CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

T O L

TOLERIUM, in *Ancient Geography*, a town of Italy, in ancient Latium, and one of those which were taken by Coriolanus, according to Plutarch and Steph. Byz.

TOLESCAPATAM, in *Geography*, a town of Hindooftan, in the Carnatic; 28 miles S.E. of Tanjore.

TOLETUM, **TOLEDO**, in *Ancient Geography*, a town of Hispânia Citerior, belonging to the Carpetani, to the S.W. upon the Tagus. According to Silva and other Spanish historians, this city was founded by a considerable body of Jews, who, on their emancipation from captivity, 540 years before the vulgar era, established themselves here, and called the place Toledoth, or Toledath, that is, mother of the people. However this be, Toletum became in process of time a Roman colony. Cæsar made it a place of arms, and Augustus rendered it the principal seat of justice for the provinces of Spain in his department. Many ancient remains, such as an aqueduct, a road, &c. have been discovered at *Toledo*; which see.

TOLETUS, (**DE TOLEDO**), FRANCIS, cardinal, in *Bio-graphy*, was born at Corduba in 1532, and studied at Salamanca, where he took the degree of doctor in theology, and was made professor of philology. At the age of twenty-seven years, he entered the society of Jesuits, and in the following year he went to Rome, and read lectures on Aristotle and theology. He acquired great popularity as a preacher, inasmuch that, when he was compared with other preachers, it was said "Toledo teaches, Panigarola pleases, and Lupo moves." He was employed by several popes in various legations, and in 1593 Clement VIII. invested him with the purple, being the first Jesuit who obtained that dignity. He died at Rome in 1596, at the age of sixty-four. Toledo was one of those theologians who were employed by Sixtus V. in revising his bible. Of his various works, we shall only mention his "Sum of Cases of Con-

VOL. XXXVI.

T O L

science, or Instructions to Priests, in eight Books," justly chargeable with the pernicious maxims of the see of Rome concerning the forfeiture of the allegiance of their subjects by excommunicated princes, and with the dangerous doctrines of equivocations and mental reservations. Dupin. Nouv. Dict. Hist.

TOLFA, in *Geography*, a town of the Popedom, in the *Patrimonio*, in the environs of which are mines of alum and iron, with warm baths, and quarries of alabaster and lapis lazuli, about four miles from the sea-coast; 25 miles N.W. of Rome.

TOLHAR, a town of Hindooftan, in Lahore; 18 miles S. of Rotas.

TOLHUYS, a town of Guelderland, on the Rhine; where the French passed that river in the year 1672, and the Hanoverians in 1758; 6 miles W.S.W. of Emmerick.

TOLI, a town of European Turkey, in Macedonia; 85 miles N.W. of Saloniki.

TOLITZIN, a town of Russia, in the government of Mogilev; 70 miles N. of Mogilev.

TOLKEMIT, a town of Prussia, in the province of Ermeland, on the Frisch Haff; 12 miles N.E. of Elbing. N. lat. 54° 18'. E. long. 10° 33'.

TOLL, **TELONIUM**, a Saxon word, though derived originally from the Latin *tollere*, to take away, or rather the Greek *τελος*, tribute, tax. It has two acceptations, denoting, first, a liberty to buy and sell within the bounds of a manor: and, secondly,

TOLL is also used for a tax or custom paid for passage, or for vending goods in a market, fair, or the like.

This tax originated in the expence attending the construction and preservation of highways, bridges, and canals: and it is evidently just that a traveller, and especially a merchant, who derives advantage from a bridge, a canal, or a

B

causeway,

caufeway, in his own paffage, and in more commodioufly conveying his merchandife, fhould contribute to the expence of thefe ufelefs eftablifhments, by a moderate contribution; and if the ftate thinks proper to exempt the citizens from paying it, it is under no obligation to gratify ftrangers in this particular. But a law fo juft in its origin, frequently degenerates into a great abufe. There are countries where no care is taken of the highways, and where they nevertheless require confiderable tolls.

Some records make mention of *toll thoro*, or *thorough toll*, which is money paid for paffage in or through fome highways, or over ferries, bridges, &c. *Toll traver*s, for paffing or driving cattle over a private man's ground. And *toll-turn*, or *turn-toll*, which is paid at the return of beafts from fairs and markets, though they are not fold.

By the ancient laws, the buyers of corn and cattle in fairs or markets were made to pay toll to the lord of the market, in testimony of the contract there lawfully made in open market, becaufe privy contracts were held unlawful.

Some interpret toll a liberty, as well to take as to be free from toll; for that they who are infeoffed with toll are custom-free.

Of this freedom from toll the city of Coventry boasts an ancient charter, granted them by Leofrick, or Luriche, earl of the Mercians, in Edward the Confeflor's time, who, at the importunity of Godeva, his lady, granted this freedom to the city.

TOLL-Bar, or *Stop*, on a canal, is a beam for ftopping boats at the toll-houfes.

TOLL-Houfes, habitations conftituted on the banks of a canal or navigation for the toll-clerks.

TOLLAND, in *Geography*, a county of America, in

the ftate of Connecticut, divided into ten townfhips, and containing 13,779 inhabitants.—Alfo, a town of the fame ftate and county; 65 miles W.S.W. of Bolton, containing 1610 inhabitants. N. lat. $41^{\circ} 58'$. W. long. $72^{\circ} 26'$.

TOLLEIT, a town of Auftria; 6 miles S.W. of Efferding.

TOLLEN, a lake of Anterior Pomerania, near Trepto.

TOLLENON, among the *Romans*, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another more than half as long, and moveable upon a centre. On one end of this crofs-beam was placed a covering of hurdles or planks, within which a few foldiers were put, and, by pulling down the other end with ropes, thefe were raifed above the walls of a befieged town.

TOLLENON was alfo an engine for raifing water out of a draw-well.

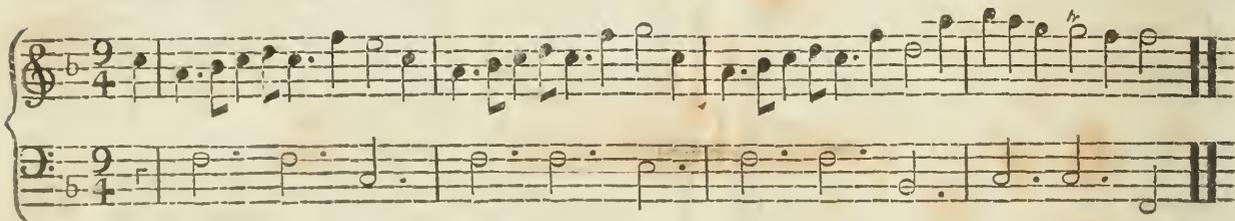

TOLLERSHAM, in *Geography*, a town of Auftria; 4 miles N.E. of Zwettl.

TOLLES, or *TOLÆ*, names given by fome to the tonfils, and by others to the glandular abfcefles fometimes affecting the limbs.

TOLLESIO, in *Geography*, a town of Sweden, in Weft Gothland; 23 miles E.N.E. of Gotheburg.

TOLLET, THOMAS, in *Biography*, a compofer for, and a performer on, the common flute, when it was in its higheft favour in England. He publifhed likewise directions for playing on the French flageolet. And, in conjunction with John Linton, whofe instrument was the flute, one of king William and queen Mary's band, publifhed a work entitled "A Confort of Mufick in Three Parts."

A ground compofed by Tollet, was much in favour during our own time.

TOLLING a Bell. See RING.

TOLLIUS, CORNELIUS, in *Biography*, a man of learning in the 17th century, was born at Utrecht, and became fecretary to Ifaac Voffius, by whom he was difmiffed under a charge of unfaithfulnefs. He was afterwards profeflor of eloquence and Greek at Harderwyk, and fecretary to the curators of that univerfity. His works were numerous: and the time of his death is unknown.

TOLLIUS, JAMES, M. D., brother of the preceding, profeflor of eloquence and Greek in the univerfity of Duisburg, was the author of many learned works, and made feveral journeys for literary purpofes, an account of which was given in a pofthumous work, entitled "Epiftolæ Itinerariæ," publifhed with notes, by Henninius at Amfterdam. A work of fomewhat fimilar title, viz. "Infignia Itinerarii Italici," was publifhed by himfelf at Utrecht in 1696, and contained the writings of fome ancient ecclefiaftical authors in Greek and Latin, with the editor's notes. He had alfo previously publifhed an edition of "Aufonius, cum Notis Variorum," 1671; of "Ciceronis Oratio pro Licinio," with notes and a commentary, 1677; and of "Longinus," Gr. and Lat. with Boileau's French tranflation, and notes by himfelf and others. He had alfo directed his attention to alchemy, as appears by his "Manufcriptio ad Cælum che-

micum;" "Sapientia infaniens, five Promiffa chemica;" and "Fortuita Sacra, in quibus, præter critica nonnulla, tota fabularis Hiftoria Græca, Phœnicia, Ægyptiaca, ad Chemiam pertinere aperitur." From this work were felected comparifons between the Greek and Latin poets, printed at Leyden under the title of "Difertationes felectæ criticæ de Poetis Græcis et Latinis." Tollius died in 1696.

Another brother of this family, named ALEXANDER, prefented to the public an edition of "Appiani Alexandr. Romanæ Hiftoriæ," Gr. and Lat. Moreri.

TOLLUNDY, in *Geography*, a town of Hindooftan, in Oudæ; 18 miles N. of Bareilly.

TOLMEZO, a town of Italy, in Friuli, with a caftle, on the Tajamento. Near the town is an extenfive and celebrated linen manufacture, which, in the year 1782, produced 40,000 pieces of printed linen for exportation; 12 miles N.W. of Gemona. N. lat. $46^{\circ} 23'$. E. long. $12^{\circ} 52'$.

TOLMIDESSA, in *Ancient Geography*, a town of Syria, in the fmall country called Chalcidica. Ptol.

TOLMINO, in *Geography*, a town of Germany, and capital of a diftrict, in the duchy of Carniola; 9 miles S.S.W. of Felde. N. lat. $46^{\circ} 12'$. E. long. $13^{\circ} 47'$.

TOLNA,

TOLNA, a town of Hungary, on the Danube; 50 miles S. of Buda. N. lat. $46^{\circ} 29'$. E. long. $18^{\circ} 41'$.

TOLNANI, a town of Hindoostan, in the country of Baglana; 70 miles W. of Burhanpour. N. lat. $21^{\circ} 15'$. E. long. $75^{\circ} 3'$.

TOLO, a town of Spain, in Catalonia; 22 miles N. of Balaguer.—Also, a town on the E. coast of the island of Morty. N. lat. $2^{\circ} 12'$. E. long. $128^{\circ} 18'$.

TOLO Bay, a large bay on the E. coast of the island of Celebes, very broad at its entrance, but becoming narrower towards the bottom. S. lat. $1^{\circ} 30'$ to $3^{\circ} 5'$. E. long. $121^{\circ} 18'$ to 123° .

TOLOMETO, a seaport of Africa, in the country of Tripoli, anciently called *Ptolemis*; 350 miles E. of Tripoli. N. lat. $32^{\circ} 30'$. E. long. $20^{\circ} 40'$.

TOLOMMEI, **CLAUDIO**, in *Biography*, a patron of literature and the arts, was born at Siena, of an ancient and noble family, in 1492. Having spent many of his earlier years at the court of Rome in the service of cardinal Ippolito de' Medici, he attached himself to the duke of Parma and Placentia. Upon his death he removed to Padua, and in 1549 was nominated to the bishopric of Corfola, an island in the Adriatic. In 1552 he became one of the sixteen conservators of the public liberty at Siena, and joined three other citizens in an embassy to France. Having spent about two years in that country, he returned to Rome, and died there in 1555. Tolommei took pains in cultivating the Italian language, and contended that it ought to be denominated the Tuscan. With a view of reducing Italian verse to the measure and harmony of the Latin, he published, in 1539, his "Versi e Regole della Poesia Nuova;" but his scheme did not succeed. To him was ascribed the foundation of the academy "Della Virtù" at Rome, for the purpose of explaining the architectural work of Vitruvius; and for which he was eminently qualified by his classical and antiquarian learning.

TOLON, in *Geography*, an island in the Grecian Archipelago. N. lat. $37^{\circ} 35'$. E. long. 23° .

TOLONÈS, one of the smaller Philippine islands, near the N. coast of Samar. N. lat. $12^{\circ} 50'$. E. long. $124^{\circ} 57'$.

TOLOSA, or **TOLOSETTA**, a town of Spain, and capital of the province of Guipuscoa, celebrated for its steel manufacture, particularly of sword-blades; 7 miles S. of St. Sebastian. N. lat. $43^{\circ} 12'$. W. long. $2^{\circ} 7'$.

TOLOSA, in *Ancient Geography*, a town of Gaul, in the Narbonne province, and diocese of Toulouse.

TOLOTÆ, a people of Africa, in Mauritania Cæsariana.

TOLOUR, in *Geography*, an island in the East Indian sea, of a triangular form, and about 45 miles in circumference, considered as one of the Salibabo islands. N. lat. $4^{\circ} 12'$. E. long. $126^{\circ} 28'$.

TOLOUS, in *Ancient Geography*, a place of Spain, between Ilerda and Pertusa. Anton. Itin.

TOLPAS, in *Geography*, a river of Russia, in the province of Ustiug, which runs into the Schugor, N. lat. $63^{\circ} 40'$. E. long. $58^{\circ} 22'$.

TOLPIS, in *Botany*, a word of which we can trace neither the derivation nor meaning, and which seems to have been actually invented by Adanson; nor is it the only instance of such a kind of forgery to be found in his book. We have sometimes been tempted to suppose these seemingly original names of Adanson might be reduced from some recondite sources of nomenclature or literature; but the search has always proved vain. He was no scholar, nor is his new French orthography founded in any extensive knowledge, much less any refined taste, in language, but in mere affect-

ation. Gærtner cannot be excused for adopting the above name, when he had the choice of an excellent one, (see *DREPIANA*), given by Jusseu to this same genus. Nevertheless, *Tolpis* is now established, and cannot without inconvenience be set aside.—Adans. Fam. des Pl. v. 2. 112. Gærtn. v. 2. 371. t. 160. Willd. Sp. Pl. v. 3. 1608. Ait. Hort. Kew. v. 4. 461. Sm. Prodr. Fl. Græc. Sibth. v. 2. 140. Lamarek Illustr. t. 651. Bivona Monogr. delle Tolpidi. (Drepania; Juss. 169. Desfont. Atlant. v. 2. 232.)—Class and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ semistefulose*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* ovate, of many linear, nearly equal, parallel, close scales, with a distinct series of somewhat scattered and lax, awl-shaped, incurved scales at the base. *Cor.* compound, imbricated, uniform; the florets numerous, equal, all perfect, each of one petal, ligulate, abrupt, five-toothed. *Stam.* Filaments five, capillary, short; anthers united into a cylindrical tube. *Pist.* Germen ovate-oblong; style thread-shaped, the length of the stamens; stigmas two, recurved. *Peric.* none, except the closed permanent calyx, tumid at the base. *Seeds* solitary, small, obovate, striated; down sessile; that of the radius of numerous, little, membranous, equal, acute, marginal teeth, or scales; that of the disk of similar scales, accompanied by two, four, or ten straight, rough bristles, longer than the seed. *Recept.* cellular, with crenate edges to the cells.

Ess. Ch. Receptacle cellular. Calyx equal, with many awl-shaped scales at the base. Seed-down of the circumference toothed: that of the disk toothed, accompanied by several bristles.

The present genus agrees most with *CREPIS* in habit. (See that article.) The seed-down affords a clear distinctive character, and the outer scales of the calyx do not assume that enlarged, dilated, tumid appearance so remarkable in *Crepis*.

1. *T. barbata*. Purple-eyed Succory-hawkweed. Willd. n. 1. Ait. n. 1. Prodr. Fl. Græc. n. 1942. Bivona Tolp. 13. t. 3. Savi Etrusc. v. 1. 183. (*Crepis barbata*; Linn. Sp. Pl. 1131. Curt. Mag. t. 35. Hieracium medio nigro bæticum majus; Herm. Parat. 185. t. 185. H. calyce barbato; Column. Ecphr. v. 2. 28. t. 27. f. 1. H. medio nigrum, flore majore; Ger. Em. 1625.)—Leaves elliptic-lanceolate, toothed. Outer scales of the calyx falcate, distant, longer than the inner. Bristles of the seeds two or four.—Native of sandy fields, or waste ground, especially near the sea, in the south of France, Italy, and the Levant, flowering in May and June. This elegant hardy annual, very easy of cultivation, has, for two hundred years past, been common in gardens, where it produces, from Midsummer till the autumnal frosts, abundance of flowers. The stems are branched, erect, spreading or decumbent, rather downy, leafy, repeatedly subdivided at the top, in a corymbose, or somewhat forked manner, the flowers, which are at first terminal and solitary, being copiously overtopped by their successors. The scales of their outer calyx are partly scattered down the stalk. *Corolla* expanded in the early part of the day only, and in sunshine, an inch, more or less, in diameter, of a delicate pale lemon-colour; a number of the central florets of a dark purplish chocolate hue, forming an almost black velvet-like spot, or eye, in the middle, which constitutes the chief beauty of the flower. The leaves are rather regularly toothed, alternate, sessile, green, slightly roughish; the upper ones mostly entire.

2. *T. quadriaristata*. Pale Succory-hawkweed. Bivona Tolp. 9. t. 1. Prodr. Fl. Græc. n. 1943. Fl. Græc. t. 810, unpubl. (*Hieracium cichorii sativi folio integro, denticulato, curvo, glaucescens*; Cupan. Phyt. ed. 2. t. 118.

