penetrating into the cavity of the pitchers, and causing them to sink, for the Egyptian earthen-ware is said to be very porous. These floats, however, were not constructed to pass up and down the Nile like boats, or properly designed for carrying goods upon them, but it is an easy mode of conveying their earthen-ware from Upper Egypt, where it is manufactured, to the lower parts of that country, where, when they reach the destined place, the float is taken to pieces, and sold to the inhabitants. Harmer's Observations, vol. iii. p. 56.

BOAT-hook an iron hook with a sharp point, having a socket in which a long pole is stuck. This is a very necessary appendage to a boat, as by means of it, any thing floating past may be hooked; the boat may be held on to the ship, or pushed along, &c.

BOAT-keeper. In the whole fishery a person is appointed to each boat, whose express duty is to steer the boat towards the fish, &c.

BOATS, bridge of. See the article BRIDGE.

BOAT, removed with steam. An experiment was lately tried on the canal between Grangemouth and Glasgow, to make a large boat or lighter move by the power of steam. As, it is presumed, the series of experiments is not yet completed, the reader is, therefore, referred to the article STEAM.

BOAT-swain, the officer who has the care of the boats, sails, rigging, colours, and anchors, committed to him, which he receives by indenture from the surveyor of the navy, and is enjoined to use great care in the disposition of them.

It is the duty of the boatswain particularly to direct whatever relates to the rigging of a ship, after she is equipped from a royal dock-yard. Thus, he is to observe that the masts are properly supported by their shrouds, stays, and back-stays, so that each of those ropes may sustain a proportional effort when the mast is strained by the violence of the wind, or the agitation of the ship. He ought also to take care that the blocks and running-ropes are regularly placed, so as to answer the purposes for which they are intended; and that the sails are properly fitted to their yards and luffs, and well furled or reefed when occasion requires. It is likewise his office to summon the crew to their duty, to assist with his mates in the necessary business of the ship; and to relieve the watch when it expires. He ought frequently to examine the condition of the masts, sails, and rigging, and remove whatever may be judged unfit for service, or supply what is deficient; and he is ordered by his instructions to perform this duty with as little noise as possible.

The boatswain is not to cut up any cordage or canvas without an order in writing from the captain, and under the inspection of the master; and always to have by him a sufficient quantity of small plats for security of the cables.

He is not to sign any accounts, books, lists, or tickets, before he has thoroughly informed himself of the truth of every particular therein contained. His accounts are to be audited and vouched by the captain and water, and presented to the surveyor of the navy; and until such accounts are passed, he is not to receive any wages. If he has cause of complaint against any of the officers of the ship, with relation to the disposition of the stores under his charge, he is

to represent the same to the Navy-board before they pay off the ship. Fifteen years servitude intitles a boatswain to superannuation.

The *Boatswain's Mate* has the charge of the long boat, anchors, cables, &c.: he must give an account of his store; and he is appointed to execute the sentence of a captain or court martial.

BOATS, train of, a number of small vessels fastened to each other, ascending up the Loir in France, by sails when the wind serves, otherwise towed by men, sometimes to the number of seventy or eighty to a single rope.

BOAT-bill, in *Ornithology*, the English name of a species of **CANCROMA, cochlearia.** Brown's Illustrations. Or, more properly, at this time the English name of the *Cancroma* genus, *C. Cochlearia* being called by the modern writers the *crested boat-bill*, and *C. Canoeborga*, the *white bellied boat-bill*. There are the two only species known. See **CANCROMA.**

BOAT, scapha, in *Surgery*, a species of bandage, used when the crown of the head and the part between that and the forehead are to be bound. It is likewise called *thelus diocleus*.

BOAT-fly, in *Entomology.* See **NOTONECTA.**

BOAT-island, in *Geography*, a small island in the gulf of St. Lawrence, near the south coast of Labrador. N. lat. 50° 2'. W. long. 60° 55'.

BOAT Passage, a channel into Facile harbour, in *Duffy* bay, New Zealand.

BOATING, a kind of punishment in use among the ancient Persians for capital offenders.

The manner of boating was thus: the person condemned to it being laid on his back in a boat, and having his hands stretched out, and tied fast on each side of it, had another boat put over him, his head being let out through a place fit for it. In this posture they fed him, forcing him to eat by thrusting sharp iron instruments into his eyes, till the worms, which were bred in the excrements he voided as he thus lay, eat out his bowels, and so caused his death, which was usually twenty days in effecting; the criminal lying all this while in most exquisite torments. On his face, placed full in the sun, they poured honey, enticing the flies and wasps to torment him. Plutarch tells us, that Mithridates, whom Artaxerxes condemned to this kind of punishment, for pretending to have killed his brother Cyrus, lived seventeen days in the utmost agony; and that, when the uppermost boat was taken off at his death, they found his flesh wholly consumed, and swarms of worms gnawing his bowels. Herodot. l. i. c. 133, 140. Plut. in vit. Artaxerxes.

BOATIUM CIVITAS, in *Antient Geography*, a town of Gaul, and one of the twelve cities of Novempopulania.

BOATSKIDS, in *Naval Architecture*, are long square pieces of fir, extending across the ship from the gang-boards, on which the boats, spare masts, &c. are stowed.

BOB, or **BALL,** in *Horology*, is the metallic weight which is attached to the lower extremity of a pendulum rod, by means of a tapped adjusting nut, at such a distance from the point of suspension as the time of a given vibration requires. (See the articles **CENTRE OF OSCILLATION** and **PENDULUM.**) In fixing upon a proper bob for any pendulum, two things are particularly to be attended to: the shape which is best calculated for meeting with the least resistance from the air; and the weight which is best adapted for preserving the isochronism of the vibrations with a given maintaining power. Each of these considerations has been the subject of much investigation. A sphere is a solid, the surface of which bears the least proportion to its solidity of any other, and a cube is one with great extent of surface compared to its solid contents; consequently, the former shape

has obtained in cannon balls, intended to pass through the air with as little obstruction as possible, and has sometimes, for the same reason, been applied as a bob for a pendulum. Such a shape is better adapted for a large bob than a small one; for the increase of the surface is in proportion to the square of the diameter, whereas the increase of weight or quantity of matter is as the cube. Mr. B. Martin (*Mathematical Institutions*, vol. ii. p. 417.) proposed two equal frustra of similar cones, to be joined together at the bases, as a figure approximating nearly to a solid of least resistance, and recommended it as that out of which the middle one of three segments, cut longitudinally, will constitute the best shape for an appended weight, to answer the purpose of avoiding resistance. Such a section, he conceived, would displace but a small quantity of air in one vibration, and the impulses of that quantity, being made obliquely on the sloping surfaces of the ends, would produce but a small effect. The lenticular shape, however, composed of two segments of a large globe joined to the line of section, has been generally adopted by clock-makers, probably because two plates of brass of that shape can be easily folded together, and left hollow, so as to be filled with lead, or other heavy metal, in order to obtain a due degree of weight without adding to the thickness, which is an advantage that brass or copper cannot have of itself in any shape. M. Ferdinand Berthoud (*Essai sur l'Horlogerie*, tome ii. chap. xiii.) made some experiments with bobs of both a spherical and lenticular shape, of equal weight, attached successively to the same free pendulum, from which it appeared, that, in the same temperature, the latter continued to vibrate seconds much longer than the former before they arrived at the quiescent state, which experiment was considered as a proof that the lenticular shape has the advantage in escaping the effect of resistance; it was discovered, however, on a repetition of the experiment, with seconds and half-seconds pendulums, that the friction at the point of suspension occasioned by heavy weights, particularly when vibrating in long arcs, made considerable alterations in the results, and proved itself a second source of resistance to the free motion of the pendulum.

The second consideration to be attended to in making the bob, as has been said, is the weight which a given pendulum requires, with a given maintaining power. No theory is adequate to determine this desideratum of itself, because the diminution of the maintaining power by the friction of the pivots and the state of the oil, the duration of the impulse on the pallets, the nature of the escapements in other respects, the resistance of the air, and at the point of suspension, and particularly the nature and quantity of momentum of the pendulum, must all enter into the calculation; and these are data, many of which are constantly varying. The momentum, or whole quantity of motion of any pendulum, is the weight multiplied into the square of its velocity, so that a large arc with a small weight, and a small arc with a corresponding large weight, *ceteris paribus*, ought to have an equal effect upon the isochronism of the same pendulum; but the theory is not perfect; for first, large circular arcs deviate considerably from cycloidal ones, which, it has been demonstrated by Huygens and others since, are those which have the isochronal property in an uniformly dense medium; and secondly, they require a greater maintaining power than calculation gives: for instance, where the arc is 10 from the point of rest, the addition to be made to the maintaining power beyond calculation is 57 parts in 100, according to Berthoud's experiments, which consideration induces him to conclude, that irregularities in the maintaining power will affect the momentum principally composed of velocity, more than the momentum principally composed of weight; each kind of momentum, however, has its peculiar disadvantage; for

great velocity is subject to great resistance from the air, and great weight to much friction at the point of suspension. Mr. Alexander Cummings was an advocate for a large arc with a small bob; but modern practice is in favour of a large ball or bob with a short arc of vibration. It seems to be generally allowed, that the momentum of a pendulum ought to be as great as possible for a given maintaining power, provided the latter be sufficient to overcome all obstacles to constant motion; but as the momentum is obtained in two different ways, it may be proper to subjoin here an illustration of them.

If a pendulum, moving in an arc of one degree from the quiescent point, with a bob or ball of six pounds, have its momentum denominated by unity, then the square of any given momentum will give its corresponding weight for another bob, moving in the same arc; or the square root of the given momentum will give the arc of semivibration with the same weight; for instance, a momentum 4 will require $6 \times 4 = 24$ for the weight where the arc remains unaltered; but the root of $4 = 2$ will be the arc from the point of rest with the same weight; again, if the momentum be required to be 9 for a given maintaining power, the weight must be 54, or the arc 3° from the point of rest, and in the same proportion for any other momentum; but, in fact, both the weight and arc may be varied according to circumstances, which latitude affords great variety in the adjustment of the bob, and matter for multiplied experiments to determine what weight and arc shall be most desirable, taken conjointly under different circumstances.

The most practicable method of adjustment of the momentum of a pendulum, where a weight is used as a maintaining power, seems to be, to vary this power instead of the weight of the bob or ball, which, when once finished of the requisite shape, is not so easily altered. In pendulum clocks, actuated by a spring as a maintaining power, such adjustment cannot indeed be made in the power properly without changing the spring, or altering the fusee after they are adjusted to each other; but as these instruments are not intended to measure time with great nicety, the adjustment of the bob to the maintaining power is exactly done by guess. In Huygens's best clock, the maintaining power was equal to three pounds, falling about 90 inches in 24 hours, and the ball of its seconds pendulum, together with the pendulum itself, was also three pounds; but the nature of his escapement required the vibrations to be performed in long arcs. Cummings tried different weights for his pendulums from 6 to 16 pounds, and various arcs from 3° to 6° from the point of rest; but it does not appear that any other standard has been adopted by clock-makers than what accords with the individual opinion of each. See MAINTAINING POWER.

BOB, in *Ringing*, denotes a peal consisting of several courses, or sets of changes.

BOB-STAY, in *Sea-Language*, a rope used to confine the bowsprit of a ship downward to the stem, or cut-water, and to counteract the force of the stays of the fore-mast, which draw it upwards.

It is fixed by thrusting one of its ends through a hole bored in the fore-part of the cut-water and then splicing both ends together, so as to make it two-fold, or like the link of a chain; a dead-eye is then seized into it, and a lead passing through this, and communicating with another dead-eye upon the bowsprit, is drawn extremely tight by help of mechanical powers. The bob-stay is the first part of a ship's rigging, which is drawn tight to support the masts. With this view, it is usual to suspend a boat anchor, or other weighty body, at the bowsprit end, to press it downwards during the operation.

BOB-STAY-HOLERS, are those holes in the stem, or fore-part of the knee of the head, to which the bob-stay is fastened.

BOBAC, in *Zoology*. The bobac of the French and English writers is a sort of MARMOT with small, and somewhat oval ears; tail hairy; a claw upon the fore thumb; and the body grey above, and yellowish beneath. Gmelin calls this animal *arctomys bobac*.

There appear to be two varieties of this species, if not more. The bobac of Rzaczinski (Nat. Hist. Pol. p. 235.) described by Brisson, in his History of Quadrupeds, under the name of *marmotta polonica*, is of yellowish colour, inclining to reddish upon the head; but the bobac described by Pallas is of a greyish brown colour, with only the under parts yellow. In every respect, except the colour of the hair, these two varieties agree.

This creature is rather larger than the rabbit, measuring about sixteen inches from the nose to the base of the tail, the latter of which is four inches and an half in length; so that the whole animal measures above twenty inches. Dr. Pallas, to whom we are chiefly indebted for an account of the bobac, tells us, that it is a native of the high, but milder and sunny sides of mountainous countries, which abound with fissile, or free-stone rocks, where it is found in dry situations, and such as are full of springs, woods, or sand. It abounds in Poland and Russia, among the Carpathian hills: it swarms in the Ukraine, about the Boristhenes, especially between the Sula and Supoy; and then again between the Boristhenes and the Don, and along the range of hills which extend to the Volga. It is found about the Yaik and the neighbouring rivers; and inhabits the southern desert in Great Tartary, and the Altaic mountains, east of the Irtis. It ceases to appear in Siberia, on account of its northern situation, but is found again beyond the lake Baikal, and about the river Argun and the lake Dalay, in the sunny mountains about the Lena, and very frequently in Kamtschatka, but rarely reaches as high as latitude 55°.

The bobac is not considered as an article of food by the Mahometan Tartars. The Cossacks and the Calmucks, on the contrary, hunt and kill them for eating; the flesh, however, is very fat, and not in much esteem for the goodness of its flavour. In its manners of life the bobac resembles those of the Alpine marmot, with which it has been apparently sometimes confounded. It inhabits deep burrows, in societies of from twenty to twenty-four in each receptacle. Their habitation is lined with the finest hay; and it is said, the quantity found in every such receptacle is sufficient for a night's provender for a horse. In the morning, or the middle of the day, when the sun shines, they go abroad in search of food, always taking the precaution to station one of the party at the entrance of their cell as a centinel, who announces the least approach of danger with a whistle; and all, if within hearing, are thus enabled to provide for themselves in the best manner circumstances may require, either by returning for shelter to their cell, or remaining at a distance till the danger is over. The marmot, when attacked, rears itself upon the haunches, and defends itself with the fore paws. It eats with the fore paws, in the same posture. The bobac is an animal of a mild and gentle disposition, and may be easily domesticated. They are torpid throughout the winter, unless kept in a warm room. They breed early in the spring, and are said to produce six or eight young. The fat of this creature is used for dressing furs and leather.

BOBAN, in *Geography*, a town of Arabia, 32 miles S of Saade.

BOBART, ROBERT, in *Biography*, curator of the botanical garden at Oxford, which had been lately instituted by lord Danby, published, in 1648, "Catalogus plantarum horti medici Oxoniensis," 8vo. The catalogue gives the names of about 1600 plants, many of them from Canada,

first the Latin, then the English names, in alphabetical order. This was re-published in 1658, considerably improved and enlarged to more than double its bulk; Bobart being assisted in the work, as he acknowledges, by Dr. Philip Stevens and Wm. Brown, M. A. Besides the trivial names of the plants, there were now added those from Gerard, Parkinson, and Bauhine, which were not in the first edition. Bobart died in 1679, at the age of 81 years.

BOBART, JACOB, who succeeded his father, as curator of the garden, published, in 1699, the third volume of Morrison's "Plantarum historia universalis Oxoniensis, seu herbarum distributio nova, per tabulas cognitionis, ex naturæ libro detecta," fol.; making up by his own industry and sagacity what was deficient in the loose and imperfect sketches left by the author at his decease. There is an ingenious paper by this writer in the Philosophical Transactions for the year 1683, on the effects of the great frost, which happened the preceding winter, on trees and other plants. Many oak, elm, ash, walnut, and other trees, were found, he says, with large rents or clefts in different parts of their trunks, in the large branches, and in such parts of their roots as were not sunk deep into the earth. Parts, he adds, that were so knotted, that they could not have been split but with great difficulty with beetles and wedges, were rent asunder by the force of the ice contained within them, making, at the time of bursting, a noise like the explosion of gunpowder. It was supposed, that the trees which suffered were diseased, that some of the vessels were distended or burst, and that the effect was produced by the freezing of the sap or other juices contained in these cavities. Philoſ. Trans. abr. vol. iii. p. 89. Haller. Bib. Botan.

BOBARTIA, in *Botany*, (named in honour of James Bobart, formerly professor of botany at Oxford), a genus formed by Linnæus for a plant said to grow in the East Indies, with the following essential character:—*Glumes of the calyx* numerous; the exterior one short, univalved; the interior longer, bivalved; *glume of the corol.* single, shorter than those of the calyx, sitting on the germ, shrivelling. This generic character was first published in the *Amœnitates Academicæ*, vol. i. p. 113. (Lugd. Bat. Ed.); and in the *Species Plantarum* a reference is given to Scheucher, Gram. 369. Reichard added another supposed synonym from Plukenet tab. 30. fig. 7. Schreber, Jullieu, La Mark, and Bosc, have all taken it up from Linnæus; and La Mark, in his *Illustrations*, has copied Plukenet's figure. Willdenow, in his new edition of the *Species Plantarum*, has abolished the genus; asserting on the authority of Schumacher (Act. Soc. Nat. Hafn), that Linnæus drew up the character of his bobartia from a mutilated specimen of *moræa spathacea*, first completely described by Thunberg, and adopted by Linnæus the younger in the *Supplementum Plantarum*, p. 99.

The mistaken synonyms of Scheucher and Plukenet are referred by Willdenow to *cyperus arenaria* of Retz, of which Plukenet's figure, copied by La Mark, is said to be a good representation. A figure of *moræa spathacea* is also given by La Mark under its proper genus.

BOBARTIA. See also *RUDBECKIA Purpurea*.

BOBBIN, in *Commerce*, a term denoting about $\frac{3}{4}$ of a hundred of undressed flax.

BOBBING, or **BOBBIN**, a little piece of wood turned into a cylindrical form, wherein thread is wound, to be used in the weaving of bone-lace.

The French also give the denomination *bobine* to what among us is more properly called a *spool* or *quill*. In which they are also followed by several English.

In this general sense, bobbins are used to wind thread-worsted, hair, cotton, silk, gold, and silver; and they are

of different lengths and sizes, according to the materials which are spun or wound.

BOBBING for Eels, among *Fishermen*, is an amusing method of catching eels, generally practised from the side of a boat, the piers of bridges, wharfs, or other situations where deep water can be at once reached. The bait made use of may be either scoured lob-worms, or garbage of any kind; which bait of whatever kind is strung lengthways on worsted, so as to completely cover it: some yards are prepared in this way, which are then tied up in links, making something like a bundle of fringe. So prepared, the bait is suspended from a strong rod or pole by two or three yards of pack-thread, leaved within a foot of the worms with more or less weight according to the strength of the current. The bait and lead must be sunk to the bottom, and suffered to remain, when the fish will soon be felt to nibble; but time must be allowed for them to make their hold secure, after which they may be gently pulled up to within a small distance, when a slight jerk will secure them. The mouths of rivers, muddy and deep places, where the tide reaches, are particularly favourable for this sport.

BOBBIO, or **BOBIO**, *Bobium*, in *Geography*, a small town of Italy, and capital of a district of the same name, formerly belonging to the duchy of Milan, seated on the river Trebia, the see of a bishop, suffragan of Genoa, 30 miles N.E. of Genoa. It is now a canton of the district of Alexandria, in the department of Marengo.

BOBBIO. See **BOBIO**.

BOBENHAUSEN, a town of Germany, in the circle of the Upper Rhine, and principality of Upper Hesse; 17 miles east of Giefen.

BOBENNEUKIRCHEN, a town of Germany, in the circle of Upper Saxony, and the Vogtland; 6 miles S.W. of Oelsnitz.

BOBER, a river which runs into the Oder, at a small distance to the west of Crossen in Silesia.—Also, a town of Lithuania. N. lat. $55^{\circ} 46'$. E. long. $25^{\circ} 46'$.

BOBERG, a high promontory in the prefecture of Boffing, and diocese of Ripen, in Denmark, near which the coast is very dangerous, and has proved fatal to many ships.

BOBERSBERG, a town of Silesia, 9 miles S. S.W. of Crossen, and 28 S. of Franckfort on the Oder.—Also, a town of Germany, in the circle of Upper Saxony, and duchy of Crossen, 6 miles S. of Crossen.

BOBI, in *Conchology*. Adanson gives this name to the variety ϵ of *voluta persicula*.

BOBISATIO, or **BOCENISATIO**, in *Music*, denotes the using of the seven syllables, *bo, ce, di, ga, lo, ma, ni*, to express the seven musical notes in lieu of the six usual ones introduced by Aretine, *ut, re, mi, fa, sol, la*, as has been sometimes done by the Netherland and German musicians since the beginning of the seventeenth century, to avoid the mutation necessary in the use of these latter.

BOBLINGEN, in *Geography*, a small town and district of the same name, of Germany, in the duchy of Wurtemberg, situate in a fertile country, and in the forest of Schonbuch, which abounds with game, having a castle seated on an eminence lying above the town. The district contains 12 parishes; and the vicinity produces some wine.

BOBR, a river of Lithuania, which runs into the Dnieper; 5 miles S. S. E. of Rohaczow.

BOBR, in *Zoology*, a kind of marine otter, so called by the Russians, who reside at Kamtschatka, the precise species of which is doubtful. Some have imagined it to be allied to the castor.

BOBRITZSCH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and country of Erzgebirg, 4 miles S. E. of Freyberg.

BOBROF, a district of the government of Voronetz, in Russia, seated on the Biliuk, falling into the Don.

BOBROWNIK, a town of Poland, in the palatinate of Lublin, 24 miles W. N. W. of Lublin.

BOBRYSLÉ, a town of Lithuania, in the palatinate of Minsk, seated near the river Berezyzna. N. lat. 53° . E. long. $29^{\circ} 12'$.

BOBRI, a town of Lithuania, in the palatinate of Troki. N. lat. 55° . E. long. $24^{\circ} 15'$.

BOCA. See **BOCCA**.

Boca Escondida, in *Geography*, a bay of North America, in the bay of Campechy, on the coast of Yucatan. N. lat. $18^{\circ} 50'$. W. long. $91^{\circ} 46'$.

Boca Grand, a bay of North America, at the mouth of the river Zucar, on the S. E. coast of Costa Rica. N. lat. $10^{\circ} 50'$. W. long. $83^{\circ} 26'$.

Boca Tora, a bay of North America, in the Caribbean sea, on the coast of Veragua. N. lat. $8^{\circ} 58'$. W. long. $82^{\circ} 1'$.

BOCABRITO, a town of North America, in the country of New Navarre, 65 miles east of Cinaloa.

BOCA-CHICA, the strait or entrance into the harbour of Carthagena, in South America; which was filled up since the attack of the English in 1741, who, having made themselves masters of the forts which defended it, entered the bay with an intent of taking the city; but their attempt miscarried, and they were obliged to retire with considerable loss. This event produced orders for opening the old entrance, by which all ships now enter the bay.

BOCA-DEL-DRAGO, a strait between the island of Trinidad and Andalusia, in the province of Terra Firma, South America.

BOCAGE, a small territory of France, in Normandy, of which the principal place was Vire.

BOCALIEAU, a small island, near the east coast of Newfoundland. N. lat. $48^{\circ} 15'$. W. long. $52^{\circ} 26'$.

BOCAMELE, in *Zoology*, the provincial name of an animal of the *MUSTELLA* tribe found in the island of Sardinia. This is believed to be the creature described by Aristotle by the name of *Isis*.

BOCANÁ, in *Ancient Geography*, a town situate in the eastern part of the isle of Taprobana. Ptolemy.

BOCARDÓ, in *Logic*, the fifth mode of the first figure of syllogisms, wherein the first proposition is particular and negative; the second, universal and affirmative; and the third, or conclusion, particular and negative. Thus:

BOC Some animal is not man.

AR Every animal has a principle of sensation.

DO Therefore something has a principle of sensation, that is not man.

BOCAS, LAS, in *Geography*, a town of North America, in New Biscay, 120 miles E. of Parmal.

BOCAT, the name of a valley in Syria, in which are the ruins of Balbec, of which Mr. Wood says, it might by a little care be made one of the richest and most beautiful spots in Syria; for it is more fertile, he adds, than the celebrated vale of Damascus, and better watered than the rich plains of Efdraelon and Rama. In its present neglected state, it produces corn, some good grapes, but very little wood. Here, it is supposed, was situated "Baal-hamon," which was the marriage portion of the bride of Solomon. Sol. Song. viii. 12. This estate was leased out to a variety of tenants, each of whom paid her a clear rental of a thousand shekels of silver, amounting to about 120 l. 16 s 8 d. sterling. Harmer's Outlines of a New Commentary on Solomon's Song, p. 35. Good's Song of Songs, Pref. p. 13. Bocat was also called "Bekaa," which see. See also **BALBEC**.

BOCAUD

BOCAUD, JOHN, in *Biography*, born at Montpellier, where he received his education. In 1540, he was made doctor; and in 1544, on the death of Denis Fontenon, professor of medicine in the university there; an office he is said to have filled with distinguished honour to the time of his death, which happened in 1558. We have only one work published by this writer; "Tabula curationum et indicationum ex prolixo Galeni methodo, in summa rerum capita contractæ." fol. Lyons. Haller. Bib. Med. Pract. Eloy. Dict. Hist. Med.

BOCCA, a term used both in the Levant and on the N.W. coast of South America, or the Spanish main, for a mouth or channel into any port or harbour, or the entrance into a found which has a passage out of it by a contrary way. See **BOCA**.

BOCCA, in *Geography*, a town of Italy in the duchy of Mantua, in the Comasenza, 5 miles N.N.E. of Sabione ta.

BOCCA Tigris, a name given by foreigners to the river Pe-kiang of China, near its discharge into the southern sea of China. See **PE-KIANG**.

BOCCA, in *Glass making*, the round hole in the working furnace, by which the metal is taken out of the great pots, and by which the pots are put into the furnace. This is to be stopped with a cover made of earth and brick, and removeable at pleasure, to preserve the eyes of the workmen from the violence of the heat.

BOCCACCI, or **BOCCACCINO, CAMILLO**, in *Biography*, a painter of history and portrait, was born at Cremona in 1511; and, having received instructions in the art of painting from his father, removed to Rome, and assumed the Roman taste. His application was indefatigable, and his improvement so observable, that he was immediately employed in several noble works for the churches and convents. He died young in 1546, when he was making rapid progress towards very high perfection. Pilkington

BOCCACCINI, ANTHONY, a surgeon of Comachio, a town in Ferrara, flourished in the early part of the last century. Reviving the practice of Magatus, in the cure of wounds and ulcers, which had fallen into disuse, he admitted no oily or greasy applications in the treatment of them, nor made use of tents or injections in the cure of abscesses, which, by irritating the parts, prevented, he said, their union, and frequently occasioned the orifices to become callous. His works, illustrating his practice, are "Cinque disinganni Chirurgicali, per la cura delle ferite," Venice 1713, 8vo. treating of the cure of gun-shot wounds; "Cinque disinganni Chirurgicali, per la cura delle ulcere," Ven. 1714, 8vo. with observations explaining and defending the doctrine of Magatus. Haller Bib. Chirurg. Eloy. Dict. Hist. Med.

BOCCACIO, or **BOCCACE, JOHN**, an eminent Italian writer, and one of the restorers of literature in Europe, was born of parents in low condition at Certaldo in Tuscany, in 1313. Declining that mercantile occupation for which he was originally designed, and in which he spent some of his earlier years, he devoted some time to the study of the canon law; but as soon as he had an opportunity of choosing for himself, he pursued a course of literature; and with this view sought instruction from the best masters, and at Florence put himself under the tuition of Leonzio Pilato for the Greek language. Besides the advantage he derived in furnishing his mind with stores of literature, and in cultivating a good taste, from conversation with the most learned men of his age, and from collecting and copying the most approved Greek and Latin writers of antiquity, he was particularly indebted for his progress in learning, and for his future reputation to the instruction and patronage of Petrarch, who was eminently useful to him both by his advice and by

supplying him with money for aiding the prosecution of his studies, when his own patrimony was exhausted. By a diligent improvement of these advantages, he acquired such reputation, that the republic of Florence conferred upon him the honour of citizenship, and employed him in a variety of public transactions. Among other important commissions with which he was entrusted, that of negotiating the return of his friend Petrarch to Florence was particularly agreeable to him. But though his message to this purpose did not succeed, it afforded him an opportunity of establishing a more intimate and confidential correspondence with this patron of his youth. In 1353, two years after his visit to Petrarch, he was sent to pope Innocent VI at Avignon. At this time he lived freely, and devoted himself chiefly to poetry and compositions of a lighter kind. During his rambles in Italy, he visited Naples, as some have said, in the year 1341, where he was favourably received by king Robert, and where he resided for some time. Here he fell in love with a young person whom he calls Fiametta, and who is commonly supposed to have been the natural daughter of Robert. In 1359, he had a conference with Petrarch at Milan, the result of which was his indulging more serious reflections than he had hitherto done; and having received an admonition in 1361, that his life would not be of long continuance, and that he would soon abandon poetry, his mind was so impressed that he immediately determined to relinquish his poetical lucubrations, and even the perusal of profane authors, and, against the counsel and remonstrance of Petrarch, to part with his library. About this time he assumed the clerical habit, and adopted a plan of conduct more guarded and regular than that of his past life. In 1362 or 1363 he again visited Naples; and without making any long stay there, went to Venice, and passed three months with his friend Petrarch. He was again deputed by his countrymen as ambassador to pope Urban V. at Avignon; and in 1367 he attended the pontiff under the same character at Rome. A public lecture on the "Comedia" of Dante, having been instituted at Florence, he commenced his expositions of that author in October, 1373; but, preferring the retirement of Certaldo, his native place, towards the close of his life, he died there in December, 1375. Boccaccio was a voluminous writer both in prose and verse. His works in Latin were, a mythological treatise in 15 books, "De Genealogia Deorum," Basil, 1532, fol. esteemed excellent at the time when it was written, but long since superseded by more valuable publications of a similar kind; to this was annexed a "Treatise on Mountains, Rivers, Seas, Lakes, &c.;" with respect to both these he has been charged with plagiarism; "An Abridgement of the Roman History," from Romulus to the year of Rome 724, with a parallel of the seven kings of Rome and of the emperors to Nero, inclusively, Cologne, 1534, 8vo.; an historical treatise, in nine books, entitled "De Casibus virorum et feminarum illustrium," beginning with Adam, and terminating with John king of France taken prisoner by the English at the battle of Poitiers, 1356, which work was translated into Italian, Spanish, French, and English, printed at Augsburgh, in 1544, and in French at Lyons, in 1483, and at Paris in 1578, by Claudius Vitart, under the title of "Traité des Malaventures des Personnes signalez," 8vo.; and another book "De claris mulieribus." He also wrote in Latin a number of eclogues. In Italian poetry, his compositions were the "Theleide," in 12 books; the "Filostrato;" the "Ninfale Fiesolano," &c. &c. But though he was reckoned one of the three princes of the poets of that age, he is ranked only as the third of the triumvirate, precedence being assigned to Dante and Petrarch. It is said

said, that he was duly sensible of his inferiority; and that, after having seen the sonnets and songs of Petrarch, he determined to throw his own into the fire. His prose works, which are more valuable, are his "Commentary on Dante," printed at Rome in 1544, 16to.; and at Florence, in 1576, 8vo. some romances of an amorous kind, intermixed with verse, as "Il Filocopo," "La Fiametta," "L'Ameto," "Il Laberinto d'Amore," &c. &c. But his most celebrated production of this kind is his "Decamerone," or collection of one hundred stories, or novels, feigned to have been recited in ten days by a company of ladies and gentlemen, who had retired into the country from the plague of Florence in 1348. These stories are partly founded on fact, and partly the productions of the author's own imagination; and they present a curious exhibition of characters and manners in all the ranks of society. They abound with satirical strokes levelled against the vices and frauds of the priests, and even the mysteries of religion; and the language, in some parts, is so free and licentious, that we may well wonder at their being recited before females of character and condition. However trite and vulgar many of the reflections may now appear, the style in which they are delivered is considered as a model of elegance and purity for the age in which they were written, and places the Italian language far beyond that of any modern nation at so early a period. No work was ever more popular, or more generally translated, than the Decamerone. The stories that occur in this work have furnished materials for some of the most popular pieces of La Fontaine and other similar writers. Boccace assumes the credit of having first brought the writings of Homer and of several other Greek authors from Greece to Tuscany; and he was, without doubt, a most industrious and indefatigable copyist of the remains of antiquity. His poetry is pronounced by his countrymen to be as feeble and languid in its character, as his prose is exquisite and admirable. His valuable library was bequeathed to a convent in Florence, where it was long preserved. For a further account of his life and writings, see Fabricius's *Bibl. Lat. medii ævi*. tom. 1. p. 248. &c.; and Tiraboschi, tom. v. p. 87. 439—451. Gen. Dict. Burney's *Gen. Hist. Music*, Vol. II. p. 338, &c.

BOCCALE, or **BOCAL**, a liquid measure used at Rome, answering to what among us is called a bottle, being equivalent to about an English quart. Seven *boccales* and an half make the *rubbia*.

BOCCALINI, **TRAJAN**, in *Biography*, a satirical writer of the 16th century, was the son of an architect at Carpi, and born at Loretto in 1556. At Rome, where he principally resided, he had access, by the vivacity of his genius, to several persons of rank, and among others to cardinal Bentivoglio, whom he instructed in geography. Protected from the danger to which his satirical turn exposed him, by the influence of the cardinals Borghese and Gaetani, he also, by their recommendation, obtained several offices of trust and honour in the ecclesiastical state, and was appointed to the government of Benevento. But his public conduct occasioned complaints, and he became obnoxious to the Spaniards, by exposing with freedom and severity their designs against the liberty of Italy, so that he was under a necessity of retiring to Venice in 1612. In the following year, it is said that he was assassinated by four ruffians, who broke into his chamber at an early hour in the morning, and beat him so severely with sand-bags as to occasion his death. Of his works, the most celebrated is his "Raggugli di Parnaso," or news from Parnassus, in which, under the fiction of a court in which Apollo presides, he takes occasion to satirize the actions and works of several persons who pass under review; but his reflections frequently betray the

want of critical judgement and of a regard to truth. A second part of this work written with the same views, is entitled "The Secretary of Apollo." His "Political Touchstone," levelled against the Spaniards, is of a similar kind. He also wrote the "Political Balance," "Commentaries on Tacitus," and some other works. Tiraboschi. *Gen. Dict.*

BOCCARELLA, in the *Glass-Manufacture*, a small hole or aperture of the furnace, one of which is placed on each side of the bocca, almost horizontally with it. Out of them the servitors take coloured or finer metal from the piling pot.

BOCCAS, in *Ichthyology*, the Arabian name of a fish belonging to the *SCOMBER* genus, observed by Forskal in the Red Sea. Vide *SCOMBER SANSUN*.

BOCCHERINI, **LUIGI**, in *Biography*, was born at Lucca in 1736, where he resided till 1768, when he went to Paris, and where he continued till 1780. He then removed to Madrid, where, if living, he still remains. His instrument is the violoncello, and though he writes but little at present, he has perhaps supplied the performers on bowed-instruments and lovers of music with more excellent compositions than any master of the present age, except Haydn. His style is at once bold, masterly, and elegant. There are movements in his works, of every style, and in the true genius of the instruments for which he writes, that place him high in rank among the greatest masters who have ever written for the violin or violoncello. There is perhaps no instrumental music more ingenious, elegant, and pleasing, than his quintets; in which invention, grace, modulation, and good taste, conspire to render them, when well executed, a treat for the most refined hearers and critical judges of musical composition. A complete list of the works of this excellent composer would be of use to judicious collectors, as his genius, taste, and judgment were too fertile and refined, to suffer him to commit to paper frivolous or indigested thoughts. His productions of 40 years ago have lost nothing of their worth, nor will 40 years more wholly deprive them of their bloom.

BOCCHETTA, in *Geography*, a chain of mountains, over which is the high road between Lombardy and Genoa; on the summit of the highest, which is very steep, is a way so narrow that three persons can hardly go a-breast, called "The Pass of Bocchetta," defended by forts, and considered as the key to the city of Genoa. In 1746 the imperialists, having made themselves masters of this pass, found little difficulty in proceeding to that capital. In 1778, a magnificent road was made from the Bocchetta to the north of Genoa, through the Polzevera, which, for the space of three years, employed from 5 to 800 men, by the patriotic munificence of one noble family, the Cambiasi. The Polzevera in the Bocchetta yields a beautiful stone which is serpentine, of various colours veined with marble.

BOCCHIANICO, a town of Italy, in the kingdom of Naples, and province of Abruzzo citra, 3 miles S.E. of Civita di Chieti.

BOCCIARDI, **CLEMENTI**, called *Clementone*, in *Biography*, a painter of history and portrait, was born at Genoa in 1020, and after having been the disciple of Bernardo Strozzi, went to Rome for improvement, by a judicious observation of the ancient sculptures, and the works of the celebrated modern artists. By the efforts of his own excellent genius, and a diligent application to design, he discovered the art of blending the antique and modern gusts in a style both of gracefulness and strength. Most of his works (his portraits excepted, which were lively, natural, and graceful,) are in the chapels of Genoa, Pisa, and other cities of Italy, where they are much esteemed. Pilkington.

BOCCOLD, **BOCKHOLDT**, or **BEUKELS**, **JOHN**, commonly called *John of Leyden*, a journeyman-taylor, of Leyden, who, in the earlier part of the 16th century, connected

connected himself with John Matthias, a baker of Haerlem, and with his assistance displayed the astonishing effects of fanaticism and enthusiasm. These two anabaptist prophets, for this was the appellation which they assumed, fixed their residence at Munster, in Westphalia, and at length gained such a number of proselytes, that they became masters of the city, and established in it a new form of government, directed by Matthias, who issued his commands, with the style, and with the authority of a prophet. Matthias, having pillaged the city, amassed large hoards of wealth, and reduced all ranks to an equality, provided for its defence, by repairing and extending its fortifications, by forming all his followers, who were capable of bearing arms, into regular bodies, and by endeavouring to add the vigour of discipline to the impetuosity of enthusiasm. After these preparations, he sent out emissaries to the anabaptists in the Low Countries, inviting them to assemble at Munster, which he dignified with the title of Mount Zion, and from thence he proposed that they should set out to reduce all the nations of the earth under their dominion. The bishop of Munster, justly alarmed by these hostile appearances, assembled an army, laid siege to the town, and slew Matthias, with 30 of his attendants, in their first frantic sally. Matthias in the same year 1534, was succeeded by Boccold, who, more cautious than his predecessor, satisfied himself with carrying on a defensive war, whilst he waited for the succours from the Low Countries, which he encouraged his deluded followers to expect. But though less daring in action than Matthias, he was a wilder enthusiast, and of more unbounded ambition. Accordingly he marched naked through the streets, and proclaimed with a loud voice, "That the kingdom of Zion was at hand; that whatever was highest on earth should be brought low, and whatever was lowest should be exalted." In order to verify his declaration, he commanded the churches, and the most lofty buildings in the city to be levelled with the ground; and depriving Cnipperdorling one of the most considerable of their proselytes of the consularship, the highest rank in the commonwealth, he degraded him to the humiliating office of common executioner. In place of the deposed senators, he named 12 judges, according to the number of tribes in Israel, and reserved to himself the authority possessed by Moses as legislator of the people. He further declared to the assembled multitude, that it was the will of God, that John Boccold should be king of Zion, and sit on the throne of David. Accepting this heavenly calling, which he pretended to have received by a special revelation, he was immediately acknowledged as monarch by the deluded multitude, and assumed all the state and pomp of royalty. He wore a crown of gold, and was clad in the most sumptuous garments. A Bible was carried by him in one hand, and a sword in the other; he appeared in public attended by a body of guards, coined money with his own image, and appointed the great officers of his household and kingdom, among whom Cnipperdorling was nominated governor of the city, as a recompence for his former submission. As the excesses of enthusiasm have usually led to sensual gratifications, Boccold instructed his prophets and teachers to inculcate the lawfulness of a plurality of wives, as one of the privileges granted by God to his saints; and he himself set the example of this Christian liberty, as he called it, by marrying at once three wives, one of whom was the beautiful widow of Matthias. He proceeded with augmenting the number of his wives to fourteen, restricting, however the title of queen to Matthias's widow, and allowing no other to share with him the splendour and ornaments of royalty. The multitude availing themselves of his example indulged their desires to the most licentious and extravagant excess; and polygamy and freedom of divorce universally prevailed. The bishop of Munster, in the mean while, aided by the German princes, pressed closer the blockade of the town into

which the siege had been converted; but its fortifications were so strong and so diligently guarded, that they durst not attempt an assault. But no succours arrived to the besieged; and after a close blockade of about fifteen months, they began to feel and lament the effects of scarcity. However, such was the fascinating influence of Boccold's promises and predictions, that no one seemed inclined, or at least possessed resolution enough to propose a surrender. One of his wives intimating a small doubt of his divine mission, was summoned before him as a blasphemer, and commanding her to kneel, he cut off her head with his own hands; his frantic followers at the same time dancing with joy round the bleeding body of their companion. Notwithstanding all the horrors of famine, the people of Munster still refused to capitulate. At length, however, a deserter made his escape to the enemy; and offered to head a party of the besiegers, under cover of the night, to a weak part of the fortifications, and less vigilantly guarded than any other. The proposal was accepted; and the party scaled the walls, seized one of the gates, and admitted the rest of the army. A dreadful carnage ensued; the king and Cnipperdorling were taken prisoners. The former, loaded with chains, was carried about from city to city, as a spectacle to the people; but notwithstanding all their insults, he maintained a firm and unbroken spirit; and adhered inflexibly to the tenets of his sect. He was afterwards brought back to Munster, and suffered the most exquisite as well as lingering tortures of death with astonishing fortitude; thus finishing an extraordinary course of delusion, at the age of 26 years. Bayle, Art. *Anabaptists*. Robertson's Hist. of Ch. V. vol. iii. p. 99. &c. Mosheim's Eccl. Hist. vol. iv. p. 452, &c.

BOCCONE, PAOLO, or PAUL, an ingenious naturalist, was born at Palermo, in Sicily, April 24th 1633. He was of a wealthy and respectable family, originally from Savona in Genoa. To improve himself in natural history, particularly in botany, to which he was early attached, he travelled over Sicily, Corsica, Malta, many parts of Germany, Holland, and England, conversing with the most eminent literary characters in the places he visited, with whom he afterwards kept up a correspondence. In the course of his travels, he was admitted doctor in medicine at Padua, was elected member of the Academ. Naturæ Curiosæ, and made botanist to the grand duke of Tuscany. In 1682, he entered among the Cistercian monks at Florence, and with the habit of the order took the name of Sylvio, which he affixed to his latter works, but he was still permitted to continue his researches in natural history. Returning at length to Sicily, he retired to one of the houses of the Cistercians near Palermo, where he died, Dec. 22, 1704. As he had been indefatigable in his researches, his collection of plants and other natural productions was very considerable. Sherrard, who saw his hortus siccus or specimens of dried plants, in 1697, was so struck with their number and beauty, that he engaged him to give a catalogue of them to the public, which he did in his "Musæo plante raræ," published at Venice in 4to. the same year. The catalogue was also published by itself. Several of his works appear to have been printed while he was on his travels. The first of them, "De abrotano mare monitum," in 1668; and in the same year, "Manifestum botanicum, de plantis Siculis," Catania, 4to. By an advertisement at the beginning of the work he offers to botanists the seeds of many of the curious and rare plants he had collected at moderate prices. Morrison published an edition of this work at Oxford in 1674, 4to. under the title of "Icones et descriptiones rariorum plantarum Sicilicæ, Melitæ, Gallicæ, et Italianæ." Many of the plants, Haller says, were new. The figures are small, and in general not well delineated or engraved. His next production was "Recherches et observations naturelles," published at Paris in

1671, 12mo. again at Amsterdam in 1674, and again in 1744, in 8vo. It consists of letters to his correspondents in France, Italy, England, &c. In 1684, in 16mo. "Operazioni naturali ove si contengono materie medico fisiche e di botanica," Bologna. The observations are 26 in number, and dedicated, or addressed to so many of the author's friends and patrons, among whom are many persons of high rank. He is very profuse in his elogia on the medical virtue of many of the plants, which he praises far beyond their real value. "Tenere oportet," Haller says, "credulum esse virum et in viribus medicis plantarum liberalem." "Musæo di fisica e di esperienze decorato di opervazioni naturali." Venet. 1697, 4to. The author here assumes the name of Sylvio. The observations are, as in the former work, dedicated to his noble patrons, and contain ample accounts of the medical virtues of various plants, much beyond what, from experience, they have been found to possess. Some smaller dissertations were printed in Miscel. Naturæ Curios. and in the Journal des Savans. On the whole, Boccone appears to have been an industrious and intelligent writer, and to be deservedly reckoned one of the promoters and improvers of botany. Haller Bib. Botan. Eloy. Dict. Hist. Méd.

BOCCONIA, in *Botany*, (named from Paolo Boccone, M.D.) a genus of the class *Dodecandria Monogynia*. Nat. Ord. *Rhœoifera*. *Papaveraceæ*, Jussieu. Lin. gen. 591 Reich. 643. Willden. 927. Schreb. 803. La Mark, p. 394. Gært. 44. Juss. 236.

Ess. Char. *Cal.* two-leaved. *Cor.* none. *Style* bifid. *Pericarp.* two-valved. *Seed* one.

Gen. Char. *Perianth* two-leaved, ovate, obtuse, concave, caducous. *Cor.* none. *Stamens*, before the opening of the flower, from 12 to 24, afterwards seldom more than 10; very short. *Anthers* linear, very large, as long as the calyx. *Pist.* germ roundish, contracted both ways, large, pedicelled. *Style* one, bifid. *Stigmas* simple, reflex. *Pericarp.* capsule subovate, attenuated to each end, compressed, one celled, two-valved. *Valves* coriaceous, opening at the base; the annular suture crowned with the permanent style. *Seed* one, globular, involved in pulp at its base, fixed to the bottom of the capsule. *Observ.* The capsule resembles a silicule in its general shape, and in the permanent suture terminated by the style.

Species, 1. *Bocconia frutescens*, shrubby bocconia tree, celandine, or parrot-weed. "Leaves oblong, sinuated. Willd." An ornamental shrub, 10 or 12 feet high, with a straight, hollow trunk filled with pith, covered with a smooth, white bark, and divided near its summit into several cylindrical branches. It abounds in all its parts with a thick, yellowish juice, similar to that of celandine. *Leaves* six or seven inches long, and about three broad; alternate, oblong, femipinnatifid; a little sinuated, with oval, unequally toothed segments; green and smooth above, glaucous, and a little tomentose beneath; on short petioles; flowers small, greenish, numerous, in large pyramidal, terminating panicles; bractes lanceolate.

It is a native of Mexico and the West Indies, where its acid juice is used to take off tetters and warts, and is also said to be employed in dyeing yellow. It has an evident affinity with the celandines in its sensible qualities and two-leaved caducous calyx, but differs remarkably from them in its incomplete flowers and monopermous fruit. La Mark conjectures that its want of a corolla is owing to the change of its natural petals into stamens: for, he observes, after the fall of the true stamens, four are constantly left, which continue as long as the calyx. See La Mark. Encyc.

The shrubby *bocconia* was first cultivated in England by Mr. Miller in 1739, and has flowered and ripened its seeds, in the physic garden at Chelsea. It is propagated by seeds,

which should be sown in a pot filled with light fresh earth, early in the spring, and then plunged into a bed of tanner's bark, and occasionally watered. When the plants are come up, they should be transplanted into separate pots filled with light sandy earth, plunged again in the hot bed, and shaded from the sun in the heat of the day, till they have taken root: at first they should be sparingly watered, but when their stems are become woody, they will require a larger supply. In about two months, they should be transplanted into larger pots, and plunged again into the bark. In warm weather they should have a good share of fresh air, but should never be taken out of the stove.

♁ *B. cordata*. "Leaves cordate, a little lobed." A native of China. *Panicle* elongated, with single, not divided, branches. *Calyx* white, as in the preceding species, but larger. *Stamens* about 24. *Style* none. *Stigma* bilamellated, sessile. Willdenow, by whom it was first described, as it should seem, from a dried specimen.

BOCCORE, in *Natural History*, בִּכְרִיָּה, q. d. first and early fruit, a name given in the kingdoms of Algiers and Tunis, and also in Palestine, to the early fig, which was produced in June, in Palestine, though the kermesz, or kermouse, the fig properly so called, which they preserved and made up into cakes, was rarely ripe before August, and sometimes hung upon the trees all the winter. The latter figs continued a long time upon the tree before they fell off; whereas the boccores dropped as soon as they were ripe, and, according to the appropriate and beautiful allusion of the prophet Nahum. (iii. 12.) fell into the mouth of the eater, upon being shaken. We learn from Jiny (N. H. l. xvi. c. 26.) that the fig-tree was bifera, or bore two crops of figs, viz. the boccore, as we may imagine, and kermouse: and it is well known that the fruit of these prolific trees always precedes the leaves; consequently, when our Saviour saw one of them, in full vigour, having leaves (Mark xi. 13) he might, according to the common course of nature, very justly look for fruit, and haply find some boccores, if not some winter-figs likewise upon it. The time of the year in which the event referred to in this passage occurred, was undoubtedly three or four days before the passover, at which our Saviour was crucified, and the passover in that year fell in the beginning of April. But it has been inquired, how Christ could expect to find ripe figs on the tree at the latter end of March? to which it is replied, because figs were ripe so soon in Judæa. It has been satisfactorily proved, that the harvest in Judæa began at the passover, and ended at pentecost; and as the barley in Judæa was ripe in March, and the wheat in April, we need not wonder, if there were ripe figs in the beginning of April too, or before the time of the passover. This, indeed, was the usual time for the first ripe figs; and therefore it was natural to expect that there should be figs at this season, more especially as the tree had leaves, before which the fruit came forth; and as the "time of figs" as bishop Kidder has shewn, the time of gathering in ripe figs, was not yet come. When St Mark says, "for the time of figs was not yet," he does not design to give a reason of what he said in the immediately foregoing clause, viz. "he found nothing but leaves," but he gives a reason of what he said in the clause before that, viz. "he came, if haply he might find any thing thereon." And it was a good reason for our Saviour's coming and seeking figs on the tree, because the time of gathering them was not yet come. The transposition above supposed, is not uncommon. See Mark, xvi. 3, 4. Gen. xiii. 10. Josh. xxii. 22. See Hallett's Notes on Texts of Scripture, vol. ii. p. 115, &c. Harmer's Observ. vol. i.

BOCH, JOHN, in *Biography*, a modern Latin poet and classical scholar, was born at Brussels in 1555; and having

entered into the service of cardinal Radzevil, accompanied him to Rome, and there studied theology under Bellarmine. He afterwards travelled into Poland, Livonia, and Russia, and was in danger of losing his feet by the frost in his journey to Moscow. Upon his return to the Low Countries, the duke of Parma appointed him secretary to the town-house of Antwerp. He died in 1609. His poetical works, consisting of epigrams, elegies, heroic poems, &c. were collected, and printed at Cologne in 1615. He has been highly esteemed as a Latin poet by the critics of his country, and called the "Belgic Virgil." Gen. Dict.

BOCH, in *Geography*, a river of the Netherlands which runs into the Meule, 5 miles below Dinant.

BOCHARIA. See BUCHARIA.

BOCHART, SAMUEL, in *Biography*, a learned orientalist, was the son of a minister of the reformed church at Rouen, where he was born in 1599. Having studied polite literature at Paris, philosophy at Sedan, and divinity, with the oriental languages, at Saumur, and made a surprising progress at a very early age, he completed his course of oriental literature under Erpenius and Ludolf at Leyden. On his return to France, he settled as minister at Caen. In 1646, he published his "Phaleg" and "Canaan," the two parts of his "Geographia Sacra," a work of very extraordinary erudition and research, in which he investigates the history of the human race as recorded in the Bible, the dispersion of mankind, and the origin of nations and languages, together with a variety of collateral subjects. Notwithstanding the charge of fanciful interpretations and chimerical conjectures, which has been alleged against some parts of this work, it has long maintained a high degree of reputation, and furnished an ample supply of materials for modern writers. In the progress of this work, the author was led to pursue a variety of inquiries concerning the animals, vegetables, and minerals mentioned in the sacred writings, on which he intended to have composed distinct treatises; but he only completed that relating to animals, which was printed at London in 1663, under the title of "Microzoicon." In this work the errors are such as must unavoidably occur at a period when the knowledge of natural history was very imperfect, compared with that of more modern times. In compliance with the invitation of queen Christina, Bochart visited Sweden in 1652, accompanied by the learned Huet, who wrote an humorous and elegant Latin poem on their journey. But finding that the capricious levity of the Swedish queen was not suited to his own grave character, he returned to France in 1653, and resumed his former studies. He was a member of the Academy at Caen, and, by his moderation and candour, maintained the distinguished reputation which he acquired by his profound erudition, together with the esteem and respect of persons of all parties, till the time of his death, which happened in consequence of an apoplectic stroke, during a disputation with Huet in the academy, May 16, 1667. Besides the learned works already mentioned, Bochart left several dissertations, particularly one, in which he attempts to prove that Æneas never was in Italy. His works were collected and printed by M. de Villemandy at Leyden in 1712, in 3 vols. folio. Gen. Dict.

BOCHO, in *Geography*, a town of Germany, in the circle of Upper Saxony, and principality of Querfurt, 3 miles S. E. of Juterbock.

BOCHOLNICZE, a town of Poland, in the palatinate of Sandomirz, 20 miles E. S. E. of Radom.

BOCHOLT, or BOCKOLT, a town of Germany, in a prefecture of the same name, in the bishopric of Munster, and circle of Westphalia; seated on the Aa, and

having iron mines in its vicinity; 36 miles W. S. W. of Munster.

BOCHOUULT, or BOCHOUT, a town of Flanders, situate on a canal cut from the Scheldt; 4 miles N. W. of Sas-de-Gent.

BOCK, BLAUER BOCK, in *Zoology*, a synonymous name of the *blue antelope*, *antilope leucophaea*. Kolbe.—Bock also signifies the male of the common goat. Gefn. Thierb.

BOCKA, or BUCKAU, in *Geography*, a mine town of Germany, in the circle of Upper Saxony, and country of Erzgebirg, 3 miles W. of Schwartzberg.

BOCKENBURG, a town of Germany, in the circle of Westphalia, and bishopric of Minden, one mile from Minden.

BOCKENHEIM, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenberg; 2 miles W. N. W. of Frankfort on the Mayne.

BOCKHORD, or BOOK-HOARD, in *Antiquity*, a place where books, evidences, or writings were kept.

BOCKHORST, JOHN VAN, in *Biography*, a painter of history and portrait of the Flemish school, was born at Munster, about the year 1610; and removing to Flanders, acquired the art of design and colouring in the school of Jacques Jordaens. He designed well; the heads of his women are generally graceful, and those of his men distinguished by character: his tone of colouring sometimes resembled that of Rubens, but more frequently that of Vandyck. His pictures have great force and harmony, and his skillful management of the chiaro-scuro produces an agreeable effect. An altar piece at the church of St. James in Ghent, representing the martyrdom of this saint, and a picture of the Annunciation in another church, painted in 1664, are distinguished performances of this master. Descamps. Pilkington.

BOCKI, in *Geography*, a small town of Poland, in Podalachia, in the palatinate of Bielsk.

BOCKING. See BRAINTREE.

BOCKING herring, in the *Dutch Trade*, signifies the same with bloated herring among us.

BOCK-KOGO, in *Geography*, a vast peak of the Brenner mountains in the Tyrol, rising little inferior to Gesorn, and in the same latitude, but towards the west.

BOCK-LAND, or BOOK-LAND, formerly denoted that which we now call FREEHOLD-land, or CHARTER-land; and it was by that name distinguished from FOLK-land, which was COPYHOLD land. In *Ancient Law-Writers*, it denotes a possession or inheritance held by evidence in writing. The word was doubtless written *bock-land*, quasi *book-land*, answering to free-land, or land held by book or charter, which was regarded as free property, and descended to the heirs of the possessor. It stood opposed to FOLK-land, which was that held without writing.

BOCKUM, BOCHUM, or BOCHEIM, in *Geography*, a town and prefecture of Germany, in the circle of Westphalia, and county of Mark; seated in a very fertile district, 24 miles N. E. of Dusseldorp, and 35 N. of Cologne.

BOCNIA, a town of Poland, in the palatinate of Cracow, famous for its salt-mines, first discovered in 1251. The small river called Raab, that falls into the Vistula, runs near this town, which is surrounded with hills and eminences. The salt-mine of Boenia is in a narrow slip of land, about 750 feet in breadth from north to south, and about 10,000 feet in length from east to west, and its greatest depth below the surface is about 1200 feet. The salt lies in veins, and is somewhat finer, especially at a certain depth, than that of Wieliczka. It is cut in small pieces, and put up in casks. Large pieces of black wood have been found in this mine, which are incrustated with salt; and likewise al-

bafter. The mines, which are very dry, are under the direction of the magistrates of Wieliczka. The town is 20 miles E. of Cracow.

BOCZEYKOWO, a small town of Lithuanian Russia, in the palatine of Polock.

BODÆUS A. STAPEL, JOHN, in *Biography*, was born at Amsterdā the beginning of the 17th century, where, at a proper age, he was admitted doctor in medicine, but attached himself particularly to botany, in which he acquired considerable celebrity. He died in 1636, at an early age, leaving a work, on which he appeared to have bestowed much labour, prepared for the press, which was published some years after, viz. Joannes Bodæus, a Stapel, in Theophrasti Historiam Plantarum, fol. Amst. 1644. Eloy's Dict. Hist. Med.

BODAIKA, in *Geography*, a town of Hungary, 7 miles W. of Patak.

BODDAERTI, in *Ichthyology*, a name given to a species of CHÆTODON. This has the body variegated with brown and blue bands, and the ventral fins armed with two spines. Schr. der. berl. naturf. Gmel. The habitat of this fish is unknown.

BODDAERTI, a species of GOÆUS, found in the Indian ocean. Pallas describes it specifically as having the rays of the anterior dorsal fin cirriform, and the third ray very long. This fish is six inches in length; the body blueish brown, pale and yellowish beneath, of a convex shape, tapering in a slight degree towards the tail, and covered with small soft scales. The head is thick, blunt, somewhat convex, and spotted with brown and white. Jaws nearly equal. Lips thick and fleshy: eyes vertical. Lateral line with scarcely perceptible papillæ, and a few snowy white spots. Each side of the back marked with seven black spots, and on the sides below these as many dots of white. Vent nearer the head than the tail; surrounded by a black circle, with a conic peduncle behind. Dorsal fins, blueish black the anterior ones spotted with white, the other with fetaceous rays, and six transverse white lines between each ray. Pectoral fin rounded. Tail blueish white. In the first dorsal fin five rays, in the second twenty-five; pectoral twenty-one; ventral thirty-four; anal twenty-five; caudal eighteen. Pallas. Gmel. &c.

BODECKEN, in *Geography*, a town of Germany, in the circle of Westphalia, and bishoprick of Paderborn, 4 miles N. N. E. of Buren.

BODEGAS, a town of North America, in the province of Verapaz, on the north-east coast of Dolce-bay. N. lat. 15° 40'. W. long. 75° 35'.

BODEGNE'E, a town of France, the principal place of a canton, in the district of Huy, and department of Ourte; the place contains 320, and the canton 7422 persons; the territory comprehends 107½ kilometres, and 17 communes.

BODEGON, a town of Spain, in Andalusia, 4 leagues from Seville.

BODEKKER, in *Biography*, a painter of portraits, was born in the country of Cleves, in 1660, and abandoning the profession of music for which his father intended him, he was placed as a disciple, in the art of painting, under John De Baan at the Hague. He commenced the exercise of his profession at Pois-le-Duc and Breda with great reputation; and having resided some time at the Hague, he closed his life in 1727, at Amsterdam, where his performances were much esteemed. Pilkington.

BODENBURG, in *Geography*, a town of Germany, in the circle of Lower Saxony, and bishopric of Hildesheim; 8 miles N. E. of Alfeld.

BODENETZ, a town of Bohemia, in the circle of Chrudim; 10 miles N. of Chrudim.

BODENFELDE, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, seated on the Wefer in the quarter of Göttingen.

BODENHAUSEN, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse, 18 miles E. N. E. of Cassel.

BODENI, in *Antient Geography*, a people of European Sarmatia, according to Ptolemy.

BODENLEICH, in *Geography*, a town of Germany in the circle of Lower Saxony, and principality of Luneburgh-Zell; 32 miles N. E. of Zell.

BODEN SEA, a name sometimes given to the gulph of Bothnia, which see.

BODENSTEIN, ADAM, in *Biography*, a celebrated German physician, son of a famous theologian, called from the place of his residence, Carlostadt, was born there in 1528. He was a pupil, and strenuous defender of the doctrines of Paracelsus, in which he appears to have placed an entire confidence. For a malignant fever raging at Basle, in 1577, he went there, armed with a Theriaca, composed on the principles of his master, with which he boasted he should be able to subdue the fever; but taking the infection, he fell a sacrifice to his credulity and temerity. Besides editing several of the works of Paracelsus, he left the following, which were collected and published in one volume folio, at Basle, in 1581.

"Epitola ad Fuggeros, in qua Argumenta Alchymiam infirmitiam, et confirmantia adducuntur; quibus et eam artem esse verissimam demonstratur; lapisque vere inventus ostenditur." "De Podagra preservatione, tractatus." "De herbis duodecim zodiaci signis, dicatis, &c." Adamus records his epitaph, placed on his monument, he says, at his own desire, in which he is said to have died, anno salutis, 1577, ætatis hebdomada septima, for seven times seven, or 49 years. Also the following lines, in which Bodenstein is supposed to say:

"Nec omnia, nec omnes mihi
Placere: quinam ego omnibus?
Non omnibus cous fenex,
Non eremita spagirus.
Nam tu viator omnibus?
Deo placere cura. Abi."

Adami Melch. Vitæ Germ. Med. Haller Bib. Med. Eloy Dict. Hist.

BODENWERDER, in *Geography*, a town of Germany, in the circle of Lower Saxony, and principality of Calenberg, seated on the Wefer; 16 miles S. of Hamelen. It has some trade with Bremen and Hamburg in coarse linen.

BODEN-ZEE a name given by the Germans to the superior lake of Constance, which see.

BODERIA, or BODOTRIA, in *Antient Geography*, an æstuary mentioned by Ptolemy in his description of Great Britain, which is the present Firth of Forth in Scotland.

BODET point, in *Geography*, lies on the north shore of Lake St. Francis, near the boundary line between Upper and Lower Canada. Bodet River runs into lake St. Francis, E. of Bodet point.

BODGURVA, a town of Asiatic Turkey, in the province of Natolia, 28 miles N. N. W. of Kastamon.

BODIANUS, or BOBIANUS, in *Antient Geography*, a borough of Italy, which was repeopled by a decree of Julius Cæsar.

BODIANUS, *Bodian*, in *Ichthyology*, a genus of *Thoracic* fishes, first established by Dr. Bloch, for the reception of such species of the two Linnæan genera SPARUS and PERCA, as have certain characters common to both, and are not therefore sufficiently distinct to be divided into two genera. The character of this new genus, as laid down in the first instance, consists in having the gill covers scaly, armed, and smooth,

smooth, or even at the edges. Under this head Dr. Bloch describes ten species only, namely, *Bodianus bodianus*, *bodianus guttatus*, *bodianus pentacanthus*, *bodianus bænac*, *bodianus aya*, *bodianus maculatus*, *bodianus apua*, *bodianus macrolepidotus*, *bodianus stellifer*, and *bodianus argenteus*. Lacepede, in adopting the genus *Bodianus*, considerably augments the number of its species by the addition of others not previously described under either of the Linnæan genera. In his "Histoire Naturelle des Poissons," there are altogether no less than four and twenty species. The generic character is modified, and two sections formed to admit them. Its essential character is thus expressed: one or more spines to the gill covers, the margins of which are neither denticulated, nor jagged; only a little beard, or sometimes none to the jaws; and a single dorsal fin.

The first section of the *Bodians* include those which have the caudal fin furcated in the form of a crescent, of which there are fourteen kinds; le bodian œilère (*bodianus palpebratus*), le bodian louti, le bodian jaguar (*bodianus pentacanthus*), le bodian macrolépidote, le bodian argenté, le bodian Bloch (*bodianus bodianus*), le bodian aya, le bodian tachté, le bodian vivanet, le bodian Fischer, le bodian décacanthe, le bodian lutjan, le bodian grosse tête, and le bodian cyclostome.

In the second division, the species of which have the tail fin entire, Lacepede describes only ten, le bodian rogaa, le bodian lunaire, le bodian mélanoleuque, le bodian Jacob Evertsen, le bodian bænac, le bodian biatule, le bodian apua, le bodian étoilé, le bodian tétracante, and le bodian six raies.

The genus *Bodianus* is recognised, and admitted by Dr. Shaw into the general zoology. He includes in this tribe precisely the same species as those described by Dr. Bloch, with five additional species described by Lacepede as *Bodians*, namely, *perca louti*, Gmel. *sparus palpebratus*, Gmel. *perca rogaa*, Gmel. *perca lunaria*, Gmel. and *bodianus melanoleucus* of Lacepede. But the generic definition of the *Bodians*, as given by this author, is evidently at variance with that assigned to it by others. The great object of the Ichthyologist, in establishing the new genus *bodianus*, must have been to separate from the two genera *perca* and *sparus*, such species as do not strictly belong to either; and unless this could be accomplished in a satisfactory manner, it were better to permit them to remain where Linnæus placed them. By some unusual oversight Dr. Shaw appears to have failed in this respect; his *bodians* are not sufficiently distinguished from the Linnæan *perca*, as the following generic character will shew: "*Habit* of the genus *perca*. Gill covers scaly, ferrated and aculeated. Scales (in most species) smooth. The gill-covers of the *perca*, according to this writer, are scaly and ferrated, and the scales of the body (in most species) hard and rough. According to this definition; a perch with smooth scales, and the denticulations of the gill covers conspicuously large, may be mistaken for a bodian; and a hard scaled bodian, on the contrary, for a perch. If we are to allow an innovation on the Linnæan arrangement by the insertion of the genus *bodianus*, its true character seems to be that the plates which constitute the gill-covers are smooth at the edges, and only armed with one or more distinct spines; while the ferrated edges of those plates as plainly point out the *perca*: and if the plates be both ferrated and aculeated, we conceive it highly proper to retain them under the old Linnæan genus *perca*.

BODIN, JOHN, in *Biography*, a famous lawyer of France, was born at Angers in 1530, he studied the law at Toulouse, and preferring the common to the civil law, quitted Toulouse and entered at the bar in Paris; but not succeeding in his expectations, he devoted himself to literature. He commenced his career as a writer, with a translation into elegant

Latin verse of "Oppian's Cynegeticon," or books of hunting, accompanied with learned notes, claimed as his own by Turnebus. His "Method of History," was published in 1566, and his "Discourse on Coins," with an answer to the paradoxes of Malestroit in 1568; but these were introductory to his great work in French, "Concerning a Republic," printed in 1576, in folio, and frequently reprinted in 8vo. To this work the president Thelusius bears very honourable testimony; it was also much commended by other persons of learning; and obtained for the author a high degree of reputation throughout Europe. It became the text-book of private lectures both at London and Cambridge. His tables of law, entitled "Juris Universi Distributio," were printed in 1578, and in the following year his "Demonomanie des Sorciers," to which was annexed "A Refutation of the book, de Lamiis," of John Wier, physician to the duke of Cleves, who had undertaken to prove that the stories of witchcraft and foreery have chiefly arisen from imposture or delusions of fancy. The literary character of Bodin, who defended this kind of superstition, incurred reproach, and he himself was suspected of being a magician. Before this time he had been invited by Henry III. to his court, who was much delighted with his conversation and treated him with attention and respect. But the royal favour was of no long continuance; for Bodin, who held an office in the presidial court of Laon, was sent, in 1576, as a deputy of the third estate of Vermandois, to the Assembly of the states-general at Blois; where he remonstrated against the project of alienating the royal demesnes belonging to that province; and this he did with such effect, that Thelusius principally ascribed the defeat of the injurious scheme of alienation to his conduct on this occasion. Bodin also resolutely opposed the party of the Guises, who were endeavouring to procure a decree for compelling all the king's subjects to profess the catholic religion. By such measures he became obnoxious at court; and he, therefore, accepted a proposal made to him by the king's brother, the duke of Alençon and Anjou, to accompany him to his government of the United Provinces. He afterwards attended him to England, and, it is said, that he advised the seizure of Antwerp, in consequence of which the duke lost both credit and influence. After the death of his patron, Bodin returned to Laon, and discharged the office of chief magistrate with great integrity. In this city he died of the plague in 1596. A work, written by him but never printed, and entitled "Heptaplomeron, five de abditis rerum sublimium arcanis," is said to have been an attack upon religion, and designed to invalidate the authority of revelation. By the seeming advantages which he gave in this work to the Jewish religion, he was suspected of being a convert to it; but it is more probable, that he was a sceptic with regard to religion, and alike indifferent to all modes of faith. A little while before his death he published a Latin treatise, entitled "Theatrum Universæ Naturæ," in which he pursues the causes and effects of things to their principles. Bodin was of an ardent and inquisitive temper; and his erudition was superior to his judgment. Gen. Diet.

BODLEY, SIR THOMAS, was born at Exeter in 1544, and at 12 years of age removed with his father to Geneva, who took his family thither to avoid the persecution of queen Mary's reign. In the university of that city he commenced his studies; and when his father returned to England, on the accession of queen Elizabeth, he was sent to Magdalen college, Oxford, where he remained for some years, and became fellow of Merton college. Here he read lectures in Greek and philosophy, and officiated as proctor and public orator. In 1576 he went abroad for improvement, and

spent four years in his travels. In 1583 he was made gentleman-usher to the queen; and having married, he entered into public life, and was employed in various foreign embassies. At the Hague, where he resided several years, his chief business was the negotiation of money-concerns between the States and queen Elizabeth. After his final return to England, in 1597, he found that his further advancement was obstructed by the intrigues and jealousies of persons in power, and he therefore formed a fixed purpose of retiring from all public affairs, devoting the remainder of his life to the laudable employment of refounding the university library at Oxford, furnishing it with books, and enlarging the building. See LIBRARY. At the accession of king James, Mr. Bodley received the honour of knighthood. He died in 1612, and was buried in Merton college choir. An annual oration is still spoken in his praise. *Biog. Brit.*

BODLEY, JOHN, who practised physic in London, in the beginning of the last century, published, in 1741, a critical essay on the works of various authors, particularly on those treating on medicine, with the view of shewing that neither those physicians who wrote the most correct and valuable treatises on medicine, nor those who were the most intelligent practitioners, were usually the most encouraged: fame and success being more commonly the appendages of craft and policy, than of skill and judgment. A similar opinion was held by the late Dr. Samuel Johnson, who thought a judicious history of the fate of physicians might prove both an entertaining and useful work. Something of this kind was done by Pierius, in his book "De Literatorum Infelicitate," but on a larger scale, embracing the whole community of letters. *Eloy. Dict. Hist.*

BODINCOMACUM, in *Ancient Geography*, the name of a borough of Italy in Liguria, where, according to Pliny, the river Eridanus was at its greatest depth; called in his time "Industria."

BODIONTICI, a people whom, according to Pliny, Galba annexed to Gallia Narbonensis; but before this time they formed a part of the Ligurians. M. D'Anville has placed them in the maritime Alps. Their capital was Dinia.

BODKIL, in *Geography*, one of the channels between Flanders and Walcheren island, in Zealand, by which great ships may sail in.

BODMER, in *Biography*, a celebrated professor and writer of Switzerland, was born at Zurich in 1698; and became professor of Helvetic history and politics in his native place. In this office he taught his pupils to think for themselves, and to make such observations on historical facts as might render them intimately acquainted with the human heart. He wrote the history of his own country in the form of dramatic dialogues. Although he became one of the most voluminous of the German poets, and contributed in a great degree to reform the taste of his contemporaries, and to familiarize them to the sublime beauties of Homer and Milton, he had scarcely written a verse in the German language before he was 50 years of age, when the first canto of Klopstock's Messiah fell into his hands, and excited his emulation. His first essays were in epic poetry, the subjects of which he took from the Scriptures, but he afterwards devoted his muse to other topics; and it is observable, that old age, which generally increases austerity of manners, had the contrary effect on Bodmer; inasmuch that his last pieces were the most gay, and that when he was 80 years old, he frequently amused himself with Tibullus and Petronius, and also with Boeace and la Fontaine. At the age of 77, he began a translation of Homer's Iliad and Odyssey, which he finished; he was 80, also, when he published his version of the Argonautics of Apollonius Rhodius. He died in 1783, at the

age of 85 years. Bodmer has been deservedly styled by the unanimous voice of his contemporaries, "the father of German literature;" whose just criticisms and correct judgment animated the poetical genius of Klopstock, Haller, and Geßner. *Bildnisse, &c. or Portraits of celebrated German Literati, &c. Rome, 1793.*

BODMIN, in *Geography*, an ancient borough and market town of Cornwall, England, is seated near the eastern borders of the county, on the confines of Devonshire. This town appears to have been formerly the principal seat of religion in the western district, and contained a priory, a collegiate church, and, according to Hals, thirteen other churches, or free chapels. The remains and foundations of some of their religious structures still exist; and the sites of others are remembered by the old inhabitants. Among these were the priory with its chapel, &c. St. Peter's church, St. Paul's church, on the northern side of the town, of which a solitary square tower remains; St. Nicholas, or the friary. The present town-hall and session house occupy the site, and are constructed with parts of the latter building. The first religious foundation of Bodmin was removed to it from Padstow, a town on the northern coast of the county, which being much infested by the Saxons and Danes, was the resort of the monks for greater protection and safety. Here they established the priory, and its various dependent buildings; all of which gradually decayed after the removal of the see. The town occupies the northern face of a hill, and consists principally of one long street stretching east and west. Near the eastern end of it is the parish church, a large ancient structure, consisting of three aisles, and a tower which is attached to the north side. The chancel part is certainly the most ancient, and was formerly connected with the priory-building. An old chapel, now appropriated to a school-room, still remains near the east end of the church, and a little farther east is a neat modern mansion, occupying the site of the domestic part of the priory. A monument richly and curiously sculptured, of one of the priors of this house, is carefully preserved in the chancel. This was made to commemorate the name and official character of Thomas Vivian, who was bishop of Megara, and died in 1533.

Bodmin is distinguished among the numerous boroughs of Cornwall, as being the only one free from the controul of a patron. It was first made a borough in the time of Henry II. and its privileges were afterwards confirmed by king James I. who incorporated it in the 15th year of his reign. In 1799, a new charter was obtained, which vested the government in a town clerk, twelve aldermen, and twenty-four common council-men, who hold the sole privilege of electing two members for parliament. About half a mile N. W. of the town is a regular, commodious county gaol, which was begun building in 1779, from designs by Sir John Call, who planned it according to the system recommended by the philanthropic Howard.

Bodmin gave birth to Dr. Richard Lower, an ingenious physician and anatomist, who made various experiments on the transfusion of blood from one animal into another. This town has a market on Saturday, is 235 miles south west from London, and contains 278 houses, and 1951 inhabitants.

BODOBRICA, in *Ancient Geography*. See BAUDUBRICUM.

BODODO, in *Geography*, a town of Africa, in the kingdom of Benin, containing about 50 houses, or little cabins, built of reeds and covered with leaves. Here a viceroy has his residence, attended by a council, whose jurisdiction extends over this canton in all civil affairs, levying taxes, and rating duties and imposts on merchandize. In criminal cases

of great importance, the viceroy and council are obliged to fend to Benin the capital, for the orders of the court.

BODOK, a district of Lower Hungary, in the province of Nitra, containing 101 large villages.

BODON. See **WIDIN**.

BODROG, a district of Hungary, near the Danube, 30 miles S. E. of Colocza, inhabited by Russians and a few Hungarians.—Also a River of Upper Hungary, which has its source in the Carpathian mountains, and discharges itself into the Theis near Tokay.

BODY, in *Zoology*, the name of a certain kind of American snake, supposed to be of the *amphibana* tribe, but of which this species is apparently doubtful. The same snake is likewise called *Ibijara*.

BODUNGEN, *Great*, in *Geography*, a market town in Germany in the circle of Upper Saxony, and county of Klettenberg, 5 miles north of Bleicherode. *Little Bodungen* lies in the bailiwick of Lora, 4 miles north of Bleicherode.

BODWELL'S FALLS, lie in Merrimack river, between Andover and Methuen, in North America, about 5 miles below Patucket falls.

BODY, in *Physics*, a solid, extended, palpable substance; of itself merely passive, and indifferent either to motion or rest; but capable of any sort of motion, and of all figures and forms.

The word alludes to the Saxon *bolige*, *stature*; and to the Belgic *boode*, *a cover*, q. d. *the tabernacle of the soul*. Body is composed, according to the Peripatetics, of *matter*, *form*, and *privation*; according to the Epicureans and Corpuscularians, of an assemblage of hooked, heavy *atoms*; according to the Cartesians, of a certain quantity of *extension*; according to the Newtonians, of a system or association of solid, massy, hard, impenetrable, moveable *particles*, ranged or disposed in this or that manner; whence result bodies of this or that form, distinguished by this or that name. These elementary or component particles of bodies must be infinitely hard; vastly harder than the bodies compounded of them; nay, so hard as never to wear, or break in pieces. "This" sir Isaac Newton observes, "is necessary in order to the world's persisting in the same state, and bodies continuing of the same nature and texture in several ages."

BODY, *affections of*. See **AFFECTION**.

BODY, *colours of*. See **COLOUR**.

BODY, *elements of*. See **ELEMENT**.

BODY, *essence of*. See **ESSENCE**.

BODY, *existence of*. See **EXISTENCE**.

BODY, *extension of*. See **EXTENSION**.

BODY, *modes of*. See **MODE**.

BODY, *motion of*. See **MOTION**.

BODY, *qualities of*. See **QUALITY**.

BODY, *solidity of*. See **SOLIDITY**.

BODY, *solid*, that whose particles cohere, or are some way connected with each other. See **SOLID**.

BODY, *fluid*, that whose particles easily slide over each other, and are of a fit size to be agitated by heat; or that whose particles do not cohere, but are easily put in motion by the smallest force. See **FLUID**.

BODY, *rough*, that whose surface is beset alternately with eminences and cavities, in contradistinction from a smooth body.

BODIES, *duãile*, those which being stretched do not break, but extend one way as much as they shrink another. Of these some are hard and malleable, as metals; others soft or viscid, as glues, gums, &c. Mem. Acad. Scien. an. 1713. p. 268.

BODIES, *flexible*, those which admit of being bent without breaking: such are thread, wire, fibres, and even glass, when

spun very fine. These are contradistinguished from brittle bodies.

BODIES, *specific gravity of*. See **GRAVITY**, and **WEIGHT**.

BODY, *dense*. See **DENSITY**.

BODY, *rare*. See **RARE**.

BODY, *luminous*, or *lucid*, that which emits its own rays, or shines by its own light.

BODY, *illuminated*, that which diffuses the light of another by reflection, or which shines by borrowed light.

BODY, *opaque*, that which intercepts the rays of light, or prevents their passage through it.

BODY, *transparent*, *diaphanous*, or *pellucid*, that which transmits the rays of light. See **TRANSPARENCY**.

BODY, *the inertia of*. See **VIS inertia**.

BODIES, *homogeneous*. See **HOMOGENEOUS**.

BODIES, *congruous*, those whose particles have the same magnitude and velocity, or at least harmonical proportions of magnitude and velocity.

BODIES, *incongruous*, those which have neither the same magnitude, nor the same degree of velocity, nor an harmonical proportion of magnitude and velocity.

BODY, *hard*. See **HARD**.

BODY, *volatile*, that which rises by the force of heat. See **VOLATILE**.

BODIES are divided into *animate* and *inanimate*; i. e. into those informed by a soul, and those which are not; or those that have life and those that have none.

Some consider bodies, either as *natural* and *sensible*; viz. as formed by physical causes, and clothed by physical qualities (in which sense, body makes the object of physics); or, as *intellectual* or *quantitative*, in the general or abstract; and according to three dimensions: in which sense, body makes the subject of geometry.

BODIES *alkaline*, *consistent*, *elastic*, *fixed*, *heterogeneous*, *atmosphere of*, *descent of*, *mercury of*. See the several articles.

BODY, with regard to animals, is used in opposition to *soul*; viz. for that part of an animal, composed of bones, muscles, canals, juices, nerves, &c. concerned in digestion, circulation, &c.

In which sense, body makes the subject of comparative anatomy. See **ANATOMY**.

BODY, *faculties of the*. See **FACULTY**.

BODY is also applied by anatomists to several particular parts of the animal fabric.—As the callous body of the brain, the cavernous or spongy bodies of the penis, &c.

BODY, *reticular*. See **RETICULAR**.

BODY, in speaking of a horse, denotes the chest, but chiefly the flanks.

A horse is said to have a good body, when he is full in the flank; a light body, when he is thin or slender in the flank. If the last of the short ribs be at a considerable distance from the haunch-bone, though such a horse may have a tolerable body for a time, if he be much laboured, he will lose it. It is a general rule never to buy a horse that is light bodied and fiery, because he will presently destroy himself.

BODY of a plant, in *Botany*. See **BOTANY**.

BODY of a piece of ordnance, in *Gunnery*, that part comprehended between the centre of the trunnions and the calcael. It ought always to be more fortified than the rest. See **CANNON**.

BODY of a pump, in *Hydraulics*, the thickest part of the barrel or pipe of a pump, within which the piston moves. See **PUMP**.

BODY, in *Geometry*, denotes the same with solid, which see.

BODIES, *regular*, or *Platonic*, are those which have all their sides, angles, and planes, similar and equal.

Of these there are only five; viz. the *tetrahedron*, consisting of four angles; the *octahedron*, of eight; the *icosahedron*, of twenty; the *dodecahedron*, of twelve pentagons; and the *cube* of six squares. See *REGULAR bodies*; see also *TETRAHEDRON*, &c.

BODY, in *Law*.—A man is said to be bound or held in *body and goods*; that is, he is liable to remain in prison in default of payment.

A woman, though in other respects she cannot engage her person but to her husband, may be *taken by the body*, when she carries on a separate trade.

BODY of the place, in *Fortification*, denotes either the buildings inclosed, or more generally the inclosure itself. Thus, to construct the body of the place, is to fortify or inclose the place with bastions and curtains.

BODY is also used for an assemblage of several different things collected into one; more particularly a number of persons united into a company or college.

A state or nation, under the administration, of one sovereign, is called a *body politic*. All large empires are unnatural, because the relation between the head and limbs is here too remote. No body, either natural or politic, can long remain sound without exercise. See *CORPORATION*.

BODY, corps, in *War*, is an aggregate or assemblage of forces, horse and foot, united and marching under some chief.

An army, ranged in form of battle, is divided into three bodies: the van-guard, the rear-guard, and the main body; which last is ordinarily the general's post.

BODY of reserve, in the *Military Art*, a draught or detachment of a number of forces out of an army, who are only to engage in case of necessity.

BODY, in matters of *Literature*, a name given to a collection of whatever relates to any particular science; thus we say, the body of the canon law; the body of the Saxon law. King James I. had a design to compile a body of the English law.

The body of the civil law consists chiefly of the Institutes, Pandects, Code, and Novels. A *glossated body*, is that to which glosses are added in the margin, composed by several lawyers.

BODY is also used figuratively, for consistence, solidity, and strength. In this sense, we say the body of a cloth, wine, &c.

Vintners have divers arts of increasing or diminishing the body of wine.

BODY, among *Painters*.—A colour is said to *bear a body*, when it is capable of being ground so fine, and mixing with the oil so entirely, as to seem only a thick oil of that colour; as white lead, lamp-black, vermilion, lake, indigo, &c. But verditers, minets, &c. will not embody with the oil, but are still apt to separate from it in working.

BODY *line*, or plane of projection, in *Ship-building*, is a section of the ship at the midship frame, or broadest place, perpendicular to the sheer and half-breadth plans. The several breadths, and the particular form of every frame of timbers, are described on this plane. As the two sides of a ship are similar to each other, it is therefore unnecessary to lay down both, hence the frames contained between the main frame and the stem are described on one side of the middle line, commonly on the right-hand side; and the after frames are described on the other side of that line.

BODZELIN, in *Geography*, a town of Poland, in the palatinate of Sandomierz, 24 miles south of Radom.

BOE, in *Ancient Geography*. See *ΒΟΕ*.

BOE, a small island of Norway, 25 leagues north of Bergen.—Also, a town of Norway, 18 miles north of Bergen.—Also, a town of Norway, 12 leagues north of Romfdale.

BOEBE, in *Ancient Geography*, the name of a lake or marsh in the island of Crete. Steph. Byz.

BOEBS, or **BOEBIAS**, a lake which some place in Bœotia, was situated near the confines of Magnesia, not far from mount Ossa. It has been since called the lake of Esero. North of this lake was a town called *Boebe*, whence the lake derived its name.

BOECE, or **BOEUS**, **HECTOR**, Lat. *Boethius*, in *Biography*, a celebrated Scottish historian, was born of an ancient family at Dundee, about the year 1470. After having studied in his native place, and also at Aberdeen, where he was professor in 1497, he went for further improvement to Paris, where he became a professor of philosophy, and where he had an opportunity of cultivating an acquaintance with several literary persons of eminence, and particularly with Erasmus. Upon the establishment of the king's college at Aberdeen, by Sir Elphinston, the bishop, about the year 1500, Boethius was sent for by the founder, and appointed principal of that university, and contributed, in concurrence with his colleague Mr Hay, to furnish the kingdom with several excellent scholars. After the death of Elphinston, his patron, in 1515, he wrote his life, together with an account of his predecessors, under the title of "*Vitæ Episcoporum Murthlæcenium et Aberdonensium*," Paris, 1522, 4to. He then engaged in his great undertaking of writing the history of Scotland, to which he prefixed a large geographical description of the country. This history was published under the title of "*Scotorum Historia ab illius gentis origine*," Paris, 1526, fol.; and he continued to improve it till his death, which happened about the year 1550. The first edition of this work consisted of 17 books, and ended with the death of king James I. The next edition printed at Laufanne and Paris, in 1574, fol. was much enlarged by the addition of the 18th and part of the 19th books. It was afterwards carried down to the end of the reign of James III. by J. Ferrerius, a native of Piedmont. The whole history was translated into the Scottish dialect by John Bellenden, archdeacon of Murray, by command of James V. and published in 1536. R. Holinshed published it in English, with considerable additions, in the first volume of his *Chronicles*. This work has been differently appreciated by national partiality on the one hand, and national prejudice on the other. Whilst it is allowed the merit of elegance and purity of style, it is charged with detailing marvellous tales and legends, and with introducing imaginary and fictitious circumstances, in order to ornament and dignify the antiquity of the Scots nation. As to his general character, Boethius was a great master of classical and polite learning, well skilled in divinity, philosophy, and history; but too credulous, and much addicted to the belief of legendary stories. With regard to his other accomplishments, he was discreet, genteel, well-bred, attentive, generous, affable and courteous. *Biog. Brit.*

BOECKEL, **JOHN**, born at Antwerp in November 1535, was admitted doctor in medicine at Bourges in 1564. At Hamburg, where he went to reside, he was soon distinguished for his superior skill, and appointed teacher of anatomy and medicine, an office he filled with sufficient reputation several years. He died there March 21st, 1605. His works are "*De peste quæ Hamburgum civitatem, anno 1565, gravissimè affixit*," Henricopoli, 1577, 8vo.; "*Synopsis novi morbi, quem plerique catarrhum febrilem vocant, qui non solum Germaniam, sed pene universam Europam gravissimè*"

vissimé affixit." Helm. 1580, 8vo. This may be considered as the earliest record of the contagious catarrhal fever, which has many times since visited the world, and which has, in this country, been familiarly denominated the influenza. "Anatomia vel descriptio partium corporis humani," Helm. 1585, 8vo. The text book from which the author gave his lectures, "De plultris. Utrum animi hominum his commoveatur, necne?" a question much agitated at that period of the world, but long since laid asleep. Haller. Bib. Anat. Eloy Bib. Hist. Med.