"*H. eichorii fativi folio, denticulato, curvo, diuturnè florens, incanum*; Cupan. Hort. Cath. 96.")—Leaves lanceolate, strongly toothed, somewhat hairy. Outer scales of the calyx lax, the length of the inner. Bristles of the seeds four or more.—Common in Sicily, by way-sides, on calcareous hills near Messina, and various parts of mount Etna, flowering in June and July. *Bivona*. Dr. Sibthorp found it in Cyprus. The *root* is perennial, tapering, milky. *Stems* one or more, erect, wand-like, somewhat angular, one and a half or two feet high, leafy, much branched and corymbose at the upper part. *Leaves* more tapering at the base, with stronger teeth, and rather more hairy than in the first species. *Flowers* numerous, about half as large as the former, of a pale sulphur-colour, reddish underneath, sometimes purplish-brown in the middle. Outer scales of the *calyx* falcate, lax, partly dispersed down the stalk, but none of them longer than the inner scales. *Bristles* on the *seeds* of the disk eight, ten, or more, even in a specimen sent by baron Bivona himself. Can the purple-eyed variety of this species be the *Hieracium medio nigrum, flore minore*, mentioned in Ger. Em. 1625, along with the preceding?

3. *T. saxariiflata*. Close-cupped Succory-hawkweed.—*Bivona* Tolp. 11. t. 2. (*T. virgata*; Savi Etrusc. v. 1. 184. *Crepis ambigua*; Balbis Crep. 4. t. 1. "Decand. Franc. 40. t. 4.")—Lower leaves lanceolate, deeply and unequally toothed; upper linear-lanceolate, entire. Outer scales of the calyx close, half as long as the inner. Bristles of the seeds six or more.—Native of hills in Italy, Sicily, and the south of France, flowering in June and July. *Root* perennial, tap-shaped. *Stem* three or four feet high. *Pubescence* of the whole plant very variable. *Radical leaves* numerous, spreading circularly on the ground, four inches long, tapering at the base; those of the stem, except a few at the bottom, slender and awl-shaped. Flowering *branches* rather more distant and slender than the last. *Calyx* mealy. *Corolla* lemon-coloured. "Bristles of the seeds usually six, sometimes only five, or four;" *Bivona*: "sometimes seven;" *Savi*.

4. *T. virgata*. Short-cupped Succory-hawkweed. *Bivona* Tolp. 15. t. 4. (*Crepis virgata*; Desfont. Actes de la Soc. d'Hist. Nat. de Paris, v. 1. 37. t. 8. Atlant. v. 2. 230. Willd. Sp. Pl. v. 3. 1600.)—Lower leaves elliptic-lanceolate, acute, unequally toothed; upper nearly entire. Flower-stalks divaricated. Outer scales of the calyx very short, capillary, rather lax. Bristles of the seed ten or more.—Native of sandy borders of fields about Tunis and Algiers, flowering in April and May. *Root* annual. *Stem* a foot or two in height, striated, leafy, smooth. *Leaves* smooth, two or three inches long; tapering at the base. *Flower-stalks* slender, spreading, gradually rising above each other, slightly scaly at the top. *Flowers* yellow; their under side reddish. *Desfontaines*.

5. *T. coronopifolia*. Fleishy-leaved Succory-hawkweed. *Bivona* Tolp. 17. t. 5. (*Crepis coronopifolia*; Desfont. Actes de la Soc. d'Hist. Nat. de Paris, v. 1. 38. t. 9, excluding the syn. of Boccone, 13. t. 7. Willd. Sp. Pl. v. 3. 1606.)—Lower leaves pinnatifid, with linear segments. Flower-stalks divaricated. Outer scales of the calyx close, very short. Bristles of the seed ten or more.—Native of the Canary islands, from whence it was brought to Kew by Mr. Masson, in 1777. A hardy annual plant, flowering in August and September. The *stem* is a yard high, round, striated, leafy, smooth, much branched. *Leaves* smooth, rather succulent, various in size; their segments decurrent, often subdivided. *Flowers* numerous, small, yellow, on slightly scaly hollow *stalks*. *Calyx* white and cottony; its outer scales awl-shaped, unequal, scarcely spreading, except

when dried. The teeth, which make a part of the *seed-down*, though here and there present, are so small as to be easily overlooked: the bristles are numerous, sessile.

TOLRE, in *Geography*, a town of Hindoostan, in the Carnatic; 15 miles E. of Volconda.

TOLSEY, in our *Old Writers*, denotes the places where merchants meet in a city or town of trade.

The word is compounded of the Saxon *tol*, *tributum*, and *see, fedes*.

TOLSTA, in *Geography*, a town of Sweden, in West Gothland; 30 miles W.S.W. of Linköping.

TOLSTA Head, a cape on the E. coast of the island of Lewis. N. lat. 58° 22'. W. long. 6° 6'.

TOLSTONOSKOI, an ostrog of Russia, in the government of Tobolsk, on the Enisei; 280 miles N.N.W. of Turuchansk. N. lat. 70° 16'. E. long. 85° 14'.

TOLT, in *Law*, a writ whereby a cause depending in a court-baron is removed into the county-court. Old Nat. Br. 4. See PONE.

TOLTEN, in *Geography*, a river of Chili, which runs into the Pacific ocean, S. lat. 38° 50'.

TOLTERCAIZTLI, in *Natural History*, the American name of a stone, much resembling the novaculum lapis, but variegated with red and black spots. They use the powder of this stone and crystal, calcined together, for diseases of the eyes.

TOLU, in *Geography*, a sea-port town of South America, in the province of Carthage, with a harbour open to the Spanish Main; in the environs of which is found the celebrated balsam to which it gives name; 50 miles S.E. of Carthage. N. lat. 9° 45'. W. long. 75° 25'.

TOLU Balsam. See BALSAM.

TOLU-Tree, Balsam of, in *Botany*. See TOLUIFERA.

TOLVA, in *Geography*, a town of Naples, in Basilicata; 9 miles S.S.E. of Acerenza.

TOLUCO, a town of Mexico, in the province of Mechoacan; 100 miles W.N.W. of Mechoacan.—Also, a town of Mexico; 28 miles S.W. of Mexico.

TOLUIFERA, in *Botany*, so called from its producing the balsam of Tolu. Linnæus attributes the name to Van Royen.—Linn. Gen. 210. Schreb. 282. Willd. Sp. Pl. v. 2. 545. Mart. Mill. Dict. v. 4. Juss. 372.—Class and order, *Decandria Monogynia*. Nat. Ord. *Lomentaceæ*, Linn. *Leguminosæ*, *sect.* 10. Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, five-toothed, nearly equal; one angle (or tooth?) more distant than the rest. *Cor.* Petals five, inserted into the receptacle; four of them equal, linear, somewhat longer than the calyx; the fifth twice as large, inversely heart-shaped, its claw the length of the calyx. *Stam.* Filaments ten, very short; anthers longer than the calyx. *Pist.* Germen oblong; style scarcely any; stigma acute. *Peric.* and *Seeds* not described.

Eff. Ch. Calyx five-toothed, bell-shaped. Petals five; the lower one very large, inversely heart-shaped. Style none.

1. *T. Balsamum*. Balsam of Tolu. Linn. Sp. Pl. 549. Willd. n. 1. Woodv. Med. Bot. t. 193. (*B. toltanum*; Dale Pharmac. 304. *B. toltanum, foliis ceratiæ similibus, quod candidum est*; Bauh. Pin. 401.)—Native of the province of Tolu, in South America. We have never seen any original specimen of this plant, nor any figure, except Dr. Woodville's, drawn from a dried specimen in sir Joseph Banks's collection, the authority for which is not mentioned. Miller appears to have raised plants from seeds sent by Houftoun, but they probably did not prosper long. Perhaps the specimen just mentioned was obtained from the same

fame source. Authors describe the tree as lofty, with large branches, and a thick greyish bark; the leaves like those of the Carob. If so, they are pinnate, as the natural order of the genus should indicate; but of which Dr. Woodville seems not to have been aware. The flowers in his figure are racemose. All we can make out respecting the characters of this tree confirm the account of Mutis, of its close affinity to MYROXYLON, see that article, sp. 1; the long-stalked germen of the latter appearing to be the only difference which is even obliquely hinted. The generic name of *Toluifera* therefore, though the most ancient, should give way to *Myroxylon*, as the most comprehensive.

T. cochinchinensis, Loureir. Cochinch. 262, having simple leaves, and a berry with one or two seeds, should seem, as Poiret observes, in Lamarck's Dict. v. 7. 696, to be very different from the original *Toluifera*, and more probably a *Burfera*.

TOLUIFERA, in *Gardening*, comprises a plant of the exotic tree kind for the stove, of which the species cultivated is the balsam of Tolu tree (*T. balsamum*).

Method of Culture.—This tree is raised from seeds, which should be obtained from its native situation, and be sown as soon as possible afterwards in pots of light earth, plunging them in the bark-bed of the stove. When the plants have three or four inches growth, they should be potted off separately, giving them water, and replunging them in the bed. They afterwards only require to be managed as other woody stove plants.

They afford variety in stove and hot-house collections among other potted plants. A balsam of great use in medicinal compositions is extracted and prepared from this tree.

TOLZ, in *Geography*, a town of Bavaria; 24 miles S. of Munich.

TOM, a river of Russia, which rises 80 miles S.E. of Kufnetz, in the government of Kolivan, and runs into the Oby, 32 miles W.N.W. of Tomsk. N. lat. $56^{\circ} 40'$. E. long. $84^{\circ} 14'$.—Also, a river of China, which runs into the Heng, 5 miles S. of Heng-chan.

Tom Zil, a town of the Arabian Irac, on the Tigris; 118 miles S.E. of Bagdat.

TOMADÆORUM INSULÆ, in *Ancient Geography*, islands situated in the Arabian gulf. Ptol.

TOMÆUS, a mountain of the Peloponnesus, in Messenia, near the promontory Coryphasium. Thucydides.

TOMAHABI, in *Geography*, a town of Peru; 60 miles S. of Potosi.

TOMAN, or TOUMAN, a kind of imaginary money used among the Persians in the keeping of their books, and to facilitate the reduction of money in the payment of considerable sums.

The toman contains 50 abassis, 100 mamoodis, 200 shatrees, 1000 dinars bistî, or 10,000 dinars simple. The toman and dinar are imaginary monies. An abassi is worth 2 mamoodis, 4 shatrees, 40 kabefquis, 20 dinars bistî, or 200 dinars.

D'Herbelot derives the word from the language of the Moguls, where it signifies the number of ten thousand. Eben Arabschah says, that the word *tomman*, when used to express a weight, or money, contains ten thousand silver Arab drachmas, called *mehkal*; which are a third lighter than the Attic.

The Moguls, &c. frequently use toman for ten thousand men; and say, *c. gr.* that the city Samarcand contains seven tomans of people fit to bear arms; and that of Andechan nine tomans.

TOMANI, in *Geography*, a kingdom of Africa, situated on the side of the river Gambia, W. of Kantor.

TOMANANISA, a town of Japan, in the island of Niphon; 75 miles W. of Meaco.

TOMAR, a circar of Bengal, bounded on the N. by Sillee, on the E. by Pachete, on the S.E. by Singboom, and on the W. by Nagpour; about 20 miles long from N. to S., and from 10 to 20 broad.—Also, a town of Bengal, and chief place of a circar of the same name; 145 miles W. of Calcutta. N. lat. $23^{\circ} 10'$. E. long. $85^{\circ} 53'$.

TOMAR. See THOMAR.

TOMARA, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptol.

TOMARE, a mountain on the confines between Thesprotia and Chaonia, two countries of Epirus.

TOMATO, in *Botany*, a word whose origin we have not ascertained, is the name of the Love-apple, or *Solanum Lycopersicum*. See SOLANUM.

TOMB, in *Geography*. See TUMB.

TOMB, includes both the grave or sepulchre, wherein a defunct is interred, and a monument erected to preserve his memory.

The word is formed from the Greek, *τυμβος*, *tumulus*, sepulchre; or, according to Menage, from the Latin, *tumba*, which signifies the same.

Among the Romans, none but the emperors, vestals, and persons signalized by great actions, were allowed to have tombs in the cities, the rest were all in the country, near the high roads; whence those common words, *Siste, Et abi, viator*, which are still retained in the inscriptions of our monuments, though set up in churches, &c.

At Anchiæle was anciently seen the tomb of Sardanapalus, with this inscription in verse: "Sardanapalus built Anchiæle and Tarsus in one day: go passenger, eat, drink, and be merry; the rest is nothing." Strab. Geo. lib. 14.

The Romans had a kind of empty tomb, called *cenotaphium*, an *honorary* tomb, in which the body of the deceased was not laid. See CENOTAPH.

The occasion of this was a superstitious notion, that the souls of those who had not funeral honours, wandered a hundred years by the banks of the rivers of hell, before they were admitted to pass over. The *κεκοιταφίον* being made, the same ceremonies were practised as at real funerals.

The cenotaphia were inscribed with the words *ob honorem*, or *memorie sacrum*, whereas other tombs in which the ashes were really deposited, were inscribed D. M. S. *q. d. sacred to the manes*. When the words *tacito omine* were added, it declared the ashes enclosed therein belonged to a person infamous for some crime.

TOMB-Stones, *Characters on*. See CHARACTER.

TOMB-Stones, *Epitaphs on*. See EPITAPH.

TOMBA, in *Geography*, a river of Peru, which runs into the Pacific ocean, S. lat. $17^{\circ} 50'$.

TOMBAC, a name given by the French to a yellow metal, very nearly approaching to what we call Prince's metal, and made by mixing and fusing together a large quantity of zinc with a smaller of copper. See GOLD-coloured Metal.

TOMBACONDA, in *Geography*, a town of the kingdom of Burfalli. N. lat. $13^{\circ} 56'$. W. long. $14^{\circ} 57'$.

TOMBALY POINT, a cape on the west coast of Africa. N. lat. $10^{\circ} 48'$. W. long. $4^{\circ} 36'$.

TOMBAY, a town of Pegu; 6 miles S. of Pegu.

TOMBECEUF, a town of France, in the department of the Lot and Garonne; 12 miles N.W. of Villeneuve d'Agen.

TOMBUCTOO.

TOMBI, a town of Africa, in Quoja. N. lat. 6° 50'.

TOMBIGHE, a river which rises in the north part of Georgia, enters West Florida, and joins the Alabama to form the Mobile, N. lat. 31° 32'. W. long. 87° 50'.—Also, a town of West Florida, on a river of the same name. N. lat. 32° 35'. W. long. 87° 50'.

TOMBUCTOO, or TIMBUCTOO, a city of Africa, the capital of a rich and populous kingdom, said to have been built in the 13th century by Soliman, pretended to be of the royal race of Morocco. The extent of its territory is very imperfectly ascertained; but it is said to extend northward to the confines of Sahara or the Desert, comprehending a tract of country about 90 miles in breadth; its western boundary being 130 miles W. of the city, and the eastern extending to the Bahar Soudan, or sea of Soudan, which is a lake formed by the Nil-El Abeede or Niger, whose opposite shore is not discernible. The city is situated on a plain, surrounded by sandy eminences about twelve miles N. of the Niger, and three days' journey from the confines of Sahara. It is said to be twelve miles in circumference, but without walls. The town of Kalra, situated on the banks of the river, is its commercial depôt, or port. By means of a water-carriage E. and W. of Kabra, the trade of Tombuctoo acquires great facility; and hence the various articles of European as well as Barbary manufactures brought by the akkabaahs, or caravans, from the N. of Africa, are distributed to the different empires and states of the Soudan and the South. This great mart is resorted to by all nations, whither they bring the various products of their respective countries, to barter for the European and Barbary manufactures. The houses at Tombuctoo have, in general, no upper apartments: they are spacious, and of a square form, with an opening in the centre, towards which the doors open. Contiguous to the door of entrance is a building, consisting of two rooms, called a *duaria*, in which visitors are received and entertained, so that they do not see the women, who are very handsome. The men are so excessively jealous of their wives, that when the latter visit a relative, they are much muffled up, in order to disguise their persons; their face is also covered with their garment, through which they peep in order to explore their way. The king, whose authority has been acknowledged at Tombuctoo ever since the death of Muley Ishmael, emperor of Morocco, is the sovereign of Bambarra: his name in 1800 was Woolo; he is a black, and a native of the country which he governs: his usual place of residence is Jinnie, though he has three palaces at Tombuctoo, which are said to contain an immense quantity of gold. Many of the civil appointments at Tombuctoo, since the decease of Muley Ishmael, and the consequent decline of the authority of the emperor of Morocco, have been occupied by Moors of Maroquin origin; but the military appointments, since the forementioned period, have been distributed among Negroes of Bambarra, assigned to them by the king Woolo. The inhabitants are chiefly Negroes, who resemble the Arabs in hospitality, and value themselves on their attention to strangers. The various costumes exhibited in the market-places and streets indicate the variety and extent of the commercial intercourse with the different nations of Central Africa; the individuals being each habited in the dress of his respective country. The toleration prevalent at Tombuctoo is worthy of notice. The divan, or Palemma, never interfere with the religious tenets professed by the different people who resort hither for commercial or other purposes. The police of this place is extolled: robberies and house-breaking are scarcely known: the inhabitants of the town are peaceable and orderly. The government of the city is

intrusted to a divan of twelve *alemma*, or men learned in the Koran, and an umpire, who retain their appointments, received from the king of Bambarra, for three years. Their power is great. The civil jurisprudence is directed by a *cadi*, who decides all judicial proceedings according to the spirit of the Koran: he has twelve attorneys, called *talbs*, who attend him, and to each of these belongs a separate department of justice. It is asserted that till of late no Jews were permitted to enter the town; and it is said, moreover, that those Jews who now resort thither, are obliged to become Mahometans. The probable reason of the exclusion of the Jews is deduced from the extreme jealousy of the individuals of the Moorish factory, whose avarice induces them to prevent any person from sharing their emoluments, whenever a plausible pretext can be found.