BOECLER, JOHN-HENRY, an eminent German philologist, was born at Cronheim in Franconia, in 1610, and preferred, at the age of 21, on account of his great learning, to the office of professor of eloquence at Strasburg. In 1648 he was invited to Sweden by queen Christina, and appointed to the chair of eloquence at Upsal, and to the office of royal historiographer; but being obliged by ill health to quit the country, he became professor of history at Strasburg. He was counsellor both to the elector of Mantz and to the emperor, and received a pension from Louis XIV. He died in 1692. His principal works are "Commentationes Pliniane;" "Timur, vulgo Tamerlanus," 4to. 1657; "Notitia Sti. Romani Imperii," 1681, 8vo; "Hillo ia, schola principum;" "Bibliographia critica," 1715, 8vo.; "Dissertationes Academicæ," 3 vols. 4to. 1710; "Animadversiones Polybium," 4to. 1611; "Commentatio in Grovii librum de jure belli et pacis," 4to. 1712. He wrote, besides, Latin commentaries on various ancient authors, and several tracts on German history. Nouv. Dict. Hist.

BOEDROMIA, in *Antiquity*, from *βοδρομιος*, *helper*, derived from *βο*, *I cry*, and *δρομα*, *I run*, solemn feasts held at Athens, in memory of the succour brought by Ion, son of Xuthus, to the Athenians, when invaded by Eumolpus, son of Neptune, in the reign of Erechtheus. Plutarch gives another account of the boedromia, which, according to him, were celebrated in memory of the victory obtained by Theseus over the Amazons, in the month Boedromion, called by the Corinthians "Panemos," which was, in the ancient chronology, the third month of the Athenian year. It consisted of thirty days, and answered to the latter part of our August and beginning of September.

BOEHM, in *Biography*. See BEHMEN.

BOEHMER, PHILIP ADOLPHUS, son of Justus B. professor of anatomy at Hall in Saxony, under whom he received his education; was admitted doctor in medicine in 1736. As he applied his mind particularly to the study of midwifery, he gave for his inaugural thesis, "De precavenda polypo um generatione." His next dissertation, which was published in 1741, in 4to. was "Situs uteri gravidæ, ac tætus, ac sede placente in utero." In this he has given a critical examination of the midwifery forceps used in England, which he compares with, and prefers to Leuret's. These pieces were added by the author to his edition of fir Richard Manningham's "Compendium artis obstetricæ," published in 1746, 4to. Having acquired celebrity by these and other works, he was adopted member of the Acad. Nat. Curios. and foreign associate of the Royal Academy of Surgery at Paris. He was also appointed to succeed his father as professor of anatomy and medicine in the university at Hall. In 1749 he published "Institutiones osteologicæ, in usum prælectionum," 8vo. Haller particularly commends in this work the engravings of the embryos, and some fœtal skeletons. His "Observationum anatomicarum, fasciculus primus," folio, was published in 1752. Among many rare and curious objects are, an engraving of a pregnant uterus, to shew the membrana decidua, and a fœtus in one of the Fallopian tubes, with the placenta. The second collection, also in folio, published in

1756, contains a smaller fœtus in one of the tubes, and a child with two bodies and only one head. For the titles of the remainder of his dissertations, see Haller. Bib. Anat. and his collection of medical theses, in which the greater part of them is inserted.

BOEHMERIA, in *Botany* (named by Jacquin in honour of George Adolph Boehmer, professor of anatomy and botany at Wittenburgh), a genus of the class *Monocœcia Tetrandria*, formed by Swartz for three plants, not described by Linnæus, natives of the West Indies, to which he added two others, the *urtica cylindrica* and the *caturus ramiflorus* of Linnæus. It constitutes a connecting link between *urtica*, and *parietaria*. Nat. Ord. *Scabridæ Urticæ* Jusseu. Schreb. 1471. Jacq. Americ. 246. Swartz. prod. 34. Jusseu. 403. Gen. Char. Male flowers on the same plant with the female, either distinct or mixed. *Cal.* perianth one-leaved, four parted to the base; segments lanceolate, acute, somewhat erect, coloured. Schreb. (tubular, Jusseu and Bosc.). *Cor.* none. *Nect.* none. *Stam.* filaments four, longer than the calyx, awl-shaped, erect; anthers roundish, ovate. Female flowers, *Cor.* none. *Pist.* germ ovate, compressed; style filiform, erect, permanent; stigma simple, pubescent. *Pericarp.* none. *Seed.* roundish, compressed, margined. Schreb. (single, very small, enclosed in the permanent calyx. Juss. Bosc.). The flowers are separated from each other by numerous, dense, ovate-acuminate, bractes or scales.

Species, 1. *B. caudata*. Brown Jam. 238. "Leaves opposite, ovate, acute, ferrate; racemes very long, pendulous; flowers diœcous; stem suffruticose." A shrub ten or twelve feet high. Brown calls it the nettle-tree. 2. *B. littoralis*. "Leaves opposite, ovate-lanceolate, ferrate; flowers conglomerate, axillary, monœcous, mixed; stem herbaceous, four-cornered." Native of Hispaniola. 3. *B. cylindrica*: "Leaves opposite, ovate, acuminate ferrate; racemes spiked, axillary, erect, simple." An annual plant, with a lucid, herbaceous stalk, dividing into several branches; leaves with three longitudinal veins; on pretty long petioles. A native of North America and Jamaica. 4. *B. ramiflora*. "Leaves alternate, broad-lanceolate, acuminate, ferrate, wrinkled; flowers aggregate, axillary and lateral, monœcous, distinct. Males three-stamened." A shrub, eight feet high, with long branches; leaves sickle-shaped, rugged on very short petioles, placed towards the end of the twigs; very different in size, some being two inches, and others a foot in length on the same twig. Male flowers small, yellowish, numerous, aggregate, on the leafless old branches. Female flowers whitish on the younger twigs to the very end. Native of Jamaica and other Islands of the West Indies. 5. *B. birta*. "Leaves alternate, ovate, acute, ferrate, hirsute; flowers monœcous, heaped, axillary, mixed." A native of Jamaica.

La Marck has not inserted this genus either in the alphabetic part of the Encyclopedic, or in the subsequent systematic series of figures. He follows Linnæus in referring the *cylindrica* to *urtica*, and the *ramiflora* to *caturus*.

BOEL, PETER, in *Biography*, an excellent painter of fruit, flowers, and animals, was born at Antwerp in 1625, and having been a disciple of Snyder's, whose widow he married, he went to Italy, where his uncle Cornelius de Waal resided, and in his return through France, was much employed, particularly at Paris, where he continued for sometime. He died in 1680. As an art he copied after nature, with a free and bold pencil, and a tint of colour that was natural and beautiful. There are some few slight, but spirited, etchings by Boel, from his own compositions, representing various animals, &c. Cornelius Boel, who flourished in 1611, and Coryn, or Quirin Boel, who flourished in 1660, both engravers, were of the same family. Pilkington. Strutt.

BOELE-BOELE, in *Geography*, a district of the island of Celebes, situated in the bay of Boni, at and near a river of the same name. To the west it has Wauwo Woelè; to the south, the river Cassa; to the north, the river Tanka; and to the east, the shores of the bay. It is sometimes called *Telbolimpoe*, and has three chief townships, viz. Boele-boele, Lamant, and Radja, which are all independent of each other. The kings of Boni consider it as an appendage of their crown.

BOELE-COMBA, a territory of Celebes, which was anciently a separate kingdom, but in later times it was subjugated by the Macassers; and is become one of the provinces belonging to the Dutch East India company. It stretches from the river Kalengkongang, which divides it from Boutain, to Bera, or rather to the river Bampang, which runs between them; to the north of it lie the mountains of Kyndang, which separate it from Boni, or rather from the highlanders of Touraayo; and to the south, it is washed by the sea. The land is fertile in rice, and abounds in game and extensive forests; but the timber is not adapted to the construction of houses. When the west monsoon renders it dangerous for ships to lie in the road before Boele-Comba, they run into the river Kalekongang, near the mouth of which stands the palisadoed fort Carolina, in which the resident of the Dutch East India company, who is a junior merchant, has his abode. The province of Bera reaches from the river Bampang eastward, along the sea-coast to the point of Lassèem or Lassoa, and thence northward to the point of Kadjang; and on the land side, it borders upon Boele-Comba, Tourang, and Kadjang, belonging to Boele-boele. This country belongs to the Dutch company. It is barren and rocky, but has some woods which furnish timber fit for building proas. The men are good warriors both by sea and land; the richest are merchants; and others employ themselves in building proas, and in manufacturing a sort of coarse white cloth from the cotton which the place supplies.

BOELON. See **BÆLON**.

BOEN, in *Geography*, a town of France in the department of the Loire, and chief place of a canton in the district of Montrbrison, seated on an eminence near the river Lignon; 6 leagues south of Roanne, and $3\frac{1}{2}$ north of Montrbrison. The place contains 1220, and the canton 10,929 persons; the territory comprehends 305 kilometres, and 22 communes.

BOENAC, in *Ichthyology*, a species of **BODIANUS**, described by Dr. Bloch. The body is of a clear olivaceous colour, marked with seven oblique brown bands; and the caudal fin is rounded. This fish is mentioned as a native of the seas about Japan, where it is called *yeau boenac*.

There are seven rays in the gill membrane of this species, fifteen in the pectoral fin, six in the ventral fin, eleven in the anal fin, sixteen in the caudal fin, and twenty-five in that on the back.

BOENASA, in *Ancient Geography*, a town of Cappadocia, in the interior of the Galatic Pontus. Ptolemy.

BOEON, a town placed by Ptolemy in the interior of the Tauric Chersonesus.

BOEON, or **BOELO**, a town of Greece, in the Doric region, according to Thucydides, near mount Parnassus. This was one of the four cities which, according to Pliny, Strabo, and Steph. Byz. gave the name of "Tetrapolis" to the country possessed by the Dorians, near mount Oeta.

BOEONUS, *Diu*, an island of India, according to the Periplus of the Erythrean sea, placed by M. d'Anville at the south-west entrance of the "Barygazenus sinus."

BÆOTIA, a name given to two ancient kingdoms of Greece; one founded, or rather restored by Cadmus, and called by him Bœotia, from the ox (*bos*), which is said to have directed him to the place where he built the capital of his kingdom, afterwards known by the name of Thebes; the other in Thessaly, said to have been founded by Bœotus, the son of Neptune, and brother of Cœolus, by Arne, the daughter of Cœolus king of Cœlis. This Bœotus, according to Bryant (*Anal. Anc. Myth. vol. ii. p. 326.*), from whom the Bœotians are supposed to be descended, and from whom this country is said, by some, to have derived its name, was an imaginary personage, and merely a variation of Boutus and Butus, the ark; which in ancient times was indifferently styled Theba, Argus, Aren, Butus, and Bœotus. This Bœotus of Greece, according to the mythology of this writer, is the same with Doutus of Egypt, Battus of Cyrene, and Buto or Budde of the Indians. The history of the origin of this kingdom is intermixed with fables; but it is more certainly known, that the possessors of this settlement held it for more than 200 years; and that when they were expelled from it by the Thessalians, they sought a new establishment in that country, which till that time had been called Cadmeis, and which was then named Bœotia. We are informed by Diodorus and Homer, that these Bœotians signified themselves at the Trojan war; and the latter adds, that five of Bœotus's grandsons were the five chiefs who led their Bœotian troops thither. Whatever be the true etymology of the name Bœotia, given to this country, it was distinguished by several other appellations, according to its supposed founders: those who ascribed it to Ogyges, called it Ogygia; others called it Cadmeis, from Cadmus; and by others it was denominated Aonia, from Aon, the son of Neptune; and Hyanthis, from Hyas, the son of Atlas. It is now called Stramulippa; and Thebes its ancient capital, Thive, and corruptly by the Greeks, Stibes or Stives.

It bordered on the east with Attica, and was in time joined to it, being parted from it by the mountain Cithæron; on the north, it was bounded by the freight Euripus, now called the Negropont; on the west it had the kingdom of Phocis; and on the south, the gulf of Corinth. Its utmost extent from east to west was $1^{\circ} 10'$, and it was nearly of the same length from north to south, but approaching to a point eastward. Ephorus, from Strabo, calls it *μοινη τριθηλας ποταμος, sola trimaris*, because it was contiguous to three seas; and by means of its commodious havens it could carry on a commerce on one side with Italy, Sicily, and Africa; and on the other, with Egypt, the isle of Cyprus, Mauritania, and the Hellepont. It had also the large lake Copais, and the two large rivers, the Asopus and Ilmenus, besides other streams, by which it was watered and rendered fertile. This country is partly hilly, especially Aonia, properly so called; the rest is low and flat, and abounding with excellent pasturage and corn; but the air was so dense and foggy, that Horace thought it influenced the genius of the inhabitants. The Bœotians, in general, were reckoned not to possess that penetration and vivacity, which characterized the Athenians, whose air was remarkably pure, though separated from them only by mount Cithæron; but this, perhaps, might have been attributed more to education than to nature. As they employed their time more in bodily than in mental exercises, they were deficient with respect to that facility of expression, those graces of elocution, the knowledge derived from study, and those pleasing manners, which are more the work of art than nature. But it should not be supposed, that Bœotia produced no men of genius. Several Thebans have done honour to the school of Socrates. Epaminondas was not less distinguished for his knowledge than

for his military talents. It should also be remembered, that Bœotia was the birth-place of Heliod, Corinna, and Pindar. Its most remarkable places were the Trophonian cave, Theſpia, Aulis, the ſtraits of Thermopylæ and Thebes, which ſee reſpectively.

The government of Bœotia was altogether monarchical, and peculiarly deſpotic, the will of the kings being the law; and of theſe ſome governed more like tyrants than moderate ſovereigns. Plutarch, in his "Morals," mentions an ancient cuſtom that prevailed among them; which was the manner of introducing their new-married women into their new habitations. They were brought home in a kind of chariot, or cart, the axle-tree of which was immediately burnt, thus intimating to the bride, that ſhe was fixed with her huſband for life, and muſt not expect to return to her parents.

The Bœotians, as to their general character, were courageous, inſolent, and vain; and with them the transition was very ſhort from paſſion to inſult, and from a contempt of law to a total diſregard of the dictates of humanity. The ſmalleft expectation of advantage gave occaſion to the groſſeſt acts of injuſtice; and murders were frequently the conſequence of the moſt frivolous quarrels. The women were tall, well-formed, and generally of a fair complexion; and their voice was remarkably ſweet and tender; whereas that of the men was harſh and diſagreeable, and in ſome meaſure ſuited to their character. Of this character for inſolence and ferocity, which generally diſtinguiſhed the Bœotians, no traces were to be found in a body of young warriors, called the "Sacred Battalion," conſiſting of 300, who were brought up together, and maintained at the public expence in the citadel. Their exerciſes, and even their amuſements, were regulated by the melodious ſounds of the flute. To prevent their courage from degenerating into blind fury, care was taken to inſpire them with the nobleſt and the moſt animated ſentiments. From this band each warrior choſe a friend, to whom he remained inſeparably united, whom it was his ambition to pleaſe, and to ſhare his pleaſures and ſufferings in life, and his labours and dangers in battle. Theſe 300 warriors were at one time diſtributed in troops at the head of the different diviſions of the army. Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almoſt all the advantages they gained over the Lacedæmonians. Philip deſtroyed this cohort, that had been invincible, at Cheronæa; and the prince when he ſaw theſe young Thebans ſtretched on the field of battle, covered with honourable wounds, and lying ſide by ſide on the ground on which they had been ſtationed, could not refrain from tears, but bore a noble teſtimony to their virtue as well as to their valour. Plut. in Pelop. t. 1. p. 287.

For the ſucceſſion of the kings of Bœotia, after Cadmus, and the hiſtory of the kingdom as a monarchy, ſee THEBES. The Bœotians, after having expelled their kings, who had reigned in ſucceſſion from Cadmus to Xanthus, for about 300 years, formed themſelves into a republic, of which the chief magiſtrates were the prætor, or ſtrategos, the Bœotarchi, and the Polemarchi. The authority of the prætor, who was choſen from among the Bœotarchi, laſted only a year, and reſembled that which was veſted in the prætors of Achaia and Ætolia. The Bœotarchi aſſiſted him with their advice, principally in time of war, and commanded under him; and they conſtituted the ſupreme court in military affairs; ſo that the prætor could not act in a manner contrary to their determinations. They alſo bore a great ſway in the civil adminiſtration, and hence derived their title. Their number was uncertain, being 7, 9, or 11; they were choſen yearly, and obliged by law, as well as the prætor, to reſign their

office on pain of death, before the firſt month of the new year was expired. The Polemarchi were altogether civil magiſtrates; it being their province to maintain peace and concord at home, while the Bœotarchi were employed in the wars of the republic. Beſides theſe officers, there were four councils in which the whole authority of the ſtate conſiſted. Theſe were compoſed of the deputies that were ſent by all the cities of Bœotia; and without their approbation, the Bœotarchi could not declare war, make peace, conclude alliances, or tranſact any buſineſs of importance. The Bœotians, and eſpecially the Thebans, were continually haraſſed by the princes of Macedon; nevertheleſs they took part with Philip againſt the Romans, and could not be prevailed upon by the Athenians and Achæans to deſert him, and to join the other ſtates of Greece, till he was entirely defeated in the famous battle of Cynocephalæ. They then, foreſeeing their danger, ſent deputies to Flaminius, imploring his protection. He received them with great humanity, and put them upon the ſame footing with the other allies of the republic in Greece. Flaminius, at their requeſt, obtained the releaſe of the Bœotians who ſerved in the Macedonian army; but notwithstanding this favour granted them by the interpoſition of the præconſul, they neglected to make the neceſſary acknowledgments, and filled up all vacant offices with perſons who were enemies to Rome, and attached to the intereſts of Macedon. Flaminius was exaſperated by this conduct; and Brachyllus, their prætor, was murdered by the friends of Rome. The murderers, however, were diſcovered, and one of them, Piſiſtratus, was put to death. For this murder of their prætor the Bœotians determined to be revenged; and they took occaſion to aſſaſſinate all the Romans whom they found wandering about in the fields. In conſequence of this outrage, Flaminius ravaged their territories; but upon their conſenting to deliver up the offenders, he deſiſted from any further acts of ſeverity; and the Bœotians duly apprized of his lenity, continued ever afterwards faithful to the Romans. But as ſome of their leading men joined Perſes, king of Macedon, in his wars againſt the Romans, the whole country was, on that account, treated with great ſeverity; Rome being at this time under no apprehenſion of an invaſion from Antiochus, as ſhe was when Flaminius was ſo eaſily appeaſed. At the diſſolution of the Achæan league, Bœotia, with the reſt of Greece, was reduced to a Roman province. See ACHÆANS.

BOER, in *Geography*, a town of Germany, in the circle of the Lower Rhine, and county of Recklinghauſen, 6 miles W.S.W. of Recklinghauſen, and 42 N. of Cologn.

BOERHAAVE, HERMAN, in *Biography*, a profeſſor of medicine and chemistry, of ſuch eminence as to form a new æra in theſe ſciences, was born at Voorhout, about two miles from Leyden, in Holland, the 31ſt of December 1668. His father, James Boerhaave, the paſtor of the village, having nine children, took on himſelf the care of their education; and, as he intended Heiman for the church, he was careful to ground him well in Greek and Latin. In theſe languages he made ſuch rapid progreſs, that when he was only fourteen years of age, his father ſent him to complete his education to the public ſchool at Leyden; and, in 1684, he went from thence to the univerſity. His father dying ſoon after, and in ſlender circumſtances, the progreſs of our young ſtudent's attainments would have been interrupted but for the friendly aſſiſtance afforded him by Daniel Van Alphin, burgomaſter of Leyden, who furniſhed him with the means of continuing his ſtudies. The kindneſs of this worthy man was remembered by Boerhaave, with gratitude, to the end of his life. He now applied to the mathematics, and to acquire a knowledge of the Hebrew and Chaldee languages; propoſing, agreeably to the intentions

of his father to qualify himself for the ministry; and that he might relieve his patron from a part of his expence, for his sustentance, he gave private lessons to the students in mathematics, and here probably laid the foundation of that excellence in the art of communicating knowledge by lectures, for which he in time became so celebrated. In 1690, he took his degree in philosophy, and gave for his inaugural thesis, "De distinctione mentis a corpore," in which he refutes in a solid and judicious manner, the errors of Hobbs and Spinoza. This, however, did not prevent his being suspected of Spinozism, which made him quit his intention of entering into the service of the church, and turn his mind to medicine, particularly to the study of chemistry, as more suited to the activity of his disposition. To acquire a knowledge of anatomy, he read the works of Vesalius, Fallopius, and Bartholine, and attended dissections under Nuck. In medicine, he studied Hippocrates, and the rest of the Greek and Latin writers in succession, but returned to Hippocrates, whose works were always mentioned by him with veneration. Among the moderns, he gave the preference to our countryman Sydenham, whom he called the Divine Sydenham.

Thus qualified, in 1693, being 25 years of age, he was admitted by the university of Harderwyck, in Guelderland, to the degree of doctor in medicine. His thesis on this occasion was "De utilitate explorandorum excrementorum in ægris, ut signum." To the urine he paid the greatest attention. He now applied to the practice of medicine, from which, however, he is said to have derived but little profit. As his practice, therefore, employed but a small portion of his time, he had leisure for examining all the theories of medicine which had prevailed, in succession, from the earliest time, and of forming from them a theory, if far from perfect, much less exceptionable than any that had preceded it; and which, when matured, superseded them, and became the reigning doctrine over all Europe for more than half a century. Drelincourt, who had long been professor of the theory of medicine. Dying in 1701, the university of Leyden seized the opportunity this event afforded them of attaching him further to that place, by placing him in the vacant chair. This they were prompted to by gratitude as well as by prudence; Boerhaave having refused an advantageous offer of settling at the Hague, and though in no public office or capacity, he had already acquired a considerable reputation, and drawn a great many foreigners to Leyden, to hear his lectures in chemistry. On the occasion of this promotion he read his "Oratio de commendando studio Hippocratico." In Hippocrates, he particularly admired the correctness of his descriptions and histories of diseases, his patience in attending to the indications of nature, or the constitution, to which, with little interference, he frequently committed the cure of the disease, and his honest and sincere account of the termination of the disease, whether in health or death. In this he has not been always followed by writers of cases. In 1703, he was invited to accept a professor's chair at Groningen; but as he had refused, when much less known, an establishment at the Hague, he had no difficulty, now that his fame was more extended, and pupils were flocking to him from all parts, in rejecting this offer. The university at Leyden thought it necessary to reward this fresh proof of his attachment to the country by augmenting his salary. About this time he delivered his "Oratio de usu ratiocinii mechanici in medicina." These compositions were all published; and as they were drawn up and polished with care, they doubtless contributed in extending the fame of our professor over Europe. On the death of Peter Hotton, curator of the university garden, in 1709, he was appointed his successor, and made professor of botany. He now read his "Oratio qua

repurgatæ medicinæ facilis asseritur simplicitas;" shewing that the knowledge of medicine would be easiest obtained by avoiding hypotheses, and attending to facts and observations; and that diseases would be more certainly cured by using only a few choice and simple medicines, than by the heterogeneous compositions then in vogue. He now, in addition to his other studies, employed himself sedulously in acquiring a more extended knowledge of plants; and this continued to be his amusement and delight to the end of his life. "Often have I seen," Haller says, "the good old man, moving slowly along the garden, at a very early hour in the morning, attending to the culture of the numerous exotics he had introduced there, classing and arranging them for his lectures." One year only after being appointed professor in botany, he published "Index plantarum quæ in horto Lugduno Batavo reperiuntur," 8vo. This work was re-published by him in 1720, much enlarged and improved, including a history of the garden, 2 vols. 8vo. In 1709, appeared his "Aphorismi de cognoscendis et curandis morbis," 8vo.; "aureus in summabrevitate libellus," Haller says. A work universally read and admired, on which baron Van Swieten, his illustrious pupil, who had attended his instructions for near twenty years, published his Commentaries, in 1742, extending it to five volumes in 4to. About the same time he published his "Institutiones rei medicæ in usus annuæ exercitationis domesticæ," 8vo. These two works, the one treating of the history and cure of diseases, the other of the physiology of the human body, improved and enlarged at different times by the author, have passed through numerous editions, and have been printed in every country, and translated into every language in Europe. Schulten says, there is a version of them also in the Arabic. Boerhaave was now in the zenith of his reputation, and had such a confluence of students from all parts of the world, as never probably before occurred to any one professor. He gave lectures on the theory of medicine, in botany, and in chemistry, and delivered them with such clearness and precision, as to fill his pupils with equal astonishment and delight. Haller, who was two years under his tuition, speaks of him with enthusiasm. "Vix fui parem habuit." We have hardly since seen, and perhaps may never again see his equal. In 1714, he was made rector of the university. On laying down this office at the end of the year, he read his discourse "De comparando certo in physicis." It is only to be acquired, he says, by experiment, and by a careful and minute examination of natural objects. Bidloo dying at this time, he was advanced to the chair of professor in the practice of medicine; and on the death of Le Mort, in 1718, he was made professor of chemistry. He was now at the head of every branch of medicine; and his pupils were become so numerous, Dr. Maty says, that Leyden was scarcely sufficiently capacious to contain them. In addition to these numerous vocations, he was frequently consulted, in cases of difficulty and danger, by physicians in all parts of the world.

With these advantages, it will not excite surprise, that his wealth should accumulate and become extremely abundant. As his diet was frugal and sparing, and he was plain in his apparel, he has been accused of being too parsimonious; but it should be considered, that attached as he was to science, and immured in business of such variety and magnitude, he had no time for expence or luxury, except in what regarded the improvement of science. In procuring rare and valuable books, and in collecting plants from distant countries for his garden, he spared, we are told, no expence.

In 1718, Boerhaave had published "De Chemia, suos errores expurgante," which was all he proposed giving on that subject; but some of his pupils having at the intigation, he says, of the booksellers, ventured to print, in his

name, transcripts of his lectures, so incorrecly taken as to materially injure his fame, to vindicate himself from the disgrace this might bring upon him, he found himself under the necessity of preparing his lectures for the press; and, in 1732, he published them under the title of, "Elementa Chemiæ, quæ anniversario labore decuit, in publicis privatique scholis, Hermannus Boerhaave," 2 vols. 4to. The work is dedicated by a most affectionate address to his brother James Boerhaave. The first volume contains the history and the theory of the art, and is furnished with numerous engravings and descriptions of furnaces, and other instruments of chemistry. The second contains the processes, or operations of chemistry. In the first volume he gives a catalogue of all the works he had published, preceding it, with much modesty, with this declaration; "Sciaque, me nihil edidisse unquam, præter sequentia, quæ non absque verecundia recitanda sũto." At the back of the title-page he says, "Ut certus sit lector, hunc librum a me editum prodire, propria manu adscribendum putavi; nec pro meo agnosco, ubi hæc adscriptio abest, Boerhaave;" uniting, as his custom was, the H and the B.

The character of Boerhaave, as a chemist, is thus given by Macquer, in his Preliminary Discourse to his Dictionary of Chemistry. "Next to Stahl we place the immortal Boerhaave, though he excelled in a different way. This powerful genius, the honour of his country, of his profession, and of his age, threw light upon every subject which he treated. To the view which he took of chemistry, we owe the finest and most methodical analysis of the vegetable kingdom; his admirable treatises on air, on water, and on earth, and particularly on fire, which is an astonishing masterpiece, is so complete, that the human understanding can scarcely make an addition to it." To his moral character his disciple Haller bears the following honourable testimony: "Some, though few, will rival him in erudition; his divine temper, kind to all, beneficent to foes and adversaries, detracting from no man's merits, and binding by favours his daily opponents, may, perhaps, never be paralleled." In his conversation he was easy and familiar, and in his demeanour grave and sober, but at the same time disposed to pleasantry, and occasionally indulging in good-humoured raillery; so that he was compared to the admirableocrates, whose bust he is also said to have resembled in features. By his pupils, whom he regarded with the kindness of a parent, he was beloved and respected in a very high degree. Piety formed a distinguishing feature of his character; and devotion was his daily exercise.

As Boerhaave was of an athletic make, had accustomed himself to exercise on horseback, to spend much of his time in the open air, and to use a frugal and plain diet, he had been enabled thus far to endure the extreme fatigue of his professional labours, with only some occasional interruptions from illness; but being grown corpulent, and incapable of riding, his constitution began to be on the decline, so that, in 1729, he found it necessary to resign his offices of professor in chemistry and botany. The speech he made on this occasion, was published under the title of "Oratio cum cathedræ chemiæ et botanices valediceret," 4to. In this he recounts some of the most memorable occurrences of his life, and speaks with gratitude of the patronage and favours he had received from individuals, in enabling him to chuse his walk in life, as well as from the members of his own profession, who had admitted his improvements in the theory and practice of the arts he taught, with more kindness and less opposition than is usually given to innovators of any kind. This doubtless arose in part from the great learning and abilities he was known to possess, and from the high reputation he had thence acquired, demanding respect; and

partly from his disposition, averse from contention, and thinking but modestly of his endowments. From whatever cause it might arise, there was never perhaps so great a revolution in any science brought about with so little opposition as was made to that produced by Boerhaave. He had before, viz. in 1728, been admitted foreign associate of the Royal Academy of Sciences in Paris; and in 1730, he was elected a fellow of the Royal Society in London. The same year he was again made rector of the university at Leyden. On quitting that office, he read his "Oratio de honore medici servitute," which was also published in 4to. In this he again insists on the necessity of attending to the method nature takes in curing diseases, or the manner in which they terminate spontaneously, as practised by Hippocrates. Though this secession from public employment procured him some respite from his labours, he still continued revising and correcting his original works. He also spent much of his time in revising the works of other writers, and published more correct editions than were before extant; as the "Opera Anatomica et Chirurgica And. Vesalii," fol.; Albinus contributed to this work; of Bellinus, "De urinis et pullibus," 4to. 1730; of Prosper Alpinus, "De præfagienda vita et morte," 4to. 1733; Aretæus, "De causis, signisque morborum," fol. 1731; Luilius, "De lue venerea," fol. 1728, and some other works. Still, however, he enjoyed ease and relaxation from the more fatiguing part of his business, and he passed the principal part of his time, during the remainder of his life, at his mansion, a small distance from Leyden, in domestic recreations, with his wife and daughter, to whom he was much attached. Here he had a garden well-stocked with every thing that could contribute to his pleasure, and here he amused himself with his violin, in which he was a proficient. Towards the end of the year 1737, he became sensibly affected with difficulty of breathing, and a sense of suffocation, which incommoded him, whether walking or lying down. This went on increasing; and a small time before his death, he perceived a strong pulsation on the right side of his neck, which he attributed to a polypous concretion in the aorta. No remedy being competent to combat this dreadful disease, he expired calmly, in the midst of his family, on the 23d of September 1738. He was buried in the church of St. Peter's at Leyden, where his fellow-citizens erected an elegant monument to his memory. The pedestal is of black marble, supporting an urn, decorated with emblematic figures, representing the four ages of man's life, and the sciences in which he excelled. On one face of the pedestal is a medallion with the head of Boerhaave, surrounded with suitable decorations, his seal hanging under it, on which is engraved his favourite motto, "Simplex sigillum veri," simplicity the seal of truth; and underneath, "Salutifero Boerhavii genio sacrum," sacred to the health-restoring genius of Boerhaave.

In the course of this sketch of the life of Boerhaave, his principal works have been noticed; for a more complete catalogue of them, see Haller's Bib. Med. Pract. Anatom. et Botan. and Eloy's Dict. Hist.

BOERHAAVE. ABRAHAM KAN, professor of medicine in the university of Petersburg, was born at the Hague in 1715. He was the son of James Kan, and of Margaret the daughter of Herman Boerhaave. After receiving a good classical education, he went to Leyden, where applying to the study of medicine, under the celebrated Albinus Gaubius, and other masters, he was admitted to the degree of doctor in 1738. He had before obtained an honorary medal from the university, for his discourse, "De gaudiis schemismarum;" though he was more particularly attached to anatomy, which he cultivated with great success. The year following he took the name of his uncle Boerhaave. In

1740 he went to Petersburg, where his talents soon procured him the situation of professor in medicine in the university there, and of one of the members of the imperial academy. By Portal and Blumenbach, he is called archiater, or aulic counsellor, and first physician to the empress, confounding him with his brother, Herman Kaan B. who about the same time enjoyed that honour. In the course of a severe and tedious illness, from which he with difficulty recovered, he lost his hearing. This happened in 1749. He died in 1753. His works are, "Periphrasis dicta Hippocrati, per universum corpus anatomicè illustrata," Lugd. B. 1738, 12mo; in which he shews there is a constant inhalation or absorption, and an exhalation, or perspiration, carried on, not only on the surface of the body, but in all the principal cavities. "Impetum faciens dictum Hippocrati per corpus consentiens, philologicè et physiologicè illustratum," Lugd. Bat. 1745, 12mo. In this he treats of the action of the mind upon the body, by the means of the nerves; of the fabric and motion of the muscles; on the effects of opium, given to a dog, &c. He also gave the anatomy of an elephant, which he had an opportunity of dissecting, and of two monstrous infants, and a dissertation on what have been called, improperly he says, hermaphrodites; no real hermaphrodite having ever been produced. Haller. Bib. Anat. Portal. Bib. Chir.

BOERHAVIA, in *Botany*, (named by Vaillant in honour of the celebrated Boerhaave.) Lin. gen. 9. Schreb. 13. Reich. v. i. p. 6. Willden. 20. Jussieu 91.; a genus placed by most botanists in the class *Monandria Monogynia*, though in different species, there are from one to four stamens. Nat. Ord. *Aggregate—Nylagenes*. Jussieu.

Gen. Char. *Cal.* oblong, tubular and angular, placed beneath the coroll, with a contracted, entire mouth, permanent. *Coroll.* monopetalous, bell-shaped, upright, obtusely five-cleft, plaited, fixed on the calyx. *Nect.* fleshy, subcylindric, with a mouth slightly toothed, surrounding the base of the germ. *Stam.* filaments one, two, three, or four, inserted on the margin of the nectary, between its teeth; capillary, near the bottom (within the calyx) more slender, upright, about the length of the corolla; anthers twinglobular. *Pist.* germ. roundish, pedicelled, the pedicel surrounded by the nectary; style thread-shaped, twisted, as long as the stamens; stigma capitate. *Pericarp.* none; calyx enlarged, closed, encrusting the seed. *Seed* one, oblong, obtuse, angular. *Observ.* It is nearly allied to *Mirabilis*. The toothlets of the nectary are sometimes triangular, very small, and sometimes obsolete.

Ess. Gen. Cha. *Cal.* small, entire. *Cor.* one-petalled, bell-shaped, plaited. *Seed* one, encrusting with the enlarged calyx.

Dahl has injudiciously abolished this genus, and placed its species with the Valerians. In the opinion of Willdenow, it belongs properly to the class *trianðria*, and may readily be distinguished from valerian by its very entire calyx, so minute, as scarcely to be visible, without the assistance of a lens, on which account it appears to have been overlooked by Linnæus and La Marek. Professor Martyn, in his edition of Miller, has inadvertently given *Calyx* none, as part of its essential general character; though in the natural character translated from Schreber, he had properly assigned it one.

Species, 1. *B. erecta*, upright hogweed. "Stem erect, smooth; *Stamens* two." Jacq. and Miller. "Stem tetragonal, smooth, with viscous joints, and flowers in a corymbose panicle." Willden. Stem two feet high, sprinkled with very minute protuberances as fine as hairs. Leaves waved, ovate, acute, rough at the margin, growing by pairs on long petioles from the joints of the stem, which are placed at a considerable distance from each other. Corolls cylindrical, white, with five reddish shades; segments acute, with small

teeth interposed. Stigma capitate. Discovered by Dr. Houston at La Vera Cruz in 1731, and since found at the Society Isles. 2. *B. adscendens*. "Leaves oblong-ovate, somewhat fleshy; flowers panicled; peduncles two-flowered; stem ascending." Willden. Stem smooth, tetragonal; leaves petiolate, opposite, veined, entire, smooth; the young leaves and the margin and petioles of the older ones hairy; hairs jointed as in veronica aphylla; panicle terminal, spreading, naked; peduncles two-flowered, involved in membranaceous bracts; fruit club-shaped, rough with small tubercles. A native of Guinea. Willden. 3. *B. diffusa*. "Stem smooth and even, spreading; leaves ovate." Linn. "Stem round, pubescent; flowers in corymbose heads." Willden. Leaves white underneath; flowers purple, with one stamen. A native of the East and West Indies. Cultivated in the royal garden at Hampton Court 1690. Mr. Miller received seeds from Jamaica by Dr. Houston. 4. *B. hirsuta*. "Stem spreading, pubescent; leaves ovate, repand, or serpentine." Reich. "Stem roundish, hairy; flowers in heads." Willden. Stems a foot high; peduncles axillary, sustaining small close heads of scarlet diandrous flowers, which generally fall off in about half a day. A native of Jamaica. 5. *B. plumbaginea*. "Leaves subcordate, orbiculate-acute, pubescent beneath; flowers in umbels." Willden. Umbels axillar, on long peduncles; coroll of a pale rose colour; stamens three; fruit turbinate, striated, crowned at the apex with pedicelled tubercles. Willden. A native of Spain. 6. *B. scandens*. La Marc. Tab. 4. "Stem erect; flowers two-stamened; leaves cordate, acute." Linn. "Stem erect, flowers two-stamened, in umbels; leaves cordate." Willden. Stem shrubby, very stiff, smooth, with alternate branches; leaves smooth; umbels of six green flowers; involucre of five leaves. A native of the rocky coasts of Jamaica and other West India islands. Cultivated in 1691, in the royal garden at Hampton court. 7. *B. excelsa*. "Stem erect; lower leaves cordate-ovate, upper ones ovate, flowers with three stamens in umbels." It resembles the scandens, but differs from it in its taller stem, in its upper ovate leaves, in its doubly larger purple flowers, and in the number of its stamens. Native place unknown. Described by Willdenow from a living plant. 8. *B. repnla*. "Stem erect; leaves cordate, repando sinuate; flowers in umbels, with three stamens." Willden. Resembles the scandens, but differs from it in its herbaceous stem and opposite branches and peduncles. A native of India and China. 9. *B. chærophyllodes*. (Valeriana Chærophyllodes. Smith Ic. ined. fusc. 5.) "Leaves bipinnatifid, toothed; flowers with three stamens in umbels." Willden. It has entirely the habit of a Boerhavia, and agrees in all the generic characters excepting only the style which is trifid. 10. *B. repens*. "Stem creeping." Linn. Native of Nubia, between Mocho and Tangos. 11. *B. angustifolia*. "Leaves linear, acute." Linn. Native place unknown. 12. *B. tetrandra*. Stem creeping; flowers with four stamens. Forst. Prod. 2. Native of the Society Isles, found by Forster in the island of Huahine 1774.

These are all the species in Willdenow's edition of the Sp. Pl. La Marek (Illust.) has made the hirsuta and the repens the same as the diffusa, and appears to have been unacquainted with the adscendens, plumbaginea, excelsa, repanda, chærophyllodes, angustifolia, and tetrandra; but has inserted two others, which as far as can be determined from their specific characters, seem to be distinct species. *B. paniculata*. "Stem erect; leaves ovate, acute, panicle naked, filiform, very viscous." A native of South America. *B. tuberosa*. "Stem erect, shrubby; root tuberose, esculent." A native of Peru. The following may possibly be the hirsuta, though he unites that species with the diffusa. *B. obtusifolia*. "Stem procumbent, spreading, viscidly pubescent;

cent; leaves ovate, obtuse; umbels small, somewhat in heads, lateral." A native of South America.

Propagation and Culture. None but the first, third, fourth, and sixth, have been cultivated in England. They will not thrive in the open air, but must be raised from seeds, and treated like other tender exotic plants. The first three are annual, and when they grow too tall to remain under a common frame, may be planted in a warm border, where, if the season prove favourable, they ripen their seeds; but a plant or two should always be placed in the stove, to ensure a succession of seeds. The fourth, which is perennial, may be preserved in a warm stove two or three years. See Martyn's Miller.

BOERNÆR, FREDERIC, in *Biography*, professor in medicine at the university of Wittemberg, in Saxony, and an active member of the Acad. Nat. Curios. received his education at Leipzig, where he was born, June 17, 1723. He published several dissertations on medical subjects, but his principal work is "Noctes guelphicæ, five opuscula medico-literaria," Roslock, 1755, 8vo. He died June 1761. Eloy. Dict. Hist.

BOERNERIANUS Codex, in *Biblical History*, a MS. of part of the N. T. noted G, in the second part of Wetstein's N.T. It belonged to Dr. C. F. Boerner, was collated by Kuster, and described in the preface to his edition of Mill's Greek Testament. It contains the epistles of St. Paul, that to the Hebrews excepted, which was formerly rejected by the church of Rome; it is written in Greek and Latin, according to one of those versions, which were in use before the time of Jerom. The Latin is interlined between the Greek, written over the text, of which it is a translation. Stemmler supposes that the Latin was written since the Greek; but professor Matthiæ, who published this MS. at Meissen in Saxony in 1791, suggests that an uniformity in the hand-writing, and a similarity in the colour of the ink evince, that both the Greek and Latin texts proceeded from the same transcriber. That it is an ancient MS. appears, says Michaelis, from the form of the characters, and the want of accents and marks of aspiration. It seems to have been written in an age when the transition was making from the uncial to the small characters; and from the correspondence of the letters *r*, *s*, and *t*, in the Latin translation, to that form which is found in the Anglo-Saxon alphabet, it is inferred, that this MS. was written in the West of Europe, and probably between the 8th and 12th centuries. This MS. is preserved at present in the electoral library at Dresden: and a copy of it is kept in the library of Trinity College, Cambridge, among the books and MSS. that were left by Dr. Bentley. Michaelis on the N. T. by Marsh, vol. ii. and iii.

BOERO, in *Geography*. See BURRO.

BOESCHOP, a town of Brabant, on the river Nethe; 12 miles N. E. of Malines.

BOESEROENS, or **BUDGEROONS**, three small uninhabited flats of the East Indies, situated in the strait that lies between the island Saleyer and the point of Celebes, called Laffem. These three islands almost block up the passage between the southern part of Celebes and the northern part of Saleyer, the whole space between which is about a league and a half. The strait is parted between the southernmost and middlemost, or between the latter, and the northernmost of the Budgeroons. This one of the most dangerous parts of the navigation for ships sailing to or from the Moluccas, or spice islands; and it cannot be avoided without going round to the south of Saleyer, which is a much more dangerous route, on account of the great number of shoals and sunken rocks, which abound there, and are not accurately laid down in the charts.

BOESIPPO. See BÆSIPPO.

BOETHICUS, in *Entomology*, a species of *HESTERIA*, (Pleb. Rur. Linn.) that inhabits India. The wings are tailed, bluish-brown, pale ash colour beneath, and undulated with whitish; a double ocellar spot in the anal angle.

BOETHIUS, ANICIUS MANLIUS TORQUATUS SEVERINUS, in *Biography*, descended from one of the most illustrious consular families of Rome, lived in the time of the emperor Zeno, near the end of the 5th century. He was born at Rome about 470, the same year with Martianus Capella, another Roman writer on music. He is said to have spent 18 years in the schools of Athens, pursuing the study of philosophy under Proclus; others, however, have questioned this fact, and it has generally been allowed, that the term of 18 years is too long. Nevertheless, his visit to Athens is justified by much internal evidence, adduced by Brucker, (Hist. Crit. Philos. t. iii. p. 524—527.) and by an expression, though vague and ambiguous, of his friend Cassiodorus, (Var. i. 45.) "longè positas Athenas introiit." It is certain, that the erudition of the Latin language was insufficient to satiate his curiosity, and that he devoted much of his time and attention to the study of Grecian science and letters. From a letter of Cassiodorus, written in the name of Theodoric, it appears that he had the honour of introducing to the Romans in their own language, the music of Pythagoras, the astronomy of Ptolemy, the arithmetic of Nicomachus, the geometry of Euclid, the logic of Aristotle, and the mechanics of Archimedes. He alone was esteemed capable of describing the wonders of art, a sun-dial, a water-clock, and a sphere which represented the motions of the planets. He commented upon parts of Aristotle, Cicero, and Porphyry; and from the commendations which he bestows upon the latter, as the best interpreter of the former, he seems to have united the Platonic with the Aristotelian doctrine. Boethius seems to have been the first who applied scholastic philosophy to the service of Christian theology; and he employed himself in defending the orthodox creed against the Eutychian, Arian, and Nestorian heresies, in a treatise "De Unitate et Uno." In civil life he attained to peculiar honours; as he was consul in 487, and also in 510; and he was also created patrician, and advanced to the post of master of the offices. He married the daughter of his friend, the patrician Symmachus, and he enjoyed the peculiar satisfaction of seeing his two sons elevated to the consulate together in 522. Few persons passed through life with a greater share of outward respect and honour; and few could be more distinguished by the testimonies that were given to his benevolence and liberality, his virtue and patriotism, as well as to his singular talents and learning. His own affection claims our assent, that he had reluctantly obeyed the divine Plato, who enjoined every virtuous citizen to rescue the state from the usurpation of ignorance and vice. For the integrity of his public conduct he appeals to the memory of his country. His authority had restrained the pride and oppression of the royal officers; he had always pitied and often relieved, the distress of the provincials, whose fortunes were exhausted by public and private rapine; and he alone had the courage to oppose the tyranny of the Barbarians, elated by conquest, excited by avarice, and as he complains, encouraged by impunity. In these honourable contests, his spirit soared above the consideration of personal danger, and perhaps of prudence. In addition to his other learned labours, he had formed a design of translating all the works of Plato and Aristotle into Latin; but was prevented from executing his purpose by a premature death. Having for some years enjoyed the favour of Theodoric, the Gothic king of Italy, he was at length suspected of being hostile to

his government, and of concurring with others, and particularly with Albinus, who was accused and convicted on the presumption of *hoping*, as it was said, the liberty of Rome. "If Albinus be criminal," exclaimed Boethius in the presence of the king, "the senate and myself are guilty of the same crime. If we are innocent, Albinus is equally entitled to the protection of the laws." The advocate of Albinus was soon involved in the danger and perhaps the guilt of his client; their signature, which they assumed to be a forgery, was affixed to the original address, inviting the emperor Justin to deliver Italy from the Goths; and three witnesses of honourable rank, but probably of infamous character, attested the treasonable designs of the Roman patrician. Upon this kind of evidence, Boethius was committed to custody, and rigorously confined in the tower of Pavia; and a servile senate, at the distance of 500 miles, pronounced a sentence of confiscation and death against the most illustrious of its members. During his confinement, he composed his treatise "De consolatione philosophiæ," mentioned in the sequel of this article; and at length the executioners of Theodoric's mandate fulfilled the savage commission with which they had been entrusted, or, perhaps, even exceeded it, by the mode of putting him to death. Some say that he was beheaded; but others relate, that a strong cord was fastened round his head, and forcibly tightened, till his eyes almost started from their socket; and he was then beaten with clubs till he expired. This event happened, according to some, in the year 526, but according to others in 524. Boethius, in his last hours, derived some comfort from the safety of his wife, of his two sons, and of his father-in-law, the venerable Symmachus. But Symmachus, perhaps indiscreet in the mode of testifying his grief, was sometime after dragged in chains from Rome to the palace of Ravenna, and there put to death, A. D. 525. Theodoric, it is said, experienced the bitterness of self-reproach, and the anguish of an unavailing repentance for the murder of these two illustrious senators, Boethius and Symmachus. His daughter Amalautha is said to have restored to the sons of Boethius the confiscated estates of their father.

His celebrated tract on music, divided into five books, was first printed in black letter, with his treatises on arithmetic and geometry, at Venice, 1499. It is remarkable, that in this copy the Greek of the famous *senatus consultum*, against Timotheus at Lacedæmon, is omitted; though it was afterwards found in a beautiful MS. of Boethius, *De musica*, 15 B. IX. of the 11th century, in the British Museum, where the infamous chromatic ($\alpha\beta\gamma\delta\epsilon\zeta\eta\theta$) is said to have been substituted by that musician to their grave and simple enharmonic ($\epsilon\upsilon\alpha\beta\gamma\delta\epsilon\zeta\eta\theta$), in the same manner as it is printed in the Oxford edit. of Aratus. (See Dissert. on the Mus. of the Ancients, p. 27.)

It seems necessary here to give some account of this famous treatise on music by Boethius, which, to read, was long thought necessary to the obtaining of a musical degree in our universities; and which, with great parade, has been so frequently praised, quoted, and pronounced, by writers on that art, to be of the greatest importance to every musician, yet contains nothing but matters of mere speculation and theory, translated from Greek writers of higher antiquity; which if necessary to be known at this time, would be more profitably studied in the original; but the theory of every art being vain and useless, unless it guide and facilitate practice, the definitions, calculations, and reveries of Boethius, are no more useful or essential to a modern musician than Newton's *Principia* to a dancer.

In the proemium, or introduction to his first book, "De Musica," he treats of the *morality* of music, and gives us all the old stories concerning its miraculous powers of exciting

virtue, repressing vice, curing diseases, &c. And in this book we find whence Zarlino, and all the Italian writers on music, down to Padre Martini, drew their extensive divisions of music into *mundane*, *human*, and *instrumental*. For Boethius says, "Tres esse Musicas," lib. i. cap. 2. So had Arist. Quintilianus informed us, long before the birth of Boethius. And as far as we are able to divine at present concerning these distinctions, the ancients meant by *mundane* music, the music of the spheres. By *human*, or *humane* music, the perfect organization of our frame, and the union of soul and body. By the last only, the instrumental, we are brought to real music, by the grateful production and union of tuneful sounds.

Then we have definitions, such as are given in Euclid, and all the Greek writers, on harmonics and speculative music in Meibomius. After which, we have the doctrines of proportion and ratios, instituted by Pythagoras, who would not trust to the various and fallacious judgment of the senses, but had recourse to reason and calculation to settle his doubts. The account of the discoveries and harmonical laws established by Pythagoras, not only inserted in Boethius, but all subsequent writers, is taken from Nicomachus, one of the seven Greek writers on music in Meibomius. In the same book, we have a very superficial and unsatisfactory account of the genera. But we are indulged with several chapters on the music of the spheres from "Cicero de Repub." lib. vi. where the supposed analogy between the planets and the septenary, or seven sounds in music, is asserted.

At the close of this book, chap. xxxiv. Boethius estimates theory and speculation far above practice in music. But what, we may ask, is the use to the world of such a theory as he describes, without practice? Or, indeed, practice, without the support of what is now understood by theory? The speculative theorists, confined to meditation and experiments in harmonics, talk of music without hearing it; and the mere practitioner hears it without understanding it. Boethius allows him only to be a musician who can examine, judge, and give reasons for what is done. Here we have the origin of the verses ascribed to Guido:

Muscorum et cantorum,
Magna est distantia, &c.

The whole second book is relative to the dispute between the Pythagoreans and Aristoxenians, which is not yet settled, about dividing the scale, whether by the ear, or by numbers. All the musicians in Europe are now disputing whether we should temper our scales on fixed instruments, or adopt the triple progression of Pythagoras, and tune by perfect 5ths. See TRIPLE PROGRESSION, and TEMPERAMENT. We have here the tone-major and tone-minor to discuss; which we talk about, but never feel or think of the distinction in our modulation or performance. The *apotome*, *comma*, and *limma*, are left for the amusement of speculative harmonists to talk about, and for musicians to practise with their ears and fingers, *sans y penser*.

In the third book, Boethius continues his controversy with the Aristoxenians, and proves what has been long settled, that there is no such thing in music as a literal *half-note*. The octave is said to contain five tones and two semitones; and in the temperament of equal participation, the twelve semitones of the octave must be nearly equal.

In book iv. the subject is pursued of splitting of tones; for the ancients could "divide and subdivide a tone from south to south-west side."

We were very much disappointed formerly at the non-performance of a promise made, book v. at chap. 3. the title of which is "Musicarum per Græcas ac Latinas literas notarum nuncupatio." But Meibomius says the promise does not extend to the Roman notation in the Selden MS. at Oxford; nor had the Romans any notation of their own

in the time of Boethius; and all the musical terms he uses are Greek, as were those of Vitruvius.

Even the eulogists of Boethius confess, that his work is so purely theoretic, that in reading it we never think of practice. Let us leave it then to philosophers who are content with imaginary sounds. The mention of instruments, or of the voice as employed in singing, never occurs. No allusions to the music of his time, but all is abstract speculation, tending doubtless to the perfection of the art, but seeming little connected with it. The harmony he talks of is more the *harmonia mundi* of Kepler, than that of Handel and Haydn. Guido said, that Boethius's work was only fit for philosophers. In the middle ages, so few understood Greek, that those who were curious to know something about the miraculous powers of that music, imagined that they should find it in Boethius's translation, who had been educated at Athens. Such speculations are curious and amusing, in moments of meditation, to scientific and inquiring minds; but practical musicians, whether composers or performers, can afford little time for such sublime and spiritual amusements. Nevertheless, he must be a dull and incurious professor, who seeks not the reason of things, the principles of his art, and origin of sounds. If he have a mathematical turn, let him read Galileo. Daniel Bartoli, D'Alembert, Holder, Rameau, Tartini, and Smith's harmonics. They are all intelligible, and lead to knowledge which he will be expected to possess; but for any thing useful that he can acquire from Boethius's speculations, or from the Greek theorists, his prototypes, that will make him a better composer or performer, the case is hopeless. Yet there are, who, after allowing that "it was of so little use in practical music, that they never thought of it in reading Boethius;" yet returning afterwards to former prejudices, it is insisted on, that "he has communicated to the world such a knowledge of the fundamental principles of the music of the ancients, as is absolutely necessary to the right understanding of our own system."

When we speak of the inutility of Boethius's work on music to the musical students of modern times, we presume not to extend our censures further. The writings of this great and good man on other subjects have been too long held in reverence to be depreciated slightly. His most celebrated production was his ethic composition "De consolatione philosophiæ," and has always been admired both for the style and sentiments. It is an imaginary conference between the author and philosophy personified, who endeavours to console and soothe him in his afflictions. The topics of consolation contained in this work, are deduced from the tenets of Plato, Zeno, and Aristotle but without any notice of the sources of consolation which are peculiar to the Christian system. It is partly in prose, and partly in verse; and was translated into Saxon by king Alfred, and illustrated with a commentary by Asser, bishop of St. David's; and into English, by Chaucer and queen Elizabeth. It was also translated into English verse by John Walton, in 1410, of which translation there is a correct manuscript on parchment in the British Museum. Few books have been more popular, especially in the middle ages, or have passed through a greater number of editions in almost all languages. It has been observed by Mr. Harris, in his "Hermes" that "with Boethius the Latin tongue, and the last remains of Roman dignity, may be said to have sunk in the western world." To the same purpose, Gibbon says, "that the senator Boethius is the last of the Romans, whom Cæsar or Tully would have acknowledged for their countryman." Fabr. Bib. Lat. tom. ii. p. 146, &c. Le Clerc, Bib. Chois. t. xvi. p. 163—275. Burney's Hist. Mus. vol. ii. p. 31, &c. Gibbon's

Hist. Rom. Emp. vol. vii. p. 43, &c. Brucker's Hist. Phil. by Enfield, vol. ii. p. 313.

BOETTICHER, GOTTLIEB, a physician of eminence, and in considerable practice at Berlin during the early part of the last century, published various works on the theory and practice of medicine. The principal are, on the existence of a nervous fluid, "De vera fluidi nervorum existentia," Berlin, 1721, 4to.; "De morborum malignorum, imprimis pestis et pestilentie explicatio," 4to. 1713; this has been several times reprinted. He contends that the plague is contagious; and that the infecting effluvia may be retained, and conveyed in full vigour, in the clothes or bedding of the sick, to distant countries; a doctrine that has been lately strongly opposed. Pregnant women, affected with the plague, constantly part with the fruit of the womb before they die. Hypochondriac persons, he thinks, are not susceptible of the contagion. But in this he is probably mistaken; as we know lunatics do not enjoy such an exemption from contagious diseases in this country. He recommends bleeding on the first attack of the fever, and then to have recourse to sudorifics. "De respiratione factus in utero," 4to, 1702. Haller Bib. Med. et Anat.

BŒUF, LE, in *Geography*, a place in the north western corner of Pennsylvania, at the head of the north branch of French creek, and 50 miles distant by water from fort Franklin, where this creek joins the Alleghany. The French fort of Le Bœuf, from whence the place has its name, lies about two miles east from Small lake, which is on the north branch of French creek; and from Le Bœuf, is a portage of 14 miles northerly to Presque isle in lake Erie, where the French had another fort. N. lat. 42° 1'. W. long. 79° 53' 20".

BŒUF, in *Ornithology*, according to Salerne, the common name of the bulfinch (*loxia pyrrhula*) in the canton of Solagne. The troglodyte, *sylvia troglodytes* of Latham, is likewise called by the same name (*bœuf*) in Switzerland.

BŒUF de Marais. The French call the common bittern (*ardea stellaris*), because it frequents marshes, and has a loud cry, and emits a sort of roaring noise that has been compared to that of an ox or bull, by this name. "Il u'y a," says Belon, "bœuf qui pût crier si haut."

BŒUF d'Afrique, in *Zoology*. By this name some French writers distinguish the buffalo; the epithet is misapplied, because that animal is equally common in India, whence indeed, it is supposed, the African buffalo first originated.

BŒUF a Besse, synonymous with *bison*. By some it is likewise called *bœuf des Illinois*.

BŒUF Guerrir. Under this denomination the French describe a race of African oxen, which the Hottentots call *backleys*; the word *backley* in their language signifying war, to the purposes of which they are trained up, in the same manner as elephants are by the Indians. War oxen of this description are instructed also to guard the herds of the common oxen.

BŒUF de Mer, in *Ichthyology*, is the name of the long-beaked ray, *raja oxyrinchus* of Linnæus.

BŒUF de Mer, in *Zoology*, the common French name for any of the *PHOCÆ* tribe of animals, corresponding with the general English name of *sea-coot*.

BOFFRAND, GERMAIN, in *Biography*, a celebrated French architect and engineer, was born at Nantes in 1667, and having been educated at Paris, he employed himself for some time in sculpture during the winter, and studied architecture in the summer. His talents at length engaged the attention and patronage of Hardouin-Mansart, an eminent architect, who obtained for him a place in the commission for the royal buildings. In 1709, he became a member of the

Royal Academy of Architecture, and was much employed at Paris, and by several German princes, in furnishing designs for various edifices. His style of building was grand and noble, and formed after the model of Palladio. He was likewise a skilful engineer, and constructed a great number of canals, sluices, bridges, and similar works. As architect to the general hospital of Paris, he gratuitously served the institution; and, as he was disinterested in his temper, he was lively and amusing in conversation; and he indulged his taste for literature by the composition of several pieces, adapted to the purpose of producing temporary gaiety and mirth, for the Italian comedy. His "Book of Architecture," with plates, was printed at Paris in 1745, folio; and contains an account of the general principles of the art, exemplified in his own works. In this work he has also introduced a curious memoir, describing the method of casting the bronze equestrian statue of Lewis XIV. He retained his gaiety of disposition to the age of 87 years, and died at Paris in 1755. *Encycl. Hist. Gen. Biog.*

BOFIN, BOFFIN, or BAFFIN *Lough*, in *Geography*, one of those large lakes in Ireland into which the river Shannon expands, situated between the counties of Roscommon and Leitrim.

BOG, derived from the Italian *bucca*, a *hole*, or rather from the Belgic *boogen*, to *bend*, on account of its giving way when trod upon, in *Agriculture*, a quaggy sort of earth, generally met with in low situations, covered with coarse grasses, but of so little solidity as to be incapable of supporting the tread of heavy animals; caused by the dissolution, decay, and deposition of different vegetable and other substances, from the stagnation and detention of the water that oozes along on the clayey or other thin tenacious strata below, or which springs up through the fissures, or other openings of them. They are of different kinds, depths, and consistencies, according to the different circumstances of the case, and the nature of the situation of the ground on which they are formed, as well as that of the earthy material that enters into their composition. Dr. James Anderson, in his treatise on draining bogs and swampy grounds, remarks, that clay is a substance that strongly resists the entrance of water into it; but, when it is long drenched with water, it is in process of time, in some measure dissolved thereby, losing its original firmness of texture and consistence, and becoming a sort of semi-fluid mass, which is called bog. And as these bogs are sometimes covered with a surface of a particular kind of grass, with very matted roots, which is strong enough to bear a small weight without breaking, although it yields very much; it is in these circumstances denominated a *swaggle*.

But whatever be the nature of the bog, it is invariably occasioned by water being forced up through a bed of clay, as just described, and dissolving or softening a part thereof. A part is only mentioned, because, whatever may be the depth of the bog or swaggle, it generally has a partition of solid clay between it and the reservoir of water under it, whence it originally proceeds. For if this were not the case, and the quantity of water were considerable, it would meet with no sufficient resistance from the bog, and would of course, issue through it with violence, and carry the whole semi-fluid mass along with it. This would more inevitably be the case, if there was at first a crust at the bottom of the bog, and if that crust should ever be broken, especially if the quantity of water under it was very considerable. And as it is probable that, in many cases of this sort, the water slowly dilutes more and more of this under-crust, no doubt is entertained but that in the revolution of many ages, a great many irruptions of this kind may have happened; although they may not have

been deemed of importance enough to have the history of them transmitted to posterity.

It has been remarked by Mr. King, in the *Philosophical Transactions*, No. 170, that the springs, with which Ireland abounds, are generally dry, or nearly dry in the summer time, and that grass and weeds grow thick about the places where they burst out. In the winter, he observes, they swell, run, soften, and loosen all the earth about them. The sward or scurf of the earth, which consists of the roots of grass, being lifted up and made fuzzy by the water, at that season (he has seen it lifted up a foot or two at the head of some springs), is dried in the spring, and does not fall together, but withers in a tuft, through which arises new grass, which is also lifted up the next winter. By this means the spring is more and more stopped, and the scurf grows thicker and thicker, till at first it makes the appearance which we call a quaking bog; and as it grows higher and drier, and the roots of the grass and other vegetables become more putrid, together with the mud and slime of the water, it acquires a blackness, and grows into that which we call a turf-bog.

It is, however, confessed, that there are quaking-bogs caused otherwise. When, it is observed, a stream or spring runs through a flat, the passage, if not kept open, fills with weeds in summer, trees fall across it and dam it up; then in winter the water stagnates further every year, till the whole flat is covered. Afterwards a coarser kind of grass shoots up, peculiar to these bogs; this grass grows in tufts, its roots consolidate together, and its height increases every year, in-somuch that he has seen it as tall as a man. This grass rots in winter, and falls on the tufts, and with it the seed, which springs up the next year; and so continues making an annual addition. Sometimes the tops of the flags and grass are interwoven on the surface of the water, and this becomes by degrees thicker till it lies like a cover on it; then herbs take root in it, and by the matting of their roots, it becomes very strong, so as to bear a man. He has gone on bogs which would rise before and behind, and sink where he stood to a considerable depth, under which was clear water.

It is further observed, that Ireland abounds in moss more than any other country; this moss is of divers kinds, and that which grows in bogs is very remarkable. The light spongy turf is nothing but a congeries of the threads of this moss, before it be sufficiently rotten; the turf then looks white, and is light. It has been seen in such quantities, and so tough, that the turf-spades could not cut it. In the north of Ireland, they denominate it old-wives tow, being not much unlike flax. The turf-holes in time grow up with it again; and all the little gutters in bogs are generally filled with it. To this he chiefly imputes the red or turf bog; and from the same cause even the hardened turf, when broken, is stringy, though there plainly appear in it parts of other vegetables; and he is almost, from some observations, tempted to believe, that the seed of this bog-moss begets heath, when it falls on dry and parched ground. However, the moss is so fuzzy and quick-growing a vegetable, that it greatly stops the spring, and contributes to thicken the scurf, especially in red bogs, where he remembers to have observed this most particularly. The situations of land may sometimes contribute to the formation of bogs in it, as flat spots of ground lower than the level of an adjoining river or lake; for when that part is filled up by the slime and earth brought from the surrounding grounds, and the rotten plants and animals, which are buried in it, have choked it up, it will become a bog; and then the water will continue to flow into it from the river or lake, especially when either of these is swelled by a fall of rain or melting of snow. These waters may also sometimes have

this effect, without a communication above ground, by soaking through a sandy or gravelly soil. And another cause that may contribute to the production of bogs, may be the fall of a number of trees, which, by occasioning a stagnation in the water brought down from higher grounds, may cause the depolition of much earthy vegetable, and other materials, and consequently the production of boggy appearances in the places where such obstructions are met with.

Bogs are discriminated by different titles, according to the nature of the circumstances under which they occur; as *peat-bogs*, *quaking-bogs*, *spring-bogs*, and *turf-bogs*. The first being that sort of bog which is principally composed of peat-earth. The second such a kind of bog as, when trodden upon, affords an elastic kind of motion, or shaking under the foot. The third is such a bog as arises from the oozing or springing up of water through the stiff strata of materials on which it is formed. Mr. Elkington, the celebrated drainer, makes two classes of this sort of bog; the first of which is distinguished by the springs rising out of the adjoining higher grounds, in a regular line, along the upper side of the wet surface; while, in the latter, the number of springs that appear are not confined to one regular direction along the upper side, but burst out promiscuously over the whole surface, especially towards the lower side, forming quagmires all round, that shake and bend under the feet like a suspended cloth, over which it is dangerous for the lightest cattle to pass, and which shew themselves at a distance by the verdure of the grass, which the quags or spots immediately round the springs produce. The last is a sort of bog constituted of materials which partake of the nature of turf.

Whenever bogs are met with, draining is unquestionably the first step to be taken towards their improvement. For the full accomplishment of this purpose, Mr. Elkington's mode may in many cases be successfully resorted to, and with great and sudden effect; though the improver should not be too sanguine in his expectations, or imagine that it is in every case an easy operation to free this sort of land from an excess of moisture. There are probably some bogs which cannot, without great difficulty, be drained at all; and others that would cost the value of the land, in drains and machinery, to effect such improvements in them. But notwithstanding unsuccessful trials may sometimes be made, the drainer ought not to be totally discouraged from further attempts, where there is a tolerable prospect of succeeding in the business at last; as the cases are no doubt very numerous, in which this sort of land may be effectually drained at an easy expence, and thereby brought from a state of inutilty to yield considerable profit to the owners and the public. See *DRAINING of Boggy Lands*.

It is observed in the appendix to Mr. Johnston's account of Mr. Elkington's mode of draining, that in the improving of bogs, after their being drained, as the great object is to get the ground brought to such a state, as to be fit for being laid down with grass seeds, when it may be considered in such a state of improvement, that any subsequent crops will require no more than ordinary management to cultivate them; the first thing to be done, where they are extensive, is to have them divided into proper inclosures by open ditches, by which means much surface water may be carried off, as well as by properly attending to the formation of the ridges and furrows in ploughing, and giving them a direction towards the open ditches, by which the rain or surface water may be discharged as it falls; and after this has been effected, to have the surface well levelled by means of the spade, as being in most cases more effectual than by the plough. The better sorts of the materials thus removed may be mixed up with lime or other substances, and set upon the land; while

those of the coarser kinds are made use of to fill up the inequalities on the surface. Paring and burning, where there is much coarse vegetable matter, may be practised with advantage. In order to this, whatever earth remains unemployed, in filling up hollows, should be burnt, together with that taken out of the ditches, unless the latter has been already carried off for fuel. The greater quantity of ashes there is, the greater will be the improvement of the soil itself, and the more will the earth be benefited. The ashes, after being well incorporated with the soil by means of light or superficial ploughing, frequently so enrich it, as to produce excellent crops for two years or more. The effects of the ashes and burnt materials have been said, in some cases, to be increased by the addition of a little lime. When the turfs have been reduced to ashes, spread over the surface of the ground, and turned in with a little furrow, turnips or potatoes ought to be the first crop. If the former, they may be sown broad-cast, and fed off by sheep, by the dung and urine of which the soil will be greatly benefited, as well as by the refuse of the plants, and the consolidation produced by their treading upon it. It will then be in a state for a crop of oats or barley, which should be sown with grass-seeds, and well rolled down. The ploughing after the turnip crop, thus eaten off, should be very slight, in order not to bury the enriching materials too deep; in which view oats ought to be preferred to barley. If the soil be full of the roots of rushes, weeds, and coarse plants, a summer fallow may be necessary before any crop be taken: and when the ashes have been made in a particular part of the field, they may be spread over the surface before the seed furrow is given, and the roots and tough clods, after being collected and burnt, may be spread along with them.

If the bog be very soft and deep of peat, so as not to admit horses for ploughing the first year, a crop of turnips broad-cast may be got by sowing the seed among the spread ashes, harrowing it in with a light harrow and roller drawn by men. This crop, being cut off as above, will leave the land the ensuing year so much consolidated as to admit the plough.

When the surface has not been pared and burnt, fallowing for two years may be necessary to reduce the soil to a proper mould, in the last stage of which the lime or other manure must be applied. In this case two white crops, with an intervening one of turnips, potatoes, &c. may be taken before the grass-seeds are sown.

Boggy soil, of whatever kind, after being once broken up and pulverised by tillage and a course of fallow, should not be over-cropped before being laid down in grass; and, when brought into a good sward of grass, should not be too soon broken up again, but continue so, bush-harrowing and top-dressing it when the herbage begins to mofs. Repeated rolling is also necessary in such soils.

It is probably a better practice to feed sheep the first and second years of the grass than to cut it for hay, as it causes the roots of the grass to strike more horizontally through the soil, and more closely to cover the surface. With this view a greater proportion of white and yellow clover, and other short grass seeds, should be sown.

In the manuring of soft boggy lands some caution is necessary; for, though the ploughings, previously to the application of the dung, may be made deep with advantage, the subsequent furrows should be very superficial, and the dung regularly and uniformly blended with the soil; for, when this is not the case, it is apt to sink down too much, and be of little utility. The same thing takes place with respect to lime; and even when marle is buried too deep it is said to lose its power as a manure.

On soft boggy ground, merely intended for pasture, nothing will produce a more rapid improvement than the application of a thin covering of marle. In order to this, the directions already given, with respect to paring and burning, should be observed.

Marle, which is often found under a gravel or clay, may also be of great service: but if a loamy earth be near at hand, it will, perhaps, be less expensive to the farmer to bring such earth to cover the bog, than it will be to dig up the clay. But of whatever kind the earth be which is laid upon the bog, the quantity should always be sufficient to cover its whole surface four, five, or six inches deep, according to the stiffness of the soil so brought.

Sea-sand, as being frequently mixed with shells, is well suited to this purpose, if the boggy ground be situated near the sea, so that it can be easily procured. The great weight of these materials tends equally to consolidate the bog, and press out the moisture from the spongy peaty earth; therefore the thicker they are applied the better. A slight sprinkling of lime over it will add to the effect, and bring up much white clover and other sweet grasses.

The most barren earths or soils, when used in this way, may have good effects; but lime-stone gravel, where it can be procured, is to be preferred to all others. After the land has been treated in this manner, and lain some years in pasture, it may be broken up for tillage, and crops of grain taken before being laid down with grass-seeds. By ploughing, part of the natural soil will be turned up, and intimately mixed with the earth, &c. that has been laid upon it, and, if lime or dung be added, will together form a very fertile mould. When boggy grounds are much over-run with rushes, and other coarse, sour, aquatic plants, scarcely any thing tends more to the first part of its improvement than that of over-stocking it with different sorts of cattle, as soon as ever it is sufficiently solid to bear them with safety; care must, however, be taken not to put them on till it is quite firm, as if that be done they will not only poach the surface, but the coarse herbage will remain without being eaten closely down. The practice of cutting the rushes frequently in their young and tender state, is also of considerable utility. By these means alone a better kind of herbage is speedily brought up, and much improvement produced.

Another considerable means of improving this sort of land, where the situation is such as to admit of it, or when it lies near the side of a large river or stream, of which, by means of proper dams and cuts, a command can be obtained, is that of floating it with water, a process that, when judiciously managed, never fails to produce abundant crops of grass. And that it is a mode of improvement well suited to this sort of land, is evident from the effects that have been produced in different instances; and from the observations of Mr. Boswell, that it requires more and longer watering than any sandy or gravelly soil: the larger the body of water that can be brought upon it the better, its weight and strength will greatly assist in compressing the soil, and destroying the roots of the weeds that grow upon it; neither can the water be kept too long upon it, especially in the winter season, immediately after the after-math is eaten; and the closer it is eaten the better. The manner of conducting the business of watering must be suited to the circumstances of the particular cases.

After being thus improved, it must next be determined to what lasting purpose it may be best applied. The too great moisture of these soils, which always lie flat, renders them unfit for continued tillage, and their mould becomes so loose by frequent ploughing, that it frequently does not afford

sufficient stability to the roots of corn. For this reason barley, oats, and rye do better here than wheat, which requires a firmer footing; but neither of them should be sowed thick, because the fruitfulness of the soil will always make up in the size of the plants, what some might think wanting in their number. The most beneficial method of employing this sort of land is, undoubtedly, that of converting it into meadow, because, when thus prepared, and not injudiciously exhausted by crops of corn, it will yield great quantities of excellent grass. It is, however, usual to begin with sowing some kind of grain on this prepared surface, to indemnify the farmer by the plentiful crop which it generally yields; such, indeed, as sometimes defrays at once the whole expence of the improvement. In some cases the most profitable method may be to sow it in the autumn with rape, the leaves of which shading the surface in hot weather, and rotting in the winter, contribute greatly to mellow the earth; the strong roots of this plant open the soil too, and its seed brings a great return when sold for making oil. One or two ploughings after this will prepare it for a crop of wheat. After this is taken off, and the stubble turned down, white clover and grass-seed should be sown, and the ground laid down for a lasting meadow; or if turnips be sown, or cabbages planted in the autumn, these in the spring may be succeeded by barley, with which the grass-seeds may be sown.

In crude moory or black peat boggy improved lands, Mr. Marshall remarks, that what is most desirable is a crop that is sown and reaped during the summer months, and which demands neither labour nor attendance in the humid seasons of autumn, winter, or spring; and such a crop is found in rape, which is luckily natural to the climate, and at the same time highly profitable. Trials with this may be made at but a trifling expence on a small portion of the ground, the proof of which answering, it is observed, "is not whether the plant will thrive as herbage, but whether it will mature its seed on the given soil in the given situation."

After a recompence has been obtained by crops of this sort, which may be repeated, as there is no danger of exhausting such deep soils, the foundation of more lasting profits is to be laid; which may be effected by sowing grass-seeds, with or over the rape crops, or after the stems have been drawn, according to seasons and the circumstances of the land, stocking, as directed above, till such time as the surface becomes sufficiently firm, and the soil has attained a suitable texture for mixed cultivation, which time may be much shortened by the application of fossil substances of the calcareous kind in any period of the improvement.

When either through necessity, or want of other arable land, or out of choice, the farmer intends to continue ploughing his improved bogs, the surface must be raised in ridges, and the further management of it may be like that of most other ploughed grounds.

If a soil of this kind happens to be situated near a town, a greater profit may accrue from planting it with garden stuffs than from any sort of grain, as beans, peas, cabbages, potatoes, turnips, carrots, &c. are found to thrive exceedingly well in earth of this kind.

Bog, moving or migrating. These soft masses of earth have been sometimes known to move out of their place. An instance of this there was in Ireland, in the year 1697, about Charleville in the county of Limerick. There was heard for some time a noise under ground like that of thunder at a great distance, or almost spent; and soon after this the earth of a large bog in the neighbourhood began to move, and a hill or rising situated in the middle of it stood no longer above the level of the rest, but sunk flat. The bog not only moved itself, but carried with it the neighbouring pasture-lands,

lands, though separated by a large and deep ditch; the motion continued a considerable time, and the surface of the moving earth rose into a sort of waves, but without breaking up or burbling any where. The pasture land rose very high, and was carried on with the same motion till it rested upon a neighbouring meadow, the whole surface of which it covered, remaining sixteen feet deep upon its surface. The whole quantity of the bog was torn from its former seat, and left great gaps in the earth where it had joined, which threw up foul water, and very stinking vapours. Phil. Trans. N^o 233. The whole country came in to see so strange a sight as this, for it continued moving a long time; but few guessed the true cause of it, which was this: a more than ordinary wet spring occasioned the rising of the bog to a great height in one part, and thence propagated itself through the whole bog; so that the hill in the midst was undermined, and naturally sunk flat; this and the more than ordinary weight of this large bog pressing upon the adjoining pasture-land, forced up its foundations, which were only a loose sand. This was pushed on sideways, where there was a descent from the bog, and at length having given the bog more room, all was quiet and remained in that state. The bog was more than forty acres of ground.

Another instance of this kind occurred, in March 1745, at the bog of Addergoole, about a mile and a half from the town of Dunmore, in the county of Galway. In consequence of a violent storm, attended with a fall of rain, resembling a water-spout, the turbary, which the turf-cutters had just left, containing about twelve acres, was put into motion, and floated till at last it subsided upon a piece of low pasture of near thirty acres, by the side of the river, where it spread and settled. The moving-bog choked up the river, which consequently overflowed the back grounds, and in a little time a lough or lake of near 55 acres covered the adjacent fields. A passage for the river was formed as speedily as possible; but before it could be finished, and the lake discharged, it was supposed to have covered 300 acres; however, in seven or eight days it gradually decreased to 50 or 60 acres, of which extent it continued. Irish Transactions, vol. ii. p. 4.

Bog, ancient *Hypanis*, in *Geography*, a river of Poland, which rises in Podolia and joins the estuary of the Dnieper or Nieper, a little above Oczakow, about N. lat. 46° 32'. E. long. 32° 32'. This river separates Poland and a portion of European Turkey from Russia. By taking up the Ingul, the Sinucha, and the Guilon, besides other streams in its course, it becomes a very considerable river.

BOGA, in *Ichthyology*, synonymous with *Bogue*, and *Sparus loops*.

BOGAERT, MARTIN VANDEN, surnamed *Desjardins*, in *Biography*, an eminent sculptor, was born at Breda, in Holland, in 1640, and settling in early life at Paris, he became a member of the Royal Academy, at the age of 31 years. The first of his most considerable works was an equestrian statue of Louis XIV. erected at Lyons in the place Bellecour. He also adorned the gate of the church of the Mazarin college with six groups of stone, representing the evangelists and the Greek and Latin fathers of the church; and besides many other works, the most distinguished was the monument erected in the place of Victory, at the expence of

marechal du Feuillade, on which the king, crowned by victory, is exhibited in a standing posture, invested with the regal ornaments, and having under his feet a cerberus, to denote his triumph on occasion of the triple alliance. This group is 30 feet high, and was formed by a single cast, under the particular direction of Desjardins. This artist died rich in 1694. *Encycl.*

BOGAHA, in *Botany* and *Mythology*, a tree held sacred in Ceylon, on account of the imagined preference given by the deity Buddou to the shade of this tree, above all others. Wherever it is found throughout the island, persons are appointed to watch over it, and preserve it from dirt or injury. It is held in the same estimation among the followers of Buddou, as the baayan tree is among the Brahmins. The Candians hold their great festival under the shade of a tree of this kind, which stands at Annarodgburro, an ancient city in the northern part of the king of Candy's dominions; and none but his own subjects are permitted to approach this sanctuary. Tradition says, that the bogaha tree suddenly flew over from some distant country and planted itself in the spot where it now stands. It was intended as a shelter for the god Buddou, and under its branches he was wont to repose, while he sojourned on earth. Near this hallowed spot 90 kings are interred, who all merited admission into the regions of bliss by the temples and images they constructed for Buddou. They are now sent as good spirits to preside over the safety of his followers, and protect them from being brought into subjection to Europeans; a calamity against which they continually pray. Around the tree are a number of huts, erected for the use of the devotees, who repair hither: and as every sort of filth and dirt must be removed from the sacred spot, people are retained for the purpose of continually sweeping the approaches before the worshippers, and to attend the priests during the performance of the ceremonies. Percival's Ceylon.

BOGANEU, in *Geography*, a town of Bohemia, in the circle of Chrudim; 6 miles S. of Chrudim.

BOGAR. See *BOKHARA*.

BOGAROVSKOI, a town of Siberia, 130 miles N. of Tobolsk.

BOGAS, or **BOGHAS**, a small town of Egypt, at the mouth of the Nile; 3 miles N. of Damietta. See *BOGHASS*.

BOGATOI, a town and district of Russia, in the government of Kursk, seated on the rivulet Penna, falling into the Psoi; 48 miles S.S.W. of Kursk.

BOGAZI, a town of Asiatic Turkey, in the country of Diarbekir, 50 miles W. of Diarbek.

BOGAZI, signifying in the Turkish language a "canal," or "strait," a name given by the Turks to two straits, adjoining to the island of Samos; one, called Little Bogazi, and scarcely half a league broad, separates Samos from the continent of Asia; the other, called the Great Bogazi, and nearly two leagues broad, lies to the west, and separates this island from the small Fournis islands, so denominated, because, at a distance, they appear like the roofs of ovens; they were anciently called "Corceæ insule." This is a passage much frequented by ships sailing from Constantinople to Syria and Egypt, and they find here good anchorages.

BOGDANA, a town of European Turkey, in Moldavia, on the borders of Transylvania; 60 miles S. of Niemez.

BOGDEN, MARTIN, in *Biography*, a favoured pupil of T. Bartholine, and strenuous defender of his fame and opinions, was born at Dresden, about the year 1630. After visiting France, England, and other parts of Europe, to improve himself in knowledge, he took the degree of doctor in medicine at Basle in Switzerland, in 1652, and at the

end of four or five years, passed principally with Bartholine, to whom he was strongly attached, he settled at Bern. His works are principally controversial, defending the priority of the discovery of the lymphatics by Bartholine, against Rudbeck the Swede, who claimed it; and who, if he did not discover them, Haller says, has the merit of having more fully and accurately described them, than Bartholine had done. Bogden, in this contest, displayed much learning, but equal roughness and ill-humour. The titles of his works are: "Rudbekii insidiæ structæ vasis lymphaticis Thomæ Bartholini," 4to. and "Apologia pro vasis lymphaticis Bartholini, adversus insidias secundo structas ab Olao Rudbek." Hafniæ, 1654, 12mo. "Simeonis Seth, de alimentorum facultatibus," Gr. and Lat. 8vo. 1658. "Observationes Medicæ ad Thomam Bath." The observations, 12 in number, are published in the "Culter Anatomicus," of Lyser; Copenh. 1665. Haller Bib. Anat. Eloy. Dict. Hist.

BOGDIKOTZ, in *Geography*, a town of Russian Siberia, on the Tchulim; 6 miles N.W. of Atchinsk.

BOGDINSKOI, or **BOGDOM DABASSU**, an inexhaustible salt-lake of Siberia, in the steppe towards Tzaritzin; the salt of which, according to Pallas, is better than that of the Elton.

BOGDO, GREAT, the highest mountain of central Asia, according to the reports of the Monguls and Tartars, is properly a central summit of the Altaian chain of mountains, which gives source to the Upper Irtysh, and seems to be delineated in Arrowsmith's map of Asia at longitude 94°, and latitude 47°. See **ALTAI** and **BELUR**.

BOGDO, Little, is a mountain of Asiatic Russia, lying to the north of the Caspian sea, near which is a salt lake of the same name.

BOGDOMANTIS, in *Ancient Geography*, a country of Asia Minor. Ptolemy.

BOGDOY, in *Geography*, a name given by the Russians to the Manchews, or Mandshurs, who inhabit the eastern part of Chinese Tartary, an extensive and populous district N.N.E. of China, and who are subject to the Chinese empire. See **MANDSHURS** and **CHINESE TARTARY**.

BOGENSEE, a town of Denmark, in the island of Funen; 12 miles N.W. of Odensee.

BOGESUND, a small town of Sweden, in West Gothland, 4 leagues S. of Falkioping.

BOGGILCUND, a district or circar of Allahabad, in Hindoostan, situate west of Benares.

BOGGY CREEK, a creek of America, which rises among the eastern branches of Poplar creek, and empties into the Tennessee, just above the Muscle shoals. Hurricane creek is a branch of Boggy creek.

BOGHASS, a canal or strait, so called in the language of the country, at the mouth of the western or Bolbitic branch of the Nile, now called the branch of Rosetta. This passage is not navigable through its whole width; there being only a narrow channel, which, owing to the instability of the bottom, and the agitation of the sea, is continually shifting. A pilot or master of the Boghass is continually employed in founding this changeable passage, and giving directions to those who navigate it. The increasing danger of this passage led to the operation of cleaning the canal of Alexandria, and thus to facilitate the communication between Alexandria and the rest of Egypt. See **BOGAS**.

BOGIA. See **BOUJEIAH**.

BOGILLANA. See **BAGLANA**.

BOGLIASCO, a town of Italy in the state of Genoa, near the sea-coast; 6 miles E. of Genoa.

BOGLIO, or **BEUIL**, a mountainous territory of Italy,

in the principality of Piedmoat, and county of Nice, seated near the Alps; its chief place has also the same name. This country was surrendered to France in May 1796.

BOGLIPOUR, a town of Hindoostan, and capital of a province in the country of Bahar, near the Ganges; 35 miles S.E. of Monghir, and 115 N.W. of Moorshedabad.

BOGLORAY, a town of Poland, in the palatinate of Sandomirz; 24 miles E.S.E. of Sandomirz.

BOGMUTTY, a river of Hindoostan, which runs into the Ganges near Monghir, in the country of Bahar.

BOGNOR, or **HOTHAMPTON**, (as it is sometimes called in honour of its founder,) is a pleasant retired hamlet on the southern coast of England, in the county of Sussex. This place has only risen into notice within a few years, being, previous to 1790, merely inhabited by a few fishermen. About this period Sir Richard Hotham purchased some ground here, where he built a house for himself, and had others erected for the accommodation of bathers. His plan of making this a fashionable bathing place has succeeded, but it was not much frequented till after his death, which happened in 1799. Soon after this event, the ground and houses were sold in different lots. Some of the purchasers have built additional dwellings, and Bognor is now become a place of great resort during the summer months. The adjacent villages of Bersted, Felpham, &c. also receive a number of summer visitors, who resort to this coast for the purpose of its fine beach and mild air. Bognor is 7 miles S. of Chichester, and 67 S.W. from London. It has a good hotel, an assembly-room, a library, and some other establishments for the accommodation and amusement of its visitors.

BOGODUKHOF, a town and district of Russia, in the government of Kharkof, seated on the Merlo, falling into the Vorokla; 84 miles N.N.W. of Kharkof.

BOGOE. See **BOOG**.

BOGOGNANO, a town of the island of Corfica, 5 leagues N.E. of Ajaccio.

BOGOI AVLANSKIO, a town of Russia, in the government of Ufa; 48 miles S. of Ufa.

BOGOI AVLANSKOI, a town of Russia, in the government of Archangel, near the coast of the White Sea; 72 miles S.W. of Archangel.—Also, a town of Russia, in the same government, near the river Onega, 100 miles S. of Archangel.—Also, a town in the same government, on the Pinega; 70 miles E. of Archangel.—Also, a town of Russia, in the province of Ulting; 51 miles E.N.E. of Ulting.—Also, a town of Siberia, on the Tchulim; 80 miles E.N.E. of Tomsk.

BOGOMILI, or **BOGARMITÆ**, in *Ecclesiastical History*, a sect sprung from the Manichees, or rather from the Mafsalians, towards the close of the eleventh century; whose chief, Basil, was burnt alive by order of the emperor Alexius Comnenus. Being condemned to be burnt, he declared that the fire would not hurt him; upon which the Greeks who carried him to execution, first took off his cloak, and flung it into the fire, to try whether it would prove incombustible; whilst it was burning, the poor fanatic cried out, "Do you not see that my cloak is untouched, and carried away in the air?" upon which they cast him also into the fire, where he was soon consumed to ashes. Du-Cange derives the name from two words in the Bulgarian language; *Bog*, *Deus*, and *milvi*, *miserere*, have mercy. The Bogomili denied the Trinity; maintaining that God had a human form; that the world and all animal bodies were created by evil angels; and hence they concluded, that the body was the prison of the immortal spirit, and that it ought to be enervated by fasting, contemplation, and other exercises, so that the soul might be gradually restored to its primitive liberty; and that wedlock

was to be avoided; and they also maintained that it was the archangel Michael that became incarnate. They rejected the books of Moses, and only admitted seven books of scripture; they maintained the Lord's prayer to be the only eucharist; that the baptism of the Catholics was only that of St. John, and their's that of Jesus Christ; and that all those of their sect conceived the Word, or *Logos*, as much as the Virgin, denying the reality of Christ's body, which they considered only as a phantom. They also held, that the body, upon its separation by death, returned to the malignant mass of matter, without either the prospect or the possibility of a future resurrection to life and felicity. *Mosh. Eccl. Hist. vol. iii. p. 110. Jortin's Rom. on Eccl. Hist. vol. v. p. 46.*

BOGORDSKOI, in *Geography*, a town of Russia, in the government of Archangel; 8 miles S. W. of Mezen.

BOGORODITZK. a town of Russia, in the government of Archangel, on the Dwina; 44 miles S. S. E. of Archangel.

BOGORODSK. a town and district of Russia, in the government of Moscow, on the Khafma; 28 miles E. of Moscow.

BOGORODSKOI, a town of Russian Siberia, in the province of Tomsk, seated on the Oby. The church belonging to this town is famous for a celebrated picture of the Virgin Mary, called "Oeditria," which is brought every year, on the 21st of May, in procession to Tomsk. There are iron works in this place.

BOGOROSTAN, a town and district of Russia, in the province of Ufa, seated on a river falling into the Samara.

BOGOTA, a town and province of New Granada, in Spanish South America, seated near the river Magdalena. The town is called *Santa Fe de Bogota*, and is the capital of the kingdom of New Granada; it is situate on the banks of the small river Pati, which runs into the Magdalena. It was made an archbishop's see by pope Julius III. in 1554, and an university was erected here in 1610. It has a sovereign court of judicature, the president of which is governor of the whole province or kingdom of New Granada. Near it are some gold mines, and the chief modern mines of Peruvian emeralds, justly preferred to all others, since those of Egypt have been neglected. Among the numerous cataracts of this country Bouguer mentions that of the river Bogota, which passes the city of the same name about 8 leagues before it joins the Magdalena, said to be a vertical fall of more than 1200 feet. N. lat. 4° 20'. W. long. 73° 40'. When the Spaniards took possession of this part of South America, they found in Bogota a nation more considerable in number, and more improved in the various arts of life, than any in America, except the Mexicans and Peruvians. The people of Bogota subsisted chiefly by agriculture. The idea of property was introduced among them, and its rights secured by laws, handed down by tradition, and observed with great care. They lived in large towns; they were decently clothed, and their houses, compared with those of surrounding tribes, might be termed commodious. Government had assumed, in this state of civilization, a regular form, and a jurisdiction was established, which took notice of different crimes, and punished them with rigour. They were acquainted with the distinction of ranks, and their chief reigned with absolute authority. He was attended by various officers and guards, carried with much pomp in a sort of palanquin, and the road was swept before him and strewed with flowers. For the support of this expence taxes were levied on the people, who regarded their prince with veneration, and seldom approached him but with an averted countenance. One of the chief causes of

that obsequious spirit, which prevailed among the people of Bogota, was the influence of superstition. The respect they paid to their monarchs was inspired by religion; and the heir apparent of the kingdom was educated in the innermost recess of their principal temple, under such austere discipline, and with such peculiar rites, as tended to fill his subjects with high sentiments concerning the sanctity of his character, and the dignity of his station. This superstition, which, in the rudest period of society, is either altogether unknown, or wastes its force in childish unmeaning practices, had acquired such an ascendant over those people of America, who had made some little progress towards refinement, that it became the chief instrument of bending their minds to an untutored servitude, and subjected them, in the beginning of their political career, to a despotism hardly less rigorous than that which awaits nations in the last stage of their corruption and decline.

The people of Bogota (as well as the tribe of the Natchez) had advanced beyond the other uncultivated nations of America, in their ideas of religion, as well as in their political institutions. The sun and moon were the chief objects of their veneration. They had temples, altars, priests, sacrifices, and that long train of ceremonies, which superstition introduces wherever she has fully established her dominion over the minds of men. But the rites of their worship were cruel and bloody; they offered human victims to their deities, and many of their practices resembled the barbarous institutions of the Mexicans. *Robertson's Hist. America, vol. ii.*

BOGRA, an uncultivated mountainous tract on the north of the barony of Muskery, in the county of Cork, and province of Munster, Ireland. It is upwards of ten miles long, and in some parts six miles in breadth; and is a common to the adjacent estates. In winter it is for the most part deep, marshy, and impassable; but in summer hard and firm, producing grass and heath, and is then grazed by vast herds of cattle, which are removed to the lower lands when this season is over. Large quantities of turf are also procured from it. Dr. Smith has applied to it these lines of Thomson:

"The brown burnt earth
Of fruits and flowers, and every verdure spoiled,
Barren and bare, a joyless dreary waste
Thin cottaged; and in time of trying need
Abandoned."

Many considerable streams flow from this high and wild tract, which discharge themselves into the Lee or Blackwater, as their direction is south and north. *Smith's Cork.*

BOGRUSH, in *Ornithology*. The *Motacilla Schanobanus*, Linn. and *Red Warbler* of Latham, is described under this name in the *Arctic Zoology*.

BOGUE, in *Ichthyology*, the French name of a fish of the *SPARUS* genus, *Sparus boops* of Linnæus.

BOGUE, BELY, in *Mythology*, the white god to whom the Slavonians paid their adorations. His statue, smeared with blood, was covered with flies. His rites consisted in diversions, games, and feasts. He was a beneficent deity, corresponding to the good principle, the "Oromazes," of the Persians. The black god, "Toherry Bogue," corresponded on the contrary to the evil principle, the maleficent being Arimanes. He was worshipped by bloody sacrifices, and the prayers of his votaries were addressed to him in a mournful and plaintive voice.

BOGUSLAW, in *Geography*, a town of Poland, in the palatinate of Kiovia; 32 miles S.E. of Bialacerkiew. N. lat. 49° 36'. E. long. 31° 12'.

BOGUTCHAR, a town and district of Russia, in the govern-

government of Voronetz, on a rivulet of the same name, falling into the Don.

BOGWANGOTD, a town of Hindoostan, near the Ganges; 11 miles N. of Moorshedabad.

BOHABOL, in *Ancient Geography*, a town of Asia in Syria.

BOHADSCHIA, in *Botany*. See **PELTARIA**.

BOHAIN, in *Geography*, a town of France, in the department of the Aisne, and chief place of a canton, in the district of St. Quentin; 10 miles N.N.E. of St. Quentin. The place contains 2152, and the canton 13781 inhabitants. The territory comprehends 172½ kilometres, and 14 communes.

BOHAR, in *Ichthyology*, a species of **SCIÆNA**, described by Forskal, as a native of Arabia. The colour is red, lined, and clouded with white. Forst. Fn. Arab.

This bears a strong affinity to another fish described by the same writer, as an inhabitant of the same country, **Kasimira**. Gmelin expresses a doubt whether it does belong to the **SCIÆNA** genus. The body is of an oblong form, and covered with smooth scales. When alive there are two large spots on the back, which disappear after the fish is dead. There are two short cirri, or beards before the nostrils: in the upper jaw two subulate teeth, which project beyond the lower, the two middlemost of which are placed remote. The lateral line runs nearer to the back. Dorsal and anal fins rounded behind, and the unarmed part of both sealed, the spines of the latter growing gradually larger: ventral connected by an intermediate membrane. Tail bifid. Gmelin.

BOHAROWCZE, in *Geography*, a town of Poland, in the palatinate of Kaminiéc; 60 miles N.W. of Kaminiéc.

BOHDANICE, a town of Bohemia, in the circle of Chrudim, which has the privilege of holding fairs.

BOHEA, in *Botany*. See **THEA**.

BOHEMIA, in *Geography*, called in German *Boierheim*, *Boiheim*, *Boheim*, and corruptly *Boehmen*, that is the habitation of the Boii (see **BOII**); a kingdom of Europe in the Austrian dominions; bounded on the north by Misnia, Lusatia, and Silesia; on the west, by the circle of the Erzgebirg, the Voghtland, the margraviate of Culmbach, and the Upper Palatinate; or, in general, by Franconia; on the south, by Bavaria and Austria; and on the east, by Moravia, Silesia, and the county of Glatz. Bohemia is environed on all sides with high mountains and large forests; towards the south it is separated from Austria by a ridge of considerable elevation, which passes to the north-east of Bavaria; and on the north-west, it is parted from Saxony by a chain of metallic mountains, called the Erzgebirg, a word denoting hills that contain mines. On the west of the river Eger, near its junction with the Elbe, stands the mountainous group of Milešou, near which is Donneberg, supposed to be the highest in the province; and on the north-east is the Sudetic chain, which branches from the Carpathian, and divides Bohemia and Moravia from Silesia and the Prussian dominions. This country was formerly remarkable for an extensive forest, a remain of the ancient *Hercynia Sylva*, which extended from the Rhine to Sarmatia, and from Cologne to Poland. The *Gabreta Sylva* lay on the south-west of the same country, where a chain of hills now divides it from Bavaria.

Bohemia, as we have already observed, derived its name from the Boii, who under their leader Segovefus, settled in that country about 590 years before the Christian era. The Boii were soon after expelled by the Marcomanni; and these, being weakened by their wars with the Romans under the conduct of Tiberius, were subdued by the Sclavi (see **SCLA-**

VONIANS), who, like the other Scythians, wandered from place to place with their families and cattle; and, as Strabo informs us, even in the time of Augustus Cæsar, lived promiscuously with the Thracians. Afterwards, spreading themselves westward, in a few centuries they possessed Illyricum, Poland, Moravia, and Bohemia. But retaining their ancient manners, they neglected to build cities; and inhabiting the country in detached hordes, they regarded only pasturage and the care of their flocks. The first ruler, or chief, mentioned by historians, was one Czechius, from whom the natives derived the appellation of Czechs, or Zechs, who, quitting Croatia, migrated first to Moravia, and from thence to Bohemia, about the middle of the sixth century, which he found covered with wood, and possessed rather by herds of wild cattle than by men. Here he settled his final colony, and taught the few inhabitants of the country to cultivate the lands, and to sow corn. After his death, the Bohemians remained for several years without a ruler or judge; but being now assembled in villages, they were anxious to obtain a more settled form of government than that which they had found effectual during their pastoral life. With this view they chose for their governor a young man whose name was Croc, distinguished by his prudence, who restored peace and order, and maintained the authority of the laws. He was succeeded by the youngest of his three daughters, Lybussa, who was respected for her skill in the art of divination; and who, about the close of the seventh century, married a country labourer of the name of Premislaus, who, being called from the plough to the dignity of governor, carried his cloak and shoes along with him, as memorials for his posterity, to prevent their being elated with the prosperity of their condition. This Premislaus is said to have founded the city of Prague, to have distributed the people into different ranks, and, after quelling some temporary insurrections, to have reigned peaceably till his death. He is said to have been the first duke, though others trace the origin of the duchy to an earlier period, and say that Czechius was the first who bore this title. The government seems afterwards to have continued hereditary in his family, though with some form of election; and a descendant, whose name was Borivorius, or Borzivori, embraced Christianity about the close of the ninth century, and, after some opposition, introduced it into his dominions. On this occasion several churches were built, and schools erected; but upon the death of his son Wratislaus I. in the beginning of the tenth century, his wife Drahomira, who assumed the government during the minority of her sons, manifested her hatred against the Christians, massacred about 300 of them in one night, burnt their temples, and ordered them to deliver up their arms. However, upon the accession of her son Wenceslaus II. A. D. 916. the Christian religion was again encouraged; and, in order to prevent disputes with his brother Boleslaus, who had been educated under his mother, he ceded to him that part of Bohemia, which lay beyond the Elbe. Wenceslaus, having obtained a victory in a duel, a challenge to which he accepted for the purpose of sparing the lives of his rebellious subjects, was invited by Otho the Great to the diet at Worms, where he offered him the title of king, which Wenceslaus declined accepting. In the year 932, Wenceslaus was murdered by his brother Boleslaus I. surnamed the Cruel, who, succeeding him, conducted his administration with great cruelty, persecuting the Christians, and expelling them the kingdom. His son and successor Boleslaus II. surnamed the Pious, founded and endowed 20 churches, and obtained leave from pope John IX. to create a bishop at Prague. His subjects formed a conspiracy against him, on account of some reforms which he attempted to introduce;

introduce;

BOHEMIA.

produce; and encamping on a mountain in the vicinity of Prague, they were expelled thence by the Christians, with the assistance of the Jews, and obliged to remain in peace. In recompence of this service, the Jews were allowed to build a synagogue at Prague. In the eleventh century, Bretislav, the son of Udalricus, having obtained the government of Moravia, kept possession of it by repulsing the Poles who invaded it; and, succeeding to the government of Bohemia, on the death of his father, A. D. 1043, he again defended it against Hungarian robbers, by whom it was ravaged, and having concluded a perpetual peace with Casimir, king of Poland, he died, leaving five sons, of whom the eldest inherited Bohemia; and Moravia was divided among the four youngest. Wratislav II. succeeded his brother, A. D. 1061; and, in 1086, was honoured with the regal title by the emperor Henry IV. who also invested him with the domains of Lusatia, Moravia, and Silesia. This dignity, however, was merely personal; and the constant title of king only commences with Premislav II. in 1199. He and his immediate successors, were styled Ottocari, or Othogari, on account of their attachment to the interest of the emperor Otho. Upon the death of Wenceslaus IV. A. D. 1255, his son Premislav Othogar succeeded him, and having settled his affairs in Bohemia, took possession of Austria, Stiria, part of Carinthia, and other provinces to the south, and carried his arms into Prussia for the defence of the Christians; and having defeated his opposers in several engagements, he prevailed on many of the people to abandon Paganism. After his return to Bohemia, in 1271, he is said disdainfully to have rejected the imperial crown, which was afterwards given to Rodolphus, count of Hapsburg; but Othogar refusing to do him homage, and to take from him the investiture of his states, alleging that he owed him nothing, and that he had paid him his wages, Rodolph having been great marshal of his court, was at length obliged to comply, and to deliver five standards to the emperor for the five sieges which he possessed. A reconciliation, however, afterwards took place, and Othogar received the investiture of Bohemia and Moravia, on condition of renouncing Austria, Carinthia, and Stiria. Wenceslaus V. succeeded his father in 1278, and was elected king of Poland; but refused the sceptre of Hungary, that was offered him in favour of his son. In 1310, the ancient lineage failed; and John, the son of the emperor Henry VII. of the family of Luxembourg, who had married the youngest sister of Wenceslaus VI., obtained possession of the kingdom of Bohemia. John, having resigned Bohemia to his son Charles, and procured for him the imperial dignity, proceeded with him to France, to the assistance of Philip against the English, and was slain in the famous battle of Crecy, in 1346. Charles IV. emperor, having succeeded his father, created his brother John marquis of Moravia, erected an university at Prague upon the plan of that at Paris, and engaged pope Clement VI. to erect the see of Prague into an archbishopric, with this privilege annexed to it, that the archbishop should have the honour of crowning the king of Bohemia. He enlarged and beautified his capital, by adding what is called the New City, in which he founded the college of Carlemin. With the assistance of several learned persons, he reduced the laws of the kingdom to writing, which are still extant under the name of "Caroline Constitutions." He greatly extended the boundaries of his hereditary dominions, and caused his son Wenceslaus to be crowned king, in the second year of his age. He also prevailed with the electors to chuse him king of the Romans, in the sixteenth year of his age; and having commenced the junction of the Moldaw with the Danube, he died before he had executed his design; and in 1378, was succeeded by his son Wenceslaus VII. In the reign of this

prince, who was notoriously dissolute, profligate, and savage, and who, by his licentiousness and cruelty, incurred the hatred of his subjects, John Huss and Jerome of Prague introduced the doctrines of the reformation into Bohemia. See HUSS, and JEROME. Wenceslaus died suddenly in 1419; and before his brother Sigismund, who succeeded him as king of Bohemia and emperor of Germany, could come from Hungary to take possession of the crown, the Hussites, under John Zisca, had acquired great strength, and, upon his approach to the kingdom, they sent deputies to him, desiring liberty of conscience; but, instead of granting their request, he only declared, that he intended to govern the kingdom as his father had done. A civil war ensued, in which the troops of Sigismund sustained several defeats; and which, after a continuance of sixteen years, occasioned by his treachery of faith to Huss and Jerome, terminated in several concessions, and in his admission into Prague with great solemnity and rejoicing. Upon the death of Sigismund, in 1438, Albert of Austria, who had married his daughter, received the crowns of Bohemia and Hungary. The succession was, however, afterwards disputed and infringed by George Podiebrad, a Hussite chief; by Uladslav, son of Casimir, king of Poland; and by Matthias, king of Hungary. Uladslav ultimately succeeded, being elected, in 1471, by the majority of the states, and soon after receiving the investiture from the emperor. Upon the death of Uladslav, in the 45th year of his reign over the Bohemians, and the 23d over the Hungarians, he was succeeded by his son Lewis in both the kingdoms of Bohemia and Hungary, A. D. 1516; but, in 1526, he engaged the Turks at Mohatz, and being utterly defeated, was drowned in the Danube, in his flight. After the death of Lewis, his dominions fell to Ferdinand, archduke of Austria, infant of Spain, and afterwards emperor, who had married Anne, the only daughter of Uladslav: and both the empire, and the kingdom of Bohemia, have ever since continued in the house of Austria. Ferdinand, at a diet of the states held in 1547, declared the kingdom hereditary and absolute; and when Ferdinand II., in 1620, had routed the army of his rival Frederick at the White Mountain near Prague, Bohemia was reduced fully to the condition of an hereditary kingdom; so that from that time the states had no concern with the right of succession. The crown, however, is conferred with some appearance of election, which right the states of that kingdom pretend to claim; although, by the treaty of Westphalia, Bohemia is declared hereditary in the house of Austria. The king of Bohemia is the first secular elector, and as such pays homage to the emperor and the empire for his states; and with this exception, he has a right to exercise, through all his dominions, the royal authority agreeably to the laws of the kingdom, which prohibit his raising contributions or taxes otherwise than at the time when the states are assembled, the appointment of which is entirely in their own power. He gives his opinion as elector, after the elector of Cologne, and formerly assisted at the assembly of the electors only at the election of an emperor, nor did he appear always at the diets of the empire. He is arch-butler, or arch-cup-bearer, of the holy Roman empire; and on this office his right to chuse a king of the Romans is said to depend. It has been alleged, that Bohemia has been of old time a genuine state of the German empire, without contributing to its taxes, which was a privilege conferred upon it by Frederick II. in 1212, who at the same time exempted it from the jurisdiction of the supreme judicatory of the empire. In 1708, it was acknowledged by the three colleges of the empire, at an act of the diet called "the admission," that the king and elector of Bohemia has an undoubted right of seat and voice in all its assemblies; in consequence of which the emperor pro-

BOHEMIA.

posed, that on account of his hereditary kingdom of Bohemia, and of the countries belonging to it, he will pay an electoral proportion of all taxes and imposts of the empire and circle, and also 300 florins yearly to the chamber-judicatory; the collective body of the empire engaging at the same time to take the kingdom of Bohemia, and the countries united with it, under its protection and defence.

Bohemia, ever since the time of Charles IV., has been divided into twelve circles, besides Prague, which is considered as a distinct territory. These are Kaurzimer (comprehending Great Prague), Pilsner, Leutmeritzer, Konigingratzer, Rakowitz (including Beraun), Chrudimer, Prachiner, Slaner (comprehending Little Prague), Bunzlauer, Saatzer, Czaflauer, and Bechiner. Each circle has two head-men, or captains, appointed annually, for the administration of the government, one from the state of lords, and the other from that of knights. The duchy of Silesia, the marquisate of Moravia, and that of Lusatia, formerly held of this crown, but at present only Moravia, which is incorporated with the kingdom of Bohemia, and is in possession of the house of Austria. In 1742, the county of Glatz was ceded to the king of Prussia, and by him added to Silesia. The government of Bohemia is managed by six different courts; *viz.* the council of the regency, or great royal council, in which presides the great judge or burgrave of Bohemia, who has under him 18 lieutenants of the king's and other assessors; the council, or superior chamber of justice, at which the great master of the kingdom is president; the chamber of fiefs; the new tribunal, to judge the appeals of the German vassals, with its president, vice-president and assessors; the royal chamber of finances, with a president, and vice-president; and the chancery, which always follows the court. The states, consisting of the clergy, nobility, and gentry, and representatives of the towns, meet at Prague, where a commissioner from the sovereign points out the necessity of granting such supplies as the court demands, which, however exorbitant, are granted without hesitation or examination, though not sometimes without subsequent complaint. The clergy are composed of the archbishop of Prague, several bishops, provosts, and abbots, besides the inferior clergy. The nobility consist of princes, counts, barons, and knights; the others are burghers, husbandmen, and peasants.

The established religion of Bohemia is popery; but there are many protestants among the inhabitants, who are now tolerated by the wise regulations of Joseph II. in the free exercise of their religion. The Jews at Prague are indulged also with a toleration. The archbishop of this city is born legate of the holy apostolic see of Rome, and crowns the king of Bohemia; he is also a prince of the holy Roman empire, primate of the kingdom, and perpetual chancellor of the university of Prague. His suffragans are the bishops of Leutmeritz and Konigingratz. The government of the church and clergy is vested in the archiepiscopal consistory, from which an appeal lies to the king or the pope.

The extent of Bohemia, and also its population, have been variously estimated. Its length is about 162 miles, and its breadth 142. Some centuries ago, the inhabitants were estimated at three millions; but in later times they have been very much diminished. It is said, that in the year 1622, and the three or four following years, no fewer than 30,000 families, and many other individuals quitted the country, among whom were many of the nobility, on account of the intestine religious wars, and the succeeding irruptions of the Swedes. In M. Hoeck's "Statistical View of the States of Germany, &c." 1801, the kingdom of Bohemia is stated to contain 962½ square miles, 250 cities, 308 market towns,

11,455 villages, 430,000 houses, 1,340,510 men, 1,466,433 women, and the total of the population 2,806,943. The number of Lutherans has been estimated at 9050, of the reformed at 25,110, and of Jews at 36,000. Some writers have stated the number of Protestants at 36,000, and that of the Jews at 40,000, of whom 8000 are settled at Prague. In their dispositions, habits, and manners, the Bohemians resemble the Germans; being indeed a mixture of Slavonians and Germans, the former of whom live in villages and are slaves. They have no middle rank of people; for every lord is a petty sovereign, and every tenant a slave. The Bohemian peasants, on the imperial demesnes, have been lately relieved from the state of villinage, in which they had been so long and so unjustly retained; and it is hoped, that the example of the emperor will be followed by that of the Bohemian nobility in general, so that their vassals may recover those rights of which they have been long deprived. The natives of this country are singularly robust and strong-built, handsome, except that their heads are somewhat too large, and active, shrewd, courageous, and sincere. The gentry are ingenuous, brave, and more inclined to arms than arts. Learning in Bohemia is in a low state: though the kingdom possesses one university, 12 gymnasia, 2,219 German schools, 200 schools of industry, and 33 ladies' schools.

The Bohemian language is a dialect of the Slavonic, but somewhat harsher than that of their neighbours, who speak the same language, and who change the consonants, and particularly the *l*, more into vowels. The Bohemians formerly used the same letters with the Russians; but in the time of Boleslaus the Pious, the Latin was introduced among them. Upon the first introduction of Christianity in this reign, the religious service was performed in the Latin tongue, a language unknown to the people; but in consequence of the representation of Methodius to pope Nicholas the Great, he allowed the prayers to be rehearsed in the vulgar tongue. But some years after, when a bishop was sent into Bohemia, the Latin tongue was again ordered to be introduced in all their churches. Persons of a superior class, from their intercourse with the court of Vienna, speak high Dutch or German, with which the language of the common people is also intermixed.

Bohemia is, upon the whole, one of the highest countries in Europe, and forms a large extended plain, surrounded, as we have observed, by high hills covered with wood. The vale in the middle, which is watered by the Elbe, the Moldaw, and the Egra, is protected from the wind, and it has neither lakes nor morasses which taint the air, which is dry and clear, with unwholesome vapours. The climate is therefore salubrious, and not liable to those sudden changes, which are so fatal to health in other places. The heat of summer, and the cold of winter are alike moderate. The soil is in general rich, though in some places it is sandy. It is fertile in corn, wine, fruits, pasture, saffron, ginger, hops, wool, flax, and timber. The Bohemian hops, which are much valued, are carried as far as the Rhine in great quantities. Bohemia produces a strong large breed of horses, many of which are purchased for the use of the French cavalry. Its mountains are the richest in Europe, in gold, silver, precious stones, copper, quicksilver, iron, lead, tin, sulphur, and saltpetre. The Bohemian tin is reckoned the best of any except the English. All kinds of marble are also found in this country, together with pit-coal, alum, muscovy-glass, excellent mineral waters, and hot baths. It also furnishes numerous herds of cattle, and abundance of game and wild fowl, and also bears, lynxes, wolves, foxes, badgers, martens, beavers, and otters. Its rivers and ponds afford a plentiful supply of fish, and such as are of the best quality and flavour.

According to the statement of M. Hoeck (ubi supra,) Bohemia had, in 1787,

	Acres.	Sq. Toises.
1. Of ploughed land, -	3,609,360	- 776
2. Ponds, - - -	69,115	- 1373
3. Fields, - - -	220,136	- 1393
4. Meadows, - - -	798,393	- 1066
5. Gardens, - - -	85,712	- 722
6. Marshy ground, -	65,515	- 970
7. Pastures and heaths, -	613,131	- 1209
8. Vineyards, - - -	4,482	- 672
9. Woods, - - -	2,319,811	- 557
Total	7,785,635	8738

The territorial produce of grain, forage, vines, woods, and rivers, amounted, in 1789, to 30,057,939 florins. Of cattle there were, in 1771, 9789 oxen, 2338 bulls, 9688 cows, 2723 calves, 8452 sheep, 16,738 hogs, 564 he-goats, 2758 she-goats, and 533 asses. The produce of grain amounted to two millions of minots (a minot being equal to three bushels) of wheat, ten millions of minots of grain, four millions of minots of barley, and eight millions of minots of oats. In the list of natural productions are also to be reckoned fruit-trees, hops, principally in the circle of Saaz, flax, tobacco, saffron, poultry, bees (of which, in 1791, there were 20,257 hives), tin (chiefly at Schlackenwalde, and there are ten mines of tin in the circle of Saaz, and two in that of Leutmeritz), cobalt, 10,000 quintals in the circle of Saaz, silver, alum, at Commothau, in 1788, 1,539 quintals. This author also states, that Bohemia had, in 1782, 95 manufactures, which employed 139,613 workmen. These manufactures are of linen, wool, cotton, silk, paper, glass, leather, &c. amounting in the whole to 35,645,447 florins, of which strangers take to the value of 11,840,757 florins. The articles of export, according to his enumeration, are alum, Epsom-salt, butter and grease, fish, flax, poultry, grain, mineral waters, hare-skins, wood, hops, cobalt, hides and skins, fruit, horses, pork, brimstone, vitriol, game, flax, tin, dimity, articles in iron, articles in glass, garnets, hats, liuens, brass, paper, pot-ash, aqua fortis, lace, cloth, and thread. The articles of import are cotton, lead, white lead, books, iron, and iron articles, colours, flax, jewellery, spicery, horned cattle from Hungary, coffee, cotton, stuffs, galls, merchandise of Lyons, liqueurs, silks, Hungarian cattle to the value of 800,000 florins, and wine to the value of 500,000 florins. The balance of trade is said to be in favour of the country. M. Hoeck also informs us, that the revenues of the state are fifteen or sixteen millions; but that the expences are so high, that out of this sum the surplus amounts only to 636,000 florins; that the contribution in 1789 was 3,646,017 florins, and the tax on the Jews 216,006 florins; and that the annual revenue from the domains of the crown was, during the life of Maria Theresa, 332,720 florins; these domains are now estimated at 177,774 acres. The number of soldiers to be furnished by Bohemia, in time of peace, is 54,964; and, in time of war, 76,896. The capital city of Bohemia is Prague; which see.

BOHEMIA, a broad navigable river of North America, 10 miles long, which runs W.N.W. into Elk river, in Maryland, 11 miles below Elkton.

BOHEMIAN, or MORAVIAN, BROTHERS, in Ecclesiastical History, is an appellation anciently given to the Protestants in Bohemia. By their adversaries they were called *Picards*, i. e. *Beghards*. They were descended from the better sort of Hussites, and were distinguished by several religious institutions of a singular nature, and well adapted to

guard the community against the reigning vices and corruptions of the times; and as soon as they heard of Luther's design of reforming the church, they sent deputies, in the year 1522, to recommend themselves to his friendship and good offices. In succeeding times, they continued to manifest the same zealous attachment to the Lutheran churches in Saxony, and also to those that were founded in other countries. Upon this their religious principles were examined, and nothing was found, either by Luther or his disciples, in their doctrine or discipline, that was liable to censure. Their confession of faith, though not altogether approved by this reformer, was regarded as an object of toleration and indulgence. Nevertheless, the death of Luther, and the expulsion of these brethren from their country, in 1547, changed their religious connections; and many of them, more especially of those who retired into Poland, embraced the religious sentiments and discipline of the reformed. Their attachment to the Lutherans seemed, however, to be revived by the convention of Sendomir in 1570; but as the articles of union, that were drawn up in that assembly, soon lost their authority, the Bohemians by degrees entered universally into the communion of the Swiss church. This union was at first formed on the express condition, that the two churches should continue to be governed by their respective laws and institutions, and should have separate places of public worship; but, in the following century, all remains of dissension were removed in the synods held at Aflrog, in 1620 and 1627, and the two congregations were formed into one, under the title of "The Church of the United Brethren." In this coalition the reconciled parties shewed to each other reciprocal marks of toleration and indulgence: for the external form of the church was modelled after the discipline of the Bohemian Brethren, and the articles of faith were taken from the creed of the Calvinists. See *UNITAS Fratrum*.

Lactius has a treatise *De Gestis Fratrum Bohemicorum*. Camerarius has also given the history of the Bohemian brethren, from whom ecclesiastical historians have derived a large train of sects, as the Hussites, Adamites, Taborites, Calixtins, &c. which see respectively.

BOHEMIAN *chatterer*, in *Ornithology*, a bird of the *Passerine* order, common in many parts of Europe, in Northern Asia, and America. It sometimes visits the southern parts of Britain in the winter. The common English name of Bohemian chatterer was imposed upon this bird by old writers, under the idea that it was peculiar to Bohemia. Later authors call it the *Waxen chatterer*, from the horny appendages at the extremity of the secondary quill-feathers, which are of a scarlet colour, and in appearance bear some resemblance to sealing-wax. This is called *Ampelis garrulus* by Linnæus. *Donov Brit. Birds, &c.*

BOHEMICUS, the name of a species of FALCON that inhabits the mountains of Bohemia. The legs of this kind are yellowish; body above cinereous, beneath hoary white; five exterior quill-feathers black on the outside; orbits of the eyes white. *Gmel. Falco Bohemicus. Maculæ habet, missyllance, Mayer.*

This bird is scarcely a foot in length; bill near the angle of the mouth yellowish; irides yellow; tail acute and long; legs thickish, and feathered below the knees; claws black and roundish. Feeds on mice.

BOHIO, in *Geography*, a river of Chili in South America.

BOHKAT, in *Ichthyology*, is the Arabic name of a sort of Ray that inhabits the Red sea, and is described by Forskal under the appellation of *Raja djiddensis*.

BOHME, in *Geography*, a river of Germany, which runs into

into the Ailer, 4 miles S.E. of Bethem, in the principality of Luneburg-zell.

BOHMISCHKRUTT, a town of Germany in the archduchy of Aultria, 5 miles S.S.W. of Feldsburg.

BOHN, JOHN, in *Biography*, was born at Leipzig the 20th of July 1640, where he received the rudiments of his education. At a proper age his father sent him to Jena, to be initiated into the study of medicine. In 1650, he returned to Leipzig, continuing his studies there, until 1663, when desirous of participating in the knowledge of the improvements making in his profession, in different parts of Europe, he went to Copenhagen, Holland, England, France, and Switzerland, every where attending the lectures of the most celebrated masters, but particularly attaching himself to Malpighi. Returning, at the end of two years, to Leipzig, he took his degree of doctor in medicine, and was in succession advanced to the rank of professor in anatomy, and in therapeutics. In 1691 he was appointed public physician to the city of Leipzig; and, in 1700, dean of the faculty of medicine, which offices he continued to hold with credit to the time of his death, in 1718.

Besides numerous dissertations on the different branches of medicine which had great merit, he published, in 1668, "Exercitationes physiologicæ xxvi." 4to. This work was afterwards considerably enlarged, and republished in 1680, under the title of "Circulus anatomico-physiologicus, sive œconomia corporis animalis," 4to. In this he examines, with accuracy and judgment, the different hypotheses then prevailing in medicine. He here first shewed the difference between the cystic and the hepatic bile. Finding the liquor amni coagulable, he supposed it contributed to the nourishment of the fœtus; which, however, later experience contradicts, as fœtuses born without heads, or where the passage through the œsophagus into the stomach has been closed, are found to attain, in utero, equal bulk and firmness, as those that are perfect. He supposed the heart to be excited to contraction by the stimulus of the blood; and shews the ossa pubis are not separated in parturition, to allow a free passage to the fœtus; which was in his time the prevailing doctrine. In his "De variolis, hæcenus in patria grassatis," published in 1679, he advises giving purgatives with calomel, on the first attack of the complaint, with the view of rendering the disease more mild; a practice of which later experience has proved the utility. In his "De Renunciacione vulnerum," 1689, 4to. Amsterdam, he shews what wounds are necessarily fatal. His treatise "De Officio medici duplici, clinico, et forensi," 4to. 1704, gives rules for the conduct of physicians, in attending their patients, and in giving evidence before a court of judicature. This is a work of great merit, and has scarcely been exceeded by any later production on the subject. These have all been frequently reprinted. Haller. Bib. Med. Eloy. Blumenbach.

BOHOL, in *Geography*, one of the Philippine islands between Maoula and Mindanao, about 16 leagues long from north to south, and 8 or 10 broad. The south coast towards Mindanao is the most populous; that is, from Lobag, the metropolis, to the little island or peninsula of Pangloo. The soil does not produce rice, but is said to be rich in gold mines, and to yield, in great abundance, cocoas, batatas, and several sorts of roots which serve instead of rice. In the mountains there are multitudes of cattle and fish in the sea, which the natives exchange with those of the neighbouring islands for cotton. N. lat. 10°. E. long. 122° 5'.

BOHONIZ, a town of Bohemia, in the circle of Bechin, 2 miles S.S.W. of Teia.

BOHRAN, a town of Silesia, in the principality of Breslaw, 16 miles south of Breslaw.

BOHRLITZ, a town of Moravia, in the circle of Brunn, 9 miles W.N.W. of Aufpitz.

BOHUS, or BAHUS, a fortified island of Sweden, in Gothland, encircled by two branches of the Gotha, about 9 miles north of Gotheborg. The fort stands on a rocky eminence, and was formerly celebrated in the history of Norway, as a place of considerable strength, and forming the frontier fortrefs during the constant wars between the Danes and Swedes. It was erected in 1309 by Haquin IV. king of Norway, and, before the invention of gun-powder, it was a wooden fortrefs; but in 1448 was built with stone by Christian I. The situation is strong, and it is garrisoned by 100 men. The summit affords a pleasing view of the Gotha, winding at the feet of barren rocks. Bohus gives name to a jurisdiction of which it is the capital. It formerly belonged to Denmark, but by the treaty of Roschild, in 1658, it was ceded to Sweden.

BOHUSLAW, a town of Poland, in the palatinate of Kioo, near the river Ros. N. lat. 49° 37'. E. long. 31° 11'.

BOJA, in *Antiquity*, a collar or chain fastened about the necks of criminals, to prevent their escape.

The word is also written *loga*, *bodja*, and *baga*.

BOIA, in *Ancient Geography*, an island in the Ægean sea. Anton. Itin.

BOJADOR, CAPE, or BAJADORE (which see), in *Geography*, lies on the western coast of North Africa, placed in the Tables of the Commissioners of Longitude, in N. lat. 26° 12' 30", W. long. 14° 27'. and, in Rennell's map, in N. lat. 26° 20', W. long. 14° 17'.—W. long. 14° 49', by M. Fleurieu, and 14° 28' Conn. de Temps. This cape was doubled by Gilianez and the Portuguese navigators, under the direction of prince Henry, and emboldened by their voyages to Madeira, which required their quitting the coast and venturing into the open sea, in the year 1433. For 20 years before this time, this cape had been the boundary of their navigation, and it had been deemed impassable. But this successful voyage, placed by the ignorance of the age on a level with the most famous exploits recorded in history, opened a new sphere to navigation, as it discovered the vast continent of Africa, still washed by the Atlantic ocean, and stretching towards the south. Of such consequence was the doubling of this cape, that the Portuguese soon after advanced within the tropics, and in the space of a few years discovered the river Senegal, and the whole coast extending from cape Blanco to cape de Verd.

BOIANO, a town of Naples, in the county of Molise, the see of a bishop, suffragan of Benevento, who resides at Campo-Basso, 9 miles south of Molise. See BOVIANUM.

BOIARDO, MATTEO-MARIA, in *Biography*, count of Scandiano, a person eminent for literature, was born at Fratta near Ferrara, about the year 1430, and educated at the university of that city, where he principally resided. Being highly esteemed by the dukes Borso and Hercules I., he was appointed by the latter governor of Reggio in the Modenese, where he died in 1494. He was well acquainted with the Greek and Latin languages; and translated into Italian, from the former, the history of Herodotus, and from the latter, the golden age of Apuleius, and the chronicle of Ricobaldo. His eclogues in Latin verse are reckoned among the most elegant productions of that age. He also wrote in Italian verse a comedy, entitled "Timon," taken from a dialogue in Lucian, and other pieces. But his greatest fame was derived from his "Orlando Innamorato," which combines with the ancient epic the extravagance of modern romance. His style was rude, and his versification stiff and harsh; but the fervour of his fancy and the liveliness of his imagery rendered this work, which he left unfinished, captivating and popular. It was continued by Niccolo Agostino, and

and recomposed and polished, about half a century afterwards, by Lud. Domenico and Fr. Berni. The work of the latter is so well executed, that it has almost superseded the original. The best edition of Boiardo's own performance is that of Venice in 1544. This work served as the model and groundwork of Ariosto's "Orlando Furioso;" which is properly a continuation of it with new adventures. Boiardo's sonnets bear the character of a much purer style than his Orlando. Moreti.

BOIARKI, in *Geography*, a town of Poland, in the palatinate of Kiow, 38 miles S. S. E. of Bialacerkiew.

BOICININGA, or, more properly, **BOICININGUA**, in *Zoology*, the Brazilian name of the most common kind of rattle-snake that is found in South America:—*Crotale boiguira* of Bosc.

BOICUAIBA, a kind of Peruvian serpent, supposed to belong to the *Boa* genus. It is described as being twenty feet long, black on the anterior part, the rest yellow.

BOIGA, the name of an American snake, called by Linæus *Coluber abastulla*.

BOIGUACU, the name of a sort of serpent, called also *iboiá*, and by the Portuguese *Cobra de veado*. The relations of those writers who speak of this extraordinary creature partake rather of the marvellous, inasmuch that we cannot but entertain considerable doubt as to the identity of the species; that it is of the *boa* tribe there can be no dispute. Perhaps it is no other than the *ibiboloca* and *boiguacu* of Seba, which Dr. Shaw describes under the name of *Boa regia*; a species somewhat allied to constrictor, and of which the history has probably been confounded with that of the latter kind. The *boiguacu* is represented as the largest of all the serpent tribe, in which it agrees with constrictor. It grows, we are told, to the length of four and twenty feet, and more. The middle of the body very thick, but becoming smaller at the head and tail. Down the middle of the back runs a chain of black spots, a hand's breadth distant from one another, each having a spot of white in its middle; and below these are two other rows of smaller black spots, towards the belly. Each jaw is said to be furnished with two rows of sharp teeth, white as pearl. The head very broad, with two protuberances over the eyes, and, in some of this species, two claws, like those of birds, behind the anus, towards the tail. The last particular of which must evidently be an absurd mistake, arising from the inattention of the describer.

We are further told, that the *boiguacu* is a terrible creature, one that preys upon the larger animals, and will seize upon a man. That it either lies in ambush in the thickets, or on the branches of large trees, from which it throws itself upon its prey. It has no venom in its bite; and its flesh is eaten and esteemed a delicacy. This sort is common in the Brazils. The size to which it attains sometimes is astonishing. Borritus preserved the skin of one (supposed to be the same) which had been killed by himself, that was twelve yards long; and he relates, that there was a serpent of this kind destroyed in Java, that measured thirteen yards and a half in length, and had, when killed, a boar in its belly. And de Laet relates, that in Rio de la Plata there are some of this kind of serpents so large, that they will swallow a whole stag, the horns not excepted. This is probably exaggerated. It is affirmed of the *boa constrictor*, by others, that when the enormous creature has gorged an animal of this kind, the horns remain sticking out of the mouth of the serpent, till the digestion of the flesh takes place, and the horns drop off. The *boiguacu* is eaten by the natives of Brazil.

BOII, in *Ancient Geography*, a people, who, according to Cæsar (lib. vi. c. 24.), were a Gaulish nation, but from Gaul passed into Germany, and, settling in the present Bohemia,

continued there till they were expelled by the Marcomanni. Strabo calls them at different times Celtes and Gauls; and M. Pelloutier is of opinion that they were a tribe of the Celts, who inhabited Thrace and Illyria. Some of these, he says, occupied the Hercynian forest on the other side of the Danube, and migrated into Bohemia; others were mixed among the inhabitants of Thrace; and others remained in Illyria, between the Danube and the Drave. Of these Boii there were, therefore, several distinct tribes. After Bellocus had made an irruption into Italy through the country of the Taurini, the Boii and Lingones entered it by the Penine Alps. These Boii occupied the more southern part of Gallia Cispadana, or Cisalpine Gaul, and were separated from Etruria by the Apennines, and from the Senones by the Rubico. Their principal city was Bononia. In the year of Rome 395, they advanced in Italy as far as the plain of Præneste, and were defeated there by the dictator C. Sulpicius. Pursued by the Romans, they retired over the Danube, and inhabited the confines of Pannonia and Illyria, along with the Taurisci and Scordisci. In this country they contended with Boerebitas, king of the Getæ, and were destroyed by his troops. Their country afterwards remained desert and uncultivated, and was called the "desert of the Boii." The Romans in process of time built here the towns of Scarabantia and Sabaria. Cæsar is supposed to have referred to these Boii, when he says, that the Boii who had remained on the other side of the Rhine, and who had descended from Noricia, where they laid siege to the town of Noreia, were summoned by the Helvetii to unite with them in an irruption into Gaul. Another body of the Boii having entered into Germany, settled on the north of the Danube, in an extensive country, almost wholly surrounded by mountains, and having on the western part the Hercynian mountains. This country was afterwards occupied by the Marcomanni, and is now called Bohemia. These Boii were blended by degrees with other nations; but retaining some kind of importance, they preserved an imperfect trace of their name in that of Boioarii, whence proceeded Bavaria. The Boii, who joined the Helvetii on their attack of the Gauls, were overpowered by Cæsar; but after their defeat, the Ædui prevailed with Cæsar to allow them a settlement, on account of their distinguished valour, in a small district of their territory. It is said that he built for them a small town called "Gergovica," of which no trace now remains. M. d'Anville places these Boii in a kind of peninsula, formed by the rivers Liger and Elaver, before their re-union. Another body of the Boii, denominated by Aufonius "Picci," occupied the western part of Gaul, comprehended in Novem-Populana, south-west of the Bituriges Vivisci, upon the sea-coast.

BOIL, or **FURUNCLE**, in *Surgery*, is a painful, circumscribed, and inflammatory tumour, seldom larger than a pigeon's egg, generally of a conical figure, seated in the subcutaneous adipose membrane, and proceeding from an internal cause. Its apex or central point is but slightly raised above the skin, and commonly tends to suppuration. No part of the surface of the body is exempt from the attacks of this disorder, but those parts are more liable to boils which abound with cellular substance. The purulent fluid they contain is usually inclosed in one or more cysts or lacculi, and is very slow in coming to a state of full maturation; so that it is requisite to aid the formation of matter, by warm stimulating applications, and at the same time to support the constitution by strengthening remedies, nutritious diet, and salubrious air.

Several boils will often appear at the same time, and after they have healed, new ones may arise; in which case, we may suspect the patient to be of an ill habit of body, and to re-

quire particular medical attention. But it is a very bad practice, though by no means uncommon, to administer frequent purges in such cases, which tend still more to diminish the tone of the patient, already too much exhausted. The state of the system must be remedied by such means as are indicated by the peculiar circumstances of the patient; for no general plan can be prescribed, which is proper in all cases.

Before a considerable boil appears, the patient sometimes feels himself indisposed, rather feverish, and is troubled with a number of slight complaints, which all disappear as soon as the tumour is formed; so that in this case it seems to have some similarity with a critical metastasis. Otherwise, boils, on account of the sense of tension and pain which they occasion, are more troublesome than dangerous.

The best common method of treating these tumours locally, is to bring them as soon as possible to suppuration, as this seems to be their natural tendency; and as the attempt to discuss them generally succeeds either very imperfectly or not at all, some few cases excepted. For discussing them are recommended the external applications of spirit of vitriol mixed with honey, strong wine-vinegar, camphorated oil, &c. In most cases, however, it is necessary that we should immediately endeavour to promote suppuration, which may be done by means of simple emollients; such as bread and milk poultices, linseed cataplasms, or a mixture of oatmeal and honey. If the pain be extremely great, we may add a small quantity of the extract of hemlock or poppies, and give a grain or two of opium internally. When the inflammation is moderate, but the hardness considerable, stimulant and calefacient remedies, such as roasted onions, white-lily roots, gum ammoniac, &c. must be combined with the emollients. Mr. Fielitz affirms that no remedy brings boils so easily and quickly to suppuration, as the leaves of the *ricinus communis* boiled in milk, and applied in the form of a poultice.

When the tumour does not burst spontaneously, which it generally does at its point, it is to be opened with a lancet. Besides the general rules, according to which such an abscess must be treated, it is necessary also that the core or membranous part of the boil should be extracted in due time, and that all the remaining hardness about the circumference of the fore should be discussed. For as long as this core remains in the cavity, the fore will not heal perfectly, neither can it be brought to heal unless the hardness be discussed, but either an ulcer or a fistula is produced, or the fore skins over, whilst an induration still remains behind, which gives rise, according to the part in which it is situated, to various troublesome symptoms, and after some time becomes again inflamed, nor does it disappear entirely till it is discussed by a complete suppuration.

We may indeed attempt to discuss such indurations by means of the usual deobstruents, such as the external applications of mercury, hemlock, soap, belladonna, &c. but they will generally fail of their effect, and we shall be obliged to wait till a new inflammation is produced. It is therefore best to support and promote the suppuration from the very commencement, and not to suffer the abscess to heal up till all remains of induration have disappeared; and when the suppuration does not proceed with sufficient vigour, it ought to be promoted by means of warm turpentine, and digestive ointment. If this do not produce the requisite effect, it should be mixed with red precipitate; and to the indurated parts we ought to apply externally hot fomentations, with other emollient and stimulant remedies, according to the general rules laid down under the article ABSCESS.

BOILS, *gum.* See GUM.

BOILEAU, NICHOLAS, named *Despreaux*, in *Biography*,

an eminent satirical poet and critic, was born either at Paris, or at Crone near that city, in 1636. Boileau himself, after having been truly ennobled by his writings, had the silly vanity to pique himself on the high antiquity of his lineage. He pretended that John Boileau, the ancestor of his family, was ennobled in 1371 by Charles V. king of France; and he boasted, in consequence of a suit instituted against his family, and occasioned by a severe scrutiny into the validity of titles assumed by the noblesse of the kingdom, under a commission of inquiry established by Lewis XIV. in 1695, that he had gained his cause with flying colours, and that he had a patent in his possession which allowed him a nobility of 400 years' antiquity. It is said, however, that the sentence passed in favour of Boileau's nobility was the result of his reputation as a poet, honoured with the protection of the king; that the titles produced had been fabricated; and that a writ had been found among the papers of the poet for 20 louis d'ors, paid by him for his share in the titles which had been forged by an obscure person of the name of Haudiquet. However this be, his own writings were unquestionably his best "lettres de noblesse." As a younger brother, he was harshly treated in his youth, more especially because his father regarded him as a heavy and stupid lad, destitute of that vivacity of temper and understanding for which his elder brothers were distinguished. We are informed also, that he underwent an operation for the stone at eight years of age. These circumstances probably induced him to declare, that if he could be restored to infancy, on the hard conditions he had experienced, he would not have accepted the grant; and hence he always disputed the common opinion that infancy is the happiest period of our lives. Despreaux, indeed, seems not to have thought the other parts of his life more happy than his infancy; to him all appeared equally miserable; youth tormented with passions, maturity with cares, and old age with infirmities; and he seemed to have adopted in some measure that philosopher's opinion, who, when he was asked "what was the happiest period of a man's life?" answered, "that which is past." "It would be difficult," says Despreaux, "to determine this question; we are sure, however, that it is hardly ever the present time." Boileau was intended by his father for the profession of an advocate; but his taste for polite literature, to the culture and gratification of which he devoted his leisure hours, disqualified him for this mode of life; and his repugnance to it was strongly indicated by his dropping asleep, while his brother-in-law, M. Dongois, a clerk of parliament was reading an arret, which he had taken great pains to compose. Upon this, he was sent home to his father as an invincible dunce, who would be nothing else but a simpleton during his life. Relieved from the embarrassment of pursuing a profession which he detested, his attention was next directed to scholastic divinity, from which he was equally averse. When his father found, that his views respecting him were altogether frustrated, he allowed him to indulge his own inclination, and to devote himself wholly to literature. At the age of thirty years, Boileau's true character, which had long been unknown to any but his intimate and confidential friends, was developed; and he appeared before the public as a "writer of satires." He began with ridiculing the numerous tribe of bad writers, and he thus excited a host of enemies. Among others the duke de Montausser reproached him on account of the severity of his personal satires as injurious to society; but he contrived to disarm his enmity by a single stroke of flattery, which verified, says D'Alembert, the lines of La Fontaine:

"Amuse the great with adulation,
Your praise to all their faults extend,

Whate'er

Whate'er their former indignation,
The bait goes down, and you're their friend."

Twelve of his satires were published; one of these was his satire against women, the most bitter and outrageous of all, which is said to have been occasioned by his having been in early life jilted by a young person to whom he was going to be married, and who ran away with a musquetaire. Racine the younger, one of his particular friends, however, says, that he never had a mistress, nor ever thought of marrying. On the publication of this satire he was attacked from all quarters; but his friend Racine consoled him as well as he could: "Courage," says he, "you have attacked a numerous corps, which is all tongue; but the storm will blow over." The best of his satires was that entitled "A son Esprit;" a piece of irony, abounding with the most keen and polished ridicule. Whatever reproach Boileau incurred for the personality of his satires, it is mentioned to his honour, that he always distinguished between folly and vice; and that he never attacked bad taste and dunces with any other arms than ridicule, while vice and profligacy were treated by him with just indignation.

The satires of Boileau were followed by his "Art of Poetry," which is reckoned the best of all the poetical works of criticism existing, equally admirable for the good sense of its maxims, and the appropriate beauties of language by which his precepts are exemplified. This was succeeded by his "Epistles," formed after the model of Horace, and rendered peculiarly pleasing by the union of morality with criticism, and description with sentiment; interspersed with characteristic traits and anecdotes of himself. In one of these, addressed to the king, he artfully, at the instigation of Colbert, endeavoured to divert the sovereign's mind from the schemes of conquest to the glory of promoting the welfare of his subjects by plans of utility and beneficence. Lewis was gratified by the delicate praise with which this advice was accompanied, and applauded the epistles; but went to war with Holland. In 1674, he published his "Lutrin," a mock-heroic kind of composition, founded on a trifling dispute between the treasurer and chanter of the holy chapel, and ranking among the first productions of this class. Boileau had now acquired a degree of reputation which recommended him to favour and patronage at court; and the king honoured him with a pension, an exclusive privilege for printing his own works, and the office, conjointly with his friend Racine, of royal historiographer. In this latter capacity, neither he nor his associate had an opportunity of appearing before the public. Boileau, indeed, published his "Ode on the taking of Namur," which is more an historical than a poetical effort. At this time he attended frequently at court; and yet he maintained a freedom and frankness of speech, more especially on topics of literature, which are not common among courtiers. When Lewis asked his opinion of some verses which he had written, he replied; "Nothing, sire, is impossible to your majesty; you wished to make bad verses, and you have succeeded." He also took part with the persecuted members of the Port-royal; and when one of the courtiers declared, that the king was making diligent search after the celebrated Arnauld, in order to put him in the Bastille, Boileau observed, "His majesty is too fortunate; he will not find him;" and when the king asked him, what was the reason why the whole world was running after a preacher, named le Tourneux, a disciple of Arnauld, "Your majesty," he replied, "knows how fond people are of novelty;—this is a minister who preaches the gospel." Boileau appears, from various circumstances, to have been no great friend to the Jesuits, whom he offended by his "Epistle on

the Love of God," and by many free speeches. By royal favour, he was admitted unanimously, in 1684, into the French academy, with which he had made very free in his epigrams; and he was also associated to the new Academy of Inscriptions and Belles Lettres, of which he appeared to be a fit member by his "Translation of Longinus on the Sublime." To science, with which he had little acquaintance, he rendered, however, important service by his burlesque "Arret in favour of the University, against an unknown personage called Reason," which was the means of preventing the establishment of a plan of intolerance in matters of philosophy. His attachment to the ancients, as the true models of literary taste and excellence, occasioned a controversy between him and Perrault concerning the comparative merit of the ancients and moderns, which was prosecuted for some time by epigrams and mutual reproaches, till at length the public began to be tired with their disputes, and a reconciliation was effected by the good offices of their common friends. This controversy laid the foundation of a lasting enmity between Boileau and Fontenelle, who inclined to the party of Perrault. Boileau, however, did not maintain his opinion with the pedantic extravagance of the Dacier; but he happily exercised his wit on the misrepresentations of the noted characters of antiquity, by the fashionable romances of the time, in his dialogue entitled "The Heroes of Romance," composed in the manner of Lucian. In opposition to the absurd opinion of father Hardouin, that most of the classical productions of ancient Rome had been written by the monks of the 13th century, Boileau pleasantly remarks, "I know nothing of all that; but though I am not very partial to the monks, I should not have been sorry to have lived with friar Tibullus, friar Juvenal, Dom Virgil, Dom Cicero, and such kind of folk." After the death of Racine, Boileau very much retired from court; induced partly by his love of liberty and independence, and partly by his dislike of that adulation which was expected, and for which the close of Lewis's reign afforded more scanty materials than its commencement. Separated in a great degree from society, he indulged that austere and misanthropical disposition, from which he was never wholly exempt. His conversation, however, was more mild and gentle than his writings; and, as he used to say of himself, without "nails or claws," it was enlivened by occasional sallies of pleasantry, and rendered instructive by judicious opinions of authors and their works. He was religious without bigotry; and he abhorred fanaticism and hypocrisy. His circumstances were easy; and his prudent economy has been charged by some with degenerating into avarice. Instances, however, occur of his liberality and beneficence. At the death of Colbert, the pension which he had given to the poet Corneille was suppressed, though he was poor, old, infirm, and dying. Boileau interceded with the king for the restoration of it, and offered to transfer his own to Corneille, telling the monarch, that he should be ashamed to receive his bounty while such a man was in want of it. He also bought, at an advanced price, the library of Patru, reduced in his circumstances, and left him in the possession of it till his death. He gave to the poor all the revenues he had received for eight years from a benefice he had enjoyed, without performing the duties of it. To indigent men of letters his purse was always open; and at his death he bequeathed almost all his possessions to the poor. Upon the whole, his temper, though naturally austere, was, on many occasions, kind and benevolent, so that it has been said of him, that he was "cruel only in verse;" and his general character was distinguished by worth and integrity, with some alloys of literary jealousy and injustice.

justice. He died of a dropfy in the breast in 1711, at the age of 75, and bequeathed the greater part of his property to charitable uses. His funeral was attended by a very considerable number of persons of rank and literature. How came this man (exclaimed a woman in the street) to have so many friends? They say he never spoke well of any body in his life.

As a poetical writer, he has been denominated the "poet of good sense," correct in his versification, choice and pure in his language, just and rational in his sentiments, always guided by judgment and taste, observing the limits of decorum, and never betrayed by wit or fancy into extravagancies. Few, if any writer, ever composed so much, with so little occasion for erasement or alteration. Voltaire, who often denied the equity of his decisions in matters of criticism, says of him, in a letter to Helvetius; "I agree with you that Boileau is not a sublime poet; but he executed admirably whatever he undertook. He is clear, easy, happy in his expression; he seldom rises very high, but he never sinks. Besides, the subjects of which he treats are not of a kind to require great elevation.—I shall, therefore, always warmly recommend that kind of writing which he has so well taught, that respect for language, that quick succession of ideas, the art and facility with which he conducts his reader from one subject to another; and above all, his simplicity, which is the true fruit of genius." Boileau, was the first writer who formed the national taste of France, and by his translations and imitations gave his countrymen a true relish for the epistles and satires of Horace, which before his time used to be much less esteemed than his odes. The great defect of Boileau, according to D'Alembert, is want of sensibility; and if enthusiasm, which is incompatible with that coldness of heart that distinguished his character, is essential to a true poet, his claim to this honourable appellation must be disallowed. Nevertheless, his works may be justly regarded as master-pieces of their kind, and can never die, as long as the language in which they are written exists. Having taken great pains in the composition of them, he was not insensible of their peculiar and characteristic excellence; accordingly, in some lines written by himself, and intended to be placed under his portrait, he makes no hesitation in affirming that he had united the merits of Persius, Juvenal, and Horace. Boileau and Pope have been thought much to resemble one another, as to both the kind and discriminating character of their writings; but, says a very competent judge, "Boileau, with a nearly equal portion of wit, has much more delicacy and correctness; while Pope as much surpasses him in force and fancy. Both abound in good sense, and each has enriched his language with nervous lines that have passed into proverbial sentences." In another place the same writer observes, that after we have rendered to Boileau Despreaux all due homage as a great poet, and as the legislator of taste, his faults as a satirist indicate an acrimonious and unfeeling character, a high conceit of his own powers and consequence, and an unpardonable disregard of the happiness and reputation of others. "If the English poet had as much causticity as the French, and more peevish irritability, he seems to have had a more feeling heart, and a nicer sense of justice." We may remark, that personal satire soon loses its salt and poignancy: and that the satires of Boileau, as well as the Dunciad of Pope, are less read now than any of their other works.

Besides the works of Boileau, already mentioned, there are several smaller pieces both in prose and verse. Of the whole there have been various editions, with explanatory notes; and of these the principal are that of Geneva, 2 vols. 4to. 1716,

with illustrations, by Brofette; that of the Hague, with Picart's figures and notes, 2 vols. fol. 1718, and 4 vols. 12 mo. 1722; that by Allix, with Cochin's figures, 2 vols. 4to. 1740; and that of Durand with illustrations, by St. Marc, 5 vols. 8vo. 1747.

Boileau had several brothers of very singular characters. *James*, a doctor of the Sorbonne, was born in 1635, studied in the university of Paris, took his degree of doctor in theology in 1662, was appointed dean of Sens, and vicar of the archbishop Gondoin, in 1667; and in 1694, was presented by the king with a canonry in the holy chapel of Paris. He died dean of the faculty of theology in 1716. He is well known by a number of works in a peculiar style, some of which were not remarkable for decency; but these he wrote in Latin, "lest the bishops," he said "should condemn them." He was not more a friend to the Jesuits than his brother; and he described them as "Men who lengthened the creed, and shortened the commandments." As dean of the chapter of Sens, he was appointed to harangue the celebrated prince of Condé, when he passed through the city. This great commander took particular pleasure on these occasions in disconcerting his panegyrist; but the doctor, perceiving his intention, counteracted great confusion, and addressed him in the following manner: "Your highness will not be surpris'd, I trust, at seeing me tremble in your presence at the head of a company of peaceful priests; I should tremble still more, if I was at the head of 30,000 soldiers." He manifested a contempt of fanaticism, as well as of decorum, by his "*Historia Flagellantium, &c.*" or, an account of the extravagant, and often indecent, practice of discipline by flagellation, in the Christian church. It was translated into French; and not many years ago (viz. 1777, 4to. and again in 1782, 8vo.) by M. de Lolme, into English. In his treatise "*De antiquo jure presbyterorum in regimine ecclesiastico,*" he discovers the greatest freedom of sentiment, endeavouring to shew, that in the primitive times the priests participated with the bishops in the government of the church. He was also the author of several other publications, displaying much curious learning and a satirical turn, which are now consign'd to oblivion.

Gilles, the eldest brother of Boileau Despreaux, was born in 1631, and had a place in the king's household. He was a man of wit and learning, and published a translation of Arrian's *Epicætetus*, with a life of the philosopher, Paris, 1655, 8vo. He also published a translation of *Diogenes Laertius*, in 2 vols. 12mo. 1668; and two dissertations against Menage and Costar. His "*Posthumous Works*" were published in 1670. He also wrote verses, in no high estimation; and his poetical pretensions excited a jealousy of his brother's rising fame, which produced an open variance between them. He was a member of the French academy; and died in 1669. *Gen. Dict. Nouv. Dict. Hist. D'Alembert's Hist. des Membres de l'Acad. Franc. 1787, and Eloges, &c. 1779,*—translated by Aikin in 2 vols. 8vo. 1799.

BOILED, or **BOYLED silks**, those which have been put, while in the balls, into hot water, to make them wind the better.

In which sense boiled silk stands opposed to raw.

BOILER, or **BOYLER**, a large copper vessel, wherein things are exposed over the fire to be boiled.

The boiler, in the alum-works, is a vessel, in which the liquor is evaporated to a consistence, and is made of lead. The general size is about eight feet square, and they contain about twelve tons each.

They make them in this manner: first, they lay long pieces of cast-iron, twelve inches square, as long as the breadth

breadth of the boiler, and at about twelve inches distance from one another. These are placed twenty-four inches above the surface of the fire. On these maffy bars of iron they lay, cross-wise, the common flat bars of iron, as close as they can lie together, and then make up the sides with brick-work. In the middle of the bottom of this boiler is laid a trough of lead, wherein they put at first about a hundred pound weight of the rock. They use Newcastle coals in the boiling; and if they find the liquor not strong enough, they add more of the rock at times, as it boils. Phil. Trans. N^o 142.

The boiler for making colours, &c. must be made of pewter; because iron and copper will be corroded by the saline substances used in the manufacture of them.

Count Rumford (see his *Essays*, vol. i. p. 220.) recommends double bottoms to boilers, and also to saucepans and kettles of all kinds, used for culinary purposes; which contrivance, he says, will, in all cases, most effectually prevent what is called by the cooks, "burning-to." The heat is so much obstructed in its passage through the thin sheet of air which, notwithstanding all the care that is taken to bring the two bottoms into actual contact, will still remain between them, that the second has time to give its heat as fast as it receives it to the fluid in the boiler; and consequently it never acquires a degree of heat sufficient for burning any thing that may be upon it. He suggests that it will probably be best to double copper saucepans and small kettles throughout: and as this may and ought to be done with a very thin sheet of metal, it would not cost much, even if the lining were to be made of silver. When the two sheets of metal that form the double bottoms of boilers are made to touch each other throughout, by hammering them together, after the false bottom has been fixed in its place, they may be tacked together, by a few small rivets placed here and there, at considerable distances from each other, and when this is done, the boiler may be tinned. In this operation, if proper care be taken, the edge of the false bottom may be soldered by the tin to the sides of the boiler, and thus the water or other liquids, put into the boiler, will be prevented from getting between the two bottoms. The Count adds, that this invention of double bottoms might be used with great success by distillers, to prevent their liquor, when it is thick, from burning to the bottom of their stills. (See *STILL*.) Having found in the course of his experiments, (See *Phil. Trans.* 1792. Part I.) that confined air is the best barrier that can be opposed to heat for the purpose of confining it, he proposed to confine the heat in the boilers of his construction, and to prevent its escape into the atmosphere, by means of double covers. These covers were made of tin, or rather of thin iron plates tinned, in the form of a hollow-cone; the height of the cone being equal to about one-third of its diameter; and thus the air which it contained was entirely shut up, the bottom of the cone being closed by a circular plate or thin sheet of tinned iron. The bottom of the cone was accurately fitted to the top of the boiler, which it completely closed by means of a rim about two inches wide, which entered the boiler; which rim was soldered to the flat sheet of tinned iron that formed the bottom of the cover. The steam, generated by the boiling liquid, was carried off by a tube about half an inch in diameter, which passed through the hollow conical cover, and which was attached to the cover, both above and below, with solder, in such a manner that the air with which the hollow cone was filled remained completely confined, and cut off from all communication with the external air of the atmosphere, as well as with the steam it generated in the boiler. For his various contrivances in the most advan-

tageous construction of boilers for the saving of fuel, and for producing the desired effect, we refer to his *Essays*, vol. ii. p. 18, &c.

BOILERY, or **BOYLARY**, in the *Salt Works*, denotes a salt-house, pit, or other place, where salt is made.

BOILING OF MEAT, in *Cookery*, is the exposing of meat to the heat of boiling water, while it is immersed in it for a certain time. By this joint application of heat and moisture, the texture is rendered more tender and more soluble in the stomach; and it is only in this way, that the firmer parts, as the tendinous, ligamentous, and membranous parts can be duly softened, and their gelatinous substance duly extracted. A moderate boiling renders the texture of animal flesh more tender, without much diminution of its nutritious quality; but if the boiling is extended to extract every thing soluble, the substance remaining becomes less soluble in the stomach, and at the same time much less nutritious. But as boiling extracts in the first place the more soluble, and therefore the saline parts; so the remainder, after boiling, is in proportion to the continuance of the operation less alkalescent, and less heating to the system.

Boiling is commonly practised in open vessels, or in vessels not closely covered; but it may be performed in digesters, or vessels accurately and tightly closed; and in such vessels the effects are very different from those that take place in open vessels. As we can hardly employ any other degree of heat than that of boiling water, the water in the digester is never made to boil, so there is no exhalation of volatile parts; and, although the solution is made with great success, and may be to any degree required, yet if it be not carried very far, the meat may be rendered very tender, while it still retains its most sapid parts; and this kind of cookery will always give the most desirable state of boiled meat. Boiling, in the ordinary way, is different, according to the proportion of water that is applied. If a small quantity be applied, and the heat in a moderate degree is continued for a long time, this is called "stewing," and has the effect of rendering the texture more tender, without extracting much of the soluble parts; and of course it leaves the meat more sapid, and sufficiently nourishing. *Cullen's Mat. Med.* vol. i. p. 400, &c.

BOILING, *ebullition*, in *Physics*, is the internal commotion excited in a mass of water or other liquefied substance, by the successive conversion of the lower portions of the fluid into vapour, and their violent effort under this expansive and elastic form to make their escape. It is usually, though not necessarily, produced by the application of heat. The circumstances which precede or accompany the phenomenon of boiling, are best observed in a thin transparent flask nearly filled with water, and suspended over a lamp or a charcoal fire. Numerous minute globules are seen collecting from all points towards the sides and rising in a stream to the surface; occasioned evidently by the discharge of air, which is always in some proportion combined with water. As the heat increases, the liquid particles near the bottom of the flask suddenly burst into steam, and shoot upwards; but in ascending through the colder mass, they again collapse, stop their progress, and seem loit. Such alternate expansions and contractions; by throwing the fluid into a gentle tremor, frequently causes a peculiar sort of singing noise, which is rightly supposed to betoken the approach of actual boiling. This singing is more likely to happen in the case where heat is applied partially; for instance, if a tea-kettle be placed at the side of the fire, since the heat is then more slowly and unequally diffused through the body of the water. But after the whole contents being fully penetrated, are warmed up to the requisite degree of intensity, the steam, as fast as it is formed,

BOILING.

formed, ascends continually and escapes unimpair'd through the fluid, which it, therefore, heaves with violent agitation.

The same appearance almost is produced by removing or even diminishing the atmospheric pressure. Thus, if a tumbler holding warm water be introduced under the receiver of an air-pump, as the exhaustion proceeds, or the incumbent weight is gradually withdrawn, the latent portion of air is discharged in a rapid flow of expanded bubbles. But this process, at some certain point of rarefaction, is succeeded by the vehement commotion which constitutes boiling; and the water, assuming its invisible form, fills the imperfect void with vapour, which betrays its existence by condensing against the sides of the receiver in copious dew. Nor is heat positively necessary towards vaporization, for it only conspires in accomplishing that effect, and supplies the want or the imperfection of our means of producing exhaustion. By help of an air-pump of the best construction, the coldest water may be made to boil, nay, ice itself could be changed into invisible steam. Hence the utter impossibility of ever obtaining a perfect vacuum, because the restraining influence of pressure being entirely removed, the liquid matter unavoidably presented would always diffuse a thin vapour.

The opposite influence of heat and pressure on the constitution of fluids is well exhibited by a very simple yet striking experiment. Take a large thin phial, and having warmed it gradually to avoid the risk of cracking the glass, fill it completely with boiling water, cork it tight, and expose it to a current of cold air. As the water cools, it necessarily contracts its volume, and leaving an imperfect vacuum below the neck of the phial, it hence becomes to a considerable degree relieved from the load of atmospheric pressure. It therefore soon begins again to boil, nay, it will boil more briskly the faster it cools; and this singular appearance, so contrary to our usual notions, may continue perhaps for the space of half an hour, till the water has grown as cold almost as the temperature of the human body. On the same principle depends the construction of what is called the *pulse glass*: this consists of two balls connected by a pretty long tube; one of these balls is filled with coloured water or spirits of wine, which having been made to boil and expel the air by its vapour, at the same instant the point projecting from the other ball is hermetically sealed. As that vapour condenses with cold, it will leave the included liquid then in a sort of vacuum, and the heat of the hand is then sufficient to cause it to boil and to flow from one ball into the other.

If a vessel containing water be placed over a steady fire, the water will grow continually hotter till it reaches the limit of boiling, after which the regular accessions of heat are wholly spent in converting it into steam. The water therefore remains at the same pitch of temperature, however fiercely it boils. The only difference is that, with a strong fire, it sooner comes to boil, and more quickly boils away. Hence the reason why a vessel full of water, and plunged into the centre of a larger one, which is likewise filled with that fluid, barely acquires the boiling heat, but will never actually boil.

The formation of steam occasions a prodigious consumption of heat; for if the time be noted in which water, by the action of a strong fire, is raised from the limit of freezing to that of boiling, it will be found to require more than five times longer a space to boil entirely away. Thus, a portion of heat corresponding to above 900 degrees by Fahrenheit's scale, is always consumed in the act of boiling, or rather it is transferred and enters into the composition of steam, the gaseous product. This absorbed heat is as constantly evolved when steam condenses and returns to its liquid form.

Hence in distillation a very large refrigeratory is required for condensing a comparatively small quantity of aqueous or spirituous vapour. Hence too the explication of the familiar remark that steam scalds more cruelly than boiling water.

The heat of boiling water, being subject to the influence of the atmospheric pressure, is thus not absolutely fixed. It varies with the variation of the barometer, and decreases as the mercury descends. The extent of this fluctuation may in our changeable climate amount to five degrees by Fahrenheit's scale, the successive difference of a degree corresponding nearly to each twentieth part of the remaining incumbent weight. On the tops of lofty mountains water will boil much sooner than in the plains below. This curious fact has been noticed by several travellers, and was particularly observed by Saussure on the summit of Mont Blanc. A still greater variation would be experienced on the peak of Chimboraco, the highest point of the Andes, where water would boil with a heat scarcely superior to that which is commonly assigned for the boiling of spirits of wine.

It is therefore evident that, under an augmented pressure, all liquids will more slowly reach the crisis of ebullition and will then have acquired a more intense heat. Thus water may be heated up many degrees above the mean point of boiling, if it be subjected to the action either of condensed air or of confined steam. Such is the principle of *Papin's Digester*; which, being nearly filled with water, is shut perfectly close, and set on a good fire. As the steam so formed is prevented from escaping, it necessarily concentrates, and exerting accumulated energy, it by its prodigious compression enables the water continually to receive additional heat. Nor would this progress at all stop, till the elasticity of the imprisoned vapour comes to surmount every obstacle, and bursts the vessel with terrible explosion. Accidents of that sort are extremely dangerous, and the experiment has consequently never been pushed to its utmost practicable limits. When the fracture takes place, not only the confined steam is liberated, but the pressure being now removed, the excess of heat instantaneously converts a part or the whole of the water likewise into steam, which augments the general effect. This we may perceive in the bursting of a glass cracker; for the little base is shivered into atoms, and the water which it contained is entirely dispersed, beating down flat the wick of the candle by the violence of the sudden expansive blast.

Hence the boiling heat of a deep cauldron is always rather greater than that of a shallow pan. This excess we might estimate at nearly one degree of Fahrenheit, for each foot of depth. The heat of ebullition must also rise somewhat higher, if the steam be not allowed to escape as fast as it is generated; for which reason there may be a slight difference of energy between rapid and slow boiling. Hence by the combined operation of both these causes, water deeply lodged in the bowels of the earth, or concealed under the dark bed of the ocean, is capable of acquiring the most intense heat from the action of subterranean fires; a principle of which Dr. Hutton has ingeniously availed himself in framing his Theory of the Earth.

But the position of the boiling point is likewise modified by the influence of chemical attraction. Thus sugar, common salt, and other saline substances, have all of them a tendency to fix water and retard the crisis of its conversion into elastic vapour. Strong brine will not boil until it is heated up several degrees above the ordinary limit. Hence a vessel containing fresh water, and immersed in another which is filled with brine, will gently boil, while the surrounding fluid only simmers. On the other hand, the addition

tion of alcohol renders water more volatile. In the distillation of spirits, the fermented liquor in the copper boils always at a lower temperature, or at some intermediate point between the ebullition of water and that of alcohol. The spirituous fumes which rise carry along with them a portion of evaporated water. Hence the necessity of rectification, or repeated distillations, to procure alcohol in its purest state; for the boiling heat is lowered, and consequently the proportion of aqueous admixture is diminished, at each successive process. See DIGESTER, EBULLITION, FIRE, FLUID, HEAT, PRESSURE, STEAM, VAPOUR.

BOILING of silk with soap, is the first preparation in order to dyeing it. Thread is also boiled in a strong *lixivium* of ashes, to prepare it for dyeing.

Boiling is also a part of the process for bleaching warp linen.

BOILING to death, *caldarius decoquere*, in the *Middle Age*, a kind of punishment inflicted on false coiners, thieves, and some other criminals.

This punishment was inflicted on those who were guilty of murder by poison, 22 Hen. VIII. cap. 19. but this act was repealed by 1 Edw. VI. cap. 12.

BOILING is also a method of trying or assaying the goodness or fullness of a colour of a dye, by boiling the stuff in water with certain drugs, different according to the kind or quality of the colour, to try whether or no it will discharge, and give a tincture to the water.

With this intention, red crimson silks are boiled with alum, and scarlets with soap, in quantity equal to the weight of the silk.

BOILING waters, in *Natural History*. See SPRING, and WATER.

BOINITZ, in *Geography*, a town of Hungary, eleven miles W. N. W. of Kremnitz.

BOIOBI, in *Zoology*, the Brazilian name of the *Linnæan* *ba carina*.

BOIODURUM, in *Ancient Geography*, a town of Vinjelicia, situate on the Danube, according to Ptolemy; the Itinerary of Antonine places it on the route from Ovilabis to Augusta Vindelicium, between Stanacum and Quintiana.

BOIOHEMUM, or BOIUM, the country of the Boii, answering to the present *Bohemia*, which see. On the south of it lay the "Gabreta Sylva," and to the south, west, and north, the "Herevni montes." The interior of it was penetrated with difficulty, and was little known.

BOJOWKA, in *Geography*, a town of Poland, in the palatinate of Braclaw, forty-eight miles east of Braclaw.

BOIQUIRA, in *Zoology*, a name by which the natives, in some parts of America, call the *rattle snake*. Supposed to be the *Crotalus horridus*, of Naturalists.

BOIREL, ANTHONY, in *Biography*, born at Argentan, in Normandy, about the year 1625, applied himself to the practice of surgery, in which he acquired considerable reputation. In 1677 he published "Traité de plaies de tête," 8vo. extracted principally from the works of Hippocrates, Galen, and of Ambrose Paré, which he appears to have studied diligently. He has added some improvements to their practice.

Nicholas Boirel his brother, physician at Argentan, published, in 1702, "Nouvelles observations sur les maladies veneriennes," 12mo. Paris, which was reprinted 1711, but contains little new on the subject. Haller Bib. Eloy. D. 3. Hist.

BOIS, CARDINAL DU. See DUBOIS.

BOIS, GERRARD DU, a member of the congregation of the Oratory, and a Latin professor in it, was born at Orleans, in 1620. Having succeeded father Le Comte, in his place of librarian to St. Honoré, and having possession of his pa-

pers, he finished for the press his eighth and last volume of the "Ecclesiastical Annals of France," which was printed in 1683; and in consequence of it he obtained a pension from the French clergy. He afterwards undertook to write the history of the Parisian church; and, in 1690, published the first volume in folio. The second, which he did not live to finish, appeared after his death, which happened in 1696. This work is written in pure elegant Latin, and contains a variety of interesting facts relating to civil as well as ecclesiastical history. Nouv. Dict. Hill.

BOIS, BOYS, or BOYSE, JOHN, an eminent divine, and one of the translators of the bible in the reign of James I. was born at Nettlestead in Suffolk, in 1560, and made such early proficiency under the instructions of his father, that at the age of five years he read the bible in Hebrew, and at six, wrote that language in a fair and elegant character. At the age of 14 he was admitted into St. John's college, Cambridge, and by his great skill in the Greek language obtained a scholarship before he had been half a year at college, and afterwards a fellowship. Declining the profession of physic, for which he was intended, he devoted himself to the study of divinity, and was ordained in 1583. He officiated for 10 years in his college as principal Greek lecturer; and as an instance of his assiduous application, and of the early hours of study at that period, it is mentioned, that he voluntarily read a Greek lecture at four in the morning, which was attended by most of the fellows. On the death of his father he succeeded him in the rectory of West-Stowe, near Bury, in Suffolk; but in 1596, he married the daughter of Mr. Holt, rector of Boxworth, in Cambridgeshire, and having before resigned West-Stowe, took possession of this living. In this situation the neglect of domestic economy involved him so much in debt, that he was under a necessity of selling his choice collection of books. Afterwards, however, he retrieved his affairs by keeping a boarding-school; and was appointed one of the Cambridge translators of the bible. (See BIBLE.) The part that fell to the lot of that class of divines, with whom he was connected, was the Apocrypha; and this he completed in four years, without deriving any advantage from it besides his commons. He was afterwards appointed one of the six delegates who met at Stationers' hall in London, for the purpose of revising the translation, and who were employed for nine months in this business, with an allowance from the Stationers' company of 30s. a-week each. For the assistance which he gave to sir Henry Saville, in the publication of St. Chrysostom's works, to which he devoted the labour of many years, he received the very inadequate recompence of a single copy of the work. However, such was his reputation, that he obtained, without solicitation, from Dr. Andrews, bishop of Ely, a prebend in his cathedral, in 1615; and he was thus enabled to spend the last 28 years of his life in tranquil retirement. Although he was always a hard student, he published nothing; but left behind him many MSS. particularly a commentary on the greatest part of the N. T. A work of which few copies were printed, and, therefore, little known, appeared after his death, under the following title "Johannis Boisii veteris Interpretis cum Beza aliisque recentioribus collatio in IV. Evangeliiis, et Actis Apostolorum," London, 1655, 8vo. He sustained the character of an excellent Latin writer, a profound scholar, a loyal subject, a strict churchman, and a plain practical preacher. It was his practice to attend the public service of the church twice, if not thrice a day; and his charity was as extensive as his devotion was regular and constant. Although he devoted eight hours a day to study even in his old age, he preserved his health by the exercise of walking, to which he had accustomed himself from his youth, by confining himself to two meals a day, dinner and supper, by sitting or walking an hour after dinner before he went into his study, by occasional fasting, sometime twice in a week,

and sometimes once in three weeks, and by not studying after supper, particularly towards the close of life, but diverting himself with cheerful conversation for two hours among his friends. When he was a young student at Cambridge, he received from the learned Dr. Whitaker these three rules for avoiding those distempers which usually attend a sedentary life, to which he adhered with equal constancy and success. The first was to study always standing; the second never to study in a window; and the third never to go to bed with his feet cold. Accordingly he attained the age of 84 years, and died in 1643. *Biog. Brit.*

Bois, Du, Lake, in *Geography*, lies in North America, to the north-west of lake Superior, and receives the river de la Pluie, in N. lat. 49°. It was formerly famous for the richness of its banks and waters, which abounded with all the necessaries of a savage life. The French had formerly several settlements in and about it; but it has since declined, though it is now recovering its pristine state. The few Indians who inhabit it might live very comfortably, if they were not so immoderately fond of spirituous liquors. This lake is rendered remarkable by its having been named on the part of the Americans, as the spot from which a line of boundary between them and British America was to run west till it struck the Mississippi, which, however, as Mr. Mackenzie observes, can never happen, because the N. W. part of the lake du Bois is in N. lat. 49° 37'. and W. long. 94° 31'. and the northernmost branch of the source of the Mississippi is in N. lat. 47° 38' and W. long. 95° 6'. ascertained by Mr. Thomson, astronomer to the North-west company, who was sent expressly for that purpose in the spring of 1793. He, in the same year, determined the northern bend of the Missouri to be in N. lat. 47° 32'. and W. long. 101° 25'. and according to the Indian accounts, it runs to the south of west, so that if the Missouri were even to be considered as the Mississippi, no western line could strike it. It does not appear, says Mackenzie, to be clearly determined what course the line is to take, or from what part of lake Superior it strikes through the country to the lake du Bois; if it were to follow the principal waters to their source, it ought to keep through lake Superior to the river St. Louis, and follow that river to its source; close to which is the source of the waters falling into the river of lake la Pluie, which is a common route of the Indians to the lake du Bois; the St. Louis passes within a short distance of a branch of the Mississippi, where it becomes navigable for canoes; and if the navigation of the Mississippi is considered as of any consequence by this country, from that part of the globe, such is the nearest way to get at it. The lake du Bois is nearly round, and the canoe course lies through the centre of it, among a cluster of islands, some of which are so extensive that they may be taken for the main land. The reduced course would be nearly north and south. But, according to the navigating course, the distance is 75 miles, though in a direct line it would not be so long. At about two-thirds of it there is a small carrying place where the water is low. The carrying place out of the lake is on an island, and named Portage du Rat, in N. lat. 49° 37'. and W. long. 94° 25'. and is about 50 paces long. The lake discharges itself at both ends of this island, and forms the river Winipic, which see. Mackenzie's voyage, &c. through the Continent of North America. *Introd. p. 59.*

Bois-belle, or Henrichemont, a small sovereignty of France before the revolution, situate in Berry, between Bourges and Sancerre, about 10 leagues in circuit, containing about 6300 inhabitants; its principal towns are Bois-belle and Henrichemont, which see.

Bois-belle, a town of France, in the department of the Cher, 15 miles N. E. of Bourges.

Bois Blancs island, situated in Upper Canada, lies in the

strait between lake Erie and lake St. Clair, containing from 150 to 200 acres of good land, covered with wood; the common channel, which is narrow, lies between it and the east shore, and forms the best harbour in this country. This island commands the Detroit river from lake Erie. A wider ship-channel, though less frequented, lies on the west of the island.

Bois-commun, a town of France, and principal place of a district in the department of the Loiret, containing about 1600 inhabitants; 7 leagues N. E. of Orleans, and 5 W. of Montargis.

Bois, Glacier des, one of the lower Glaciers of the Alpine mountains adjoining to Mont Blanc, and the valley of Chamouny in Swisserland, from the thawed ice of which flows the river Arveron. This glacier is more than 15 miles long, and above three in its greatest breadth. The general thickness of the ice was found by M. Sauffure to be from 80 to 100 feet.

Bois-le-duc, or the *Duke's wood*, a city of Dutch Brabant, seated on the river Dommel, where it receives the waters of the Aa; so called from its situation in a woody country, to which the dukes of Brabant were accustomed to resort for the purpose of hunting. The woods were cut down by order of Godfrey III. duke of Brabant; and he laid the foundation of a city in 1184, which was finished in 1196, by his son duke Henry I. and much enlarged in 1352, 1453, and 1559. The city is encompassed by the Dommel and Aa, by the waters of which it may be easily inundated; and it is sometimes inaccessible except by boats. The principal forts that defend it are those of Crevecoeur, near the Meuse; another called Isabella; and a small fort called St. Antoine, towards Brabant. It has also a castle, built by order of the States General, in the 17th century, as a check on the Roman catholics then more numerous than the reformed. It has four gates; and its walls are flanked with bastions; the approach to it by land is on canieways, and by water at three gates or avenues. The cathedral, erected in 1366, and dedicated to St. John the Evangelist, is one of the most beautiful structures in the Low Countries. Its wooden tower which was very lofty and supported by four stone pillars, was destroyed by lightning in 1584. It has had several other churches and monasteries. This city suffered very much in the 16th century, during the religious wars; but at length the Dutch made themselves masters of it in 1629. Pope Paul IV. founded a bishopric at Bois-le-duc in 1559, having jurisdiction over ten cities and 189 villages; the chief revenue of which arose from the abbey of Tongerlo. The district of Bois-le-duc, called "Mayerey," is situated between Holland and Guelderland, having Holland to the N., Upper Guelderland and the duchy of Cleves to the E., the quarter of Antwerp to the W., and the bishopric of Liege to the S. It is divided into five small districts, and comprehends 102 villages, and three cities, Bois-le-duc, Helmont, and Eyndhoven. On the 14th of September 1794, an engagement took place near this town between the British army and the French, in which the latter were victorious; and on the 9th of October, in the same year, the town was taken by the French. It is 18 miles E. N. E. of Breda, and 42 S. S. E. of Amsterdam. N. lat. 51° 42'. E. long. 4° 59'.

Bois, St. Marie, le, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Charolles, 7 miles S. E. of Charolles.

Bois d'Oingt, a town of France, in the department of the Rhone, and chief place of a canton, in the district of Villefranche, 4½ leagues N. W. of Lyons. The place contains 900, and the canton 13,501 inhabitants; the territory comprehends 192½ kilometres, and 18 communes.

BOISEAU, in *Commerce*, a measure of two bushels and half of a peck at Bourdeaux in France.

BOISMONT, NICHOLAS THEINEL DE, in *Biography*, abbot of Grestain, preacher in ordinary to the king, doctor in theology, and member of the French academy, was born in 1715, and obtained great reputation for eloquence, particularly in the composition of funeral orations. His principal works are, a panegyric of St. Lewis, and funeral orations on the Dauphin, on the queen of Lewis XV. and on that king himself. These pieces are distinguished by great fertility of ideas, a rapid and animated style, lively and noble imagery, and philosophical reflection. On sterile subjects, the orator exercises too much art in decoration, and is too fond of antitheses. He is reckoned, however, the most eloquent of French orators in this department, and M. D'Almbert has alluded to him in a strain of high applause in his eulogy of Flechier. *Nouv. Dict. Hist.*

BOISROBERT, FRANCIS LE METEL DE, a man of wit and pleasantry, much favoured by cardinal Richelieu, was born at Caen in 1592, and contributed much to the establishment of the French academy, of which he was a member. He wrote poems, comedies, tragedies, tales, letters, romances, &c. which succeeded for a time, but are now almost forgotten. He was the amusing companion of Richelieu, and gained by his buffooneries the abbacy of Châtillon-sur-Seine, though his habits were far from being clerical. He was generous and beneficent, and took pleasure in serving men of letters. He died in 1661. *Nouv. Dict. Hist.*

BOISSARD, JOHN JAMES, an eminent antiquary, was born at Befançon in 1528, and travelled for the purpose of collecting antiquities, into Italy, the isles of Corfu, Cephalonia, and Zante, and the Morea. After his return home, he was made governor to the sons of the baron de Clerveut, and travelled with them into France, Germany, and Italy. Having lost a great part of his valuable collection at Montbelliard, when the Lorrainers ravaged Franche Comté, he took pains in repairing his loss, and published his great work, much valued by antiquaries, and now scarce, entitled "De Romanæ urbis topographia et antiquitate," in 4 vols. fol. 1597—1602, enriched with many engravings by Theodore de Bry, and his sons. He also published a work, entitled "Theatrum vitæ humanæ," 1597—1599, 4to. consisting of the lives of 198 illustrious persons with their portraits. His "Book of Emblems" was published, with figures, by Theodore de Bry, in 1593, 4to. His Latin verses were inserted by Gruter, in the "Deliciæ Poetarum Gallorum;" and after his death was printed his work "De Divinatione et magicis prestigiis," fol. He finally settled at Metz, and died there in 1602. *Gen. Dict. Nouv. Dict. Hist.*

BOISSEAUUX, in *Geography*, a town of France, in the department of the Loiret, 4 leagues N. of Neuvill.

BOISSEZON d'Aumontel, a town of France, in the department of the Tarr, and chief place of a canton in the district of Castres, 2½ leagues E.S.E. of Castres.