The climate of Tombuctoo is much extolled as salubrious and invigorating; inasmuch that there is no man of the age of eighteen, who has not his wives or concubines; and it is a disgrace for a man to attain the age of puberty without being married. The natives possess an elegance and suavity of manners, a great flow of animal spirits, and an invincible attachment to their country. The accommodation for travellers is very simple; camels, horses, drivers and merchants, rendezvous at a large house, with an open space in the middle, round which are rooms sufficient for containing a bed and a table. The merchants are accommodated with houses during the period of their stay, for bartering and exchanging their commodities, which they invest in the produce of Soudan as speedily as possible, so that they may be ready about September for the akkabaah, and proceed to Morocco, Cairo, Jidda, or some other place. The manufactures of different kinds of apparel are prepared chiefly by the women in their own houses, whenever they cannot procure European cloths and linens, or when there is a great scarcity of Fez and Taflet manufactures of silk, cotton, and woollen. The soil about Tombuctoo is generally fertile, and near the river produces rice, millet, Indian corn, and other grain; wheat and barley grow in the plains, and are cultivated principally by the Arabs of the tribe of Brabeeha, who receive a tribute from the town for forbearing to plunder the caravans from the north which pass through their territory. Coffee grows wild here, as does also indigo, which latter is occasionally cultivated, and produces a very fine blue dye used in their various cotton manufactures. The husbandmen are very expert in the management of bees: honey and wax are abundant, the former being used at Tombuctoo as an article of food, and the latter for candles. The river about Kabra affords a supply of fish. The mines of gold which lie S. of the bed of the river belong to the sultan Woolo, who resides at Jinnie; but his gold is deposited in his palaces at Tombuctoo. The exact bearing and distances of places from Tombuctoo are not satisfactorily ascertained. The city appears, says Mr. Jackson, to be situated 1500 miles S.S.E. of Fez, 1150 miles about S.S.E. of Akka, Tatta, and Wedinoo; 1300 miles in nearly the same direction from Morocco; 1320 miles from Taflet; about 230 miles E. of Jinnie; and 1000 miles E. of Houffa. Major Rennell, in his Geographical Elucidations annexed to the Proceedings of the Association for discovering the Interior of Africa, says that Tombuctoo is fifty days' caravan travelling from Tatta, a place situated on the frontiers of Morocco, Drah, and Zenhaga, and on the route from Morocco and Suz to Tombuctoo. Tatta is found to be nine and a half days' journey from Morocco: and one day short of a station on the Wad-drah or Drah river, which station is four days, or sixty-six miles lower down than Tinguleen, a place in D'Anville's and De Lisle's map of Africa.

Africa. It was also twelve days' journey from the city of Nun, or Non, which city, by Ben Alli's account, is two days from the sea-coast, and well known to be opposite to a cape of the same name. These authorities, says the major, enable us to place Tatta 170 miles S.S.E. from Morocco. Thus, 50 days from Tatta to Tombuctoo, at 13 miles each day, produce 650 miles. By Ben Alli's report, Tombuctoo is 48 days from the capital of sultan Fullan, lying within the district of Gallan, on the river Senegal: 48 days, at 13 each day, produce 620 miles; and this line of distance meets that from Tatta in lat. $19^{\circ} 40'$, and nearly midway between Gallan and Cahna. In this position it falls only 28 miles to the N.W. of D'Anville's Tombuctoo.

The country north of Tombuctoo is inhabited by a powerful tribe of Arabs, called Brabeesha, whose original stock emigrated in the eighth century, and took possession of a tract of country bordering on Egypt westward: they are a turbulent, restless, and warlike tribe, but much afraid of fire-arms, as they have no such, being armed only with the lance, and occasionally with knives or daggers. There is another nation, situated many journies south-east of Tombuctoo, who worship the sun, and abstain from animal food, subsisting on milk and vegetables. In a part of the country between Tombuctoo and Cahna is discovered a race of people, compared by the Arabs to the English, who speak a language different from all the others known in Africa, and resembling the whistling of birds, to which they compare the English language. They ride on saddles like those used in England, and wear rowelled spurs, which are peculiar to themselves. Their faces are covered by turbans, and their weapons are swords, bows, arrows, and lances. They are said to be a grossly superstitious people; their bodies, as well as their houses, being covered with charms or amulets. It is said that there is a water communication between Tombuctoo and Cairo; but the expence of land-carriage by camels being more moderate, the other is not used.

Tombuctoo has, from time immemorial, been the great emporium of Central Africa; an extensive and profitable trade having been carried on with the various maritime states of North Africa, *viz.* Morocco, Tunis, Algiers, Tripoli, Egypt, &c. by means of akkabaahs, or accumulated caravans, which cross the Sahara, or Great Desert, generally between the months of September and April: these akkabaahs consist of several hundred loaded camels, accompanied by the Arabs who let them to the merchants. The articles transported from Fez to Tombuctoo are principally the following; *viz.* various kinds of German linens, Irish linens, muslins, cambrics, fine cloths, coral beads, amber beads, pearls, Bengal raw silk, brags nails, coffee, fine hyson teas, refined sugar, and various manufactures of Fez and Tafilet, such as shawls and shawes of silk and gold, hayks or pieces of silk, of cotton and silk mixed, of cotton and wool: to which may be added red woollen caps, turbans, Italian silks, nutmegs, cloves, ginger, and pepper, Venetian beads, cowries, tobacco and salt. The produce of Soudan in return for these articles, consists principally in gold-dust, twisted gold rings of Wangara, gold rings made at Jinnie, bars of gold, elephants' teeth, gum of Soudan, grains of Sahara, or grains of paradise, odoriferous gums, and a great number of slaves purchased at Tombuctoo of the states or slave merchants, and brought from those regions which border on the mountains of the Moon. To these we may add ostrich-feathers and ambergris, collected on the confines of the Desert. The circulating medium at Tombuctoo is (tubber) gold-dust, which is exchanged for mer-

chandize; a plattilia being worth 20 mizans of gold, and the value of a mizan being about 11s. sterling. Jackson's Morocco.

To the account above given of Tombuctoo, we shall subjoin a few extracts from the narrative of Robert Adams, a sailor, who was wrecked on the western coast of Africa, in the year 1810, and detained three years in slavery by the Arabs of the Great Desert, and resided several months in the city of Tombuctoo, 4to. London, 1816.

Tombuctoo, according to this narrative, stands on a level plain, having a river about two hundred yards from the town on the S.E., named La Mar Zarah, three quarters of a mile in width, appearing to have but little current, and that little flowing to the S.W. The city seemed to Adams to cover as much ground as Lisbon: but the houses were not continuous, had a ground-floor only, were built of sticks, clay, and grass, and were furnished merely with the rudest domestic implements: the town had no exterior walls, or fortifications; and the population, of which our informant could not make a regular estimate, bore no corresponding proportion to the area of the place, if compared with European towns, as indeed we may infer from the nature of the houses. The river-water, although somewhat brackish, is constantly used for drink; and Adams does not believe that there were any wells at Tombuctoo. The natives have no larger boats or vessels than canoes, of about ten feet in length, made very inartificially. Of the natural productions, vegetable and animal, we will specify a few. The principal fruits are cocoa-nuts, dates, figs, pine-apples, and sweet fruit of the peach kind: the vegetables are, carrots, turnips, sweet potatoes, negro-beans, and small cabbages: the grain consists chiefly of rice and guinea-corn; and the cultivation of the land is performed solely with a kind of hoe, the only implement of husbandry that Adams observed. The animals are elephants, cows, goats, asses, camels, dromedaries, dogs, antelopes, rabbits, and a creature called *beirie*, resembling a very small camel, and used only for riding. Besides these, there is, in the vicinity of Tombuctoo, a most extraordinary animal named *courcoo*, somewhat resembling a very large dog, but having an opening or hollow on its back like a pocket, in which it carries its prey. It has short-pointed ears and a short tail. Its skin is of a uniform reddish-brown on its back, like a fox, but its belly is of a light-grey colour. It will ascend trees with great agility, and gather cocoa-nuts, which Adams supposes to be a part of its food. But it also devours goats and even young children, and the negroes were greatly afraid of it. Its cry is like that of an owl. The natives of Tombuctoo are a stout healthy race, and are seldom sick, although they expose themselves by lying out in the sun at mid-day, when the heat is almost insupportable to a white man. It is the universal practice of both sexes to grease themselves all over with butter produced from goats' milk, which makes the skin smooth, and gives it a shining appearance. This is usually renewed every day; when neglected, the skin becomes rough, greyish, and extremely ugly. They usually sleep under cover at night; but sometimes, in the hottest weather, they will lie exposed to the night-air with little or no covering, notwithstanding that the fog which rises from the river descends like dew, and, in fact, at that season, supplies the want of rain.

All the males of Tombuctoo have an incision on their faces, from the top of the forehead down to the nose, from which proceed other lateral incisions over the eye-brows, into all of which is inserted a blue dye, produced from a kind of ore which is found in the neighbouring mountains. The women have also incisions on their faces, but in a dif-

ferent

ferent fashion; the lines being from two to five in number, cut on each cheek-bone, from the temple straight downwards: they are also stained with blue. These incisions being made on the faces of both sexes when they are about twelve months old, the dyeing material which is inserted in them becomes scarcely visible as they grow up. The ornaments of the natives are similar to those which are generally found among savage tribes. It does not appear that they hold any public exercise of religion, or have any house of worship, or ever meet to pray, though some ceremony, seemingly religious, was observed at the burial of the dead: but Adams was probably not a very accurate inquirer into these matters. Park describes the natives of Soudan as saying a prayer on the appearance of the new moon; and if the religious observances of these people were so rare of occurrence, it is not surprizing that they escaped the seaman's notice.

Adams says that he saw no shops at Tombuctoo. The articles bought for sale, which consisted chiefly of tobacco, tar, gunpowder, blue nankeens, blankets, earthen jars, and some silks, are obtained from the Moors, and remain in the king's house until disposed of. The only other objects of trade seemed to be slaves. Gunpowder appeared to be more valuable than gold, since a greater weight of the former was given in a barter of the two articles. The exports of this people were chiefly gold-dust, ivory, gum, cowries, ostrich-feathers, and goat-skins, the latter stained red and yellow. Slaves were procured by purchase, and also by predatory incursions into neighbouring states. The king of Tombuctoo seemed to be despotic, but the government was mildly exercised; he and his wife were old and grey-headed: blue nankeen, adorned with gold lace, formed the usual dress of both; and the queen was accustomed to sit and look at Adams and Stevens for hours together. The palace consisted simply of eight or ten small rooms on a ground-floor, not even white-washed, and built of clay and grass. To the surprise of the African committee, Adams did not recollect to have heard there of the Joliba river, a subject of such interesting research: but we should consider that the same river would probably pass under different appellations in the territories of different states. The name of La Mar Zarah closely corresponds with that of the Zayr, or Congo river, presumed by Park to be the termination of the Niger in the Atlantic ocean: but the distance from Tombuctoo to that mouth renders it highly improbable that the river should preserve its name throughout. It should be added, also, that the Tombuctoo river is supposed to fall into the Niger at twelve miles distance from that town; yet the breadth ascribed to it by Adams will not allow us to consider it as a merely subsidiary stream. The editor draws two simple conclusions from this information relative to Tombuctoo; the one, he says, propitious, and the other adverse to the progress of discovery and civilization: *viz.* "the mild and tractable manners of the Pagan Negroes of Soudan, and their friendly deportment towards strangers," on the one hand;—and on the other, "the extended and baneful range of that original feature of African society—Slavery."

TOME, a small island near the west coast of France. N. lat. 48° 50'. W. long. 3° 24'.

TOME, *τομῆς*, a bound book or writing that makes a volume.

TOMEION, formed from *τομῆς*, *section*, a general name used to express any sharp or cutting instrument, used either in surgery or in the mechanic arts.

TOMELLOSO, in *Geography*, a town of Spain, in New Castile; 58 miles S.E. of Toledo.

TOMENTOSE LEAF, among *Botanists*. See LEAF.
TOMENTUM, properly signifies flocks or locks of wool, but by botanists is used for that soft downy matter which grows on the leaves of some plants, hence denominated *tomentose*; as *verbascum tomentosum*, *carduus tomentosus*, &c.

TOMENTUM Cerebri, in *Anatomy*, the flocculent internal surface of the pia mater, with its waving productions belonging to the intervals of the convolutions. The vessels, which enter the cerebral substance, give to the whole a completely villous appearance: it is best seen when the vessels have been injected, and the membrane floats in water.

TOMEPENDA, in *Geography*, a town of South America, in the audience of Quito; 5 miles S.E. of Jaen de Bracamoros.

TOMERIT, a mountain of European Turkey, in Albania; 12 miles E. of Dulcigno.

TOMEROS, in *Ancient Geography*, a river of Asia, in Carmania. Arrian.

TOMERUS, a river of India, W. of the Indus and Arabus, so named by Nearchus. It had its source towards 27° 20' of lat. traversed the country of the Oritæ, and discharged itself into the sea about 25° lat.

TOMESOBI, in *Geography*, a lake of Lower Canada, whence issues the branch of the river St. Francis, on the borders of Vermont.

TOMEX, in *Botany*, from *tomentum*, woolly down, alluding to the pubescence of the plant. The original *Tomex* of Linnæus proving a *CALICARPA*, see that article, sp. 3, Thunberg transferred the name to a new Japanese genus, with which it now remains. Such adaptations of discarded names are not entirely to be commended, and yet we cannot but think them more allowable than the too frequent practice of Linnæus, of applying ancient Greek or Latin ones to new genera, avowedly different from the original plants, though the latter could not be ascertained.—Thunb. Jap. 10. Nov. Gen. 65. Schreb. 315. Willd. Sp. Pl. v. 2. 839. Mart. Mill. Dict. v. 4. Juss. 440. Poiret in Lamarck Dict. v. 7. 696.—This genus is the same with *TETRANTHERA*; see that article.

TOMI, in *Ancient Geography*, a town of Lower Mæsia, towards the mouth of the Danube, near the Euxine sea. This town was considerable, and was the place of Ovid's exile. It was the metropolis of Pontic Scythia. According to this poet, in his third book of *Tristes*, this city was founded by a colony sent thither from Miletus. Tomi was declared the metropolis of Scythia under the emperor Theodosius, and it was the see of the bishop of that country.

TOMIAS, *τομιας*, in *Antiquity*, an appellation given to the sacrifice offered at the ratification of solemn leagues. It was so called because they cut out the testicles of the victim, and took the oath standing upon them.

TOMIDA, in *Geography*, a town of Japan, in the island of Nippon; 5 miles S.S.W. of Quano.

TOMIN, in our *Old Writers*, a weight of twelve grains, used by goldsmiths and jewellers.

TOMINA, in *Geography*, a government of Peru, in the viceroyalty of Buenos Ayres, and archbishopric of La Plata, which begins about sixteen leagues south-east from the city of La Plata. The climate here is hot, and consequently its productions are such as are common to hot countries. Some parts have vineyards, and in others are made considerable quantities of sugar. It also abounds in cattle and sheep. Its extent in some parts is near forty leagues. The vicinity of some free Indians is a continual uneasiness to the towns in this jurisdiction, and even to the city

city of Plata itself, as they have often attempted to surprize it. Tomina, the chief town, is situated 60 miles E.N.E. of La Plata. S. lat. $19^{\circ} 10'$. W. long. $65^{\circ} 46'$.

TOMINE, in *Commerce*, a weight for gold and silver in Spain. Gold is weighed by the Castilian mark of 50 castellanos, 400 tomines, or 4800 grains. Silver is weighed by the same mark, but it is divided into 8 ounces, 64 ochavos, 128 adarnes, 384 tomines, or 4608 grains. The Castilian mark weighs 3557 English troy grains; hence 144 such marks correspond nearly to 89lbs. English troy weight; and, therefore, 96 Castilian ounces = 89 troy ounces.

TOMINEIO, in *Ornithology*, a name by which some authors have called the *guainumbi*, or humming-bird, the smallest of all birds.

The name seems derived from the Spanish *tomine*, a grain weight, as if they would call it a bird of a grain weight.

TOMINY, in *Geography*, a town on the east coast of the island of Celebes, in a bay to which it gives name. S. lat. $0^{\circ} 45'$.

TOMINY Bay. See GUNONG-TELLU.

TOMISA, in *Ancient Geography*, a small country of Asia Minor, which separated Cappadocia from mount Taurus.—Also, a town of Asia, upon the eastern bank of the Euphrates.

TOMISUM, or TOMISUS, a town of Asia, in Greater Armenia, in the country named Sophené. Strabo.

TOMKIN and TOMPION. See TAMPION.

TOMKINS, THOMAS, in *Biography*, a disciple of Bird, M. B. and gentleman of his majesty's chapel (James I.) was an excellent musician. He published songs of three, four, five, and six parts, without a date. But it appears by a copy of these songs in the library of Christ-church college, Oxon. that they were published in 1622.

There are two very curious compositions by Tomkins in the 3d vol. of Dr. Tudway's "Collection of Cathedral Music," in the British Museum: the one is a full anthem, in twelve parts; and the other an anthem in canon throughout, of four parts in one, both well worthy the disciple of the admirable Bird. Indeed, by the compositions we have scored, or examined in score, of Tomkins, he seems to us to have had more force and facility than Morley. In his songs there are melody and accent, as well as pure harmony and ingenious contrivance.

Thomas Tomkins, the father of Bird's disciple, was chanter of the choir at Gloucester, whose family produced more able musicians, during the 16th and 17th centuries, than any other which England can boast. Thomas, the younger, had several brothers, musicians, &c. who distinguished themselves both in composition and performance; among whom was Giles Tomkins, according to Anthony Wood, a most excellent organist of the cathedral at Salisbury; John Tomkins, organist of St. Paul's cathedral, and afterwards gentleman of the chapel-royal; and Nicholas Tomkins, one of the gentlemen of the privy-chamber to Charles I. Thomas, the subject of the present article, the disciple of Bird, and bachelor of music, was afterwards organist of the cathedral of Worcester, gentleman of his majesty's chapel, and, at length, organist. Though he contributed to the "Triumphs of Oriana" in the reign of queen Elizabeth, he was living after the breaking out of the grand rebellion, about which time he published a work in ten books, or separate parts, entitled "Musica Deo sacra et Ecclesie Anglicanæ," consisting of anthems, hymns, and other compositions suited to the church-service. The copy of these compositions, in Clirill-

church college, Oxford, is dated 1664. If this was not a second edition, it is probable that his son was either the author, or at least the editor of the work. By a copy of his songs, in the same collection, that have been said above to be of uncertain date, they appear to have been printed in 1622.

Butler, in his "Principles of Music," published 1636, speaking of the *Lydian mood* of the ancients, which he seems to have persuaded himself he understood, says, "of this mood is that passionate lamentation of the musical king, for the death of his son Absalom, composed in five parts by Mr. Thomas Tomkins, now organist of his majesty's chapel; the melodious harmony of which, when I heard it in the music-school (Oxon.), whether I should more admire the sweet well-governed voices, with consonant instruments, of the fingers, or the exquisite invention, wit, and art of the composer, it was hard to determine." And he calls Mr. Thomas and Mr. J. Tomkins *aurum par Musicorum*.

A set of his vocal church music, in four and five parts, MS. is lodged in Magdalen college, and a printed copy in Christ-church, Oxford. The manuscript copy was presented to Magdalen college by James Clifford, who, in 1663, published a collection of the words, with the names of the composers of such services and anthems as continued to be sung in our cathedrals. To this book Ant. Wood and others frequently refer in speaking of our choral music.

Besides the compositions by Tomkins, mentioned above, in the collection made for lord Harley, British Museum, there are likewise several very learned and curious compositions by this author; particularly full anthems in eight, ten, and twelve real parts, *fugato*. About this time there was a rage for multiplying parts in musical compositions all over Europe; and Herculean labours of this kind, achieved by Tallis, Bird, Benevoli, and others, have been already mentioned.

TOMLINSON'S RUN, in *Geography*, a river of Virginia, which runs into the Ohio, N. lat. $40^{\circ} 29'$. W. long. $80^{\circ} 41'$.

TOMMASI, GUISEPPE-MARIA, in *Biography*, a learned cardinal, was born at Alicata, in Sicily, in 1649, and at the age of fifteen entered among the Theatines at Palermo. He finished his studies at Rome, where he devoted himself to ecclesiastical literature, and from the austerity of his mode of life, and the frequency of his devotional exercises, he was regarded as a model of the religious character. In order to the more successful prosecution of his favourite studies, he obtained access to the principal libraries at Rome, and in 1680 he published his "Codices Sacramentorum nongentis annis vetustiores," 4to. dedicated to Christina, queen of Sweden. This was followed by some other works, and particularly, in 1688, by his "Sacrorum Bibliorum Tituli, &c." 4to. in which he directed his attention to the ancient mode of dividing the Bible. Indefatigably employed in the kind of study to which he was addicted, he published several works in Latin and Italian, chiefly on subjects of religious worship. In consequence of these labours, Clement XI. raised him to the dignity of cardinal in 1712, against his own inclination; but though his revenue was thus increased, he retained his former mode of life, and devoted the residue of his income to the benefit of the needy. He was a regular preacher, a diligent instructor of the poor, and a zealous promoter of a general reformation of manners in Rome. But death prevented the full execution of his laudable purposes in 1713, in his 64th year. The sanctity of his life procured

for him the title of "Venerable." A collection of his works was published at Rome in 7 vols. 4to. from 1747-54. Moreri.

TOMMASINI, JACOPO FILIPPO, a learned ecclesiastic, was born of a noble family at Padua, in 1597, and having entered into the congregation of St. George in Alga, he was made a doctor in theology, and advanced to the first offices in his order. In 1642 he was nominated by pope Urban VIII. to the see of Citta-Nuova, in Istria, where he died in 1654. His writings were numerous; but one of the most interesting was his "Petrarcha Redivivus," 4to. 1635 and 1650, and the "Life of Petrarch." His works are distinguished by the researches of the learned and industrious author into the antiquities and literature of Padua. Moreri.

TOMMOND, in *Commerce*, a measure for rice at Betefagui, or Betefackee, in Arabia. It contains 40 kellas, and weighs 168lbs. avoirdupois.

TOMOGUY, in *Geography*, an island in the East Indian sea, about two miles in circumference, shaped like a horseshoe; subject to the sultan of Bachian. S. lat. $0^{\circ} 15'$. E. long. $127^{\circ} 4'$.

TOMOLO, in *Commerce*, a corn-measure at Naples, and other parts of Italy: a carro contains 36 tomoli; and a tomolo of wheat weighs about 45 rottoli; 69 tomoli = 100 English bushels nearly.

TOM-OTHELE, in *Geography*, a town of United America, in Tennessee; 20 miles S. of Tellico.

TOMOTOCIA, a word used by some authors to express the Cæsarion section.

TOMOU, in *Modern History*, the name of a head-dress which the women wear at Otahcite, consisting of human hair plaited in threads, scarcely thicker than sewing silk, some of which are above a mile in length, without a knot. Hawkesworth's Voy. vol. ii. p. 193.

TOMPEQUE, in *Geography*, a town of Mexico, in the province of Guafteca.

TOMPKINS, a post-township of New York, in the S.W. extremity of Delaware county, 100 miles from Albany; bounded on the N.W. by Mafonville, N.E. by Walton, S.E. by Hancock, W. by Broome county, and a small angle on the state of Pennsylvania. The river Delaware traverses it centrally to the W. line, where it bends southward, and forms about half the western boundary. The land is broken by hills and vallies. This town was erected in 1806, from Walton, and called Pinefield till 1808, when it received its present name, in honour of governor Tompkins of this state. In 1810, the whole population was 896, with 153 families, 48 senatorial electors, 118 taxable inhabitants, and an aggregate of real and personal property, amounting to 143,405 dollars.

TOMPSONSTOWN, a town of Pennsylvania; 22 miles from Lewistown.

TOM-QUAM HOTUN, a town of Corea, on the river Toumen; 633 miles E.N.E. of Peking. N. lat. $42^{\circ} 52'$. E. long. $129^{\circ} 35'$.

TOMS CREEK, a river of New Jersey, which runs between Dover and Shrewsbury.

TOMSEH, a town of Asiatic Turkey, in the province of Diarbekir, on the Euphrates; 70 miles W. of Diarbekir.

TOM-SHOT POINT, a cape on the coast of Africa. N. lat. $4^{\circ} 40'$. E. long. $7^{\circ} 40'$.

TOMSK, a town of Russia, in the government of Tobolsk, on the Tom. The foundation of Tomsk was laid in the reign of the czar Feoder Iwanowitz, who built an ostrog on this spot; and this happened about twenty years before the building of the town of Kuznetzsk. Several

nations of these countries having been reduced by force of arms, and others voluntarily submitted to the Ruffians, the ostrog was, by degrees, converted into a fort, and the fort in time increased to a town; which at present contains above 2000 houses within its circuit. The number of inhabitants is said to be about 8000. It was at first next to Tobolsk, the second principal city in Siberia, and continued so for some years. On the highest part of the town stands a small wooden castle, defended by fourteen pieces of cannon; and in it are a cathedral built of wood, the woiwode's house, the governor's chancery, and an arsenal. Near the fort stand several private houses and a church. The lower part of the town is the most populous. This town is extremely well situated for commerce, and the inhabitants carry on a considerable trade. It lies in the road from Enifeisk, and all the towns in the eastern and northern parts of Siberia; so that all caravans going to and from China pass every year through this town, besides a caravan or two going from the country of the Kalmucks. Here are, indeed, all kinds of tradesmen and artificers; but they are extremely indolent and slothful; 540 miles E. of Tobolsk. N. lat. $56^{\circ} 30'$. E. long. $85^{\circ} 14'$.

TOMSKIAN TARTARS, are Tartars who dwell on both sides of the river Tom, above and below the city of Tomsk. According to the census of 1760, they were only taxed at 430 males.

TOMSKOIZOV, a town of Russia, in the government of Kolivan; 80 miles E.S.E. of Kolivan.

TOMU, a sea-port of Japan, on the south coast of the island of Niphon; 115 miles S.W. of Meaco.

TON, in *Commerce*, a weight in England containing 20 hundreds. (See WEIGHT.)—Also, a measure of capacity. See MEASURE and TUN.

TON, with regard to a *ship*. See TONNAGE.

TON, or *Ton-chun*, in *Geography*, a city of China, of the second rank, in Yun-nan; 1150 miles S.W. of Peking. N. lat. $26^{\circ} 39'$. E. long. $100^{\circ} 23'$.

TONABEA, in *Botany*, Juss. Gen. 262, is merely altered from Aublet's TAONABO; see that article and TERNSTROMIA. Jussieu, p. 451, points out the *Arbor*, n. 3, or Scarlet-feed, Browne's Jamaica, 368. t. 20. f. 3, as of the same genus.

TONAGAYON BAY, in *Geography*, a bay in lake Ontario, near the E. end of Amherst island.

TONAL, a mountain of the Tyrol; 28 miles N.W. of Trent.

TONAMY, a town of Japan, on the N. coast of Niphon; 155 miles N.W. of Jedo.

TONAWALD, a town of Bohemia, in the circle of Boleslau; 10 miles N.E. of Turnau.

TONCAT, TUNKAT, or Tangut, a town of Turkestan, near the river Sirr. Before the time of Jenghis Khan, it was inclosed with a wall, and had a castle for its defence, with a palace for the prince. It was the nursery of many learned men, and called *Dar Al Ilm*, that is, the Palace of the Sciences, on account of its academy. It was a place so charming, that it became a faying, "that God never made a more delicious dwelling than at Toncat." Jenghis Khan held a general diet here in 1224, which was so numerous, that its plain, though twenty miles in length, was scarcely able to contain the great mass of people who were assembled on the occasion; 250 miles N.E. of Samarcand. N. lat. $43^{\circ} 10'$. E. long. $64^{\circ} 15'$.

TONC-CHONG, a town of Thibet; 192 miles S.E. of Lassa.

TONDARBA, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptol.

TONDELO, in *Geography*, a river of Mexico, which runs into the bay of Campeachy.

TONDEMANAR, a town on the N. coast of Ceylon; 12 miles N. of Jaffnapatam.

TONDERN, a town of Denmark, in the duchy of Sleswick, and next to Sleswick one of the most ancient in the duchy; it is well built, though not very large, and the inhabitants carry on a considerable trade in corn, cattle, and fine lace. The old palace was formerly fortified, but is now dismantled and in ruins; 22 miles S. of Ripen. N. lat. 54° 59'. E. long. 8° 50'.

TONDEROS, in *Ancient Geography*, a river of Asia, in the environs of Aria, between the rivers Indus and Arabis or Arbis; called Tuberon by Mela, and Tomeros by Arrian.

TONDIN, or **TANDINO**, in *Architecture*. See **TORE**.

TONDINGA-MATOOR, in *Geography*, a town of Hindoostan, in the circar of Rajamundry; 48 miles E. of Rajamundry.

TONDIVANUM, a town of Hindoostan, in the Carnatic; 15 miles S. of Wandiwash.

TONDOLY, a town on the W. coast of the island of Celebes. N. lat. 0° 57'. E. long. 120° 27'.

TONDORF, a town of Germany, in the territory of Erfurt; 9 miles S.E. of Erfurt.—Also, a town of Bohemia, in the circle of Koniggratz; 9 miles W. of Branau.

TONDOW, a town of Bootan; 25 miles S. of Taffafudon.

TONDRAY, one of the Shetland islands, about six miles in circumference, near the W. coast of Shetland. N. lat. 60° 9'. W. long. 1° 30'.

TONDY, a town of Hindoostan, in Marawar, on the sea-coast; 35 miles S.S.E. of Trumian. N. lat. 9° 42'. E. long. 79° 2'.

TONE, a river of England, which rises about six miles N. from Wivelscombe, passes by Taunton, and runs into the Parret, between Langford and Bridgewater.

TONE, or *Tune*, in *Music*, a property of sound, by which it comes under the regulation of *grave* and *acute*; or, the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of the sonorous body.

For the cause, measure, degree, difference, &c. of tones, see **TUNE**.

The variety of tones in human voices arises partly from the dimensions of the wind-pipe, which, like a flute, the longer and narrower it is, the sharper the tone it gives; but principally from the head of the larynx, or knot of the throat; the tone of the voice being more or less grave, as the rima, or cleft of it, is more or less open.

The word *tone* is taken in four different senses among the ancients: 1. For any sound. 2. For a certain interval, as when it is said the difference between the diapente and diatessaron is a tone. 3. For a certain *locus* or compass of the voice; in which sense they use the Dorian, Phrygian, Lydian tones. 4. For tension, as when they speak of an acute, grave, or a middle tone. Wallis's Append. Ptolem. Harm. p. 172.

The word *tone* has many different applications. In the first place, a tone, distinguished from a semitone, is the characteristic of the diatonic genus, which entirely consists of tones and semitones. Of tones there are two kinds; major and minor. The tone major is in the ratio of 8 to 9, which results from the difference between the 4th and 5th: the tone minor is in the ratio of 9 to 10, and results from the difference between the minor 3d and the 4th.

The generation of the tone major and that of the tone minor is equally found at the second 5th D, beginning from

C: for the quantity by which this D surpasses the octave of the first C, is precisely in the ratio of 8 to 9; and that by which this same D is surpassed by E, major 3d to the octave C, is in the ratio of 9 to 10.

2dly. *Tone* is used in France for the English word *pitch*, or degree of elevation of the whole scale: as *ton d'église*, cathedral pitch; *ton de l'opera*, opera pitch, concert pitch, Roman pitch, &c. At present, concert pitch is nearly the same every where in England, except in our churches, where all our old organs are nearly half a note above concert pitch. The Roman pitch used to be very low; and in organs, a high pitch saves metal. A low pitch in an orchestra may save fiddle-strings, and give ease and courage to fingers fearful of high notes.

The tone of an instrument is good, bad, even, or unequal.

The tone of a voice is sweet or harsh, of a good or bad quality.

To speak *with a tone*, is a canting kind of speech, more resembling bad singing than good speaking.

Tone of colour, in painting, is a metaphorical expression taken from music; as *clair obscure*, light and shade, in music, is from painting.

The French describe an intelligent well-bred person, who has kept good company, by a metaphor from the key in music: when they say that he or she has *le ton de la bonne conversation*.

TONE, in *Physiology*, a term used without any very definite meaning, generally to express the state in which the functions are healthily performed. *Tonic power* is another vague expression, usually applied to those motions of the animal parts which are not obvious to our senses, although sufficiently evinced by their results; as nutrition, secretion, the passage of fluids along excretory ducts, &c. See **LIFE**.

TONE, in *Rhetoric*, denotes a certain inflexion or modulation of the voice, sometimes called *accent*, which corresponds to, and expresses the sensations and emotions of the mind. The skill and success of a reader or speaker very much depend on the proper management of these tones. See **GESTURE**, **PRONUNCIATION**, and **VOICE**.

TONE, *Diæzæutic*. See **DIÆZÆUTIC**.

TONEWANTO, in *Geography*, a town of New York, on a creek of the same name, which runs into the Niagara river, 15 miles E. from the falls of Niagara.

TONG, a city of China, of the second rank, in Pe-tche-li, situated on the river Pai-ho. The walls are substantially built of brick, and higher than the houses they inclose, which mostly are of wood. The city walls are washed by the river on one side, and defended by a broad wet ditch on the other. In the year 1793, there were no guns upon the ramparts, but a few swivels were placed upright near the gates. The principal streets were straight, paved with broad flag-stones, with a raised foot-path on each side. An awning across the streets shaded them from the scorching heat of the sun's rays. Many, however, of the labouring people were naked from the waist upwards. Several extensive buildings contained grain of different kinds, of which it was said a provision for several years is always kept in store for the consumption of the capital. Most of the houses had shops or work-rooms in front; and an industry was displayed such as the neighbourhood of Peking was likely to excite. The outside of the shops was painted with a variety of lively colours, as well as gilt, with rich ensigns before them, and long labels, inviting customers. Among the chief articles exposed to sale, were tea, silks, and porcelain, imported from the southward; and furs of different

different kinds, most of which were brought from Tartary. It was a pleasing circumstance to observe, also, among other goods, some English cloths, though in no considerable quantities; 10 miles E. of Peking. N. lat. $40^{\circ} 56'$. E. long. $116^{\circ} 20'$.—Also, a city of China, of the second rank, in Kiang-nan, at the mouth of the Yang-tse river; 347 miles S.S.E. of Peking. N. lat. 32° . E. long. $120^{\circ} 19'$.—Also, a city of China, of the second rank, in Ho-nan; 490 miles S.S.W. of Peking. N. lat. $32^{\circ} 48'$. E. long. $111^{\circ} 42'$.—Also, a city of China, of the second rank, in Chen-hi, on the river Lo; 447 miles S.W. of Peking. N. lat. $34^{\circ} 32'$. E. long. $109^{\circ} 30'$.—Also, a river of Benguela, which runs into the Atlantic, S. lat. $14^{\circ} 25'$.

TONGA ISLANDS, a cluster of islands in the South Pacific ocean, consisting of the island of Tonga, which gives name to the whole of the cluster called Hapace, and the island of Vavao. It is a part of the group to which captain Cook gave the name of Friendly islands, but he did not include in his chart Vavao or Vavaou, which he did not visit; though this is the largest, and now comparatively the most important of all those belonging to the same Archipelago, which, in his time, were under the same government, and still speak precisely the same language, and observe the same customs. An account has been lately published from documents furnished by Mr. William Mariner, four years resident in those islands; 2 vols. 8vo. 1817. See FEEJEE, FRIENDLY, HAPACE, TONGATABOO, VAVAO, &c.

TONGATABOO ISLAND, one of the Friendly islands in the South Pacific ocean, first discovered by Tafinan, who called it Amsterdam; seen by captain Cook in the year 1773, and visited by him again in 1777. Tongataboo, or Tonga, is about sixty miles in circuit, somewhat oblong, though by much broadest at the E. end; and its greatest length from E. to W. The south shore is straight, and consists of coral rocks, eight or ten feet high, terminating perpendicularly, except in some places, where it is interrupted by small sandy beaches; on which, at low water, a range of black rocks may be seen. The west end is not above five or six miles broad, but has a shore somewhat like that of the south side; whereas the whole north side is environed with shoals and islands, and the shore within them low and sandy. The east side or end is most probably like the south; as the shore begins to assume a rocky appearance towards the north-east point, though not above seven or eight feet high. The island may with the greatest propriety be called a low one, as the trees on the west part, where captain Cook lay at anchor, only appeared; and the only eminent part which can be seen from a ship, is the south-east point; though many gentle rising and declining grounds are observable by one who is ashore. The general appearance of the country is that of great want of fertility. At a distance the surface seems entirely clothed with trees of various sizes; some of which are very large. But above the rest, the tall cocoa-palms always raised their tufted heads; and are a very considerable ornament to any country that produces them. The boogo, which is a species of fig, with narrow pointed leaves, is the largest tree of the island. The winds are, for the most part, from some point between south and east; and when moderate, are commonly attended with fine weather. The basis of the island, as far as it could be observed, is entirely a coral rock, which is the only sort that presents itself on the shore. Of cultivated fruits, the principal are plantains, of which they have fifteen different sorts or varieties; bread-fruit; two sorts of fruit found at Otahcite, and known there under the name of jambu and eeevec, the latter a kind of plum; and a vast number of shaddocks, which however are found as often in a natural state as planted.