BOISSIERE, LA, a town of France, in the department of the Somme, and chief place of a canton, in the district of Montdidier, 2 leagues E.N.E. of Montdidier.

BOISSIEU, BARTHOLOMIW, CAMILLUS DE, son of a physician at Lyons, was born in the year 1734. His father dying when he was only six years of age, his mother is said to have taken on herself the care of his education, until he was sufficiently advanced to be fit to be sent to Montpellier. Passing through the usual stage, in 1756 he was admitted doctor in medicine, and went thence to Paris, where he continued his studios for twelve months longer. He here became acquainted with Sauvage, with whom he afterwards kept up an epistolary correspondence. He now returned to Lyons, and was admitted of the college of

physicians, and attained to considerable practice. His career was however short, for he died in 1770, aged only 36 years. He was author of two dissertations, the one on the power of antiseptic medicines, the other containing a comparative view of the cordial or heating, and the cooling or antiphlogistic, mode of treating fevers, and gives the preference to the latter. He received for each of them a medal from the academy at Dijon. They were published in the years 1770, and 1772. *Eloy. Dict. Hist.*

BOISSY, LOUIS DE, a dramatic writer of France, was born at Vic, in Auvergne, in 1694, and, though originally destined for the church, indulged his more prevalent inclination to the theatre. His first performance was a tragedy, which failed of success; but he was more prosperous in comedy. His best pieces are "L'Impatient," "Le François à Londres," "Les Dehors Trompeurs," "Le Babilard," "La Surprise de la Haine," "Le Compte de Neuilly," and "La Pièce sans Titre." Boissy's distinguishing merit consisted in availing himself of the ridicule of the day. His verses are often ingenious, but his plots are defective. He became a member of the French academy in 1751: and had the honour of reviving the credit of a periodical publication, called the French Mercury. He died in 1758. His dramatic works have been collected in 9 volumes, 8vo. *Nouv. Dict. Hist.*

BOISSY, St. Ager, in *Geography*, a town of France, in the department of the Seine-et-Oise, and principal place of a canton, in the district of Corbeil; the place contains 47, and the canton 14,224 inhabitants; the territory comprehends 177½ kilonnetres, and 26 communes.

BOISZKY, a town of Poland, in the palatinate of Bielsk, 12 miles S.W. of Bielsk.

BOITIAPO, in *Zoology*, a sort of serpent that inhabits Brazil, and is called by the Portuguese *cobra de cipo*. This is an ambiguous species. It is described as being seven or eight feet long, as thick as a man's arm, round, and pointed towards the tail, like a shoemaker's awl. The body covered with fine sub-triangular scales, the colour olive and yellowish. It lives on frogs, and must be of the poisonous kinds, since its bite is represented dangerous.

BOITMANZDORF, or BOESDORF, in *Geography*, a town of Silesia, in the principality of Neysf, 5 miles N.N.E. of Neysf.

BOITZENBURG, a town of Germany, in the circle of Upper Saxony, and Ucker Marck of Brandenburg, 8 miles S.W. of Prenzlau.

BOITZENBURG, or BOTZENBURG, a town of Germany, in the circle of Lower Saxony, and duchy of Mecklenburg, at the conflux of the Boitze and the Elbe. It was surrounded with walls in the 14th century; at this town, vessels that pass the river pay a toll, producing annually 40,000 dollars, of which the duke of Mecklenburg-Strelitz is entitled to 9000; 3 leagues E. of Lauenburg.

BOIVIN, LOUIS, in *Biography*, a distinguished scholar and pensionary of the academy of belles lettres, was born at Mentreuil l'Argillé in Upper Normandy, and educated, first under the Jesuits at Rouen, and afterwards at Paris, where he settled. His acquirements in literature were various and extensive; but his temper, according to his own account, was intractable and unfocial, enterprising, vain, and versatile. He was employed by several eminent magistrates as the associate and director of their private studies; but the litigiousness of his disposition involved himself in great trouble and expence. He published some learned dissertations on historical subjects, in the "Memoirs of the Academy of Belles Lettres;" and made great progress towards a new edition of Josephus. He died in 1724, aged 75 years.

BOIVIN, JOHN, a younger brother of the preceding, was born in 1612, and instructed by his brother, established his reputation as a man of letters at Paris, at the age of 18 years. His disposition was a counterpart to that of his brother, and he was much esteemed for his amiable temper and manners. The abbé de Louvois assigned him a considerable pension, and in 1714 procured for him the place of under-keeper of the king's library. In 1721, he was admitted member of the French Academy, and became pensionary of that of belles lettres in 1724, on the death of his brother. He excelled in the Greek language, of which he was professor in the royal college. His printed works are "An apology for Homer, and the shield of Achilles," 12mo: a French translation of "Homer's Batrachomyomachia;" a French translation of the "Oedipus of Sophocles, and the birds of Aristophanes;" "Greek Poems," much admired for their anaacreontic delicacy; an edition of the "Mathematici Veteres," 1693, fol.; a Latin "Life of Claude Pelletier;" a Latin translation of the "Byzantine History of Nicephorus Gregoras, with notes," 1702, which is esteemed faithful, learned and elegant. He also published several dissertations on historical and literary topics in the "Memoirs of the Academy of Belles Lettres." He died in 1726. *Nouv. Dict. Hist.*

BOIUM, in *Ancient Geography*, one of the four principal cities of the Doride country in Greece. It was seated on the river Pindus, to the east of Erineus.

BOKEA, in *Botany*, (*Aubl. Guian. Sup.* 38. t. 391.) fructification unknown.

Species. *B. pronacensis*. A tree sixty feet high, three feet and a half in diameter. *Trunk* with a greyish, smooth bark, throwing out at its summit a great number of branches, some upright, others inclining, and almost horizontal, which spread in all directions. *Leaves* alternate, oval lanceolate, entire, terminated by a long, tender point, smooth, firm, green, on short petioles; two caducous stipules at the base of each petiole; the exterior part of the wood is white, the interior brown, intermixed with yellowish green. The latter is very firm and compact. It is a native of Guiana. See *La Marek. Eye. Method.*

BOKELMAN, JOHN FREDERIC, in *Biography*, published the beginning of the last century at Leyden, "*Medicus Romanus servus, sexaginta solidis aestimatus.*" On this subject, a most interesting controversy was carried on some years after, between Drs. Mead and Middleton, in which many of the literati took part; and this dissertation, originally written to convey a censure on Drelincourt, was republished. The subject will be noticed again in the life of Dr Mead. *Haller Bib. Med.*

BOKENEM, in *Geography*, a town of Germany, in the circle of Lower Saxony, and bishopric of Hildesheim, 16 miles S.S.E. of Hildesheim.

BOKET, a town of Germany, in the circle of Franconia, and bishopric of Wurtzburg, 4 miles N. of Kissingen.

BOKHARA, BUCHARIA, or BOGAR, a famous city of Great Bucharia (see *BUCHARIA*), seated on the river Sogd, in that district, lying N.E. of the river Jihon, or Oxus, called Sogdiana, or Al Sogd. It is situated very advantageously for trade, in a delightful and fertile country, and has repeatedly contested the metropolitan dignity with Samarcand. Besides its own wall, which was very strong, it had an outward inclosure, comprehending not only the suburbs, but a district about four leagues in extent on each side, which contained several villages and farms, watered by the river Sogd. The Sogd, which is the valley or plain of Samarcand on the east, and the mountain called Vorka on the north, were the boundaries of this territory; although its jurisdiction ex-

tended to several towns which were situated beyond its great wall. Mirkhond, in his history of the posterity of Japhet, affirms, that Bokhara was the capital of Turquestan, in the time of Oguz Khan, one of the most ancient kings of the Moguls, or Tartars, and reckoned by the Mahomeddan Tartars the eighth in descent from Japhet; and enumerates several towns which were dependent upon it. Bokhara afterwards became the capital of the state of the Samanides founded by Ismael, the great grandson of Saman, in the year of the Hegira, 297, or of Christ 909, under the caliph Motadhed. After the fall of the empire of the Samanides, the Moguls of Cathai made themselves masters of this city; but it was retaken by Mohammed, king of Karafin, in the year of the Hegira 594, or A.D. 1197. This conquest of the Karafinians alarmed the nations of the north, and drew towards Jihon very powerful armies of Moguls and Tartars, who desolated some of the finest provinces of Asia. In the year of the Hegira 617, or A.D. 1220, Jenghiz Khan, after a siege of some continuance, took this city, and ordered it to be set on fire; so that nothing of it remained, except the sultan's palace, called "Ark," constructed of stone, and some few private houses built of stone, all the rest having been wooden edifices. He then caused a search to be made in the palace and houses, and commanded all the soldiers, who had concealed themselves, to be put to death. Bokhara continued for some years in this desolate state; but at length the Khan ordered it to be rebuilt, not long before his death. In the year of the Hegira 772, A.D. 1370, Tamerlane took this city from sultan Hassain, who was the last prince of the house of Jenghiz Khan; and the Timurides, or descendants of Tamerlane, retained possession of it till about the year of the Hegira 904, A.D. 1498; when Babur was despoiled of all his territories in Transfoxana and Khorasan by Schaibek Khan, who obliged him to fly to India; and from that time Bokhara has always belonged to the Usbeks, who have maintained it by frequent wars with the Persians. *Herbelot Bib. Or.* p. 190.

Bokhara was eminently distinguished in former times by the arts and sciences which flourished in it, and by its famous university, to which students resorted from all parts, and in which the celebrated Avicenna was educated. As an emporium of commerce, it was also no less famous. To this place merchants repaired from all parts of India, from the different countries inhabited by the Tartars, from Persia, and even from the dominions of the grand signior on one side, and from Russia and Poland on the other; so that in the warehouses and markets of this city might be seen a great variety of oriental and European merchandize. About the middle of the 16th century it was visited by Anthony Jenkins, an Englishman, whose curious and interesting account of the mart of this city has been translated into several languages, and copied by the best writers. See *Hackluyt's Collection*, p. 355. At that period, indeed, it sustained some injury from the vicinity of Samarcand; but since it became the seat of the khan of the Usbek Tartars, who is master also of Samarcand, which he visits only in the summer season, its commerce has revived, to which the convenience of its situation in no small degree contributes. When it was visited by the English agents in 1741, (see *Hanway's Travels*, i. 242.) it was large and populous, subject to its khan; standing on a rising ground, with a slender wall of earth; the houses of clay, but the numerous mosques of brick. The citizens manufactured soap and calico; and the chief products were cotton, rice, and cattle. From the Kalmuks they received rhubarb and musk; and from Badakshan, they used to receive lapis lazuli, and other precious stones; that city being computed at 16 days' journey from Bokhara.

Bokhara. There was gold and copper coin; and after Nadir took this city, the Persian and Indian silver became common. The inhabitants were civilized, but perfidious. In the 10th century it was distinguished by the manufacture of fine linen. N. lat. 29° 24'. E. long. 62°.

BOKI, a river of Africa, which rises in the country called Jalionkadov, between the heads of the Senegal and Johba, and joins the Barching, or an arm of the Senegal, in the district of Brooko, in N. lat. 13° 11'. W. long. 8° 31'.

BOKIRA, a river of India, which runs into the sea, 50 miles W. of Junagur.

BOKSAN, a town of Hungary, 10 miles south of Lugos.

BOL, FERDINAND, in *Biography*, a painter of history and portrait, was born at Dort in 1611, educated at Amsterdam, and placed as a disciple in the school of Rembrandt. He was chiefly distinguished by his portraits, which he painted in a free, bold manner, but not with that clearness of flesh, and remarkable relieve, for which his master was famous. His colouring was too much tinged with brown in the carnations; but with this exception, his portraits had a great appearance of life and nature. As a painter of history, he manifested a good taste of composition, as well as a tolerable expression in some of his figures; but he was deficient in grace and elegance. His "Appointment of the 70 elders in the camp of the Israelites," and "Moses breaking the tables of stone," in the council chamber of Dort, are well designed and executed. In the chamber of the burgo-masters there is an historical picture of "Fabricius in the camp of Pyrrhus," which is exceedingly admired. The etchings of this artist are bold and free. The following, from his own compositions, are generally much esteemed; viz. "Abraham's Sacrifice," "St. Jerom, seated in a cavern, holding a crucifix," and a "Philosopher, holding a book." Bol died in 1681. Pilkington and Strutt.

BOL, JOHN, a painter of landscapes, history, and animals, was born at Mechlin in 1534, and completed his studies at Heidelberg. His subjects were views of several cities and towns in the Low Countries, and different prospects of Amsterdam; and in his pictures the vessels, with the reflections of them from the water, are admirably executed. His invention and composition were very pleasing; his colouring possesses great harmony and union; and his manner of sketching and pencilling is broad and free. Van Mander highly commends one of the paintings of Bol, in distemper, the story of which is "Dædalus and Icarus." This artist etched a set of landscapes, which are "views in Holland," in the style of a master. He died in 1593. Pilkington and Strutt.

BOLA, in *Ancient Geography*, a town of Italy, the capital of the country of the Æqui, situate, according to Plutarch, 30 miles from Rome. Pliny places it in Latium. See ÆQUI.

BOLABOLA, more usually pronounced BORABORA, in *Geography*, one of the Society islands in the southern Pacific ocean, situate four leagues N. W. of Otaha, and inferior to it in extent, being about seven leagues in circumference. The reef that surrounds it is nearly full of islets, much larger than those that are scattered among the rocks, enclosing Otaha and Ulietea. It differs from those islands, and from Huaheine, in having only one harbour on its coast; whereas the shores of the others, being strongly indented, form, like the coasts of Eimeo, numerous places of shelter for shipping. It is also distinguished by a very lofty, double-peaked mountain in its centre, and is more rude and craggy than the other Society isles. Its eastern side appears barren; the western is more fertile; a low border, which surrounds

the whole, and also the islands on the reef, are productive and populous. Its earliest inhabitants are said to have been malefactors banished from the neighbouring islands. As their number rapidly increased, and their military prowess gained reputation, they established their authority in Ulietea and Otaha, and also in Maurōva and Toobāe. Their conquests acquired so much respect, that the supposed tutelary divinity of Bolabola, named Oorā, or Oraa, had been adopted by the people of Teiarraboo, in preference to two imaginary deities whom they formerly worshipped. The Bolabolan warriors are punctured in a different manner from those of the more eastern islands. Bolabola was discovered by captain Cook, together with the group called by him the "Society islands," in July 1769; but though he took possession of it in the king's name, he did not land upon it either in his first or second voyage. But in 1777, he landed on this island, notwithstanding the account which he had received of its inhabitants, and was introduced to Opoone, who had been represented as a very formidable chief, but whom he found old and feeble, though still much esteemed and feared. Opoone was succeeded in his government of this and the neighbouring islands by his daughter, who, in 1774, at the age of 12 years, had been betrothed to a chief named Boba, who governed Otaha under Opoone, and was designed to succeed him in the sovereignty. In 1791, when captain Edwards visited Bolabola, a man named Tatahoo, had the chief authority. S. lat. 16° 32' 30". W. long. 151° 52'. Missionary Voyage. Intro. p. 41.

BOLACA, in *Ancient Geography*, a town of Peiopponefus in Triphylia, a country of Elis. Polybius.

BOLAVOSANSKA, in *Geography*, a town of Siberia, in the government of Irkutzk, 80 miles N. W. of Ilimsk.

BOLBACH, a river of Germany, in the duchy of Stiria, which rises in a lake, 10 miles S. W. of Voitzberg, and runs into the Sulm, near Wipplepach.

BOLBÆ, in *Ancient Geography*, a town of Asia Minor, in Caria, called also Heraclea.

BOLBE, a marsh of Macedonia, near the Ionian sea, before Apollonia, according to Scylax.

BOLBEC, or BOLLEBEC, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Havre; the place contains 4921, and the canton 14,171 inhabitants; the territory comprehends 105 kilometres, and 18 communes.

BOLBENA, in *Ancient Geography*, the name of a country in Asia, in the greater Armenia. Ptolemy.

BOLBITINA, a town of Egypt, situate near the second mouth of the Nile, adjoining to the spot where Rosetta now stands.

BOLBITINUM *Ossium*, a name given by Ptolemy and Pliny to the second mouth of the Nile, from that of the town, Bolbitina, seated near the canal called "Tuli." The Bolbitine branch is now called that of Rosetta, Rosetta, or Raschid, which see. Strabo informs us (l. 17. tom. ii. p. 1153.) that under the reign of Ptolemy, the Milesians, with 30 vessels, landed at the Bolbitine, or Bolbitic branch, and there fortified themselves.

BOLBONACH, in *Botany*. See LUNARIA.

BOLBULÆ, in *Ancient Geography*, a name given by Pliny to an island of Asia Minor, situate on the coast of Ionia.

BOLCA, in *Geography*, a branch of the Tyrolese Alps, situate 50 miles N. W. of Venice, and noted for fossil salt, in argillaceous schist.

BOLCHERETSKOI, a town of Kamshatka. N. lat. 52° 54' 30". E. long. 156° 37' 30".

BOLCHOF, or **BOLKOF**, a town and district of Russia, in the government of Orel, seated on the river Nugra, falling into the Oeca; 32 miles N.N.W. of Orel.

BOLD SHORE, in *Sea Language*, a steep coast or shore, so that ships may approach close to it.

BOLDSON, an island of Sweden, in the province of Hallingland, having a good harbour.

BOLE, in *Mineralogy*, *Bol*, Germ. *Bol*. Fr. *Argilla bolus*, Werner. The colour of bole is generally an obscure fabella yellow, or reddish, or whitish brown; it is also sometimes, though rarely, met with of a greyish yellow, or fleshed; its surface is often marked with black spots and dendritic figures. It occurs generally massive, seldom disseminated. Internally it exhibits a slight glimmering lustre. Its fracture is perfectly conchoidal. It flies, when broken, into irregular, sharp-edged fragments. The dark coloured varieties are opaque, the lighter coloured are more or less translucent. It has a greasy feel; adheres strongly to the tongue; gives a shining streak; is very soft, and easily frangible. Sp. gr. 1.4 to 2.

When put into water it absorbs a portion with great eagerness, and then breaks down into small fragments, with a very sensible crackling noise; but is not reduced to an impalpable powder. When finely pulverized, and diffused through boiling water, it remains suspended in this fluid a much less time than any of the plastic clays, and is entirely separable by the filter.

Before the blow pipe it turns black, and melts without addition, though with some difficulty, into a porous, greenish, grey slag.

According to a somewhat inaccurate analysis of Bergman, the Lemnian bole contains

Siliceous Powder	-	47.
Carbonated lime	•	5.4
Carbonated magnesia	-	6.2
Alumine	-	21.
Oxyd of iron	-	5.4
Moisture and volatile matter		17.

102.0

Bole occurs in beds of wakke at Strigau in Silesia, and in basalt at Scheibenberg in Saxony; it is found also in Tuscany and Sienna in Italy, and in the island Lemnos in the Archipelago.

The only use of bole, at present, is as a coarse red pigment; for which purpose it is calcined and levigated, and is vended in Germany under the names of Berlin and English red. Anciently, however, a very high rank was assigned to bole among the articles of the *Materia Medica*; it was considered as a powerful astringent, sudorific, and alexipharmic, that from Armenia and Lemnos being particularly esteemed. The Lemnian bole, in the time of Dioscorides, was dug up in the presence of the priests of Venus, and after being mixed by them with goats' blood, was moulded into cakes, which were impressed with the figure of a goat, in order to authenticate them; hence it was called *Σφραγίς αιγός*, *sigillum caprinum*: It still continued to be a consecrated remedy even in the 15th century; according to Beson, the vein was opened annually on the 6th of August, and after prayers said by the priests, as much of the earth was taken out as was thought sufficient for the ensuing year; the entrance to the vein was then closed, and the severest punishments were denounced against any one who should open it without permission. Part of the earth was sent to Constantinople, where it was made up into small cakes, and received the seal of the emperor; the

remainder was prepared in the island itself, and was impressed with the seal of the governor. The profits of this manufacture were too considerable not to be encroached upon, and the solar earths, and even the clayey marls of Italy, France, and Germany, obtained a place in the *Materia Medica*, under the general name of *Terra sigillata*, from which, however, they, together with the Lemnian earth, have, been at length deservedly excluded.

BOLE is also used for the body or trunk of a tree; and hence boring trees are those whose heads and branches are cut off.

BOLEMOW, in *Geography*, a small town of Poland, in the palatinate of Rawa.

BOLENA, a town of the Morea, in the duchy of Clarence, 5 leagues from the gulf of Lepanto; the see of a bishop, suffragan of the archbishop of Patras.

BOLENBERG, a small town of the duchy of Mecklenburg, on the Baltic.

BOLENE, or **BOLLENE**, a town of France, in the department of Vaucluse, and chief place of a canton in the district of Orange, 3 leagues north of Orange. The town contains 4064, and the canton 10,852, inhabitants; the territory comprehends 132½ kilometres, and 7 communes.

BOLENIÆ, or **ΒΟΡÆ**, in *Natural History*, a name given by ancient writers to a sort of stone of a roundish figure, and marked with several ridges and lines. They are supposed to be the same with those called *Brontia* and *Ombria*, both being imagined to fall from the clouds in time of thunderstorms; but they are really no other than a common species of *Echinita*.

BOLERA, in *Geography*, a town of Spain in Arragon, 4 leagues from Huesca.

BOLERAZ, a small town of Lower Hungary, in the upper outward district of the county of Presburg.

BOLESKO, a town of Hungary, 28 miles north of Topoltzan.

BOLESLAW, or **BUNTZLAW**, a circle of Bohemia, on the confines of Lusatia and Silesia, from which it is separated by mountains. The capital is Buntzlaw.

BOLESLAWIEC, a town of Poland, in the palatinate of Siradia, 24 miles S.S.W. of Siradia.

BOLETUS, in *Botany* (Gr. *βωλίτη*; from its globular form), a genus of the class *cryptogamia*, and of the order *fungi*, formed by Linnæus, and distinguished from the agarics by having what is generally the lower surface composed of tubes instead of gills. The name was given by the Romans to a species of esculent fungus, esteemed by them a great delicacy, and celebrated by their historians and poets for being the vehicle of the poison administered to Claudius Cæsar, by his wife the younger Agrippina. This has been generally supposed by modern botanists to be the *Agaricus xerampelinus*, thence called by Scheffer *Cæsareus*; but Withering thinks it was the *deliciosus* of Linnæus. See *AGARIC*.

Among the moderns it was first adopted as a generic name by Tournefort, who applied it to the common morel, the fungus faviginosus of some of the older botanists, afterwards referred by Linnæus to his genus phallus. La Marck, displeased with Linnæus for altering Tournefort's names, has restored the name boletus to the morel, and has separated it from phallus on account of its not being perforated at its summit. He has, in consequence, divided Linnæus's genus boletus into two; calling those that are sessile and woody, agaricus, and those that are pedicelled and soft, fuillus. The Linnæan agaricus he has named amanita, as Dillierius and Haller had done before him. Jussieu and Poiret concur with him in these alterations. But this, as Boiss well observes (Nouveau

BOLETUS.

Dictionary, sub voce Boletus), is to increase a confusion already too great, and to overturn a nomenclature which has been generally adopted in Europe since the publication of the sexual system. For, however Linnæus may in some cases have capriciously changed ancient names, and however it may be wished that, in the present instance, he had called his boletus, agaricus, which would have preserved to the official agaric its customary generic denomination, it is better to let things remain as they are, than again to unsettle the language of the science, and thereby to impede its farther advancement. We shall, therefore, go on as we have begun, in adhering strictly to the Linnæan nomenclature, where we are not induced to depart from it by weighty scientific reasons.

Linnæus has enumerated only fourteen species, and Reichard has made no addition to the number. Gmelin has extended them to a hundred and seven; but there is reason to suspect, that he has sometimes given the same species more than once under a different name. The settling of synonyms is in every part of botany an intricate and often unsatisfactory business, but peculiarly so in the class *cryptogamia*. Withering, in the third edition of his Arrangement of British plants, has described fifty-one species, many of which have several varieties. In this number are included eight of the Linnæan species. He disposes them under three grand divisions, as they have central, lateral, or no stems; and subdivides them according to the colour of their tubes. None of them being cultivated, we shall confine ourselves to those which are of British growth.

Stem Central.

* *Tubes white*. 1. *B. pellucidus*. "Tubes decurrent, very short; pores minute, angular; pileus concave, rich brown, scaly; stem whitish, thick, short." 2. *B. subfuscus*. "Tubes very short; pileus light brown, smooth, clothy to the touch, regularly convex; flesh very white; stem pale brown, covered with a beautiful white net-work over its whole surface; root conical; resembles the elephantinus in habit." 3. *B. cyanescens*. "Tubes brownish with age, not decurrent; pileus brown, convex, very fleshy; flesh white, changing to a fine blue when exposed to the air; stem brown, rounded at the base." 4. *B. polyporus*. "Tubes very short; pores circular, extremely minute; pileus brown, irregular; flesh very thin; stem brown, varying from perfectly central to perfectly lateral, tough, thickening upwards." 5. *B. leptocephalus*. "Tubes very short; pileus tawny bay, flat, thin, leather-like; stem brownish, thick as a crow-quill." First observed in Britain by Mr. Dickson, growing on rotten sticks. 6. *B. aurantiacus*. "Tubes not decurrent, readily parting from the pileus; pileus convex, full orange-red, viscid, thin at the edge, and without tubes for about one-tenth of an inch; stem whitish, rough, with coloured pimples, spongy, filken." It is eaten in France when young. * *Tubes brown*. 7. *B. bovinus*, Linn. "Tubes not touching the stem, unequal in length; pileus thin at the edge, brown or olive, clammy, large; flesh spongy, white; stem dirty white, with reddish stains, from three to seven inches high, and about an inch in diameter." It varies in the colour of its tubes and pileus, and in the smoothness or roughness of its stem. 8. *B. subsquamosus*. "Tubes decurrent, oblong; pileus yellowish brown, with red brown, scurfy, scales, the centre hollowed; flesh solid, pure white; stem brownish, tapering downwards." 9. *B. perennis*, Linn. "Tubes decurrent, not separating from the pileus, very short; pileus flattish, hollow in the centre, striated with hairs, marked with alternate circles of brown and tawny, leathery; stem red brown, often excentric, short, wiry, frequently coming up so thick that the piles run into one another." There

is a variety of a cinnamon colour, within and without, the *B. cinnamomeus* of Jacquin, first found in this kingdom by Mr. Dickson. 10. *B. fulmentosus*, Linn. "Tubes rather angular, of different shapes; pileus yellow, convex, fleshy, somewhat woolly; stem yellow." 11. *B. rubecularius*. "Tubes olive-colour, fixed to the stem; pores rich red brown, mostly oval; pileus red cinnamon, convex, soft to the touch, rather clammy; flesh thick, spongy, buff-colour, instantly turning blue when wounded; stem red cinnamon, spongy within, and rich yellow, but instantly changing to a blue." 12. *B. piperatus*. "Tubes decurrent, deep orange, or earthy red; pores browner, open, irregular; pileus yellow, smooth, nearly flat, thin at the edge; stem greenish yellow." Its pungency on the tongue and throat is like that of a capficum. First found in England by Mr. Sowerby, in Hainault forest, Essex. * *Tubes buff*. 13. *B. nummularius*. "Tubes loose from the stem, very short; pores angular; pileus colour of brown horn, with a black circle at the edge, convex, dimpled, leathery, smooth, very thin, about an inch in diameter; stem colour of brown horn, black at the base, smooth." Chiefly found on rotten branches of hazle. 14. *B. nigripes*. "Tubes decurrent, very short; pileus whitish, the size of a sixpence; stem black at the bottom." * *Tubes yellow*. 15. *B. elephantinus*. "Tubes short, adhering firmly to the pileus; pileus dead white, convex, but very irregular; stem yellow, thick and short." 16. *B. edulis*. "Tubes not fixed to the stem, readily parting from the pileus; pores circular, small; pileus brown, with rust-coloured patches, nearly globular, seven or eight inches across when fully expanded; flesh white, greenish when wounded; stem light brownish yellow, tapering upwards." Bulliard reckons it a variety of *bovinus*. 17. *B. gregarius*. "Tubes short; pores oblong, unequal; pileus chestnut, smooth, thin, flattish; flesh white, about three inches over; stem pale chestnut, pinky below, insensibly swelling into the pileus. 18. *B. luteus*. "Tubes readily separating from the pileus; pores round, small; pileus deep bay, rather conical, striated, viscid; flesh white, not changing; stem dirty white, cylindrical, widening at top; ring permanent." 19. *B. olivaceus*. "Tubes instantly turning blue when wounded; pores bright yellow, round or oval; pileus olive-brown; flesh bright yellow, turning blue when exposed to the air; stem brown below, yellow or crimson above." 20. *B. sanguineus*. "Tubes a little decurrent, unequal in length, changing to deep blue; pores lemon-yellow, angular; pileus crimson, changing to rich red brown, semi-globular; flesh white, changing slowly to a bluish cast when wounded; stem yellow, with broad crimson streaks, apparently twisted." Found by Dr. Withering, near Birmingham, but only in one place. 21. *B. chrysenteron*. "Tubes decurrent; pileus gently convex, pinky-red; stem yellow below, pinky upwards, swelling in the middle." 22. *B. flavus*. "Tubes a little decurrent; pores irregular in shape and size; pileus convex, deep orange when young, shining with a viscid varnish; stem yellow, cylindrical; curtain white, leaving a ring." 23. *B. lactifluis*. "Tubes in contact with the stem; pores very minute; pileus reddish-buff, very convex, viscid; stem bright yellow." The plant abounds with a mild milky juice. Its flavour is like that of the agaricus campestris. 24. *B. substrictus*. "Tubes short; pores minute; pileus yellow, brown, olive, convex, thin, smooth, leathery; flesh thin, white; stem dirty yellow, hard, tough, sometimes excentric.

Stem lateral.

* *Tubes white*. 25. *B. albidus*. "Tubes decurrent, not perpendicular to the pileus; pores angular, very irregular in shape; pileus white, lobed; stem solid, sometimes only a knob." The whole plant white, with a cottony substance,

which

which is easily rubbed off. 26. *B. rugosus* (*lucidus*, Curtis). "Pores very small; pileus chestnut coloured, shining, flat, marked with concentric grooves; edge thick, wrinkled; stem chestnut coloured, hard, uneven, shining." 27. *B. frondosus*. "Tubes decurrent; pores very small, sometimes confluent; pileus brown, lobed, tiled, leathery; stem black at the base, very irregular and misshapen; sometimes nearly two feet across." 28. *B. betulinus*. "Tubes very short; pileus pinky-brown, smooth, oblong, convex, thin, curled in at the edge; flesh white; stem black; whole plant leathery." 29. *B. cristatus*. "Tubes short, not separating; pores irregular; pileus golden yellow, variously shaped, jagged, curled; stem brown, woody, distorted, thick, porous." 30. *B. squamosus*. "Tubes short, slanting; pores large, angular; pileus pale buff, pencilled with feather-like scales; flesh firm, white, elastic; stem dark coloured, white within." * *Tubes yellowish*. 31. *B. rangiferinus*. "Tubes decurrent, ragged at the extremity; pileus an expansion of the stem, dirty yellow; stem dark brown, with one or more lateral branches, splitting at the end into several horn-shaped branches, either expanding into the pileus, or barren with yellow tops." The whole plant resembles the palmated branches of some of the larger species of deer. 32. *B. calcicolus*. "Tubes decurrent; pores small, unequal; pileus deep buff to chestnut, of a substance like cork, hollowed in the middle, thin, and waved at the edge; stem tough, white, conical." 33. *B. lateralis*. "Tubes very short; pores very minute; pileus yellow, smooth, flat, very thin leathery; stem yellow, spreading out at the top to form the pileus."

Stemless.

* *Tubes white*. 34. *B. suberosus*. "Tubes pointed; pores irregular; pileus white, convex, thin, downy when young, smooth when old, perfectly resembling cork." 35. *B. medullipanis*. "Wholly white, crustaceous, spreading; pores small, on the upper surface only." On decayed wood and branches of trees. 36. *B. salicinus*. "Tubes very short; pileus semicircular, whitish, smooth, thin, soft, leathery." 37. *B. suaveolens* (*discoideus*, Dickson). "Tubes very long, changing first to straw-colour, then to tawny; pores irregular; pileus smooth, semi-circular, white or tawny; flesh yellow brown." 38. *B. spongiosus*. "Pores fringed, angular; pileus often very large, brown, woolly, turning quite black when old." 39. *B. lachrymans*. "Pileus orange coloured, wrinkled, reticulated, with a broad, white, arched border; pores chiefly on the upper surface of the white border." Frequent in damp cellars. 40. *B. variegatus*. "Tubes short, minute; pileus thin, velvety, striped with concentric circles of various colours." * *Tubes brown*. 41. *B. cuticularis*. "Tubes long; pores minute, rich yellow brown; pileus rich dark red brown, semicircular, very uneven, with concentric ridges." 42. *B. cryptarum*. "Tubes very long; pores minute; pileus leathery, thin, supine, becoming woody when old." 43. *B. labyrinthiformis*. "Tubes long; pores sinuous; pileus rugged, zoned, woody; lobes many from one root." 44. *B. unicolor*. "Tubes short; pores labyrinthiformed; pileus leathery, woolly, with different shades of the same colour." * *Tubes red*. 45. *B. laciniatus*. "Tubes very short; pileus brownish, arched, warty, thin, fringed at the edge." 46. *B. alietinus*. "Pores angular; pileus thin, gently convex, wrinkled, woolly, greyish, whiter at the edge." 47. *B. bispidus*. "Tubes fringed; pileus bright red brown, in old age black, rough with bristly hairs." Possibly a variety of the *velutinus*. * *Tubes yellow*. 48. *B. sulphureus*. "Tubes short; pores minute, irregular; pileus bright aurora, streaked." 49. *B. velutinus*. "Pores angular, irregular; pileus large, very irregular in shape, covered with a dense pile of a silvery grey colour." * *Tubes green*.

50. *B. igniarius*. "Tubes very slender; pores very fine, yellowish, changing to red brown; pileus shaped like a horse's hoof, smooth, red brown to blackish." It is the official agaric, the *agaric amadouvier* of La Marek. For the domestic and surgical uses to which it is applied, in different parts of the continent of Europe, and the manner in which it is prepared, see the article AGARIC, in *Pharmacy*. 51. *B. foenicarius*. "Pores circular, equal; pileus white, convex, thick at the edge, uneven."

To these La Marek adds the *agaricus quercinus* of Linnaeus, and observes, that it properly belongs to this species; for though it has the appearance of gills, they are really tubes with large misshapen pores, which near the edge of the pileus have a more regular form. Bulliard and Woodward incline to the same opinion; and we ourselves have already suggested that it seems to connect the agarici with the boleti. See AGARICUS.

BOLETUS (Haller). See HELVELLA MITRA.

BOLETUS (Tournefort). See CLATHRUS CANCELLATUS.

BOLETUS (Tourn. Michel. and Haller). See PHALLUS ESCULENTUS.

BOLETUS (Gled.). See HYDNUM REPANDUM and AURISCALPIUM.

BOLI, or BOLLI, in *Geography*, a town of Asiatic Turkey, in the province of Natolia, 140 miles east of Constantinople, and 74 N.W. of Angora. This town is situated on a small river, which discharges itself into the Black sea. It is the capital of a maritime canton, called by the Turks "Bolivialicti," and in the interior part of its extent very mountainous. N. lat. 40° 45' E. long. 31° 26'.

BOLIDES, in *Meteorology*. See FIRE-BALLS.

BOLINA, in *Ancient Geography*, a sea-port town of the Peloponnesus, in Achaia, near Argyra.

BOLINÆUS, a river of the Peloponnesus, which watered the towns of Argyra and Bolina, according to Pausanias. It discharged itself into the small gulf of Panormus.

BOLINAO, in *Geography*, a sea-port town on the island of Luçon, or Manilla.

BOLINBROKE, a town of America, in Talbot county, on the eastern shore of Maryland, 5 miles E. of Oxford. It lies on the N.W. point of Choptank river.

BOLINGÆ, in *Ancient Geography*, a people of India, near the Indus, mentioned by Pliny, Ptolemy, and Steph. Byz.

BOLINGBROKE, in *Geography*, a small town of Lincolnshire, England, is seated in a valley between the river Witham and the sea-coast. Here was formerly a very considerable castle, which was nearly demolished by Oliver Cromwell and his partizans, who also laid other parts of the town, with the church, in ruins. In the times of feudal vassalage, the castle at Bolingbroke was distinguished among the pompous mansions of the nobles. Here the celebrated John of Gaunt, duke of Lancaster, occasionally held his court, and it was the birth-place of his fourth son, who was afterwards crowned king of England. He was the fourth Henry who sat on the English throne, and from the place of his birth was known by the name of Henry of Bolingbroke. The St. John family also derive the title of viscount from this town. The only manufacture of the place is earthenware, and that is very inconsiderable. In the parish are 72 houses, and 283 inhabitants.

BOLINTHOS, in *Natural History*, a name given by Aristotle, and some of the other ancient Greeks, to the *monops* of Ælian, that is, the BONASUS.

BOLIPLEIKA, in *Geography*, a town of Russia, in the government of Saratof, on the west side of the Volga; 124 miles south of Saratof.

BOLISSUS, in *Ancient Geography*, a town of Asia, in Aolia, near Chio, according to Herodotus. Thucydides (l. 8.) mentions a victory gained by the Athenians over the inhabitants of Chio near this town.

BOLKOF, in *Geography*. See *Волкоф*.

BOLKOWITZ, a town of Silesia, 20 miles south of Glogaw.

BOLLANDISTS, in *Literary History*, a denomination given to certain Jesuits of Antwerp, who were a considerable time employed in collecting the lives and acts of the saints.—Thus called from J. Bollandus, one of the first and chief of the association.

BOLLANDUS, JOHN, in *Biography*, a famous ecclesiastical historian, was born at Tillemont in the Low Countries, in 1596, and educated among the Jesuits, by whom he was employed in collecting memorials of the church-saints, under the title of "Acta Sanctorum." The plan of the work was formed by father Rosweide, and it was to be arranged according to the order of celebrating their memories in the calendar. Bollandus, in 1643, published "The Lives of the Saints of the Month of January," in 2 vols. fol.; followed in 1658, by those of February, in 3 vols. fol. He had begun those of March, when he died in 1665. This work was continued by Henschenius, Papebroch, and others, on a scale of such extent, that the commencement of October reaches the 47th volume folio. *Nouv. Dict. Hist.*

BOLLARDS, large posts set in the ground on each side of a dock. On docking or undocking ships, large blocks are lashed to them; and through these blocks are reeved the transporting haulers to be brought to the capstans.

BOLLEN, in *Geography*, a town of Germany, in the circle of Aultria, and duchy of Carinthia, 7 miles east of Mellitat.

BOLLENZ. See *BREGNO*.

BOLLIN, a river of England, which runs into the Mersey, 4 miles E. N. E. of Warrington.

BOLLITO, in the *Glass Works*, a name by which the Italians called a sea-green colour, or artificial crystal.

To prepare this colour you must have in the furnace a pot filled with forty pounds of good crystal, first carefully skimmed, boiled, and purified, without any manganese; you must then have twelve ounces of the powder of small leaves of copper, thrice calcined, and half an ounce of zaffer powder; mix them together, and put them at four times into the pot, that they may the better mix with the glass; stirring them well at each time of putting in the powder, lest they should swell too much and run over.

BOLLOS, in the mines of Peru, a denomination given to the ingots or bars of silver procured there from the ore by the operation of the fire, and the use of aqua fortis.

BOLM, in *Geography*. See *BULAM*.

BOLNEST, EDWARD, in *Biography*, practised medicine in London in the beginning of the 17th century. He published, in 1605, "Chemia Medicina illustrata," or the true grounds and principles of the art of physic, 8vo. London, and the following year a translation of it into Latin "De lineatio fundamenti art. med.;" also "Auroa chemica seu naturalis methodus preparandi animalia, vegetabilia, et mineralia," 1675, 8vo. An edition of this work was published in English, in 1672. "A rational way of preparing animals, vegetables, and minerals, for physical uses." Haller. *Bib. Med.*

VOL. IV.

BOLNKI, in *Geography*, a town of Lithuania, in the province of Wilna, 14 miles E. S. E. of Wilcomirz.

BOLOGNA, or *BONONIA*, a city of Italy, the capital of the Bolognese duchy, is, next to Rome, the largest, finest, and richest city in the Ecclesiastical State. Its ancient name was *Felina*, derived from Felinus, a Tuscan king, who is supposed to have built it 25 years before the foundation of Rome. The name of Bononia is traced by some to a successor of Felinus, called Boius; but others deduce it from the Boii. Its circuit is between five and six Italian miles, and the number of its inhabitants is estimated at 80,000; but the whole district, which includes 308 cities, towns, and villages, is said to contain 300,000 persons. Its figure is oblong, the length of it much exceeding the breadth; and viewed at a distance, it bears some resemblance of a ship, the tower of Asinelli, which is 371 feet high, being the mast. It is surrounded by a solid and lofty brick wall, well built, and adorned with piazzas, which extend through the streets, and under which passengers may walk without being incommoded by the sun or rain. The houses in general have lofty porticoes, which would have a better effect if the streets were not so narrow; but in this particular, magnificence is sacrificed to convenience, for, in Italy, shade is considered as a luxury. This city is seated at the foot of the Apennines, in an extensive, fertile plain, which liberally supplies the inhabitants with its rich produce. The river Savona washes its walls, and the rivulet Reno passes through it, parting into several small streams; and the latter, by means of a canal, communicates with the Po, and affords great advantage to the city.

The public edifices of various kinds are numerous and magnificent. In the centre of the city stands a high tower, called *Degli Asinelli*, from Gerardo Asinelli, who built it at his own charge in 1109; near it is the leaning tower, called *Garisenda*, which by a fall of part of it is now reduced to the height of 130 feet, and which inclines, so that a plumb-line let down from the top deviates seven feet from the wall at the bottom. Of the palaces in Bologna, that which is denominated the Public Palace is much the most spacious, though not the most elegant. In this the cardinal legate is lodged; and it has also apartments for the Gonfalonier, as well as halls, or chambers, for some of the courts of justice. This edifice contains some very magnificent apartments, and a few good pictures, of which the most esteemed are, a large one, by Guido, of the Virgin, and the infant Jesus, seated on a rainbow; a Sampson, also by Guido, refreshing himself with the water which issues from the jaw-bone, with which he has just defeated the Philistines; and a St. John the Baptist, by Raphael. The first object which strikes the eye of a stranger on his arrival at this town, is a noble marble fountain in the area before the Palazzo Publico. The principal figure is a statue of Neptune, 11 feet high, with one hand stretched out, and the other holding the trident. The body and limbs are finely proportioned, the anatomy perfect, and the character of the countenance severe and majestic. This figure of Neptune, as well as all the others of boys, dolphins, and sirens, which surround it, are in bronze. The whole is the workmanship of Giovanni di Bologna, and is highly esteemed; and yet there seems to be an impropriety in making water flow from the breasts of the sea nymphs or sirens. Over the entrance of this palace is a bronze statue of pope Gregory XIII., weighing 11,300 pounds, and executed by Minganti. Near it is another statue of pope Boniface VIII. The interview between the emperor Charles V. and pope Clement VII. in 1529, when that prince submitted to be crowned by the pope, is recorded by an inscription on a copper-plate. In the Sampieri palace

are several pieces by the three Caraccis; one of the best ever done by Albano, representing Cupid kissing his mother Venus, and, with an air of triumph, pointing at the rape of Proserpine by Pluto; and another, more admired than all the rest, and considered by the judges as the master-piece of Guido, the subject of which is the "Repentance of St. Peter," and consisting of two figures, that of the faint who weeps, and a young apostle who endeavours to comfort him. Although the nobility of Bologna are not now very rich, many of their palaces are furnished in a magnificent taste, and contain paintings, particularly those of the celebrated masters which this city had the honour of producing, that are their chief ornaments, and are held in high estimation. The palaces were built, and ornamented, when the proprietors were richer, and when the finest works of architecture, sculpture, and painting, could be procured on easier terms than at present. The galleries and apartments are spacious and magnificent; and yet there are circumstances in the most splendid, that must hurt the eyes of those who are accustomed to that perfect exactness in finishing, which prevails in English houses. The glass of the windows of some palaces is divided into little square panes, which are joined together by lead; and the floors of all are so indifferently laid, that you often feel a loose brick shaking under your feet, as you walk through the finest apartments.

Bologna is also embellished with a great number of churches and convents, which are enriched with a variety of paintings, sculptures, &c. Of the churches, of which there are said to be 200, that of St. Petronius is the largest. In this church the emperor Charles V. was crowned in 1530; and on the pavement of it, Cassini drew his meridian line, consisting of pieces of red and white marble inlaid, of a hand's breadth; those in which the signs of the zodiac are cut, are a foot square. This line is half the length of the church, which is 360 feet; and at its commencement is a Latin inscription, expressing that "the whole length of this meridian line, distinguished by the signs, &c. is the six hundred thousandth part of the circumference of the terraqueous globe." On the pavement, at the end of the line, is an inscription in white marble, denoting "the meridian line from the zenith to the tropic of Capricorn." Opposite to the vertical point, is the date MDCLII. A small round aperture has been made in the roof of the church, towards the south, through which the rays of the sun form a circular luminous spot, about eight inches in diameter, on the pavement, which shews the proper meridional point on the line every day. The church of the Dominicans is one of the most magnificent in Bologna. The chapel, dedicated to the honour of St. Dominic, who is said to have died at Bologna in 1221, is much admired. It consists of a curious dome, in which the glittering of gold appears throughout, adorned with the most capital paintings, representing the history of his life. His monument is of white marble, ornamented with beautiful basso-relievos, by Michael Angelo; and the altar, together with the large candlesticks that stand upon it, are of silver. The pavement and the walls are inlaid with marble of different colours. In the vestry is deposited, amidst jewels and various treasures, a manuscript of the Old Testament, or at least of the Pentateuch, pretended to have been written by Ezra himself. See BIBLE. It is a large folio, carefully preserved in a glass case, and was presented to the convent by the Jews, when they removed thither from Rome, and were allowed to erect a noble synagogue about the close of the 14th century. The other principal churches are the Franciscan, in which are paintings by Facini, Luigi, Caracci, Brizio, Guido, and Tiarini; that of St. Agnes, containing, over the high altar, the martyrdom of the saint,

by Domenichino; St. Bartholomew, before which stands a marble statue of St. Petronius, by Brunelli, and in which are an announcement, the nativity, and the flight into Egypt, by Albano; the church of the Capuchins, in the vestry of which is a crucifixion, by Guido; that of S. Giovanni in Monte, famous for an admirable picture of St. Cecilia, by Raphael, which is much extolled by Addison, and reckoned one of Raphael's capital pieces, &c. &c. The convents also are enriched with valuable paintings and other ornaments, as well as the palaces and churches. A Dominican convent, seated on the top of a hill, about three miles from the city, is in possession of a portrait of the virgin Mary, said to have been painted by St. Luke. Sigoni says, that it was brought from the church of Sancta Sophia at Constantinople in 1160; and it is thought to have wrought many miracles in favour of the inhabitants of Bologna. A curious gallery, open to the south and closed by a wall to the north, is built all the way from the city to the convent; on the open side it is supported by a long row of pillars; and was erected by voluntary contribution in honour of the virgin, and for the convenience of pilgrims. This long colonnade is about twelve feet in breadth, from the pillars to the wall, and about fifteen feet high; all the communities of the town walk, once a year in solemn procession, to the convent, and bring the holy picture to visit the city. It is carried through the principal streets, attended by every inhabitant who can afford to purchase a wax taper. During this procession, the bells continue ringing, the cannon are fired, and the troops under arms practise the same ceremonies when the picture passes, as if it were commander in chief of the forces. In the library of the convent, belonging to the church di S. Salvatore, are many curious MSS.; particularly one of the history of queen Esther, written on yellow coarse leather in large Hebrew characters, and done up in a roll or volume, according to the original signification of the word. The canons pretend that this was written by Ezra. Here is also shewn a Hebrew MS. of the O. T. written on vellum, in 3 vols. fol. said to have been written in 953; it has, however, points or vowels. Among other MSS. amounting to about 300 in number, are the N. T. called the "Codex Bononiensis," said to be of the 11th century, containing the whole N. T. except the apocalypse, abounding with abbreviations; and a Greek version of the minor prophets and Daniel, supposed to be of the 10th century; and among the printed books are Manutius's edition of Cicero's works, 4 vols. fol. published at Milan in 1498, and a Latin bible in folio, which, by a printed advertisement annexed to it, appears to have been completed at Mentz by John Fust and Peter Schoiffer in 1462.

The university of Bologna is one of the most ancient and most celebrated seats of literature in Europe; it was founded, as some say, by the emperor Theodosius in 433, but others, with greater probability, attribute it to Charles the Great. For an account of the academy of sciences, see ACADEMY. Over the gate of the magnificent edifice appropriated to that academy, is the following liberal inscription: "Bononiense Scientiarum atque artium institutum ad publicum totius orbis usum." Here are an observatory, with the necessary instruments for astronomical observations; a very valuable library, in three spacious rooms, where any person may study and have the use of the books four hours every day; also, apartments for the students of sculpture, painting, architecture, chemistry, anatomy, astronomy, and every branch of natural philosophy. They are all ornamented with designs, models, instruments, and every kind of apparatus requisite for illustrating those sciences. There are also professors who regularly read lectures. There is a hall full of models,

models in architecture and fortification, a valuable collection of medals, and another of natural curiosities, as animals, earths, ores, minerals; and a complete collection, to assist the study of the *materia medica*, and every part of natural history. There is also a gallery of statues, consisting of a few originals, and very fine casts of the best statues in Italy. Honorary premiums are distributed every year among the artists, for the best designs in painting, sculpture, and architecture.

The anatomical theatre is adorned with statues of celebrated physicians; and the museum belonging to it supplies an abundance of anatomical preparations, and a complete suite of anatomical figures in wax: a man and woman are exhibited in the natural state; the same with the skin and cellular membrane removed, so that the external muscles of the whole body and limbs appear. In the subsequent figures the more external muscles are gradually removed, till nothing but the simple skeleton remains. These figures are very well formed, preserving the natural appearance and situation of the muscles and blood-vessels with as great exactness as could be expected in a work of this nature. There are also models in wax, of particular parts, and of several of the viscera of the human body separately.

The inhabitants of Bologna carry on a very considerable trade in silks and velvets, and leather bottles, which are manufactured here in great perfection. The country produces immense quantities of oil, wine, honey, wax, flax, and hemp; and furnishes all Europe with hams, dried tongues, sausages, macaroni, sweetmeat, olive, perfumes, wash-balls, liqueurs, and essences. The people are industrious, and allowed to enjoy the fruits of their labour; the nuns are very ingenious in making artificial flowers, and imitating fruits of various kinds; and very beautiful works are also made of walnut-tree and rock-crystal. The markets are plentifully supplied with provisions; fruit is had in great variety, and of excellent quality; and the common wine of the country is a light white wine of an agreeable taste, which is preferred by strangers to any of the French or German wines that may be had there. The inhabitants, in general, are facetious and polite to strangers, who may receive at Bologna every kind of accommodation that may suit their taste.

Bologna long retained the name of a republic, sent an ambassador to the pope's court, and the word "Libertas" was inscribed on the arms and coin of the state, with the flattering capitals S. P. Q. R. The civil government and police of the town were allowed to remain in the hands of the magistrates, who were chosen by the senate, which formerly consisted of 40 members; but since this republic came under the protection, as it is called, of the pope, he thought proper to add ten more; but the whole 50 still retain the name of the "Quaranta." One of the senators presided in the senate, and was called the "Gonfalonier," from his carrying the standard (Gonfalone) of the republic. He was the chief magistrate, was attended by guards, and was constantly at the palace, or near it, to be ready on any emergency; but he remained only two months in office, and the senators took it by turns. In the midst of all this appearance of independence, a cardinal legate from Rome governed this republic; he was appointed by the pope, with a vice-legate, and other assistants. The orders which the legate issued, were supposed to be with the approbation of the senate; or at least, they never disputed the office, which was of higher dignity than any other in the gift of the court of Rome, and continued for three years; at the expiration of that time, his holiness either appointed a new legate, or confirmed the old one in the office for three years longer. This ecclesiastical vicerey lived in great magnificence, and had a numerous suite of pages, equerries, and hal-

berdiers, who attended him in the city. When he went into the country, he was accompanied by guards on horseback. The gonfalonier and magistrates regulated all the usual matters which regarded the police, and decided, in common causes, according to the laws and ancient forms of the republic; but in affairs of great importance, and, indeed, as often as he chose to interfere, the cardinal legate without doubt influenced all decisions. This must be mortifying to the senators and noble families; but was less felt by the people in general, who exhibited every appearance of living under a mild and beneficent government. Bologna was the see of an archbishop; who had for his suffragans the bishops of Crema, Borgo, St. Domino, Modena, Parma, Piacenza, and Reggio. Bologna is 23 miles S.W. of Modena, and 145 N. W. of Rome. N. lat. 44° 29' 36". E. long. 11° 21' 15". Keyser's Travels, vol. iii. p. 247. Moore's View of Society, &c. in Italy, vol. i. p. 252. See BOLOGNESE.

BOLOGNA bottles. See UNANNEALED Bottles.

BOLOGNA stone. See BONONIAN Stone, and PHOSPHORUS.

BOLOGNE, in Geography, a town of France, in the department of the Upper Marne, and chief place of a canton in the district of Chaumont, 6 miles north of Chaumont.

BOLOGNESE, FRANCISCO, in Biography, an eminent painter of landscape and history, whose original name was *Francisco Grimaldi*, was born at Bologna in 1606, and educated in the school of Annibal Caracci. He completed his studies at Rome; and his improvement was such, as to attract the attention of pope Innocent X. by whom he was employed both in the gallery of his palace at Monte Cavallo, and in the Vatican. Among his numerous admirers and friends were the prince Pamfili, the pope's nephew, and many of the principal nobility at Rome; Lewis XIV. and cardinal Mazarin at Paris, who procured for him a large pension; and employed him in decorating the Louvre; and after his return to Italy, the popes Alexander VII. and Clement IX. He was peculiarly happy in his execution of landscape: and was distinguished by his fresh and bold colouring, light and fine touch, and an elegant mode of composition. His landscapes in the manner of Caracci are models of the style of that school, though the colouring of them is thought to be somewhat too green. He understood architecture, and also etched, with great freedom, taste, and spirit, a great number of landscapes, partly from his own designs, and five after Titian. His agreeable manners and amiable disposition attached universal esteem. His benevolence was singularly manifested towards a Sicilian gentleman and his daughter, who had retired to Rome from the troubles of his country. They lodged near him, and were known to be so poor as to want bread. As soon as Bolognese was apprized of their situation, he repeatedly knocked at their door in the morning, threw in some money, and withdrew undiscovered. The Sicilian at length detected him in one of his acts of beneficence, and in token of gratitude fell at his feet. The painter raised and embraced him, and they continued mutual friends through life. Bolognese died at Rome in 1680, and bequeathed considerable property to his six children. His principal works are at Rome, and consist of large landscapes, and historical pieces in fresco. The pictures of his best time are very rare, and afford large prices. His son *Alexander* was a good painter in the style and taste of his father, though much inferior. Among his engravings are the "Brazen Serpent," from a composition of his own, which, though slight, is a spirited, free etching, in the style of a painter. Pilkington and Strutt.

BOLOGNESE, or the *duchy of Bologna*, in Geography, a territory

ritory of Italy, in the ecclesiastical state, bounded on the north by the Ferrarese, on the east by Romagna, on the south by Tuscany, and on the west by Modena; anciently inhabited by the Boii and Ligures. It was formerly a republic, under the protection of the emperor of Germany; but, in 1278, it became subject to pope Nicholas III. After many vicissitudes, pope Julius II. in 1513, annexed the city of Bologna, and all its dependencies, to the papal dominions; and in consequence of its voluntary submission to the see of Rome, it was indulged in several privileges, which it continued long to enjoy without molestation. But after the city of Bologna was taken by the French in the campaign of 1796, the legations of Bologna, Ferrara, Modena, and Reggio, entered into a treaty to form a republic, under the name of the "Republica Cispadana," or "Cisalpine Republic;" which was confirmed by the eighth article of the treaty of Campo Formio, October 17, 1797.

The soil of this territory is rich and fertile, and in the vicinity of Bologna it is so much improved by cultivation, that it appears like one continued garden. The vineyards are not divided by hedges, but by rows of elms and mulberry trees; and the vines hang in a very beautiful picturesque manner, in festoons from one tree to another. The country is not only fertile in vines, but likewise in corn, olives, and pasturage, and has, not without reason, acquired the name of "Bologna la Grassa." The Bolognese affirm, that their cheese is not inferior to that of Parma, and they sell a great quantity of it under the name of Parmesan cheese. See **Bologna**.

BOLOGNETTI, POMPEY, in *Biography*, was born at Bologna, in Italy, about the year 1616, where he received his education, and attaching himself to the practice of physic, was admitted doctor, and then professor in medicine, at the university there, in which capacity he was much admired, his lectures being numerously attended. His works are "Concilium de precautionibus occasione mercium, ab insultibus imminentes contagii," Bono. 1630, folio; which, perhaps, gave birth to Dr. Mead's work on that subject, or suggested the idea of it. "Remora senectutis," 1650, 4to. Haller. Bib. Med. Eloy. Dict. Hist.

BOLOGNINI, ANGELUS, a celebrated professor of medicine and surgery, who flourished in the beginning of the 16th century, was born in the neighbourhood of Padua, but practised and taught medicine at Bologna. At the earnest intreaty of his pupils, he says, he published, in 1508, "De cura ulcerum interiorum, et de unguentis communibus in solutione continui," 4to. which has been frequently re-printed. He was of the school of Avicenna, on whose works he commented in his lectures. He gives forms for preparing ointments with mercury, which he highly extols, and says, they cure the lues, though the salivary glands should not be affected, which, however, he admits to be desirable. The latter part of his life was spent in retirement at Padua. Astruc. de Morb. Gal. Hall. Bib. Med.

BOLOTOVA, in *Geography*, a town of Siberia, 24 miles N.E. of Nertschink.

BOLSCHAJA, a town of Siberia, on the Irtysh, 240 miles E.S.E. of Tobolsk.

BOLSCHAKINA, a town of Siberia, 68 miles south of Orlenga.

BOLSEC, JEROM, in *Biography*, a carmelite of Paris in the 16th century, who deserted his order on account of some free opinions, and became a refugee at Ferrara. There he commenced the profession of physic, and being acquainted with Calvin, removed to Geneva. In this city he divulged some opinions concerning predestination, which excited the resentment of the Genevan reformer, and which induced the magistrates of Geneva, probably at his instigation, first to

imprison him, and finally to banish him, as one convicted of sedition and Pelagianism. He was afterwards expelled from the canton of Bern, whither he had retired; and failing in his endeavours to ingratiate himself with the Protestants of Paris and Orleans, he returned to the bosom of the Catholic church. He then revenged himself by writing a very slanderous account of the life of Calvin in 1577, and another of that of Beza in 1582, the falsities of which sober Catholics are ashamed to quote. He also wrote against Calvin's institution, and his arguments were afterwards made use of by Cardinal de Richelieu. Bolsec practised physic at Autun, and at Lyons, in which latter city he died, a few years after he had written Beza's life. Gen. Dict.

BOLSENA, in *Geography*, a town of Italy, in the ecclesiastical state, and patrimony of St. Peter, delightfully situated on a lake that is of the same name, which is about 35 Italian miles in circumference. In this lake are two islands, namely, Bisentina and Martana, with a church in each island; in the former the unfortunate Amalafunta, daughter of Theodorice, king of the Ostrogoths, is said to have been put to death in 534, by order of the ungrateful Theodatus, her cousin, whom she had admitted to a share in the government. We learn from Pliny, (Hist. Nat. l. ii. c. 95,) that in his time these two islands were floating. He calls this lake Tarquinian, a name which it derived from Tarquinium, one of the principal 12 Etrurian cities, whose territories anciently extended to this lake; but it has been doubted, whether Pliny refers to the islands of this lake. Bolsena is environed with mountains, covered with trees, forming a kind of august amphitheatre. On an eminence near it may be seen the ruins of the ancient "Vulturnum." It is 7 miles S. of Orvieto.

BOLSOVER, a considerable market town of Derbyshire, England, has been noted for its manufactories of buckles, spurs, bridle-bits, stirrup-irons, and other similar articles; but the greater part of them is now made in Birmingham, and its vicinity. The town is governed by a constable, and two head boroughs; and a copy-hold court is held here every three weeks. Here was formerly a castle, which, according to the Doom-day book, was possessed, at the Norman conquest of England, by William Peverel. It was of considerable extent, and from its remaining fortifications was evidently of great strength. Its fortrefs is mentioned by Leland, as being in ruins when he visited this part of England, in the time of Henry the Eighth. A modern mansion, still called the castle, occupies the site of the ancient buildings, and was erected by sir Charles Cavendish in 1613. It is of square shape, and assumes the castellated character by towers at the four corners, and an embattled parapet. In this mansion, a superb entertainment was given by William Duke of Newcastle, to Charles the First and his queen in the year 1633. Upon this occasion, all the neighbouring gentry were invited to partake of the festival, which was conducted upon so magnificent a scale, that the expenses were estimated as amounting to 15,000*l*. Grand pageants, &c. were represented before the royal guests, and the fancy and taste of Ben Jonson were employed in preparing speeches and scenery upon the occasion. It now belongs to the duke of Portland, whose family obtained it by marriage with a daughter of the earl of Oxford. In the parish church is a magnificent monument to the memory of the above-named sir Charles Cavendish, many of whose family are also interred here. Bolsover has a weekly market on Fridays, one annual fair, and a statute fair for hiring servants, &c. It is 8 miles from Mansfield, and 145 N.W. from London. In the parish are 435 houses, and 1091 inhabitants.

At *Elmton*, a small village three miles N. E. of *Bolfover*, was born *Jedediah Buxton*, a man who, though only a poor labourer, acquired extraordinary celebrity, for his retentive memory, and recondite powers of calculation.

Three miles north of *Bolfover* are the great coal works, called *Norbrig's Colliery*. These belong to the Duke of *Portland*, and are let out to a company of persons who send great quantities by the canal to *Workop*, *Redford*, *Stockwith*, &c. *Bibliotheca Topographica*, No. 32.

BOLSTER, among *Surgeons*, a soft yielding substance either laid under the head or a broken limb.

BOLSTER is also used for a stuffing, intending to fill out or raise a flat, sinking, or hollow part. In which sense bolsters are contrived for crooked, bunched, and other distorted backs, shoulders, &c.

BOLSTERS of a *saddle*, in the *Manege*, those parts which are raised on the bows, both before and behind, to rest the rider's thighs, and keep him in a posture of withstanding the disorders which the horse may occasion. Common saddles have no bolsters behind or even before.

BOLSTERS, in *Sea Language*, small cushions or bags, filled with tarred canvas or rope yarn, &c. and placed under the shrouds and stays, to prevent their chafing against the trestle-trees, by the motion of the mast, when the ship rocks at sea.

BOLSTERS are also pieces of fir fayed upon the upper side of the trestle-trees, and against the thwart-ship sides of the mast-head. They must be sufficiently long to clear the sid-hole and after cross-tree, and broad enough to project one inch and a half, or more, without the trestle-trees, and the same in depth, and rounded from the upper to the lower edge on the outside, and nailed to the trestle-trees at each end. Their use is to prevent the shrouds chafing by the motion of the masts.

BOLSTERS of an anchor are cylindrical pieces of iron, with a hole through the middle, used when holes are to be punched, or opened with pins.

BOLSWAERT, **BOLSWERD**, or **BOLSWERT**, in *Geography*, a town of *Friesland*, in the United Netherlands, said to have been built in 713 by *Bolswine*, son of *Radbode*, king of *Friesland*, from whom it took its name. It was almost burnt down in 1475, and again in 1515, when it was rebuilt and encompassed with a rampart of earth. About a league from this town is a port, which, though much obstructed by sand, is very useful to the inhabitants. *Bolswaert* is about two miles in circumference, and was formerly one of the *Hanse* towns; and a great part of the *Friesland* baize, which formed a considerable article of exportation, was wove in this place. It is distant 13 miles S. W. of *Leewarden*, and 7 S. S. E. of *Harlingen*. N. lat. 53° 2'. E. long. 5° 24'.

BOLSWERT, or **BOLSWERD**, **BOETIUS ADAM A**, in *Biography*, an engraver and printseller of *Antwerp*, derived his name from *Bolswaert* in *Friesland*, where his family resided, and flourished about the year 1620. He worked only with the graver, and successfully imitated the free, open style of the *Bloemarts*, in whose school he probably perfected himself in his art. When he worked from *Rubens*, he altered that stile, and his plates are neater, fuller of colour, and more highly finished. His plates from *Bloemart* are a set of "Twenty landscapes," "The forest of the hermits and hermitesses of *Egypt* and *Palestine*," and "The Nativity of *Christ*:" and those from *Rubens*, in a more finished stile, are the "Resurrection of *Lazarus*," and its companion "The Last Supper," which is a very beautiful engraving. *Strutt*.

BOLSWERT, or **BOLSWERD**, **SOBELTIUS A**, brother of

the preceding, flourished about 1626, and worked entirely with the graver. His general character, as an artist, is thus described by *Bassan*: "We have a large number of prints, which are held in great esteem, by this artist, from various masters, but especially from *Rubens*, whose pictures he has copied with all possible knowledge, taste, and great effect. The freedom with which this excellent artist handled the graver, the picturesque roughness of etching, which he could imitate without any other assisting instrument, and the ability he possessed of distinguishing the different masses of colours, have always been admired by the connoisseurs, and give him a place in the number of those celebrated engravers, who are desirous of rendering their works as useful as they are agreeable, and of acquiring a reputation, as lasting as it is justly merited." His prints are the exact transcripts of the pictures from which he engraved them; and his last works, though not equally neat or finished, are always beautiful and indicate the hand of a master. His boldest engravings are from *Rubens*; and his neatest from *Vandyck* and *Jordans*. Some of this master's works have been carefully copied, so as easily to deceive the unskilful. Amongst the estimable engravings of this artist the following are mentioned: viz. the "Brazen Serpent," from *Rubens*, "Abraham offering his son *Isaac*," from *Theodore Rombout*, the "Education of the *Virgin*, by *St. Anne*," the "Marriage of the *Virgin*," the "Nativity of *Christ*," the "Adoration of the *Wise Men*," the "Feast of *Herod*," in which the daughter of *Herodias* is exhibited, presenting the head of *John the Baptist* to her mother, and the "Miraculous Draught of *Fishes*," all from *Rubens*; "Christ crowned with thorns," from *Vandyck*, and a "Crucifixion," from the same, in which a figure appears presenting the sponge to *Christ*; *St. John* and the *Virgin* are seen standing at the foot of the cross, and *Mary Magdalene* reclining towards it. This is one of his most beautiful engravings. The first impressions, in which the left hand of *St. John* is not seen, are very scarce; in the second, the hand appears upon the shoulder of the *Virgin*; but in subsequent impressions, the hand was again erased. *Strutt*.

BOLT, in *Building*, an iron fastening for a door, moved with the hand, and catching in a staple or notch made to receive it. Bolts are chiefly of three kinds: *plate*, *round*, and *spring-bolts*.

BOLT of a lock is the piece of iron which, entering the staple, fastens the door; being the part which is moved backwards and forwards by turning the key.

Of these there are two sorts; one shuts of itself by only putting to the door, and is called a *spring-bolt*; the other, which only moves when the key opens or shuts it, is called a *dormant-bolt*.

BOLT is also used for a large iron pin, having a round head at one end, and at the other a key-hole or slit, wherein to put a pin or fastening, serving to make fast the bar of a door, window-shutter, or the like.

This is more particularly called a *round-bolt*, or *window bolt*.

BOLTS, in the *Artillery*, are of several sorts; those which go betwixt the cheeks of a carriage to strengthen the trunnions are called *trunnion-bolts*. The large iron bolts or knobs on the cheeks of a carriage, keep the handspike from sliding, when it is passing up the breech of the piece. The two short bolts that being put one in each end of an English mortar-carriage, serve to traverse her, are called *traverse-bolts*. The bolts that go through the cheeks of a mortar, and, by the help of quoins, keep her fixed at the elevation given her, are called *bracket-bolts*. And the four bolts that fasten the bracket or cheeks of a mortar to the bed, are called

called *bed-bolts*. Besides these there are *bolster*, *eye*, *breeching*, *garnish*, *joint*, *stool-bed*, and *axletree bolts*. See *CARRIAGE*.

BOLTS, in *Carpentry*, denote pieces of wood cleft with wedges, in order to be split into laths.

BOLTS, or iron pins, in a *Ship*, are of several sorts, of which the most common have small round heads, and are used to unite two or more pieces together. Some have round flat heads, called *faucet-heads*, with a mortise in the other end, or point, and are used to fasten moveable pieces to those that are fixed; others have an eye at one end, for lashing or hooking blocks, &c. and are driven in *malt-heads*, *yards*, *caps*, &c. Some have a square part left at the back of the eye, that they may not be driven on the eye, and endanger splitting. Bolts are frequently distinguished according to the places where they are used; as, *ebain-bolts*, *bolts for carriages*, &c.; *ring-bolts*, serving for the bringing-to of the planks, &c. *drive-bolts*, used to drive out others; *set-bolts*, employed for forcing the planks, and other works, and bringing them close to one another; *rag-bolts*, on each side full of jags or barbs, to keep them from flying out of their holes; *clench-bolts*, those which are clenched or fastened at the ends where they come through; *fore-lock-bolts*, made like locks with an eye at each end, whereunto a fore-lock of iron is driven to prevent starting out; *fend*, or *fender-bolts*, made with long and thick heads, struck into the outermost bends or wales of a ship, to save her sides from bruises and hurts. The following machine for drawing bolts in and out of ships was invented by Captain Bolton of the Navy, and obtained from the Society of Arts their prize of the gold medal. A model of it is preserved in the repository of the society for the use of the public. The description of it (See *Transactions of the Society*, vol. xvi.) is as follows:

AAAAAA (*Plate of ships*) is the frame of the machine. B, a cylindrical tube, having a female screw in the inside. C, a wheel with teeth attached to the cylinder B. D, an endless screw adapted to the wheel C. E, handle of the winch. F, the bolt drawing out. GG, blocks to support the frame. H, a hollow piece of steel, having on its outside a male screw, whose threads work within the female screw in the cylinder B. To this piece of steel the bolt is to be rivetted. I, a semicircular piece of steel, which is to be introduced into the notches on H, when a similar notch has been cut in the head of the copper bolt, which by this means is prevented from turning in H, while drawing. K, the bolt, as prepared to receive the machine. L, a steel bar, somewhat smaller than the bolt to be drawn, having at one end a male screw, A, and at the other end another male screw that fits into the female screw in B. M, a section of a male screw, having a square hole larger than the bolt. N, a bolt with a male screw at one end ready to be drawn in.

The machine, of which a plate is annexed, consists of a frame supporting a cylindrical female screw tube. On this tube is mounted a wheel with teeth adapted to an endless screw fitted to the frame, and worked by a handle.

To draw the bolt out.

The head of the bolt must be cut off, and a hole made in the timber big enough to receive the male screw H, which is put over the bolt: a slit is then to be made, either by a saw or cold chisel, in the head of the bolt, to receive the key I, and which corresponds to the slit in H; the bolt head is then to be rivetted as firmly as possible upon H; the cylindrical tube, B, is then to be screwed on, turning the whole machine round till it can be done no longer, when the endless screw is to be used. If the machine is of a pro-

per strength, and the rivetting well done, the power is such as to extract the bolt or break it, but generally it will be drawn out uninjured. See *DRAWING*, &c.

To draw bolts into ships.

It will be necessary to have a bar, L, which is recommended to be made of steel, long enough to pass from the inside to the outside of the ship, and somewhat smaller than the copper bolt intended to be drawn in. This may be called a conductor. On one end should be a male screw, a; the bolt to be drawn in should be tapped at one end to receive the male screw, a, on the conductor; and at the other end should be another male screw that fits into the female screw in B; after which the operation is the same as drawing a bolt out, and the machine should be applied accordingly. When the bolt arrives at its destined place, it may be secured on the inside by a nut, which is as good a way of fastening as clinching, and much more expeditious.

This machine though only of the height of eighteen inches, will draw bolts in or out of any length; for, after the bolt has risen to the top of the tube, it will only be necessary to screw the machine back, and follow up the work with blocks of timber, as represented in the drawing.

Note. If the upper part of the hole in H be made square, larger than the round hole as shewn at M, and the head of the bolt rivetted into it, it will do away the necessity of the key, I, render the machine less complicated, and save much time and trouble.

BOLTS of an Anchor, are cylindrical iron pins for fastening the two parts of the flock together.

BOLTS for whirls, in *Rope-making*, are large iron pins with round heads, driven in the board over the crank-wheel for the whirls to run on.

BOLT is also used for a measure or certain quantity of canvas, amounting to twenty-eight ells.

BOLT of silk or stuff denotes a long narrow piece, of indefinite measure.

BOLT, pease, in *Essex*, denotes the pease-straw, when the grain is threshed out of it.

BOLT, thunder. See *THUNDER-bolt*.

BOLT-rope, in *Sea Language*, is a rope sewed to the edges of a sail, to prevent it from rending by the force of the wind, or any other cause.

A bolt rope should be made of fine yarn spun from the best hemp, and sewed neatly on with good twine. To avoid stretching, the rope must be kept well twisted while sewing on, and care taken that neither too much nor too little slack is taken in: that part of the rope at the leech of the sail is to be cross stitched at every foot in length, at every seam, and in the middle of every cloth at the foot, with three cross stitches: four cross stitches should be taken at all the beginnings and fastenings off; the first stitch given twice, and the last three times. Small sails have two cross stitches at every seam, and three at every fastening off.

BOLTED flour, that which has passed through the **BOLTERS**.

BOLTTEL, in *Building*, any prominence or jutting out, as of a piece of timber, end of a beam, or the like, advancing beyond the naked of the wall.

BOLTERS, or **BOULTERS**, a kind of sieves for meal, having the buttons made of woollen, hair, or even wire. The word seems derived from the German, *beutel*, a sieve; whence also *beutel*, to bolt. The bakers use bolters, which are worked by the hand; millers have a large sort, wrought by the motion of the mill.

BOLT-HEAD, a vessel used by the chemists, the same as *matras*; which see.

BOLT-HEAD, in *Geography*, a promontory of England, on the

the south-coast of the county of Devon, 19 miles S.E. of Plymouth. N. lat. 50° 9'. W. long. 30° 47'. The promontory 4½ miles W.N.W. of this is called *bolt-tail*.

BOLT and **TUN**, in *Heraldry*, is a bird bolt in pale piercing through a ton.

BOLTING, or **BOULTING**, the act of separating the flour from the bran, by means of a sieve or bolter.

BOLTING-cloth, or **BOLTER-cloth**, sometimes also called *lulling cloth*, denotes a linen or hair-cloth for sifting of meal or flour.

That kind of bolting-cloth which is used for sifting of meal, and also for a variety of needle work, for young ladies' samplers, and for filling up the frames of window-screens, &c. is wove after the manner of gauze of fine spun woollen-yarn. The wool necessary for making this cloth must be long, well-washed, and spun to a fine equal thread, which, before it is scowered, must be scalded in hot water, to prevent it from shrinking. The web must be stiffened; and in the manufacture of it the English have the advantage of the Germans, whose cloth of this kind is much cheaper, but much inferior in value to that of England. The bolting-cloth of this country is stiffer, as well as smoother, and the flour passes through it much better than through that of the Germans, which is either very little or not at all stiffened. A manufactory of this cloth was established at Ostra, near Dresden, by one Daniel Kratt, about the end of the 17th century; and at Hartau near Zittau, it was introduced by one Plefsky, who learned the art of making it in Hungary. The cloth which is sent from hence for sale, not only every where round the country, but also to Bohemia, Moravia, and Silesia, is wove in pieces, containing each from 64 to 65 Leipick ells; the narrowest being 10, and the widest 14 inches in breadth. Large quantities of it are also made by a company in the duchy of Wurtemberg. Bolting-cloth is also made at Gera, as well as at Potsdam and Berlin; at the latter of which places there is a manufactory of it carried on by the Jews.

BOLTING-mill, a versatile engine for sifting with more ease and expedition. The cloth round this is called the bolter.

The method of applying a sieve in the form of an extended bag to the works of the mill, that the meal might fall into it as it came from the stones, and of causing it to be turned and shaken by the machinery, was first made known in the beginning of the 16th century, as we are expressly told in several ancient chronicles.

BOLTING, or **BOULTING**, among *Sportsmen*, signifies rousing or dislodging a fox, rabbit, or badger, from its resting place.

BOLTING, in *Law*, a method of pleading, or arguing, formerly in use in the inns of court; inferior to mooting. The case is argued first by three students, then by two barristers; an ancient, and two barristers sitting as judges.

The word comes from the Saxon *bolt*, a *house*; because done privately within doors, for instruction.

BOLTON, **EDMUND**, in *Biography*, an English antiquarian writer of the 17th century. By religious profession he was a Roman Catholic, and probably enjoyed some office under Villiers duke of Buckingham. He was diligent in his researches into subjects of history and antiquities, and was the author of several works, of which the principal are the following; viz. "A Life of Henry II.," "Elements of Armories," Lond. 4to, 1610; "A translation of Florus," "Nero Cæsar, or Monarchy depraved," Lond. fol. 1624, in which he attempts to establish the improbable opinion, that Stonehenge was a monument to the memory of queen Boadicea. His "Vindiciæ Britannicæ," left in

MS., was designed to prove the great antiquity and early importance of London. From all his performances, Bolton appears to have possessed the credulity, nationality, and love of trifles, often attendant on antiquarian studies, when they are not directed by taste and judgment. The time of his death is not known. *Biog. Brit.*

BOLTON, in *Geography*, a village of Yorkshire, in England, had a very considerable monastery of canons regular, of the order of St. Austin, founded in 1120 by Robert de Romeli, and this had afterwards other benefactors, and at the dissolution its annual revenues were valued at 212*l*. Part of the religious house still remains, and one room is appropriated to a free school, which was founded by Robert Boyle, esq. This village is rendered remarkable from being the birth-place and residence of Henry Jenkins, who was born in the year 1500, and lived to the great age of 169 years. He enjoyed a constant state of good health, and possessed his faculties to the last year of his life. See **LONGEVITY**.

BOLTON-le-Moors, is an ancient manufacturing town of considerable consequence in Lancashire, in England. It may be considered as the original seat of the cotton trade in this country, and for the manufacture of ornamental and fancy good is still particularly celebrated. Leland, in his Itinerary, notices the cottons (then a species of woollen) and coarse yarns which were brought to this town in his time, and observes, that many villages in the vicinity were engaged in this manufacture. Coal-pits were also worked at that time, and coals are still obtained in abundance from pits in the neighbourhood. The making of fustians was introduced into this town, at a very early period, and still continues a prominent object of trade. During the civil wars in the reign of Charles I., Bolton was besieged by prince Rupert in 1644, and many of the inhabitants were killed. The town is well built, and has rapidly increased in size and population. It is seated in a flat district, as its name partly implies. The advantage of canal conveyance to Manchester and Bury, has proved highly important to the town, whose manufactories are thereby greatly promoted. Bolton has a free school, of which Ainsworth, the author of the Latin dictionary, was once a master. The prosperity of Bolton may be partly estimated from the following comparative state of its population. In the year 1773, there were 5339 inhabitants in this town and Little Bolton. These were augmented to 11,739 persons in 1789; and in 1801, when the population of the country was estimated by order of the house of Commons, there were found to be 3476 houses, and 17,413 inhabitants in the township and chapelry of Great and Little Bolton. The principal mart for the sale of goods made at this place is Manchester, where the manufacturers resort on Tuesdays, Thursdays, and Saturdays. "The neighbourhood of Bolton," observes the judicious Dr. Aikin, "has been distinguished for producing men of great talents in mechanical invention, who have generally been wholly uneducated, and indebted only to native powers, and the habit of observation. The most celebrated of these was sir Richard Arkwright, of whom false pride and prejudice alone can think it derogatory to say, that he passed a great part of his life in the humble station of a barber in the town of Bolton. His mind was so ardently engaged in the improvement of the mechanism used in the manufactures, that he could scarcely keep above want by the exercise of his proper profession; but his perseverance and ingenuity were at length rewarded with a measure of opulence, which nothing but the tide of prosperity in a commercial nation could bestow." See **ARKWRIGHT**.

At *Smithels*, an old hall, or mansion, north of Bolton, formerly belonging to the Fauconberg family, is a curious old

old wainscotted room, the pannels of which are adorned with upwards of 50 heads, cut in wood. This hall is shewn and visited as a curiosity, from a superstitious prevalent opinion that an impression of a foot may be seen in the stone floor made by one Marth a martyr, in the reign of queen Mary.

Rivington, in the parish of Bolton, is a conspicuous hill, crowned with a building called Rivington-pike. Some veins of lead and calamine have been worked in this neighbourhood, but have not hitherto proved very fortunate to the adventurers.

Bolton is 11 miles from Manchester, and 197 miles N.W. of London. It has a market on Mondays, and two fairs annually. Aikin's Description of the Country round Manchester, 4to. 1795.

BOLTON, a township of America, in Chittenden county, Vermont, seated on Onion river, about 104 miles N.N.E. from Bennington, containing 88 inhabitants.—Also, a township in Tolland county, Connecticut, incorporated in 1720, and settled from Weathersfield, Hartford, and Windsor, 14 miles E. from Hartford.—Also, a township in Worcester county, Massachusetts, 18 miles N. E. from Worcester, and 34 W. from Bolton; containing 945 inhabitants, and a good bed of limestone.—Also a township in Washington county, New York, between Scroon lake and lake George, distant 10 or 12 miles S.E. of Ticonderoga, and containing 959 inhabitants.

BOLTONIA, in *Botany*, (named by L'Heretier, in honour of James Bolton, late of Halifax, in Yorkshire, a self-taught naturalist and artist in a humble sphere of life, author of the "History of British Singing Birds," 2 vols. 4to. of "British Ferns," 4to. and of "Funguses growing about Halifax," 4 vols. 4to. with figures of the species, all drawn, etched, and coloured by himself.) L'Heret. Sert. Angl. p. 35, 36. Schreb. 1309. Jussieu 450. Bosc. Nov. Dict. Clais, *Syngenesia Polygamia Superflua*. Nat. Ord. *Composita radiata*.—*Corymbifera*. Juss.

Gen. Char. *Cal.* common; imbricate, with nearly equal linear, acute scales. *Cor.* compound, radiate; florets of the disk tubular, funnel-shaped, five-cleft, numerous; of the ray many, linear, entire, pistiferous. (Schreb.) three-toothed. (Bosc.) *Pist.* germ oblong; style filiform; stigmas two, those of the ray revolute. *Pericarp.* none; calyx unchanged. *Seed* solitary, compressed, slightly toothed, two-horned; receptacle naked, honey-combed, hemispheric.

Ess. Char. *Cal.* common, imbricate, with linear scales. *Cor.* radiate. *Germ*s compressed, vertical. *Seed* obscurely toothed, two-horned. *Recept.* honey-combed.

Species, 1. *B. asferoides*, (matricaria alt. Linn. Mant. 116.) "Leaves quite entire." Stem upright, two feet high, even, scarcely angular, slightly streaked; leaves alternate, remote, sessile, lanceolate, even, bent down at the base, ragged about the edge; panicle thin, stiffish, with one-flowered peduncles; disk yellow; ray pale flesh-colour. 2. *B. glaberrima*. "Lower leaves serrate." Five or six feet high. Both species are natives of South America, flower late in the autumn, and were cultivated by Mr. Miller in 1758.

BOLTSACKEN, or BOLTSACK, in *Geography*, rocks at the N. entrance of the Great Belt, 5 miles S. E. from the island of Samsoe. N. lat. 55° 48'. E. long. 10° 40'.

BOLTY, in *Ichthyology*, a fish of the *LABRUS* genus. (*Labrus niloticus* of Linnæus), that is found in the Nile. It is figured and described by Sonnini, in his "Voyage en Egypte." This, it is observed, is one among the small number of fishes that inhabit the river Nile, the flesh of which is delicate, and of a good flavour. Daubenton, in the French Encyclopædia, calls the species *Nébuloux*, on account of the obscure spots with which the fins are marked.

BOLTZNITZ, in *Geography*, a river of Germany, which runs into the Elster near Elsterwerda, in the margraviate of Meissen.

BOLU, a mountain of Asia, in Armenia, 144 miles S.E. of Erivan.

BOLUADIN, a town of Asiatic Turkey, in the province of Natolia, 28 miles N. of Kara-hissar.

BOLUCBASSI, in the *Turkish Affairs*, denotes the chief of a company; or a captain who has the command of an hundred janizaries.

BOLURUS, in *Ancient Geography*, a town of Greece, in Thesprotia.—Also a town of Illyria, which belonged to the Trallians. Steph. Byz.

BOLUS, in *Pharmacy*, is a very useful form of extemporaneous prescription adapted to a variety of cases in which a more solid or a more liquid form would not answer the purpose. The consistence of a bolus is the same as that of an electuary, that is, about as soft as dough, so as easily to slip down the throat without falling to pieces. As it must in some degree be tasted while swallowed, it generally consists of the medicine in powder, worked up to the proper tenacity by means of some grateful syrup, soft extract of liquorice, or a palatable conserve; or, if the medicine be an oil, balsam, or other liquid, dry sugar, with flour, almond-paste, and the like, are added to bring it to the due consistence. It is intended to be only a single dose.

The substances most proper to be exhibited in this form are those that are very heavy, and scarcely to be suspended in any liquid so as to be drank off, such as calomel, tin-powder, steel filings, æthiops mineral, or those that are too bulky to be made into a convenient number of pills, and are nauseated by the patient in a liquid form, such as cinchona, chamomile, burnt-sponge, Dover's powder, valerian root; or some of the stronger acids and aromatics, as guaiacum, camphor, musk, castor, ammonia: or those that are little soluble in the stomach, unless previously mixed with some easily soluble matter, and yet do not readily combine with liquid sufficient to be drank off, as oil of turpentine, the balsams and the like, mixed with sugar and flour. Bolusses differ from troches in this, that the latter are made firmer, though equally soluble, and being intended for slow solution in the mouth; they consist only of insipid, or not unpalatable ingredients. Substances that readily become very moist, such as the kali preparatum, should not be used in this form, unless the bolus is intended to be taken immediately: but on this head less caution is required than in compounding electuaries.

This form of medicine should be avoided where the patient is in a state in which the power of swallowing is with difficulty exercised, as in apoplexy, and other comatose disorders; in some spasmodic and painful affections of the throat; or where the œsophagus is naturally very narrow. Alarming accidents have sometimes arisen from a neglect of these precautions. It is likewise difficult to get very young children to swallow them, unless made extremely thin. These minutæ will not appear trifling to those who are in the habit of personally witnessing the trouble and difficulty which daily attend the exhibition of medicines, and are so liable to defeat the most judicious plans of the prescriber.

In hospitals and dispensaries this form is very commonly adopted, as it is prepared with little trouble, and is economical in the more expensive drugs; no more of them being employed than the immediate wants of the patient require.

BOLUS-HEAD, in *Geography*, a cape of Ireland, on the south-west coast of the county of Kerry, 38 miles S. W. of Killarney. N. lat. 51° 44'. W. long. 10° 12'.

BOLWICK,

BOLWYCK, a town of Norway, 40 miles W. of Tonsberg.

BOLZANI, **URBANO VALERIANO**, in *Biography*, one of the revivers of literature in the 15th century, was born at Belluno about the year 1440. Having entered, when young, into the order of the Minorites, he travelled through Egypt, Palestine, Syria, Arabia, Greece, and Thrace, observing whatever was curious either in nature or art. In the course of his perambulations, he twice ascended the summit of *Ætna*, and surveyed its crater. As a strict observer of his vows, he declined accepting the honours and dignities which were offered him. His fixed abode was at Venice, where he taught the Greek language, and, among other scholars, instructed the learned Gen. Antonio Flaminio, and John d'Medici, afterwards pope Leo X. He was the first who facilitated the attainment of the Greek, by composing a grammar in that language; of which the first edition was printed in 1497, and a second, much enlarged, in 1512. He died in 1524.

BOLZANO, or **BOLZEN**, in *Geography*, a town of Germany, in the Tyrol, seated on the river *Eysac*, near its confluence with the *Adige*, famous for its four annual fairs, each of which continues a fortnight, which are much resorted to by Italian and German merchants; 6 leagues S. W. of Brixen, and 9 N. of Trent. It was taken by the French in March, 1797. N. lat. 46° 28'. E. long. 11° 14'.

BOLZANO, a town of Italy, in the Vicentin, belonging to the state of Venice, 2 leagues E. of Vicenza.