The roots are yams, of which are two sorts; one black, and so large that it often weighs twenty or thirty pounds; the other white and long, seldom weighing a pound; a large root, called kappe; one not unlike our white potatoes, called mawhaha; the talo, or coccos of other places; and another named jeejee. Besides great numbers of cocoa-nut trees, there are three other sorts of palms, two of which are very scarce. The only quadrupeds, besides hogs, are a few rats, and some dogs, which are not natives of the place, but produced from some left by captain Cook in the year 1773, and by others got from Feejee. Fowls, which are of a large breed, are domesticated here. Amongst the birds are parrots, somewhat smaller than the common grey ones, of an indifferent green on the back and wings, the tail bluish, and the rest of a footy or chocolate brown; parroquets not larger than a sparrow, of a fine yellowish-green, with bright azure on the crown of the head, and the throat and belly red; besides another sort as large as a dove, with a blue crown and thighs, the throat and under part of the head crimson, as also part of the belly, and the rest a beautiful green; owls, cuckoos, king-fishers, and a bird of the thrush kind. The other land birds are rails, fly-catchers, and three sorts of pigeons. Of water-fowl, and such as frequent the sea, are ducks, blue and white herons, tropic birds, noddies, and white terns. The only noxious or disgusting animals of the reptile or insect tribe are sea-snakes, scorpions, and centipedes. The insects amount to about fifty different sorts. The sea abounds with fish, though the variety is less than might be expected. The most common sorts are mullets, several sorts of parrot-fish, silver-fish, and albigores; some sharks, rays, pipe-fish, a sort of pike, and some curious devil-fish. The many reefs and shoals on the north side of the island, afford shelter for an endless variety of shell-fish; amongst which are many that are esteemed precious in Europe, such as the hammer-oyster, of which, however, none could be obtained entire; a large indented oyster and several others, but none of the common sort; panamas; cones; a sort of gigantic cockle, found also in the East Indies; pearl-shell oysters, and many others. There are likewise several sorts of sea-eggs, and many fine star-fish, besides a considerable variety of corals, amongst which are two red sorts, the one most elegantly branched, the other tubulous. And there is no less variety among the crabs and cray-fish, which are very numerous. To which may be added, several sorts of the sponge, the sea-hare, and the like. See TONGA. S. lat. $21^{\circ} 9'$. E. long. $185^{\circ} 14'$. Cook's Third Voyage, vol. i.

TONGATORE, a town of Hindoostan, in Golconda; 30 miles S.E. of Hydrabad.

TONGBLOW, a town of Burmah; 12 miles from Raynangong.

TONGE, NIEUWE, a town of Holland, in the island of Overflakee; 3 miles S. of Sommerdyck.

TONGE, *Oude*, a town of Holland, in the island of Overflakee; 4 miles S.E. of Sommerdyck.

TONGELREP, a river of Brabant, which runs into the Dommel, near Eyndhoven.

TONGEREN, or TONGRES, a town of France, in the department of the Lower Meuse, late in the bishopric of Liege. This town is ancient, and was formerly governed by dukes. The collegiate church of Tongres is very ancient; they say it was the first on this side the Alps, built by St. Materne, who was sent by St. Peter to preach the gospel in Lower Germany, and became the first bishop of Tongres; which was erected into a diocese. It has three parish churches, and several religious houses. The French, in the year 1677, committed a thousand sacrileges and infidelities,

lencies, without regard to age or sex, and set fire to the town-house, the churches, several convents, and above 600 houses: and their fury was again repeated, under a pretence that the inhabitants had refused their contributions, and assisted the troops of the allies; 9 miles N.N.W. of Liege. N. lat. $50^{\circ} 46'$. E. long. $5^{\circ} 28'$.

TONGERLOO, a town of France, in the department of the Dyle; 9 miles N. of Aerschot.—Also, a river of France, which runs into the Meuse, 3 miles below Maesfick.—Also, a town of France, in the department of the Lower Meuse; 4 miles N.W. of Stockem.

TONG-GIN, a city of China, of the first rank, in Koei-tcheou, on the borders of Houquang. In the environs are gold and copper mines; 850 miles S.S.W. of Peking. N. lat. $27^{\circ} 39'$. E. long. $108^{\circ} 37'$.

TONGHO, a town of Birma, and capital of a province, strongly fortified. Here are manufactures of cotton cloth, and the environs produce the best beetle in the empire.

TONGKEEL, one of the Sooloo islands. N. lat. $6^{\circ} 2'$. E. long. $121^{\circ} 50'$.

TONG-KIN-TSIN-FOU, a town of Corea; 48 miles W.S.W. of King-ki-tao.

TONG-LAI, a town of Corea; 70 miles S. of Koang-tcheou.

TONG-LAN, a town of China, of the second rank, in Quang-fi; 1077 miles S.S.W. of Peking. N. lat. $24^{\circ} 27'$. E. long. $106^{\circ} 26'$.

TONGOI-PATCHI, a town of Thibet; 30 miles N. of Oramtchi Hotun.

TONGOLORE, a town of Hindoostan, in the Carnatic; 10 miles S. of Ongole.

TONGOY, a river of Chili, which runs into the Pacific ocean, S. lat. $30^{\circ} 10'$.

TONG-PIN, a city of China, of the second rank, in Chan-tong, on the river Ta-tsin; 190 miles S. of Peking. N. lat. $36^{\circ} 6'$. E. long. $115^{\circ} 56'$.

TONGPOTRA, a town of Pegu; 50 miles S. of Lundfey.

TONG-TCHANG, a city of China, of the first rank, in Chan-tong, on the grand canal; 212 miles S. of Peking. N. lat. $36^{\circ} 34'$. E. long. $115^{\circ} 40'$.

TONG-TCHOUEN, a city of China, of the second rank, in Se-tchuen; 720 miles S.W. of Peking. N. lat. $31^{\circ} 6'$. E. long. $114^{\circ} 44'$.—Also, a city of China, of the first rank, in Se-tchuen. This city is strongly fortified, and is called a military city, because the inhabitants are all soldiers; the profession descending from father to son. Besides their pay, they have the lands which surround the city. These troops are disbanded in time of peace, and to make them amends, they are placed in all the garrisons that are in the frontiers of the empire; 1000 miles S.W. of Peking. N. lat. $26^{\circ} 20'$. E. long. $103^{\circ} 2'$.

TONG-TCHUEN, a town of Corea; 85 miles E.N.E. of King-ki-tao.

TONG-TIN-HOU, a lake of China, in the province of Hou-quang, more than 80 leagues in circumference.

TONGTREE, in *Rural Economy*, a term applied to the pole of an ox-cart, or that of a waggon, and perhaps some other sorts of carriages.

TONGUE, *LINGUA*, in *Anatomy*, an oblong member, whose form and situation are sufficiently known, and whose use is to be the organ of taste, and the principal instrument of speech and deglutition. See *DEGLUTITION*.

The upper side of the tongue is covered with a papillary nervous substance, over which are spread two membranes. The outer of these membranes is pretty thick, and full of papillæ, of a pyramidal figure, especially towards the tip, which pa-

pillæ stand pointing towards the root of the tongue in a bending posture, which makes their figure to be concavo-convex. These apices, or papillæ, are so very minute and slender in men, that they make the coat appear on the upper part villous, especially as they approach nearer to the root. The figure of the papillæ, in human tongues, is not so plainly discernible to the naked eye as not to need the microscope. In brutes they are generally larger, stiffer, and more conspicuous; and in some almost cartilaginous, as may be felt in the tongues of cats and oxen, but more sensibly in lions. On the upper side, at a little distance from the tip, this membrane becomes thin, smooth, and glabrous, and, as it were, polished by the lower parts of the mouth on which it slides.

Under this lies a thin, soft, reticular kind of coat, punched through with innumerable holes, and always lined with a thick and white, or yellowish mucus. This membrane is so exceedingly tender, and full of mucus, that it is not to be examined by the naked eye, unless boiled; by which it grows tough, and easily separable from the external membrane, and from the nervous part of the tongue, which lies immediately under it. After boiling, it appears like a kind of gauze, between whose threads innumerable holes appear, through which the apices of the papillary body underneath it are exerted. This membrane on the upper side, next the outward, appears white, with a cast towards yellow, but is black on the side next the tongue.

Many authors do not allow this to be a membrane, and will only have it to be a mucus hardened by boiling; but since it has so much of the resemblance of a membrane, and that authors agree in allowing two membranes to the tongue, Dr. Drake does not scruple to number it among them, since there does not appear to be any other second membrane; reckoning, with Malpighi, the smooth part under the tongue a part of the outer membrane; some, however, have considered it as a continuation of a distinct membrane, which covers that of a papillary texture.

Immediately under this appears a nervous papillary body, spreading itself to a moderate thickness over the whole surface of the tongue. This body, on the under side, is every where level and smooth, except in some few places, where it is connected to the subjacent muscular part by some nervous twigs which it sends into it. Malpighi distinguishes the papillæ, which make the principal part hereof, into three kinds, from their different magnitudes and figures when observed with the microscope; of which those seated on the sides and tip are very singular, resembling little round pyramids, with globes on their tips like the horns of snails. All these papillæ, which are the immediate organs of tasting, send their apices, or extremities, through the mucous membrane into the pyramidal papillæ of the outer membrane, which are hollow to receive them, and seem to be nothing else but a kind of cases to defend these nervous papillæ from injuries, which the salts and asperities of those bodies which we might take into our mouths might do them. See *TASTING*.

However necessary an organ the tongue be in speech, &c. yet instances have occurred, in which persons, who have lost their tongues, have spoken distinctly.

We have had in England an instance of this kind in one Margaret Cutting. See *Philos. Trans.* N^o 464. or *Abr.* vol. ix. p. 126. *Idem*, vol. xlv. p. 621.

Another occurs in Lamberti's Memoirs, and another in the Memoirs of the Academy of Sciences.

To the instances briefly mentioned above, we may add the following account of a man at Montagu, in the Bas Poitou, who being seized with the small-pox in his fifth

TONGUE.

or sixth year, lost his whole tongue by gangrene, or putrefaction; yet, notwithstanding, performed in perfection the five actions belonging to the tongue, *viz.* speaking, talking, spitting, chewing, and swallowing; nature having, with infinite artifice, given a new conformation to the mouth, proper to supply the want of the last organ. See Jac. Rolandi Aglossiographia, five Descriptio Oris sine Lingua quod perfecte loquitur et reliquas suas Functiones naturaliter exercet; first published in French at Saumur, in 1630, translated into Latin by Car. Ruygerus, and published in the Ephem. German. D. an. 3.

For speech, instead of the ordinary provision, the little fleshy part of the tongue remaining was inserted in the middle towards the palate, the teeth inverted, and long inwards, the muscoli buccinatores easily contracting between the dentes molares. In fine, there was a disposition in all the organs to produce speech without a tongue; for the breath issuing at the oval aperture of the larynx, was farther broken, and rendered vocal by the inflation of the fleshy body, the motion of the lips, the retraction of the buccinatores, the tremulous agitation of the uvula, and the commotion of the lower jaw. Lastly, by the inversion of the teeth, the depression of the palate, the abundance of saliva, and the capacity of the mouth, the sound was still farther modified and determined, so as to render it articulate. Habit, too, and the repeated attempts to speak at an age when the parts were easily flexible, had contributed greatly to the distinctness of it.

For tasting, it is evident from this, as well as other considerations, that the tongue is not the only organ of it, but that the palate is also a seat of this sense. For chewing, the office of turning the meat in the mouth was here performed by the lips and cheeks, the muscles of which repelled towards the maxillares such parts as in mastication might fall from one side to the other. For the first morsel he took, he could only chew on that side into which he put it with his hand; the second he put in like manner on the other side, and thus varied and supplied each alternately. For swallowing, the gravity of the food contributed something to this, which he farther promoted by stretching out his neck, inclining his head, and drawing back the buccinatores within his teeth; all which were seconded by the mouth and fauces being well moistened with plenty of saliva. In effect, divers animals, as the tortoise and the crocodile, stork, &c. swallow without any tongue; and fish, though their tongue is fixed immoveable to their palate. For spitting, it was performed by the lips, aided by the internal contraction of the mouth, and the retraction of the buccinatores over the grinders.

Roland's instance was singular at that time, but a parallel one has been since observed in a girl at Lisbon, fifteen years old; of which an account was given, in 1718, to the Royal Academy of Sciences, by M. de Jussieu. Upon inspecting the mouth of this girl, there appeared nothing in all that part ordinarily possessed by the tongue, but a little eminence in form of a papilla, between three and four lines high, in the middle of her mouth, scarcely perceivable by the eye. Upon pressing this with the finger, a kind of motion of contraction and dilatation was perceived in it, which shewed, that though the tongue was wanting, the muscles of which it was formed, and which were destined to give it motion, were nevertheless there. With the help of these she spoke as distinctly and easily as if nothing had been wanting: she distinguished tastes like other people. For mastication, it was chiefly effected by the motion of the lower jaw, which she drew nearer to, or farther from, the grinders of the upper, under which the food to be chewed was. In this

action she sometimes also made use of her fingers, but much more in the action of swallowing, in order to protrude the masticated food towards the orifice of the œsophagus. For drinking, she performed it like other people, excepting the attention she employed to prevent the liquor going down too fast; in order to which she kept her head a little inclined forwards. Lastly, the action of spitting was supplied by the muscles of the papilla, which filled the lower part of her mouth; these rising almost to a level with the teeth of the lower jaw, and the buccinatores approaching towards both jaws, expressed the saliva, and conducted it to the sphincter of the lips, from whence the air, driven with violence from the larynx, served as a vehicle to expel it out of the mouth. Mem. de l'Acad. Scienc. ann. 1718, p. 6—16. Jussieu, loc. cit. p. 7, seq.

Dr. Mortimer, from a MS. account of the life of the Rev. Mr. Henry Wharton, chaplain to archbishop Sancroft, informs us, that he was born with two tongues. Phil. Transf. vol. xlv. p. 232.

TONGUE, Injuries and Diseases of. Wounds of the tongue have generally been divided, by writers on *Surgery*, into longitudinal and transverse. The former rarely happen, and seldom demand any but ordinary treatment. The same may be said of punctured wounds of this organ; cases which are occasionally met with in practice.

The most frequent wounds of the tongue are those which are transverse. They are hardly ever produced by outward means; but usually by the teeth, when the lower jaw is forcibly and spasmodically brought against the upper one, while the tongue is out of the mouth, as sometimes happens in epilepsy and falls upon the chin. In this way, transverse wounds of considerable extent frequently happen, almost separating, in some instances, the apex from the body of the tongue. In such cases, the injury may easily be converted into a sort of cleft, which may remain for ever afterwards, and more or less interfere with the functions of the organ. This disagreeable consequence is more likely to happen, when no care is taken to keep the opposite sides of the wound in proper contact, and hinder them from becoming distant from each other.

Hence, certain writers on surgery have recommended all wounds of the tongue to be immediately closed with a future; and Richter, though by no means a constant advocate for this method, is candid enough to allow, that it has succeeded in the best manner, even in cases where the tongue was bitten nearly through. Anfangsgr. der Wundurzn. b. iii. p. 24.

The application of a future to the tongue being attended with some pain and difficulty, a very simple bandage has been proposed for uniting transverse wounds of this part. (Pibrac, Mem. de l'Acad. de Chirurgie, tom. ix. p. 22. pl. 9. Le Blanc, Précis d'Opérations.) Richter maintains, however, that the invention referred to does not answer expectation. The main portion of it is a little sort of bag, in which the fore part of the tongue is confined. Thus all motions of this organ forwards, or laterally, may be effectually prevented; but the patient is not deprived of the power of drawing it backward, that very action, which has a direct tendency to make the sides of a transverse wound separate from each other. In some cases, indeed, as Richter observes, the apparatus seems rather to do harm. Children, to whom it proves exceedingly irksome, are made restless by it, so that they keep moving their tongue and jaw about, to the great irritation and disturbance of the wound.

Richter further objects to Pibrac's bandage, that it is decidedly unnecessary; for, such motions of the tongue, as it directly restrains, namely, those forwards, or to either side,

sive, may be hindered by applying a bandage to the jaw, and making the patient refrain from talking and mastication. The same author affirms, that such treatment has answered as well as could be desired, in numerous cases, some of which were large transverse wounds in restless and unmanageable children. During the treatment, however, the patient is to be allowed only liquid nourishment, which must be imbibed through a tube.

Perhaps, however, on the whole, the propriety of employing a future must depend entirely on considerations of the following kind. When the transverse wound is deep, and extends quite across the dorsum of the tongue; when it is situated towards the apex, and is inconveniently within reach; and when the patient is uncontrollable, and cannot be made to keep the tongue and lower jaw quiet; a future may be advantageous. On the other hand, when the wound is at the back part of the tongue, (a case by the bye that is unfrequent,) and a future must be difficult of application; when the wound is trivial, likely to heal of itself, and there is no risk of its occasioning any material cleft in the part; and when the patient is docile, and attentive to the advice given him; the most judicious practice is to apply such a bandage as is recommended for the fractured jaw, and to forbid all motion of the tongue and lower jaw, by speaking, masticating, &c. nothing but liquid food being allowed to be drunk through a tube.

If the wound should be so deep, as almost to separate the anterior part of the tongue from the rest of this organ, the remaining connection is not to be divided; but an endeavour made to bring about an union. There are numerous cases on record, encouraging the practitioner to expect the best consequences from the attempt. Richter's *Anfangsgr. der Wundarzn.* b. iv. p. 26.

With regard to other circumstances, relating to wounds of the tongue, the treatment of these cases does not differ from that of wounds in general.