BOM, in *Zoology*, the name of an American serpent of the *Boa* genus, called likewise *bome*, and *boma*. It is said to grow to a vast size, and to be perfectly harmless; but the latter assertion is improbable; it is not certainly of the poisonous race of serpents. This is called the *bom*, because it emits a remarkable noise resembling the sound of that word, when pronounced with a deep hollow voice.

BOMAL, or **BOHEMAL**, in *Geography*, a town of Germany, in the duchy of Luxemburg, seated on the Ourte, 7 miles S. W. of Spa, and 53 N. W. of Luxemburg.

BOMANGOY, a town of Africa, in the kingdom of Angoy, or *Gov* (which see), situate on the north bank of the river *Zaire*. S. lat. 5° 36'. W. long. 13°.

BOMARZO, a town of Italy, in the ecclesiastical state, and patrimony of St. Peter, once episcopal; 14 miles from *Civita Castellana*.

BOMB, in the *Military Art*, a hollow iron ball, or shell, furnished with a vent, by which it is filled with gun-powder, and which is fitted with a fusee, or hollow plug, by which it gives fire, when thrown out of a mortar.

In the English artillery, bombs are now commonly called shells.

The word *bomb* comes from the Latin *bombus*, *crepitus*, or *fibilus ani*: by reason of the noise it makes.

The method of preparing a bomb is as follows: a hollow iron globe *A B* (*Plate Gunnery*), is cast pretty thick, having a round aperture *A*, by which it may be filled and lighted; and circular *anse* *C*, *D*, of hammered iron fixed in the mould when they are cast, for the commodious putting it into the mortar, as well as for carrying it from one place to another. In France, the handles are cast iron: but they are thus rendered more clumsy, and liable to break sooner than the others.

It has been usual to make the lower part of the bomb the thickest, that it may fall on that side, and never on the fusee, and that it may also better resist the shock, or impression of the powder by which it is discharged from the mortar; but Mr. Muller thinks that neither of these considerations is

of any great importance, and recommends rather to make them every where equally thick, because they would thus burst into a greater number of pieces. *Artillery*, p. 151. in his System, &c. vol. v.

After the shells have been gauged and examined as to their dimensions and weight, they must be well searched within and without by means of a copper grater, to ascertain whether there be any holes or cavities in them; and the iron pin or spike at the bottom of the inside, which supports the corp when they are cast, should be beat down or broken off. They are then to be hammered all over, to knock off the scales, and discover flaws; and no hole, in the large shells, is allowed, of more than $\frac{1}{2}$ of an inch deep. An empty fusee is then driven into the fusee hole; and the shell is suspended in a tub of water, so that the water may cover it, without running into the fusee; in this situation the nose of a pair of bellows is introduced into the fusee hole, and several strong puffs given with the bellows; and if no bubbles rise in the water, it is concluded that there are no holes in the shell, but that it is found and fit for service.

When the shell has been thus proved, and is found to be dry within, gun-powder is introduced into its cavity, by means of a funnel; but it is not quite filled. Artillerists, though they agree that shells should not be quite full, have not ascertained the precise quantity which would serve for their bursting into the greatest number of pieces. Captain *Defaguilliers*, after having made several experiments, apprehends, that the most proper quantity of powder is two thirds of the weight which would fill the cavity. A little space or liberty is left, that when a fusee or wooden tube *a*, *c*, of the figure of a truncated cone, is driven through the aperture, the powder may not be bruised. This fusee is pressed in at first by the hand as far as it will go, and then drove with a mallet as hard as possible, taking care, however, not to split it; for if the least crack were in it, the composition would give fire to the powder, and the shell would burst either in the mortar, or in the air, and thus do no execution. For the method of preparing and filling the fusee, see *FUSEE*.

This fusee is set on fire, and burns slowly till it reaches the gun-powder, which goes off at once, bursting the shell to pieces with incredible violence; whence the use of bombs in besieging towns. Special care, however, must be taken, that the fusee be so proportioned, as that the gun-powder do not take fire before the shell arrives at the destined place; to prevent which, the fusee is frequently wound round with a wet clammy thread.

The fusees are driven into the shell, so as that only about an inch and a half come out beyond the fusee-hole; and then the shell is said to be fixed. They are charged long before there is occasion to use them; and in order to secure the composition with which they are filled, the two ends are covered with a mixture of two parts of pitch, one of rosin, and three of bees-wax, which will guard the composition within from the access of air; and it will thus keep as long as you please. When the fusee is to be put into the shell, the little end is opened or cut off; but the great end is never opened till the mortar is to be fired.

Bombs or shells are made of different magnitudes, from that of 17 or 18 inches diameter downwards; the very large ones are not used by the English, that of 13 inches diameter being the largest size now employed by them. The following table shews the weight, dimensions, &c. of English and French shells.

B O M B.

SHELLS.—Their Dimensions, Weight, &c.

Nature.	Weight.				Diameter.	Powder contained in Shells.		Powder for Bursting.		Diameter of Fusée Hole.		Thickness of Metal.
										Outside.	Inside.	
	Ct.	Qr.	lbs.	oz.	Inches.	lbs.	oz.	lbs.	oz.	Inches.	Inches.	Inches.
13 Inch	1	3	2		$12\frac{3}{4}$	10	4	6	12	1.837	1.696	2.05
10 —	0	3	9		$9\frac{1}{4}$	4	5	2	10	1.57	1.45	1.575
8 —	0	1	$11\frac{1}{2}$		$7\frac{1}{4}$	2	12	1	14	1.219	1.127	1.2
$5\frac{1}{2}$ —	0	0	$15\frac{1}{4}$		$5\frac{1}{4}$	1	0	0	12	.894	.826	0.822
$4\frac{1}{2}$ —	0	0	8		$4\frac{1}{2}$	0	7	0	5	.832	.769	0.653
H. Gren. {	0	0	3	11	3.49							
	0	0	1	13	2.77			0	$1\frac{1}{2}$			

French Shells, in French Weights and Measures.

Inches.	lbs.					Lines Po.	Lines Po.	Lines.			
12-Inch	150	12	17	0	5	0	15	9	15	0	16
10 —	100	10	10	0	3	0	15	9	15	0	16
8 —	43	8	4	1	1	0	12	0	11	0	10
6 —	23	6	2	8	0	12	11	0	10	6	10

Mr. Muller gives the following proportions, from the 13 inch bombs, now commonly used, and observes that they may be easily adjusted to any other calibre, by making the diameter of the shell to 30, as any part expressed in inches, to the same part expressed in parts of the diameter divided into 30 equal parts.

Diameter of the bore	-	-	-	-	30
Diameter of the shell	-	-	-	-	29.5
Diameter of the hollow sphere	-	-	-	-	21
Thickness of the metal at the fusée-hole	-	-	-	-	3.5
Thickness at the opposite part	-	-	-	-	5
Diameter of the fusée-hole	-	-	-	-	4

Weight of the shell unloaded,	—
	11.7
	<i>d</i>

Weight of the powder contained in the shell —————
236.5

N. B. The letter *d* denotes the cube of the diameter of the bore.

But shells have also been lately made with the metal every where of the same thickness, and are found to burst into a greater number of pieces by this construction. The Germans do not name their shells from the diameter of the bore which receives them, but from the weight of a stone-ball that fits the same bore as the shell. Thus a 7lb. howitzer admits a stone-ball of that weight; the shell for this weighs 15lbs. and corresponds to the English $5\frac{1}{2}$ inch. The 30lbs. howitzer shell weighs 60lbs., and is rather more than 8 inches in diameter. At the siege of Gibraltar, small shells, as $4\frac{1}{2}$ inches, and hand-granades, were quilted into grape for 13-inch mortars. The fuses were turned inwards next the iron-tampion, and leaders of quick-match for communicating fire to the fuses were introduced through holes made in the wood-bottom, and placed as near the fuses as possible in the centre of the grape. These answered very well for short ranges. In general, the windage, or difference between the diameter of the shell and mortar, is $\frac{1}{60}$ th of the latter; and the diameter of the hollow part of the shell is $\frac{7}{10}$ ths of the same. For finding the weight of an iron-shell, the following rule has been given. Take $\frac{6}{34}$ of the difference of the cubes of the external and internal diameters, and this will be its weight.

In order to find how much powder will fill a shell; divide the cube of the internal diameter of the shell in inches by 57.3, which will be the number of pounds of powder. To find the size of a shell for containing a given weight of powder; multiply the number of pounds of powder by 57.3, and the cube root of the product will be the diameter in inches.

Bombs only differ from granades, in that the latter are much less; and instead of mortars are thrown out of the hand. Bombs are thrown not only out of mortars and howitzers, but out of cannon. The following shells may be fired from guns; viz. hand-granades from 6-pounders; $4\frac{1}{2}$ shells from 12-pounders; $5\frac{1}{2}$ shells from 24-pounders; and 8-inch shells from 68-pr-carronades. Shells may be also thrown from guns to short distances, in case of necessity, though the bore be not of a diameter sufficient to admit the shell. For this purpose the gun may be elevated to any degree that will retain the shell upon its muzzle, which may be assisted by a small line passing from the lugs of the shell round the neck of the gun. To produce a greater effect, the space between the shell and the charge may be filled with wads, or some other substance.

Bombs may be used without mortar-pieces, in the manner practised by the Venetians at Candia, when the Turks had possessed themselves of the ditch, rolling down bombs upon them, along a plank set sloping towards their works, with ledges on the sides to keep the bomb right forwards. They are sometimes also buried under ground to blow up. See CAISSON.

M. Blondel, who has written on the art of throwing bombs, observes that the first bombs were those thrown into the city of Watchendonch, in Guelderland, in 1588, though others pretend they were in use a century before, viz. at the siege of Naples by Charles VIII. in 1495. Stowe says (p. 584), that mortars and bombs were invented in 1544 by foreigners, whom Henry VIII. employed. But they came not into common use before the year 1634, and then only in the Dutch and Spanish armies. One Malthus, an English engineer, is said to have first carried them into France, where they were put in use at the siege of Collioure, in 1642.

The art of throwing bombs makes a branch of gunnery, founded on the theory of projectiles, and the laws and quantities of gun-powder.

Mess. Blondel, Guisnée, de Reffons, de la Hire, and others have written expressly on the art of throwing bombs.

BOMB-battery. See BATTERY.

BOMB-chest, is a kind of chest filled usually with bombs, sometimes only with gun-powder, placed under ground, to tear and blow it up in the air, with those who stand on it.

Bomb-chests were formerly much used to drive enemies from a post they had seized, or were about to take possession of: they were set on fire by means of a *suicidee* fastened at one end, but they are now much disused.

BOMB, water. See WATER-bomb.

BOMB-veffels, which are small ships formed for throwing bombs into a fortress, are said to be the invention of M. Reyneau, or Renard, and to have been first used at the bombardment of Algiers, in 1681. Till then, it had been judged impracticable to bombard a place from the sea.

The bomb-ketches on the old establishment carry one 13-inch, and one 10-inch mortar; with eight 6-pounders, besides swivels, for their own immediate defence. The modern bomb-veffels carry two 10-inch mortars, four 68-pounders, and six 18-pounders caronades; and the mortars may be fired at as low an angle as 20 degrees; though these mortars are not intended to be used at sea, but on very particular occasions, their principal use, at these low angles, being to cover the landing of troops, and to protect our coasts and harbours. A bomb-ketch is generally from 60 to 70 feet long from stem to stern, and draws eight or nine feet water. The tender is generally a brig, on board of which the party of artillery remain, till their services are required on board the bomb-veffel. The following instructions serve for their management and security in action.

1. A Dutch pump, filled with water, must be placed in each round-top, one upon the fore-castle, one on the main-deck, and one on the quarter-deck; and furnished with leather buckets, for a fresh supply of water.

2. The booms must be wetted by the pumps before the tarpaulins and mortar-hatches are taken off; and a wooden screen, 5 feet square, is to be hung under the booms, over each mortar, to receive the fire from the vents.

3. The embrasures being fixed and properly secured, the port must be let down low enough to be covered by the sole of the embrasure. Previous to its being let down, a spar must be lashed across it, to which the tackles for raising it again must be fixed: this spar serves to project the tackles clear of the explosion.

4. The mortars must not be fired through the embrasure at a lower angle than 20 degrees, nor with a greater charge than 5 lbs. of powder.

5. Previous to firing, the doors of the bulk-head, under the quarter-deck, must be shut, to prevent the cabin being injured by the explosion.

6. The bed must be wedged in the circular curb, as soon as the mortar is pointed, to prevent re-action; the first wedge being driven tight before the rear ones are fixed, in order to give the full bearing on the table, as well as the rear of the bed.—The holes for dog-bolts must be corked up to prevent the sparks falling into them.

7. When any shells are to be used on board the bomb, they must be fixed on board the tender, and brought from thence, in boxes in her long-boat; and kept along-side the bomb-ship till wanted, carefully covered up.

8. In the old constructed bomb-veffels it is necessary to hoist out the booms, and raft them along-side previous to firing; but in these new ones, with embrasures, only the boats need be hoisted out; after which the mortars may be prepared for action in 10 minutes. See KETCH.

BOMBA, in *Zoology*, a species of TRICHODA, one of

the genera of Animalcule or Vermes infusoria. This kind is briefly described as being of a changeable form, with a few hairs on the anterior part. This is found abundant in stagnant water; the body is thick, somewhat pellucid, of a yellowish colour, and filled with paler molecules. Müll. Gmel. &c.

BOMBARD, BOMBARDA, a piece of artillery anciently in use, exceedingly short and thick, and with a very large mouth, by some also called *tafflyk*, by the Dutch *donderbus*. Some derive the word, by corruption, from *Lombard*, as supposing this piece first used in Lombardy. Du-Cange, after Vofsius, derives it from *bombus* and *ardeo*; Menage, from the German *bombarden*, the plural of *bomber*, *lallyta*. But we doubt whether the Germans knew any such word. It is no unusual thing with Menage, and many other etymologists, to give derivations from words of their own making.

There were some of these pieces said to have carried balls of 300 pounds weight; Froissart mentions one of fifty feet long. To load them, they made use of cranes, &c. The bombard is supposed to have been in use before the invention of cannon.

Bombards can hardly be supposed to have been of metal, nor charged with gun-powder. They were rather a sort of baliste for throwing stones, and were played with ropes.

BOMBARDE, in *Geography*, a fort and village of the island of St. Domingo, about 3 leagues N. of La PlateForme; 6 S. E. of the Mole, and 22 from Port de Paix. N. lat. 19 42'.

BOMBARDIER, an engineer, or person, whose business is to take care of the firing and throwing bombs out of mortars.—He first drives the fusee, then fixes the shell, points, loads, and fires.

BOMBARDIER, in *Entomology*. See CARABUS.

BOMBARDING, the art or act of attacking a city or fortress, by throwing bombs into it, in order to ruin or set on fire the houses and magazines, and do other mischiefs.

Bombarding is not reckoned the most honourable method of making war, as it rather tends to do mischief to the inhabitants than to the works.

BOMBARIN, in *Zoology*, the name used by some old writers for the Hippopotamus.

BOMBASINE, in *Commerce*, a kind of silk stuff manufactured at Milan, and thence sent into France and other countries. The French also use the word bombasine for stuff made of cotton, more properly called dimity.

BOMBAST, in *Rhetoric*, denotes a style too high and pompous for the subject and occasion; or a certain manner of elocution and action, which is grand when supported by dignity in the sentiment, and force in the expression, but never fails to appear ridiculous where the sentiment is mean, and the expression flat. See STYLE.

BOMBAX, in *Botany*, (a name given to the common cotton tree by Serapion an Arabian physician in the beginning of the ninth century; Pliny had before called cotton Bombyx. Gr. *βουβαξ*. Suid.) silk cotton. Lin. Gen. 835. Reich. 901. Schreb. 1127. Jussieu, 275. Willden. 1284. La Marek. *Fromager*. Class and order *Monadelphica Polyandria*. Nat. Ord. *Columnifera*—*Malvaceae*. Juss.

Gen. Char. *Cal.* permanent, either of one leaf, tubular-campanulate, three, four, or five-cleft; or of five unequal leaves. *Cor.* either five petals, or one petal five-cleft. *Stam.* filaments five or more, connate at the base, sometimes slightly, sometimes tubular. *Pist.* germ superior, turbinate-oblong. *Stigma* capitate, with five teeth more or less developed. *Pericarp.* large obovate-oblong, membranous and almost woody, five-celled, five-valved. *Seeds* numerous, round, woolly. *Recept.* columnar five-cornered, forming the partitions.

Eff. Char. *Cal.* simple. *Capfule* fomewhat woody, five-celled, five-valved. *Seeds* woolly. *Recept.* five-cornered.

Species, 1. *B. pentandrum.* (La Marck Tab. 587.) "Flowers pentandrous." Linn. "Anthers bent; leaves in fevens." Willden. A tree fixty or eighty feet high. Bark greenifh, fmoother, eafily feperated from the wood; often fprinkled, efppecially when young, with large, conic, fpinous tubercles; branches near the fummit, pendant; leaves on long petioles, digitate, folioles from five to nine, either entire or ferrate, lanceolate, ending in a point; flowers in a fimple umbel; partial peduncles about an inch long, with feveral alternate bractes; petals five, white, and velvety without, fmoother, concave, and of a purple or delicate rofe colour within; anthers two or three, on a filament, twifted together; fruit half a foot long, fhaped like a cucumber, very flender at its bafe; feeds oval with a fharpifh point, enveloped with a great quantity of fhort dark cotton which is not fpun, but ufed for fluffing pillows, mattraffes, &c. Rumphius fays that the valves open at the bafe. Plumier afferts the contrary. Jacquin, who faw the living plant in fruit, gives no information on the fubject. A native of both Indies. Cultivated by Mr. Miller in 1739. 2. *B. erianthos.* (Cavan. Tab. 152.) "Flowers pentandrous; anthers fimple, erect; leaves in fevens." Willd. Trunk very fpinous; leaves terminated by a filament, very fmoother; calyx fhort and very large: petals three inches long, whitifh, covered without with a fhort thick down, fmoother within, concave, and rounded at their extremity; tube formed by the lower part of the filaments, bottle fhaped; anther linear, longitudinally fixed to the upper part of the filament. Found by Commerfon in Brazil. 3. *B. pyramidale.* "Stem without thorns; leaves cordate, angular; flower pentandrous; anthers united; fruit very long, pyramidal." Cavan. A large tree with very fpreading branches; wood white and fo light that fifhers ufe it inftead of cork; bark thick, fibrous, cinereous, marked with whitifh fspots, and reddifh wrinkles; leaves a foot in diameter, ftrongly nerved, green on the upper, yellowifh and downy on the lower furface, on long and thick petioles; flowers numerous on long peduncles; coroll large, monopetalous, campanulate, deeply divided into five fegments; calyx large, reddifh, green, campanulate, with five blunt divifions; filaments five, thick, fupporting as many large nearly arrow-fhaped anthers which are fpirally united and enclofe the fummit of the fstyle; fstyle reddifh, club-fhaped, marked at the end with five fpiral furrows; capfule furrowed, from eight to ten inches long; feeds very fmall, fomewhat egg-fhaped, enveloped with fine, fhort, reddifh cotton. A native of the Antilles. 4. *B. grandiflora.* "Leaves in fevens; flowers pentapetalous, large, polyandrous; flamens united into a tube at the bafe." Cavan. Calyx large, expanding with four blunt divifions; coroll fuperb, of five petals, each five inches long, but narrow in proportion to their length, whitifh, fleshy at their bafe, velvety without, fmoother within, and rounded at their extremities, inferted at the bafe of the tube of the filaments, which is naked, entire in its whole length, and terminated by a prodigious number of red filaments a little fhorter than the coroll; anthers kidney-fhaped, fmall and loofely attached to the filaments; fstyle filiform, thick, longer than the flamens, with five fmall teeth; fruit unknown. Described by Cavanilles from a fpecimen in the Herbarium of Thouin. It grows about Rio-Janeiro. 5. *B. Ceiba.* "Flowers polyandrous; leaves in fives." Linn. Trunk clofely armed with fhort, ftrong fpires, fo large as to be hollowed out into canoes of twenty-five tons burden; calyx fmall, campanulate, with five fmall teeth: coroll monopetalous; tube ftraight, twice as long as the calyx; border divided into five

long, concave obtufe fegments; filaments numerous, proceeding from five diftinct bodies, which are united at the bafe and form a conic tube adhering to the bafe of the coroll; anthers oblong, loofe; germ fomewhat ovate, with five angles; capfule oblong, fmall at the bafe; feeds nearly round, covered with down, which is ufed by the lower ranks to fluff pillows and chairs. A native of South America, near Carthageua. Cultivated at Hampton Court in 1692. 6. *B. heptaphyllum.* "Flowers polyandrous; leaves in fevens." Linn. "Stamens in five bodies." Cavan. A tree fifty feet high, fix feet diameter at its bafe; wood foft, light, and brittle; bark thick, cinereous, fpinous when young; leaves digitate; calyx four-cleft; flowers numerous, large, odorous; coroll of five petals, downy without, attached by its bafe to the bottom of the tube of the filaments; filaments very numerous, kidney-fhaped, fhorter than the coroll, loofely attached; fruit elongated. 7. *B. globofum.* "Leaves in fives or fevens, obovate, emarginate; fruit globular." Willd. (Aub. Gu'aa. Tab. 281.) A tree thirty feet high; trunk a foot and a half in diameter; leaves palmate, green, fmoother, oval, obtufe, flightly crenulated at the fummit, the middle one the largeft, on long petioles, with two long, pointed, caducous ftipules at their bafe; flowers unknown; fruit in axillary and terminating racemes. A native of Cayenne. 8. *B. goffypium.* "Leaves five-lobed, acuminate, tomentofe beneath." Linn. A large tree with green, nearly fmoother bark; leaves alternate on long, flender, pubefcent petioles; flowers large, in fimple panicles on downy peduncles; calyx of five unequal leaves; petals five, as long again as the calyx, expanding, yellow; filaments numerous, flightly united at their bafe; anthers oblong, curved; capfule oval-obtufe; feeds kidney-fhaped. A native of the eaft of Coromandel.

The fpecies known to Linnæus were at firft placed by him with the common cotton and its congeners, under the old Greek name Xylon; but afterwards feperated on account of the fimple calyx. Thofe with the double calyx he then called goffypium; thofe with the fimple one bombax. The fpecies of the genus bombax, as it now ftands, differ fo much from each other in moft of the parts of fructification, as almoft to juftify the divifion of them into diftinct genera. The calyx, the coroll, the number and fupport of the flamens, the form and infertion of the anthers, all vary: nothing is conflant but the fimple calyx; the five-celled, five-valved capfule, and the woolly feeds. We have altered the natural and effential generic characters, and fo formed them as not to exclude any of the fpecies.

Propagation and Culture. Silk cotton is propagated by feeds fown in a hot-bed in the fpring. In about two months it fhould be tranfplanted into a fmall pot filled with frefh loamy earth, and plunged into a moderate hot-bed of tanners' bark. At firft it fhould be fhaded from the fun; but afterwards, when the weather is warm, fhould be allowed frefh air, and frequent fupplies of water in fmall quantities, with a uniform degree of heat. In autumn it muft be removed into the bark-ftove and fparingly fupplied with moifture. It makes a pleafing variety in a large ftove, but is not likely to produce flowers in England. See Miller, Gardener's Dictionary.

BOMBAY, in *Geography*, a fmall ifland in the Indian Sea, near the weftern coaft of Hindooftan, about 7 miles in length and very narrow, containing a very ftrong and capacious fortrefs, a large city, a dock-yard, and marine arsenal. It is feperated on the N.E. by a narrow ftrait from Salfette, another ifland, and thefe two, together with the neighbouring fhores of the continent, form a large found, in which are feveral other iflands, particularly Caranjah and Elephanta;

Elephant; the latter (which see) being famous for its subterraneous temple, and both of them acquisitions from the Mahrattas. It was first taken possession of by the Portuguese, soon after their arrival in India, and called by them *Buon Bahia*, or Good Bay, from the excellence of its harbour, which is so spacious as to accommodate, as it is affirmed, a thousand ships at anchor, and well sheltered from all winds. The Portuguese ceded it to the English in 1662, as part of the dower of the Infanta, queen of Charles II. After the king's marriage, a fleet under the command of lord Malborough was sent to take possession of it; and sir Abraham Shipman was appointed governor. But upon their arrival in September 1663, the viceroy, actuated by the Popish clergy, who objected to the cession of the island to heretics, refused to surrender it. At length, however, in 1664, he was terrified into compliance, and a treaty was established, by which Mr. Cook, upon the death of Shipman, was invested with the possession of the island, in quality of governor. By this treaty the inhabitants were to be continued in the free exercise of their religion, and in the undisturbed possession of their estates under the crown of England. Although the trade of Bombay was at this time very prosperous, it was soon found, that the royal revenues were not sufficient for defraying the charge of the establishment, and that the trade itself was subject to very considerable obstructions; so that the king found it expedient to make a full grant in fee-tail of the port and territory to our East India Company, which was done by charter, dated 2^d March 1668, and thus they have continued to hold it to the present time.

The city of Bombay, the principal port and settlement of the English in this part of India, is situated in the northern part of the island, N. lat. 18° 58', E. long. 72° 38'. It is about a mile in length, but narrow; and defended both towards the sea and land with various fortifications, which have been constructed at a great expence, and which have rendered it the most considerable fortress in India. On the island also there are small forts sufficient for protecting it from any irruption of the Indians; and in the harbour there are basons hewn out in the rock, for the purpose of careening ships. The houses of Bombay are in general neither splendid nor commodious; but there are several handsome buildings, among which are the governor's palace, and a large, elegant church near it; the houses are not flat-roofed, as they are in other parts of the East, but they are covered with tiles in the European fashion. The English have glass windows. The other inhabitants of the island have their windows of small pieces of transparent shells framed in wood, which render the apartments very dark. The soil of the island is sterile, and incapable of any great improvement; its chief produce consists of cocoas and rice, besides mangoes and some Indian fruits. It draws a considerable supply of provisions from the continent, and from the fertile island of Salsette. Large quantities of salt are manufactured on the shore, from the sea-water that flows into pits adapted to this purpose. The sea-breezes and frequent rains cool the atmosphere, and render the climate of this island temperate; and though the air is not so pure as at Madras, yet it is much more wholesome than at Bengal; the coast of Malabar being pretty healthy, though less so than the coast of Coromandel. The island of Bombay has been rendered much more healthy than it was formerly, by a wall, which has been built to prevent the encroachment of the sea, where it formed a salt marsh, by draining the marshes in its environs, and by an order that none of the natives should manure their cocoa-nut trees with putrid fish. Nevertheless, many Europeans, especially on their first arrival,

are seized with fevers, fluxes, and other disorders, which prove fatal; and others shorten their days by not adhering to a mode of life suitable to the climate. The natives, however, and others, who abstain from excess of animal food and strong liquors, enjoy a good share of health, and live to a considerable age. The want of fresh water is an inconvenience to which the inhabitants are subject; the best being that which they preserve in cisterns after rain; whereas that which is supplied by their wells has a brackish taste.

This island is become very populous, in consequence of the toleration which is granted by the English to persons of every religious profession. The number of inhabitants is estimated by Niebuhr at 140,000, and of these the Europeans form the most inconsiderable class. The other inhabitants are Portuguese, or Indian Catholics; Hindoos, the original possessors of the country; Persians from Kerman; Mahometans of different sects; and some Oriental Christians. The English have a handsome church at Bombay, but they are disadvantageously circumstanced with regard to officiating clergy. The Catholics are much more numerous than the Protestants, and have many priests, as well Europeans as Indians, who attend their studies at Goa. The pope, many years ago, appointed for their superintendance a bishop of Bombay, but he was dismissed by the governor of the island. The Catholic churches are decent buildings, and are within sumptuously ornamented. The Jews had once a college and a synagogue in the middle of this island; but the college was converted into a country-house for the English governor, and the synagogue into a suite of assembly rooms.

Bombay is the seat of the English government for the coast of Malabar; as Madras is for the Coromandel coast, Calcutta for Bengal, and as Bencoolen was for Sumatra. These four governments, of which that of Bengal has the superiority and control, are obliged, by an act of the British parliament passed in 1773, (13 Geo. III. c. 63.) to afford mutual assistance in cases of extraordinary exigence. The different establishments are under similar administration, and all processes between subjects of the company are determined by the law of England. The council or regency of Bombay (as well as that of Bengal) consists of a governor and three members of council. The other servants of the company are factors and writers of different ranks, and are sometimes transferred from one department to another. The governor and members of council of the other presidencies are to be under the control of the government-general of Bengal, with respect to treaties with the native powers of India, levying war, making peace, collecting and applying revenues, levying and employing forces, or other matters of civil and military government; and they are required in all cases to obey the orders of the said government-general, unless the directors of the company shall have sent to these settlements any contrary orders not known to the government-general, of which, in that case, they are to give this government immediate advice. The Court of Directors are to appoint to these several governments, and likewise the commander in chief of all the forces, and the three provincial commanders in chief. All governors and counsellors are prohibited from trading, except from the company, 24 Geo. III. sess. 2. c. 25. 33 Geo. III. c. 52. See BOARD of *Controul* and *East India Company*.

BOMBAY Hook, an island of America at the mouth of Delaware river, about 8 miles long and 2 broad, formed by the Delaware on the eastern side, and Duck Creek and Little Duck Creek on the Maryland side; these are united together by a natural canal. The N. W. end of Bombay Hook is about 47 miles from Capes Henlopen and May; from the Hook to Reedy Island is 9 miles.

BOMBAZINE RAPIDS, lie on a river in Lincoln county, and district of Maine in America, and are navigable for boats with some lading, at a middling pitch of water. They took their name from Bombazine, an Indian warrior, who was slain by the English in attempting to cross them.

BOMBAZINE, a lake, seven or eight miles long, in the township of Cattleton, county of Rutland, and state of Vermont.

BOMBELLA, in *Entomology*, a species of **BOMBYX**, of a middle size, that inhabits Austria, the wings of which are cinereous, sprinkled with fuscous. Fabr. Mant. This is *Tinea Bombycella* of the Vienna catalogue. (Wien. Schmet. terl.)

BOMBERG, DANIEL, in *Biography*, one of the early printers, was a native of Antwerp, and settled at Venice, where, in 1518, he printed a folio edition of the Hebrew Bible. See **BIBLE**. He also began an edition of the Talmud, in 1520, and completed it some years afterwards in eleven volumes folio. Each of the three impressions of this immense work is said to have cost him 100,000 crowns. His whole property was devoted to the impressions of valuable editions of Hebrew Bibles and rabbinical works, for which purpose he employed a great number, as some say, more than 100 of learned Jews. Bomberg was himself a Hebrew scholar. He died about the middle of the 16th century.

BOMBIC ACID. The silk worm has a small reservoir near the anus, from which, when full grown, or especially when in the chrysalis state, a minute quantity of an acid liquor is seen to ooze out. If the entire animal is bruised, it gives a liquor containing the usual soft animal matters, together with a native acid. Alcohol separates the former, and leaves the latter in solution, which, by evaporation, furnishes a very four pungent yellow fluid, which shews all the marks of an acid by reddening blue vegetables, and uniting with alkalis and some earths. The discoverer, Chauffier, considers it as peculiar, and hence it has obtained a separate place in the list of animal acids; but from analogy with the experiments on the *formic* acid, and other circumstances, the separate existence of the bombic acid is very questionable. No other chemist has yet undertaken to confirm or dispute the original statement. Mem. de l'Acad. de Dijon. 1783.

BOMBICHIE, in *Geography*, a town of Asia in Syria, 44 miles E. N. E. of Aleppo.

BOMBINA, in *Entomology*, a large species of **CURCULIO**, described by Fabricius, as a native of Cayenne. The colour of this insect is ferruginous brown, and the wing-cases striated, with black elevated tubercles.

BOMBINA, in *Zoology*, a species of **RANA**, or frog, the belly of which is orange, spotted with sky-blue, and the pupil of the eye triangular. Blumenb. This kind appears to be extremely variable in point of colour and markings. In the tenth edition of the Linn. Syst. Nat. it is described as the *Rana variegata*. Roefel, in his "History of Frogs and Toads," calls it *Bufo igneus*, (*bufo vulgo igneus dictus*). It is likewise *La sonnante*, and *le couleur de feu*, of Lacepede, and *Rana ignea*, or fire-frog, of Dr. Shaw.

The permanent varieties, if they may be so expressed, of this particular species, do not seem to be very correctly ascertained. Gmelin, upon the authority of preceding writers, constitutes the following varieties: β has the belly black, with clear white spots and speckles; γ is of a fuscous colour; and δ is distinguished by its loud sonorous voice.

This is the smallest of the European kinds of either the frog or toad. The general habit resembles that of a toad, but it is said to leap and swim with as much or even greater facility than the common frog. Dr. Shaw observes, that he places it among the frogs instead of toads, on account of its depositing its ova in clustered heaps; not in strings like the latter

animals. In Germany, Italy, and other European countries, which this creature inhabits, it is known to delight in marshy places. The sound of the male, which alone is vocal, is clear and sharp, and is thought by some to resemble, in a very peculiar manner, that of a man giggling with laughter. This, indeed, is not the universal opinion; some authors compare it to the tone of a bell, or the note of a cuckow, for which reason it has obtained the name of *bombycina*.

This animal, according to Dr. Shaw, may be considered rather as an aquatic than terrestrial species; being rarely found on land, but chiefly inhabiting turbid stagnant waters, in which, in the month of June, it deposits its spawn, the ova being much larger in proportion than in most others of the genus. The tadpoles are hatched towards the end of June, and are of a pale yellowish brown colour; and, when young, are often observed to hang from the surface of leaves, &c. by a glutinous thread proceeding from the small tube or sucker beneath the lower lip. They arrive at their full size towards the close of September, and at that period are remarkable for the fleshy or muscular appearance of the tail, which is stronger in proportion than in most other tadpoles. About the beginning of October they assume their complete or ultimate form; and when the tail has so far decreased as to be still a quarter of an inch in length, that remaining portion becomes entirely obliterated in the space of about twelve hours. The fire-frog is a lively active animal; leaping and swimming admirably well. When surprised on land, or unable to escape, it squats close to the ground; at the same time turning back its head and limbs in a singular manner, and if farther teized and irritated, evacuates from the hinder part of the thighs, a kind of saponaceous frothy fluid, of no bad scent, but which, in some circumstances, has been found to excite a slight sensation of acrimony in the eyes and nostrils. This species is observed to breed at the age of three years, and may be supposed to live about ten; but this is not entirely ascertained.

It ought not to escape remark, that the triangular form of the pupil of the eye, which Gmelin and others consider as the most striking criterion of this species, can only be observed in a full light, for when examined in the shade its shape is circular.

BOMBOESKJE, in *Zoology*, the **SCIURUS ASIATICUS** in Le Bruyn's It. p. 434, t. 254.

BOMBUS, in *Medicine*. See **FLATULENCY**.

BOMBUS, in *Music*, an artificial motion with the hands, imitating, in cadence and harmony, the buzzing of bees. The word is originally Greek, and signifies the buzz or noise of bees, gnats, and the like. In this sense, *bombus* made one of the species of applause used by the ancient auditories.

BOMBYCILLA BOHEMICA, in *Ornithology*, the name under which Brisson describes the Bohemian chatterer, *Ampelis Garrulus*. The same author likewise calls an American variety of this bird *Bombycilla Carolinensis*.

BOMBYCINUM, in *Ancient Writers*, properly denoted a species of silk, brought from Assyria and the island of Cos. In which sense it stood distinguished from *Sericum*, another sort of silk brought from the Indies.

BOMBYCINUM VELAMENTUM. See **VELAMENTUM**.

BOMBYLIUS, in *Entomology*, a genus of **DIPTEROUS** insects, distinguished by the following character: beak or sucker very long, setaceous, straight, and consisting of two unequal valves, within which three setaceous bristles are contained; feelers two, short and hairy: antennæ subulate, and connected at the base. Linn. Gmel. &c.

The antennæ of the insects in this genus are short, and contain three articulations, the first of which is long, the second short, and the third or last conicle, and terminating

in a kind of appendage, almost forming a fourth joint, as is to be observed with the assistance of glasses. Those who have carefully examined the structure of the trunk with the microscope affirm, that the number of valves or bristles concealed within the external bivalve sheath are four instead of three, as Gmelin describes them. The antennæ are inserted at the base of the trunk.

Insects of this genus have the head comparatively of a small size, of a form somewhat rotund, and almost wholly occupied by the eyes. The thorax large, the abdomen bulky, and rounded at the extremity as in the bee. Both the thorax and abdomen are hairy, or covered with down. The wings longer than the body, and extended horizontally. Legs long and slender.

The size and rotundity of the body afford an excellent natural character, by which this tribe of insects may be distinguished from those of the genera *Empis* and *Astilus*, with which some naturalists have confounded them. The Fabrician species of *Volucella*, *Cytherea*, and *Anthrax*, have been referred to the *Bombylius* genus with very little propriety.

The true *Bombylius* is a lively active tribe of insects, that subsist entirely on the nectareous juices they extract from flowers, with the assistance of their long proboscis or trunk. They fly with much rapidity, making all the time a soft humming noise similar to that of the bee. In England the largest species (major) has acquired the name of the humble bee fly. The insects of this tribe are found in the winged state in the summer, but their metamorphose is utterly unknown.

Only a small number of species in this genus are at present known, namely major, medius, minor, minimus, ater, fuscus, griseus, virescens, and albifrons: these are natives of Europe. The extra-European kinds are *æqualis*, *capensis*, *cupreus*, *maculatus*, *pygmaeus*, and *vericolor*.

BOMBYX, a genus of **LEPIDOPTEROUS** insects, or rather one of the subdivisions of the **PHALÆNA**, an extensive genus, in which all the insects of the moth tribe are comprised by Linnæus. Fabricius, in his "Entomologia Systematica," admits the *Bombyx* as a genus, applying the term *Phalæna*, which Linnæus gave indiscriminately to all the species of the moth tribe, as a general name to that particular description of moths which have the palpi cylindrical, the tongue advanced and membranaceous, and the antennæ filiform.

The true definition of the *Bombyces*, whether considered as a subdivision of the *Phalæna*, or as constituting a genus of themselves, is not sufficiently explicit. A great number of the species may be readily referred to their proper station in the genus, by observing with attention the characters laid down by Linnæus; but there are others which cannot be so accurately distinguished from the *Noctua* as we could wish, by the assistance of those characters. If, for instance, we advert to the earlier editions of the Linnæan *Systema Naturæ*, we shall find even in the small number of species which that naturalist describes, that the greatest confusion prevails in this respect. Had Linnæus been himself correct in his ideas of the natural character of the *Bombyces*, we are almost persuaded he would not have considered *Phalæna bucephala* as a *Noctua*, any more than *dominula*, *fuliginosa*, *Jacobææ*, and some others, which he includes as such in his arrangement of the *Lepidoptera*.

Linnæus thought at first the pectinated antennæ of the *Lepidoptera* a sufficient criterion of the *Bombyces*, provided the wings were incumbent and depressed, while the insect remained in a resting position, because the geometræ, though often furnished with pectinated antennæ, have the wings expanded horizontally when at rest. But later observations of

other naturalists have determined this character of the *Bombyx* to be insufficient to distinguish it.

In the *Systema Naturæ*, Linnæus divides the *Bombyces* into sections in the following order; the *elingues*, or those without a manifest spiral tongue, and the *spirilingues*, having an involuted spiral tongue. These two principal sections are subdivided again; the *elingues*, into those with the back smooth or not crested,—with expanded wings,—with reversed wings,—with deflected wings,—with erect crests, or tufts on the back; and the *spirilingues*, those smooth, with expanded wings,—with deflected wings,—and with the back crested.

This mode of arrangement is entirely superseded by the *Entomologia Systematica* of Fabricius. The latter writer takes his characters, as usual, chiefly from the tongue and palpi. His *Bombyx* is thus generically described; feelers two, compressed, reflected; tongue short, and membranaceous; antennæ filiform. By this many of the Linnæan *Bombyces* are excluded, for the reception of which he establishes two other genera, those of *Cossus* and *Hepialus*, both of which most strictly appertain to the Linnæan *Bombyces*. The *Bombyx cossus* gave Fabricius the idea of forming a distinct genus of the species analogous to this insect. The characters, he lays down for the *Cossus* are these; the palpi or feelers two, compressed, cylindrical; with no tongue; and the antennæ short and filiform. His *Hepialus* has two hairy feelers, between which is the rudiment of a bifid tongue; and the antennæ are moniliform.

Gmelin, in the last edition of the *Syst. nat.* endeavours to reconcile the Fabrician genera as subdivisions to the principal Linnæan genus *Phalæna*. His *Bombyces* consist of the *Attaei*, which have the wings expanded, and the *Bombyces* (strictly so) which have not the wings expanded, and these latter are again arranged in subdivisions in the following order: first, those with reversed wings, as in *Quercifolia*; second, those with deflected wings, as in *Bucephala* and *Hebe*; third, those with incumbent wings, as in *Antiqua*; and fourth, those with convoluted wings, as in *Bella*. The four families, into which Olivier separates the *Bombyces*, scarcely differ from the preceding; they consist of those with expanded wings, with wings reversed, with wings bent down (deflected), and with wings recovered (incumbent).

The *Bombyces* are to be considered as a true natural family of the moth tribe, which for the most part may be distinguished by the casual observer, who will attend to the structure of the antennæ, the form of the body, the position of the wings, and some few other particulars to be mentioned hereafter. The antennæ, which are filiform, and either pectinated or ciliated, differ greatly in the two sexes of the same species; the male being generally distinguished by having the antennæ much broader, or larger, than in the other sex. The thorax of the *Bombyx* is rather more bulky, and the body thicker than in the *Noctua*, especially in the females. Thus far consistent with the Linnæan character; but a strict attention to the feelers and structure of the tongue, as Fabricius observes, will be also necessary to determine many of the *Bombyces*, which approach so closely to the *Noctua* as not to be accurately distinguished by any other means. For this reason Fabricius is commendable in having endeavoured to define the precise limits between the *Bombyces* and their analogous tribes: his character is more definite than that which Linnæus had previously assigned to this family. The discrimination of Fabricius is obvious in separating the two tribes or genera of *Cossus* and *Hepialus* from the *Bombyces*, under which head Linnæus comprehends them; for those insects certainly form distinct natural families, both in their general appearance, their metamorphoses, their habits of life, and other peculiarities, from that

which

BOMBYX.

which ought to be considered as the natural family of bombyces.

The insects of the bombyx tribe never fly except in the evening. During the day time they secrete themselves under the leaves, or beneath the branches, in the clefts of trees, where they may remain secure till about sun-set, at which time they appear to be on the alert, at first crawling about the branches, then fluttering their wings, and becoming brisker in all their motions as the evening comes on. The larger sort of moths, which we see first starting from the woods or hedges after some of the geometræ, are the *swifts*, the Fabrician hepiali, which fly swiftly as their trivial name implies, but low or near the surface of the ground; these at twilight are succeeded by the bombyces and noctuæ, whose flight is more elevated. They continue to sport about till it becomes quite dark. The males of the bombyces are commonly first upon the wing in search of the females, which latter are in some few species entirely destitute of wings, or at least have only the rudiments of them close to the thorax; in which case the female waits upon the trees or herbage for the arrival of the male; the female of bombyx antiqua, the vapourer moth, is a striking proof of this, for it has so little the appearance of a moth that any one, except an entomologist, would mistake it for an apterous or wingless insect. Those females which have wings are commonly larger even than the males.

The bombyces are produced from a larva, or as it is more usually termed by common observers, a caterpillar. This is of a long cylindrical form, having in some species a smooth skin, or in others more or less tuberculated; sometimes the skin is covered with a fine silky down, or with hairs; and some of the larger kinds are armed with spines and bristles. All the larvæ of the bombyces subsist on vegetables. Their jaws are strong, and of a horny texture, and below them is a small opening, through which the creature draws the silky thread of so much utility in its general economy. Most of these larvæ have sixteen feet, some have only fourteen feet, and others no more than twelve, six of which are hooked, and situated on the three first annulations near the head, the others towards the lower extremity of the body are short, broad, and very different in structure.

The greater number of species in the bombyx tribe, when in the larva state, lead a solitary life, in which case they separate as soon as they are hatched from the eggs, and crawl about to provide for themselves, the smallest of these even being able to obtain its own subsistence; they can eat as readily, and spin, or throw out the silky thread with as much facility as when grown bigger. The latter is of considerable utility to the larva, for when it wishes to descend from one branch of the tree or bush to another, instead of being obliged to pursue a circuitous course, by crawling or walking, it need only fasten one end of the silken thread to any particular spot and lower itself by its assistance to the branch desired; or when suspended mid-way between the branches, it can pass aside with a swing to any other point within a convenient distance. In like manner, when observed by birds or other enemies, it can drop in an instant and elude the enemy, waiting concealed below among the leaves or on the ground till the danger is over, and then remounting to the former spot by the aid of this thread. This is a provision of nature for the security of the larvæ of the bombyces, in common with that of other lepidopterous insects.

Some species of the bombyces live in societies, as may be observed, for instance, in *bombyx neustria* of entomologists, (the *lackey-moth* of English collectors). The larvæ of this species, by their united labours, spin a capacious habitation, in which the infant brood is hatched from the egg, and after

undergoing their several transformations finally become moths.

Like other larvæ of the moth tribe, those of the bombyces cast their skin several times. When full grown, and approaching the pupa state, those of the bombyx kind spin a sort of web, in which we find the most valuable silk produced by these creatures at any time of their lives. The silk spun by the hairy larvæ is observed to be of little value, because the creature interweaves it with the hairs it plucks off its skin for this purpose. The common silk worm (*bombyx mori*), whose cocoon consists of the most valuable kind of silk, as is well known, has the skin perfectly smooth, or free from hair. There are certain species of the larger bombyces, the larvæ of which have smooth skins, but still beset with annular series of spines or bristles, that produce very strong silk, and are reared with the view of obtaining the cocoons for the manufacture of silk in the East Indies. The breed of these useful insects has long been cultivated in India, although the silk produced from them is very little, if at all, known in Europe. See *SILK*. The bombyces remain in the pupa state for a certain time, varying according to the species, some only a few days or weeks, others six or twelve months, two years, or even three. The same day that the creatures emerge from the pupa state they are in a condition to perpetuate their race. Almost immediately after coupling the males die; the females live long enough to deposit the eggs in a proper place for their security, and where the infant brood may find subsistence, after which they perish likewise.

The species of the bombyx tribe are numerous. Those already described by naturalists amount to a large number; and there are, in the cabinets of the curious, many more, especially of the extra-European species, that have never been described; even in the collections of this country, those of the latter description are numerous. The following are described by Linnæus and Fabricius, and enumerated by Gmelin: atlas, hesperus, arotus, cecropia, paphia, polyphemus, cypria, cytherea, mulitta, promothea, erythrina, janus, megera, hippodamia, nictitans, semiramis, boreas, luna, epimethea, argus, pavonia, minor, media, major, achelous, angulata, liberia, tau, jo, abas, salmonea, proterpina, fenestra, penelope, tyrrhea, perspicua, armida, militaris, castalia, populifolia, quercifolia, illicifolia, promula, cassandra, capensis, aluco, australasia, quadricincta, rubi, pruni, amphione, potatoria, ocularia, hibisci, cynira, cerati, pini, trifolii, quercus, stigma, lusca, dumeti, catax, lanetrus, vinula, fagi, versicolor, mori, populi, eueria neustria, tricolor, castrensis, francoica, taraxaconis, cinerea, mali, avellanae, processionea, pityocampa, rurea, atra, rufa, lagopus, imperialis, crassicornis, hyphinoë, cyane, bucephala, helops, oleagina, cava, pudica, casta, maculosa, virgo, mene, deflorata, tarquinia, tarquinius, hebe, villica, plantaginis, vittata, monacha, flava, lutea, dispar, amasis, chrysothorax, auriflua, bicolor, falcis, cassina, centrolinea mendica, advena, rutila, lentifera, crataegi, eridanus, tibialis nitidula, plumigera, obsoleta, coronae festiva, dryas, coryli, flavomaculata, nuda, furcula, curtula, reclusa anachoreta, anastomosis, testudo, afella, bufo, cippus, pudibundus, scopularia, fascelina, tremula, cæruleocephala, argentina, decora, rufa, dictæa, elegans tritophus, ziczac, dromedarius, terebra, cossus, palpina trepida, quæna, gnoma, arenaceus, morio, rubea, alphas, purpurea, ceraria, murina, nebulosa, strigosa albida, aulica, helvola, undulata, lubricipes, lota, læta, communimacula, compressa, milhauseri, spreta, lincus, strigula, begga, vni-grum, rufula, rufina, grammica, striata, matronula, parthenias, leporina, celsa, dione, capucina, camelina, oo, aesculi, antiqua gonostigma, paradoxa, zona, pylotis,

pylotis, graminis, popularis, fulminea, glorioſæ, crini, roſea, luſoria, cribrum, libatrix, lectrix, credula, dominula, hera, ſanguinolenta, ricini, crotalariæ, colon, populeti, ancilla, conſperſa, fuliginofa, ornatricis, priverna, franciſca, jeſuita, viciella, veſtita, muſcella, bombella, pectinella, annulata, grifea, jacobææ, rubicollis, pulchella, bella, hiſtrio, and umber. To which are to be added bombyx figura Donov. Ind. Inf.; hepialus mappa Donov. Brit. Inf.; coſſus labyrinthicus, argenteus, lituratus, and nebulofus, Donov. Inf. New Holland.

In adhering to the Fabrician ſyſtem, in preference to that of Linnaeus, we are to exclude from the foregoing liſt of bombyces the following ſpecies: lagopus, roſtrata, ſagitta, gemina, deſorata, and ſaga, all of which are to be referred to the Fabrician genus *hybla*; hamuli, jodutta, lupulina, heceta, obliqua, canna, crux teſtudo, afella, bufo, and mappa, ſpecies of the *hepialus* genus of Fabricius: and coſſus, unguiculatæ, terebra, aefculi, ſcalaris, pyrina, labyrinthicus, argenteus, lituratus, and nebulofus, which ſtrictly belong to the Fabrician genus *coſſus*.

BOMBYX is alſo a name given to the *Silk-worm*.

BOMBYX, in the *Ancient Muſic*, a kind of inſtrument, which, in Ariſtotle's time, was made of a reed, calamus, and, by reaſon of its length, was difficult to play on.

The word ſeems alſo to have been uſed for a key, or contrivance for ſhutting and opening the holes of wind inſtruments.

BOMBYX, in the *Ancient Naturaliſts*, ſignifies indifferently either ſilk or cotton.

BOMENE, in *Geography*, a port town of Zealand, one of the provinces of Holland, on the north ſhore of Schouwin iſland, one league eaſt of Brouwerſhaven.

BOMING, an iſland of Aſia, in the mouth of the Ganges. N. lat. 22° 45'. E. long. 91° 25'.

BOMIO, in *Ancient Geography*, a ſtation near Axbridge, according to Antonine's Itinerary; but placed by Camden and Gale at Boverton, in Glamorganſhire.

BOMMEL, in *Geography*, a town of Holland, in the iſland of Over-Flahee, 7 miles W. of Willemladt.

BOMMEL, a ſtrong town of the duchy of Gueldres, ſeated on the Wahal, in the iſland of Bommel-Waert, firſt ſurrounded with a wall by Otho III. count of Gueldres, in 1229; 60 miles N. E. of Antwerp, and 7 N. of Bois-le-Duc. Bommel was taken by the republican troops of France, October 4, 1794.

BOMMEL-Waert, a kind of iſland, in the province of Gueldres, about five leagues in length from Louveſtein N. W. to Fort St. Andrew S. E., and two in its greateſt breadth, formed by the rivers Maes and Wahal. It is defended by three forts, viz. St. Andrew, Voorn, and Crevecœur. The firſt has five baſtions, and was built in 1599 by the admiral of Arragon, and the cardinal Andrew of Auſtria, lieutenant-general of the Spaniſh forces; the ſecond is ſituated at a ſmall iſland, called Voorn, at the eaſt end of Bommel-Waert, and was conſtructed by the prince of Orange, and on that account is ſometimes called Fort Naſſau; and the third is at the ſouth ſide of the iſland towards Bois-le-Duc. Theſe three forts were conſtrained to ſurrender to prince Maurice in the year 1600. In 1672, the French took the iſland under maſhal Turenne, who, after deſtroying the fortifications, abandoned it in the following year. At the commencement of the religious diſputes, count Charles de Manſvelt, paſſing this iſland with ſome Spaniſh troops, was encamped by ſeveral Dutch ſhips under the command of count Hohenlo, who ordered the dykes to be opened, and thus totally inundated the iſland, ſo that the Spaniards were obliged to retire to the citadel, and would

have miſerably perished, if a ſudden froſt had not conſtrained the count to abandon the ſiege, and to allow them liberty to retire. In commemoration of this deliverance a chapel was built at Bruſſels, in honour of the immaculate conception of the Virgin, next the Dominican church, which, being deſtroyed in 1695, was afterwards re-built with greater magnificence. In 1794, the republican troops of France, having compelled the Dutch to abandon Bommel, overtook them in their retreat, and compelled a great part of them to ſurrender. They afterwards availed themſelves of the frozen ſtate of the Wahal, and were making progreſs towards Gorcum and Calenberg; but they were attacked by the Britiſh troops in conjunction with the Heſſians, and driven acroſs the river, with the loſs of a conſiderable number of men and four pieces of artillery. But this temporary ſucceſs was of no permanent avail for reſtraining the progreſs of the French army.

This iſland belonged to the province of Guelderland, except the town of Louveſtein, which, with a very ſmall diſtrict at the weſtern end of the iſland, belonged to Holland.

BOMO, in *Ancient Geography*, a name given to the iſland of Eubœa, from the cattle with which it was ſtored; the ancient Arabian word *bomo*, or *bohmo*, ſignifying, according to Heſychius, cattle, or herds of cattle. This is, probably, the moſt ancient appellation; the iſland having been firſt peopled, as Strabo informs us, by the inhabitants of Arabia and Phœnicæ.

BOMOA, in *Geography*, a town of North America, in New Navarre, 10 miles S. of Cinaloa.

BOMONICA, in *Antiquity*, an appellation given at Sparta to the children, who, in the ſacrifices of Diana, ſtrove who ſhould receive the greateſt number of ſtripes with rods, which they ſometimes continued to do the whole day, and even, as Plutarch relates, to death itſelf.

The word is formed from *βημας*, *altar*, and *νικη*, *victory*; importing as much as *victor ad aras*, or *conqueror at the altars*.

BOMPART, MARCELLUS, in *Biography*, practiſed medicine at Clermont Ferrand the early part of the ſeventeenth century, and was auſic counſellor to the king. No memoirs of his life are known; but his work "Miſer Homo," in which he gives a ſuccinct account of all the principal diſeaſes afflicting the human frame, was much eſteemed. It was dedicated to Pietre, Riolan, and Gny Patin; and to be patroniſed by them was highly creditable: alſo "Nouveau Chaffé Peſté," Paris, 1630, 8vo.; and "Lettres d'Hippocrates traduites et commentées," 1632, 8vo. Haller. Bib. Med. Eloy. Diſt. Hiſt.

BOMPÉL, in *Geography*, a town of Hindooſtan, in the Panjab, 15 coſſes eaſt of Seba, and 3 miles S. E. of Nadone, a town on the Beyah. N. lat. 31° 55'. E. long. 75° 57'.

BOMRAUZE, a town of Hindooſtan, in the Carnatic, 58 miles W. N. W. of Madras, and 36 N. of Arcot. N. lat. 13° 24'. E. long. 79° 38'.

BOMY, a town of France, in the department of the ſtraits of Calais, and chief place of a canton in the diſtrict of St. Omer, 8 miles S. W. of Aire.

BON, JOHN, LL, in *Biography*, a native of Anterville, in Champagne, and eminent in his time for his knowledge in medicine, phyſician to the king of France, and to the cardinal de Guiſe, published, in 1571, "Therapeia Puero-rum," 16to. Paris, "induced to it," he ſays, "by the ignorance of the ſurgeons, midwives, and tonſors, who attended women in child-birth. By their blunders and inexperience in their art, many women loſt their lives, and many children

children were destroyed." His work is very full on the subject, giving rules for the management of women before, during, and after parturition. He has left formulæ for a variety of ointments, with which he directs the pudenda of the women to be anointed, and which he thought conduced much to accelerate the birth of the child. When these failed, lapis ætites was to be tied to one of the thighs of the woman, and polipody of the oak to the feet. But these, he gravely admonishes, are to be taken away as soon as the child is born, lest they should draw away the womb also. Such mighty power was attributed to these trifles! It is probable, however, that the author only meant by these processes to gain time, and to prevent the too hasty interference of the midwives, surgeons, &c.; and as there was nothing in the remedies that could injure the woman, who would frequently be delivered by the natural pains, during their use, he might not be sorry to find the attendants attributing the safety of the woman and child, and the happy termination of the labour, to them. Whatever his real opinion might be, it is certain, that, among the people, these kinds of remedies acquired great credit, and the use of them was continued for near a century after his time. Among other objects that engrossed the attention of this writer, we find him giving formulæ for ointments for smoothing the wrinkles of the abdomen, and for preventing the breasts of women who had borne children from becoming large and pendulous. "Ne venter rugis indecorus," he says, "et statens, eas viris suis ingratas, parum amabiles, et abominandas reddat; ne mammæ in majorem molem extendantur." His book appears to have been in great request, as it passed through many editions, and is inserted in the "Collection of Treatises on disorders attending pregnancy and child-birth," by Caspar Wolfius, published in 1586, re-edited by H. Spachius, fol. 1597, under the title of "Gynecia, sive de mulierum morbis," from which the above quotations have been taken. Haller. Bib. Med.

BON, JOHN PHILIP, probably of the same family with John le Bon, published, at Padua, "De Concordantiis Philosophiæ et Medicinæ," 4to. 1573; he was also author of several poetical works, which were much esteemed in their time. Eloy. Dict. Hist.

BON, in *Botany*, (*Alpinus*). See COFFEE.

BON, *Cape*, in *Geography*, called by the Moors *Ras-Addar*, and the promontory of Mercury, or Hermes, of the ancients, is a cape of Africa, in the kingdom of Tunis, in the Mediterranean sea, distant 11 leagues E.S.E. from that of Zibeeb, and forming the eastern point, as Zibeeb does the western, of the gulf of Tunis. It is so high, that from its summit the mountains of Sicily, distant more than 20 leagues, may be discovered in fair weather. See ÆGIMURUS, and DAKHUL. Cape Bon is situated about N.N.E. from Tunis. N. lat. 36° 50'. E. long. 11° 15'.

BON, in *Modern History*, the name of a feast celebrated annually by the Japanese in honour of the dead. On this occasion they use a great number of lights, and run with eagerness to the tombs of their departed relations with such choice meats as they conceive to be suited to the taste and nourishment of the dead.

BON, Fr.; *Buono*, Ital.; as *tems bon*, and *tempo buono*, used, in *Music*, to express the accented parts of a bar. It is the first note of binary measure of two minims or two crotchets in a bar; the first note of the ternary measure of $\frac{3}{4}$ or $\frac{3}{8}$, and the first and third notes of common time. It is opposed to *tems mauvais* and *tempo cattivo*, the unaccented part of a bar. The French at present, distinguish these portions of a bar by the terms *tems fort* and *tems foible*, strong and weak, and almost loud and soft parts of a bar. It is on

the accented part of a bar that a discord regularly prepared is struck, and resolved on the unaccented part.

BOVA, JOHN, *Cardinal*, in *Biography*, was born at Mondovi, in Piedmont, in 1609, and entered at an early age into a reformed congregation of Cistercians. After having studied philosophy and theology at Rome, he returned to his own country, and became, in 1651, general of the congregation; and he was, at length, viz. in 1669, nominated a cardinal by pope Clement IX. Upon the death of this pontiff, he was thought of as a fit person to succeed him; but another was elected. The cardinal spent the remainder of his days in study and pious exercises, and died at Rome in 1674. He was the author of several works, chiefly of a devotional kind; such as, "De Divina Psalmodia, deque variis ritibus omnium ecclesiarum in psallendis divinis officiiis," 4to. containing an historical account of the practice of psalmody in the Christian church; and "Rerum Liturgicarum libri duo," 4to. giving a similar account of the celebration of the mass. Both these works have been often reprinted; and of the latter an edition much enlarged was published at Turin, in 1747, by father Salas, in 4 vols. fol. Gen. Dict.

BOVA, JOHN DE, professor of medicine at Padua, published, 1758, "Historiæ aliquot curationum, mercurio sublimato corrodente, perfectarum," Verona, 4to. This medicine was much commended by baron Van Swieten, and forms probably the basis of most of our nostrums celebrated for their power of removing pimples, blotches, &c. from the face and other parts of the skin. It was intended by the author to supersede salivation in the cure of lues venerea, and in some cases it has been used with complete success; but it too often disappoints the expectation of the prescriber, to be entirely depended on. "Tractatus de Scorbuto," 4to, 1761. The author shews that this disease, though most frequent in cold marshy places, is not unfrequent in warm countries. "Dell uso e dell abuso dell caffè," Venet. 1761. Coffee, which is hot and drying, should only be used, he says, by persons of cold phlegmatic constitutions. In the quantity it is usually taken in this country, it will scarce be hurtful to any habit or constitution. "Osservationes medicæ ad praxim in nosocomio, anno," 1765, 8vo. Patav. 1766. Haller Bib. Anat.

BOVA, in *Botany* (*Dodoens*). See VICIA *Narbonensis*, and FABA.

BOVA *Nox*. See SMILAX.

BOVA, in *Geography*, a sea-port town of Africa, in the eastern or Levantine government of the kingdom of Algiers, and province of Constantina; known to the Moors by the name of Blaid el Aneb, or the town of jujebs, from the plenty of fruit which is gathered in the neighbourhood. Bona, says Dr. Shaw (*Travels*, p. 46.), is, without doubt, a corruption of Hippo, or Hippona, though the ruins of the ancient Hippo-regius are situated somewhat more than a mile to the south, and furnished materials for the erection of Bona, which is the Aphrodisium of Ptolemy, and placed by him 15' to the north of Hippo. Bona was formerly rich and populous, but is now poorly built and thinly inhabited. Bona, besides its capacious harbour to the east, had formerly a convenient little port under its walls towards the south; but by the constant discharge of ballast into the one, and a neglect of cleansing the other, both are rendered unsafe and inconvenient. However, a great quantity of corn, wool, hides, and wax, are every year permitted to be shipped off from this place; and, by proper management, it might be rendered the most flourishing city in Barbary; and, by introducing a supply of fresh water, it would also become one of the most convenient and delightful. The

adjacent country produces corn and fruit, and great numbers of small and large cattle, but is much exposed to the incursions of the plundering Arabs. The French have a factory at Bona, where they purchase corn, oil, leather, wax, and wool, and constantly keep a resident agent, who has charge of the correspondence between Bona, Algiers, La Calle, and Marseilles. N. lat. 37°. W. long. 7° 50'.

BONA Fortuna, Cape, is a cape of Russia, in the White Sea. N. lat. 65° 35'. E. long. 58° 25'.

BONA Sbaals. See *BASSAUS*.

BONA Dea, the good goddess, in *Mythology*, a mysterious kind of divinity, whose name was unknown to men, and whose sacred rites, performed by the Vestal virgins for the safety of the Roman people, were attended only by women. Some have supposed that this name belonged to Cybele, or the earth, as the source of all good things. Plutarch confounds her with Flora. Varro pretends that she was the wife of Faunus; and that she maintained her character for chastity to such a degree, as never to allow herself to look upon any man besides her husband. Lactantius, on the contrary, says, that this wife of Faunus, having drunk wine in violation of the prevailing custom of the period in which she lived, was whipped to death by her husband with rods of myrtle; and that he, afterwards repenting of the deed, and lamenting the loss of his wife, placed her in the rank of divinities. The feasts of the Bona Dea were annually celebrated, with peculiar solemnity, on the first day of May. The house, in which the rites of the festival were performed, was adorned at a great expence; and as the night was the season appropriated to this purpose, the apartments were illuminated with a great number of lights. The vestals were conveyed into the house of the sovereign pontiff, or one of the chief magistrates; and care was taken to exclude all males, and all animals of this species; and every thing masculine was so scrupulously excluded, that even pictures of that sort were covered during the ceremony. To this purpose, Juvenal (vi. 339.) says:

“ — ubi velari pictura jubetur
Quæcunque alterius sexus imitata figuram est.”

It was supposed, that if a man by chance, and without any deliberate intention, became the witness of these mysteries, he would be struck blind. Clodius, however, was guilty of polluting these mysteries. Whilst Pompeia, the wife of Cæsar, with whom he had an intrigue, was, according to annual custom, celebrating in her house the awful and mystic sacrifices of the “Bona Dea,” Clodius determined to gain access to his mistress, even in the season of her holy ministry. Accordingly, he dressed himself in a woman’s habit, and by the benefit of his smooth face, and the introduction of one of the female servants who was in the secret, hoped to pass without discovery. But by some mistake between him and his guide, he lost his way when he came into the house, and unluckily fell in among the other female servants, who, detecting him by his voice, alarmed the whole company by their shrieks, to the great amazement of the matrons, who presently threw a veil over the sacred mysteries, while Clodius found an opportunity of making his escape by the favour of some of the damsels. This story was presently spread abroad, and raised a general scandal and horror through the whole city. Cæsar put away his wife upon it; and persons of all ranks were desirous of availing themselves of this circumstance to get rid of a citizen, who by this, as well as other specimens of his audaciousness, seemed born to create much disturbance to the state. It had been the constant belief of the populace, that if a man should ever pry into these mysteries, he would be instantly deprived of sight; but it was not possible, as Ci-

cero says, to know the truth of it before, till Clodius ventured upon the experiment; though it was now found, as he tells him, that the blindness of the eye was converted to that of the mind. The affair was soon brought before the senate, and by them referred to the college of priests, who declared it to be an abominable impiety: upon which the consuls were ordered to provide a law for bringing Clodius to a trial for it before the people. Clodius’s faction, however, ultimately prevailed; and when the trial came to the issue, 25 condemned, and 31 absolved him. When Cæsar, on this occasion was summoned to give evidence, he declared, that he knew nothing at all of the matter, though his mother Aurelia, and sister Julia, who were examined before him, had given a punctual relation of the whole fact; and being interrogated, how he came then to part with his wife? he replied, “that all who belonged to him ought to be free from suspicion as well as guilt.” Cicero, in his oration for Milo against Clodius, often refers to this sacrilege, with a view of rendering his adversary odious to the people. Many Roman writers have exclaimed against the licentiousness and infamy of these mysteries, called by way of eminence the Roman mysteries, and celebrated on the 4th of December, though those of the goddess Cybele were celebrated on the first of May. Nevertheless, this goddess is called *holy* in an inscription recorded by Gruter, “*Bonæ Deæ Sanctæ sacrum, &c.*” Lucretius (ii. 598.) depicts the good goddess as bearing a mural crown, and drawn in a chariot by lions. She is also thus represented on the medals of the emperor Philip. The Greeks also had their good goddesses, whom they denominated the goddesses of women; and the Carthaginians paid divine honours to a goddess under this appellation, whom they believed to be Juno.

BONA Fides, or *Bona Fide*, is used in speaking of things done with an honest intention, in opposition to those done with a design of fraud and deceit, said to be *mala fide*. In this sense, we say, a grant, a conveyance, *bona fide*.

In many cases, in the civil law, the *bona fide* of an action excuses the want of some of the customary forms

Contracts *bonæ fidei* among *Civilians*, stand contradistinguished from those *stricti juris*; the former being gained by plain honesty and conscience, which sometimes include several things not expressly mentioned; whereas the latter are restrained to the express terms of the deed. A buyer *bonæ fidei*, is he who really believed the thing to belong to the seller at the time when he purchased it. A possessor *bonæ fidei*, is he who is in possession of a thing belonging to another, but which he truly believes his own. To be entitled to the benefits of next accession, it is requisite the persons have possessed the thing *bona fide*, or really thought themselves the proprietors.

Prescription cannot arise from acts done *mala fide*; since what was unjust in its origin, can never be made just by time and continuance. See *PRESCRIPTION*.

BONÆ Fidei Actions, those wherein for farther light, the judge might take cognizance of things not mentioned between the parties.

BONA Fide Judgment, that wherein the parties are obliged to pay each other what is due *bona fide*, i. e. justly and equitably; and the judge has a power of estimating what is thus due to the actor or plaintiff; a power given him by the formula of the prætor, viz. *ex fide bona, vel quantum æquitas melius*.

BONA Gestura. See *GOOD A-BEARING*.

BONA Gratia, a phrase antiently used in speaking of divorces, which were brought amicably about for some just reason, with the consent of both parties, and without any

crime on the part of either, as in case of old age, disease, barrenness, monachism, captivity, or the like.

BONA Defuncti ad colligendum. See *COLLIGENDUM*.

BONA Mobilia. See *MOBILIA*.

BONA Notabilia, in *Law*. Where a person dying has goods, or good debts, in another diocese, but within the same province, besides his goods in the diocese where he dies, amounting to the value of five pounds at least, he is said to have *bona notabilia*: in which case, the probate of his will, &c. belongs not to the bishop of the diocese where he dies, whose jurisdiction cannot extend beyond the bounds of his own diocese, but to the archbishop of the province.

Though if a person happens to die in another diocese than that wherein he lives, on a journey; what he hath about him above the value of five pounds, &c. shall not be *bona notabilia*.

BONA Patria, a jury or assise of countrymen, or good neighbours. See *ASSISE* and *JURY*.

BONA peritura, perishable goods. By stat. 13 Ed. I. cap. 4. the cargo of a ship that hath been cast away shall be kept for a year and a day, and restored to the rightful owner; but if the goods be such as will not endure so long, they are *bona peritura*, which the sheriff is allowed to sell, and to account in money for the value.

BONA vacantia, goods, such as royal fish, shipwrecks, treasure-trove, waifs, and estrays, in which no one can claim a property. These goods, by the law of nature, and by the imperial law, belonged to the first occupant or finder; but in the modern constitutions of European governments, they are annexed to the supreme power by the positive laws of the state.

BONACCIOLUS, LEWIS, in *Biography*, a physician of great eminence and authority, practised medicine at Ferrara, in the early part of the 16th century. His great work "Æneæ muliebris, sive de fœtus formatione," was first published in 1503, in fol. "qua, præter alia, plurima quoque ad coitum, et ad rem veneream facientia, dictione liberima describuntur." It was nevertheless dedicated to Lucretia, daughter to pope Alexander VI. But the dedication, Blomenbach observes, is only to be found to the folio edition, princip. which is extremely rare. A copy of this edition was sold by Paterfon, in 1791, with the splendid Paris library. This writer, Douglas says, was the first who distinguished the clitoris from the nymphæ, and shewed them to be distinct parts. The *Æneæ* was again printed in 1587. It was also inserted by Caspar Wollius in his Collection of Treatises, called "Gynecia, sive de mulierum morbis," 4to. 1586, re-edited by H. Spaelius, fol. 1597; and with Pinæus's physiological treatises. Though of little value now, the work was for a long time held in great esteem; the author having given in it a more accurate anatomy of the fœtus, and of the partes generationi subservientes, than any preceding writer. Douglas Bib. Hal. Bib. Anat.

BONACHI, in *Geography*, a town of North America, in New Navarre, 180 miles S. of Casa grand.

BONACOPUS, HERCULES, in *Biography*, of Ferrara, and for some years professor in medicine at Bologna, published, in 1552, "De affectu quem Latini tormina appellant," 4to.; "De humorum exuperantium signis ac ferapiis, de compositione Theriacæ, de modo preparandi aquam ligni sancti, &c." 4to. 1553; the latter medicine was now in the zenith of its reputation for its powers in curing the lues venerea; "De curatione pleuritidis, ab Hippocratis, Galeni, &c. monumentis deprompta," 4to. 1553. He died in 1558. Bonacopus had much learning, and contributed by his works to revive among his compatriots a taste for literature, particularly for the works of the ancient Greek fathers in medi-

cine. His brother, or near relative, James Bonacopus, was also much in esteem. He was physician to pope Paul III. He died in 1553, aged 69 years. Astruc. de Morb. Gall. Haller. Bib. Med.

BONAFIDES, FRANCIS, professor in the practice of medicine at Padua, published, in 1533, "Quæstio de cura pleuritidis per venæsectionem, adversus Curtium," 4to. Venet. He defends the practice of the Arabian physicians, who recommended bleeding by the vena saphæna, on the side opposite to the part affected, in plethoric habits; in debilitated constitutions by the basilica in the arm, of the side where the pain was felt; a distinction not attended to in modern practice. Haller. Bib. Med.

BONAIRE, in *Geography*, an island almost uninhabited, near the coast of South America, about 20 leagues from the continent, and 14 S. E. of Curaçoa, belonging to the Dutch. It is about 50 miles in compass, and has on the S. W. side near the middle of the island, a good bay and road. Here were formerly a few houses, with a fort guarded by a small number of soldiers; and five or six Indian families resided here, and cultivated maize, yams, potatoes, &c. The island has plenty of cattle and goats, which are annually salted and sent to Curaçoa. On the south side is a good salt pond, from whence the Dutch procure salt. N. lat. 12° 16'. W. long. 68° 18'.

BONAMES, a town of Germany in the circle of the Upper Rhine, 3 miles N. N. W. of Frankfort on the Mayne.

BONAMY, PETER-NICHOLAS, in *Biography*, was born at Louvres, in the district of Paris, in 1694, and educated for the ecclesiastical profession. But, devoting himself entirely to literature, he became under-librarian of St. Victor, and distinguished both by the politeness of his manners, and the variety as well as assiduity of his studies. In 1727, he was admitted a member of the Academy of Inscriptions and Belles Letters, and made many valuable contributions to its Memoirs. His papers are characterised by simple but correct language, variety of erudition, clearness of argument, and solidity of criticism. At the instigation of M. Turgot, a place was created of historiographer of Paris, and Bonamy was appointed to occupy it. He was thus led to write various memoirs relative to the history and antiquities of the city; and on occasion of a bequest of a curious library to the city, he was made librarian. From the year 1747, he conducted the "Journal of Verdun" with the strictest propriety and decorum. In universal esteem for candour and probity, as well as learning, he died at Paris, in 1770, aged 76. Gen. Biog.

BONAMY'S Point, in *Geography*, lies on the southern side of Chaleur bay, at the N. W. extremity of Eel river cove, and forms the S. limit of Ristigouche river.

BONANA, in *Ornithology*, a species of *ORIOULUS*, of a fulvous colour, with the head and breast chestnut; back quill, and tail feathers, black. Gmel.

This is called by Brisson *xanthornus*, and *le carouge*. It is supposed to be the *xochitotol* of Heru. Mex. and *xochitotol altera* of Ray. Brown names it the bonana bird.

The length of this bird is seven inches: bill black; base of the lower mandible grey; head, neck, and breast chestnut; upper part of the back velvet black; lower part, with the rump, belly, thighs, and under the wings, a deep orange red; vent the same, tipped with chestnut; greater wing coverts, quills and tail, black; legs and claws grey. The female differs in having the colours less vivid than in the male.

The bonana bird is a native of Martinico, Jamaica, and the other islands in the West Indies, where it chiefly inha-

bits woods. The nest of this species is of a curious structure, being composed of leaves and fibres of vegetables, sewed with the greatest ingenuity to the leaf of a banana plant, in such a manner that the leaf itself forms one of the sides to the nest; when completed, it is said to be exactly in shape of the fourth part of a globe.

Another bird, of a species very analogous to the above, is described by Ray and Sloane under the names of *watchy picket*, *Spanish nightingale*, *American hang-nest*, and *idærus minor nidum suspendens*. This appears to have been confounded with the former kind. Brisson, deeming them both the same, included the synonyms of the two species together, which led later observers into an error. Dr. Latham separates them; and, upon the authority of this able ornithologist, Gmelin gives the *watchy picket* as a distinct species under the name of *oriolus nidipendulus*. This specific name is chosen, in allusion to the manner in which the nest is fastened to the extremity of the further twigs of the trees in which it lives. The nest of the banana bird is before described; that of the *watchy picket* is very different, being of a long cylindrical form, composed of stalks, fibres, and the inward hairs of the "old man's beard," which latter bears a strong resemblance to horse-hair. The two opposite methods of constructing, as well as placing the nest, as Dr. Latham judiciously observes, cannot surely belong to one bird. See *NIDIPENDULUS*.

Obs. Gmelin places the *watchy picket*, with a note of scepticism, as a synonym to *motacilla calidris*. This might possibly mislead, without observing that Sloane, Ray, &c. describe more than one bird under that name; the latter is the *American nightingale* of Edwards, and the *hang-nest warbler* of Latham, the bird called the *watchy picket* by Sloane, *Hist. Jam.* 2. p. 299.

BONANNI, PADRE FILIPPO, in *Biography*, a Jesuit, who published at Rome, in 1722, in 4to. drawings of a curious collection of musical instruments, represented in the hands of the performers; entitled "Gabinetto Armonico Pieno d'Instrumenti Sonori indicati e spiccati—ed offerto al fanto Re David." The collection is curious, and the instruments are not ill executed; but we are not sure that the drawings are always correct.

BONARATTE, in *Geography*, a small island of the Indian ocean, south-east of Saleyer, ceded by the Macassers to a raja of Boni, in Celebes, who used it as a place of education for his dancing girls, and appropriated to the same purpose by the kings of Boni. It is chiefly inhabited by Bougenese.

BONARELLI, GUIDUBALDO, *Count*, in *Biography*, an Italian poet, was born in 1563, in the palace of the duke of Urbino, to whom his father was favourite minister; and, after previous instruction at home, was sent to study theology at Pont à Mousson, in France, where he made such proficiency, that he was invited, at the age of 19, to take the chair of philosophy at the Sorbonne. He returned, however, into Italy, and was employed by Cæsar, duke of Modena, in some important negotiations at the courts of Rome and France; but incurring disgrace by his marriage, he withdrew to Ferrara, and, in 1607, published the pastoral drama by which he acquired celebrity. This drama was acted by the academy of "Intrepidi" at this place, of which Bonarelli had been one of the founders. In his way to Rome, for the purpose of assuming the office of major-domo to cardinal Este, he was seized at Fano with a disorder, which terminated his life, Jan. 8, 1608. The drama of Bonarelli, entitled "Filli di Sciro," was much applauded both in Italy and other countries at its first appearance, and was ranked by common opinion next to the *Aminto* of Tasso, and the

Pastor Fido of Guarini. Although this pastoral has many poetical beauties, it strongly indicates the corrupt taste which then prevailed; nevertheless it maintains its place among Italian pastorals. Many editions of it have been printed: and it has been translated into the French and English languages. *Gen. Biog.*

BONARES, in *Geography*, a town of Spain, in Andalusia; one league from Lucena.

BONARIENSIS, in *Ornithology*, that species of *LOXIA* or *grof-beak*, described by Buffon under the name of *noir-fouci*. The head and back of the neck are blue; body above blackish, beneath yellow; belly and vent sulphur colour; wings and tail blackish, edged with blue.

This bird is about seven inches long, and is observed generally to fly in pairs; they haunt gardens, where they do much mischief, as they feed on seeds. The bill is blackish; legs reddish; claws acute, curved, and grooved; the hind claw largest. This is the *marigold grof-beak* of Latham.

BONARIENSIS, a species of *TANAGRA*, that inhabits Bonaria. This is eight inches long; the colour black, glossed with violet, and with greenish on the wings and tail. Gmel. &c. Buffon calls this bird *tangavio*. The beak is black, the legs blackish, with large claws. The female is of a brown colour, with the head black, and glossed with blue.

BONARIENSIS, a species of *MOTACILLA*, of a black colour; throat and sides ferruginous; face, chin, middle of the belly, and exterior tail feathers, white. This bird is of the size of a linnet; bill blackish; hind-claw large. Buffon calls this *demi-fin noir et roux*. It is the *white-chinned warbler* of Latham.

BONAROTA, in *Botany*, Michel. and Scopol. See *PÆDEROTA*.

BONASCOLA, in *Geography*, a town of Italy, in the state of Genoa, near the sea-coast; 4½ miles S.S.W. of Brugnatto.

BONASIA, in *Entomology*, a species of *CICADA* (*membracis, cruciata*) found in America. Fabricius describes it as having the thorax bicornuted, produced behind, and edged with white; at the base of the wings is a white spot.

BONASIA, is also the name of a species of *PAPILIO* (*Heliconius*), the wings of which are fuscous, with a common fulvous band; the lower pair spotted at the base with black.

BONASIA, in *Ornithology*. Under this name Brisson describes several species of the *TETRAO* genus; as for instance, *tetrao Canadensis* he calls *bonasia freti Hudsonis*; *tetrao Canace*, *bonasia Canadensis*; *tetrao lagopus*, *bonasia fœtica*; and *tetrao togatus*, *bonasia major Canadensis*.

BONASUS, in *Zoology*, one of the synonyms of the wild ox. See *Bos TAURUS*.

By some the *bonasus* is understood to be that particular kind of wild ox which has the horns bent back, and the mane very long. *Bonafus* of Pliny, &c. *bos cornibus in flexis, juba longissima*. Linn. *Syst. Nat.* The bison is thought by Gesner to be the *bonafus* of Aristotle.

BONAT, in *Geography*, a town of France, in the department of the Creuse, and chief place of a canton, in the district of Gueret, 3½ leagues N. of Gueret.

BONAVENTURA, ST., in *Biography*, a cardinal of Rome, and entitled the "Seraphic doctor," was born at Bagnarea, in Tuscany, in 1221; and having entered into the order of Minorites, in 1243, studied at Paris under Alexander de Hales, and there taught theology with great applause. He received his doctor's degree in 1255, and in the following year was made general of his order. He declined accepting the archbishoprick of York, to which he

was nominated by pope Clement IV. in 1265; and, after his death, the choice of a successor was referred by the cardinals to Bonaventura, who fixed on Gregory X. by whom he was made cardinal, and whom he attended to the second council of Lyons, in 1274, where he died in the same year. He was canonized by Sixtus IV. in 1482, and declared a doctor of the church by Sixtus V. in 1588. His works have been collected in 8 vols. fol. and were printed at Rome in 1588; and an edition of them in 14 vols. 4to. has also been published. Among these are his "Life of St. Francis," the founder of his order, and "A Commentary on the Master of the Sentences," in which he appears to be a complete master of the theology of the 13th century. To him has been ascribed the institution of religious confraternities; and though his private character, and literary talents, are commended both by protestants and catholics, he has incurred some reproach for the zeal with which he promoted the worship of the virgin Mary, as the mother of God. *Moreri. Encycl. Melacim vol. iii.*

BONAVENTURA, FREDERIC, an eminent scholar and physician of Urbino, in Italy, who flourished in the early part of the 17th century, published, in 1601, "De natura partus octometris, adversus vulgarem opinionem, libri decem," Francof. folio; an enormous volume, containing upwards of one thousand pages, on this uninteresting subject, in which he has introduced the opinions of different writers, and accounts of all the controversies that have been held on the legitimate period of utero-gestation in women. The author had published a dissertation on the subject, in the preceding year, which he incorporated in the great work, but with which a modern reader would probably have been fully contented. *Haller. Bib. Med.*

BONAVENTURA, Cape, in *Geography*, is situate on the coast of New Guinea, in S. lat. $6^{\circ} 15'$, and about 65 leagues N. E. from port St. Augustine. The land is low and luxuriant, and produces the cocoa-nut, bread-fruit, plantain, &c.

BONAVENTURA, the name of an island, north-east of the bay of Chaleur, off the coast of New Brunswick, in the gulf of St. Lawrence, and a little to the south-west of the point which forms the south-east entrance into that river; about a league from Gaspé bay.—Also, an island on the starboard side of the entrance into Porto-Bello harbour, opposite to the mouth of Guanches river. See **PORTO-BELLO**.

BONAVENTURE, or **BUENEVENTURA**, a river, bay, harbour, and fort, on the coast of Papayan, in South America, nearly south from Panama bay. N. lat. $3^{\circ} 20'$. W. long. $75^{\circ} 18'$. Barks and sloops of 40 or 50 tons may go up to a village a league beyond the fort. Bonaventure is the staple port of Cali, Papayan, Sta. Fé, &c.

BONAVENTURE, Cape and Port, are situated on the east coast of Newfoundland, about south-west of Bonavista cape, and form the north entrance into Smith's sound, from whence the coast runs S. by W. into Trinity bay.—Also, a bay on the east side of the island of St. Vincent. N. lat. $13^{\circ} 9'$. W. long. $61^{\circ} 18'$.

BONAVISTA, so called in reference to its beautiful appearance at sea, the most easterly of the Cape de Verde islands, about 20 miles long, and 12 broad, and distant about 70 leagues west from the coast of Africa. Its surface is low towards the sea, but within hilly, particularly towards the north-east extremity, where is a hill, which, from its conical and truncated shape, appears to have been a volcano; and there is another hill, much higher towards the south-west end, with high land to the westward of it. The soil is sandy, barren, and uncultivated; milk, goats, fish, and turtle, are the principal food of the inhabitants. It affords some salt; and if the culture of it were not neglected, it

would yield cotton and indigo. It is known at a distance by several white banks on its north side, where the shore is bold, and where a rapid river discharges itself into the sea. This island has a good harbour on its west side, where vessels may lie in 15 or 16 fathoms water. At the distance of a league or a league and a half from the south-east point of the island is a reef of rocks; and over this point, says Capt. Cook, there is a pretty high round mountain, rising not far from the shore. This point, by his observations, is in N. lat. $16^{\circ} 0'$, and longitude from London, by account, $21^{\circ} 51' W$. The latitude of the north end of the island is $16^{\circ} 12' N$. and of the south end $15^{\circ} 57' N$. but that at the east end was not ascertained. Mr. Wales, in the second voyage, determined the latitudes of these three points as follows: north point $16^{\circ} 13\frac{1}{2}' N$. east point $16^{\circ} 3\frac{1}{2}' N$. and latitude of the south point $15^{\circ} 58' N$. Stavonius says, that this island has two eminences of a middling height, that appear distinctly upon it; and that there are two reefs, one at the north side, and one at the south side, which stretch out to the eastward, and which are both very dangerous. According to the account in lord Macartney's embassy to China, the sea-coast, on the south-east side was guarded by rocks; but towards the south-east end the shore was much covered with white sand. On that side there seemed to be neither cultivation nor inhabitants. The latitude of Bonavista, was $16^{\circ} 6' N$. and the longitude $22^{\circ} 47' W$. The variation $12^{\circ} 36'$ to the westward of the pole. This island belongs to the Portuguese.

BONAVISTA, Cape, the extreme N. W. point of the island of Cuba in the West Indies, opening into the gulf of Mexico, from whence the land falls off southerly to cape St. Antonio.

BONAVISTA, Cape and Bay of, lie on the east side of Newfoundland island, the cape lies in N. lat. $48^{\circ} 54'$, and W. long. $52^{\circ} 33'$, and was discovered by John Cabot and his son Sebastian, in 1497, under a commission for exploring unknown lands, obtained from Henry VII. The bay is formed by this cape and cape Freels, 15 leagues apart.

BONAYE, a town of France in the department of the Lower Loire, and chief place of a canton, in the district of Nantes. The place contains 834, and the canton 9,530, inhabitants; its territory comprehends 135 kilometres and 7 communes.

BONCAT, a town of France, in the department of the Lower Pyrenées, 6 leagues N. of Bayonne.

BONCHAMPS, a town of France, in the department of the Mayenne, 2 miles S. W. of Craon.

BONCONICA, OPPENHEIM, in *Ancient Geography*, a town of Gaul, placed between Mogontia to the north, and Borbatomagus to the south, seated on the river Rhemus, in Germania prima.

BONCONVENTO, or **BUON-CONVENTO**, in *Geography*, a town of Italy, in the territory of Sienna, where the emperor Henry VII. died; 12 miles S. of Sienna.

BONCORE, THOMAS, doctor in philosophy, medicine, and law, in *Biography*, has left a memorial of a destructive pestilence, which raged at Naples, where he was in high credit, as a practitioner in medicine, in the year 1622. "De populi, horribili, ac pestilenti gutturis affectione, nobilissimam urbem Neapolim vexante, consilium," 4to. 1622, Neap. An early account of the scarlatina anginosa, or malignant sore throat, which has of late years made such frequent appearance, and proved so destructive, among children particularly, in this country. *Eloy. Bib. Hist.*

BOND, JOHN, an English grammarian of the 16th century, was a native of Somersetshire, and after finishing his

his grammatical education at Winchester school, was entered, in 1569, at the age of 19 years, a student in the university of Oxford, where he was distinguished by his proficiency in academical learning: Having taken his degrees of bachelor and master of arts, the former in 1573, and the latter in 1579, he was promoted by the master and wardens of New College to the mastership of the free-school at Taunton, in Somersetshire, which office he occupied with reputation for several years. At length he quitted the laborious station of school-master, and directed his attention to physic, which he practised more for amusement than profit. He died in 1612, and was buried in the chancel of the church at Taunton. He wrote "Commentaries on Horace and on Persius."