Bleeding from the Tongue.—An hæmorrhage from the raninal vessels sometimes follows accidental wounds, and surgical operations on the tongue. When it is an artery that bleeds, the accident may prove dangerous, and even fatal, especially in children, who by moving the tongue and jaw about, and continually sucking, promote the hæmorrhage, and render the adoption of the measures necessary for its suppression extremely difficult. As, in these cases, a ligature, compression, and styptics, hardly admit of being applied, the bleeding cannot be stopped, without much trouble. Whether the raninal arteries can be tied in the manner suggested below, remains to be proved; but, certainly, they are rather too far out of reach to be tied in the common way. Nor can compression, as ordinarily performed, be trusted, since it operates against soft yielding parts, and not upon any fixed point. Strong styptics, even were they deemed worthy of trial, could not well be employed, since they would be apt to mix with the saliva, and be swallowed. Yet, there are some means, by which the most perilous bleedings of this sort have been stopped.

Among the most celebrated of these last methods is the actual cautery, which is preferred by several of the continental surgeons, and may, perhaps, in this solitary instance, seem almost justifiable to British surgeons, averse as they properly are to this barbarous practice.

Another plan is that of directing an assistant to keep a compress on the bleeding vessels, as long as necessary, with his finger; while, with his thumb, he takes care to make counterpressure under the jaw. M. Jourdain stopped a considerable hæmorrhage from the raninal vessels, by laying a piece of ice under the tongue. M. Petit was the inventor

of an apparatus for stopping such bleedings, which is at once simple, ingenious, and effectual. The surgeon is to get a piece of birch, and cut it through below the place where two branches of equal size unite. It is to be made to resemble a sort of fork, the prongs of which are to be about eight lines long, and the handle four. It is then to be covered all over with linen, and put under the tongue in such a way, that the end of the handle is to rest against the middle of the concavity of the arch of the jaw, while the prongs embrace the frænum, and compress the bleeding vessels. The middle of a roller is next to be applied to the dorsum of the tongue, as far back as possible; and the ends, after crossing each other under the chin, are to be pinned to the child's night-cap.

If a surgeon were to be averse to these plans, or find them unavailing, there is yet one resource left, namely, that of cutting down to, and tying the trunk of the lingual artery, just where it passes over the cornu of the os hyoides.

Hæmorrhage from the raninal vessels occasionally arises quite independently of a wound. In one such example, the bleeding proceeded from a varicose vessel under the tongue, and was effectually stopped with the cautery. See *Default's Journ. de Chirurg.*

Dangerous Enlargement of the Tongue from Inflammation.— Sometimes when this organ is inflamed, it swells so prodigiously, that it protrudes between the teeth, entirely fills the cavity of the mouth, and obstructs speech, deglutition, and even respiration. In such a case, the most prompt assistance is demanded. Ordinary evacuations of blood, and other antiphlogistic measures, here seldom bring relief with sufficient celerity. According to surgical authors, the most certain plan consists in making two longitudinal cuts along the edges of the dorsum of the tongue, from one to two inches in length. A copious bleeding generally follows, which soon brings about a diminution of the swelling. No troublesome consequences are to be apprehended from such incisions, which heal with ease, and scarcely leave any scar behind. De la Malle, *Mem. de l'Acad. de Chir.* tom. v.

Jourdain succeeded in affording prompt relief, by taking blood from one of the raninal veins. This method seems liable to no objection, except perhaps that of being difficult, when the tongue is enormously swelled. *Traité des Maladies de la Bouche, &c.*

In one example, the disease resisted every means until a blister was applied to the throat. Richter's *Anfangsgr.* band. iv. p. 29.

Some inflammations of the tongue have been observed to originate from the lodgement of foreign bodies in it, which ought to be extracted; as, for instance, a fish-bone, or a needle. (Jourdain, *Traité des Mal. de la Bouche, &c.*) Other cases have arisen from the injudicious employment of mercury, and the excitement of a sudden and immoderate salivation. Many examples are connected with violent inflammation of the parts about the throat.

Sometimes inflammations of the tongue terminate in supuration. Such abscesses rarely admit of being opened, and hardly allow the use of any means, except emollient gargles.

Cases have occurred, in which inflammation of the tongue has induced mortification, and the loss of the greater part of this organ. The treatment of such instances must conform to the general rules delivered in the article GAN- GRENE.

When, in consequence of any enlargement of the tongue, or other disease in the mouth, the necessary food and medicines are, for a considerable time, prevented from being taken, they may be injected into the stomach through an elastic

TONGUE.

elastic catheter, which is to be passed through one of the nostrils into the œsophagus. It has been recommended to have the outer end of the instrument to turn upward out of the nostril, and shaped like a funnel, whereby it is supposed fluids might be more conveniently introduced. (Libouton, *Journal de Médecine*, tom. xxxiv.) But we do not consider this any material improvement, since all liquids may be easily injected with an elastic gum syringe, such as is used for injecting hydroceles, without having the external end of the catheter made in the manner above suggested.

Ulcers, Indurations, and Tumours of the Tongue.—Ulcers on the tongue, of an exceedingly painful, obstinate, and malignant looking nature, are sometimes produced by the sharp or rough edge of a tooth. This mechanical kind of cause is easily detected on examination with the finger. If the tooth be found, the projection or roughness must be filed off; if it be carious, the best plan is to extract it. When these objects are accomplished, the sore usually heals without further trouble.

Some very obstinate ulcers, which originate on the tongue, and are connected with disorder of the digestive organs, may be cured by a long perseverance in the use of the antim. tart. exhibited alternately in small doses, and then in larger ones, so as to excite vomiting.

Ulcers, deserving the epithets malignant and cancerous, not unfrequently form on the tongue. Sometimes the malady, in its most incipient state, appears as a sore. Sometimes a circumscribed moveable, or immoveable, scirrhous swelling is first observable, which gradually becomes painful, and ulcerates. In other instances, there is, in the beginning, only an induration in the substance of the tongue, without the smallest appearance of any swelling. The ulcers, under consideration, are always surrounded by hardness. They may make their first appearance either at the edges or at the apex of the tongue. In certain cases, the whole, or a large portion, of this organ is covered with numerous small scirrhous tubercles, which gradually fall into a state of ulceration. These we have seen greatly diminished by a gentle course of mercury. All the medicines, tried in other cases of cancer, may be exhibited in the present ones; but, on the whole, the timely employment of the knife merits the most confidence.

However, the following kinds of cases have yielded to particular remedies.

A malignant exceedingly painful ulcer on the tongue, surrounded with a good deal of inflammatory hardness, has been cured by the continued internal use of opium. The dose is to be gradually augmented; patients are stated to have taken, at last, eighteen grains in one day.

One species of malignant ulcer yields to the long continued exhibition of tartar emetic. The doses must be increased, in proportion to the time which elapses from the first taking of the medicine.

Very malignant and unyielding sores on the tongue are said to have been cured by repeatedly applying leeches to the under surface of this organ. *Med. Commen.* vol. ii.

It would be inexcusable to pass over in silence such ill-conditioned ulcers of the tongue, as originate during violent salivations. Sometimes similar sores, produced by the same cause, take place, at the same time, on the tonsils; and, in this circumstance, inexperienced surgeons, or mistaken practitioners, who are blinded with the fear of syphilis, are very apt to suppose the sores to be venereal ones. This error leads to the freer use of mercury: the sores frequently slough; and the patient's health becoming greatly deranged, he is thrown into a state of great peril. In this case, it is hardly necessary to observe, that the use of mercury must

be immediately omitted, and the mouth very frequently washed with a solution of alum.

Violent inflammations, followed by ulcerations of this sort, are particularly apt to occur, when patients catch cold, while they are under the influence of mercury.

For the removal of a cancerous portion of the tongue, a bistoury is the best instrument; and the patient's mouth should be kept open during the operation, by the interposition of something between the teeth. The hæmorrhage is generally what is most apprehended; but we have instances related of large portions, and even of the anterior half of the tongue, being amputated, and of the bleeding being easily suppressed, either by the actual cautery, or some of the ordinary means for the suppression of hæmorrhage. It appears to us, that a tolerably dexterous man might tie the mouth of an artery in this situation, with the assistance of two pair of forceps to tighten the ligature, when the noose has been put over the tenaculum round the bleeding point. Certainly, cancerous diseases of the tongue may have advanced to such a degree, that an operation cannot be prudently undertaken. The bleeding would be a serious objection; the whole distemper of the tongue itself might not be removeable; and the contaminated state of the adjacent lymphatic glands below the jaw, usually existing in this advanced state of the malady, would, according to received opinions, render a radical cure quite impracticable.

When the disease is not in the vicinity of the apex of the tongue, the operator may find it difficult to draw the part sufficiently forwards, and keep it in this position. In this circumstance, surgical authors recommend the employment of a pair of forceps for the purpose, the blades of which are to be covered with rag. Should this instrument be found ineffectual, they advise the surgeon to use a pair of forceps, the blades of which terminate in two short double hooks. As being painful, one should always avoid, if possible, the employment of such an instrument.

Here, as in all other cancerous cases, it is the duty of the surgeon to take care that no point, suspected of participating in the disease, be left behind. Unless this maxim be attended to, the operation will mostly be followed by a relapse.

Abroad, surgeons have sometimes effected a cure by applying the cautery, notwithstanding the wound after the operation had put on an unhealthy and fungous appearance. (*Journ. de Méd.* tom. xviii.) In this country, practitioners might hope for similar success from the cautious employment of caustic; for the revival of the cautery, under any circumstances, is an idea now almost intolerable to every British practitioner.

After the excision of a diseased portion of the tongue, local applications cannot be very well used; nor are they in general necessary, when the patient moves the part as little as possible, and avoids putting stimulating food and liquids into his mouth.

Cancerous portions of the tongue may also be extirpated, by passing a double ligature through this organ, and firmly tying one part of the ligature over each side of it.

This plan must be infinitely more painful, than the removal of the diseased part with a knife. To the latter method, the hæmorrhage is the only objection; and, notwithstanding all that has been said, we think no surgeon ought to venture to cut away a diseased tongue, without having first made up his mind respecting what method should be adopted for stopping the bleeding.

When much of the tongue has been lost, there certainly is reason to expect, that its functions will afterwards be performed in a very imperfect manner. However, there

are on record several examples, in which the greater part of this organ was lost, and yet the patients retained the faculties of tasting, masticating, swallowing, and articulating words, with considerable perfection. See Mem. Physiolog. &c. sur la Langue par M. Louis in Mem. de l'Acad. de Chir. tom. xiv.

The removal of scirrhus and sarcomatous tumours of the tongue may be most conveniently accomplished with a scalpel and a tenaculum. Encysted swellings of this organ are generally of the meliceris kind, and ought, if possible, to be dissected out, without opening the cyst at all.

Authors relate examples, in which the tongue has been of extraordinary magnitude, either in consequence of original malformation, or a peculiar sort of disease. Excepting the deformity, arising from the projection of the part out of the mouth, some of these patients experienced no particular inconvenience, as they could speak, masticate, and swallow tolerably well. Under such circumstances, the removal of the redundant portion would not be adviseable; but if the disfigurement were combined with much inconvenience, the operation would be proper, especially as the cut part would be so forward in the mouth, that the bleeding vessels could be tied. First Lines of the Practice of Surgery, by S. Cooper, edit. 3.

TONGUE-grafting. See ENGRAFTING.

TONGUE-tied, the popular name for a distemperature of the tongue in children, when it is tied down too close to the bottom of the mouth, by a ligament connected all along its middle, and called its frænulum, which requires to be divided to give the tongue its proper motion.

This is sometimes the case in adults, but oftener in children, who cannot then exert their tongues to suck. This is, however, by no means so common as the women usually imagine; not so much as one child in a thousand being afflicted with it; nor is the operation in cutting it of little consequence, since often bad accidents follow it, and sometimes the loss of a child's life. When the infant can put its tongue out of its mouth, the frænulum wants no incision; but when the tongue cannot be extended beyond the teeth, the operation is necessary.

To perform this, the end of the tongue should be covered with a linen rag, and held with the fingers to prevent its slipping, and the ligament of the tongue running between the ranular veins and internal salival ducts, is to be divided by a pair of obtuse pointed scissars, till it gives room enough for sucking or speaking; but in doing this, great care must be taken not to wound the salival ducts, or the proper veins and arteries of the tongue; for children have been known to perish upon the spot from cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers as soon as the child is born; but this is a dangerous practice. Heister. See INFANTS.

TONGUE of Fish. All fish have either a perfect tongue, or the rudiments of one, in their mouth; but this organ is very different in the various species, in its figure, mobility, and other qualities and properties; as to the figure, it is in some pointed before, as in the clupeæ; in others it is rounded in this part, as the perch and claræ have it; and in others it is somewhat bifid, as in the pike. In some it is smooth on the upper part, as in the gadi, cyprini, and mackarel; in others it is rough and dentated in this part, as in the salmon, mullet, &c. In many fish, the tongue is immovable, adhering firmly to the bottom of the mouth, as in the perch, cyprinus, and, indeed, in the greater part of fish; in others it is loose, as in the whale.

In the cetaceous fish, the tongue being loose, as in quadrupeds, it is used by the animal in the same manner; but

in other fishes it is of no use in the moving of the food about in the mouth, nor is it the genuine organ of taste, being in many a cartilaginous substance, and therefore not proper for receiving the notices of that sense. The principal use of the tongue in these fish seems to be in its serving as an assistant organ of swallowing, its being more elevated than the other parts of the mouth, rendering it fit for the tossing of the food down the throat. The true use of the tongue in those fish which have it dentated is, that it serves to retain the prey from running out of the mouth, and afterwards in the swallowing of it: what renders them more fit for this use is, that they have always the prickles turning inwards. It is the opinion of Mr. Ray, that the tongues of the cartilaginous kinds have some sense of taste, and this is more probable, than that the more hard and rigid ones should have any such sense. Artedi de Piscib. See FISH.

TONGUE of a Muscle. What is vulgarly called the tongue in this fish from its shape, is truly an organ, by means of which it spins a sort of threads in the manner of spiders or caterpillars, to fix itself to the rocks by. See MUSCLE.

TONGUE, in the *Manege*. The aid of the tongue or voice, is a sort of agreeable clacking, or a certain sound formed by the cavalier, in striking his tongue against the roof of his mouth, when he means to animate the horse, and sustain him, and make him work well in the manege. See AID.

TONGUE, To swallow the. A horse is said to draw in, or swallow his tongue, when he turns it down his throat, which makes him wheeze as if he were short-winded. This fault is cured by giving him a bit with a liberty for the tongue.

TONGUE, Serpent's, in *Botany*. See ADDER'S Tongue.

TONGUES, Serpents', in *Natural History*. See SERPENTS' Tongues, and GLOSSOPTERA.

TONGUE, in *Mast-making*, the taper part at the lower end of a spindle, or of a scarf. In *Rigging*, a short piece of rope spliced into the upper part of standing-backstays, &c. to the size of the top-mast-heads: it is served over with spun-yarn, and its use is to keep them open to the size of the mast-heads.

TONGUES, Confusion of. See CONFUSION.

TONGUE, in *Geography*, a town of Scotland, on the north coast of the county of Sutherland, situated on a bay called the Kyle of Tongue. N. lat. 58° 27'. W. long. 4° 14'.

TONGUE Island, a small island in the Mergui Archipelago. N. lat. 9° 52'.

TONGUEY. See TANGUEY.

TONGUNEMEW, a town of Birmah; 35 miles S. of Raynangong.

TONGURAHUA, a town of South America, in the province of Quito; 20 miles E.N.E. of Riobamba.

TONGUSY TARTARS. See TUNGUSES.

TONHOF, a lake of Norway, in the province of Agderhus; 55 miles N.W. of Christiania.

TONIATO, a small island in the St. Laurencç. N. lat. 44° 30'. W. long. 75° 53'.

TONIC, τόνικος, formed from τένω, to stretch, in *Medicine*, is applied to a certain motion of the muscles, in which the fibres being extended, continue their extension in such manner, as that the part seems immovable, though in reality it be in motion. See MUSCLE.

Such is the case of a man standing, of birds plating or swimming through the air, &c. Galen says, that the muscles act even when at rest; for after having made any contraction to fix themselves in a certain state or disposition, the preserving of that contraction is what we call the tonic motion.

TONIC, in *Music*. See GENUS.

TONIC Accent. See ACCENT.

TONICAL ECHO. See ECHO.

TONICHI, in *Geography*, a town of New Mexico, in the province of Hiaqui; 25 miles N. of Riochico.

TONIKAKY, an island in the East Indian ocean, near the north coast of Celebes. N. lat. $5^{\circ} 31'$. E. long. $99^{\circ} 31'$.

TONINA, in *Botany*, an unexplained name of Aublet's. See HYPHYDRA.

TONIQUE, in *French Music*, is equal to key-note in English music, or the principal found of a composition which generates all the rest.

TONISKA, in *Geography*, a town of Russia, in the government of Irkutsk; 40 miles E.S.E. of Stretensk.

TONKER. See LASSA.

TONKER-SONG, a town of Thibet; 504 miles E. of Lassa. N. lat. $25^{\circ} 57'$. E. long. $99^{\circ} 46'$.

TONKEY, in *Agriculture*, a term provincially made use of to signify short-legged and deep-carcafed, as is the case in the Chinese breed of swine. It is consequently a term sometimes applied to that breed of swine. See SWINE.

TONKIN, in *Geography*. See TONQUIN.

TONNA. See TANNA.

TONNAGE, the weight of goods carried in a boat; also, the rates, tolls, or fums *per ton*, *per mile*, or otherwise, which are payable to the proprietors of the navigation for the liberty of using the same. See TUNNAGE.

TONNAGE, *Duty of*. See DUTY.

TONNAGE, in *Ship-building*, the cubical content, or burthen, of a ship in tons; which is commonly estimated by a given rule not answering the above purpose, but producing what is denominated the builder's tonnage. The real burthen a ship is to carry, when brought down in the water to the load-draught of water intended in the construction, may be nearly found by the rules given in the article SHIP-BUILDING (*Tonnage or Burthen*). See also BURDEN of a Ship.

The word is derived from a ton, or weight of water equal to 2000 pounds; for it appears that, anciently, a cubic foot of water, weighing $62\frac{1}{2}$ pounds, was assumed as a general standard for liquids. This cubic foot, multiplied by 32, gives 2000, the original weight of a ton. Hence eight cubic feet of water made a hogshhead, and four hogshheads a ton, in capacity and denomination as well as weight.

TONNAGHAN, or DONAGHAN, in *Geography*, a river of Canada which runs into lake Superior, on the side of which is found a quantity of virgin copper.

TONNAY-BOUTONNE, a town of France, in the department of the Lower Charente; 10 miles W. of Rochfort.

TONNAY-CHARENTE, a town of France, in the department of the Lower Charente; 3 miles E. of Rochfort.

TONNEAU, in *Commerce*, a measure of capacity in many parts of Germany, both for wine and dry commodities. The tonne, as a measure for corn, contains 8 scheffels, or 32 viertels, 100 of which tonnes yield about 49 English quarters. A tonne of beer contains 128 quarters, or 25 English beer gallons. At Konigsberg, a last contains 24 tonnes, $56\frac{1}{2}$ new scheffels, 60 old ditto, 240 viertels, or 960 metzens. A new scheffel contains 3152 English cubic inches, and 43 scheffels = 63 English bushels nearly, and 20 Konigsberg lasts = 207 English quarters. The last of Spanish and French salt is reckoned at 18 tonnes, or 6000 lbs.; the last of herrings at 12 tonnes; a last of green marbled soap at 3 tonnes, or 12 viertels. See TUN.

TONNEAU, a corn measure in some parts of France.—Also, a weight of 2000 lbs. French, by which the burden of ships is reckoned.—Also, a general term in France for a cask.

TONNEINS, in *Geography*, a town of France, and principal place of a district, in the department of the Lot and Garonne; $13\frac{3}{4}$ posts S.E. of Bourdeaux. N. lat. $44^{\circ} 23'$. E. long. $0^{\circ} 24'$.

TONNERRE, a town of France, and principal place of a district, in the department of the Yonne; 18 miles E.N.E. of Auxerre. N. lat. $47^{\circ} 51'$. E. long. $4^{\circ} 3'$.

TONNERRE, a mountain of France, which gives name to a department; 15 miles N.W. of Worms.

TONNING. See TUNNING.

TONNINGEN, in *Geography*, a seaport town of Denmark, in the duchy of Sleswick, situated on a peninsula, formed by the Eider. In the year 1613, the harbour was enlarged and repaired at a considerable expence; but in 1675, during the war with Sweden, the duke, pursuant to the treaty of Rendsberg, was obliged to cede this town to the king, who caused the fortifications of it to be demolished. But when the duke recovered the town in the year 1679, they were repaired, and improved with additional works; so that when king Frederick IV. besieged it, he was not able to make himself master of it. In the year 1713, the Swedes were obliged to surrender themselves prisoners of war to Denmark; and in the year 1714, the king having got possession of the town, the fortifications were demolished a second time. Tonningen has been in a defenceless condition ever since that time. It had once a noble castle, but that was likewise demolished by the king's orders, in the year 1734; 57 miles N.N.W. of Hamburgh. N. lat. $54^{\circ} 23'$. E. long. $9^{\circ} 0'$.

TONNOMAIA, one of the smaller Friendly islands; 11 miles S. of Annamooka.

TONO, a town of Chili; 70 miles S. of St. Yago de la Nouvelle Estremadura.

TONON. See THONON.

TONORIUM, in *Ancient History*. Roman orators, though not constantly accompanied by a flute, had their voices frequently regulated by an instrument which Quintilian calls a *tonorium*, Cicero, a *flulula*, and Plutarch, *συνεληγιον*, or *syrix*, which is the same thing; and this instrument served as a kind of pitch-pipe. Both Cicero (*De Orat. lib. iii.*) and Plutarch (*In Vit. C. Gracch.*) relate the well-known story of the voice of the furious tribune, Caius Gracchus, being brought down to its natural pitch, after he had lost it in a transport of passion, by means of a servant placed behind him with one of these instruments. Cicero tells us that this *tibicen*, with his *flapper*, *qui staret occulte post ipsum*, and was not seen by the people, does not confine his employment to appeasing the passion of his master; he was, upon occasion, to incite it: "Qui inflaret celeriter eum sonum, quo illum aut remissum excitaret, aut à contentione revocaret." It is not easy, however, to conceive of what use this expedient could be, unless rhetorical tones were regulated by those of music.

TONOS, a word used by Hippocrates, to express in general any nerve, whether arising from the brain or spinal marrow. It is also used to express a tension in any part.

TONOSA, in *Ancient Geography*, a town of Asia, situated on the river Melas, W. of Godala.

TONOSA, or *Tonoza*, a town of Asia, in Cappadocia, on the route from Sebaste to Cocufon, between Sebaste and Ariathia. Anton. Itin.

TONOUWAH, in *Geography*, a kingdom of Africa, S. of the Niger, the capital of which is Affentai (the Affienté of D'Anville,) situated midway between Kalanshee, a dependency of the kingdom of Tonouwah, and the sea-coast; that is, about eighteen days' journey from each. It is said that there is no communication between this coast (probably the Gold Coast) and the country of Gorjah; as the king of Affentai,

Affentai, who possesses the intervening space, prohibits his inland neighbours from passing through his country. On the other hand, a gentleman (Mr. Norris) who resided many years in Whydah, says, that there are other states (that is, the Fantees, and their confederates) lying between Affentai and the sea; and that the Affentais have often attempted, but without success, to open a communication with the coast, from that part of the Niger which forms the southern limit of the great empire of Cashna. In the kingdom of Tonou-wah, which is said to border on the coast of the Christians, and of which, as we have said, Affentai, or Affienté, is the capital, a succession of hills, among which are mountains of a stupendous height, diversifies, or constitutes the general face of the country. Some of the lands are cleared, but other districts are still incumbered with woods of a vast extent; and though for the most part the highlands are pastured by innumerable flocks of sheep, and by herds of cows and goats, and the vales exhibit the captivating view of successive villages, encompassed with corn and rice, and fruits of various kinds, yet these are places of native sterility and eternal barrenness.

TONQUIN, or TUNQUIN, signifying "the Court of the East," because when this country was a province of China, it was the imperial residence; though, with regard to its position with respect to China, it should rather be called "the Court of the West," and denominated by the natives *An-nam*, *Anam*, or *Ngan-nan*, *i. e.* the repose of the south, is separated from Cochin-china by a small river, and may now be considered as incorporated with it by conquest. It is bounded on the E. and N. by China, on the S. by Cochin-china, on the W. by the kingdoms of Laos and Baos, the latter being unknown to geographers. Tonquin may be regarded as consisting of eleven provinces; that of the North being the largest; its boundaries being Laos on the W., China on the N. and E., and Baos on the N.W. With regard to its aspect and surface, it may be divided into two portions, the mountains and the plain. Towards China, Cochin-china, and Laos, the mountains are extensive, but neither rocky nor precipitous; and they are partly covered with forests. In this part are found mines of gold, silver, and iron, and also of copper, which is in high estimation. The lower part of Tonquin much resembles Holland, being partly land and partly water, and intersected by canals and dykes, and also by numerous rivers and lakes. The province denominated "of the West" is watered by seven great rivers, which unite about fifteen leagues above the royal city, and form a kind of sea, or large lake, which sends out various branches. The southern part of the kingdom, though in the torrid zone, superabounds with waters covered with boats. A navigable river, called Songkoy, traverses the kingdom from N. to S., and receives various streams, which are also partly navigable; and canals which serve for the cultivation of rice are numerous. The rivers of Tonquin rise from the mountains of Yunnan, and in the rainy season, from May to September, inundate the adjacent country. The chief of these is the Holi Kian, which, after receiving the Li-sien, passes by Kecho the capital. The population of this country is said to be considerable. Although it has few towns, it has several villages which contain many inhabitants. The capital of the kingdom and royal residence is Kacho, Kecho, or *Kesho* (which see). The next remarkable town is Hean, containing about 2000 houses, situated on the right bank of the river, at the distance of four or five days from its entrance into the sea. Formerly the French had a factory in this place, and the trade was considerable. (See HEAN.) At the distance of five or six leagues from the mouth of the river is another town,

called Domea, much less than Hean. These towns, as well as most of the villages, and some houses belonging to persons of wealth, are surrounded with live hedges of bamboo; and to the houses and gardens are annexed alleys of areca trees, which exhibit a picturesque appearance. The high roads, which are scarcely passable in the wet season, are maintained at the public expense. The rich use horses, or litters carried by men. In the mountains the houses are dispersed, and the people almost savage. The chief product of agriculture is rice, which affords two harvests annually in the low country, but in the high lands only one. The rivers and canals abound with fish of various kinds: wheat and wine are unknown: the mulberry-tree is common: silk is in general use among the poorer people: the sugar-cane is indigenous, but the art of refining the juice is unknown. The plough used in agriculture, consists of three pieces of wood, a pole, a handle, and a third piece, almost at right angles with the last, for opening the ground, and they are simply fixed with straps of leather: this plough is drawn by oxen or buffaloes. The horses are small, but lively and robust: but they are little used, as the inhabitants prefer travelling by water. Asses and sheep are unknown; goats are few, and swine abundant. The people eat dogs, cats, and rats: poultry, ducks, and geese abound, and are found wild in the forests. The eggs of ducks are heated in ovens, and produce young, which swarm on the canals and ponds. The forests contain deer, boars, peacocks, a peculiar kind of partridge, and quails. The tigers are large and destructive; one of which is said to have entered a town, and to have destroyed eighty-five people. The wild elephants are also very dangerous: apes are found in these forests, and some of them of large size: these and the parrots are not a little destructive of the rice and fruits. The manners of the people are less civilized than those of the Chinese: they are in general of middle stature, with broad faces, not so flat as those of the Chinese; eyes and nose small, and long black hair. The men have little beard, and do not shave. Few of the people are deformed, and the women are rather handsome. The complexion of people of rank approaches that of the Portuguese and Spaniards. At the age of seventeen or eighteen they begin to blacken their teeth, regarding white teeth as the praise of dogs: like the Chinese, the fashion of suffering their nails to grow is restricted to the Mandarins, the men of letters, and other distinguished persons. The ladies tinge their nails with red, and sometimes their hands and feet. The dress of the men consists of a piece of silk, several yards long, wrapped about the loins, and a long robe with loose sleeves, thrown off in travelling or during labour. The women of the lower orders are modestly clothed in a long petticoat, and one or more robes like those of the men. They cover their bosoms with a piece of linen or silk in form of a heart: they use ear-rings and bracelets of gold or silver. They commonly appear with naked legs and feet, like the men; but the rich and persons of dignity wear long drawers. The most general colour of the silk and linen is white. Black is only worn by persons of distinction. The men and women fasten their hair behind in a knot; but in the presence of a superior they let it fall, in token of respect.

The people are indolent, and loaded with heavy taxes. The public services required from them occupy about six months in the year. The learned language in Tonquin is that of China, but it degenerates into a kind of dialect which cannot be understood by a Chinese, and the words are all in single syllables, and expressing different things according to the accents and mode of enunciation. The language of Tonquin, and also of Cochin-china, called

the Anam language, says Dr. Leyden, is simple, original, and monosyllabic. It has little affinity to the Mandarin or court language of China, to that of Canton, to the copious polysyllabic and inflected Japanese, or to any other of the Indo-Chinese languages. Barrow, in his voyage to Cochin-china, seems to consider it as a derivative from the Chinese; but Dr. Leyden perceives no similarity between the Chinese and Anam, unless that they are both monosyllabic languages, and that the signification of terms is regulated, in a great measure, by their accentuation. But though the same monosyllables occur, and though they are also accentuated frequently in a similar manner, yet even in this case, the signification of these monosyllables is for the most part totally different. In the syntax or construction of the two languages, there is also a very great difference. The Anam language has neither genders, numbers, nor cases, moods, tenses, nor conjugations; all which are supplied by the use of particles and the juxtaposition of words, as in the other monosyllabic languages. The same word has often the signification of both a noun and a verb, and its particular use, in such a case, is to be determined by the context, and the collocation of words in the sentence. The principles of collocation in sentences are equally simple as in the other monosyllabic languages; many instances of which are specified by Dr. Leyden. The accents in the Anam tongue are of such indispensable utility, that they have been very properly termed the soul of the language, while the primary monosyllables, varied by accent, have been made to represent its body. The Anam style is sometimes highly bold and figurative, and attains a degree of animation which is not very common among the Indo-Chinese nations of the continent. The ancient code of Tonquin laws possessed great celebrity, and was highly venerated previous to the conquest of that country by the Cochin-chinese. It is represented by the missionary Le Roy, as composed in the most elevated style of Chinese, and full of uncommon modes of expression. He also mentions, that it was printed with an Anam translation, composed by an ancient Tonquin Mandarin. The religion of the Anam nation is a modification of the Buddhist system, nearly resembling that which prevails in China. Many local and peculiar superstitions, however, are blended with it, such as the worship of the dog and tiger, to the first of which human excrement, and to the second, human flesh is offered. Traces of this worship are found among the mountaineers on the borders of India, as well as in the proper Indo-Chinese countries. There the tiger is worshipped by the Hajin tribe, in the vicinity of the Garrows or Garadas.

The Quau-tô, an ancient race, as the name signifies, who inhabit Kaubang, or the mountainous range which divides the Anam countries from China, regard themselves as the original inhabitants of Tonquin and Cochin-china, and consider the Anam as a Chinese colony. The Quau-tô have a peculiar language, and write with a style, on the leaves of a plant, termed in Anam "jiwa." The Moi and Muong are also mountaineer tribes, who speak languages different from the Anam; but it is hitherto unknown, whether they are original races, or only branches of the Quau-tô. Asiatic Researches, vol. x.

Marriage is contracted without priest or ceremony, the consent of the parents forming the only ceremony. The husband may repudiate or sell his wife, but the wife cannot leave her husband without his consent. The right of primogeniture predominates, and daughters derive little benefit from the estate of their father. Polygamy is common; divorces are rare: children are not exposed as in China. The inhumanity of creditors equals that of ancient Rome,

and the accumulation of usury renders the state of debtors very perilous. An abominable and cruel custom prevails, which is that of putting some person to death at the beginning of a new year, and with this view they poison the fowls and fruit which are brought to market: examples of this horrid practice, which, it is thought, will secure them good fortune, are frequent, but the punishment is rare. The chief amusements are plays, dances, and cock-fighting. The general food is rice, and pulse is also in request. The nests of a species of swallow are also held here, as well as in China, in great esteem. The chief drink is derived from a kind of coarse tea, but arrack is also much prized.

The climate of Tonquin is not very hot. From the month of September till March, it is temperate and healthy; in January and February the weather is cold, but neither snow nor ice is seen, and hail is very rare; the temperature of the air becomes rather insalubrious in the months of April, May, and June, which is the season of fogs and heavy rains; and great heat is felt in July and August. In the flat country, and on part of the mountains, the winds regularly blow six months from the N. and six from the S., the first beginning in November. Among the maladies of this country, the most grievous is a kind of leprosy, which devours the extremities of the hands and feet. The funeral ceremonies resemble those of China: pieces of gold or silver, or small pearls, are put into the mouths of the dead, that they may not enter poor into another world. Their religion resembles that of the Chinese, but the sect of Foo is most regarded. Every town or village has a tutelary genius. Sometimes the supposed genii are vile animals, as serpents, dogs, cats, oxen, fish: but more frequently men, who have deserved well of their country. The natives are not a little addicted to magic. The sciences, like those in China, are chiefly sought in the writings of Confucius and his commentators; the principal branches being morality, mathematics, physics, and astronomy, with the history and laws of the country. Knowledge is highly esteemed: and the men of letters are regarded as the sole nobility in the kingdom. All the offices and dignities of the state are the recompense of literary merit. Printing is known here, as in China; but painting and sculpture are in a low state. The chief trade is with China, which supplies Tonquin with fine teas, porcelain, silks, and painted linens, prepared sugars, wheat and barley, flour, kitchen utensils, iron, spices, flax and lint, wax, cotton, glass, and toys. Strangers export from Tonquin varnish, silk raw or wrought, chiefly strong stuffs; beautiful cloth resembling linen, made of the bark of trees, different works of mother of pearl, ebony, ivory, tortoise-shell, cinnamon, copper, cotton, and several other articles. Calamine is also exported from Tonquin by the Dutch and carried to Japan, where it is used in the manufacture of brass. The interior commerce of Tonquin is considerable, consisting chiefly of fruits of different kinds, silk and cotton cloths, with those made of the inner bark of the paper-bearing mulberry. The cinnamon, duly cultivated, would be valuable. The trees that produce the varnish distil a juice resembling turpentine, and the quantity is increased by incisions. Sugar might form a considerable article, if the people knew how to prepare it. Paper, made of the bamboo, mulberry, elm, cotton-tree, and all kinds of white and sappy woods, is a considerable article. Salt procured from the sea, is a commodity of great demand in the interior of the country. The troops of Tonquin amount to about 140,000, of which about 8000 or 10,000 are cavalry. Elephants were formerly used in war, but the introduction of fire-arms has diminished their number. Since the revolution in Cochin-china, when the Chova rendered himself independent

pendent of Tonquin, and assumed the royal title, a body of 10,000 men has been stationed on that frontier. Every governor of a province has at his disposal 700 men and one elephant. The remaining force, amounting to about 100,000, is placed in the royal city, or in an adjacent camp.