BOND, or *Obligation*, in Law, is a deed whereby the obligor, or person bound, obliges himself, his heirs, executors, and administrators, to pay a certain sum of money to another called the obligee, at a day appointed. If this be all, the bond is called a single one, "Simplex obligatio;" but there is generally a condition added, that if the obligor does some particular act, the obligation shall be void, or else shall remain in full force; as payment of rent, performances of covenants in a deed, or repayment of a principal sum of money borrowed of the obligee, with interest, which principal sum is usually one half of the penal sum specified in the bond. In case this condition is not performed, the bond becomes forfeited or absolute at law, and charges the obligor while living; and after his death the obligation descends upon his heir, who, on defect of personal assets, is bound to discharge it, provided he has real assets, by descent as a recompence. So that it may be called, though not a *direct*, yet a *collateral*, charge upon the lands.

This security is called a "specialty;" the debt being therein particularly specified in writing, and the party's seal, acknowledging the debt or duty, and confirming the contract, rendering it a security of a higher nature than those entered into without the solemnity of a seal. In order to make a good obligation, it has been held that three things are necessary, *viz.* writing in paper or parchment, sealing, and delivery: but it hath been adjudged not to be necessary, that the obligor should sign or subscribe his name, sealing being deemed sufficient, and subscribing being no essential part of the deed. And though the seal be necessary, yet if the word seal be wanting, it is remedied by verdict and pleading over, for all necessary circumstances shall be intended; and if it were not sealed, it could not be the deed or obligation of the party. Moreover, though sealing and delivery be essential in an obligation, it is not necessary to mention in the bond, that it was sealed and delivered, because, according to lord Coke, (2 Co. 5 a.) these are things which are done afterwards. The name of the obligor subscribed is sufficient, though there is a blank for his Christian name in the bond; and where the obligor's name is omitted to be inserted in the bond, if he signs and seals it, the court of chancery may make good such an accident.

An obligation is good, though it has no date, or a false or impossible date; the date not being of the substance of the deed; but the day of the delivery is the day of date, though no day be set forth. Every deed is supposed to be delivered and made on the day of its date; and if the plaintiff declare on a date, he cannot afterwards reply, that it was first delivered at another day. A plaintiff may suggest a date in a bond which has none, or one that is impossible, &c. provided that the parties and sum are sufficiently expressed. A person shall not be charged by a bond, though signed and sealed, without delivery, or words, or other act, amounting to a delivery. But it may be delivered by mere words;

and an actual delivery without speaking any word, is sufficient. If a bond be altered by interlineation in a material part, it becomes void, and it may be made void by rasure, &c. or by rasing the date, &c. after delivery. If the words at the end of the condition, "that then this obligation to be void," are omitted, the condition will be void, but not the obligation. If the condition of a bond be impossible at the time of making it, or be to do a thing contrary to some rule of law that is merely positive, or be uncertain or insensible, the condition alone is void, and the bond shall stand single and unconditional; for it is the folly of the obligor to enter into such an obligation, from which he can never be released. If it be to do a thing that is *malum in se*, the obligation itself is void; for the whole is an unlawful contract, and the obligee shall take no advantage from such a transaction. And if the condition be possible at the time of making it, and afterwards becomes impossible by the act of God, the act of law, or the act of the obligee himself, there the penalty of the obligation is saved; for no prudence or foresight of the obligor could guard against such a contingency. Co. Litt. 206. When a condition is doubtful, it is always taken most favourably for the obligor, and against the obligee; but so that a reasonable construction may be made as nearly as possible according to the intention of the parties. If no time be limited in a bond for payment of the money, it is due presently and payable on demand. 1 Brownl. 53.; and if a condition be impossible in respect of time, it shall be paid presently. Jones 140. 1 Leon, 101. If the party, who is bound to perform the condition, disables himself, this is a breach. A bond made with condition not to give evidence against a felon, &c. is void; but the defendant must plead the special matter. 2 Wilf. 741, &c. Condition of a bond to indemnify a person from any legal prosecution is against law, and void. 1 Lutw. 667. And if a sheriff takes a bond as a reward for doing of a thing, it is void. 3 Salk. 75. See **CONDITION**.

On the forfeiture of a bond, or its becoming single, the whole penalty was formerly recoverable at law; but here the courts of equity interposed, and would not permit a man to take more than in conscience he ought, *viz.* his principal, interest, and expences, in case of the forfeiture accrued by non-payment of money borrowed; the damages sustained, upon non-performance of covenants; and the like. And a similar practice having gained some footing in the courts of law, see 2 (Keb. 55). 555. Salk. 596, 597. 6 Mod. 11. 6. 101.), the statute 4 and 5 Ann. c. 16. at length enacted, in the same spirit of equity, that, in case of a bond, conditioned for the payment of money, the payment or tender of the principal sum due, with interest and costs, even though the bond be forfeited and a suit commenced thereon, shall be a full satisfaction and discharge. The court of Chancery will not generally carry the debt beyond the penalty of a bond; yet in a case, where a plaintiff sought relief against such penalty, though it was decreed, it was on the payment of the principal money, interest, and costs; and notwithstanding they exceeded the penalty, this was affirmed, 1 Vern. 350. 1 Eq. Ab. 92. 6 Vin. tit. *Penalty*. 3 Comm. 435. And where the condition of a bond is to perform a collateral act, damages may be recovered beyond the penalty, and the court of K. B. will not stay the proceedings on payment of the money into court. 2 Term Rep 388.

All persons who are enabled to contract, and who are supposed in law to have sufficient freedom and understanding for that purpose, may bind themselves by bonds and obligations. 5 Co. 119. 4 Co. 124. 1 Roll. Abr. 340. If a person, illegally imprisoned, enters into a bond, during such restraint, to the person who causes it, the same may be avoided

avoided for dures of imprisonment. Co. Litt. 253, 2 Inst. 482. The bond of a feme covert is *ipso facto* void, and shall bind neither her nor her husband. The bond of an infant, even for necessities, with a penalty for payment, is void. But if an infant, feme covert, &c. enter with a stranger, who is not subject to their disabilities, into an obligation, the stranger shall be bound by it. However, infants, idiots, feme coverts, and aliens, may be obligees. Sole corporations, such as bishops, prebends, parsons, vicars, &c. cannot be obligees; but a corporation aggregate may take any chattel, as bonds, leases, &c. in its political capacity, which shall pass in succession, because it is always in being. Cro. Eliz. 464. Dyer, 48 a. Co. Litt. 9 a. 46 a. Hob. 64. 1 Rol. Abr. 515. If a drunken man gives his bond, it binds him; and a bond without consideration is obligatory, and no relief shall be had against it, for it is voluntary, and as a gift. Jenk. Cent. 109. But on the general issue, the defendant may give in evidence that they made him sign the bond when he was so drunk that he knew not what he did; and though a voluntary bond cannot be relieved against in equity, it may not be paid in a course of administration, so as to take place of real debts, even by simple contract; yet it shall be paid before legacies. 1 Chan. Caf. 157. An heir is not bound, unless he be expressly named in the bond, though the executors and administrators are. Dyer 13. Two or more persons may bind themselves jointly in an obligation, or they may bind themselves jointly and severally; in which last case, the obligee may free them jointly, or he may free any one of them at his election; but if they are jointly and not separately bound, they must be freed jointly; and in such case, if one of them dies, his executor is totally discharged, and the survivor or survivors only chargeable. 2 Rol. Abr. 148. Dyer 19 310. 5 Co. 19. 1 Salk. 393. 1 Lutw. 696.

With regard to discharge of bonds, if a lesser sum be paid before it is due, and the payment is accepted, it shall be good in satisfaction of a greater sum; but after the money is due, a lesser sum, though accepted, shall not be a satisfaction for a greater sum. Moore, 677. 3 Bult. 301. 1 Lutw. 464. It has been adjudged, that the acceptance of one bond cannot be pleaded in satisfaction of another bond. Cro. Car. 85. Moore, 872. Cro. Eliz. 716. 727. 2 Cro. 579. A bond, on which neither principal nor interest has been demanded for 20 years, will be presumed in equity to be satisfied, and be decreed to be cancelled; and a perpetual injunction granted to stay proceedings thereon. 1 Ch. Rep. 79. Finch. Rep. 78. Satisfaction, moreover, may be presumed within a less period, if any evidence can be adduced in aid of the presumption, such as the settlement of an account in the intermediate time, without any demand. Yet length of time is no *legal* bar; and is only a ground for the jury to presume satisfaction. 1 Term Rep. 270. As to the pleading of performance of a condition, the defendant must set forth in what manner he has performed it. By stat. 8 and 9 Will. III. c. 11. § 8. in actions on bonds for performance of covenants, the plaintiff may assign as many breaches as he pleases, and the jury may assess damages. In debt on a bond, the defendant may have several pleas in bar. 1 Salk. 180. But a defendant in an action on a bond cannot plead, "Non est factum;" and a tender as to part. 5 Term Rep. 97. In debt on an obligation the defendant cannot plead, "Nil debet," but must deny the deed by pleading "Non est factum;" for the seal of the party continuing, it must be dissolved, "Eo ligamine quo ligatur." Hard. 332. Hob. 218. In bonds to save harmless, the defendant being prosecuted, is to plead "Non damnificatus, &c." The stealing of any bond, bill, &c. for money,

being the property of any one, is made felony, as if offenders had taken other goods of like value. Stat. 2 Geo. II. c. 25.

Form of a bond or obligation, with condition for the payment of money. "Know all men by these presents, that I David Edwards, of Lincoln's Inn, in the county of Middlesex, esquire, am held and firmly bound to Abraham Barker, of Dale-hall, in the county of Norfolk, esquire, in ten thousand pounds of lawful money of Great Britain, to be paid to the said Abraham Barker, or his certain attorney, executors, administrators, or assigns; for which payment well and truly to be made, I bind myself, my heirs, executors, and administrators, firmly by these presents, sealed with my seal. Dated the fourth day of September, in the twenty-first year of the reign of our sovereign lord George the third, by the grace of God king of Great Britain, France, and Ireland, defender of the faith, and so forth, and in the year of our Lord one thousand seven hundred and ———."

The condition of this obligation is such, that if the above bounden David Edwards, his heirs, executors, or administrators, do and shall, well and truly pay, or cause to be paid, unto the above named Abraham Barker, his executors, administrators, or assigns, the full sum of five thousand pounds of lawful money of Great Britain, with lawful interest for the same, on the fourth day of March next ensuing the date of the above written obligation, then this obligation shall be void and of none effect, or else shall be and remain in full force and virtue.

DAVID EDWARDS, (*L. S.*)

Sealed and delivered, being first duly stamped, in the presence of

GEORGE CARTER,

WILLIAM BROWNE.

Blackstone's Com. ii. 340. Jacob's Law Dict. by Tomlins, vol. i. tit. *Bond*.

BOND of Arbitration. See ARBITRATION.

BOND, Assignment of. See ASSIGNMENT.

BOND, bail. See BAIL.

BOND, counter. See COUNTER-BOND.

BOND of resignation. See RESIGNATION.

BOND-tenants, are the same, in respect to the nature of their tenure, with copy-holders, and customary-tenants. Blackstone's Com. vol. ii. p. 148.

Bond, in *Masonry* and *Brick-laying*, is when bricks or stones are, as it were, knit and interwoven; and when they lay, make good bond, they mean that the joints are not made over, or upon other joints; but reach at least six inches, both within the wall and on the surface, as the art of building requires.

BONDAGE properly denotes a state of servitude or slavery.

BONDAGE, bondagium, in *English Law Writers*, the same with *VILLENAGE*.

Tenants in bondage, paid heriots, and did fealty; they were not to fell trees in their own garden, without licence of the lord.

The widow of a tenant in bondage held her husband's estate, *quandiu vixerit sine marito*.

BONDAGE by the forelock, or *bondagium per anteriores crines capitis*, was when a freeman renounced his liberty, and became slave to some great man; which was done by the ceremony of cutting off a lock of hair on the forehead, and delivering it to his lord; denoting, that he was to be maintained for the future.

Such a bondman, if he reclaimed his liberty, or were fugitive from his master, might be drawn again to his servitude

by the nose; whence the origin of the popular menace, *to pull a man by the nose*.

BONDELLIA, in *Ancient Geography*, a town of Italy, in Etruria. Ptolemy.

BONDENO, or BUONDENO, in *Geography*, a town of Italy, in the duchy of Ferrara, at the conflux of the Panaro and Po, 9 miles W. of Ferrara.

BONDMAN, *BONDUS*, formed from the Saxon *bond*, signifying a fetter, in the *English Law*, is used for a villain, or tenant in vilenage. See VILLAIN.

The Romans had two kinds of bondmen; one called *servi*, who were those either bought for money, taken in war, left by succession, or purchased by some other lawful acquisition; or else born of their bondwomen, and called *verne*. Both are called in our law villains in gross, as being immediately bound to the person and his heirs. We may add a third kind of bondmen mentioned by Justinian, called *adscriptitii glebe*, or *agricensii*; who were not bound to the person, but to the ground or place, and followed him who had the land. These, in our law, are called *villains regardants*, as belonging to the manor or place.

In the English as well as Scottish laws, those called by the Romans *verne*, are sometimes also denominated *nativi*, as being born on the land. See NATIVUS.

BONDORF, in *Geography*, a country of Germany, in the circle of Swabia, about five leagues long, and between one and three broad, lying between the Brisgaw and the landgraviates of Baar and Stuhlingen. It had formerly lords of its own, but in 1613 was purchased by the abbey of St. Blaife. It is assailed in the imperial matricula, at 25 florins, 30 kruitzers; and its contingency to the chamber, at Wetzlar, is 12 rixdollars, 15½ kruitzers. This territory comprehends the town of Bondorf, 28 miles N.N.W. of Zurich, and several villages.

BONDOUN, a kingdom of Western Africa (formerly a part of the kingdom of Bambock), the capital of which is Fatteconda, near the eastern bank of the river Faleme. This kingdom is bounded on the north by Kajaaga, on the east by Bambock, on the south-east and south by Tenda and the Simbani wilderness, on the south-west by Woolli, and on the west by Foota Torra. It lies between N. lat. 13° 32' and 14° 32', and between W. long. 10° 8' and 11° 18'. Mr. Park, in his journey through this kingdom towards the east, found that the country, though covered with woods, like that of Woolli, rose into hills, especially towards the Faleme river, and that the soil varied to a considerable degree; but wherever the land was cleared, great natural fertility was observable. Bondou, in particular, may literally be pronounced "a land flowing with milk and honey." Both these articles, together with rice, and Indian corn of two or three species, were to be obtained at a small expence. Of their honey, the unconverted or pagan natives make an intoxicating liquor, much the same as the mead, or metheglin, of Europe; and this, and the wine of the palm-tree, constitute their principal liquors. The price of a fowl in Bondou was a button, or a small bit of amber; goat's flesh and mutton were proportionably cheap; and for six or eight amber beads Mr. Park might at any time have purchased a bullock. The domestic animals are nearly the same as in Europe. Swine are found in the woods, but their flesh is not esteemed. Probably the marked abhorrence with which this animal is held by the votaries of Mahomet has spread itself among the Pagans. Poultry of all kinds, the turkey excepted, may be had every where. The Guinea fowl and red partridge abound in the fields; and the woods furnish a small species of antelope, of which the venison is highly and deservedly prized. Of the other wild animals in the Man-

dingo countries, the most common are the hyæna, the panther, and the elephant. But of the method of taming the latter animal, and applying his services to the use of man, the natives of Africa are totally ignorant; and when they were told by Mr. Park, that this was done in the east, they treated the information with contempt, and exclaimed "Tobaubio fonnio," i. e. the white man's lie. They find means, however, to destroy the wild elephants by fire-arms for the sake of their teeth, which they transfer in barter to those who sell them again to the Europeans. They eat the flesh, and deem it a great delicacy. The pastures of Bondou furnish an excellent breed of horses; but the usual beast of burthen in all the negro territories is the ass. The application of animal labour to the purposes of agriculture is no where adopted, and the plough is an instrument altogether unknown. The chief implement used in husbandry is the hoe, which in different districts is of various forms; and labour is universally performed by slaves. The Mandingoes cultivate, besides the grains proper to tropical climates, ground-nuts, yams, and pumpions. They likewise raise cotton and indigo, and they produce of these materials a tolerably fine cloth, of a rich blue colour; and they make good soap from a mixture of ground-nuts and a ley of wood-ashes. Their trade with the whites is composed of slaves, gold-dust, ivory, and bees-wax. Their inland traffic consists chiefly of salt, which is procured from the Moors, in barter for corn and blue cloth, and of warlike stores which are obtained from the European traders on the Gambia river. These are sold again to itinerant merchants, called "Slattees," who come down annually from distant countries, with slaves, and a commodity called "Shea-toulou," which is an excellent sort of butter, produced from the kernel of a nut boiled in water. They also bring down small quantities of iron, which is manufactured in the interior districts; but those articles of this metal which are in use among the natives of the coast, are made of iron from Europe. The natives of the Gambia countries are also supplied, in considerable quantities, with sweet smelling gums and frankincense, which are the produce of Bondou.

Bondou is chiefly inhabited by Foulahs, a race of negroes, who lead a wandering life, and employ themselves chiefly in the pasturage of cattle, and the cultivation of corn. Among these, however, are a great number of Mandingoes, by whom the trade of the country is chiefly conducted. The government in Bondou, and in all the adjacent petty states, is monarchical, but no where absolute. The persons, who are called chief-men, constitute a sort of aristocracy, which serves much to restrain the powers of the sovereign. The king cannot declare war, nor conclude a peace, without their advice. When Mr. Park visited Bondou, the king was a "Soninke," or Pagan, like the king of Woolli; but he had adopted the Moorish name of Almami, and with the name he seemed to have imbibed somewhat of the Moorish disposition; for although the traveller had presented to him his umbrella, and some other articles, he compelled him, as he had before compelled major Houghton, to strip in his presence, and surrender his coat, which, he said, he should reserve for his own wearing, on great and public festivals. In return, however, he gave Mr. Park five minkallies (drams) of gold-dust, and loaded him with provisions. Every considerable town is under the immediate government of a magistrate, called the "Alkaid;" by whom the duties and customs on itinerant traders, which are paid in kind (the only system of taxation), are levied. The office is hereditary. The people of the lower classes are in a state of slavery, or vassalage, to individual proprietors; but the power of the master is far from being unlimited. He may punish his

slave corporally; but cannot deprive him of life for any offence, nor even sell him to a stranger, without first bringing him to a public trial, called a "Palaver," before the chief men of the town; and on such occasions the cause of the slaves is pleaded by the native Mahometans, who are a sort of professional advocates. These indulgences indeed extend only to native or domestic slaves; for captives taken in war, and those who are obtained in traffic, may be sold at pleasure, and treated as the owner thinks proper. Park's Travels into Africa. Rennell's Proceedings of the African association.

BONDUR, a town of Asiatic Turkey, in the province of Natolia, 24 miles west of Irbarteh.

BONDRE'E, in *Ornithology*, the honey buzzard (*falco apivorus*.) stands under this name in Buffon's History of Birds. The French writers of the present day also call it bondrée.

BONDUC, and BONDUCELLA, in *Botany*, (Plumier). See GUILLANDINA.

BONDUCH, in the *Materia Medica*, a name by which many authors have called the Molucca, Marfao, or Bezoar nuts.

BONE, in *Anatomy*. The bones are the most solid parts of animals, and may be regarded as the walls of a building supporting and containing the other parts. The human body is composed of a pile of bones, the extremities of which are variously shaped, and adapted to each other, and calculated to admit of a variety of motions. Bones appear to be composed of a vascular substance, not differing materially in structure from that of the rest of the body, except that there is deposited in its interstices phosphat of lime, which gives to the whole mass rigidity, strength, and a permanent figure. That state of the vessels in which they secrete, and deposit, earthy matter, occurs in diseases of other parts of the body. The nutrient vessels of arteries, membranes, and ligaments, occasionally deposit lime, and cause the ossification of those parts. The earth of bone is also deposited in some species of tumours, and often in considerable quantity, and in an irregular manner in the cellular substance of a limb, when the bone of it is diseased. After this general view of the subject, we proceed to give an account of the structure of a bone, both with respect to the arrangement of its earthy particles, and with relation to its vascular texture.

It is customary, however, in giving an account of the structure of bones, first to describe their original formation in the fœtus; and this is useful, because it demonstrates the simplicity of the process, and tends to refute old and erroneous ideas respecting it. The parts of the young fœtus which are afterwards to become bones, are merely a vascular, gelatinous substance, scarcely distinguishable from the other parts; afterwards the outline of the bone becomes evident, and its substance is rendered white and firm, in proportion to the quantity of lime deposited in it. The quantity deposited in it, even at the time of birth, is only sufficient to give firmness to the whole mass, but not to prevent its flexibility. The extremities of all the long bones consist of large portions of cartilage, and these, by degrees, become bony. This change is effected by an alteration, first, in the organization of the part; the cartilage is absorbed, the vessels enlarge, so as to admit of injection, and then they appear to have the power of depositing earthy matter, or forming bone. The formation of bone begins in the centre of a cartilage, and gradually extends from thence to the remote parts, so that the separate piece of bone, formed at the extremity, remains to nearly the period of puberty, conjoined to the body of the bone, by a crust of cartilage. In this state it is technically termed an epiphysis. The observation of these facts

led formerly to the erroneous notion, that it was necessary that cartilage should exist, prior to the formation of bone; and that it was converted by pressure, or in some inexplicable manner, into bone. It were a waste of argument to refute this opinion. We can perceive a striking advantage that results from the bones of the fœtus being formed as they are. Their flexibility admits of the form of limbs becoming adapted to the varying figure of the pelvis, through which they must pass, and their elasticity, which is powerful, restores them afterwards to their natural shape.

The subject which first engages our attention, in examining the structure of bone, is the arrangement of the earthy parts. The phosphat of lime is deposited by the arteries in minute points or particles, and these being placed lengthwise, with respect to each other, form fibres; again these fibres being placed parallel to one another, form bony plates, scales, or laminæ. That bones are fibrous and laminous, is evident from a mere inspection of them in the fœtal state; that they are so in the adult subject may be demonstrated by calcination, or long exposure to weather: in which cases the connecting vascular substance is more suddenly or slowly dissipated, and thus the arrangement of the earthy matter is rendered visible. The earthy fibres of long bones extend themselves in a direction parallel to the axis of the bone; in broad bones they shoot out in every direction, like rays from a centre. In long bones the earthy matter is consolidated in the circumference and sides, so as to form thick and strong walls; whilst a tube or more spongy bony structure is found in their centre. In broad bones a similar structure is observed; the earthy matter is consolidated exteriorly, so as to form dense plates or tables; whilst interiorly the fabric of the bones is spongy or cancellous. In the internal spongy part of bones the marrow is deposited. In the middle part of long bones the walls are very thick, being composed of a great number of bony lamellæ, and these walls gradually become attenuated as they approach to the extremities of the bone, where they are proportionally very thin. Long bones are also slender in the middle, but at the same time strong, on account of the great quantity of earthy matter thus consolidated to form their walls; whilst there is but little cavity or medullary structure. These bones expand greatly at their extremities, in order to afford an extent of surface for the formation of joints, and for the support of the weight of the body. In the extremities of long bones, though the walls are thin, there yet exists a great deal of bony matter, which is deposited so as to leave interspaces between its fibres, forming what is termed the cancellous structure, or lattice-work of bones. It has been therefore concluded, that the quantity of earthy matter may be nearly equal in each part of a bone, and give to it an equal degree of strength; but that it has this difference of arrangement, that in the middle it is compacted so as to form very thick and dense walls, occupying but little space, and leaving but little internal cavity, whilst in the extremities it occupies a greater space, and forms a less solid kind of fabric. It would be desirable to ascertain, with some precision, where similar circumstances are to be met with in broad bones; and though no precise rules can be given, yet this may be admitted as a general truth, that where a broad bone swells out into a protuberance, there we shall find the walls or tables thin, and the cancellous structure abundant; and, on the contrary, where a broad bone is condensed so as to occupy but little space, there we shall find the tables proportionately thicker, and the cancellous structure less in quantity.

Having thus described the arrangement of the earth of bones, we may next enquire into the advantages which result from this structure. The long bones are made slender

in the middle, to allow of the convenient arrangement of large muscles round them; they become expanded at their extremities to afford an extent of surface for the formation of joints, and the support of the weight of the body. A cavity is left in the middle; for if all the earthy matter had been compacted into the smallest possible space, the bones would have been such slender stems, as to be very unsuitable to their offices; and if they had been of their present dimensions and solid throughout, they would have been unnecessarily strong and weighty. Besides, it can be proved by mathematical demonstration, that the strength of the bone becomes augmented, in proportion as its fibres are placed at a greater distance from its centre.

With regard to the vascular structure of bones, there can be no doubt but that it exactly resembles that of the rest of the body. That bones possess numerous arteries, is proved by the injection of young bones from the general arterious system of the subject; for they are made very red by the injection conveyed into them by numerous, though minute arteries, which enter them by pores evident on their surface. The effect of feeding animals with madder is an additional and striking proof of the same fact; for the bone becomes deeply tinged with the red colour of the madder. The cause of this phenomenon has of late been explained by Dr. Rutherford: he has shewn that it arises from a chemical attraction that exists between earths and certain colouring materials, which causes them to combine so intimately as to form pigments which are called lakes by painters. Dr. Rutherford dissolved madder in distilled water, and added to it muriate of lime, which produced no change of appearance in the solution; on the further addition of phosphat of soda, a double decomposition took place; the muriatic acid combined with the soda, and the phosphoric acid with the lime. The phosphat of lime also combined with the madder, and they were together precipitated, forming a beautiful red powder. If blood be constantly conveyed into bones by numerous arteries, it must be returned from them again by veins, or otherwise it must accumulate in them in considerable quantities. That bones possess absorbents in common with other parts is equally clear, and is proved by their mode of growth, and also by their diseases. The growth of the tube of a bone is a proof of the mutation of its parts by absorption; for if bones grew merely by new matter deposited on the surface, the tube of the bone should be of the same dimensions in the adult as in the fœtus: on the contrary, however, the tube enlarges, and bears the same proportion to the whole bone in either state. If any number of laminae of the sides of a bone, or if a portion of its whole substance perish, the mortified part is detached in the same manner that it is in soft parts; and this detachment is manifestly the effect, in the first instance, of the agency of the absorbing vessels. Though a portion of animal substance has perished, it still possesses the same powers of cohesive attraction that it did while living; it still tenaciously adheres to the living parts; but a space takes place all round the dead portion, and the production of that space can only rationally be attributed to the removal of parts by the absorbents. In diseases of bones their form becomes entirely altered, if an increased deposition of matter takes place in their internal parts; and this alteration of form could not happen unless the walls were removed by absorption, and deposited anew in conformity to the augmented bulk and figure, which the diseased deposition had occasioned. Not to cite lesser instances, one may be mentioned, which Mr. Hunter used to shew in his lectures, of a very large and globular bony tumour, which had formed in the extremity of one of the bones of the leg in an ox. The tumour was so solid, that

the section of it admitted of being polished, and the walls of the bone had become thin, and of a spherical form, so as to make a neat kind of case containing this bony tumour. That bones possess nerves as well as arteries, veins, and absorbents, cannot be doubted; for though they have naturally but little sensibility, they become extremely painful when diseased; and again a fungus sometimes grows out of a bone, which is sensible, though it may have no connection whatever with the surrounding soft parts; of course it must have derived its nerves, by means of which it possesses its sensation, from the bone out of which it arose. That the vessels and nerves of a bone are connected together by common cellular substances, as in other parts of the body, is demonstrated by soaking a bone in dilute muriatic acid, which dissolves all the lime, and leaves the vascular matter a little thickened, but perfectly flexible. We then see that this vascular and cellular matter has a laminated arrangement corresponding to that of the earthy, which has been described, so that between each layer of earthy matter, there is a layer of soft substance, and of course the different layers of soft substance are connected by vessels and cellular membrane, which intervene between the bony fibres, and connect the different strata together. Bones are covered by a strong, firm, fibrous substance, termed periosteum, on which the vessels are first distributed; from this they descend, connected by cellular substance, between the fibres of the bone. The vessels and nerves of the bone enter it through holes which are evident on the surface, and which are larger and more numerous in the extremities of the long bones than in the middle. The vessels do not penetrate the bone in a transverse direction, but obliquely, running transversely through a certain number of lamellæ, and then taking a perpendicular course between others, which prevents the bone from being weakened, particularly at any one part, by that want of earthy matter which is necessary to leave room for the admission and distribution of vessels.

The marrow that is contained in bones is of an unctuous nature, and in herbaceous animals, hardens when it becomes cold; but it remains fluid in those which are carnivorous. Some of the red parts of the blood are deposited with it in young animals, but in those that are adult it is no longer tinged with blood. The marrow is contained in fine cells, which do not communicate with one another, like those of the common cellular substance. This is proved by sawing a bone through, and keeping it in a temperature which will preserve the marrow fluid, with the part which is sawn downwards. Under these circumstances, if the cells communicated, the gravitation of the liquid marrow would cause it quickly to drop out, and leave the cells empty; but this does not happen. The cells which contain the marrow are lodged in the cancelli of the bone, at the extremities of the long bones; but in the middle they are unsupported by this kind of osseous structure. The cellular substance which contains the marrow, being condensed upon the inside of the walls of the bone, and adhering to them, has been termed the periosteum internum. In the principal bones we perceive arteries, much larger than those for the nutrition of the bone, which penetrate the walls obliquely, and spread their branches upon the medullary cells, for the nourishment of these parts. That these are the chief nutrient arteries of the marrow cannot be doubted; and it has been contended, that they have exclusively this power, and that they do not anastomose with the nutrient arteries of the bone. This opinion has been formed, because in some cases of accidental injury, in which the medullary artery has been destroyed, the marrow has, as it were, perished. This opinion, however, stands in direct opposition to all analogy; and it must indeed be con-

sidered as a very strange peculiarity, were not the minute contiguous nutrient arteries to inoculate with one another. The writer of this article is of opinion, that they do in this, as in other instances, for it is common in amputation to cut off the trunks of the medullary arteries, and yet the marrow of the remaining bone does not perish; and, again, the bone may be injected from the medullary artery alone. We may next inquire into the uses of the marrow. Havers thought that it transfused through the bone, and by this means prevented it from becoming brittle; nay, he even described the pores through which such transfusion was supposed to take place. The cells, however, which contain the marrow are perfect vesicles; and we know that no transfusion of contained fluids takes place through the membranes which contain them during life, though in consequence of putrefaction it does after death. If a bone be deprived of its periosteum in a living body, no transfusion of oil from its surface takes place; and even after death a recent bone may be deprived of its periosteum, and put in warm water for a considerable time, and yet no sudden transfusion of oil from the surface will take place, as might be expected if there were natural channels for this purpose. The canals which Havers described, are probably the passages through which the vessels are transmitted. If then this opinion of the use of the marrow be unfounded, we have still to inquire, for what purpose is it designed? The utility of the bones being formed as they are, small and tubular in their middle, expanded and spongy at their extremities, has been already explained. If then spaces are necessarily left in their interior parts, those spaces must be filled with something, for they cannot be left void, or the immense pressure of the atmosphere would crush their parietes, and abolish the vacuum. There is no matter in the animal body more suitable to fill their spaces than the marrow; and it is to be regarded as a part of the adipose system of the animal. In corroboration of this remark, it has been observed, that in impoverished and dropical subjects, where there is no fat in other parts, there is likewise none even in the bones; and if a bone be sawn, and the medullary cells broken down, so that the fluid which they contain may drop out upon paper, that it will not penetrate it, and render it transparent like oil; but, on the contrary, that it will encrust upon it, from its being of a gelatinous nature, like that fluid which is found in the interstices of the common reticular or cellular substance. From the circumstances which have been detailed in the foregoing account, viz. the great and general vascularity of bones;—the quantity of soft substance existing in every part of them;—their growth and mutation of form in disease, &c.;—it is natural to conclude, that there exist in the composition of every bony fibre, arteries for its formation, absorbents for its removal, cellular substance for the connection of its parts, and nerves to give animation to the whole. In this view of the subject, we perceive no essential difference of structure between bones and other parts of the body; nor do we expect any essential difference in the functions of their nutrient, and other vessels. We naturally conclude that bony fibres are formed and repaired, and that they undergo mutation or removal in the same manner, and from the same causes, that soft parts do. Mr. Hunter, however, from observing the striated appearance of the bones of animals, who have been at one time fed with madder, and at another with common food, and observing that the exterior stria was red if the animal was killed after having been for some time fed with madder, and white if it had only taken its ordinary food, concluded that bones grew by a deposition on their surface, and a correspondent removal of the internal part of the walls of the bone. Mr. Hunter also, to investigate the truth of Du Hamel's opinion respecting the growth

of bones, bored two holes in the tibia of a pig, one near the upper end, and the other near the lower; the space between the holes was exactly two inches; a small leaden shot was inserted into each hole: when the bone had been increased in its length by the growth of the animal the pig was killed, and the space between the two shots was exactly two inches. Mr. Hunter's experiments and opinions are published by Mr. Home in the second volume of Transactions of a Society for the improvement of Medical and Chirurgical Knowledge. We forbear to give a more detailed account of them, or enter into any discussion of the subject, but refer the reader to the original paper, because we believe that no theory will be found, on consideration, to be adequate to account for the phenomena of the growth and diseases of bones, except that which admits the bony fibres to be of the same structure as the soft fibres of the body, and consequently concludes that both are formed, removed, and renovated in the same manner. We subjoin some references to the instructive works on the structure of the bones. *Albini icones ossium fœtus, cui accedit osteogen. brevis historia.*—Annot. Acad. J. G. BONE, in Chemistry and the Arts. The analysis of bone, and the products obtained from it by various chemical processes, deserve considerable attention, as this great class of animal substances ranks among the most important to the chemist.

So great a similarity is found in the composition of the bones of different animals, that their properties may first be described generally.

Bone, when first taken from the animal, is moist and greasy on its surface; and if cylindrical, it contains a quantity of the peculiar fat called *marrow*. When this is separated, and the bone exposed to the air, it gradually dries, becomes brittle and whiter; but the articulating heads long remain moist, greasy, and yellow. When once dry, and kept in a dry and airy place, they are scarcely susceptible of further spontaneous alteration.

The effect of mere heat on bone has long been known to chemistry and the arts, as furnishing some very important articles of chemical manufacture. Heated in the open air, bone first becomes oily and yellow, gives out a watery vapour, to which succeeds a thick, dense, fetid smoke, which readily takes fire, and when once kindled, affords heat enough, when the bones are in sufficient quantity, to complete the entire calcination, which lasts for many hours, during which they become successively black and carbonaceous, brittle, and at last, when every thing combustible is consumed, they remain nearly white, friable, light, and extremely porous or cellular in texture, and retaining their original shape and bulk. This process of burning bones in the open air, in large heaps, is performed near great towns for the sake of the earthy salt *bone-ash*, which is left behind, and forms on an average about half the weight of the fresh bone. It is composed chiefly of phosphat of lime, and is used by the assayers as the material for cupels, and for a few other purposes.

But the volatile products which are wasted in the above process, are highly valuable when the bones are distilled in close vessels, without addition as before, but with a proper apparatus to receive and condense the volatile products. In these circumstances, with a heat at first gentle, but gradually

increasing,

increasing, bone yields, at first, a limpid water, with a peculiar animal oily smell, which soon becomes impregnated with carbonated ammonia, together with an oil, at first of a clear yellow, pungent, and not ungrateful to the smell, but afterwards rendered brown, and even black, by the increasing heat, strongly fetid and ammoniacal. With the empyreumatic oil, a large quantity of sulphurated hydrogen, of carbonated hydrogen, and of carbonic acid gas escapes. The products of this distillation, when condensed, are the ammoniacal water, and the empyreumatic oil; the former contains, besides carbonat of ammonia, a portion of sebatic and prussic acid united with the alkali; the oil may be separated into the less and more empyreumatic, by changing the receiver occasionally, and keeping apart the first portions of the oil as the purest. If this oil is again repeatedly distilled by itself from clean vessels with gentle heat, it becomes at last as colourless as water, pungent, and not very unpleasant to the smell, so volatile at a common temperature as only to be kept by inverting under water the mouths of the vessels that contain it, and acting in medicine as a powerful sudorific. It is called from the name of the inventor, *DIPPEL'S OIL*, which see.

The only valuable part of the products of the distillation of bone is the ammonia, or volatile alkali, which is mixed with every part of the distilled liquid, and is afterwards purified by subsequent processes, assisting in the formation of the *MURIAT of ammonia*, or forming the pure *CARBONAT of ammonia* of the shops, the *sal volatile*, *spirit of hartshorn*, &c. When the distillation is discontinued, the bones remain in the retort of a brown colour, and swimming in a black, thick, extremely fetid, tenacious oil. If they are then gradually heated to redness in close iron vessels, every thing volatile is dissipated, and the earthy part remains dry and friable, still retaining the original form of the bones, but thoroughly impregnated with the charcoal of the oil, so as to become a fine glossy black. This is afterwards ground to a fine powder, mixed with size into cakes of a convenient weight, and forms one of the species of *lamp-black*, used very largely as a pigment. The harder and compacter bones, such as ivory, furnish a similar and more valuable black pigment, simply by heating to redness in close vessels.

But the analysis by heat, though it furnishes some valuable articles of commerce, is not well calculated to exhibit the constituent parts of bone in their proper characters.

In fact the ammonia, probably much of the oil, and all the gasses, are formed by the action of heat out of the real constituents of bone, as they exist in the animal.

Water and acids are the chief re-agents to be used by the chemist.

Cold water has scarcely any action on bone, but by long maceration its texture becomes more loose and open, and the gelatinous part becomes gradually changed, as by slow animal putrefaction.

Hot water acts with great ease upon bone, when reduced to small pieces by rasping or bruising; the first effect is to separate most of the *natural* oil of bone which rises to the top, and when cool concretes to a fatty fat. The water then dissolves the *gelatin*, which is found to compose a very considerable part of the substance, even of the driest and most compact bone; and in this method a clear insipid pure jelly is extracted, rendering the water, even when in large proportion, of a stiff, tremulous consistence when cooled, which, by evaporation, leaves at last a strong, hard *glue*.

The experiments of M. Pelletier on this subject are important. This accurate practical chemist took six pounds of dry bone shavings, procured from the button-mould makers, macerated them for two days in cold water, and then boiled them for nine hours with 24 quarts of water. The product

was a very strong clear jelly, and at the bottom of the vessel the *marc*, or earthy residue, which was pressed in order to separate the portion of somewhat turbid jelly, with which it was entangled. By subsequent boiling down, the jelly became so stiff when cold, as to bear to be cut into firm slices, which were hung up on strings in a place under cover from the weather (as in the common manufacture of glue), and in a fortnight became hard, brittle glue of good quality. The produce was 15½ ounces of clear glue, half an ounce more from the *marc*, and somewhat foul, and the *marc* itself weighed 4 lb. 3 oz. The loss in the operation amounted to 13 oz. In like manner 50 lb. of ivory shavings, exhausted by repeated boiling, gave 9½ lb. of clear glue, and 30 lb. of the *marc* remained.

These facts are important to the manufacturer; nor is the use of bone less interesting as an article capable of supplying much good and wholesome nutriment to man and other animals. In the making of soups it is a matter of common observation, that bones contribute, when boiled with the meat, to the richness of the liquor; but it is not commonly known how much they may be made to add to the nutritious quality; nor is it generally known that the hardest and driest bones, even those that have been kept for years, retain their gelatinous part unchanged.

The exact proportion of jelly cannot easily be ascertained by extraction with water, for even when converted into the hardest glue, it has become intimately united with a portion of this fluid; and it is by no means certain that the utmost defecation of glue equals the degree of dryness of natural gelatin, as it exists in the more solid bones.

The quantity of jelly is also much increased, either by giving the water by which it is extracted a higher heat than the boiling point, or by reducing the bones to a fine powder, and using repeated coction and pulverization.

The former method was used by Papin, who, in his valuable experiments on the solubility of animal substances, when confined with highly heated water in his *Digester*, found that he was able to extract every thing from powdered bone, but the mere earthy part. The latter mode has been brought into notice by M. Proust, in an important economic-chemical memoir on the "Method of ameliorating the subsistence of the Soldier," published at Madrid, in 1791.

Though there is a great general similarity between the bones taken from different parts of the body, they differ much in the relative portion of fat, of gelatin, and of earth. The younger the animal is, the less earthy salt, *ceteris paribus*, is contained in its bones. The large, round, joint-heads of the thigh, and other large bones, contain much more oil than the rib or blade bones, as is seen when they are exposed to the air; the latter soon becoming dry and clean, but the former remaining long foul and greasy.

No method of extracting all the soluble part of bone answers the purpose so completely, as long boiling in Papin's digester with a very great heat; the earthy residue then remains quite friable in the fingers, and gives little, if any, volatile, oily, or ammoniacal product on burning. But the jelly which remains in the water, and the oil which swims at the top, are found to have acquired a burnt unpleasant taste; and in the process, a considerable quantity of gas is generated, doubtless from partial decomposition of the soluble part. On the other hand, even after repeated boiling and laborious pulverization, unassisted by a higher heat than that of boiling water, the earthy residue still feels clammy and cohesive between the fingers, and retains some of the oil.

M. Proust asserts, that the knuckle and joint bones simply chopped into small pieces, and boiled for a quarter of an hour in a common copper, yielded no less than one fourth of their weight of fine insipid fat, which rose to the top of

B O N E.

the water, and on cooling concreted into the consistence of suet. The haunch bones yielded about one eighth of fat. The utmost economy of bones, therefore, when used as human food, may be obtained in the following method. First chop the fresh bones into small pieces, and extract the fat in the way just mentioned; then dry the bones, and powder, or reduce them to a fine paste, by some pretty strong mechanical power; and boil them with about ten times their weight of water, for some hours, till half the water is wasted, more or less according to the kind of bone; the joint and thick bones making a richer jelly than the thin bones, and therefore requiring somewhat less boiling down to make a jelly of a determinate consistence.

M. Proust finds that this proportion of water is sufficient to leave a jelly of about the same richness as would be produced by dissolving one ounce of bone jelly, dried to the consistence of portable soup, in thirty-one ounces of water, and makes a jelly of a very agreeable degree of richness. The extraction is much assisted by using an iron vessel with a close lid, to give a heat somewhat greater than that of boiling water, though not to the degree of a Papin's digester.

In all the above experiments on the extraction of jelly and fat from bones, the uncooked bone is understood to be used. The bones of *boiled* meat, though deprived of some of their extractive matter, are still rich in nutriment; but *roasting* renders them entirely unfit for this purpose.

The earthy part, which composes on an average about half the weight of the larger bones of animals, was discovered first by Gahn, a Swedish chemist, to consist of the phosphoric acid united with a large proportion of lime. It will be more minutely described under the article *PHOSPHAT OF Lime*; and it is the most convenient substance from which *PHOSPHORUS* is prepared. It may here be mentioned, that the stronger acids, such as the sulphuric or nitric separate a part of the lime from this earthy salt, but only a part, for when sulphuric acid is added to bone ash, sulphat of lime is formed in great quantity, most of which remains at the bottom of a supernatant liquor, consisting of a great excess of phosphoric acid united with a small portion of lime, and also some sulphat of lime dissolved therein. It should be remarked in the analysis of this salt, that this acid phosphat of lime, is not decomposed by any single acid, nor even by the pure or carbonated alkalies; for, on adding the latter, the precipitate is not carbonated lime, but still the phosphat.

This earthy salt, when in solution, is, however, entirely decomposed by the nitrat or acetite of lead; the lime remaining dissolved in the liquor by the nitric or acetic acid, and the phosphat of lead forming an insoluble precipitate. Phosphat of lead is distinguishable from sulphat of the same metal by being readily soluble in nitric acid. If the phosphat is sprinkled on hot charcoal, the lead is reduced, and the luminousness and peculiar smell of phosphorus are perceivable. The phosphat of lime is equally distinguishable from the sulphat of lime by being very soluble in most acids, even when dilute.

Much light has been thrown on the analysis, and with it the physical structure of bone, and of most other of the hard supporting or protecting parts of the body, by the accurate and numerous experiments of Mr. Hatchett, whose researches into these subjects are admirably calculated to shew the extreme advantage which physiology derives from the labours of the chemist, when assisted by accurate knowledge, and guided by a philosophical spirit.

When bones, boiled or fresh, are steeped in any acid, a slight effervescence is perceived, and they presently are rendered soft and flexible by the gradual abstraction of the

earthy basis (chiefly phosphat of lime), which becomes dissolved in the acid. If the bone be previously boiled for a long time in water, its gelatin is removed by this liquid; but if the bone is in its natural state, the gelatin also is gradually dissolved in the acid, rendering it yellow and somewhat tenacious. The insoluble residue (except in a few kinds of bone, such as the enamel of the teeth) is either a membrane or a spongy cartilage, retaining the form of the original bone; for, in the process of ossification, membrane or cartilage forms the first basis or rudiments of bone, which is afterwards completed by the gradual deposition of the earthy salts. Though phosphat of lime forms the chief ingredient in the earth of bones of all animals, a small portion of sulphat of lime is mixed with it: and Mr. Hatchett has detected also a little carbonate of lime. The carbonic acid of this is that which occasions the slight effervescence during the action of the acid; the lime remains dissolved in the acid after the precipitation of the phosphat of lime by pure ammonia. A carbonated alkali then precipitates it together with the now decomposed earth of the calcareous sulphat.

We have thus shewn the great constituent parts of bone to be *gelatin*, soluble by boiling in water, and giving a fine clear jelly; *oil*, separable, during the boiling, by rising to the top of the water, and when cold concreting into a suet; *phosphat of lime*, soluble in dilute nitrous muriatic or acetic acid, and precipitable thence by pure ammonia; some *sulphat of lime*; a little *carbonate of lime*; and a *membranous or cartilaginous* substance, retaining the form of the bone after every thing else has been extracted by water and an acid.

For a highly probable opinion on the nature and origin of this membrane or cartilage, we are indebted to Mr. Hatchett who has shewn a number of characteristic marks, in which it most strongly resembles inspissated albumen, and by which it differs from gelatin. The chief of these are the following:

When dry, it is semi-transparent like horn, and more or less brittle. In this state it resists the action of water very powerfully; for when boiled for many days with this fluid, a scarcely perceptible precipitate is given by nitro-muriat of tin; a test of dissolved albumen. In this it strikingly resembles coagulated albumen, and as pointedly differs from gelatin, which, as we have seen, is readily extracted by water even from the driest and hardest bones.

This bony membrane, as well as albumen, is scarcely acted on by cold muriatic and sulphuric and dilute nitric acids, which last readily extracts gelatin from bone. However, after an immersion in these acids of some weeks, the bony cartilage, when taken out and steeped in ammonia, gradually dissolves into a blood-red liquor. But if the nitric acid is heated, the albuminous membrane is rapidly dissolved with the copious discharge of nitrous gas.

With caustic fixed alkali, the bony membrane or cartilage is readily dissolved into a perfect animal soap (a strong mark of resemblance to albumen, and difference from gelatin), and during the process much ammonia is given out. Acids again separate the albumen from the soap, unaltered in chemical properties.

Lastly, the bony cartilage is extremely slow to enter into a state of putrefaction, though kept moist and warm for many weeks: and in this too it resembles coagulated albumen.

Therefore in addition to the above-mentioned constituent parts of bone, we may add *albumen*, in a condensed state, forming the substance of the original cartilaginous or membranous structure, both of all the organized bones, and, as Mr. Hatchett has also shewn, of most of the hard parts which serve for the covering, protection, and arming of almost

almost every part of the animal creation. See the articles SHELL, HORN, &c.

The enamel of the tooth is a singular variety of the bone, being entirely destitute of the albuminous membrane. When an entire tooth is immersed in dilute nitrous acid, the enamel totally dissolves without residue; but the core of the tooth is acted on like other bone, leaving a cartilage of the same shape. The solution of enamel is found to be almost entirely phosphat of lime, by the tests already mentioned, being precipitable by pure ammonia, giving phosphat of lead, by adding the acetate of this metal, &c.

Fish-bones Mr. Hatchett found to contain rather a larger quantity of cartilage, in proportion to the phosphat of lime, than the bones of quadrupeds. Of the different kinds of horn and defensive weapons, the stag's-horn, elephant's-tusks, and the other hard and heavy defences, entirely resemble bone; but the horns of cattle, rams, and the softer species, contain so little earthy residue, that they owe their solidity entirely to the extreme condensation of the other constituents, the gelatin and albumen.

Bones may be softened by a short immersion in a weak acid. This arises from the partial abstraction of the earthy basis; and advantage may be taken of this property in the working of bone, for the various purposes of manufacture to which this article is applied by the turner, comb-maker, cutler, &c. Bone thus softened, is again made hard, by being steeped in alum-water. Alkalies also soften bone, as they do every other animal matter, by beginning to act upon the softer parts. See IVORY.

Bones readily take various colours, which, if dissolved in an acid, sink deep into the substance of the bone, and produce a pleasing effect. The metallic solutions are generally preferred for this purpose. To give a green, dissolve verdigris in distilled vinegar, immerse the bones in the solution, put the whole in a vessel, very well closed, and bury it in a dunghill, or give it a slow and uniform warmth in any other way for about ten or twelve days. The bones are then found very deeply and permanently dyed green, and capable of a good polish. The once prized *Turquoise* stone is fossil bone of various animals, accidentally impregnated with sulphat of copper whilst buried in the earth. To give the artificially dyed bones a finer colour, boil them in nut-oil, and they will then take a very high polish.

A permanent black is given to bone, either by nitrated silver, or in the following manner: boil equal parts of litharge and quick-lime in water, and the bones along with them for some hours, stirring them frequently. Other metallic solutions may be used for different colours.

Or the dye may be given by preparing the vegetable coloured lakes, or concentrated dyes; and by rubbing the bone, first with dilute nitrous acid to open its texture, and then rubbing in the dye for some time. This may be applied in various ways, first softening the bone by a weak acid, whereby it is made fit to receive the colour.

Bones are whitened by simple exposure to sun, wind, and weather, being first thoroughly cleaned, and particularly by occasional immersion in brine: thus the bones of sea-birds and fish, left for some time on the shore, are found beautifully white and clean. The same effect is produced much more speedily, but perhaps less permanently, by the oxy muriatic acid, the bone being exposed for some hours to this acid gas in close vessels, as Mr. Smith of Bristol has observed. The acid first makes the bone yellow, which, by exposure to air goes off, and leaves the bone beautifully white. This colour a little fades, when the bone is kept in close cases excluded from the light. See SKELETON.

From all that has preceded, it will appear obvious that

to the chemist and manufacturer, bone is one of the most curious and valuable of the animal substances, though considered vulgarly as little better than refuse, and scattered about without care. Besides its use as a hard and good material for turnery and workmanship of various kinds, it gives, by chemical decomposition, a large quantity of useful, nutritive jelly, fit for human food, or the same, in the form of glue, for the arts. When subjected to fire, it yields a vast quantity of ammonia, and is actually the material used in very many manufactures of the ammoniacal salts; and the residue, strongly calcined in close vessels, (and therefore retaining its carbonaceous ingredient,) produces useful and fine black pigments; or, burned with access of air, leaves an earthy salt, necessary to some important chemical processes.

Some of the preparations from bone are only used in medicine. Of these, are Dippel's oil, and the less rectified *oleum cornu cervi*, (oil of hartshorn,) both powerful sudorifics, and supposed antispasmodics; the *spiritus cornu cervi*, (spirits of hartshorn,) so universally known as a stimulant and cordial; and the carbonat of ammonia, often called salt of hartshorn. The white calcined earth of bones, *cornu cervi calcinatum*, enters into the composition of one or two pharmaceutical preparations, but without exhibiting any obvious properties. In diseases of the bones, where the softening and spontaneous deformity shews an evident want of their earthy basis, this calcareous phosphat has been given with apparent advantage. Of the unprepared bones, the elk's tooth, rhinoceros's horn, and shavings of the dried human skull, &c. are medicines entirely exploded only within a few years from the European pharmacopœias, and still maintaining high credit in the countries whose characteristic credulity and superstition in medicine first brought them into repute. The only real utility of unprepared bone in medicines is found in furnishing, when boiled in water, a light and nutritive jelly for the invalid; and for this purpose, hartshorn shavings are employed with advantage. *Memoirs de Pelletier*, tom. ii. Proust in the *Journal de Physique*, tom. liii. Hatchett in the *Phil. Trans.* for 1799 and 1800. Smith in Beddoes's *West of England Contributions*. Johnson's *Animal Chemistry*. *Encycl. Method. Arts and Metiers*, (Article *Ecaille*), &c. &c.

BONES, Diseases of the, in Surgery. As bones are organized parts of the animal body, they are liable to most of the diseases with which the softer organs are affected. They are either spontaneous, or accidental; but, from the hardness of their composition, and the small degree of vascularity and sensibility they possess, there must necessarily be a considerable difference between the phenomena and symptoms of diseased bones, compared with those of the soft parts. They are naturally endowed with little or no sensation; but are extremely painful in an inflamed state, when the blood-vessels, which enter their substance, are distended, and the nervous filaments are kept upon the stretch, as in the case of venereal nodes, &c.

Bones may be wounded with a sharp instrument, or contused with a blunt one, in the same manner as the muscles, or integuments; and they will re-unite again, if the injury they suffer be not so extensive as to intercept the circulation, or destroy their vitality. But, if a bone be so injured as to perish, its substance will either be gradually comminuted and dissolved, or cast off in a larger portion, by the process we denominate *exfoliation*. If any two ulcerated surfaces of flesh (suppose two contiguous fingers) be applied together, and allowed to heal, they will coalesce, and the vessels from one part will shoot into the other: in like manner, if the articulating surfaces of two contiguous bones (suppose

(suppose of the tibia and femur), be deviated of their cartilage by ulceration, their extremities may coalesce, and form one continuous bone, which is named *anchylosis*. A stiff joint, from this cause, is irremediable, and in general it may be considered as the most favourable termination of diseased joints; for they too commonly are attended with such distressing symptoms as to require amputation, in order to preserve the patient's life. See WHITE SWELLING, and *Diseases of the JOINTS*.

The consideration of *Fractions* and *Dislocations* is reserved for their proper places in the Cyclopædia, where will be likewise described the manner of reducing bones, vulgarly called *bone-setting*. This art, (which requires a very correct acquaintance with the anatomy of the joints and muscles), has, most unaccountably, been often left to ignorant farriers and mechanics, who are totally destitute of knowledge on these subjects! We might, with as much reason, entrust the repairing of a watch, or a mill, to persons who never had an opportunity of examining their mechanism! By accident, it is barely possible, some good might be done; but the greater chance is, that the instrument would be damaged rather than rectified, in the hands of such unskilful operators.

Bones will, in ricketty and serofulous constitutions, pass into a state of spontaneous enlargement, or decay, or flexibility, &c. The spongy parts of bones, e. g. the extremities of cylindrical bones, are most liable to become diseased in such subjects, especially during the early period of life; but in venereal patients, who are also very susceptible of morbid changes in the bones, they are their hard parts chiefly which become affected, as in the middle of the tibia, or ulna, or upon the central portions of the frontal and parietal bones. See RICKETS, SCROFULA, and LUES VENEREA. Some observations on the surgical treatment of diseased bones will be also made under the heads of CARIES, NECROSIS, SPINA BIFIDA, DISTORTION, CURVATURE, MOLLITIES, and EXOSTOSIS.

The structure of bones may be altered from several causes; but principally, from either a deficiency, or a redundancy of the phosphat of lime, which enters into their composition, and gives them solidity. When there is too little phosphat of lime, the gelatinous parts of the bones being unable to sustain much weight or resistance, they will become preternaturally flexible; and, on the contrary, when there is too much phosphat of lime, in proportion to the gelatinous part, the bones will be very fragile, and perhaps, may even break from the mere action of the muscles. The flexible state is most common in young persons, and the superabundance of osseous matter is chiefly predominant in old age; but either condition of the bones may occur at any period of life, from peculiar morbid dispositions. The popular notion of our bones being more frangible in cold weather than in hot, is erroneous, and without foundation; since the difference of season makes no difference in the texture of the living bones: and the only natural cause to be assigned for the fracture of our limbs more frequently in the winter than in the summer, is that of an increased slipperiness and hardness in the ground from frost, &c. which must necessarily occasion more physical violence and frequency in our falls.

BONES, in the funeral solemnities of the ancients.—Divers usages and ceremonies relating to the bones of the dead, have obtained in different ages; as gathering them from the funeral pile, washing, anointing, and depositing them in urns, and thence into tombs; translating them, which was not to be done without the authority of the pontiffs; not to say worshipping them, still practised to the bones of the

saints in the Romish church. Among the ancients, the bones of travellers, and soldiers dying in foreign countries, were brought home to be buried, till, by an express S. C. made during the Italic war it was forbid, and the soldiers' bones ordered to be buried where they died; the reason was, lest the melancholy sight should discourage the people from venturing their lives. Antiquaries are divided as to the manner of distinguishing the bones of the deceased, from those of the beasts and slaves, who were sacrificed at his funeral, and thrown into the same fire: probably it was done by disposing the body of the dead in the middle of the pile, and the others towards the sides. Potter's *Archæol.* tom. ii. lib. iv. cap. 6.

The Romans had a peculiar deity, under the denomination of *Osifago*, to whom the care of the induration and knitting of the human bones was committed: and who, on that account, was the object of the adoration of all breeding women. Pitisc. *Ant.* tom. ii. p. 341.

BONES, *fossile*, or *petrified*, are those found in the earth, frequently at great depths in all the strata, even in the bodies of stones and rocks.

There are divers sorts of fossile bone; some of a huge size, usually supposed to be the bones of giants, but more truly of elephants or hippopotami; others smaller, as vertebrae, teeth, and the like.

It has been disputed whether these be really animal substances, or mineral, that is, stones thus figured. Modern naturalists generally allow them to be animal, not merely on account of their figure and resemblance, but of their chemical principles, which are found to be wholly of the animal kind. It is supposed they were repositied in those strata at a time when all things were in a state of solution, and that they incorporated and petrified with the bodies where they happened to be lodged.

In the Philosophical Transactions (vol. lxxxiv. p. 407, &c.) we have some observations on fossile bones by the late Mr. John Hunter. They were occasioned by an examination of bones of this kind, found in the caves of Gailenreuth and Klausstein, two small villages in the principality of Bayreuth, (or Bareith), and presented to the Royal Society by the margrave of Anspach. These bones are considered more as incrufted bodies than extraneous fossils, since their external surface has only acquired a covering of crystallized earth with little or no change in their internal structure. The principal earth with which bones are most commonly incrufted is the calcareous; and this happens either by the bones being immersed in water, in which this earth is suspended, or by water's passing through masses of this earth, which it dissolves, and afterwards deposits upon bones which lie underneath. Bones which are incrufted seem never to undergo this change in the earth, or under the water, where the soft parts were destroyed; while bones that are fossilized become so in the medium, in which they were deposited at the animal's death. The incrufted bones have been previously exposed to the air; which is evidently the case with these bones, and also with those of the rock at Gibraltar, those found in Dalmatia, and those of the island of Cerigo. They are thus distinguished from fossilized bones: but as they are found in different situations, it is more difficult to account for their present state. Those in Germany are found in caves; the coast of Dalmatia is said to be wholly formed of them; and this is the case with a large portion of the rock of Gibraltar. With respect to the first class of bones, as they are those of carnivorous animals, resembling, in some respects, those of the white bear, and yet differing, in some circumstances, from the present animal of that species, Mr. Hunter suggests, that the animals to which they

They belong resorted at different periods to these caves, as places of retreat, and perished in them. In Gibraltar, they are mostly the bones of animals of the ruminating tribe, of the hare kind, and of birds, with some of a small dog, or fox, and likewise shells. Those in Dalmatia appear to be mostly of the ruminating tribe. From these facts, it may be presumed, that their accumulation did not arise from any instinctive mode of living, as the same mode could not suit both carnivorous and herbivorous animals. As to the local distribution of these bones, it is necessary to recur to successive shiftings of the situation of the sea, in consequence of which we may have a stratum of marine extraneous fossils, one of earth, mixed probably with vegetables and bones of land animals, a stratum of terrestrial extraneous fossils, then one of marine productions; but as the sea carries its inhabitants along with it, wherever there are those of land animals, there will also be a mixture of marine ones; and from the sea commonly remaining thousands of years nearly in the same situation, we have marine fossils unmingled with any others. As all operations respecting the decomposition, as well as the growth, of animal and vegetable substances, proceed more rapidly on the surface of the earth, to which the air has access, than within it, we shall find fewer changes as we descend into the earth, and at last probably arrive at a certain depth, where no change takes place. Substances, therefore, that are fossilized at a great depth, and deposited in stone, clay, &c. are preserved for a very long time from putrefaction; as much so as if they were in a vacuum; the heat also in such situations being uniform, commonly about 52° or 53°; and in the colder regions they are still longer preserved. It has been generally understood, that in extraneous fossils the animal part is destroyed: but Mr. Hunter has not found this to be the case. Shells, and bones of fish, must probably have the least in quantity, having been longest in that state, otherwise they should have the most; for the harder and the more compact the earth, the better is the animal part preserved; and this is an argument in proof of their having been longest in a fossil state. In the fossil bones of sea-animals, as the vertebrae of the whale, the animal part is in large quantity, and exists in two states; the one having some tenacity, but the other like wet dust; in some of the harder bones it is more firm. In the fossil bones of land animals, and those which inhabit the waters, as the sea-horse, otter, crocodile, and turtle, the animal part is in great quantity. In the horns of stags dug up in Great Britain and Ireland, when the earth is dissolved, the animal part is in considerable quantity, and very firm. The same observations apply to the fossil bones of the elephant found in England, Siberia, and other parts of the globe; also those of the ox kind; and more particularly to their teeth, especially those from the lakes in America, in which the animal part has suffered very little: the inhabitants finding little difference in the ivory of such tusks from the recent, except its having a yellow stain; the cold may probably assist in their preservation. In incrusted bones, the quantity of animal substance is very different in different bones: in those of Gibraltar, there is very little; it partly retains its tenacity, and is transparent, but the superficial part dissolves into mucus. Those from Dalmatia furnish similar results. Those from Germany, especially the harder bones and teeth, seem to contain all the animal substance natural to them, though in this respect they differ among themselves. The bones of land animals have their calcareous earth united with the phosphoric acid of the aerial, and retain it, when fossilized, as Mr. Hunter thinks, in proportion to the quantity of animal matter they contain. This he infers from the quantity of effervescence. In some bones of the whale, put in-

to the muriatic acid, the effervescence is very great; in the Dalmatia and Gibraltar bones it is less; and in those of the German caves, it is very little, since they contain by much the largest proportion of animal substance. From the experiments and observation of the ingenious Mr. Hatchett, (see Phil. Trans. vol. lxxxix. p. 333.) we learn that the bones of the Gibraltar rock consist principally of phosphat of lime; and that the cavities have been partly filled by the carbonate of lime, which cements them together. Fossil bones, he says, resemble bones which, by combustion, have been deprived of their cartilaginous part: for they retain the figure of the original bone, without being bone in reality, as one of the most essential parts has been taken away. Such fossil, or burned bones, can no more be regarded as bone, than charcoal can be considered as the vegetable of which it retains the figure and fibrous texture. Bones which keep their figure after combustion, resemble charcoal made from vegetables replete with fibre; and cartilaginous bones, which lose their shape by the same cause, may be compared to succulent plants which are reduced in bulk and shape in a similar manner. Hence he is led to question if bodies, consisting of phosphat of lime, like bones, have concurred materially, to form strata of limestone, or chalk; as it appears to be improbable, that phosphat is converted into carbonate of lime, after these bodies have become extraneous fossils. The destruction, or decomposition of the cartilaginous parts of teeth and bones in a fossil state, must have been the work of a very long period of time, unless accelerated by the action of some mineral principle; for, after having, in the usual manner, steeped in muriatic acid the os humeri of a man, brought from Hythe in Kent, and said to have been taken from a Saxon tomb, Mr. Hatchett found the remaining cartilage nearly as complete as that of a recent bone.

M. Cuvier communicated to the Société d'Histoire Naturelle at Paris, a curious memoir upon the fossil bones of animals. The following abridgment has been taken from the Société Philomatique, N° 18. Year VI. In order to determine the relations and differences that subsist between the several species of animals that do exist, or have existed on the surface of the globe he directed his attention to the following. 1. The animal which afforded the bones and teeth, called the bones and horns of the mammoth, by the Russians and Siberians, and of which remains are found in Europe, is a species of elephant, resembling the elephant of Asia; but differing from it in the alveolæ of its teeth, its tusks being longer, the angle of its lower jaw more obtuse, and the laminae of which its grinders are composed thinner. The true analogous living animal is not known, though it has been hitherto considered as the ordinary elephant. 2. The animal, of which the remains are found on the banks of the Ohio in North America, which the Americans and English have also named mammoth, though it differs much from the former. Remains of it are found in Europe and Asia. It must have been nearly as high as the elephant, but more bulky; its tusks are smaller; its grinders are armed with large cutting points, of which the section by wear presents double transversal lozenges. There are three molar teeth on each side, one of four, one having six, and one eight points. 3. The animal of which the teeth tinged by copper afford the turquois stone, and of which there was a mine at Simore, in Languedoc. The remains of this species are found in the department of Ain, in Peru, and elsewhere. It must have considerably resembled the former; but the points of its molar teeth are round, and when worn, their section presents first, a circle, then a semi-oval, and afterwards a figure of a trefoil, which has caused them to be confounded with the teeth of the rhinoceros;

some of these teeth have 12 points, others 6, others 4. 4. The rhinoceros. The feet and fragments of the jaws of this animal are found in France, and elsewhere, in which the author has hitherto observed nothing which differs from the common rhinoceros; but, as he has not yet seen an entire bone, he cannot positively affirm that they are identical. 5. The species of rhinoceros, with an oblong cranium, which is found in Siberia, Germany, and other countries. The author has seen teeth, and parts of the jaw-bones, found in France, which appeared to him likewise to belong to this animal; the principal character of this species consists in the long closure of the nose: the living analogous animal is unknown. 6. A molar tooth with two transversal eminences, which is in the possession of Citizen Gillet; and of which the National Museum possesses a young tooth that resembles neither the teeth nor the germs of any animal yet known, whether living or fossil: the only tooth which this slightly resembles is the last molar tooth of the rhinoceros. This tooth, therefore, indicates the existence of a sixth fossil species, of which the living analogous animal is unknown. 7. The animal twelve feet in length, and six in height, of which the skeleton was found under ground at Paraguay, and is preserved in the royal cabinet of Spain, at Madrid. The author proves by a detailed comparison of the bones, with those of all the known quadrupeds, that it is a proper and distinct species, more nearly approaching the sloth than any other genus, and that it may be called the giant sloth. Citizen Cuvier, in this place, communicates the interesting discovery he has made, that the sloth (*Bradypus tridactylus*, Lin.) has naturally and constantly nine cervical vertebrae. It is the first known exception established by Citizen Daubenton, that all quadrupeds have neither more nor less than seven cervical vertebrae. 8. The animal, of which the remains are found in the caverns near Gaylenreuth and Muggendorf, in the margraviate of Bayreuth, in Franconia. Various authors have considered it as a white bear; but it differs from this animal, as well as from all the known bears, in the form of its head, which is particularly characterized by the projection of the front, by the absence of the small tooth, which all the known bears have behind each canine tooth, by the oleous channel of the humerus, in which the brachial artery passes, and by several other circumstances in the figure and proportion of the bones. This animal, however, resembles the bear more particularly than any other kind. 9. The carnivorous animal of which the bones are found in the plaster-stone of Montemartre: the form of its jaws, the number of its molar teeth, and the points with which they are armed, indicate that this species is referable to the genus *canis*; but it does not completely resemble any species of this genus. The most striking distinctive mark is, that the seventh molar tooth is the greatest in the animal of Montemartre, whereas the fifth is the largest in dogs, wolves, foxes, &c. 10. The animal of which the lower jaw was found near Verona, has been considered by Joseph Monti as a portion of the cranium of the sea-cow; a notion which all the geologists have adopted, though it be contrary to the most simple notions of comparative anatomy. This jaw, according to Cuvier, has belonged to an animal resembling, though specifically different from, the mammoth, the animal of the Ohio, and that of Simore. Its most particular character consists in the curve which forms its symphyfis. 11. The animal of the stag kind of which the bones and the antlers are found in Ireland, in England, at Maestricht, &c. It is sufficiently different from all the stags, and even the elk, to which it has been referred, by the enormous magnitude of its antlers, the flattening of their superior part, and the branches which spring from

their base. Several figures of these are given in the Philosophical Transactions. 12. The genus of the ox or beeve alone affords several fossil species: the craniums of two were found in Siberia, which have been described by Pallas, who referred one of them to the ordinary buffalo; but he has since attributed them to a peculiar species, natives of Thibet, named arui. Citizen Cuvier proves, by osteologic comparison, that those craniums have not belonged to the buffalo. The other appeared to Pallas to have belonged to the buffalo of the Cape, or the musk ox of Canada. Citizen Cuvier shews that they cannot have belonged to the former; but not being in possession of the cranium of the arui, nor the musk ox, he makes no decision respecting their identity with the fossil craniums.

The author likewise describes two kinds of craniums which have been found in the turf-pits of the department of La Somme, which greatly resemble our common ox, and that of L'Aurouchs, but are more than one fourth longer.

From this inquiry the Citizen Cuvier concludes, 1. That it is not true to affirm that the animals of the south have formerly lived in the north, their species not being perfectly identical. 2. That in every country there have lived animals which do not at present exist, either on the same spot, or elsewhere in any known country. Hence he leaves to geologists, the task of making, in their systems, such changes or additions as they may think best suited to explain the facts which he has thus established.

BONE is also applied abusively in speaking of other matters which bear some analogy, either in respect of structure or office, to the bones of animals.

In this sense rocks are sometimes called the bones of the earth. Divers species of figured stones, as the *cephalites*, *cardites* &c. are denominated mineral bones, *cnosta*, *osteocolla*, &c. Some naturalists consider shells as a species of bones. The lobster, according to Fontenelle, is an animal which carries its bones on its outside.

BONES, *Giants*. See GIANTS BONES.

BONES, *Mammoth*. See MAMMOUTH.

BONE-fire. See Bon-FIRE.

BONE-lace. See LACE.

BONE, *burle*, *Neper's*, *quitter*, *ring*, *whale*. See the several articles.

BONEF, in *Geography*, a town and abbey of the Netherlands, in the county of Namur, 3 leagues north of Namur.

BONCONTRÉ, a town of France in the department of the Coté d'Or, and chief place of a canton, 5 miles S.W. of St. Jean.

BONETTA *Shoal*, lies about N.E. by E. from Bonavista island, one of the Cape de Verd islands, distant from it about 12 or 14 leagues.

BONEZIDA, a town of Transilvania, on the Samos, 12 miles N. of Clausenburg.

BONFADIO, JAMES, in *Biography*, an eminent Italian scholar of the 16th century, was born at Gorzano, in the Breseian territory, and studied in the university of Padua. From thence he went to Rome, where, for some time, he served the cardinals Merino and Ghinucci, as secretary; and after wandering from place to place, he resumed his studies at Padua, where he was probably employed in the instruction of youth. Deriving from none of his employments more than a precarious subsistence, he was, in 1545, invited to the chair of philosophy, in the city of Genoa, to which was united the office of historiographer, with a considerable pension. Whilst he was busily prosecuting his studies, he was charged and convicted of an unnatural crime; beheaded in prison; and his body was publicly burnt in July 1550. As a writer in the Latin and Italian languages, both in prose and verse,

he excelled; and his translation of Cicero's oration for Milo, is reckoned one of the most elegant pieces of Italian prose which the century affords. His capital work is the "Annals of the republic of Genoa," written in Latin, and comprising the history from 1528, where Giustiniani left off, to February 1550. It was first published at Padua, in 1586, 4to. and translated into Italian by Paschetti. The style is elegantly simple, the narrative lively, and the sentiments elevated. His Italian letters and poems were printed at Brescia in 1746—47. Gen. Dict. Nouv. Dict. Hist.

BONFATTI, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Calabria citra, 3 leagues W. of St. Marco.

BONFINI, ANTHONY, in *Biography*, was born at Aicoli, and after being some years professor of belles-lettres, at Recanati, was invited by Matthias Corvinus king of Hungary, in 1484, to his court, where he was employed in writing the history of the Huns. Here he enjoyed the office of tutor to the queen, Beatrice of Arragon, and received many honours from Matthias, and his successor Ladislaus. He died in 1501, aged 75. Of the history of Hungary he left 4½ decads, brought down to 1495; of which 3, or 30 books were printed, by Martin Breuer, in 1543, and the remaining 15 books were added to a new edition by Sambucus, in 1568. This work is written with elegance, and is classed among the best modern histories in Latin. He also wrote an account of the capture of Belgrade by Mahomet II.; and a work entitled "Symposion Beatricis, seu dialogorum de fide conjugali et virginitate, lib. iii." He likewise translated, from the Greek into Latin, the works of Philostratus, Herodotus, and Herodian. Gen. Dict.

BONGARS, JAMES, a polite scholar and able negotiator, was born of protestant parents at Orleans in 1554. Having studied first at Strasburg, and attended a course of law under Cujacius, he entered into the service of the king of Navarre, afterwards Henry IV. by whom he was employed for 30 years in various negotiations, particularly with the German princes. Being at Rome in 1585, he wrote a severe reply to the violent bull fulminated by Pope Sixtus V. against Henry IV.; and he also published a spirited answer to a German piece, imputing the bad success of the joint expedition in 1587, to the misconduct of the French. He was distinguished by his knowledge of books, and had collected a large library, a great part of which was at length annexed to the public library of Bera. As a critic he became known by a valuable edition of "Justin," Paris, 1581, 8vo. He also edited a collection of the Hungarian writers, and the "Gesta Dei per Francos." But his reputation was principally owing to his Latin letters, written during his negotiations, and published after his death, at Leyden, in 1647, and afterwards translated into French. The style is clear, easy, and polished, and they seem to have been dictated by an honest heart. A collection of his French letters, "Le Secretaire fans fard," has also been published. Although a Calvinist, Bongars disapproved of the religious wars of that party. He died at Paris in 1612. Gen. Dict.

BONGO, or BUNGO, in *Geography*, one of the islands of Japan. The principal town, seated on the east side of the island, is called by the same name. This is a port opposite to Tonfa, and separated from it only by a narrow channel. N. lat. 32° 41'. E. long. 131° 57'.

BONGO PALA, in *Botany*, Piso. See *MYRISTICA aromatica*.

BONGUATRORA, *Serpens ornatissima amboinensis bonguatrora* of Seba, in *Zoology*, the name the coluber *abatulla* bears among the natives in the island of Amboyna. See *ABATULLA*.

BONHAMPTON, in *Geography*, a town of America,

in Middlesex county, and state of New Jersey; about 6 miles N.E. from New Brunswick.

BONI, a kingdom of the island of Celebes, which lies on the western side of a bay, called on that account the bay of Boni, is the second kingdom, in point of importance, in the island. Its extent from the river Chiarana to the river Salenico is about 20 leagues; and within land it is bordered upon Soping, Lamoree, Macaffer, and Bosleboele. In ancient times this kingdom was independent of, and unconnected with any other. It is still in close alliance with the two small kingdoms of Soping and Loeboe, or Loehoe. The natives of Boni, that they may not appear inferior to the Macassers, deduce their origin in like manner from the gods. The first king they say, descended from heaven, and was known by the name "Matta Salompo," that is, the all-seeing. This sovereign, their first monarch, instituted the laws of the country, which are still observed; made the royal standard, called "Worong Porong;" and appointed seven electors, under the denomination of "Matoua petoes." The prince or sovereign is called "pajong;" and he is elected for life by seven nobles, which number is kept up by the pajong, and they are appointed by him from certain freeholders. The pajong is often restrained by a sort of parliament, elected by the freeholders; it consists of 400 members, 200 of which are called "mattona," 100 are called "pabicharro," and 100 are called "galarang." The first sovereign, after reigning 40 years, reigned the kingdom to his son, and, with his wife, ascended again to heaven; and from him all the succeeding kings of Boni are descended; none others, besides his posterity, born of marriages with royal princesses, being entitled to the crown. Notwithstanding the common descent of the rulers of Boni and Macaffer from the gods, these two nations are avowed enemies. About the beginning of the 17th century the Bouginefe, or people of Boni, and their queen, were compelled to conform to the mahometan religion; and the condition imposed upon them was, that the enemies of Macaffer should likewise be the enemies of Boni, but not the enemies of Boni those of Macaffer. At this time Boni was able to bring 70,000 fighting men into the field. The hatred which was thus excited among the Bouginefe against the Macassers, and their incessant quarrels, enabled the Dutch, who, as their interest required, favoured sometimes the one party, and sometimes the other, to make themselves masters of the island. The princes of Boni, Soping, &c. united themselves to the Dutch by the Boni contract, which was concluded November 18th, 1667; and to this the Macassers were afterwards compelled to accede. At present the Bouginefe are the most powerful, as the Macassers were about a century ago.

The Bouginefe, or Buggesses as they are usually called by the English, are of a middle size, and have a brown, but not dark, complexion. Among the female sex in particular, some are found almost entirely fair. Their features in general are agreeable, only that their nose is a little flattened. They are less open and more treacherous in their dispositions than the Macassers; and never attack their enemies openly, but endeavour to fall upon them by surprise. Those who never did them an injury are not secure from being murdered by them, when they can do it with privacy; and they often commit such actions for no other reason, as they say, than to try the goodness of their knives, or daggers. Many Macassers, as well as Europeans, have fallen sacrifices to this thirst for blood. Their daggers and assagays are commonly poisoned, as well as their small darts, which they can shoot at their enemies to a considerable distance by blowing them through a tube. Their clothing consists of a piece of red or blue cotton cloth wrapped round the body, and drawn

between the legs. The upper part of the body is quite naked. On the head they wear a piece of cotton cloth in the form of an handkerchief, with which they cover their hair, which is as black as pitch, and very long. On the other parts of the body, neither the men nor women suffer any hair to grow; they pull it out by the roots, in the same manner as the Mahometans and Indians do, as soon as it appears. The food is chiefly rice, fish, and pigings; and their beverage is water, though they are not destitute of "saqueer," or palm wine. The Bouginese women are in general much handsomer than those of the other Indian tribes; some of them, if their complexion had the same mixture of red and white as our females, would be accounted beauties in Europe. They are naturally of an amorous disposition, and are capable of undertaking any thing to gratify their inclinations. The Bouginese, who have in general adopted the mahometan religion, may have four wives, provided the husband can maintain them; but if they are not satisfied with each other, they may separate with as little trouble as they were united. They are a high spirited people, fond of adventures and emigration, and capable of undertaking the most dangerous enterprises. The appellation "Bugguese," has become, among Europeans in the east of India, synonymous with soldier, just as seapoy is in the west. The people of Celebes are very industrious, and they are very adventurous merchants; and the Bugguese, in particular, often find their way to the spice islands, in spite of the vigilance of the Dutch. They write their language from left to right, in a character peculiar to themselves; on the sea-coast they universally speak the Malay tongue, and have many Malay phrases in their own language. Their funerals are attended with very little ceremony. The body is wrapped up in a piece of white cotton cloth, and deposited in the grave, over which some sweet scented flowers are strewed, and two stones are erected, one at the head and another at the feet. Stavorinus's Voyage to the East Indies, vol. ii.

BONI, *bay of*, a bay in the kingdom of Boni, in the southern part of the island of Celebes. It is called Sewa by the natives, and Bugguese, or long bay, by the English. Of this bay we have the following account by Captain Forest. Having passed the strait between Celebes and Saleyer, called the "Budgeroons," keep on in a direction N.E. by N. about 130 miles, and you will find, near the west coast of the Sewa, a small island called "Baloonroo," visible 8 or 10 leagues off, and having some rocky islets at its east end. Farther on, about a day's sail, or about 60 miles, is the mouth of the river Chinrana, which takes its rise in the Warjoo country, the capital of which is Tofforo, lying a day's journey by water from the mouth of the river; it afterwards passes through Boni; it has a good muddy bar, passable by large ships, and is navigable a good way up; it has several mouths, and on its banks are many towns, which carry on a great trade in gold, rice, sago, cassia, tortoiseshell, pearls, &c. The anchorage is good off the river's mouth. Half a day's sail farther north, along the west coast of the Sewa, is the river Peenekee, which is not very considerable. Farther on are two places called Akolingan and Telludopin, which are pretty well inhabited. Continuing still north, you come to the river Sewa, not very considerable; then to the river Loo, famous for boat-building; then you come to Mankakoo, where are gold and plenty of sago, very cheap, and also cassia and seed-pearl. Being now come to the bottom of "Buggese bay," the sago-tree abounds very much; and in many parts of the Sewa, there are spots of foul ground, on which they fish for swallow, which they generally carry to Macasser, to sell to the China

junk. On the east side of the Sewa the country is not so well inhabited as on the west side. The south-east point of the Sewa is called "Pajungan;" where is a cluster of islands, rather small, among which is good anchorage. Stavorinus's Voyage, vol. ii. p. 213.

BONIEUX, a town of France, in the department of the Vaucluse, and chief place of a canton, in the district of the Apt. The place contains 2450, and the canton 6178 inhabitants; the territory comprehends 130 kilometres, and 6 communes; 8 leagues E. of Avignon.

BONIFACE, in *Biography*. There are nine popes of this name. *Boniface I.* succeeded Zosimus in the year 418; and when the schism, occasioned by a party that favoured Eulalius, was terminated, he was fully established in possession of the papal see in 419. Before his election he was a presbyter of irreproachable character, and after his advancement he was a lover of peace; and though he maintained what he called the just rights of the Roman see, in the jurisdiction which his predecessor had exercised over the bishops of Illyricum, he made no attempt to extend his authority and claims. He revoked the privileges granted by Zosimus to the see of Arles, and restored them to the sees of Narbonne and Vienne, which had been unjustly deprived of them; and with a moderation that redounds much to his honour, he refused to interfere in a dispute which took place between the clergy of Valence and Maximus, their bishop. He died at a very advanced age, November 4, 422; was canonized as a saint in the church of Rome; and his festival was kept on the 25th of October. Bede gives credit to the relation of miracles wrought by this pope, and Baronius (ad ann. 423.) says, that he relieved Rome in the time of a famine.

Boniface II., a Roman by birth, and a Goth by descent, supplied the vacancy occasioned by the death of Felix III. in 520; and upon the death of a competitor, named Dioscorus, obtained quiet possession of the papal chair. This pope confirmed the decrees of some Gallican bishops, who condemned the semipelagian doctrine; and in 531 he proposed to alter the mode of electing a pope, and to assume the prerogative of appointing his successor. He obtained a decree for this purpose, and actually nominated a deacon, whose name was Vigilus. But at a second council the Roman senate, in concurrence with the bishops and clergy, obliged the pope to revoke his former decree, and to acknowledge himself guilty of high treason. Boniface died in October, 532.

Boniface III., a native of Rome, succeeded Sabinian, after a vacancy of almost a year, in 607; and having ingratiated himself with the emperor Phocas, to whom he was deputed as a nuncio by pope Gregory, in 603, he obtained from this tyrant the title of "universal bishop," and "head of the church," which was taken from the bishop of Constantinople, and transferred to Boniface and his successors in the see of Rome. Thus, says Bower, was the power of the pope, as universal bishop and head of the church, or in other words, the papal "supremacy," first introduced. It owed its original to the worst of men; it was procured by the basest means, or by flattering a tyrant in his wickedness and tyranny; and according to the previously declared judgment of Gregory the great, it was in itself "anti-christian, heretical, blasphemous, and diabolical." Boniface afterwards assembled a council for settling the election of bishops, in which they were forbidden to nominate their own successors, and the consent of the people, clergy, and sovereign, and the confirmation of the pope, were made necessary. Boniface died in November 607.

Boniface IV., a native of Valeria, in the country of the Maris,

BONIFACE.

Mari, was elected to the papal see in August 608; and having obtained from Phocas the grant of the pantheon, converted it into a church, dedicating it to the Mother of God and the Christian Martyrs. He held a council at Rome to settle some affairs of the English church, at which Mellitus, the first bishop of London, is said, by Bede, to have attended; but the acts of this council, and some pieces ascribed to Boniface, are thought to be spurious. He died in 615, and was sainted.

Boniface V., a native of Campania, and a presbyter of the Roman church, succeeded Deusedit in December 619. In 624 he sent the pall to Justus, the successor of Mellitus in the see of Canterbury, and interested himself in the propagation of Christianity in Britain, by sending letters and presents to Edwin the king of Northumberland, and also to his queen Edelberg, sister of Eadbald king of Kent, who having assumed the Christian profession, was allowed by her marriage articles the free exercise of it. He died in October 625. Some decretal epistles, relating to matters of small importance, are ascribed to him. According to Mosheim (*Ecc. Hist.* vol. ii. p. 185), this Boniface enacted that infamous law, by which the churches became places of refuge to all who fled thither for protection; a law which procured a sort of impunity to the most enormous crimes, and gave a loose rein to the licentiousness of the most abandoned profligates.

Boniface VI., was a Roman of infamous character, and succeeded Formosus in 896. Baronius (*ad ann.* 897.) will not allow him a place among the popes. He died soon after his election.

Boniface VII., denominated "Anti-pope," was a deacon of the Roman church, of the name of Franco, and advanced to the papal chair in 975, upon the death of Benedict VI. to whose murder he is said to have contributed. Soon after his election he was constrained by an adverse party to leave Rome and to fly to Constantinople; but he carried with him the treasures of St. Peter. Gerbert styles him "of all monsters of wickedness the most wicked." Upon the death of the emperor Otho II. in 984, he returned to Rome, and occupied the see in the room of John XIV. whom he displaced, imprisoned, and put to death. Franco died in 985; and he had rendered himself so odious by his tyrannical conduct, that his corpse was treated with the utmost indignity, and dragged naked through the streets.

Boniface VIII., a native of Anagni, and a descendant of the noble family of Cajetani, was employed by popes Martin IV. and Nicholas IV. in several important legations, and succeeded pope Celestine V. whom he artfully persuaded to resign, in December 1294. The beginning of the following year he was enthroned at Rome with great solemnity and parade; in the procession from St. Peter's, where he was consecrated and crowned, to the Lateran, for the purpose of being enthroned, he was mounted on a white horse, richly caparisoned, with the crown on his head, whilst the king of Apulia held the bridle in his right hand, and the king of Hungary in the left, both on foot. His subsequent conduct corresponded to the haughty grandeur of his installation. In order to secure himself against any future trouble from Celestine, he confined him in prison at Anagni, where he died. Failing to mediate a peace between James king of Arragon, and Charles II. king of Sicily, he formed an alliance against Frederic of Arragon, whom the Sicilians had made their king, and proceeded to excommunicate him and all his adherents; but he was at length obliged to confirm him in his dominions. His next measure was that of humbling the family of Colonna, two cardinals of which had opposed his election; for this purpose, after having declared the

whole family infamous by a public decree, confiscating their estates, and excommunicating all who countenanced or protected them, he ordered a crusade to be preached against them and their friends, demolished their houses and castles, and obliged them to seek shelter in foreign countries; and he moreover punished with utter demolition the city of Præneste, for its attachment to them. To Boniface is commonly ascribed the institution of the jubilee in 1300. See **JUBILEE**. In his attempt to mediate a peace between Philip the Fair king of France, and Edward I. king of England, he was charged with partiality to the latter, so that Philip could be prevailed on merely to agree upon a truce; and his enmity against Boniface, which was smothered for some time, at length broke out into a flame. Philip, with a view of supporting the war against England, prohibited the exportation of any gold or silver from the kingdom without his permission; and Boniface, apprized that this order was levelled against the see of Rome, issued a bull, forbidding secular princes to exact, and the clergy to pay, any sums from the ecclesiastical revenues, without his approbation. The animosity between the pope and the French potentate was increased by the arrogance with which a legate from Rome delivered the pope's message, enjoining the king of France, in common with other Christian princes, to aid the king of Tartary in a war against the Saracens, and by the subsequent arrest of the legate. Boniface, much enraged, dispatched a nuncio to demand his release; and in case of refusal, threatened to declare the kingdom devolved to the holy see, to absolve his subjects from their allegiance, and to summon all the Gallican bishops to Rome. The king resented this violent proceeding, renewed the prohibition against carrying money out of the kingdom, and forbade his ecclesiastics on any pretence to visit Rome. In these hostile measures the king was supported by the states of the nation, which appealed to a general council, and Boniface prepared to fulminate a decree of excommunication and forfeiture of his crown against Philip. Nogaret and Sciarra Colonna were sent, on this occasion, into Italy to excite the persecuted Ghibellines against the pope, who was then at his palace in Anagni. They secretly approached it with a body of troops, and made themselves masters of the person of Boniface and all his treasures. During the three days of his confinement the pope was treated with great indignity, particularly by Colonna. At length the people of Anagni, recovering from their consternation, rescued the pope from his captivity: who returned to Rome, where he was seized with a fever, which terminated his life in October 1303. He was buried at St. Peter's in a grand mausoleum, which he had erected for himself. Although Boniface has been jully extolled for his learning, intrepidity, and experience in public affairs, and for his patronage of literature; he was arrogant and overbearing, ambitious, crafty, and violent, and avaricious to such a degree, that he was intent upon accumulating riches to exalt the church and aggrandize his own relations. He was the author of several works, such as epistles and decrees, two discourses on the canonization of Lewis IX. of France, called St. Lewis; two famous prayers, one to our Saviour, and the other to the Virgin. He also caused to be published the sixth book of the decretals, and wrote a treatise entitled "De regulis juris."

Boniface IX., a native of Naples, descended from a noble family in reduced circumstances, whose name was Peter Thomacelli, was more distinguished by his prudence and address than for his profound and extensive learning, and was elected pope at Rome upon the death of Urban VI. in 1389. The greatest part of his pontificate was devoted to negotiations with his rivals at Avignon, Clement VII. and Benedict XIII.

BONIFACE.

in which were displayed on both sides much cunning and artifice, and at the same time an inflexible resolution of retaining the tiara. Boniface was arbitrary in the exercise of power; and towards the end of the year 1394 he would have been massacred by the people, if he had not been seasonably rescued from the enraged multitude by the interposition of Ladislaus, king of Naples, who happened to be then at Rome. He afterwards retired to Perugia, and from thence he removed to Assisi; but on the approach of the jubilee year, 1400, the Roman people, apprehending, that in the absence of the pope it would not be celebrated with the usual solemnity, and the pecuniary interests affected, deputed an embassy to invite his holiness to Rome. Upon his arrival he was received with joy and invested with extraordinary powers, in the exercise of which he repaired and fortified the walls and towers of the city, and the castle of Angelo, and also placed garrisons in them, so that he made himself absolute master of the city. Some ascribe to Boniface the institution of Annates (See ANNATES); but though the origin of these is of more ancient date, he is allowed to have been in a very high degree avaricious and rapacious, to have sold church preferments to the best bidder, without regard to merit or learning, and to have made it his constant study to enrich his family and relations. He died of a paroxysm of the stone in 1404. Bower's Hist. of the Popes.

BONIFACE, called the "Apostle of the Germans," was a native of England, whose original name was "Winifrid," born in Devonshire, A.D. 670, and was educated in a Benedictine monastery at Exeter. This famous ecclesiastic, who was ordained a priest A.D. 700, with two companions, passed over into Friesland in 703, in order to preach the gospel among the heathens; but failing in his first attempt, on account of a war which broke out between Radbod the king of that country, and Charles Martel, he returned to England. However, he resumed his pious undertaking in 718; and at Rome he was solemnly empowered by the Roman pontiff, Gregory II. to preach the gospel not only in Friesland, but throughout Germany; which commission he executed with considerable success. In the year 723, he was consecrated bishop by Gregory II., who changed his name of Winifrid into that of Boniface; and he is said to have been the first who took a solemn oath of obedience to the pope, which he did at this time. Upon his return to Germany, with the instructions of the pope, and the peculiar protection of Charles Martel, he preached in Thuringia, Hesse, and Bavaria, and erected a great number of Christian churches. As these were too numerous to be governed by one bishop, this prelate was advanced to the dignity of archbishop, in 732, by Gregory III., under whose authority, and the auspicious protection of Carloman and Pepin, the sons of Charles Martel, he founded in Germany the bishoprics of Wurtzbourg, Buraubourg, Erfurt, and Aichstadt; to which he added, in 744, the famous monastery of Fulda. His last promotion, and the last recompence of his assiduous labours in the propagation of the truth, was his advancement to the archiepiscopal see of Mentz, A.D. 746, by pope Zachary, by whom he was at the same time created primate of Germany and Belgium. In his old age he returned again to Friesland, that he might finish his ministry in the scene of its commencement; but his piety and zeal were ill rewarded by that barbarous people, by whom he was murdered in 754, together with fifty ecclesiastics, who accompanied him, and who shared the same fate. He was interred in the abbey of Fulda, and canonized by the church of Rome, to which he was ardently devoted. His zeal for the glory and authority of the Roman pontiff equalled, if it did not surpass, his

folicitude for the service of Christ, and the propagation of his religion; and in combating the heathen superstitions, he resorted to other weapons than those which Christianity recommended, employing violence and terror, and sometimes artifice and fraud, in order to multiply the number of Christians. His epistles, and those of his coadjutors, first published with notes by Serrarius, in 1605, and re-published in 1629, are written in a barbarous style, and discover an imperious arrogant temper, a cunning and insidious turn of mind, an excessive zeal for increasing the honours and pretensions of the sacerdotal order, and a profound ignorance of many things, the knowledge of which was indispensably necessary in an apostle, and particularly of the true nature and genius of the Christian Religion. The Benedictines have published his statutes, and some of his sermons. Bower's Hist. of the Popes, vol. iii. Mosheim's Eccl. Hist. vol. ii. p. 205, &c. Cave's Hist. Lit. t. 1. p. 622. Dupin, Eccl. Hist. cent. 8.

BONIFACE, count of the Roman empire, one of the two generals of Placidia, the mother of Valentinian III., Aetius being the other (see AETIUS), who have been deservedly named as the last of the Romans; was the intimate friend of St. Augustine, bishop of Hippo, but incurred his displeasure by marrying a wife of the Arian sect, after a solemn vow of chastity, and a resolution of retiring from the world, and by some other instances of licentious conduct with which he was charged. However the people applauded his spotless integrity, and the army dreaded his impartial and inexorable justice. Of his justice, the following singular fact is recorded. A peasant, who complained of the criminal intimacy between his wife and a Gothic soldier, was directed to attend his tribunal the following day; in the evening, the count, who had diligently informed himself of the time and place of the assignation, mounted his horse, rode ten miles into the country, surprized the guilty couple, punished the soldier with instant death, and silenced the complaints of the husband by presenting him, next morning, with the head of the adulterer. Boniface, having defended Marseilles, when attacked by Ataulphus, was rewarded by the emperor Honorius with the command of the troops in Africa, which province he rescued from the repeated attempts of John, who usurped the empire. Placidia, who assumed the government of the empire during the minority of her son, highly pleased with his bravery and loyalty, called him to court upon the death of that usurper, preferred him to the post of "comes domesticorum," and sent him into Africa with unlimited power. These marks of favour excited the jealousy of Aetius (see AETIUS), who artfully contrived, under the mask of friendship, to engage Boniface in a revolt, which took place in 427. Accordingly, Placidia declared him a public enemy, and sent troops against him. Having defended himself for some time, he found at length that he was likely to be overpowered; and therefore, after some hesitation, the last struggle of prudence and loyalty, he dispatched a trusty friend to the camp of Gonderic, king of the Vandals, with the proposal of a strict alliance, and the offer of an advantageous and perpetual settlement. The Vandals accepted the proposal, and Genserich, who succeeded his brother, and whose ambition had neither bounds nor scruples, transported his troops from Spain into Africa in 429, and obtained, by the concurrence of several favourable circumstances, an easy conquest. Placidia discovered, when it was too late, the artifice that had been practised by Aetius; and Boniface, who also perceived and lamented his error, returned to his allegiance. But his efforts to recover Africa were unavailing; and he was under a necessity of abandoning the country, and of returning to Ravenna, where

where he was kindly received by Placidia, and advanced to the rank of patrician, and the dignity of master-general of the Roman armies. The haughty and perfidious soul of Aetius was exasperated by the honourable mode of his reception, and he hastened to return from Gaul to Italy, with an army of Barbarian followers, and to decide his quarrel with Boniface in a bloody battle. Boniface was successful; but in the conflict he received a wound from the spear of his adversary, of which he expired within a few days, A.D. 432. Before his death he is said to have testified his forgiveness of Aetius's treacherous conduct, to such a degree, as to exhort his wife, a rich heiress of Spain, to accept him for her second husband. *Anc. Un. Hist. vol. xiv. Gibbon's Hist. &c. vol. vi.*

BONIFACE, NATALIS, an engraver of great merit, who flourished in Italy, towards the conclusion of the 16th century. His works are chiefly etchings, performed in a slight, fine style; and his small figures he executed with great spirit. His chief work was the plates composed by D. Fontana, architect to pope Sixtus V. concerning the removal of the Vatican obelisks. *Strutt.*

BONIFACIA, in *Botany* (J. Bauhin). See *Ruscus racemosus*.

BONIFACIO, or **BONFACIO**, in *Geography*, a sea-port town of the island of Corsica, department of Liamone, and chief place of a canton, in the district of Sartene, on the south coast, and in the strait between the islands of Sardinia and Corsica. The town is small and fortified, and the canton contains 3172 inhabitants; 28 leagues south of Bastia. N. lat. 41° 24'. E. long 9° 20'.

BONIFACIO Point. See **BALDIVIA**.

BONIFACIO Strait, commences near the town of the same name, on the S. E. of the island of Corsica; and its length to point Tico, the most northerly point of Sardinia, is 2½ leagues.

BONING, in *Surveying and Levelling*, &c. is the placing of three or more rods or poles, all of the same length, in or upon the ground, in such a manner, that the tops of them all may be in one continued straight line, whether it be horizontal or inclined, so that the eye may look along the tops of them all, from one end of the line to the other.

BONJOUR, WILLIAM, in *Biography*, a learned Augustin, was born at Toulouse in 1670; and at Rome, whither he was sent for by cardinal Norris in 1695, he became distinguished by his learning and piety. He was employed by pope Clement XI. in several matters of importance, and particularly in the examination of the Gregorian calendar. Bonjour had also the superintendance of the seminary established by cardinal Barbarigo at Montefuscone, and denominated the Academy of Sacred Letters. He was acquainted with almost all the oriental tongues, and more especially with the Coptic, or ancient Egyptian. Actuated by a zeal for acquiring knowledge, and for propagating the gospel, he visited China, where he died in 1714, whilst he was employed in forming a map of that empire. His works are, "Select Dissertations on the Scriptures;" "An Account of the Coptic MSS. in the Vatican;" "A Coptic Grammar;" and "A Roman Calendar." *Moreri.*

BONIS ARRELANDIS NE DISSIPENTER. See **ARRISTANDIS**.

BONIS non amovendis, a writ directed to the sheriffs of London, &c. where a writ of error is brought, to charge them that the person against whom judgment is obtained be not suffered to remove his goods, till the error is tried and determined.

BONIS, terris, et catallis rehavendis post purgationem. See **TERRIS**.

Arresto fatto super BONIS mercatorum. See **ARRESTO**.

BONITO, in *Ichthyology*, synonymous with the French *bonite*. This appears to be a name assigned indiscriminately to more than one or two kinds of fishes, although it seems to be confined in some degree to those of the **SCOMBER** genus. The *scomber pelamis* of Loefl. is the fish mentioned under the name of *bonito* by Osbeck, who also calls it *scomber pulcher*. The *bonito* is vaguely described as a large sea-fish, with a long, broad, and thick body; eyes, and likewise the gills, large; and the greater part of the body free from scales. It is observed still further to be a fish of great beauty, and very common in some seas; our East India ships usually falling in with immense shoals of them. It is impossible to say whether this may be the *scomber pelamis*, or not; but as a matter of opinion, we think it to be the same, because the latter is found in immense shoals between the tropics, and in the Atlantic ocean. The bonito of Bloch (*le bonite de Bloch*) bears the Latin name of *scomber farda*.

BONITON, the common French name of **SCOMBER amia** of Linnaeus.

BONIZO, in *Geography*, a town of Italy, in the duchy of Mantua, on the south side of the Po, opposite to Ostiglia.

BONKOSE, in *Ichthyology*, the *Sciæna nebulosa*, a fish discovered by Forkal in the Red sea. Bonkose is the name it bears in Arabia.

BONLIEU, in *Geography*, a town of France, in the department of the Ardeche; 5 leagues N. N. W. of Tournon.

BONN, in Latin *Bonna*, a small but populous and fortified city of Germany, in the circle of the Lower Rhine, and electorate of Cologne, or, according to the French arrangement, the chief place of a district, in the department of the Rhine and Moselle; the place contains 8837, and the canton 18,951 inhabitants; and its number of communes is 31. The number of houses is said not to exceed a thousand; and as it has little foreign trade, most of the inhabitants are attracted thither by its being the residence of the elector of Cologne. The streets are narrow, crooked, dirty, and badly paved, and in winter badly lighted. The public walks are few, and not very agreeable. The churches are flatly; and the town-house is adorned with fine paintings. The Jews at Bonn have a street to themselves, consisting of 21 houses; and their number is estimated at 250. Bonn was taken from Louis XIV. into whose hands it was surrendered by the elector, in 1673, by William prince of Orange; in 1689, by the marquis of Brandenburg; in 1703, by a detachment of the duke of Marlborough's army, after a siege of three weeks, and the loss on both sides of 2000 men; and on the 6th of October, 1794, by the troops of the French republic. It is situated 14 miles S. S. E. of Cologne, 30 E. of Aix-la-Chapelle, and 28 N. N. W. of Coblenz. N. lat. 50° 40'. E. long. 7'.

BONNA, in *Zoology*, synonymous with **BONASUS**; which see.

BONNAGHT, or **BONNAGH**, an old tenn, which occurs frequently in *Irish history*, and was the same with *coin and livery*; being a certain proportion of meat, drink, and money for the maintenance of a soldier, and sometimes free quarter. Hollingshead speaks of it as an Irish imposition, which beggared the farmers; and sir John Davis, the eminent attorney-general of Ireland in the reign of James I. in his justly admired tract, entitled "A Discovery of the Causes, why Ireland was never subdued," has these words: "But the most wicked and mischievous custom of all others, was that of *coin and livery*, which consisted in taking of man's meat, horse meat, and money, of all the inhabitants of

of the country, at the will and pleasure of the soldier, who, as the phrase of the Scripture is, *did eat up the people, as it were bread*, for that he had no other entertainment. This extortion was originally Irish, for they used to lay *bonnaght* upon their people, and never gave their soldiers any other pay. But when the English had learned it, they used it with more insolence, and made it more intolerable; for this oppression was not temporary, nor limited either to place or time, but because there was every where a continual war, either offensive or defensive, and every lord of a country, and every marcher, made war and peace at his pleasure, it became universal and perpetual, and was indeed the most heavy oppression that ever was used in any Christian or Heathen kingdom." The curious reader will do well to consult the whole passage in Sir J. Davis's Historical Tracts, p. 132. et seq. of the edition printed in 8vo. Dublin, 1787. This practice was forbiddea by the statute of Kilkenny passed in 1450, and by several succeeding acts, in one of which (under Henry VII.) it is called a *damnable custom*. Spenser, in his "View of the state of Ireland," seems, however, to think the statute unnecessarily severe in making it treason. Hollingshead. Irish Statutes. Spenser's State of Ireland.

BONNART, JOHN, in *Biography*, barber surgeon, and master of the college of surgeons at Paris, published, in 1629, "La Semaine des medicamens observée, et chefs d'œuvres des maitres barbiers chirurgiens de Paris," 8vo. It contains a course of study necessary for young men previous to their being elected into the college, with observations on the method of treating such complaints as come under their care. The author strongly recommends opening the jugular vein in cases of quinley. "Methode pour bien feigner les accidens qui arrive pour etre mal fait," 8vo. 1628. Haller Bib. Med. Eloy.

BONNAT, in *Geography*, a town of France, and chief place of a canton, in the department of the Creuse, and district of Gueret; the place contains 2032, and the canton 10,804 inhabitants; the territory comprehends 257½ kilometres, and 12 communes.

BONNAUD, in *Biography*, published, in 1770, "Degradation de l'espece humaine par l'usage des corps de baleine," 12mo. Paris. In this very sensible and ingenious little work, the author forcibly represents the various evils consequent on using staves stiffened with whale-bone: these are indigestion, and other disorders of the stomach, ruptures, and difficult respiration, often terminating in consumptions; besides, they not unfrequently occasion deformity of the body, which they are supposed by their admirers to contribute in preventing. Haller Bib. Med.

BONNAY, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Besançon, 2 leagues N. of Besançon.

BONNE, a town of Savoy, in the Lower Faucigny, 10 miles E. S. E. of Geneva. N. lat. 46° 11'. E. long. 6° 7'.

BONNE, a bay on the west coast of Newfoundland. N. lat. 49° 35'. W. long. 53°.—Also, a bay on the coast of Spain in the Mediterranean, nearly east from Malaga. N. lat. 36° 42'. W. long. 2° 40'.

BONNEBOSQ, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Pont l'Evêque, 2 leagues S. W. of Pont l'Evêque.

BONNEFONS, JOHN, or BONNEFONIUS, in *Biography*, was born, in 1554, at Clermont in Auvergne, became an advocate in Paris, and, in 1584, lieutenant-general at Bar-sur-Seine, and died in 1614. He was distinguished as a Latin poet, and particularly by that kind of poetry, which

is the short verse of Catullus, abounding with diminutives and tender expressions. Of this kind is the piece entitled "Pancharis," which is reckoned the most elegant performance of any modern writer. It seems to have been the aim of Bonnefonius to imitate Joannes Secundus, the celebrated author of the *Basia*; and his resemblance, with regard to softness and sweetness, has approached the extreme of lasciviousness and effeminacy. His poems in heroic verse have also been esteemed. The *Pancharis* was published at Paris in 1588, and translated into French by La Bergerie; and all the poems of Bonnefonius are printed after those of Beza, in Barbon's edition of the latter, Paris, 1757. There are London editions in 1720 and 1727. A son of Bonnefonius distinguished himself by Latin poetry, chiefly written on public characters and events. *Nouv. Dict. Hist.*

BONNER, EDMUND, an English prelate of detestable memory as a persecutor of Protestants, was born, as it is generally believed, of poor parents at Hanley, in Worcestershire; but some have affirmed that he was the natural son of George Savage, rector of Davenham, in Cheshire. About the year 1512, he was admitted a student of Broadgate hall (now Pembroke college) in the university of Oxford, famous at that time for the education of civilians and canonists. In 1519, he took his degrees of bachelor of the canon, and bachelor of the civil law; and about the same time entered into holy orders. In 1525, he was created doctor of the canon law. More distinguished by his talents for business than for his learning, he was appointed commissary of the faculties by cardinal Wolsey, who conferred upon him a plurality of ecclesiastical benefices. After the cardinal's death, he contrived to insinuate himself into the favour of king Henry VIII., and became a zealous promoter of the reformation, as well as an advocate for the king's divorce from queen Catharine, and a strenuous supporter of the measures that were adopted for abolishing the pope's supremacy in this kingdom. He was also patronized by Cromwell, secretary of state, and employed as ambassador at several courts. In 1532, he was deputed on an embassy to Rome, to excuse the king's appearance to a citation at that court; and in 1533, he was sent to pope Clement VII. then at Marfeilles, to deliver the king's appeal from the pope to the next general council against his excommunication; and on this occasion he exposed himself by his boldness and indecent warmth to personal danger. He was likewise employed in other embassies to the kings of Denmark and France, and to the emperor of Germany. Being recalled from France in 1538, on account of the boldness with which he remonstrated against the protection afforded to an English traitor, he was nominated to the bishopric of Hereford, and, before his consecration, translated to the see of London in 1539. At the time of the king's death in 1547, he was ambassador at the court of Charles V. Till this time he appears to have concurred in promoting the reformation; and by the subserviency of his principles to his interest, as well as by his capacity for public business, he secured the favour and confidence of his tyrannical master. But from his subsequent conduct it is evident that he was secretly attached to the Romish religion; for soon after the accession of Edward VI., he scrupled to take the oath that was required for renouncing the pope's authority, and he protested against the king's injunctions and homilies, which, however, he had never read. But being committed to prison for disobedience, he afterwards recanted, and was released. Whilst he outwardly professed zeal for the reformation, he privately used all the means in his power for obstructing its progress and establishment. His conduct warranted the suspicions that were entertained of his sincerity; and in order to bring it to a test, he

he was ordered by the privy council to preach at St. Paul's cross on certain articles, connected with the principles of the reformation, and given to him in writing. But he performed this service in a manner so unsatisfactory, that, upon the complaints of Hooper and Latimer, commissioners were appointed to proceed summarily against him; the result of which was, that he was committed to prison, and deprived of his bishopric. These proceedings, allowed even by his enemies to be arbitrary and severe, roused his resentment; nor was he long obliged to wait for an opportunity of ample retaliation. Upon the accession of Mary to the throne, he was restored to his bishopric, by a commission dated August 1553; and in the convocation of the following year, he was appointed president in the room of Cranmer, who was committed to the tower. In this year he visited his diocese, and industriously rooted up all the seeds of the reformation. In the four succeeding years he was an active and savage persecutor; and he is said to have committed to the flames 200 persons, who avowed their firm adherence to the protestant religion, and who refused to embrace the gross errors of popery, besides imprisoning and torturing many more. Bonner's disposition was in the highest degree cruel and ferocious; and religious bigotry, grafted on a temper naturally savage, rendered him a fit instrument to be employed by the artful Gardiner in the condemnation and execution of heretics. But though his nature did not seem to recoil at this savage employment, he dreaded the increased odium that attended it, and refused any longer to be the executioner of the laws. However, in 1556, he concurred in the degradation of Cranmer, and enjoyed the malignant pleasure of triumphing over him with his usual insolence. In the following year his name was inserted in a kind of inquisitorial commission for searching after, and punishing all heretics, as all persons who were of the protestant religion were then denominated. Upon the accession of Elizabeth, he had the effrontery to accompany the other bishops in their progress for meeting her at Highgate; but she looked upon him with feelings of just indignation and horror, as a man polluted with blood. He remained for some months unmolested; but in May 1559, he was summoned before the privy council; and refusing to take the oaths of allegiance and supremacy that were tendered to him, he was deprived of his bishopric, and committed to prison. In this state of confinement he remained for some years, bearing his reverse of condition with a degree of cheerfulness which might have become a better man, and occasionally warding off, by keen and humorous repartees, the popular insults that were offered him. He died in prison, September 5, 1569; and was buried at midnight in St. George's church-yard, Southwark, lest any indignities should be offered to his remains by the incensed populace. Bonner was singularly savage in his natural temper, blustering and prophane in his conversation and manners, furious and violent in his conduct, gross and corpulent in his person, and in every respect fitted for the part he acted, as an unrelenting and brutal persecutor. He was generally regarded as a devotee of any fixed principles; and he has been charged even with Atheism. As a canonist and politician he was allowed to excel; but his knowledge of divinity was very imperfect, and he had no reputation for learning. However, several pieces, theological, controversial, and pastoral, were published under his name. By his interest with queen Mary, he obtained several advantages for the see of London, which his successors have enjoyed. *Biog. Brit.*

BONNET, CHARLES, an eminent natural philosopher, was born at Geneva in 1720, and educated under a domestic tutor, whom his father provided for him, as affording super-

rior advantages to those which he enjoyed in any of the public schools. At the early age of 16, he discovered that peculiar inclination of his mind, which led him to those studies that laid the foundation of his future fame and excellence. From the perusal of the *Speçtaele de la Nature*, he was induced to direct his particular attention to the structure and manners of the ant-lion, and added many curious observations relating to it, to the facts that had been previously collected by Mess. Poupard and Reaumur; and he was further led by the *Memoirs on Insects*, published by the latter, to repeat many of his experiments, and to discover new facts, which indicated in a youth of 18 a degree of sagacity and research that surprised and gratified this eminent naturalist, by whom he was encouraged to proceed. The interesting observations which he made on different species of caterpillars, and other insects, in the years 1738 and 1739, were communicated by him to Reaumur. His father had destined him to the profession of the law; but the study of natural history was his chosen and favourite employment. Having, in 1740, decided a question that had been left unsettled by Reaumur, respecting the multiplication of tree-lice, or aphides, without actual conjunction, he communicated a paper on this subject to the Academy of Sciences at Paris, and in consequence of it, had the honour of becoming a correspondent of that illustrious body. His eyesight was irreparably injured by the minuteness of his researches on the generation of these animals. In 1741, he found that many species of worms possess, in a degree, the reproductive power of the polype; and in 1742, he discovered that the respiration of caterpillars and butterflies, was effected by means of their pores called "Stigmata." The tænia, or tape-worm, was also a subject of his successful investigation. In 1743, he was advanced to the rank of doctor of laws, and on this occasion he totally abandoned the profession of the law. A paper on insects, which was this year communicated to the Royal Society of London, obtained for him the honour of being elected a member. His observations on aphides and worms, under the title of "*Insectology*," were published in 1744; and this work was introduced with a preface, in which he gave a brief sketch of his ideas concerning the developement of germs, and the scale of organized beings. This work was very favourably received by the public; but such had been the nature of his researches and the assiduity of his application, that his eyes and his health failed him; and he was reduced to the distressing necessity of laying aside his microscope, and of desisting from reading and writing. This self-denial, peculiarly afflictive to his ardent mind, he bore, however, with philosophical resignation; and by a total intermission of his studies he had the satisfaction of regaining a considerable degree of health and ease, though he was never able to employ his eyes as he had been accustomed to do. In 1746, he commenced a course of experiments on the vegetation of plants in moss and other singular substances; and in the following year he examined with minute attention the leaves of plants, with a view of ascertaining the appropriate action of their upper and under surfaces. He also employed coloured injections for the purpose of determining whether the sap ascends by the bark or wood; and he made various observations on vegetable monsters, and other circumstances of vegetation, which were communicated to the public in one of the most curious and original of his works, entitled, "*Inquiries into the use of the leaves of plants*," first published at Leyden, in 1754, 4to.; to which supplements have been added as late as the year 1779.

Bonnet, probably constrained to remit his attention to experiments by the circumstances already mentioned, directed

his speculative researches to the faculties of the human mind; and having collected a mass of materials on this subject, he published a kind of abridgment of them, under the title of an "Essay on Physiology," in 1755, at London. This work, which appeared without his name, and which he did not acknowledge for 30 years, contains a concise statement of the fundamental principles of his philosophy. "It traces the origin and progress of the human mind, from the first germ of life, to the development of all its faculties, the mutual dependence of which it points out, as deduced from actual observation. It enters into the difficult subject of human liberty, and endeavours to reconcile it with the divine prescience, and with the philosophical principle, that every effect must have an adequate cause. From the essential properties of the activity of the soul, and the effects of habit upon it, the whole art of education and government is deduced; and a system of the former is laid down, materially different from the usually established methods." Our author's metaphysical ideas were evidently founded on the principles of Malebranche and Leibnitz; but as he had freely discussed some points of a delicate nature, and which were likely to involve him in personal controversy, he chose to conceal his name. His next work, the fruit of five years' labour, was an "Analytical Essay on the faculties of the Soul," first printed at Copenhagen in 1760, 4to. at the expense of the king of Denmark. In this work he assumes the hypothesis of a statue organized like the human body, which he animates by degrees, and shews how its ideas would arise from impressions on the organs of sense. Although this performance was well received by some philosophers, it soon subjected the author to the charge of materialism and fatalism; but to this charge he made no reply. Accustomed to retirement, to which mode of life he was obliged to recur, on account of his deafness and other bodily infirmities, he sought the comforts of a domestic life; and in 1759, he married a lady of respectable family, the aunt of the celebrated Sauffure, with whom he passed 37 years of connubial felicity. In the prosecution of his physical system, Bonnet published at Amsterdam in 1762, his "Considerations on organized bodies," 2 vols. 8vo. The principal objects of this work were, to detail, in an abridged form, all the most interesting and well ascertained facts, respecting the origin, development, and reproduction of organized bodies; to refute the different systems founded upon "epigenesis;" and to explain and defend the system of germs. His "Contemplation of Nature," which appeared in 1764, Amst. 2 vols. 8vo., was a popular work, displaying the principal facts relating to the different orders of created beings, in an instructive and entertaining manner, and recommended by the charms of an eloquent style, with a constant reference to final causes, and the proofs of wisdom and benevolence in the creator. This was translated into several European languages, and enriched with notes by the author himself, and also by others, in a new edition. His concluding work was his "Palinogénie Philosophique," printed at Geneva in 1769, 2 vols. 8vo. This treats on the past and future state of living beings, and supports the idea of the revival of all animals, and the perfecting of their faculties in a future state. To this work he annexed "An inquiry into the evidences of the Christian revelation, and the doctrines of Christianity, which, with a piece "On the existence of God," was published separately at Geneva in 1770.

Towards the year 1773 he resumed his attention to natural history, and published, in Rozier's journal, a memoir on the method of preserving insects and fish in cabinets. In the following year he sent to the same journal a memoir on

the loves of plants, originating in the discovery of a kind of cleft or mouth in the pupil of a lily. Other memoirs contained a detail of his experiments on the reproduction of the heads of snails, and of the limbs and organs of the water salamander. He also made observations on the pipa or Surinam toad, on bees, on the blue colour acquired by mushrooms from exposure to the air, and on various other subjects in natural history. His reputation introduced him as an associate into most of the literary societies of Europe; and in 1783 he was elected into the select number of foreign associates of the academy of sciences in Paris. His correspondence was extensive, and his attention to public duties exemplary. In the great council of the republic into which he entered in 1752, and in which he had a seat till 1768, he distinguished himself by his manly eloquence in the support of wise and moderate measures, and his constant zeal in the cause of morals and religion, with which, in his opinion, the prosperity of the state was essentially connected. The last 25 years of his life were spent altogether in the country, where he enjoyed, with a competence, the intercourse of chosen friends. Some part of his time was employed in the education of youth, for which office he was admirably qualified. The revival of his works occupied near eight years of his life, and required a degree of application which was injurious to his health. This collection appeared at Neuchâtel, in 9 vols. 4to. or 18 vols. 8vo. and contains, besides the works already mentioned, several smaller pieces in natural history and metaphysics. They are all written in French. Towards the year 1788 he manifested alarming symptoms of a dropsy in the breast; and these became more aggravated in process of time, and occasioned a variety of sufferings which he endured with patience and serenity, till at length he was released by death, May 20, 1793, at the age of 73 years. Public honours were rendered to his remains by his fellow citizens: and his funeral eulogy was pronounced by his illustrious friend and kinsman, M. de Sauffure. *Mem. pour servir à l'Hist. de la Vie et des ouvrages de M. Charles Bonnet; Berne 1794. Gen. Biog.*

BONNET, JACQUES, published, in 1726, at Amsterdam, "Histoire de la musique," the history of music and of its effects, from its origin to the present time, explaining, in what its beauty consists, 4 vols. 12mo. This history was at first undertaken by the abbé Bourdelot, uncle to the editor of this work, and distinguished by his erudition. Bonnet, Bourdelot, brother of Bonnet, the first physician to the dukes of Burgundy, continued it after the death of his uncle, and at length arranged and digested the materials which he found among the MS. papers of his uncle and his brother. Indeed the first volume only was written by Bonnet; the three last were compiled in a patriotic fury by Frensch, a physician, in 1705; who died in 1707, in the flower of his age, having only arrived at his 33d year. He seems to have been wholly stimulated to this undertaking by the abbé Ragenet's parallel between the music of the Italians and the French, which, though written with the utmost circumspection and civility to France, M. Frensch thought too favourable to Italy; and instead of a continuation of the history of music, has given us nothing but a violent philippic against the abbé Ragenet, for daring to draw a parallel between the music of France and Italy, and a censure of all the most illustrious Italians of the 17th century, such as Carissimi, Luigi Rossi, Scarlatti, and Corelli; and setting up Lulli against them all, has formed his refutation of the abbé into three dialogues; in which two of the interlocutors are champions for Lulli, and only one, and that a lady, neither a deep logician, nor a powerful advocate for the Italians, is the heroine that undertakes their defence. But the poor Italians have no quarter

far given them; not only their music and fingering, but even their language is censured for its elisions, its metaphors, its similes, construction, and inverted phrases.

The execution of the Italians he compares to the dexterity of the soldier who was brought to Alexander, to exhibit a trick which he had acquired by infinite pains and practice, of chucking a pea into a distant hole which just fitted it. When all the reward which the great conqueror bestowed upon the soldier for his useless application of time was, to order him a peck of peas.

Indeed all the praise that is due to Bonnet for the first part of what he calls a history of music, is, the having collected materials towards a history of the art; but he was no musician, and equally unable to explain the theory of the ancients as the practice of the moderns; so that his work is totally devoid of taste, order, and useful information.

BONNET, or BONET. THEOPHILUS, an eminent and respectable practising physician, and voluminous writer in medicine, of Geneva, where he was born, March 5th, 1620. Following in the steps of his father and grandfather, he early attached himself to the practice of physic. After visiting several foreign academies, he was admitted doctor in medicine at Bologna, in 1643, and was soon after made physician to the duke de Longueville. Though he soon attained to high credit in his profession, and had a large share of practice, he dedicated a considerable portion of his time to reading, and to dissecting such subjects as the hospital afforded him, with a view of discovering the seats of the diseases, under which the patient had laboured; mistaking every deviation he observed from the natural structure of the viscera, or other parts of the body, and thus opening a new road for improving the science he cultivated. He also appears to have made extracts of every thing he deemed worthy of notice, from the various works he read. His hearing from some accident becoming defective, he withdrew from practice, and employed the last ten or twelve years of his life in arranging the materials he had collected. The first fruit of his labour, which he gave to the public, in 1668, was "Pharos medicorum," 2 vols. 12mo. This was printed again, much improved and enlarged, in 1679, in 4to. under the title of "Labyrinthi medici, extricati," &c. compiled principally from Bellonius and Septalius. In 1675, "Prothromus anatomice practicae, five de abditis morborum causis," fol.; the precursor of his principal work, "Sepulchretum, seu anatomie practicae, ex cadaveribus morbo denatis proponens historias et observationes," &c. 2 vols. fol. Gen. 1679, which far exceeded the expectation raised by the prodromus. It was enlarged by nearly a third part, and republished by Manget, 2 vols. fol. 1700, and was afterwards taken by Morgagni, as the basis of his work, "De sedibus, et causis morborum," by which the sepulchretum is in a great measure superseded. The author begins with observations on the appearances of the brain and other parts of the head; then of the contents of the thorax, abdomen, and pelvis; and lastly, of the extremities; forming an immense body of dissections, which he has illustrated by many pertinent and ingenious observations. "Cours de médecine, et de la chirurgie," 2 vols. 4to. 1679. An epitome of the art of surgery, with some sections relating to the practice of medicine, selected from the most accredited authors of the age. "Medicina septentrionalis, collectitia," 2 vols. fol. 1684. Shewing how largely the practitioners of the northern parts of Europe, Sweden, Denmark, Germany, Holland, and England, have contributed to the improvement of anatomy, surgery, and medicine, by extracts and accounts of the works of the principal writers of those countries. "Mercurius compilatitius, seu index medico-practicus, decisiones,

cautiones, observationes in singulis affectibus, &c. ostende istam medendi viam," fol. 1682. A most useful work, shewing under the name of every disease or affection where cases or observations may be found, and what authors have written upon them. Such an index continued to the present time, though very voluminous, would be highly useful. Bonnet also published "Epitome operum Sennerti," fol. 1685, and "J. D. Turqueti de Mayerne, de Arthritide," 1671, 12mo. and "Robaulti tractatus physicus, e Gallico in Latinam versus," 1675, 8vo. He died of a dropsy, March 3, 1689. Hall. Bib. Med.

BONNET, in a general sense. See CAP, HAT, MITRE, &c.

BONNET, in *Fortification*, a kind of little ravelin, without a ditch, having a parapet three feet high; anciently placed before the points of the salient angles of the *glacis*; being palisadoed round; of late also used before the angles of bastions, and the points of ravelins, and faussebrayes. See *Plate Fortif.*

The bonnet has two faces, from ten to fifteen, or more rods long: the parapet is made of earth, from thirty to thirty-six feet thick, and from nine to twelve feet high; it is environed with a double row of palisades ten or twelve paces distant from each other; hath a parapet three feet high, and is like a little advanced *corps du guard*.

BONNET à prêtre, or *priest's cap*, is an outwork, having at the head three salient angles, and two inwards.

It differs from the *double tenaille* only in this, that its sides, instead of being parallel, grow narrower, or closer at the gorge, and open wider at the front; on which account it is also denominated *queue d'aronde*, or swallow's tail.

BONNET, in *Geography*, a river of the county of Leitrim, in Ireland, which passes within four miles of Lough Clean, from which the Shannon issues, and carries boats into Lough Gilly, and thence into Sligo bay. Dr. Beaufort observes, that the day may come, when the spirit of enterprise and commerce will open itself a passage by this channel also. Beaufort.

BONNET, *St.* a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap, 2½ leagues N. of Gap. The place contains 1508, and the canton 10,284 inhabitants; the territory comprehends 245 kilometres, and 20 communes.

BONNET le Chateau, *St.* a town of France, in the department of the Loire, and chief place of a canton, in the district of Montbrison, 4 leagues S. of Montbrison. The town contains 1506, and the canton 12,945 inhabitants. The extent of the territory includes 192½ kilometres, and 10 communes.

BONNET le Castel, *St.* a town of France, in the department of the Pay de Dôme; 5 leagues N. E. of Brioude.

BONNET de Bruyères, *St.* a town of France, in the department of the Rhone and Loire, and chief place of a canton, in the district of Villefranche, 6 leagues N. of Villefranche.

BONNET de Chavagne, *St.* a town of France, in the department of the Isere, and chief place of a canton, in the district of St. Marcellin, 1½ league S. W. of St. Marcellin.

BONNET de Joux, *St.* a town of France, in the department of the Saône and Loire, and chief place of a canton, in the district of Charolles, 2½ leagues N. E. of Charolles. The town contains 1321, and the canton 6140 inhabitants; the territory comprehends 160 kilometres, and 7 communes.

BONNET, in *Heraldry*, a cap of velvet worn within a coronet.

BONNET pepper, in *Botany*. See CAPSICUM ANNUUM.
BONNET, in *Sea-Language*, an additional part of a sail.

fixed at the bottom or foot of the fore-sail, try-sail, and storm main-sails, of some vessels with one mast, in moderate winds. It is made like the foot of the sail for which it is intended, and has latches in the upper part, to correspond with and fall through holes in the foot of the sail, by which it is fastened.

The words in reference to it are, *lace on the bonnet*, that is, fasten it to the course; *shake off the bonnet*, that is, take it off the course.

BONNET *chinois*, in *Conchology*, is the common or trivial name applied by French collectors to the *PATELLA CHINENSIS*, in the same manner as we should call it in English the *Chinese bennet*, or limpet shell; thus also the French *Bonnet de Pologne*, for the *Limæan Buccinum testiculus*, &c.

BONNET *chinois*, in *Zoology*, the French name of *SIMIA SINICA*, Gmel. or Chinese ape of Pennant's synopsis, a species that inhabits the country of Bengal. See *SINICA*. Obs! The same animal is called *Gucnon couronnee*, by late French writers.

BONNETABLE, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Mamers. The place contains 4587, and the canton 11051 inhabitants; the territory comprehends 105 kilometres, and 10 communes.

BONNETELLA, in *Entomology*, an European species of *TINEA*, described by Linnæus, in *Fn. Succ.* Fabricius and others. The wings are white, with two little silvery lines, the posterior one of which is waved.

BONNETIA, in *Botany*, (in honour of Charles Bonnet of Geneva,) Schreb. 915. Willden 1050. *Mahuria Aublet* 222. Juss. 434. *Encyc. method.* Class and order, *Polyandria Monogynia*. Nat. Ord. uncertain. Juss. *Gen. Char. Cal.* of one leaf deeply divided into five ovate, acute, concave segments, two larger than the others. *Cor.* petals five, ovate, somewhat obtuse, concave, longer than the calyx, the three superior smaller, upright; two lower larger, inclined, at a distance from each other. *Stam.* filaments very numerous, inserted into the receptacle, shorter than the coroll, dilated at the top. Anthers yellow, oblong, tetragonal. *Pist.* germ superior small, oblong. Style incurved. Stigma hollow, three-lobed. *Pericarp.* capsule dry, membranous, oblong, three-celled, three-valved, valves sharp pointed. *Seeds* many, small, black, oblong, involved in a coloured membrane, affixed to the three-sided receptacle.

Ess. Char. Cal. five-parted, two parts larger. *Cor.* five-parted, three smaller upright, two larger inclining. *Caps.* oblong, three-celled, three-valved, many-seeded.

Species. B. palustris. Lamark. *Illust. tab.* 464. A tree fifteen feet high, seven or eight inches in diameter; branches upright, chiefly towards the top of the trunk; leaves alternate, petioled, ovate, entire, smooth; petioles channelled, with two small stipules at their base; flowers purple, spiked, one, two, or three together, furnished with three icaly bractes, one larger at the base of the peduncle, the two others lateral. A native of Cayenne and Guiana.

BONNEVAL, CLAUDE-ALEXANDER, *Count of*, in *Biography*, a descendant of an ancient family of Limousin, was born in 1672, and having entered betimes into the army, served with distinction in Italy under Catinat and Vendome. Abandoning his country in 1706, and entering into the service of the emperor, a sentence was procured against him by the minister Chamillart, which subjected him to decapitation. Notwithstanding this proscription, he ventured to Paris, and publicly married a lady of the family of Biron. In 1716 he served against the Turks under prince Eugene, and was a major at the battle of Peter-Waradin, where he behaved with singular valour; but in 1720 he had a dis-

pute with prince Eugene, and challenged him, for which offence he was deprived of his employment, and condemned to a year's imprisonment. Upon regaining his liberty he meditated revenge, went over into Turkey, became a musk-man, and was created a bashaw of three tails, general of artillery, and at last master of the ordnance. In this situation he introduced European improvements among the Turks, and lived much esteemed to the age of 75 years. He left a son, who succeeded him in the office. He was a man of quick parts, courage, and ability; but singular in his conduct, quarrelsome in his disposition, and addicted to satire. Upon changing his religion, he said, "It was only changing his night-cap for a turban." With all his eccentricities he preserved a calm temper; and said, "In all my persecutions I never lost my appetite or good humour. Happy those who have philosophy in their blood!" His "True Memoirs," and his "New Romantic Memoirs," were published in London, in 1755. *Nouv. Dict. Hist.*

BONNEVAL, in *Geography*, a town of France, in the department of the Eure and Loire, and chief place of a canton, in the district of Chateaudun, seated on the Loire. The place contains 1551, and the canton 10,638 inhabitants; the territory comprehends 337½ kilometres, and 27 communes.

BONNEVILLE, a town of Savoy, the chief place of a district in the department of Lemau, and before the French revolution, the capital of Faucigny, seated on the banks of the Arve, at the bottom of a chain of rocks, which from this place diminish into hills. The adjacent country is a rich plain, producing plenty of wine and corn, but neither populous nor well cultivated. The place contains 990, and the canton 9286 inhabitants; the territory comprehends 165 kilometres, and 15 communes. N. lat. 46° 11' E. long. 6° 15'.

BONNEVILLE-des-Bouchoux. See **BOUCHOUX**.

BONNIE RES, a town of France, in the department of the Seine and Oise, and chief place of a canton in the district of Mantua; the place contains 769, and the canton 11,984 inhabitants; the territory comprehends 207½ kilometres and 27 communes.

BONNY, a town of France, in the department of the Loiret, and chief place of a canton in the district of Gien; containing about 1300 inhabitants; 3 leagues S.S.E. of Gien.

BONNY, a river of North Africa, which forms the æstuary of New Calabar, in the kingdom of Benin, discharging itself into the bay of Biafra. N. lat. 4° 40'. E. long. 6° 30'.

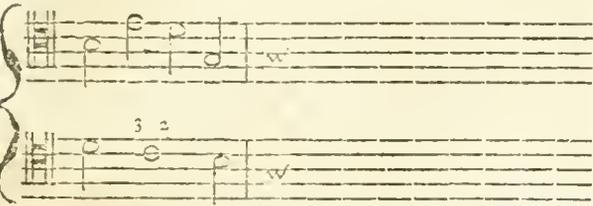

BONNY, in *Mineralogy*, a name given by our miners to a bed of ore found in many places in hills, not forming a vein, nor communicating with any other vein, nor terminating in strings, as the true veins do; it is a bed of ore of five or six fathoms deep, and two, or somewhat less than that, in thickness, in the larger sort; but there are smaller, to those of a foot long. They have their trains of float-stones from them, and often deceive the miners from the expectation of a rich lead vein. They differ from the squatts only in being round beds of ore, whereas those are flat. *Phil. Trans.* N° 69. p. 2098.

BONO *et malo*, *Writ, de*, in *Law*, a special writ of gaol-delivery was anciently used for each particular prisoner under this title: but these being found inconvenient and oppressive, a general commission for all the prisoners has long been established in their stead. 2 *Inft.* 43.

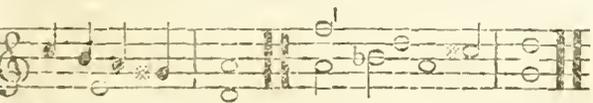

BONONCINI, GIO. MARIA, in *Biography*, Modanese Accademico Filarmonico di Bologna, and father of the celebrated John and Anthony Bononcini, published in 1673, a

BONONCINI.

work entitled "Il Musico Pratico," or the Practical Musician, dedicated to the emperor Leopold, in thin quarto. This treatise contains many useful precepts and examples of composition; but is neither so accurate as to be implicitly followed, nor so ample as to supply all the wants of a musical student of the present times. Page 18, he speaks of a canon, in his opera terza, for fifteen hundred and ninety-two voices, or six hundred and forty-eight choirs; which, on account of the difficulty of finding such a number of singers, assembled together, he has reduced to twenty-two. In the historical part of this tract, his knowledge is not very profound, or reading extensive; and the authors he cites, in support of his information, give it no additional weight. The examples he has given of the use of the second, page 64, are, in many instances, erroneous, and such as can be found in the works of no good contrapuntist of the last century. The second is not only confounded with the ninth by this author, page 64, but improperly prepared and resolved.

This discord of the second seems to require one of the parts to remain stationary, till the suspended harmony is completed; but Bononcini often puts both parts in motion. In his example of counterpoint upon a plain song, page 76, there are other disallowances.

Much explanation and instruction are given for the ecclesiastical modes, but none of the keys, used in secular music, are defined or ascertained.

BONONCINI, JOHN, the celebrated opera composer and rival of Handel, was the son of Gio. Maria Bononcini, of Bologna, the subject of the preceding article. He first arrived in England in 1720, on the establishment of our famous "Corporation of the Royal Academy of Music," under the auspices of king George I. and the principal nobility and gentry in the kingdom; for the support of which 50,000*l.* were subscribed. We have now before us the original deed and covenant, with the seal and sign manual of all the subscribers, who became academicians, and bound themselves and their respective executors, administrators and assigns, to pay all such respective sum or sums as shall from time to time be demanded out of their subscription, &c. The king subscribed 1000*l.* and the rest, to the number of 73, in this original list, 200*l.* each.

It is a curious record to be in possession of the autography of such a number of the heads of our most ancient and illustrious families thus preserved. It is not, indeed, equally

important or honourable with the list of the barons who signed the Magna Charta; but it is such a memorial of our prosperity, good-humour, patronage of a polite art, and happiness, that we would give a fac-simile of each signature on a copper-plate, if we had room.

In order to render this academy as complete as possible, it was determined by the directors not only to engage a lyric poet in their service, but the best vocal performers that could be found in the several parts of Europe where there was a musical theatre, and the three most eminent composers then living who could be prevailed upon to visit this country. For this purpose Bononcini was invited from Rome, as he tells us himself, in the dedication of his Cantatas and Duets to George I. (*Qui mi trovo, eliamata da Roma per servizio della real Accademia di Musica*). Attilio Ariosti, from Berlin, was likewise engaged as a composer on this occasion; and Handel, who resided at this time with the duke of Chandos, at Cannons, was not only included in the triumvirate, but commissioned to engage the singers.

During the first year of this establishment, these three composers furnished new operas alternately, till January 1721, when, for dispatch, an act of the opera of Muzio Scavola was assigned to each of these masters; the first act to Attilio, probably from seniority, as he was far from young when he came hither; the second act to Bononcini, at that time about 50; and the third to Handel, the youngest of the three.

As this division of the drama seemed to imply a contention and trial of skill, the public took sides, perhaps less from feeling than the spirit of party; for party whets our appetites for pleasure as well as politics. Many of the nobility and gentry, who had been in Italy, and had witnessed the applause which Bononcini had received there as a composer, were partial to him here. While others who had visited the court of Hanover before the decease of queen Anne, and knew the favour in which Handel had stood with the elector, as a great performer on the organ and harpsichord, before his compositions were much known, and afterwards had heard his productions performed in London, were unwilling to be pleased with the compositions of his principal rival. Attilio, though a good musician, seems to have been out of the question; neither his same nor talents being equally splendid with those of the other two, by whom, and for whom, the conflict continued with as great a rage as between the houses of York and Lancaster, till the year 1727; when Bononcini, after the run of the last and best opera which he had composed in England, "*Astyanax*," quitted the contest with Handel, and ceased to write for the stage. But the feuds among the friends of these great musicians, which Swift's epigram had rendered so risible, did not end here, but continued as long as Bononcini remained in this country.

Here, as his biographer, it seems our duty to give his real character as a composer. He was seldom heard on the violoncello in this country, though as a performer on that instrument he was extremely admired in Italy; and his melody was, perhaps, more polished and vocal, though not so new as that of his powerful Saxon rival. Having been born and nursed in Italy, where singing was so highly cultivated, he was reported by all his countrymen to sing in a most exquisite taste. His recitative too, both in writing and utterance, was universally allowed to be the best of the time, and in the true genius of the Italian language; but as a correct, powerful, and inventive composer, he was an infant compared with Handel.

Of all the works which this celebrated composer published in England, his book of "*Cantate e Duetti*," dedicated to

BONONCINI.

his majesty George I. in 1721, the year after his arrival here, seems the best. In 1722, his "Divertimenti da Camera, tradotti (translated or accommodated) pel Cembalo, da quelli composti pel Violino e Flauto," were published by himself, and sold at his lodgings in Suffolk-street. In these we meet with pleasing and masterly passages, but they are inferior in force, contrivance, and invention, to the lessons of Handel, that even his admirers, on a comparative view, must have regarded them as frivolous and trivial. The *adagios* are the best movements in them, and have notes of taste and passages of expression, which must have been then new to English ears. Bononcini, however, like other composers of his time, is very sparing of his passages, and indulges idleness and want of invention by frequent *rosalias*, or repetitions, which Handel seems always to avoid more than any composer of this period, except the Scarlattis, father and son. In several of these lessons the subject is heard in one part or other throughout a whole movement; as in the minuet, page 35, the first bar is perpetual.

His funeral anthem for the duke of Marlborough was set and performed the same year, 1722. The short symphony, and whole first movement are grand, and of a melancholy cast. The second movement has not much to recommend it. The third is more languid, than passionate or pathetic. The fourth is plaintive, but was not new at the time it was written. The fifth and last movement has musical merit, but none of true feeling, or genius; no "heart-rending sighs," or such exclamations of sorrow and affliction as would naturally be expected from a man of great abilities, who either felt the words or the loss of his patron.

Bononcini was a celebrated and voluminous composer long before he arrived in England: his eighth work, consisting of "Duetti da Camera," was dedicated to the emperor Leopold, and published at Bologna in 1691. The seven operas he composed during his residence in England, make but a small part of his dramatic productions. He produced two operas at Rome in 1694; after this he went to Vienna, where he composed many operas and oratorios for the imperial court and chapel. In 1720, he was again in high reputation as a dramatic composer at Rome, whence he was invited to London by the directors of the Royal Academy of Music. In 1732, he published "Twelve Sonatas for two Violins and a Bass." It was about this time that he was accused of arrogating to himself a madrigal composed by Lotti of Venice, and published in that city in 1705, in a work entitled "Duetti, Terzetti, e Madrigali a più Voci," dedicated to the emperor Joseph. The title of the madrigal is "La vita caduca," and has for initial line "In una siepe ombrosa." We are in possession of the book in which this composition was printed, and, upon examination, are extremely astonished that Bononcini would risk the great reputation of which he was already in possession, for a production which could increase it so little. The counterpoint of this madrigal is certainly correct, but it is dry, and all the subjects of fugue are such as had been used by thousands before Lotti was born. There are many madrigals by much older masters, particularly Luca Marenzio, Stradella, and the elder Scarlatti, that are learned and pleasing in modulation, and more fanciful and agreeable in the traits of melody that are used as subjects of imitation. Indeed, Bononcini's plagiarism was as weak as wicked. We need not doubt the truth of the charge, from an idea that his reputation was so well established, and his genius so fertile, that he had not the least occasion to have recourse to such illicit means of extending it. The crime of theft is very much aggravated, when the thief is not impelled to it by want. Rich men and misers have, however, been often detected in illegal appropriation. Yet upon

a careful and critical examination of the works of John Bononcini, we think his wealth did not consist in rich and deep mines of science, nor were his resources in learned and elaborate composition, either in the ecclesiastical or madrigal style, very great. His performance on the violoncello, his cantatas, and his operas, had been admired in every part of Europe; but not content with partial fame, he aimed at universality. In his anthem for the funeral of the duke of Marlborough, he attempted to rival Handel in his grand church style; and finding in how much veneration well written madrigals were held at the Academy of Ancient Music in London, where Handel at this time was regarded as a modern, and an innovator, he was tempted to risk the reputation he had fairly acquired, by trying to augment it in an illegal manner. Tradition had filled our minds with ideas of his abilities, which the examination of his works has diminished; while a strict scrutiny into the productions of Handel has greatly augmented our veneration for that composer. We have now before us, in a printed pamphlet, all the letters that passed between the secretary of the Academy of Ancient Music and signor Ant. Lotti on this occasion, with such testimonies and certificates, from the most respectable professors at Venice and Vienna, in proof of the madrigal in dispute having been composed by that master and not by Bononcini, that not the least doubt remains of the fact.

Soon after the funeral of the duke of Marlborough, the countess of Godolphin, who, upon the decease of her father, became duchess of Marlborough, as settled in his patent of creation, received Bononcini into her house in the Stable-yard, St. James's, and settled on him a pension of 500l. a year. Here he lived in ease and affluence, enjoying as an artist the *otium cum dignitate* in its full extent; the duchess having concerts twice a week, in which no other music was performed to the first people in the kingdom than the compositions of her favourite master, executed by the principal fingers of the opera. It is supposed that he gained a 1000l. by the book of cantatas which he published by a two-guinea subscription; many of the nobility subscribing for five or ten copies; the duke and duchess of Queensbury for twenty-five books each, and the countess of Sunderland alone for fifty. After the dispute concerning this madrigal, his importance and reputation diminished considerably; and about the year 1733 he quitted the kingdom. After which he resided at Paris for several years, where he composed masses and motets for the chapel royal. At the conclusion of the peace of Aix la Chapelle in 1748, he was invited to Vienna by the emperor of Germany to compose the music for that occasion, and is said to have been presented with eight hundred ducats for his trouble. After the celebration of the peace was over, quitting Vienna in company with Monticelli, he set off in the same post-chaise with this celebrated singer for Venice; where they were both engaged, Bononcini as composer, and Monticelli as first man, in the operas for the ensuing Carnival in that city. Here we lose sight of this renowned composer; who if we suppose him to have been no more than thirty years of age in 1691, when his eighth work was printed at Bologna, and dedicated to the emperor Leopold, he must at this time have attained his eighty-seventh year; which will give weight to the general opinion, that his life was extended to near a century!

BONONCINI, ANTONIO, brother of John, and an opera composer, little less renowned in Italy, than the author of *Griselda* and *Affyanax*. It has always been imagined that the famous opera of *Camilla*, the second attempt at that species of drama in England, in 1706, was set by John Bononcini; but we can find no proof of it in any one of the numerous volumes of operas in our possession, or dramatic records

records that we have been able to consult. "Camilla Regina de Volsci," written by Stampiglia, and set by Marc Antonio Bononcini, the brother of John, for the imperial court of Vienna, about the year 1697, was in such favour all over Italy, that it was performed at Venice, 1698; Bologna, 1705; Ferrara, and Padua, 1707; Bologna again, 1709; Udine, 1715; and a third time at Bologna, 1719; and seems to have been the opera that was performed in England, during 1706, fifteen times; 1707, twenty; 1708, ten; and 1709, eighteen; in all sixty-four times!

BONONIA, in *Ancient Geography*, a town of Gallia Cispadana, called Felinae, at the time when the Etruscans were masters of the northern part of Italy, and then their capital; supposed by some to have been founded by an Etruscan prince, denominated Felinus. But when these first possessors were driven away by the Boians, it acquired the name of Bononia. In the year of Rome 564, the Romans conducted a colony to this place, with a view of fortifying this side of the country. It afterwards became a municipal city; and owed much of its magnificence to Augustus. See *BOZOGVA*.—Also, a town of Upper Pannonia, placed by Ptolemy on the Drave.—Also, a town of Dacia Ripensis. Not. Imp.—Also, a town of Upper Mœsia, in the route from Viminacium to Nicomedia, between Dortion and Ratiaria. It. Antonin.—Also, a town of Lower Pannonia, in the route along the Danube, between Cusi and Cucci, 19 miles from Sirmium, according to Ammianus Marcellinus.

BONONIAN STONE, a small, grey, soft, glossy, fibrous, ponderous, sulphureous stone, about the bigness of a large walnut, or even of an orange; when broken, having a kind of crystal, or sparry tale within; found in the neighbourhood of Bologna, or Bononia, in Italy; and, when duly prepared, making a species of phosphorus. It is of no certain figure; but is sometimes round, sometimes oblong and cylindric, and sometimes denticular, which last kind is said to be the most shining and transparent. Its colours are various; some being ash-coloured, others of a sky-blue, some of a ferruginous colour, others yellow, others greyish white, and some almost perfectly white. The best for use are said to be the sky-coloured and the white. This stone is found in several parts of Italy, but especially in the district of Bologna, towards the Apennine mountains, and on mount Paterno, or Paterno, about five Italian miles from Bologna. They are most commonly found after heavy rains, among the earth washed off from the neighbouring mountains. In this case the several masses of it appear, when the earth is washed away, as bright as burnished silver, or with the glittering of tale resembling the gloss of a looking-glass. This stone is the ponderous spar, or combination of vitriolic acid with ponderous earth. See *SPAR*.

A chemist, whose name was Vincenzo Casciarolo, having gathered some pieces in a river at the foot of mount Paterno, carried them home, in hopes by the fire to draw silver out of them; but instead of what he expected, found that admirable phenomenon they exhibit, which consists in this, that having been exposed to the light, they retain it, and shine in the dark. This discovery was made about the year 1630.

The property of this stone is, that though it has no lucid appearance in the dark, until it undergoes a particular calcination, it becomes capable, by previous preparation, of imbibing, when exposed for a few minutes to the light of day, or even to the flame of a candle, such a quantity of light, that it afterwards shines in the dark for an interval from eight to fifteen minutes, like a glowing coal, but without any sensible heat. The light it emits is sufficient to read by, if the letters be placed near it. It does not retain its light long, but requires often renewing; and when well prepared,

its virtue will last five or six years, but seldom longer. The method of using it to the greatest advantage, is to remain for some time in a dark room, and to introduce the calcined substance immediately after its being exposed to the light.

M. Homberg is said to be the first person who taught us the true manner of preparing and calcining the Bononian stone, having made a journey to Italy on purpose to learn it. Though others allege, that the true art of preparing and calcining the stone is lost; there having been but one, an ecclesiastic, who had the true secret, and who is since dead, without communicating it to any person. See *Phil. Trans* N 21.

M. Homberg, on his return from his travels in Italy, brought with him a great number of these stones, and calcined 200 of them in so many different ways, that he at last found out the secret. His method was as follows:—He first scraped the stone all over, till it appeared like tale; then, having soaked it thoroughly in brandy, and inclosed it in a paste or crust made of other stones of the same kind pulverized, he calcined it in the fire, or a small furnace. After this operation, he took off all the powder of the crust in which the stone was inclosed. Both the powder and the stone, when brought into the dark from the open air, make a luminous appearance; and the former, if kept in a strong and well-stopped phial, when exposed to the air, imbibes the light, and if sprinkled on pictures and letters, illuminates them in the dark. In preparing the paste, the stone must be pulverized in a brass mortar. This circumstance is mentioned by Lemery, who, in his "Cours de Chymie," describes at large the whole process of preparing this stone, which he acknowledges to have learnt from Homberg himself.

The whole art of preparing this stone, so as to make it shine in the dark, is described at large in Hook's "Philosophical Collections," by sir Marc Antonio Cellio; and in a book of the same author, published at Rome in 1740, on this subject; and the substance has hence been called "Il Fosforo de Marc Antoa. Cellio."

The following has been stated as an approved method of calcining this stone. Make a cylindric furnace of iron or copper plates, 7 inches in diameter, and as many in height. Line the inside of it with a strong lute, so that the inside may be 6 inches wide in the clear hollow; at the top of this make four notches, 2½ inches deep, and 1½ inch wide; to this annex a cylindrical part of the same diameter, but a little higher; and at the bottom make two ash-holes, or air-holes, big enough to admit the hand. Line this, like the other, with good lute, and give it a bottom of lute, that it may more powerfully reflect the heat; and line the cover for the top with lute. Into this furnace introduce an iron-wire grate near the bottom, for sustaining the coals, and so as to admit of free access of air. On this grate lay some pieces of lighted charcoal, and over these some pieces not lighted; all bruised to the size of about a walnut. Some of the stones must be powdered, and those which are to be calcined must be dipped in stroga aqua vitæ, and while wet rolled in the powder, or the powder itself may be made up into thin cakes with mucilage of gum tragacanth. The stones, thus covered, or the cakes, must be laid upon the bed of charcoal close to one another, and another bed of small pieces of charcoal laid over them to the top of the furnace; the cover of the furnace is then to be put on, and the fire lighted. When the charcoal is entirely consumed, and the whole is cold, take out the stones, and, separating the crust from them, wrap them up in silk or cotton, and keep them close in a box for use. Preserve the crust taken off the stones;

for this shines as well as the stone; and being pulverized, may be rubbed over any surface for emitting light, the surface being first daubed over with the white of an egg in order to make it adhere; and this will shine like the stone. This kind of furnace is not absolutely necessary to the operation; but it is convenient to know the quantity of charcoal requisite for giving the shining quality to the stone; since an excess of heat destroys it, and too small a degree is not sufficient to produce it. The greatest degree of phosphorence seems to depend on a due application of the heat. An extreme degree of heat fuses the stone. For other methods of preparing this kind of phosphorus, see PHOSPHORUS. See also LIENT.

This property of affording a phosphorus by calcination, is common to the other gypsums, when pure from metallic or other heterogeneous mixtures; the artificial gypsums succeed equally with the natural, and it is found to belong to a variety of other substances. M. Margraaf observes, that all substances which have this property contain a vitriolic acid, united to an alkaline or calcareous earth.

M. Elpigni observes, that one Zagonius had a method of making statues and pictures of the Bononian stone, which would shine variously in the dark; but he adds, the person died without discovering his secret. See Phil. Trans. N^o 134.

BONONIENSIS, in *Ornithology*, the specific name of the greater lapwing, *tringa bononiensis* of Gmelin, and *vanellus bononiensis major* of Brisson. The legs of this kind are ochraceous; head and upper part of the neck chestnut; body above black, beneath white; throat and breast spotted with ferruginous. Gmel. *Obs.* This is larger than the common lapwing (*tringa vanellus*); the beak is yellowish and black at the tip.

BONONIENSIS, *passerculus bononiensis* of Brisson. This is *fringilla brachyura* of Gmelin, or short-tailed sparrow.

BONOSIANI, or **BONOSIACI**, in *Ecclesiastical History*, an ancient branch of **ADOPTIANI**, in the fourth century, denominated from their leader Bonosus, a bishop of Macedonia.

BONPLANDIA, in *Botany*. Cavan. 532. Clafs and order, *Pentandria Monogynia*.

Gen. Char. *Cal.* tubular, five-toothed. *Cor.* monopetalous, almost labiate; tube longer than the calyx; border with fine emarginate divisions; the two superior long and straight, the three inferior pendant. *Stam.* five inclining. *Pist.* germ superior; style capillary; stigma bifid; *Pericarp.* capsule ovate, three-fided; cells three; seeds three.

Species, *B. geminiflora*, an annual plant; leaves alternate, smooth, lanceolate, toothed; flowers violet, large, axillary, growing in pairs. A native of New Spain.

BONPOURNIKEL, a denomination given to a coarse kind of bread used in Westphalia. See **BREAD**.

BONS-HOMMES, or **BON-HOMMES**, in *Ecclesiastical History*, a sect of hermits of St. Augustin, founded by F. de Paula. They were brought over into England in 1283, by Edmund, earl of Cornwall, and settled at Ashing, in Bucks, besides which they had only one house more at Edington in Wiltshire. They followed the rule of St. Austin, and wore a blue habit.

The name is said to have arisen from Louis XI. of France, who used to call F. de Paula, prior of the order, *le bon homme*. Till then they had been called the *Minimi*, or order of Grammont. See **ALBIGENSES**.

BONSDORFII, in *Entomology*, a species of **CURCULIO**, of an oblong form. Colour white, with a black band and spots; snout fulcated and brown. Bonfd. Curc. Succ. Inhabits Sweden, and is half the size of *curculio fulciferis*.

BONTAIN, in *Geography*, a kingdom of the island of Celebes, situate on the south coast, and on the east shore of the bay of Boni. It is bounded on the west by the river Tino, which divides it from the kingdom of Tourattea; on the north, by the mountains which bear its own name; on the east, by the river Kalekongang; and on the south by the sea. It was anciently considered among the dependent allies of Macasser, and governed by their kings; but it has been twice conquered by the arms of the Dutch East India company and their allies, and was ceded to them, in property, by the treaty of Boni. The country is pleasant, and fertile in rice. It has a large bay, where ships may lie in perfect safety during both the monsoons. The soundings are good and regular, and the bottom soft mud; nor is there any danger in coming in, except from a ridge of rocks, which are above water, and are a good mark for anchoring. The highest land in sight is called "Bontain-hill." S. lat. 5° 30'; and when a ship is in the offing, at the distance of 2 or 3 miles from the land, she should bring this hill N. or N^{W.}, and then run in with it and anchor. In this bay there are several small towns; that which is called "Bontain," lies in the N.E. part of it (S. lat. 5° 10'. E. long. 117° 28'); and here is a small palisadoed fort, on which are mounted eight guns, that carry a ball of about eight pounds weight; it is just sufficient to keep the country people in subjection, and is intended for no other purpose; it lies on the south side of a small river, and there is water for a ship to come close to it. Wood and water are to be procured here in great plenty; likewise plenty of fresh provisions, at a reasonable rate: the beef is excellent, but it would not be easy to procure enough of it for a squadron. Rice may be had in any quantity, and also fowls and fruit: in the woods there are herds of wild hogs, which may be purchased at a low price, as the natives, who are Mahometans, never eat them; and fish may be caught with the seine. The tides are very irregular; it is commonly but once high and once low water in 24 hours, and there is seldom a difference of six feet between them. The inhabitants of Bontain, and those of Boele-Comba and Bera, are the best humoured, most peaceful and most tractable of all the subjects belonging to the Dutch company, in the whole island of Celebes.

BONTEMPI, **ANGELINI**, in *Biography*, a native of Perugia, and author of the first history of music in the Italian language with which we are acquainted. He was an able professor, of considerable learning, who flourished about the middle of the 17th century. His work, which has for title "Historia Musica di Gio. And. Angelini Bontempi," was published at Perugia, in small folio, 1695. It is become somewhat scarce, which enhances its value with collectors of books; and having being long unable to procure a copy, we imagined when one was found, from Brossard's character of the work, that we were in possession of a greater treasure than on examination it proved to be. For with great parade of his learning, science, and acquaintance with the Greek *theorists*, that are come down to us, he leaves us in as utter darkness concerning the *prædices* of ancient music as ever; and, to say the truth, he has furnished us with but little information concerning the modern of his own time, with which, however, as a contrapuntist, he seems to have been perfectly well acquainted. Indeed, by the frequent use he makes of scientific terms, his book, when casually opened, has more the appearance of a dry mathematical treatise, than the history of an elegant art.

The most curious and interesting part of his work, is the account which he gives of the discipline of the college of singers in the service of the pontifical chapel, and of the great masters who then flourished at Rome, who had distinguished

gained themselves in writing "Aila Palestrina" for the church; secular music was then but little cultivated, and less respected there, till operas and oratorios had made some progress in polishing melody, and in the just accentuation and expression of words.

BONTIA, in *Botany*, (in honour of Jacobus Bontius, a physician at Batavia, author of a treatise "De Medicina Indorum"). Linn. species 800. Syst. 579. Reich. 3. 200. Willden. 1208. Schreb. 1062. Jussieu 127. Class and order, *Didynamia Angiosperma*. Nat. Ord. *Personata*—allied to the *Solanæ*. Juss.

Gen. Char. *Per.* calyx one-leaved, five-parted; segments obtuse, erect, permanent. *Cor.* one-petalled, ringent; tube long, cylindrical; border gaping; upper lip erect, reflexed near the end, emarginate; lower semitrid, the size of the upper. *Stam.* filaments fimbriate, bending to the upper lip, the length of the corolla; anthers simple. *Pist.* germ ovate; style simple; stigma bifid, obtuse. *Pericarp.* drupe ovate, with an oblique apex. *Seed*, nut oval, one-celled, germinating.

Ess. Char. *Cal.* five-parted. *Cor.* two-lipped; lower lip three-parted, revolute. *Drup.* ovate, one-seeded, with an oblique apex.

Species, *B. daphnoides*, Barbadoes wild olive. (La Marek Illust. Tab. 546.) "Leaves alternate; peduncles one-flowered." Linn. A shrub four or five feet high; leaves rather stiff, lanceolate, smooth, green on both sides, lower ones serrate, upper ones entire. *Flowers* yellowish, with a line of dusky purple across the lower lip; axillary single, or in pairs; tube and lower lip hairy. It was cultivated by Mr. Bentick in 1695, and flowered with Dr. Sherard in June 1723.

Propagation and Culture. It is cultivated in Barbadoes for making hedges, and may be raised in England from seeds sown on a hot-bed early in the spring. It must afterwards be transplanted into a small pot filled with light earth, and plunged into a moderate tanner's bark hot-bed, with a large allowance of air and water in hot weather, but should always remain in the stove. It may also be propagated by cuttings in the summer. Being ever green, and growing in a pyramidal form, it makes a pretty variety in the stove.

BONTIA, (Brown Jamaic.) See *AVICENNIA germirans*.

BONTIA, (Pet.). See *EPIDENDRON carinatum*.

BONTIA, in *Conchology*, a species of *HELIX*, of which several varieties are described by Chemnitz. This shell is somewhat conic, ventricose, perforated, and pellucid, with the tip black; on the first whorl three yellowish bands; aperture ovate. *Helix bontia* is a native of Bengal; the shell is extremely fragile.

BONTIUS, JAMES, in *Biography*, a native of Leyden, was educated in philosophy and medicine, under his father Gerard; and being sent to the East Indies, practised physic at Batavia about the middle of the seventeenth century. On his return to Europe he wrote several valuable works on the diseases and practice of medicine of India. These are, "De conservanda valetudine, ac diæta sanis in India observandis;" "Methodus medendi, quæ oportet in India orientali uti;" "Observationes selectæ ex dissectione cadaverum ac autopsia descriptæ." He also published curious observations relating to the botany and natural history of those regions, more especially the vegetables used in medicine and diet in his work entitled "De Medicina Indorum," 1642, and afterwards, with Alpinus's work "De Medicina Ægyptiorum," 4to. 1718. He also published "Historia Nat. et Med. Indiæ orientalis," fol. in 1658. His brother Regnier was many years professor of medicine at Leyden, and rector of the university. He died in 1623. Haller. Bib. Med. Pract. et Botan.

BONTORY, in *Geography*, a town of Poland, in the palatinate of Bracław, 20 miles east of Bracław.

BONVINCINO, ALESSANDRO, called *Le Moretto*, in *Biography*, an eminent painter of history and portrait, was born at Rovate in 1514, and studied for some years under Titian, but he was enamoured with the designs of Raphael, which he accidentally saw; and devoting himself to the assiduous study of those master-pieces of art and genius, he became an exceeding good painter. His works are eagerly bought, and much admired for the tenderness of the penciling, the correctness and spirited expression of the figures, the neatness of the finishing, and the rich variety of the draperies, consisting of velvets, damasks, or satins, copied after nature, and wonderfully imitated. He was equally excellent in portrait, and placed by some persons in competition with Titian. He died in 1564. Pilkington.

BONUS HENRICUS, in *Botany*, (*Bauh. &c.*) See *CHENOPodium*.

BONZES, or **BONZUS**, a name given to the priests and religious of China, Japan, and Tonquin. This is the appellation under which the priests, who are attached to the worship of Fo (see Fo,) are generally known among Europeans. They are called "Talapoins" by the Siamese, "Lamas" by the Tartars, "Ho-shang" in China, and "Bonzes" in Japan. They generally live in a sort of community, in places apart, or consigned wholly to them. The island Pou-to, near Chufan, is a famous seat of bonzes, being wholly inhabited by them, to the number of 3000, all of the sect of Hoishang, or unmarried bonzes.

They live a kind of Pythagorean life, and have not less than four hundred pagodas, or temples, in this little island. They have also females, called bonzesses, a sort of nuns, who dedicate themselves to the worship and service of some temples or idols. They are obliged to abstain from all converse with men, and on that account are cloistered in large monasteries, like those of the Romish and Greek church. For incontinency these bonzesses are condemned by the mandarins to a kind of pillory called *Ranghi*, which see.

These bonzes, or Chinese priests of Fo, worship him under the forms of several animals, through which they pretend that he had transmigrated before he was deified; and ingrossing the worship of this imaginary deity to themselves, in the Chinese temples, they support and propagate it, with a view to their own personal emolument and influence, by the most unwarrantable impostures. They admit, however, the distinction between good and evil; and they declare, that, after death, rewards will be bestowed on the good, and punishments inflicted on the wicked, in places destined for the souls of each. They teach, that the god Fo appeared on earth for the purpose of saving mankind, and of restoring to the paths of salvation those who have strayed; that it is by him their sins are expiated; and that he alone can procure for them a happy regeneration in a future life. They enjoin the strict observance of five precepts; of which the first forbids the killing of any living creature, of whatever nature it may be; the second, the taking away of the goods of another; the third forbids men to pollute themselves by uncleanness; the fourth, to lye; and the fifth to drink wine. They, above all, recommend the practice of certain acts of mercy; such as, treating their bonzes well, building monasteries and temples for them, and supplying them with every thing necessary for their maintenance, as the most effectual means of participating the benefit of their prayers, mortifications, penances, and other meritorious actions, towards the atonement of their own sins, and for obtaining a happy transmigration in another life. On the other hand, they terrify those who withhold their benefactions from them with menaces; assuring them, that the y

shall hereafter revive in the form of dogs, rats, serpents, horses, and mules; and that they shall be for ever exposed to the most degrading and wretched transmigrations. These menaces seldom fail of making a deep impression on the minds of the credulous vulgar, inasmuch that they often persuade them to burn, at the funerals of their deceased relatives, paper gilt, or washed with silver, silk, cloth, and other garments, which, they pretend, will be converted into substantial gold and silver, and superb vestments, for the use of their parents and friends. Le Compte relates a story of an old man, who was led to believe, by the representations of these bonzes, that his soul should pass into the body of one of the emperor's post horses. The poor man was so distressed, that he could neither eat nor sleep, and his grief was such as to threaten the speedy termination of his life. He learned, however, that the souls of the Christians were exempted from these dreadful metamorphoses; upon which, he applied to one of the Jesuits for Christian baptism, assuring him, that he would rather be of that, or any religion, than transmigrate into a post-horse. The Jesuit complied with his request, and made his mind easy. These bonzes are perfectly acquainted with all the arts of hypocrisy and deceit; and dextrously practise them as occasions occur. They addict themselves to rigorous fasting, frequent watchings, and long prayers before the altars of Fo. When they cannot obtain gifts by cunning and address, they endeavour to procure them by exciting compassion, and by submitting to the severest penances, and practising the most rigorous austerities. With this view they often appear in public places, as frightful spectacles of mortification. They often drag along the streets heavy chains fastened round their necks, arms, and legs: they beat their heads against the stones and posts, and mangle their bodies, so that they are smeared with blood; they carry burning coals upon the tops of their naked heads; and some of them are carried about in a kind of sedan, the inside of which is stuck full of nails and spikes, so that they cannot stir without wounding themselves; and these nails they sell to the populace for a few pence, as amulets and preservatives against all harm, and as efficacious means of bringing down blessings on the purchaser and his family. By pretending to know the present state of the dead, and the future condition of the living, they contrive to extort money from the surviving friends, in order to procure for the deceased a speedy release and passage into a better state. Many other instances of their knavery are related by Du Halde, Le Compte, and other writers. Some of these are so atrocious in their nature, that the relation of them cannot be read without horror; and we are led to hope, that they are recited by the Jesuit missionaries, to whom the bonzes have been great enemies, and against whom they have excited various persecutions, with some exaggeration.

We read of their privately seizing men and women, and hurrying them away in a close sedan, where nothing is to be seen but the tops of their heads, and their eyes moving in a terrifying manner, to the next river or canal, and drowning them without mercy, before crowds of spectators, who are harangued by one of the fraternity into a firm belief that the persons so treated had earnestly requested to be thus dispatched out of the world, in order to obtain immortality in a future state. With all the external appearances of sanctity and austerity, these bonzes unite voluptuous manners and secret profligacy, of which various instances are recited. Notwithstanding the infatuation which induces the vulgar to support the popular superstition of the country, the condition and character of a bonze are generally despised in China. Most of these fanatical impostors are sprung from the dregs of the people. Those of Pegu, however, are said to be generally gentlemen of the highest extraction. See *PREV.* To

recruit and perpetuate their sect, they purchase young children, whom they betimes initiate in all their mysteries, and whom they instruct in every trick and deception which may render their profession profitable; these afterwards succeed them, and transmit their arts to other young bonzes, who are educated in the same manner. They are, in general, very ignorant, and unable to give an exact account even of the true doctrine of their sect. Although they have no regular hierarchy, they acknowledge superiors, whom they call "ta-ho-shang," or grand bonzes. This rank secures to those who have attained it particular distinction, and the first place in all religious assemblies at which they may be present. There are bonzes of all conditions; some destined only for collecting alms; others, better skilled in the art of speaking, and who have acquired some knowledge of the Chinese literature, are commissioned to visit the literati, and to insinuate themselves into the houses of the great; old men, rendered venerable by age, and by a grave deportment, are employed to exercise their talents among the female sex; these preside in all their assemblies, which, though not common, are held, however, in several provinces. These religious clubs are very lucrative to the bonzes. One of these priests enters the chapel, where the female devotees are assembled, and sings some anthems to the god Fo. At length, after having for some time repeated "Omio Fo," (Omio being the name of another deity more ancient than Fo, and worshipped by the Japanese under the name of Amida, which see), and after being stunned with the tinkling noise of several small kettles, upon which they beat, they place themselves at table, and the noisy devotion terminates with mirth and a good repast. On days of greater solemnity, the bonzes adorn their places of worship with several idols, and numerous paintings, exhibiting under various forms the different punishments inflicted on the wicked in hell. The prayers and fasting continue seven days, during which their chief business is to prepare and consecrate treasures for the other world. In every province of China there are temples, to which numerous votaries repair; some of them making pilgrimages thither from very remote places. The pilgrims climb these sacred mountains with great difficulty, and are sometimes dragged up on their bended knees. Those, whose age or infirmities, or urgent business, will not allow of their joining these devout caravans, commission some of their friends to bring them a large leaf filled with characters, and stamped by the bonzes in a particular corner. The centre of this leaf is occupied by the image of the good Fo. On the vestments of the god, and around his figure, are traced out a multitude of circles, intended for the following purpose.—The devotees of the god, whether male or female, wear hanging from their necks, or around their arms, a kind of chaplet, composed of 100 beads of moderate size, divided by three which are much larger; and a bead, still bigger, in form of a small gourd, ornaments the top of the chaplet. These beads they roll between their fingers, pronouncing the mysterious words "O-mi-to, Fo!" and each of these invocations is accompanied by a genuflection. When they have completed the number of 100, equal to that of the beads, they mark with a red stroke one of the circles which surround the figure of the god Fo, on the leaf stamped by the bonzes. This leaf becomes the register of all the prayers which they have repeated in the course of their lives. To verify its authenticity, the bonzes are, from time to time, invited to their houses, where they must attest the number of circles marked with red strokes, and imprint their seals on the leaf. When any of them dies, this valuable memorial is carried at the funeral with the greatest solemnity, and deposited in a small box closely shut and sealed: this they call "lou-in," or a passport for the other world; and it costs

costs a large sum of money to have all these formalities observed.

It has been already hinted, that the bonzes are peculiarly inimical to the progress of the Christian religion in China, Japan, &c.; and that they have excited a spirit of persecution against the European missionaries, who have hitherto been chiefly Jesuits of the church of Rome. These strangers, they say, have introduced themselves into China for the purpose of invading it; the new doctrine they preach is calculated, as they pretend, to procure followers, and a number of partisans, sufficient to second their efforts, when European troops and fleets shall be ready to attack them; and sometimes they allege, that the missionaries persuade people to embrace their doctrine merely by the aid of sorcery, and that they gain converts, and fix their attachment by lavishing gold and silver among them, of which they have great abundance, because they possess the secret of imitating and counterfeiting these precious metals. By such and similar representations, they have checked the zeal, and counteracted the efforts of Christian missionaries. *Le Compte. State of China. Du Halde's China, vol. i. Grossiere's China, vol. ii.*

It has been observed (see Embassy to China, vol. ii. p. 100.), that the likeness is so strong between the apparent worship of many of the priests of Fo, and that which is exhibited in churches of the Roman faith, that a Chinese, conveyed into one of the latter, might imagine the votaries he saw were then adoring the deities of his own country. On the altar of a Chinese temple, behind a screen, is frequently a representation which might serve for that of the Virgin Mary, in the person of "Shin-moo," or the sacred mother, sitting in an alcove with a child in her arms, and rays proceeding from a circle, which are called a glory, round her head, with tapers burning constantly before her. The long coarse gowns of the Ho-thangs, or priests of Fo, bound with cords round the waist, would almost equally suit the friars of the order of St. Francis. The former live, like the latter, in a state of celibacy, reside together in monasteries, and impose occasionally upon themselves voluntary penance and rigorous abstinence.

BOO-HADJAR, in *Geography*. See **AGAR**.

Boo-Jeamah, a river of Africa, in the province of Constantina, which runs along the western side of the marsh which separates betwixt Bona and the ancient Hippo. Over this river is a bridge of Roman structure.

Boo-Shatter, a town of Africa, in the kingdom of Tunis, said by Shaw (*Trav. p. 79.*) to be built on the ruins of the ancient Utica, which see.

BOOBERAK, a river of Africa, in the kingdom of Algiers, formed by the junction of the Nissah and Bugdourah. Its mouth, which is made up of a number of branches, is the eastern boundary of the province of Titterie.

BOOBY, a word of uncertain etymology, derived by Skinner from the Spanish *bofo*, foolish; but deduced by Junius from *bowbard*, an old Scottish word for a coward or contemptible fellow; denotes a dull, heavy, stupid person.

BOOBY island, in *Geography*, a small island in the West Indies, lying directly opposite to Mosquito bay, at the S. E. extremity of the island of St. Christopher's, and more than half a league from it, off the north end of Nevis island.—Also, a small island, supposed to be one of the islands called Prince of Wales's islands, extending from thence and Wallis's island, as far as New Guinea.

BOOBY, in *Ornithology*, the name of *pelecanus fula* in Cateby's Natural History of Carolina. The great booby of Cateby is a variety of *pelecanus bassanus*. *Brown booby* of

Latham, *pelecanus fiber*; *lesser booby*, *pelecanus parvus*; *spotted booby*, *pelecanus maculatus*.

BOODGE-BOODGE, or **BOOGE-BOOGE**, in *Geography*, a town of Hindoostan, the present capital of the territory of Cutch, and residence of its rajah. It is also called Booz, and placed in a map, to which Mr. Rennell refers, about 34 geographical miles to the E. or E. S. E. of the eastern branch of the Indus; 120 miles S. E. of Tatta, and about 200 W. of Ahmedabad.

BOODH, *Bouddha*, *Budha*, or *Buddou*, in *Mythology*, a deity very anciently and very generally worshipped in India. The name of this deity is variously expressed by different writers. In the Pali language, and among the Cingalese, his common name is Bouddha. Mr. Chambers, in the Asiatic Researches, writes Buddou; and Paulinus (Mus. Borg.), Budha; and from these two appellations we may easily deduce the Buddha or Butta of Beaufoibre and Bochart, the Bod of the Arabians, Bodda of Edrissi, *Bouddz* of Clemens Alexandrinus, and Baouth of M. Gentil. The name is said to be an appellation, synonymous with sage or philosopher, and expressive of wisdom. By Budha, says the learned Bryant, (*Anal. Anc. Mythol. vol. iii. p. 573.*) we are certainly to understand the idolatrous symbol, called by some nations Buddo; the same as Argus and Theba. In the mythology transmitted concerning it we may see a reference both to the machine itself, and to the person preserved in it. In consequence of which we find this person also styled Bod, Budhu, and Buddo; and in the west Butus, Battus, and Bæotus. He was said by the Indians not to have been born in the ordinary way; but to have come to light indirectly through the side of his mother. By Clemens of Alexandria, he is called Bounta; and in the history of this person, however varied, we may perceive a relation to the Arkite deity of the sea, called Poseidon; also to Aercalus and Dionusius; styled Bæotus and Thebanus. Different learned men have supposed Bouddha to have been the same with Noah, Moses, or Siphos the 35th king of Egypt; and sir William Jones supposed Bouddha to have been the same with Sefac or Sesostris, king of Egypt, who by conquest spread a new system of religion and philosophy from the Nile to the Ganges, about 1000 years before Christ. In order to reconcile some differences of opinion among the Hindoos, with regard to the time of Bouddha's appearance, this learned writer agrees with Giorgi in supposing, that they have confounded two Bouddhas; the younger of whom established the new religion, which gave great offence to the bramius in India, and was introduced into China in the first century of our æra; whereas the more ancient Bouddha preceded him by many centuries, and is referred by sir W. Jones, after a variety of computations, to the year 1027 before Christ. For want of adverting to this circumstance, he confounded the latter Bouddha with the Woden of the Goths. Mr. Chambers also remarked, that Pood or Poaden, which is the Siamese mode of pronouncing the Boodh of the Indians and Birmans, bears a striking resemblance to the Gothic Woden; and it is further suggested, that Boodh is the Dies Mercurii, the Wednesday, or Woden's day, of all Hindoos. But etymological reasoning, more especially when it interferes with chronology, is not sufficient to establish the identity of Boodh and Woden. According to the chronology of the Hindoos, which sir W. Jones has minutely investigated and detailed, Boudha was the ninth "Avatar," or descent of the deity, in his capacity of preserver, or the ninth incarnation of Vishnou, which was long antecedent to the existence of the deified hero of Scandinavia, who, according to some writers, was a contemporary of Pompey and Julius Cæsar, and who is placed by the author of the Northern

Antiquities, 70 years after the Christian æra. Besides, the attributes of Boodh and Odin are very different. The deity, whose doctrines were introduced into Scandinavia, was a god of terror, and his votaries carried desolation and the sword throughout whole regions; whereas the ninth Avatar (see Maurice's *Hist. of Hindoostan*, vol. ii. part 3.) introduced the peaceful olive, and appeared in the world for the purpose of preventing sanguinary acts. He severely censured the sacrifice of cattle, or depriving any being of life, and is denominated the author of happiness. His place of residence is said to have been discovered at Boodha Gaya in Bengal, by the illustrious Amara, renowned amongst men; and according to an inscription in Sanscrit, found on a stone in this place, and translated by Mr. Wilkins, (*Asiatic Researches*, vol. i. p. 284.) he caused an image of the supreme spirit Bood-dha to be made, and worshipped it according to the law, with perfumes, incense, and the like; and he thus glorified the name of that supreme being, the incarnation of a portion of Veechnoo: "Reverence be unto thee in the form of Bood-dha! reverence be unto the lord of the earth! reverence be unto thee, an incarnation of the deity and the eternal one! reverence be unto thee, O God, in the form of the God of mercy, the dispeller of pain and trouble, the lord of all things, the deity who overcometh the sins of the Kalee Yoog, the guardian of the universe, the emblem of mercy toward those who serve thee!" &c. As the doctrines of Boodh and Woden are different, and their æras are very remote, they must of course be different persons. The Buddha of the Hindoos is unquestionably, says sir W. Jones, the Foe or Fo of China; and M. de Guignes, on the authority of four Chinese historians, asserts, that Fo was born about the year before Christ 1027, in the kingdom of Cashmir. Mr. Chambers, following M. Gentil, and followed by Paulinus, conceives, by a very forced train of etymology, the Fo or Fohi of the Chinese to be a corruption of Boud-dha. Nor is the derivation of Tautos, Toth, or Touth, the Egyptian name for Hermes from Bouddha, less fanciful; and yet Fo-li, the progenitor of the Chinese, a military tribe, whom the Hindoos call the Chandravansa, or children of the moon, was, according to their Puranas or legends, Buddha, or the genius of the planet Mercury.

Among the various appellations by which the deity Buddha is known in several parts of the East, that of Godama is very common. This Godama, Gaudma, or Gotma, &c. as his name is differently expressed, is said to have been a philosopher, and is believed by the Birmans to have flourished above 2300 years ago; he is said to have taught in the Indian schools the heterodox religion and philosophy of Boodh. See **GODAMA**. The image that represents Boodh is called Gaudma or Goutum, which is now a commonly received appellation of Boodh himself: this image is the primary object of worship in all countries situated between Bengal and China. The sectaries of Boodh contend with those of Brahma for the honours of antiquity, and are certainly far more numerous. The Cingalese in Ceylon are Boodhists of the purest source, and the Birmans acknowledge to have received their religion from that island, which they call Zehoo. From thence it was brought, as the Rhahaans say, to Arracan, and it was then introduced into Ava, and probably into China; for the Birmans confidently assert, that the Chinese are Boodhists. Kæmpfer, speaking of the Budz, or Seaka, (Shaka, Shakya, Sjaka, or Sakya, denoting, according to Paulinus, the cunning, or the god of good and bad fortune,) says, (*Hist. Japan*. b. iv. c. 6.) "I have strong reasons to believe, both from the affinity of the name, and the very nature of this religion, that its author and founder is the very same person whom the Bramins call Buddha, and believe to be the

essential spirit of their Wisna (Vishnou) or their deity, who made his ninth appearance in the world under this name; the Peguers call him Samana Khutana." Where he treats concerning the introduction of Boodh into China, he says, (*id. ibid.*) "about the year of Christ 518, one Darma, a great saint, and twenty-third successor in the holy see of Seaka (Buddha), came over into China from Seitensoku, as the Japanese writers explain it, that is, from that part of the world, which lies westward with regard to Japan, and laid, properly speaking, the first firm foundation of the Boodhism in that mighty empire." Others say, that the sect of Boudha was introduced into China in the year of our æra 630, and that from China it extended itself to Japan, Tonquin, Cochinchina, and the most remote parts of Tartary.

Whatever may be the antiquity of the worship of Boodh, or Buddha, we can entertain no doubt of the wide extent of its reception and prevalence. In the island of Ceylon, in the extensive Birman empire, in the kingdoms of Siam and Cambodia, the prevailing religion is that of Bouddha or Godama, and Mr. Chambers (*Asiatic Researches*, vol. i. p. 162, &c.) has given very good reasons for believing that the worship of Bouddha extended all over India, and was not rooted out by the Bramins in the Deccan, so lately as the 9th, or even the 12th century of the Christian æra. From the history of Cashmire, presented to the sultan Aebur, on his first entrance into that kingdom, we learn, that Jelowk, one of its most powerful princes, tolerated the doctrine of Bouddh; and that it was not till the reign of Nerklh the 59th prince, A. D. 342, that the Bramins acquired the ascendancy over the followers of Boodh, and burned down their temples. In Nepal the most ancient religion is that professed by a sect who call themselves "Baryefu," and who seem to be worshippers of Bouddha. In Narhoara or Nehrwalch, the capital of the kingdom of Guzerat, we find that even after the Mahometan invasion, in the 11th century of our æra, Edrifi, who wrote in the 12th century, informs us, that the people continued in the worship of the idol Bodda or Bud. This Arabian geographer adds, that the worship of the prince of this country, who reigned on the Malabar coast, with the title of Balhara, and whose dominions extended over Guzerat, and the greatest part, if not the whole of Viliapour, was addressed to Bodda, who, according to St. Jerome and Clemens Alexandrinus, was the founder of the sect of the Gymnosophists, in like manner, says M. d'Anville, as the Bramins were used to attribute their institution to Brahma. If the conjectures of sir William Jones, relating to the inscriptions found at Mongheer, and on the pillar of Buddal, be well founded, the governing powers on the banks of the Ganges, as late as about the time of the birth of Christ, were of the sect of Bouddha; and however idle and ridiculous the legends and notions of the worshippers of Bouddha may be, they have been in a great measure adopted by the Bramins; but with all their defects and extravagances much aggravated, rajahs and heroes being converted into gods, and impossibilities accumulated on improbabilities. From various authorities, to which we might refer, it sufficiently appears, that the worship of Bouddha, or Buddou, has prevailed in several parts of India at a period prior to that of the Bramins; and that this has been the case even so late as the 9th and the 12th centuries of the Christian æra; and that this system forms the basis of that religion which the Bramins have brought with them into the southern parts of the peninsula of Hindoostan, into Madura, Tanjore, and Mysore. In those parts of India, and chiefly on the coast of Coromandel, and in Ceylon, the god Baouth, says M. Gentil, of whom, at present, they know no more in India than the name, was the object of worship;

but it is now totally abolished; except that there may be found some families of Indians, who have remained faithful to Baouth, and do not acknowledge the religion of the Brahmins; and on that account separated from and despised by the other cast. It is generally allowed, that about the time of Christ the Brahmins gained a superiority over the worshippers of Bouddha; and about 900 years afterwards, we find them totally overthrowing his doctrine in its native country, and persecuting his followers. The Vedas, which are commonly supposed to be the oldest books of the Brahmins, are of later date than the time of Bouddha, as is evident from the mention which they make of that personage. Asiatic Researches, vols. i. ii. and iv. Symes's Embassy to Ava, vol. ii. ch. 13. For a further account of the votaries of Bouddha, as well as the principles and rites of his worship; see BRACHMANS, GONDAMA, RAHANS, SAMANEANS and TIRINANNES. See also BIRMAN empire, CEYLON, CHINA, COCHINCHINA, SIAM, &c.

BOODICOTTA, in *Geography*, a town of the peninsula of India, in the Mysore country; 87 miles E. N. E. of Serriugapatam, and 33 E. S. E. of Bangalore. N. lat. 12 50'. E. long. 78 20'.

BOOG, or **BOGOE**, a small island of Denmark, between the island of Moen and Falster.

BOOGOO, in *Zoology*, the species of BAROON called *Simia maimon*, by Linnæus. See MAIMON.

BOOK, a writing composed on some point of knowledge by a person intelligent therein, for the instruction or amusement of the reader.

The word is formed from the Saxon *boc*, which comes from the Northern *buech*, of *buechans*, a *beech* or *service-tree*, on the bark of which our ancestors used to write.

Book may be defined more precisely, a composition of some man of wit or learning, designed to communicate, to prove, or illustrate some science, art, truth, or invention.

Book is distinguished from pamphlet, or single paper, by its great length; and from tome or volume, by its containing the whole writing on the subject. Isidore makes this distinction between *liber* and *codex*; that the former denotes a single book, the latter a collection of several; though, according to Scipio Maffei, *codex* signifies a book in the square form; *liber*, a book in the roll form. The primary distinction between *liber* and *codex* seems to have been derived, as Dr. Heylin has observed, from the different materials used for writing, among the ancients. From the inner side of the bark of a tree, used for this purpose, and called in Latin *liber*, the name of *liber* applied to a book was deduced; and from tablet, formed from the main body of a tree, called *caudex*, was derived the appellation of *codex*.

We say an old book, a new book; a Latin, a Greek book; to read, to write, to publish a book; the preface, the title, the dedication, the index of a book. To collate a book, is to see that it be perfect, and that none of the sheets be either wanting or transposed. Book-binders speak of folding, sewing, beating, pressing, covering, gilding, and lettering of books. See BOOKBINDING.

A large collection of books is called a library. An inventory of a library, in order to the reader's finding any book, is called a catalogue.

The history or *notitia* of books makes the first part, according to some the whole, of the literary science.—The principal points of the *notitia* of a book are, its author, date, printer, edition, versions, comments, epitomes, success, eulogies, censures, condemnation, suppression, adversaries, vindicators, continuators, and the like.

The history of a book is either of its contents, which is

given by analysing it, as is done by journalists and reviewers; or of its appendages, and accidents, which is the more immediate province of those called literators, and bibliothecarians.

The contents of a book are the matters delivered in it; which make the province of the author. Of these there is one principal matter, called the subject; in respect of which the rest are only incidents.

The appendages of a book are, the title, preface, epistle dedicatory, summaries, table of contents, index, and the like, which are the proper province of the editor, unless perhaps the title page, which is frequently usurped by the bookseller.

In the composition of a book, there occur sentiments, which are also the materials of it; method, the order where-in these are disposed; and style, or expression, which is the language in which they are clothed.

The giving of histories, catalogues, and bibliotecas of books, is said to have been first introduced by the Germans; we may add, that they have best succeeded in them; and to them the chief works of this kind are owing. 1. Alb. Fabricius has given us the history of the Greek and Latin books; Wolfius, that of the Hebrew books; Boecler, of the principal books in each science and faculty; Struvius, of the books of history, law, and philosophy; the abbot Fabricius, of the books of his own library; Lambecius, of those in the Vienna library; Le Long, of the books of Scripture; Mattaire, of the books printed before the year 1550; and Morhoff, a general literary history of this kind, under the title of Polybiblior. The various catalogues of choice libraries are useful and necessary for the same purposes: so are likewise the relations, &c. and the reviews which have been periodically published. See BIBLIOTHECA.

Books, as *to the materials of*, they were first written on stones, witness the Decalogue given to Moses (which is the oldest book we have any warranted account of); then, on the parts of plants, e. gr. the leaves, chiefly of the palm-tree; the rinds and barks especially of the tilla or philyra, and the Egyptian papyrus. By degrees, wax, then leather, were introduced, especially the skins of goats and sheep, of which, at length, parchment was prepared: then lead came in use; also linen, silk, horn, and lastly, paper itself. See PAPER.

The parts of vegetables continued long the common matter of books; inasmuch that most of the names and terms belonging to books, in most languages, are taken thence: as the Greek *libros*, the Latin *liber*, *codex*, *folium*, *tabula*, and the English *book* itself. We may add, that vegetable barks appear still in some measure retained for books in certain of the northern countries, as among the Calmuc Tartars, where a library was discovered by the Russians, of an unusual form as well as matter: the books were exceedingly long, but of no breadth; the leaves very thick, and made of barks of trees, smeared over with a double varnish; the ink, or writing, being white on a black ground. Hist. Acad. R. Infer. t. iii. p. 6.

Whatever were the materials used by the ancients for their books, they were liable to be easily destroyed by the damp, when hidden in the earth; and in times of war, devastation, and rapacity, it was necessary to bury in the earth whatever they wished to preserve from the attacks of fraud and violence. Accordingly, it is well known that persons, whose property was thus exposed, concealed in this manner, not only silver and gold, but wheat, barley, oil, and honey; and also their garments, and their writings. With this view, Jeremiah ordered the writings, which he delivered to Baruch, to be put in an earthen vessel. See chap. xxxii. In the same manner the ancient Egyptians made use of earthen urns, or pots of a proper shape, for containing what-

whatever they wanted to inter in the earth, and which, without such care, would have been soon destroyed. We need not wonder then, that the prophet Jeremiah should think it necessary to enclose those writings in an earthen pot, which were to be buried in Judæa, in some place where they might be found without much difficulty on the return of the Jews from captivity. Accordingly two different writings, or small rolls of writing, called books in the original Hebrew, were designed to be enclosed in such an earthen vessel; but commentators have been much embarrassed in giving any probable account of the necessity of two writings, one sealed, the other open; or, as the passage has been commonly understood, the one *sealed up*, the other left *open* for any one to read; more especially, as both were to be alike buried in the earth and concealed from every eye, and both were to be examined at the return from the captivity. In order to solve this difficulty, the ingenious Mr. Harmer (*Obf. on Script.* vol. iv. p. 4.) remarks, that though one of them is said to be *sealed*, it doth not follow that it was sealed in such a manner as not to be opened. Like modern deeds for the conveyance of land, it might have been sealed, though not with wax, yet, according to the present eastern manner, with ink, so as to be valid. Moreover, the word translated *open*, in reference to the evidence, or book which was open, is not the same that is twice used by Nehemiah, ch. viii. 5.; but it is a word, which signifies (1 Sam. iii. 7. 21. Dan. ii. 19. 30. x. 1.) the revealing of future events to the minds of men by a divine agency; and it is particularly used in the book of Esther, (ch. viii. 13.) to express a book's making known the decree of an earthly king. Consequently the *open book* of Jeremiah seems to signify, not its being then lying open or unrolled before them, while the other was sealed up; but the book that had revealed the will of God, to bring back Israel into their own country, and to cause buying and selling of houses and lands again to take place among them. This was a *book of prophecy*, opening and revealing the future return of Israel, and the other little book, which was ordered to be buried along with it, was the purchase deed. By adverting to the different modes of writing in the East, we obtain a satisfactory interpretation of a passage in the book of Job, (ch. xix. 23, 24.) and a distinct view of the beautiful gradation which is lost in our translation: "O that my words were now written! O that they were printed (written) in a book! that they were graven—in the rock for ever!" In the East there is a mode of writing, which is designed to fix words in the memory, but the writing is not intended for duration. Accordingly, we are informed by Dr. Shaw, (*Trav.* p. 194.) that children learn to write in Barbary by means of a smooth thin board, slightly covered with whiting, which may be wiped off, or renewed at pleasure. As many occurrences were effaced from the memory of the Arabs in the time of Job, as well as from their writing tables, as it now often happens in Barbary; Job expresses his wish not only that his words were written, and written in a book, from which they should not be blotted out, and graven in a rock, the most permanent mode of recording them, and much more effectual for perpetuating them than a book.

We find in Signior Castagnatta's account of the asbestos, a scheme for the making of a book, which from its imperishable nature, he is for calling the *book of eternity*. The leaves of this book were to be of the asbestos paper, the covers of a thicker sort of work of the same matter, and the whole sewed together with thread spun from the same substance. The things to be commemorated in this book were to be written in letters of gold, so that the whole matter of the book being incombustible and everlastingly permanent

against the force of all the elements, and subject to no changes from fire, water, or air, must remain for ever, and always preserve the writing committed to it. See PAPER.

Books, form of. The first books were in the form of blocks and tables, of which we find frequent mention in Scripture, under the appellation *sepher*, which the Septuagint render *αζυρις*, q. d. *square tables*: of which form the book of the covenant, book of the law, book, or bill of divorce, book of curses, &c. appear to have been. As flexible matters came to be wrote on, they found it more convenient to make their books in form of rolls, called by the Greeks *ρολωνια*, by the Latins *volumina*, which appear to have been in use among the ancient Jews as well as Grecians, Romans, Persians, and even Indians. And of such did the libraries chiefly consist, till some centuries after Christ. The form which obtains among us is the square, composed of separate leaves; which was also known, though little used, among the ancients; having been invented by Attalus, king of Pergamus, the same also who invented parchment: but it has now been so long in possession, that the oldest manuscripts are found in it. Montfaucon assures us, that of all the ancient Greek manuscripts he has seen, there are but two in the roll form; the rest being made up much after the manner of the modern books. See BOOK-BINDING.

The rolls, or volumes, were composed of several sheets, fastened to each other, and rolled upon a stick, or *umbilicus*; the whole making a kind of column, or cylinder, which was to be managed by the *umbilicus*, as a handle; it being reputed a kind of crime to take hold of the roll itself. The outside of the volume was called *front*; the ends of the *umbilicus*, were called *cornua*, *horns*; which were usually carved and adorned likewise with bits of silver, ivory, or even gold and precious stones. The title *Συλλαβος* was stuck on the outside. The whole volume, when extended, might make a yard and a half wide, and fifty long. Fabric. *Bibl. Antiq.* c. 19. § 7. p. 607.

Sir John Chardin informs us, in a note on *Is.* viii. 1. that the eastern people roll their papers, and do not fold them, because their paper is apt to fret. Whilst the Ægyptian papyrus was in common use, its brittle nature made it proper to roll up what they wrote: and as this had been a customary practice, many continued it when they used other materials, which might very safely have been treated in a different manner. This method of rolling up their books is referred to in the New Testament; and that they were of the same form much more anciently, we learn from *Jer.* xxxvi. 2. *Pf.* xl. 7, &c. &c.

It is customary not only to wrap up Oriental books and letters which are rolled up, in an elegant and costly covering; but to inscribe words on these coverings, which give a general notion of their contents. This practice of writing on the outside of the case of a letter, or book rolled up, seems to be at least as ancient as the time of Chrysostom, as we learn from a note of Lambert Bos on *Pf.* xxxix. 7. as it occurs in the *LXX.* v. 40, in our version. Chrysostom remarks, that they call a wrapper (*ελλημα*) the *Κεφαλις*, which is the word the Septuagint translators make use of to express the Hebrew word we translate volume: "In the volume of the book it is written of me." The learned father seems to suppose, that there was written *in* or *on* the covering of the sacred volume, a word or words which signified the "coming of the Messiah." But Chrysostom would hardly have thought of such an interpretation, if it had not been frequently done at Constantinople in his time, or by the more eastern princes that had business to transact with the Greek emperors, or been known to have been practised

B O O K.

practised before those times among the Jews. Chrysoftom lived in the 4th century. Aquila, who is thought to have lived above 100 years sooner, and is allowed to be a most close translator of the Hebrew, uses, according to Bos, the same word *επιθυμα*, or wrapper, to express the Hebrew word we translate volume. He therefore supposed that what was written, to which this passage refers, was written on the covering or wrapper of the sacred books. This explanation suggests a much more agreeable mode of rendering the word than our English term *volume*; since every ancient Hebrew book was a volume, or roll, and consequently the passage merely expresses; "In the book it is written of me." But if we understand it of the *case* in which their books were wrapped up, the thought is not only clear and distinct, but very energetic, and amounts to this, that the sum and substance of the sacred books is, that "the Messiah cometh;" and that those words accordingly might be wrote or embroidered, with great propriety, on the wrapper, or case in which they were kept.

Another translation renders the word *επιθυμα*, which intimates that the motto was inscribed on the cylinder, round which books of this form were wont to be rolled. In this case, it was probably written on that part of the cylinder which reached beyond the parchment, linen, or whatever material was used, and which was convenient enough for exhibiting, in brief, what the purport of the volume was. Mr. Harmer (*Obs. on Script.* vol. iv. p. 111.) suggests, that the circle of gold, with the name of one of our Saxon princes upon it, and ornamented after the manner of those times, might be designed to case the end of the cylinder, or one of the cylinders, on which some book belonging to that monarch, or relating to him, was rolled; of which ancient piece of gold an engraving is given in the seventh volume of the *Archæologia*, or *Transactions of the Antiquarian Society*. This sort of casing to those cylinders used to be called the "Aestel."

To the form of books belongs also the *economy of the inside*, or the order and arrangement of points and letters into lines and pages, with margins, and other appurtenances. This has undergone many varieties: at first, the letters were only divided into lines, then into separate words; which, by degrees, were noted with accents, and distributed by points and stops into periods, paragraphs, chapters, and other divisions. In some countries, as among the Orientals, the lines began from the right, and ran to the left; in others, as in Northern and Western nations, from the left to right; others, as the Grecians, followed both directions alternately, going in the one, and returning in the other, called *boustrophedon*. In the Chinese books, the lines ran from top to bottom. Again, the page in some is entire, and uniform; in others, divided into columns; in others, distinguished into texts and notes, either marginal, or at the bottom: usually it is furnished with signatures and catch-words; also with a register to discover whether the book be complete. To these are occasionally added the apparatus of summaries, or side notes; the embellishments of red, gold, or figured initial letters, head-pieces, tail-pieces, effigies, schemes, maps, and the like. The end of the book now denoted by *finis*, was anciently marked with a *Ϸ*, called *coronis*, and the whole frequently washed with an oil drawn from cedar, or citron chips, strewed between the leaves to preserve it from rotting. There also occur certain *formula* at the beginning and end of books; as among the Jews, the word *תורתך*, *esto fortis*, which we find at the end of the books of Exodus, Leviticus, Numbers, Ezekiel, &c. to exhort the reader to be courageous, and proceed on to the following book. The conclusions were

also often guarded with imprecations against such as should falsify them; of which we have an instance in the Apocalypse. The Mahometans, for the like reason, place the name of God at the beginning of all their books, which cannot fail to procure them protection, on account of the infinite regard had among them to that name, wherever found. For the like reason it is, that divers of the laws of the ancient emperors begin with the *formula*, *In nomine Dei*. At the end of each book the Jews also added the number of verses contained in it, and at the end of the Pentateuch the number of sections; that it might be transmitted to posterity entire. The Masoretes and Mahometan doctors have gone farther; so as to number the several words and letters in each book, chapter, verse, &c. of the Old Testament, and the Alcoran. See *ALCORAN*, *BIBLE*, *MASSORA*, &c.

The kinds and denominations of books are various.

Books, with regard to their *use and authority*, may be divided into *human and divine*, also called *sacred and inspired* books.

Books, *Sibylline*, those composed by certain pretended prophetesses, deposited in the Capitol, under the care of *Dumoviri*. See *SIBYLS*.

Books, *Canonical*, those received and allowed by the church as parts of holy scripture. Such are the books of the Old and New Testament, as commonly bound up together. See *CANON* and *BIBLE*.

Books, *Apocryphal*, those excluded out of the canon, yet received and read in some churches. See *APOCRYPHAL*.

Books, *Authentic*, those which are decisive, and of authority: such, in the civil law, are the Code, Digest, &c. in our law, the Statutes, &c. Bacon de Augm. Sc. l. 8. c. 3.

Books, *Auxiliary*, those less essential, yet of use, as subservient to the others: as in the study of the law, books of Institutes, Formulæ, Maxims, Reports, &c.

Books, *Elementary*, those which deliver the first principles of sciences: such are those under the titles of Rudiments, Methods, Grammars, &c. by which they stand contradistinguished from books of a superior order, which aim at making farther advances in the sciences.

Books, *Library*, such as are not ordinarily read over, but turned to, and consulted occasionally; such are dictionaries, &c.

Books, *Exoteric*, those intended for the use of popular and ordinary readers.

Books, *Acroamatic*, those containing more secret and sublime matters, calculated for adepts and proficients in the subject.

Books, *Public*, the records of past times and transactions kept by public authority.

Books, *Church*, or *Ecclesiastical*, those used in the public offices of religion.

Books, again, with regard to their *scope and subject*, may be divided into *historical*, those which relate facts, either by nature or mankind; *dogmatical*, those which lay down doctrines, or general truths; *miscellaneous*, those of a neutral kind, containing both facts and doctrines; *historico-dogmatical*, those which only rehearse doctrines, or, at most, indicate the arguments by which they are proved, as Mallet's Geometry; *scientifico-dogmatical*, those which not only recite the doctrines, but demonstrate them, as Euclid's Elements. Wolf. Phil. Rat. § 3. c. 1. § 744. 750. 751. &c.

Books, *Pontifical*, among the Romans, were those appointed by Numa to be kept by the *pontifex maximus*; describing

cribing all the ceremonies, sacrifices, feasts, prayers, and other religious matters, with the manner, and circumstances, wherewith each was to be celebrated; these were also called *indigitamenta*, as containing the names of all the gods and the occasions, and *formulae* of invoking each. Liv. i. p. 23.

Books, *Ritual*, those which directed the order and manner of founding, building, and consecrating cities, temples, and altars; the ceremonies belonging to walls, gates, tribes, curiae, camps, and the like.

Books, *Augural*, called by Cicero *reconditi*, were those wherein the science of foretelling futurity, from the flight and chattering of birds, was contained. Cicero. Orat. pro domo sua ad pontiff. Serv. ad Æn. l. 5. v. 738. Lomei, de Bibl. c. 6.

Books, *Aruspicine*, those wherein the mysteries of divining from the entrails of victims are prescribed.

Books, *Acherontic*, those wherein the ceremonies and discipline of Acheron were contained; sometimes also called *libri Etrusci*, as being supposed to have been composed by Tages the Etrurian; though others pretend, that he had received them from Jupiter himself: some suppose these to have been the same with the *libri fatales*; others with the *libri aruspicini*. Serv. ad Æn. l. 8. v. 598. Lomei, ubi supra.

Books, *Fulgural*, those written touching thunder and lightning, and their interpretation. As that composed by the Tuscan nymph Bigois, preserved in the temple of Apollo. Serv. ad Æn. l. 6. v. 72.

Books, *Fatal*, those wherein the ages, or terms of the life of men were written, according to the Etrurian discipline. These were consulted by the Romans in all public calamities; and instructions taken from them, how to expiate the offended deities. Censor. de Die Natal. c. 14.

Books, *Black*, those which treat of necromancy, and witchcraft; or those which are printed in the old black letter, the Celtic character, now only retained by the Germans. The same denomination is also given to some other books, on account of the colour of their backs, or the dismalness of their contents; whence also *Red-book* and *Domesday-book*.

Books, *Good*, in the common usage, are those of devotion and piety, as soliloquies, meditations, prayers, &c. Vide Shaftesb. Charact. tom. i. p. 155. idem. tom. iii. p. 327. A *good book* in the bookseller's language, is a saleable one; in the language of the curious, a scarce one; in that of men of sense, an useful and instructive one.

Among five principal things which Rabbi Akiba recommended to his son, one was, that if he studied the law, he should take care to do it in a *good book*, lest he should be obliged to unlearn all again. Vide Cren. de Furib. Librar. See also farther, on the head of judging and choosing of Books.

Books, *Spiritual*, those which treat more expressly on the spiritual or Christian life, and their exercises, as to contemplation, &c.

Books, *Prophane*, such as do not treat of matters of religion.

Books, with regard to their authors, may be divided into *anonymous*, those without any author's name; *cryptonymous*, those whose authors' names are concealed in some anagram, or the like; *pseudonymous*, those which bear false names of authors; *posthumous*, those published after the author's death; *genuine*, those really written by the persons whom they pretend for their authors, and still remaining in the state wherein they were left by them; *spurious*, or *suppositi-*

tious, those pretended to be written by others than their real authors; *interpolated*, those which since their composition have been corrupted by spurious additions or insertions.

Books, with regard to their *qualities*, may be divided into *clear* or *perspicuous*, which, in the dogmatical kind, are those where the authors define all their terms accurately, and keep strictly to those definitions in the course of their works: *obscure*, those where words are used vaguely, and without defining; *prolix*, those which contain more things than were necessary to the author's design; as if in a book of surveying, a man should give all Euclid; *useful*, those which deliver things necessary to be known, either in other sciences, or in the business of life; *complete*, those which contain all that is known concerning the subject; *relatively complete*, those which contain all that was known concerning the subject, at a certain time; or, if a book were written with any particular design, or view, it may be said to be *complete*, if it contain neither more nor less than is necessary for the accomplishing of that end: in contrary cases, books are said to be *incomplete*.

Books, with regard to the *matter* of which they consist, may be divided into *paper-books*, those written either on linen and cotton paper, or on the papyrus, of which last kind few are now remaining. Montfaucon Pal. Græc. l. i. c. 2. p. 13. *Parchment-books*, *libri in membrana*, those written on skins, or pelts, chiefly of sheep. *Linen-books*, *libri lintei*, among the Romans, were those written on blocks, or tables, covered with a linen cloth. Such were the Sibylline books, and divers ancient laws, epistles of princes, leagues, annals, &c. Plin. Hist. Nat. l. xiii. c. 2. *Leathern books*, *libri in corio*, mentioned by Ulpian, are by Guilandinus taken for such as were written on barks, different from that usually written on; which was the *tilia*: by Scaliger, with more probability, for such as were written on certain skins, or certain parts of skins, different from those commonly used, which were the pelts, or back parts of sheep. Ulp. l. 52. Guiland. Papyr. Membr. 3. n. 50. Scaliger, and Guiland. *Block books*, *libri in scbedis*, those written on wooden planks; or tablets, smoothed for that purpose with an *ascia*, and a plane. Such were the ordinary books among the Romans. *Waxen-books*, *libri in ceris*, mentioned by Pliny, have occasioned some dispute. Herm. Barbarus suspects the term to be a corruption, and inclines to read *in scbedis*, instead of *in ceris*, on the authority of some ancient MSS. Others see no need of the emendation, since it is known the Romans sometimes covered their planks or *scbedæ*, with a thin skin of wax, to make them susceptible of erasements and amendments, which the *libri in scbedis* were not, and consequently were less fit for works that required elegance and accuracy than the waxen ones, which are also called *cera* or *libri ceri*. *Elephantine books*, according to Turnebus, were those written on thin slices, or leaves of ivory; according to Scaliger, those made of the guts of elephants; according to others, those wherein the acts of the senate, relating to the emperors, were written; according to others, certain huge or bulky books, consisting of 35 volumes, containing all the names of the 35 tribes. Salmuth. ad Pancirol. p. ii. p. 255. Guiland. Pap. Mem. 2. n. 48. Scal. ad Guil. p. 16. Calv. Lex. Jur. p. 534. Fabr. Descript. Urb. c. 6.

Books, with regard to their *manufacture* and *commerce*, may be divided into *manuscript*, those written with the hand, whether originally by the authors, called *autographi*, or at second hand by *librarii*, or *copyists*; *printed*, those wrought off from the press; *books in quires* or *sheets*, those not bound or stitched; *books in folio*, those wherein a sheet is folded but once, or makes two leaves, or four pages; *books in 4°*, where

where it makes four leaves; in 8°, where eight; in *duodecimo*, where twelve; in 16°, where sixteen; in 24°, where twenty-four.

Books, with regard to *circumstances* and *accidents*, may be divided into *lost*, those which have perished by the injuries of time, or the malice or zeal of enemies. Such are divers even of the ancient books of Scripture, written by Solomon, and others of the prophets. Fabr. Cod. Pseud. Vet. Test. tom. ii. p. 171. p. 247. Books *promised*, those which authors have given expectations of, which they have never accomplished. Janf. ab Almelooven has given a Bibliotheca of books promised, but still latent, or not published. Books *fictitious*, those which never existed: to which may be added divers feigned titles of books. Loefcher has published a great number of plans, or projects of books, many of them good and useful enough, if there were but books written corresponding to them. M. Dugono has a whole volume of *schemes* or *projects of books*, containing no less than 3000.

Books in *Ana*, *Anti*, &c. See *ANA*, *ANTI*, &c.

Books, the *scope* or *design* of, is various; that of some is to trace the origin of things discovered; of others, to fix and establish some truth, or raise some doctrine to a higher pitch or subtilty; of others, to remove some scruple, or prejudice, which had before obtained, or fix more accurate and precise ideas of things: of others, to explain the names and words used in different nations, ages, and sects; of others, to improve our knowledge of facts, and events, and shew the order and ways of Providence; lastly, others aim at divers, or all of these ends.

Books, the *uses* of, are numerous; they make one of the chief instruments, or means of acquiring knowledge: they are the repositories of laws, and the vehicles of learning of every kind: our religion itself is founded on books: "Without them," says Bartholin, "God is silent, justice dormant, physic at a stand, philosophy lame, letters dumb, and all things involved in Cimmerian darkness." De Libr. Legend. Diff. i. p. 5.

The eulogiums which have been bestowed on books are infinite: they are represented "as the refuge of truth, which is banished out of conversation; as standing counsellors, and preachers, always at hand, and always disinterested; having this advantage over oral instructors, that they are ready to repeat their lesson, as oft as we please." Books supply the want of masters, and even, in some measure, the want of genius and invention: and can raise the dullest persons, who have memory, above the level of the brightest without them. An author who wrote not inelegantly, though in a barbarous age, sums up all their praises. Vide Lucas de Penna ap. Morhoff. Polyhist. lib. i. cap. 3. p. 27. "Liber est lumen cordis, speculum corporis, virtutum magister, vitiorum depulsor, corona prudentum, comes itineris, domesticus amicus, congerio talentis, collega & consiliarius praesidentis, myrothecium eloquentiae, hortus plenus fructibus, pratum floribus distinctum, memoriae penus, vita recordationis; vocatus properat, justus festinat, semper praesto est, nunquam non morigerus, rogatus confestim respondet; arcanam revelat, obscura illustrat, ambigua certiorat, perplexa resolvit, contra adversam fortunam defensor, secundae moderator, opes adauget, jacturam propulsat," &c.

Perhaps their greatest glory is, the affection borne them by many of the greatest men in all ages: M. Cato, the elder Pliny, the emperor Julian, and others, are on record for a very extraordinary devotion to books. This last has perpetuated his passion by some Greek epigrams in their praise. Richard Bury, bishop of Durham, and lord chancellor of England, has a treatise express on the love of books. Philobiblion, five de Amore Librorum. Vide Plin. Epist. vii. lib. iii.

Cato's attachment to books may be observed in the following paragraph.

"M. Catonem vidi in bibliotheca sedentem multis circumfusum Stoicorum libris. Erat enim, ut scis, in eo inexhausta aviditas legendi, nec satiari poterat: quippe qui, ne reprehensionem vulgi inanem reformidans, in ipsa curia soleret legere, saepe dum fenatus cogere, nihil operæ reipublicæ detrahebat." Vide Cic. de Divin. lib. iii. n. 11. See also Cic. Orat. pro Arch. tom. iv. p. 2182.

Books, the *ill effects* objected to, are, that they employ too much of our time and attention; engage us in pursuits of no use to the commonwealth, and indispose us for the functions of civil life; that they render men lazy, and prevent their exerting their own talents, by furnishing them, on every occasion, with things that are the productions of others; and that our natural lights become weakened and extinguished, by inuring ourselves to see only with foreign lights: besides, that ill men are hereby furnished with means of poisoning the people, and propagating superstition, immorality, enthusiasm, or irreligion, which will always spread faster, and be received more greedily, than lessons of truth and virtue. Many other things are added concerning the emptiness of books, and the errors, fables, and follies they are fraught with: which, together with the multitude and perplexity of them, are such, that it may seem easier to discover truth in the nature and reason of things, than in the uncertainty and confusion of books. Add, that books have turned the other instruments of knowledge out of doors, as experiments, observations, furnaces, and the like, without which the natural sciences can never be cultivated to purpose; and that, in mathematics, books have so far superseded the exercise of invention, that the generality of mathematicians are now contented to learn the solution of problems from others; which is to relinquish the chief end of their science; since what is contained in mathematical books is properly the history only of mathematics, not the science, art, or talent of solving questions; which is hardly to be had from books, but only from nature and meditation.

Books, for the art of *writing*, or *composing*, we have much fewer helps and instructions than for the art of speaking; though the former be the more difficult of the two; as a reader is not so easy to be imposed upon, but has better opportunities of detecting faults than a hearer. A great cardinal, indeed, reduces an author's business to a few heads; were they but as easily practised as prescribed; "Let him consider who it is writes, what, how, why, and to whom." August. Valer. di Caut. in edend. lib. *The conditions required in a book* are, according to Selden, "solidity, perspicuity, and brevity:" the first will be best attained, by keeping the piece long by us, often reviewing and correcting it by the advice of friends: the *second*, by disposing the sentiments in a due order, and delivering them under proper and usual expressions: the *third*, by throwing every thing aside that does not immediately concern the subject. Were these rules observed, it would scarcely be possible for any, except an angel from heaven, to write many books. "Vix totidem quot Thebarum portæ vel divitiis ostia Nili." The custom is much altered since the times of the ancients, who carried their scrupulousness into what relates to the composition of books beyond all that has been above expressed; so August was the idea they formed of a book, that nothing would suffice less than its being a treasure: "thesaurus oportet esse, non libros:" no labour, no assiduity and exactness, were thought enough to fit a work for the public view: every sentiment and expression were to be maturely weighed, and turned on all sides; and not suffered to pass, unless every word were a pearl, and every page beset with

gems. So that they put the reader in possession in a single hour, of what had cost them perhaps ten years' intense thought and application. Such were those books, which were reputed "cedro digni," fit to be anointed with cedar-juice, and thus rendered incorruptible, for the instruction of all future ages.

Books, for the origin of, we have nothing that is clear: the books of Moses are doubtless the oldest of all that are extant; but there were books before them, for Moses cites several. A book of Enoch is cited in the epistle of Jude, v. 14. and 15. from which some endeavour to prove the reality of antediluvian writings; but the book cited by that apostle is generally allowed both by ancient and modern writers to be spurious. See BIBLE.

Of prophane books, the oldest extant are Homer's poems, which were even so in the time of Sextus Empiricus; though we find mention in Greek writers, of about seventy others prior to Homer; as Hermes, Orpheus, Daphne, Horus, Linus, Musæus, Palamedes, Zoroaster, &c. but of the greater part of these, there is not the least fragment remaining; and of the others, the pieces which go under their names are generally held by the learned supposititious. F. Hardouin goes farther: charging all the ancient books, both Greek and Latin, except Cicero, Pliny, Virgil's Georgics, Horace's Satires and Epistles, Herodotus, and Homer, as spurious, and forged in the thirteenth century, by a club of persons under the direction of one Severus Arcontius. Fab. Bib. Græc. lib. i. cap. 1. § 1. § 6. tom. i. Hardouin de Num. Herod. in Proluf. Act. Erud. Lips. an. 1710. p. 70.

Among the Greeks, it is to be observed, the oldest books were in verse, which was prior to prose; Herodotus's history is the oldest book extant of the prosaic kind. Strabo. Geog. lib. i. Heuman. Via ad Hist. Liter. § 20. p. 50. § 21. p. 52.

Books, the multitude of, has been long complained of: the complaint is as old as Solomon, who lived three thousand years ago: they are grown too numerous, not only to procure and read, but to see, to learn the names of, or even to number. England has more to fear on this score, than other countries; since, besides our own produce, we have, for some years past, drained our neighbours. However, as bishop Caramuel's scheme miscarried, which was to write about a hundred volumes in folio, and then prevail on the civil and military powers to oblige all their subjects to read them, we need not much regret the multitude of books.

In reality, there are few of the immense number of books which deserve seriously to be studied: for the rest, part of them, like this, are only to be occasionally consulted, and the rest read for amusement. A mathematician, for instance, ought not to be entirely ignorant of what is contained in the mathematical books: but then a general knowledge is sufficient, which may easily be had by running over the chief authors; out of whom references may be made, directing to the places where they may be found, when wanted. For there are many things which are much better preserved in books than in the memory; as astronomical observations, tables, rules, theorems, proportions, and in fine, whatever does not spontaneously adhere to the memory, when once known. For the less we crowd that faculty, the readier and freer will the genius remain for inventing.

Other books may be valuable in themselves, for some special purpose, or in some peculiar science, but are not fit to be perused except by those who are engaged in that particular science, or business. To what use is it for a divine, or a physician, or a tradesman, to read over the huge volumes of reports of adjudged cases in the law? Or for a lawyer to learn Hebrew and read the Rabbins, unless his inclination

leads him, and his leisure allows him to employ himself in this way? For improvement of knowledge and saving of time, it is of great importance for young persons to have the most proper books for his reading, recommended by a judicious friend.

Books of importance of any kind, and especially complete treatises on any subject, should be first read in a more general and cursory manner, to learn in some degree what the treatise promises, and what you may expect from the writer's manner and skill. For this purpose let the preface be read, and the table of contents, if there be any, before this first survey of the book. By this means you will not only be better fitted to give the book a first reading, but be much assisted in a second perusal of it, which should be done with greater attention and deliberation, and you will learn with more ease and readiness what the author professes to teach. In reading it will be useful to mark what is new or unknown to you before, and to review those chapters, pages, or paragraphs. Unless a reader has an uncommon and most retentive memory, we may venture to affirm, that there is scarcely any book or chapter worth reading once, that is not worthy of a second perusal. At least it will be proper carefully to review all the lines or paragraphs which were previously marked, and to recollect the sections which were thought truly valuable. There is another reason why it will be useful to take a superficial and cursory survey of a book, before we sit down to read it, and to dwell upon it with studious attention; and that is, that there may be several difficulties in it, which we cannot easily understand and resolve at the first reading, for want of a fuller comprehension of the author's whole scheme. Many such difficulties would be unravelled when we have proceeded farther in such books, or would vanish themselves upon a second reading. What we cannot thoroughly understand at first may be noted down as matter of subsequent consideration and inquiry, if the pages that follow do not happen to strike a complete light on those which went before. In perusing books that treat of subjects of natural, moral, or divine science, it should be considered that it is our business, not merely to know the opinion of the author, for this is but the mere knowledge of history; but truly to reflect, whether his opinions are just or not, and to improve our own knowledge of the subject by a careful investigation of it. With this view we should deal freely with every author whose works we read, and yield our assent only to evidence and just reasoning. If a writer on any particular subject, to which your attention is directed, maintains sentiments similar to your own, but does not explain his ideas, or prove his positions to your satisfaction, mark his defects, or faults, and endeavour to do it better, either in the margin of your book, or rather on some papers of your own. e. g. When the author is obscure, enlighten him; where he is imperfect, supply his deficiencies; where he is too concise, amplify, and set his notion, in a fairer view; where he is redundant, mark the paragraphs that ought to be retrenched; where he trifles and indulges to impertinence, abandon those passages, or pages; where he argues, observe whether his reasons be conclusive; if the conclusion be true, but the argument weak, endeavour to confirm it by better proofs; where he deduces any propositions obscurely, or doubtfully, make the justness of the inference to appear, and add further inferences or corollaries, if such occur to your mind; where you suppose he is mistaken, propose your objections, and correct his errors; what he writes so well as to approve itself to your judgment, as both just and useful, treasure up in your memory, and count it a part of your intellectual gains. If the method of a book be irregular, reduce it into form,

by an analysis of your own, or by hints in the margin : if those things are heaped together, which should be separated, distinguish and divide them. If several things relating to the same subject are scattered through various parts of the same treatise, let them be brought together into one view, by suitable references ; or if the matter of a book be really valuable and deserving the labour, you may arrange it in a better method, reduce it to a more logical scheme, or abridge it into a lesser form. All these practices will have a tendency to advance your own skill in logic and method, to improve your judgment in general, and to give you a more comprehensive survey of that subject in particular. When you have finished the treatise, with all your observations upon it, recollect and determine what real improvements you have made by reading that author. If a book have no index, or good table of contents, it is useful to make such as you are reading it ; taking notice merely of those parts which are new and well written, and well worthy of remembrance, or review. If the writer be remarkable for any peculiar excellencies, or defects in his style, or manner of writing, attentively observe them, and whatever ornaments or blemishes occur in the language, or manner of the writer, you may make just remarks upon them. One book perused in the manner now proposed, will tend more to enrich the understanding, than skimming over the surface of 20 authors. " There are many who read," says the excellent author of whose useful observations we are now availing ourselves, (see Watts's Improvement of the Mind) " with constancy and diligence, and yet make no advances in true knowledge by it. They are delighted with the notions which they read, or hear, as they would be with stories that are told, but they do not weigh them in their minds as in a just balance, in order to determine their truth, or falshood ; they make no observations upon them, or inference from them. Perhaps their eye slides over the pages, or the words slide over their ears, and vanish like a rhapsody of evening tales, or the shadows of a cloud flying over a green field in a summer's day ; or, if they review them sufficiently to fix them in their remembrance, it is merely with a design to tell the tale over again, and to shew what men of learning they are. Thus they dream out their days in a course of reading without real advantage. As a man may be eating all day, and for want of digestion is never nourished ; so these endless readers may cram themselves in vain with intellectual food, and without real improvement of their minds, for want of digesting it by proper reflection."

" Never apply yourselves," says the same writer, " to read any human author with a determination, before-hand, either for or against him, or with a settled resolution to believe, or disbelieve, to confirm, or oppose whatsoever he saith ; but always read with a design to lay your mind open to truth, and to embrace it wheresoever you find it, as well as to reject every falshood, though it appear under never so fair a disguise. How unhappy are those men, who seldom take an author in their hands, but they have determined before they begin, whether they will like or dislike him ! They have got some notion of his name, his character, his party, or his principles, by general conversation, or perhaps by some slight view of a few pages ; and having all their own opinions adjusted before-hand, they read all that he writes with a prepossession either for or against him : unhappy those who hunt and purvey for a party, and scrape together out of every author, all those things, and those only which favour their own tenets, while they despise and neglect all the rest !" The author subjoins an useful caution ; and wishes not to be understood, as persuading a person to live without any settled principles, by which to judge of books, men, and

things, or to be always doubting about his foundations. But having settled, upon good grounds, the most necessary and important principles of science, prudence, and religion, we should read, with a just freedom of thought, all those books which treat of such subjects as may admit of doubt, or reasonable dispute. When we peruse those authors who defend our own settled sentiments, we should not hastily conclude that all their reasonings are just and solid ; nor eagerly embrace all their lesser opinions, because we agree with them in the greater. When we read those authors who oppose our most certain and established principles, we should be ready to receive any information from them in other points, and not abandon every thing they say, though we are well fixed in opposition to their main object :

" Seize upon truth where-e'er 'tis found,
Amongst your friends, amongst your foes,
On Christian, or on heathen ground ;
The flower's divine where-e'er it grows ;
Neglect the prickles, and assume the rose."

Upon the plan of reading above stated and recommended, a few books well chosen, and thoroughly studied, may suffice. It may be added, that as knowledge is naturally advantageous, and as every man ought to be in the way of information, even a superfluity of books is not without its use, since hereby they are brought to obtrude themselves on us, and engage us when we had least design. This advantage, an ancient father observes, we owe to the multiplicity of books on the same subject, that one falls in the way of one man, and another best suits the level, or the apprehension, of another. " Every thing that is written," says he, " does not come into the hands of all persons : perhaps some may meet with my books, who may hear nothing of others which have treated better of the same subject. It is of service, therefore, that the same questions be handled by several persons, and after different methods, though all on the same principles, that the explications of difficulties, and arguments for the truth, may come to the knowledge of every one, by one way or other." Add, that the multitude is the only security against the total loss or destruction of books : it is this that has preserved them against the injuries of time, the rage of tyrants, the zeal of persecutors, and the ravages of barbarians ; and handed them down, through long intervals of darkness and ignorance, safe to our days. " Solaque non norunt hec monumenta mori." *Bac. de Augm. Sc. lib. i. August. de Trin. lib. i. cap. 3. Barthol. lib. cit. Diff. i. p. 8, &c.*

Books, *the scarcity of*, is an evil much more to be lamented, in the survey of past ages, than their multitude at any later period. Before the art of printing was invented, the trouble and expence of procuring copies very much retarded the progress of literature. The universal ignorance that prevailed in Europe, from the seventh to the eleventh century, may be ascribed to the scarcity of books during that period, and the difficulty of rendering them more common, concurring with other causes arising from the state of government and manners. The Romans wrote their books either on parchment, or on paper made of the Egyptian papyrus. The latter, being the cheapest, was of course the most commonly used. But after the Saracens conquered Egypt, in the seventh century, the communication between that country and the people settled in Italy, or in other parts of Europe, was almost entirely broken off, and the papyrus was no longer in use among them. They were obliged on that account to write all their books upon parchment ; and as the price of that was high, books became extremely rare and of great value. We may judge of the scarcity of materials for writing them from one circumstance.

There still remain several manuscripts of the 8th, 9th, and following centuries, wrote on parchment, from which some former writing had been erased, in order to substitute a new composition in its place. Thus, it is probable, several of the works of the ancients perished. A book of Livy or of Tacitus might be erased, to make room for the legendary tale of a saint, or the superstitious prayers of a missal. As the want of materials for writing accounts for the loss of many of the works of the ancients, and for the small number of MSS. previous to the 11th century, many facts prove the scarcity of books at this period. Private persons seldom possessed any books whatever; and even monasteries of note had only one missal. Towards the end of the seventh century, even in the papal library at Rome, the number of books was so inconsiderable, that pope St. Martin requested Sanctamand, bishop of Maestricht, if possible, to supply this defect from the remotest parts of Germany. In the year 855, Lupus, abbot of Ferrieres in France, sent two of his monks to pope Benedict III. to beg a copy of Cicero de Oratore and Quintilian's Institutes; "for," says the abbot, "although we have part of these books, there is no complete copy of them in all France." At the beginning of the tenth century books were so scarce in Spain, that one and the same copy of the bible, Jerome's epistles, and some volumes of ecclesiastical offices and martyrologies, often served several different monasteries. Among the constitutions given to the monks of England by archbishop Lanfranc, in 1072, the following injunction occurs: At the beginning of Lent, the librarian is ordered to deliver a book to each of the religious, for the perusal of which a whole year was allowed; and at the returning Lent, those monks who had neglected to read the books they had respectively received, are commanded to prostrate themselves before the abbot, and supplicate his forgiveness. In 1299, John de Pontiffara, bishop of Winchester, borrows of his cathedral convent of St. Swithin, at Winchester, "bibliam bene glossatam," that is, the bible, with marginal annotations, in two folio volumes; but gives a bond for the return of it, drawn up with great solemnity. For the bequest of this bible to the convent, and 100 marks, the monks founded a daily mass for the soul of the donor. If any person gave a book to a religious house, he believed, that so valuable a donation merited eternal salvation, and he offered it on the altar with great ceremony. The prior and convent of Rochester declare, that they will every year pronounce the irrevocable sentence of damnation on him, who shall purloin or conceal a Latin translation of Aristotle's Poetics, or even obliterate the title. Sometimes a book was given to a monastery, on condition that the donor should have the use of it for his life; and sometimes to a private person, with the reservation that he who receives it should pray for the soul of his benefactor. In the year 1225, Roger de Infula, dean of York, gave several Latin bibles to the university of Oxford, on condition that the students who perused them, should deposit a cautionary pledge. The library of that university, before the year 1300, consisted only of a few tracts, chained or kept in chests, in the choir of St. Mary's church. Among the statutes of St. Mary's college at Oxford, in 1446, one is, that no scholar should occupy a book in the library above one hour, or two hours at most, so that others shall be hindered from the use of the same. The famous library established in the university of Oxford by Humphrey duke of Gloucester, a munificent patron of literature, contained only 600 volumes. About the beginning of the 14th century, there were only four classics in the university of Paris, which were single copies of Cicero, Ovid, Lucan, and Boethius.

The price of books became so high, that persons of a moderate fortune could not afford to purchase them. In the year 1174, Walter, prior of St. Swithin's at Winchester, purchased of the monks of Dorchester, in Oxfordshire, Bede's homilies and St. Austin's psalter for twelve measures of barley and a pall, on which was embroidered in silver the history of St. Birinus converting a Saxon king. About the year 1400, a copy of John of Meun's "Roman de la Rose" was sold before the palace-gate at Paris for 40 crowns, or 33l. 6s. 6d. The countess of Anjou paid, for a copy of the homilies of Haimon, bishop of Halberstadt, 200 sheep, five quarters of wheat, and the same quantity of rye and millet. Even so late as the year 1471, when Louis XI. of France borrowed the works of Rhafis, the Arabian physician, from the faculty of medicine at Paris, he not only deposited by way of pledge a considerable quantity of plate, but he was obliged to procure a nobleman to join with him as surety in a deed, binding himself under a great forfeiture to restore it. Many other instances might be cited, in order to shew how scarce books were at the period to which we now refer, and with what difficulty, and at what extravagant prices, copies of them were procured; and therefore we can be at no loss in accounting for the extreme ignorance that prevailed. But when, in the 11th century, the art of making paper was invented, and more especially after the manufacture became general, the number of MSS. increased, and the study of the sciences was wonderfully facilitated. Indeed, the invention of the art of making paper, and the invention of the art of printing, are two very memorable events in the history of literature and of human civilization. It is remarkable, that the former preceded the first dawning of letters and improvement in knowledge, towards the close of the eleventh century; and the latter ushered in the light which spread over Europe at the æra of the reformation. Murat. Antiq. Ital. vol. iii. vol. ix. Mem. de l'Acad. des Inscrip. tom. ix. Hist. Lit. de France, par des Religieux Benedictins, tom. vii. Naudé Addit. a l'histoire de Louis XI. par Comines, ed. Frefroy, tom. iv. Robertson's Hist. Ch. v. vol. i. Wharton's Eng. Poetry, vol. i. diss. 2.

Books, to form a judgment of. Those who have treated of the subject, direct us to observe the title, the author's or editor's name, the number of the edition, the place where and the year when it is printed (which in old books is frequently marked at the end), and the printer's name, especially if it be a celebrated one; proceed then to the preface, and index of contents, and look for the author's design, and the occasion of his writing; consider also his country (each nation having its peculiar genius), which may sometimes be learned from the dedication; if his life be annexed, run it over, and note his profession, what rank he was of, and any thing remarkable that attended his education, studies, conversation, or correspondences with learned men; not forgetting the eulogies which have been given to the author, which often occur at the beginning, or even any critique or censure, especially if made by a man of judgment. If the preface does not give an account of the method of the work, run briefly over the order and disposition of it, and note what points the author has handled; observe whether the things and sentiments he produces be trite and vulgar, or solid, and fetched from greater depths. Note, whether he go in the common road, or make any innovation, and introduce any new principle.

But it is a small number of books we have opportunity of thus judging of by perusing them; besides, when we have read a book over, the judgment comes too late for many purposes. Life is too short, and time is too precious, to read every new book quite over, in order to find that it is

not worth reading. It seems necessary, therefore, to have other indications, whereby to prevent our being at the charge of procuring, or the pains of perusing a worthless book. Divers rules of this kind are given by Baillet, Struvius, Stollius, and others; which, though in reality no more than presumptions, and frequently liable to be falsified, are not without their use. The journalists de Trevoux objected to them all: "The shortest way," say they, "to judge of a book is to read it, if you be qualified in the subject; otherwise to refer yourself to those who are so." Heuman is somewhat more explicit; making it a mark that "a book is good, when it is esteemed by persons intelligent in the subject it treats of; and when those who commend it receive no advantage from the applause they bestow on it, nor are leagued with the author in any cabal, for espousing any particular principle, system, or party, in religion or learning." Baillet, Jugem. des Scav. tom. i. b. ii. p. 121. Struv. Introd. ad Not. Rei Liter. cap. 5. § 3. p. 390. Stoll. Introd. Hist. Liter. p. i. § 11. p. 9. Budd. de Criteriis boni libri, passim. Mem. de Trev. an. 1712. Art. 17. Heuman. Comp. Reipubl. Liter. cap. vi. § 11. p. 280.

But more particularly, it is an indication that a book is good; 1. If the author be known to excel in that talent more immediately necessary for such a subject; or have already published any thing on the same that is esteemed. Thus we may conclude, that Julius Cæsar will teach us the art of war better than Peter Ramus; Cato, Palladius, and Columella, agriculture better than Aristotle; and Cicero, oratory better than M. Varro: add, that it is not enough the author be skilled in the faculty, but that he be so in the particular branches of it, concerning which he treats; some, for instance, excel in the civil law, yet not in the public law; Salmatus proved himself an excellent critic in his Exercitatus. Plinian. but was much inferior to Milton in his Defensio Regia. 2. If the book be on a subject that requires great reading, it may be presumed good, if the author had a copious library, or could have access to one; or if he lived in a place where books were not wanting; though here is danger too of running into excess of quotations; especially, says Struvius, if the author be a lawyer. 3. A book which took up a long time in composing, cannot often fail of being good. 4. Books on points of doctrine by eclectic writers, are to be presumed better than those writ by the retainers to particular sects. 5. The age of a writer may also give us some indication: books, which require labour, are usually better performed by younger persons than those who are far advanced in years. 6. Another indication may be taken from the author's state and condition: thus, history written by a person who was an eye-witness to what he relates, or is concerned in public affairs, or has access to the public records, or other monuments, from whence intelligence may be drawn; who is not biassed by party, or any other indirect or sinister motive, will be supposed to be good. Thus Sallust and Cicero were well able to write the history of Cataline's conspiracy. D'Avila, de Comines, Guicciardin, Clarendon, &c. were present in the civil wars they describe; Xenophon, having an employment in the Spartan state, has treated excellently of that commonwealth; and Amelot de la Houffaye, by living long at Venice, was enabled to explain the secrets of their policy. Camden wrote annals of the affairs of his own time; Thuanus had correspondence with the best writers in every country; and Puffendorf had access to the public archives. So, in literary matters, we give credit to those who have the direction of libraries. 7. The time or age wherein the author lived may give some light; every age having, according to Barclay, its peculiar

genius and excellency. See Bartholin. Struv. Budd Heuman. Bail. lib. cit.

Some judge by the bulk or size of books; following the grammarian Callimachus's rule, that every great book is of course an ill one, *μεγα βιβλιον, μεγα κικρον*; a single leaf of the Sybil was doubtless preferable to the vast annals of Volubius: yet Pliny's observations will nevertheless hold true, that "a good book is so much the better by how much it is bigger." Plin. Epist. 20. lib. i. Martial prescribes a remedy against the largeness of a book, when that is the only complaint, read but a little of it:

"Si nimius videar, seraque coronide longus
Esse liber, legito pauca, libellus ero."

Yet is the smallness of a book a real presumption in its favour: he must be a poor author, who cannot furnish a pamphlet, or loose sheet, with things curious, and written with spirit; but to support the fame through a volume in folio, requires very extraordinary abilities indeed. Addis. in Spec. N^o 124.

There are some general mistakes, which persons are frequently guilty of in passing judgment on the books which they read. One is, when a treatise is written but tolerably well, we are ready to pronounce a favourable judgment of it, and sometimes to exalt its character far beyond its merit, if it agree with our own principles and support the opinions of our party. On the other hand, if the author be of different sentiments, and espouse contrary principles, we can find neither wit nor reason, good sense, nor good language in it. For avoiding or correcting this error, it should be considered, that books are never to be judged of merely by their subject, or the opinion they represent, but by the justness of their sentiments, the beauty of their manner, the force of their expression, or the strength of reason, and the weight of just and proper argument, which appear in them. Another mistake, which some persons fall into, is this: When they read a treatise on any subject, with which they have but little acquaintance, they find almost every thing new and strange to them, their understandings are much gratified and improved by many things unknown to them before; and hence they are led to admire the treatise, and commend the author: whereas, if they had previously attained a considerable degree of skill in that science, perhaps they would have found that the author had written very indifferently, that neither his sense nor his method was just and proper, and that he delivered nothing that was not very common or very trivial, in his discourses on that subject. On the other hand, if we have made ourselves masters of any particular theme of knowledge, and surveyed it long on all sides, there is scarcely any writer who much pleases us afterwards, because we find little or nothing new in him; and yet in a true judgment perhaps his sentiments are unexceptionably just, his illustrations clear, and his reasonings forcible, and all the parts of the discourse are well connected and set in a happy light; but we knew most of these things before, and therefore they do not strike us, and we are in danger of discommending them. There are some other follies into which persons are apt to be betrayed in forming their judgment of books. Some persons, who are of a forward and lively temper, and who are fond of intermeddling with all appearances of knowledge, will give their judgment of a book as soon as the title of it is mentioned. for they would not seem ignorant of any thing that others know; and especially, if they happen to have any superior character or possessions, they fancy they have a right to talk freely and to pronounce magisterially on every thing, even of a literary kind, that occurs. Thus, blind men will talk of the beauty

beauty of colours, and of the harmony or disproportion of figures in painting; the deaf will prate of discords in music; and those who have no pretensions to literature, will pronounce, with an unpardonable presumption, on books of science; and those who have little or no acquaintance with either the speculative or practical principles of religion, will arraign the best treatise on divine subjects, though they do not understand the very language of the Scripture, nor the common terms or phrases used in Christianity. Judges of another description set themselves up to decide in favour of an author, or against him, according to the company they have kept, and the judgment pronounced concerning a book by others of their own stamp or size, though they have no knowledge or taste of the subject themselves. These, with a fluent and voluble tongue, become mere echoes of the praises or censures of other men. Others, again, pass judgment from the secret stimulations of vanity, pride, or envy; and in order to justify an unwarrantable and severe censure, they will allege a mistake or two, which they have discovered, or a few sentiments and expressions not suited to their capricious taste and humour. It is, however, an indication of perverseness and prejudice, to rail at any human performance because it is not absolutely perfect. Horace has given us a better example:

“Sunt delicta tamen, quibus ignovisse velimus:
Nam neque chorda sonum reddit, quem vult manus, et
mens,

Posteque gravem per sepe remittit acutum;
Nec semper feriet quodcumque minabitur arcus
Verum, ubi plura nitent in carmine, non ego paucis
Offendam maculis, quas aut incuria fudit,
Aut humana parum cavit natura.”— De Art. Poet.

“Be not too rigidly censorious:
A string may jar in the best master’s hand,
And the most skilful archer miss his aim;
So in a poem elegantly writ,
I will not quarrel with a small mistake,
Such as our nature’s frailty may excuse.” RosCOMMON.

Another, and very frequent fault in passing judgment upon books, is this, that persons spread the same praises, or the same reproaches, over a whole treatise, which are justly applicable only to some detached parts of it. After all, when any person pretends to give his judgment of a book, we should consider whether he be a capable judge, or whether he may not lie under some unhappy bias or prejudice, for or against it, or whether he has made a sufficient inquiry to enable him for forming a just opinion. Watts’s Improvement of the Mind apud Works, vol. v. ch. 4—5.

See farther concerning books, in the writers on literary history, libraries, studies, learning, arts, and sciences; more especially in Salden, Bartholin, Hodannus, Sacchinus, Baillet, Buddeus, Saalbach, Putherbeus, Raynaud, Schufner, Lauffer, Schwartzius, Crenius, Morhoff, and others, who have written treatises expressly concerning books. Erud. Lips. an. 1704*, p. 526, & seq.

The importation or sale of mass-books, or other popish books, is by stat. 3 Jac. I. c. 5. § 25. liable to a penalty of forty shillings.

The importation of books first printed in this kingdom, and reprinted abroad, is prohibited under a penalty of 5l. and double the value of every book so imported and sold. *Vide stat. 12 Geo. II. c. 36. § 1.*

There was a clause in the statute of the 8th of queen Anne, c. 19. empowering the chancellor, and some other great officers of state, to set the price of books; but this is now repealed by 12 Geo. II. c. 36. § 2.

The sole right of printing books bequeathed to the two universities of England, the four universities of Scotland, and the colleges of Eton, Westminster, and Winchester, are secured to them by stat. 15 Geo. III. c. 53. See *LITERARY Property*.

Books, *burning of*, was a kind of punishment sanctioned, both among the Greeks and Romans, by legal sentence. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected, were burnt by the public crier. Diogenes Laert. l. ix. 52. At Rome, the writings of Numa, which had been found in his grave, were, by order of the senate, condemned to the fire, because they were contrary to the religion which he had introduced. Liv. l. xl. c. 29. Plin. xiii. 13. Plutarch. in vit. Numæ. As the populace of Rome were, in times of public calamity, more addicted to superstition than seemed proper to the government, an order was issued that all superstitious and astrological books should be delivered into the hands of the prætor. This order was often repeated; and the emperor Augustus caused more than 20,000 of these books to be burned at one time. Liv. l. xxv. c. 1. l. xxxix. 16. Tacit. *Annal.* vi. 12. Sueton. l. ii. c. 31. Sometimes the care of the execution of the sentence for burning books was committed to *triumviri* appointed on purpose; sometimes to the prætors; and sometimes to the ædiles. Labienus, whom from his satirical spirit some have called *Rabienus*, is said to have been the first who underwent the severity of it, under the emperor Augustus. His enemies procured a *senatusconsultum*, whereby all his books, published during several years, were ordered to be collected and burnt. The thing, says Seneca, (in the introduction to the fifth, or, as others reckon, the 10th book of his “*Controvertiæ*,”) then appeared new and strange to take revenge on learning! “*Res nova et infæcta, supplicia de studiis sumi!*” Cassius Severus, a friend of Labienus, hearing the sentence pronounced, cried aloud, that they must burn him too, since he had got all the books by heart; “*Nunc me vivum uri oportet, qui illos edidici.*” Labienus could not survive his books; but shutting himself up in the tomb of his ancestors, pined away, and was buried alive. It is related as somewhat singular, that a few years after, the writings of the person, who had been the cause of the order for burning Labienus’s books, shared the like fate, and were also publicly burned. In a manner somewhat similar, the works of Ben-Arias Montanus, who assisted to make the first catalogue of prohibited books, in the Netherlands,

therlands, were afterwards inserted in a catalogue of the same kind. The expression of Cassius above cited gave occasion to a law of Augustus against abusive writings. Tacit. Annal. l. i. c. 72. When Crenutius Cordus, in his History, called C. Cassius the last of the Romans, the ferate, in order to flatter Tiberius, caused the book to be burned; but a number of copies were concealed and preserved from the flames. Tacit. Annal. l. iv. c. 35. Antiochus Epiphanes caused the books of the Jews to be burned; and in the first centuries of our era, the books of the Christians were treated with equal severity, of which Arnobius (Adv. Gentes, l. iii. & iv.) bitterly complains. Eusebius informs us (Hist. Eccl. l. viii. c. 2.), that Dioclesian caused the sacred scriptures to be burned. After the spreading of the Christian religion, the clergy exercised against books that were either unfavourable or disagreeable to them, the same severity which they had censured in the heathens as foolish and prejudicial to their own cause. Thus, were the writings of Arius condemned to the flames at the council of Nice; and Constantine threatened with the punishment of death those who should conceal them. Socrates, l. i. c. 6. The clergy assembled at the council of Ephesus, requested the emperor Theodosius II. to cause the works of Nestorius to be burned, and their request was complied with. Cod. l. i. tit. 5, 6. The writings of Eutyches shared the like fate at the council of Chalcedon; and the same practice of burning books thought to be heretical with regard to religion, or injurious to the state in a political view, has been imitated in subsequent ages, and in various nations even of the Christian world.

Divers other ancient testimonies concerning the burning of books are given in Reimm. Idea Syst. Antiq. Liter. p. 389.

BOOKS, *whitening of.* The following process for whitening prints, printed books, and paper, has been announced and described by M. Chaptal. Simple immersion in oxygenated muriatic acid, for a longer or shorter space of time, according to the strength of the liquid, will suffice to whiten an engraving. But in whitening the paper of a bound book, it is necessary that all the leaves should be moistened by the acid, and therefore the book must be well opened, and the leaves separated; and the boards must be made to rest on the edge of the vessel containing the whitening liquor. This liquor in the process assumes a yellow tint, and the paper becomes proportionably white. At the end of two or three hours, the book may be taken from the acid liquor and plunged into pure water; and the water should be renewed every hour to extract the remaining acid, and to dissipate the disagreeable smell. In order to render this process more effectual, the book-binders destroy the binding, unfasten the book, and separate its leaves; they then place these in cases formed in a leaden tub, with very thin slips of wood or glass, so that the leaves may lie flat and separate from one another at very small intervals. The acid is then gently poured into the tub, without deranging the leaves. When the paper is become sufficiently white, the acid liquor is drawn off by a cock at the bottom of the tub; and its place is supplied by clear, fresh water. The leaves are then dried, and, after being pressed, re-bound. The leaves may with greater advantage be placed vertically in the tub. With this view, M. Chaptal constructed a wooden frame, adjusted to the proper height, according to the size of the leaves proposed to be whitened. This frame supported very thin slips of wood, at the distance from one another of half a line. In each of these intervals he placed two leaves, and kept them

fixed in their place by two small wooden wedges, pushed in between the slips. When the paper was whitened, he lifted up the frame with the leaves, and plunged them into cold water, to take off the remaining acid, as well as the smell. By this operation books are not only cleaned, but the paper acquires a degree of whiteness superior to what it possessed when first made. This acid will also serve to destroy ink spots; but it has no action upon spots of oil, or animal grease; however, a weak solution of pot-ash will effectually remove stains of that kind. To oxygenate the muriatic acid, it is only necessary to dilute it, and mix it in a very strong glass vessel with manganese, in such a manner that the mixture may not occupy the whole content of the glass. Air-bubbles are formed upon the surface of the liquor; the empty space is filled with a greenish vapour; and, at the end of some hours, the acid may be further diluted with water, and then used. In order to remove spots of grease from books and prints, M. Deschamps, member of the Philosophical Society at Lyons, recommends to take out as much as possible of it by means of blotting paper; and then to dip a small brush in the essential oil of well rectified spirit of turpentine, heated almost to ebullition, and draw it gently over both sides of the paper, which must be carefully kept warm. This operation must be repeated as often as the quantity of grease imbibed by the paper, or the thickness of the paper, may render necessary. When the grease is entirely removed, the paper may be restored to its former whiteness, by dipping another brush in highly rectified spirit of wine, and drawing it, in like manner, over the place which was stained, and particularly round the edges, to remove the border that would still present a stain. Bibliotheque Economique, vol. i. See BLEACHING.

BOOK, *common-place.* See COMMON-PLACE.

BOOK, *text.* See TEXT.

BOOK, is also used for a part or division of a volume, or large work.

In this sense we say the book of Genesis, the first book of Kings, the five books of Moses, &c.—The Digest is contained in fifty books, the Code in twelve books.

Books are usually subdivided into chapters, sometimes into sections, or paragraphs: accurate writers quote chapter and book.

BOOK is also used for a list or catalogue of persons' names.—Such among the ancients were the *censores' books*, being tables or registers containing the names of all those who were censured or taxed under Augustus. Tertullian assures us, that our Saviour's name was found in the censorial book of Augustus. Adv. Marcion. lib. iv. cap. 7. See CENSUS.

BOOKS, in *Matters of Commerce*, denote the several registers wherein merchants and other dealers keep their accounts. Hence to *book*, is to register in a book.

We say, such a person's books are in good order; merchants cannot possibly do without books; they are even obliged by the laws to keep books. But more or fewer are required, according to the nature or extent of their dealings, or the precision and exactness they desire therein.

The ancients had also their books of accounts; witness the *codex accepti & expensi*, so often mentioned in Roman writers; and the *patrimonial books*, which were rentals, containing an account of the lands, goods, and chattels, and other effects belonging to each person.

Among the defects to which the trial by jury is subject, one is the want of a compulsive power for the production of books and papers belonging to the parties. In the hands of third persons, they can generally be obtained by rule of court, or by adding a clause of requisition to the writ or "subpoena," which is then called a "subpoena duces tecum."

But, in mercantile transactions especially, the right of the party's own books is frequently decisive; as the day-book of a trader, when the transaction was recently entered, as really understood at the time; though subsequent events may tempt him to give it a different colour. And, as this evidence may finally be obtained, and produced on a trial at law, by the circuitous course of filing a bill in equity, the want of an original power for the same purposes in the courts of law is a material defect.

BOOK-BINDING, the art of sewing together the sheets of a book, and covering them with a back, and strong paste-board sides, secured with leather, &c.

Binding is distinguished from stitching, as in the latter the leaves are only sewed, without bands or backs.

We say, *French-binding*, *law-binding*, *marble-binding*, *binding* in parchment, in sheep, in calves leather, &c. also *half-binding*, wherein the leaves are generally left uncut, and only the back covered with leather, the pasteboard sides being covered with marbled, or blue paper. *Dutch-binding* is where the backs are of vellum. The Italians are still contented to bind in a coarse, thick paper, called *binding alla rustica*, the inconvenience of which is its being liable to wear out without careful use. Without doubt, the art of binding is almost as ancient as the science of composing books; and both the one and the other followed immediately the first invention of letters. Whatever the matter might be, on which men first wrote, there was a necessity of uniting the several parts together; as well for the making them of one piece, as for the better preserving them; hence the origin of *book-binding*.

According to Olympiodorus (apud Phot.) it was one Phillatius, a learned man at Athens, who first taught the use of a kind of glue, to fasten the several leaves together; on which account a statue was erected to him.

Books, the manner of binding in volumes, i. e. of gluing the leaves together; that of rolling them on round pieces, or cylinders of wood, appears the most ancient; though that of binding them square, and of sewing several quires one over another, lays claim to considerable antiquity. The first of the two, which we call *Egyptian* binding, held a long time after the age of Augustus; but it is now disused, excepting in the Jewish synagogues, where they continue to write the books of the law on vellum sewed together; making, as it were, only one long page, with two rollers and their clasps of gold and silver, at each extremity.

The form now in use is the *square-binding*, which is said to have been invented by one of the Attali, kings of Pergamus; to whom we likewise owe the manner of preparing parchment, called in Latin, from the name of his capital, *Pergamena*, or *Charta Pergamea*.

Books, manner of binding. The first operation is to fold the sheets according to the form, viz. into two leaves for folios, four for quartos, eight for octavos, &c. which the workmen do with a slip of ivory or box, called a *folding-stick*; in this they are directed by the catch-words and signatures, which are the letters with the numbers annexed to them, at the bottom of the pages. The leaves thus folded, and laid over each other in the order of the signatures, are beaten on a stone with a heavy hammer to make them solid and smooth, and then pressed. Being thus prepared, they are sewed in a sewing-press, upon pack-threads or cords, which are called bands, at a proper distance from each other, and in a convenient number; which is done by drawing a thread through the middle of each sheet, and giving it a turn round each band, beginning with the first, and proceeding to the last. The common number of bands is six in folios, and five in quartos, octavos, &c. Sometimes they use a

saw to make places for the bands, which are sunk into the paper, so that the back of the book, when bound, is smooth, without any appearance of bands. After this the backs are glued, the ends of the bands being opened, and scraped with a knife, for the more convenient fixing of the paste-boards; then the back is turned with a hammer, the book being fixed in a press between boards, called *backing-boards*, in order to make a groove for admitting the paste-boards. The boards being then applied, holes are made for drawing the bands through, the superfluous ends being cut off, and the parts hammered smooth. Then the book is pressed in order for cutting; which is performed by a particular machine called a *plough*, to which is fixed a knife. After this the book is put into a press called the *cutting-press*, betwixt two boards, the one lying even with the press, for the knife to run upon; the other above it, for the knife to cut against.

The book being cut, the pasteboards are squared with a proper pair of iron shears; and it is then ready for sprinkling, gilding, blacking, or marbling the leaves. The colours with which it is sprinkled, are usually vermilion, or sap-green; which is done with a brush made with hog's bristles, holding the brush in one hand, and moving the hair with the other.

In the *French-binding* a book is put in parchment, i. e. a slip of parchment is applied over the back between each band, and the ends pasted on the inside of each paste-board. This preparation, called *indorsing*, seems peculiar to the French binders; who are enjoined by ordonnance to back their books with parchment on the penalty of 30 livres, and the re-binding of the book; it is done in the press, where the back being grated to make the paste take hold, the parchment is applied; and they afterwards add glue to fortify it.

In 1799 a patent was granted to Mr. John Williams and Mr. Joseph Williams, stationers, London, for an improved method of binding all sorts of books. By the specification it appears, that this invention consists of a back, of a semi-circular, semi-oval, or any other curved form, turned a little at the edges, made of iron, steel, copper, brass, tin, or any other metal, ivory, bone, wood, vellum, paper, leather, or any material capable of retaining a firm situation. This back, being put on the book before bound, so as just to cover but not to press the edges of the paper, will, when the book is opened, prevent its spreading on either side, and cause it to rise in any part which is opened to nearly a level surface. This firm back, turned at the edges, so as to cause all sorts of books to open freely, is the object of this patent. The method of binding, practised by the inventors, is as follows: they forward the paper in the usual manner; sew on vellum slips, glue, cut, clothe, and board, or half-board; and put on the firm back by fastening it at the sides, through holes, by vellum, or securing it by inclosing it in vellum or ferret wrappers, or other matters, passed down upon, or drawn through the boards. Mr. Ebenezer Palmer, stationer of London, obtained a patent in 1800 for an improvement in the mode of binding books, particularly account books of merchants. This consists in the addition of a certain metallic chain, which is made or applied in the following manner: first, provide several small bars of metal, about the thickness of a shilling, or more, according to the size and thickness of the book; the length of each bar being from half an inch to several inches long, in proportion to the strength required in the back of the book. At each end of every bar is made a pivot of different lengths, in proportion to the thickness of two links, which they are to receive. Each link is made in an oval form, and contains two holes, proportioned

portioned to the sizes of the pivots; and these links are of the same metal as the hinge; each of them being nearly equal in length to the width of two bars. The links are then rivetted on the pivots, each pivot receiving two of them, and thus holding the hinge together, on the principle of a link-chain or hinge. There are further two holes or more of different sizes, as required in each bar of the hinge or chain, by means of which each section of the book is strongly fastened to the same; which hinge, so fastened, operates with the back of the book, when bound, in such manner as to occasion the several sections to open so as to bring them on a parallel with each other, and consequently admit the ruled lines being written into, without any inconvenience, close to the back.

Manner of gilding books on the edges. The book, being put tight into the press, between two boards, is scraped with a knife called a *scraper*; and after that with another called a *smoother*, in order to take out all scratches. Being thus made smooth, they scrape a little yellow ochre upon the book, wet it with a little size-water, and rub it off with some clean shavings. The gilding-size is made with the white of an egg, mixed with water, and beat well together. The leaves being wetted with the size-water, with a brush, the gold is then laid upon it, and afterwards dried before the fire. When dried, it is burnished off with a dog's tooth set in a handle. See *GILDING ON PAPER*, &c. Blacking the leaves is done with fine antimony, the leaves being wet, and the antimony rubbed upon them until quite dry, when it is burnished like the gold.

The head-band is now added, which is an ornament of thread or silk, of two or three colours, placed at each extreme of the book, across the leaves, and woven or twisted, sometimes about a single, and sometimes a double piece of rolled paper, or, what is more lasting, of glued paper-thread.

For the covers; the skins used undergo several preparations, which we shall explain in calf, as being the leather most used; and as being that to which all the rest with a little variation may be referred. The calf-skin, being moistened in water, is cut to the size of the book, and the thickness of the edges pared off on a marble stone kept for that purpose. The cover is next smeared over with paste, made of wheat-flour; then stretched over the paste-board on the out-side, and doubled over the edges withinside. They then *cord the book*, or *bind it* firmly between two boards, to make the cover stick the stronger to the paste-boards and the back; on the exact performance of which depends a great part of the truth and neatness of the book. The back is then warmed at the fire to soften the glue, and the leather of the back is rubbed down, with a folding-stick or bodkin, to set and fix it close to the back of the book. It is now set to dry, and when dry, uncorded: the book is then washed over with a little paste and water, the edges and squares blacked with ink, and then sprinkled fine with a brush, by striking it against the hand, or a stick; or with larger spots

mixed with vitriol, which is called *marbling*. Two blank leaves, on each side, are then to be pasted down to the cover, and, when dry, the leaves are *burnished* in the press, and the cover rolled on the edges.

The cover is now glazed twice with the white of an egg; it is then filleted plain, or with gold; and at last polished with a polishing iron, passed hot over the glazed colour. If the book be required to be lettered, they paste a piece of red Morocco on the back, between the first and second band to receive the title in gold letters; and sometimes a second between the next bands underneath, to receive the number of the volume.

The plain binding, properly so called, is now complete; the gilding on the back and cover, as it makes a part of the *book-binder's* business among us (though, with the French, &c. it is a distinct profession), we shall here subjoin.

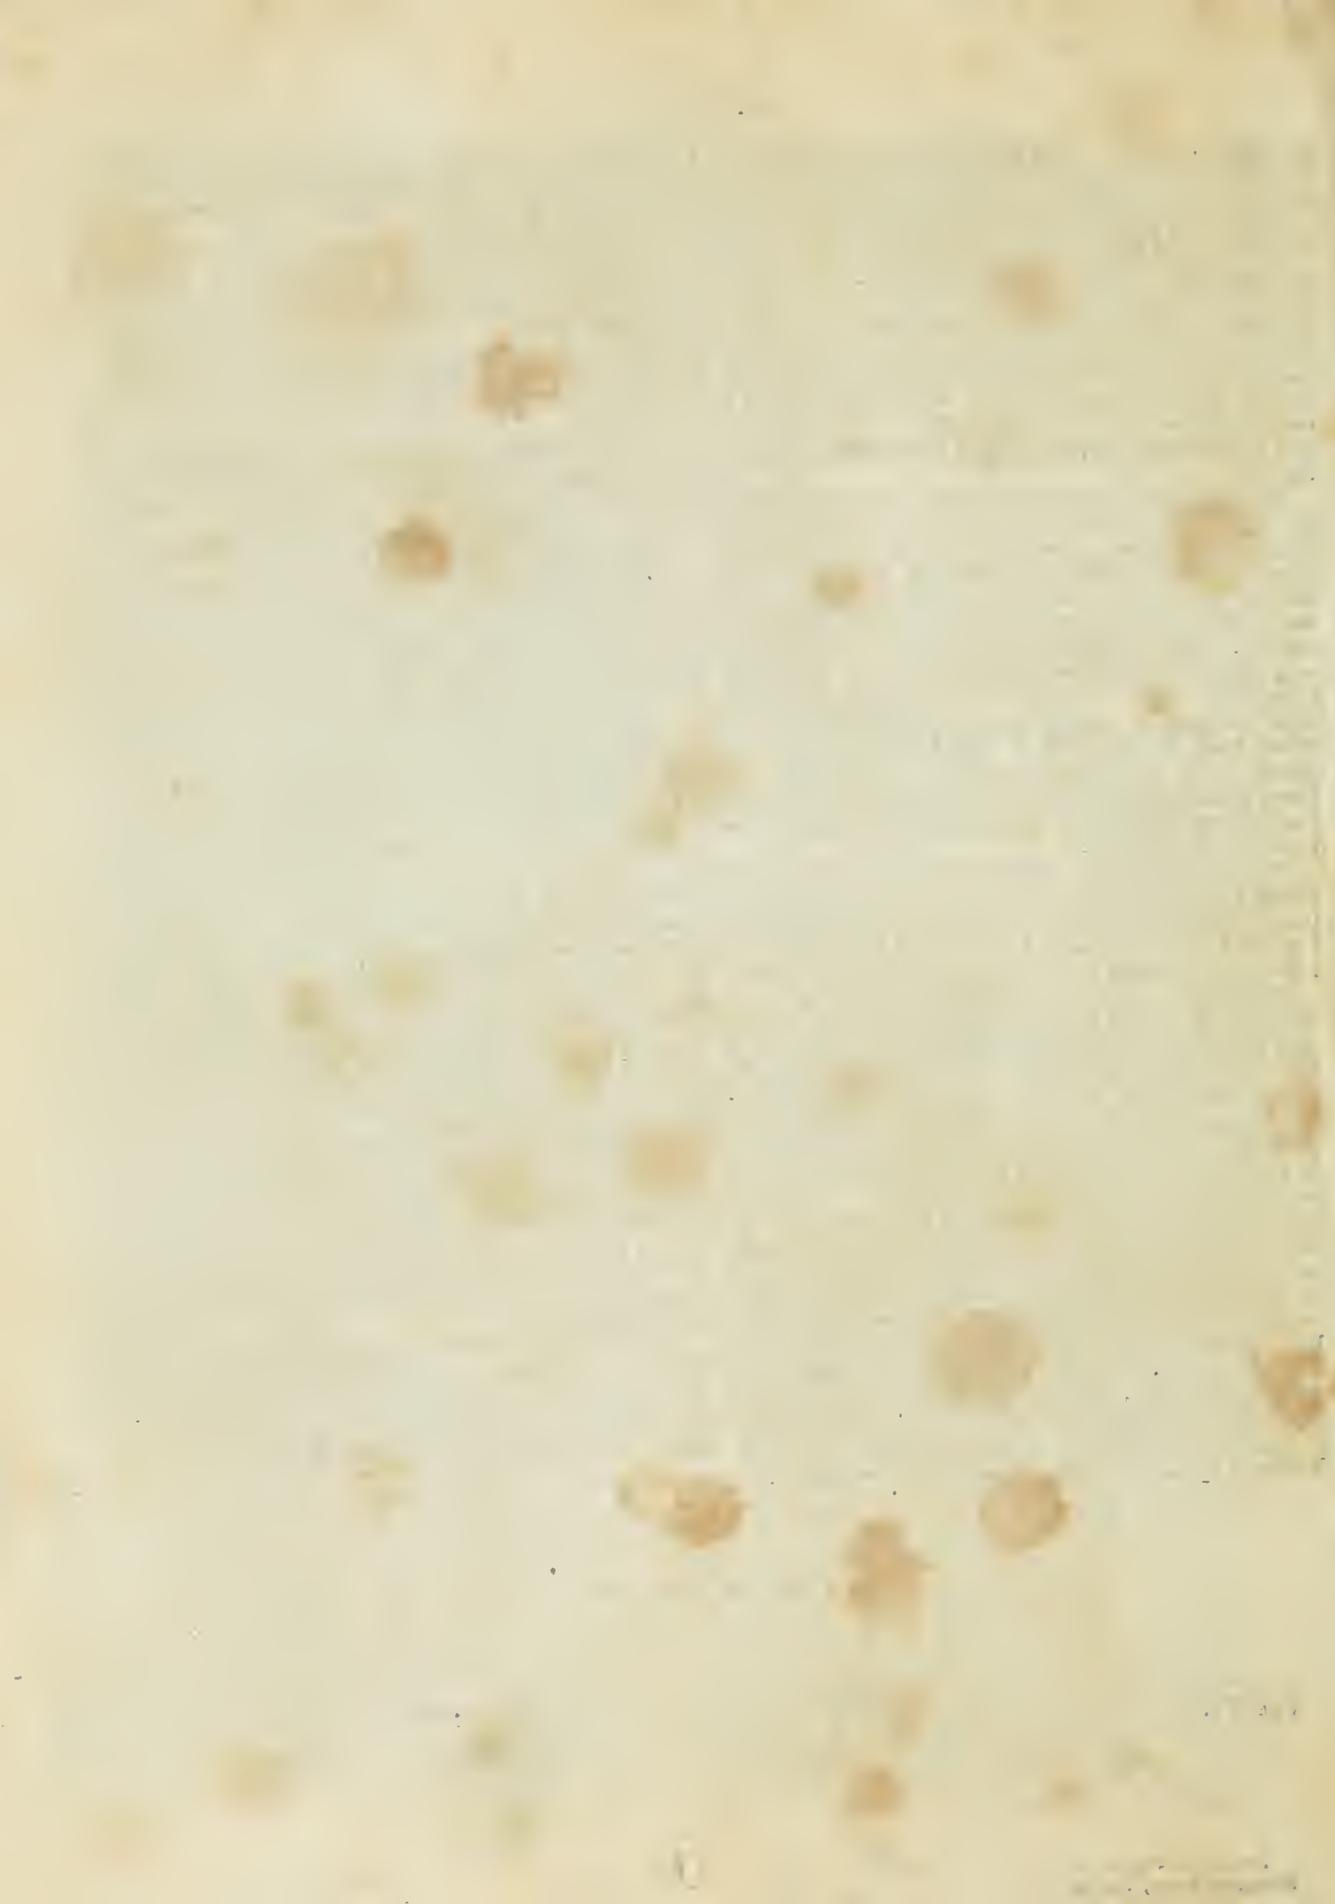

Manner of gilding books on the back and covers. In ordinary binding, they gild little else but the backs, and the outward edges of the cover. On the backs are gilt the title of the book, &c. with flowers, roses, knots, stars, &c. between the bands: on the covers are sometimes added compartments, arms, &c. All these ornaments are made with each its several gilding tool, engraved in *relievo*; either on the points of puncheons, as those of letters, roses, stars, &c. or around little cylinders of brass, as the lines, embroideries, &c. The puncheons make their impression, by being pressed flat down; and the cylinders by being rolled along by a handle, to which they are fitted on an iron stay, or axis.

To apply the gold, they glaze those parts of the leather, whereon the tools are to be applied, three or four times with a liquor made of the whites of eggs diluted with water by means of a sponge; and, when nearly dry, they slightly oil them, and then lay on pieces of leaf-gold, and on these apply the tools, with a careful even pressure of the hand, or roll the cylinders, both the one and the other, reasonably hot. If the figures be large, and require a *great relievo*, as arms, &c. they are beat or pressed down. The gilding thus finished, they rub off the superfluous gold, and polish the whole; the gloss of which is greatly assisted by a final pressing between horns peculiar for the purpose.

Our book-binders, for gilding on rough leather, make use of resin dried and powdered, instead of whites of eggs; and the gold leaf, first cut to a proper size, is laid on a hot somewhat oiled stamp, and pressed down: and thus the resin melts only in those parts where the hot stamp is applied, and the gold fixes on it, whilst the other parts of the leather remain rough as at first. Dr. Lewis's Com. Phil. Tech. p. 615. See *GILDING*.

Ahas. Fritsch, chancellor of the university of Jena, has a dissertation express concerning book-binders, *De Biblioprogis*; wherein he treats of the laws prescribed by these artificers, and the tax or price settled by the magistrate for binding books, of every sort in sheep-skin, vellum, &c.