The arms of the Tonquinese are the ancient musket fired with a match, the modern firelock being unknown there, bows, sabres, pikes and half-pikes, and a defensive buckler. The troops of the king's household, which are reckoned among the best troops of the East, are clothed in blue and red. The navy amounts to about two or three hundred galleys, navigated with oars, and fitter for the rivers of the country than for the open sea. The king of Tonquin is reckoned among the rich sovereigns of the East, as he possesses valuable treasures and an ample revenue, derived from rice, a tax upon land, a capitation tax, the sale of dignities, and the duties on merchant-vessels, amounting to about one-tenth of the merchandize. The laws of Tonquin, like those of China, are founded on the single principle of paternal authority and filial obedience. The magistrates are denominated Mandarins, from the Portuguese *mandar*, to command, by the Europeans; but in the native languages both of China and Tonquin, the appellation is "Quan." The tenure of lands and right of inheritance are respected even by the sovereign; and the successions in land are determined by one tribunal, and that of houses and personal property by another. The judges are corrupt, and justice is sold. The military and civil offices are venal. Executions are rare, not exceeding through the whole kingdom twenty or thirty in a year. Decapitation is counted ignominious: princes and persons of rank have the privilege of strangulation. Female criminals are trampled to death by elephants. The dignity of public executioner is hereditary. Other punishments are exile, perpetual imprisonment, and personal chastisement, sometimes with the mutilation of a finger or ear. The prisons are said to be in a shocking state. On a general view of Tonquin, the country and the despot are extremely rich, and the people are very poor. The Jesuits, soon after the commencement of the 17th century, made an attempt to introduce into this country the Christian faith; but their efforts have not been very successful; several instances having occurred of the persecution of Christians.

In the gulf of Tonquin there is a small isle, which is said to afford the musk animal; and in the vicinity is a pearl fishery. The chief entrance of the river, called Domea by the Europeans, is obstructed by a bar, and requires the guidance of a native pilot. In this gulf, as well as the adjacent Chinese sea, the "typhoons," or "typhons," are tremendous. They are preceded by very fine weather; a presaging cloud appears in the N.E. black near the horizon, edged with copper-colour on the upper part, fading into a glaring white. It often exhibits a ghastly appearance twelve hours before the typhon bursts; its rage lasts many hours from the N.E., attended with dreadful claps of thunder, large and frequent flashes of lightning, and excessive hard rains: then it sinks into a dead calm, after which it begins again with redoubled rage from the S.W., and continues for an equal length of time. Abbé Richard's compilation from the papers of the abbé St. Phalle, a missionary in Tonquin for twelve years, who died at Paris in 1766; cited by Mr. Pinkerton, in his *Geography*, vol. ii. For an account of the revolutions in Tonquin from the earliest period of historical account, see *Grosier's China*, vol. i.

TONQUIN Bean, in *Botany*, sometimes called *Tongo Bean*, is the seed of *DIPTERYX odorata*. See that article.

TONQUIN Medicine. See *HYDROPHOBIA*.

TONS de l'Eglise, Fr.; *Tuoni ecclesiastici*, Ital.; the ecclesiastical modes or tones in canto fermo. See *PLEIN-CHANT*, *CANTO FERMO*, and *Ecclesiastical MODES*, *AUTHENTIC* and *PLAGAL*.

For the history of the establishment of the modes at Milan and at Rome, see *St. AMBROSE* and *St. GREGORY*.

The modes of the Roman church are eight: four authentic, and four plagal. The four authentic, or principal, are the odd numbers: 1st, 3d, 5th, and 7th; the plagal are the even numbers: 2d, 4th, 6th, and 8th; which answer to D and A minor, and C and D major, for the authentic: and G and A minor, and F and G major, for the plagal. These are described by Dr. Pepusch, Padre Martini, and Rousseau, and all their several scales may be seen in Burney's *General History of Music*, vol. ii.

We have drawn out the scales of all the eight modes or tones ascending and descending (see *Plates of Music*), by which it will appear from the imperfection of these scales in most of the tones, that they are only capable of melody; and in the common service of Roman Catholic churches, when the priests perform the duty without the assistance of professed musicians, no harmony is attempted to be given to mere canto fermo. In cathedrals, the motets and parts of the mass are sung by choirmen and children, as the anthems and services are in our cathedrals.

Notwithstanding the imperfection of the scales, and little variety of keys in the ecclesiastical chants, secular music seems for many ages to have had no other rules, but to have been strictly confined to a few keys in the diatonic genus, without the liberty of transpositions. Hence came the timorous pedantry of excluding all other keys and scales but those used in the church; which kept every kind of melody meagre and insipid, and in subjection to the rules of ecclesiastical chanting. For it appears, that the only major keys used in canto fermo are C and its two fifths F and G; and the only minor keys A, E, and D. And in four of these keys the scale is deficient, as there is no seventh or *note-sensible* to G, A, or D. This accounts for so small a number of the twenty-four keys which the general system and scale of modern music furnishes, having been used by the old composers; as well as for the temperament of the organs by which these modes were afterwards accompanied. And as all music in parts seems, for many ages after the first attempts at counterpoint, to have been composed for the service of religion upon canto fermo and its principles; it likewise accounts for the long infancy and childhood of the art, till it broke loose from the trammels of the church, by which it was bound in Gothic times: and by the cultivation of the musical drama sacred and secular, the ideas of composers were enlarged, and the talents of performers improved by new exertions, which brought the art nearer perfection during the two last centuries, than it had attained in seven hundred years from the time of Guido.

In implicit and religious obedience to the laws of canto fermo, no accidental flat or sharp was ever to appear; all the eight tones being rigidly in the diatonic genus in the keys of C and A natural, with no other semitones than from E to F, and B to C. When the scales of these tones are drawn out at full length, they seem nothing more than different species of octave.

All these scales descending, might, however, be made perfect by a single flat or sharp at the clef: as the first tone by a flat, the third by a sharp. The 2d is perfect, descending; the 4th wants a sharp or two at the clef to determine it to be in the key of E or B minor. A flat would make the 5th complete in the key of F; and a sharp the 7th in that of

G. The

G. The 6th is in the key of C natural, ascending complete; and with a flat to B in the key of F, descending; the 8th with one sharp would be in G, and with two sharps in D major. But these were licences which no one thought of, or at least had the courage to practise, till counterpoint began to gain ground. And even then, the *musica ficta*, or false music, as that in transposed keys was called, no one dared to write till lately. Even the orthodox and good Padre Martini, at length vanquished his fears of the impiety of using an accidental flat or sharp in the inward parts of canto fermo.

Lorente, author of the famous Spanish treatise called "El porque de la Musica," without which Geminiani made Dr. Worgan believe it impossible for any one to understand counterpoint, has written the scales of the eight tones as we have done; but has not ventured to harmonize them, as accidental sharps and flats must have been expressed or understood in the additional parts.

TONSA, in *Geography*, a river of European Turkey, which runs into the Mariza, near Adrianople.

TONSÆ, among the *Romans*, the blades of oars, or that part of them which beats against the water.

TONSBERG, in *Geography*, a seaport town of Norway, in the province of Aggerhuus, situated on a bay of the Baltic; built upwards of 800 years since. It formerly contained nine churches, but now has only two. The inhabitants carry on a considerable trade in furs and butter. In the year 1536, it was laid in ashes by the Swedes, since which, it has greatly declined; 42 miles S. of Christiania. N. lat. $59^{\circ} 23'$. E. long. $10^{\circ} 12'$.

TONSELLA, in *Botany*, a name made by Schreber, out of the *Tontelea* of Aublet, which is itself taken from the Caribbean appellation of the same shrub, *Ravoua-tontelle*. Schreber perhaps meant to give the word a classical air, by approaching it either to *Tonsa*, an oar, or *Tonsilla*, a mooring post, or a cable, for which indeed there seems no foundation in any recorded use of the plant. Possibly he might have in view *tonsilis*, a word applied to the box, or other trees fit for clipping. This idea is, however, no less inapplicable to our *Tonsella* than the former.—Schreb. Gen. 34. Willd. Sp. Pl. v. 1. 194. Vahl. Enum. v. 2. 29. Mart. Mill. Dict. v. 4. (*Tontelea*; Aubl. Guian. v. 1. 31. Juss. 436. Lamarck Illustr. t. 26.)—Class and order, *Triandria Monogynia*. Nat. Ord. uncertain, Juss.—It seems akin to *Eunonymus*, and therefore probably belongs to his *Rhamnii*.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, permanent, in five deep, ovate, acute segments. Cor. Petals five, ovate, thick, permanent, longer than the calyx, inserted into the receptacle. Nectary cup-shaped, entire, surrounding the germen. Stam. Filaments three, thread-shaped, reflexed, inserted into the inside of the nectary, rather shorter than the petals; anthers roundish. Pist. Germen superior, roundish, surrounded by the nectary; style cylindrical, shorter than the stamens; stigma simple. Peric. Berry spherical, seated on the permanent calyx and corolla, of one cell. Seeds four.

Ess. Ch. Calyx in five deep segments, permanent. Petals five. Nectary cup-shaped. Berry of one cell, with four seeds.

Obs. Jussieu appears to have been undetermined about the natural affinity of this genus, from having preconceived the germen to be inferior, which it surely is not.

1. *T. scandens*. Climbing Tonsella. Willd. n. 1. Vahl. Symb. v. 2. 17? (*T. scabra*; Vahl. Enum. n. 1. *Tontelea scandens*; Aubl. Guian. 31. t. 10.)—Leaves pointed, entire. Branches round, warty.—Gathered by Aublet in the forests of Guiana, near the river of Sinemari, thirty

leagues above its mouth; flowering in October.—Von Rohr is said to have found the same in the island of Trinidad. The former terms it a *shrub*, climbing to the tops of the loftiest trees, and covering them with its opposite, repeatedly compound *branches*, which at length become pendent, even to the ground. In his own specimen before us they are slender, round, covered with minute warts burbling through the cuticle, and bear several short opposite shoots, leafy at the extremity. We find no sign of hairiness. The *leaves* are opposite, on thick, channelled, smooth stalks elliptical, entire, two or three inches long, with a short blunt point; they are smooth on both sides, coriaceous, rather shining, with one rib, and many reticulated veins. *Flowers* green, very small, about the ends of the branches, in partly terminal, partly axillary, small clusters, whose partial stalks are opposite.

Vahl describes the plant of Von Rohr as a *tree*, whose *branches* have a purplish roughish bark, and are hairy in their upper part. The *leaves* are roughish on both sides; their veins villous at the back. *Flower-stalks* downy. *Calyx* and *petals* hoary; the latter fringed. We have seen no specimens of this, nor indeed of the *flowers* of Aublet's plant, but we cannot help supposing they may be different species, though we do not feel authorized to define them as such.

2. *T. africana*. Toothed African Tonsella. Willd. n. 2. Vahl. n. 3.—"Leaves obtuse, with glandular teeth."—Native of Guinea.—Similar to *T. scandens*, but different, having smaller and obtuse *leaves*, furnished with very distant glandular teeth; a larger *corolla*, and sessile *anthers*. *Berry*, according to Vahl, the size of an apricot, smooth, orange-coloured, globular with three slight angles, and from six to ten seeds.

3. *T. angulosa*. Entire-leaved African Tonsella.—Leaves pointed, entire. Branches angular, smooth.—Brought from Sierra Leone, by professor Afzelius. The dried specimens are of a peculiarly fresh light green, and quite smooth. *Branches* with four, not very prominent, angles, slender and wavy. *Leaves* two and a half inches long, elliptical, with a linear blunt point, quite entire, veiny. *Flowers* small, green, in small, axillary, stalked tufts, whose common stalks, like the *footstalks*, are about a quarter of an inch long. *Fruit* the size of a pea, apparently a tough-coated berry.

4. *T. decussata*. Cross-branched Tonsella. Vahl. n. 2. ("Anthodon decussatum; Fl. Peruv. v. 1. 45. t. 74. f. b.")—"Leaves oblong-ovate, obtusely serrated, polished. Panicles forked."—Native of woods upon the Andes. A *shrub*, with crossing greyish copious *branches*; purplish when young. *Leaves* pointed, smooth on both sides, on twisted stalks. *Flower-stalks* opposite, square, shorter than the leaves, compound, forked. *Flowers* small, yellow. *Fruit* unknown, but the affinity of the plant to *T. scandens* has induced Vahl to place it in the same genus.

5. *T. senegalensis*. Senegal Tonsella. Vahl. n. 4. (*Hippocratea senegalensis*; Lamarck Illustr. v. 1. 101.)—"Leaves oblong, pointed, smooth, polished; serrated towards the extremity. Stalks crowded, single-flowered. Branches rough."—Native of Senegal.—*Branches* alternate, destitute of hairiness. *Leaves* about an inch long, with a bluntish point, half as long as the nail, their margins obscurely serrated, and appearing under a magnifier to be bordered with a yellow thickened line. *Flower-stalks* capillary, about half an inch long, numerous, from a short axillary tubercle. *Petals* linear, smooth.

6. *T. madagascariensis*. Madagascar Tonsella. Vahl. n. 5. (*Hippocratea madagascariensis*; Lamarck Illustr. v. 1. 101.)—"Leaves lanceolate-oblong, pointed, smooth, polished,

polished, nearly entire. 'Stalks crowded, single-flowered. Branches rough.'—Native of Madagafcar, as the uncouth name, which ought to have been changed, implies. The *branches* are said to be opposite, leprous, but not downy nor hairy. *Leaves* an inch and half long, or somewhat more, rather coriaceous, sometimes slightly toothed towards the end. *Flower-stalks* very numerous, from each axillary tubercle. *Flowers* drooping, smooth. *Petals* linear.

7. *T. multiflora*. Many-flowered Tonsella. Vahl. n. 6. (Hippocratea multiflora; Lamarck Illustr. v. 1. 101. H. obovata; Richard Act. Soc. Hist. Nat. Paris. v. 1. 106.)—"Leaves obovate, entire, polished. Stalks crowded, each bearing two or three flowers."—Found by Richard in Cayenne. *Branches* opposite, smooth. *Leaves* three or four inches long, sometimes oblong-ovate, very smooth, destitute of veins. *Flower-stalks* numerous, scarcely half an inch long, each divided into two or three simple partial stalks, about the same length, with minute *bractææ* at the base of each. *Petals* oblong, smooth. The fruit of these three last plants has not been examined, but Vahl was induced, as in the similar case of our fourth species, to remove them hither, on account of their very close affinity to *T. africana*.

The author just mentioned considers this genus as very nearly related to the Linnæan SALACIA, see that article. This opinion is extremely probable, and if it be correct, the name of *Tonsella* must give place to *Salacia*. In the habit of the plants we find no grounds for any distinction.

TONSET, in *Geography*, a town of Norway, in the province of Aggerhuus; 145 miles N. of Christiania.

TONSILS, in *Anatomy*, the glandular bodies, also called from their size and shape *amygdalæ*, placed at the passage from the mouth to the pharynx. See DEGLUTITION.

TONSILS, *Diseases and Extirpation of*. The tonsils are exceedingly liable to inflame; and sometimes the swelling thus produced is so great as to obstruct deglutition and respiration in a very dangerous degree. Prompt succour is now most urgently required; and relief may commonly be obtained by scarifying the enlarged tonsils, and promoting the bleeding with warm gargles.

This operation may be done with an ordinary lancet, or with a broad one contained in a sheath, and constructed so that its point can only be pushed out to a certain distance. Pharyngotomus is the name usually given to this instrument. Abscesses in the tonsils are also to be opened, when the swelling causes serious inconvenience.

When scarifications cannot be made, the best means are venesection, applying leeches to the throat, exhibiting mercurial medicines, inhaling the steam of hot water, and using proper gargles.

Abscesses of the tonsils have been observed of considerable extent, not bursting in the mouth, as is usual, but in the Eustachian tube, or even the meatus auditorius externus, attended with caries of the mastoid process, deafness, and fistulæ. Such cases are frequently incurable.

The tonsils sometimes become enlarged, without being inflamed. This swelling is improperly termed scirrhus. The glands are only swollen and of moderate firmness. A portion of a tonsil, thus enlarged, may be cut off, without the least danger of the rest assuming a malignant nature. This preternatural swelling of the tonsils is mostly owing to repeated inflammations. Sometimes there is no palpable cause. The malady is constantly free from pain. When the tumefaction is considerable, it obstructs the speech, deglutition, and respiration.

Diluent and astringent applications here prove ineffectual. The tumour admits of being removed; but it is

unnecessary and improper to take away the whole tonsil, as a dangerous and even fatal hæmorrhage might be the consequence. Only so much of the swelling should be removed, as is sufficient to afford relief. The remaining portion in general heals, without the least difficulty: a clear proof that the disease is not of a malignant nor cancerous nature.

The extirpation of a part of a tonsil, thus diseased, has been accomplished with caustics, the actual cautery, the ligature, and cutting instruments. The first of these plans was successfully practised by Wiseman; but is now quite abandoned. The second is also relinquished, as no modern surgeons employ it, except now and then, with a view of destroying fungous excrescences, which, in a few instances, originate after a part of the tumour has been removed by some other operation.

A variety of instruments has been devised for putting a ligature round diseased tonsils.

There are very good surgeons, who still preferring diseased tonsils to cutting them away, and the mode to be adopted differs according as the swelling has a narrow or broad base. The ligature ought to be made of silver wire, or catgut. When the tumour has a narrow neck, the ligature is to be doubled, and introduced through the nostril, so that the noose may be seen in the throat. With the aid of a pair of forceps, the noose may then be easily placed round the neck of the tumour. The ends of the ligature are then to be brought through a double cannula, and the latter instrument introduced as far as the tonsil. The ligature on each side is then to be drawn tightly, and fastened round rings at the end of the cannula. The instrument may next be twisted, till a due degree of constriction is produced.

Default employed an instrument, called a *ferre-nœud*, for putting the noose of the ligature over a diseased tonsil, and producing the necessary degree of constriction. The *ferre-nœud* was nothing more than a little ring, mounted on a longitudinal, narrow piece of steel, about five inches long, the other end of which was grooved, or rather forked. The diseased tonsil was first taken hold of with a double hook. With the ring, the noose was conducted along the hook, and put over the tonsil; the ligature was then drawn out, while the ring pressed the noose downward and backward. Thus the due constriction was made, and it was next maintained by twisting the ends of the ligature round the forked extremity of the instrument, on the outside of the mouth. Default par Bichat, tom. ii. p. 233.

When the disease had a broad base, and was of a conical shape, so that the ligature was apt to slip off, Cheselden has recommended the use of an instrument like a crooked needle, set in a handle, with an eye near the point, threaded with a ligature, which is to be thrust through the bottom of the gland, and laid hold of with a hook. The needle is then to be withdrawn. The double ligature is next to be brought forwards, and one part tied above, the other below the tumour. The ligatures are now to be cut off near the knots.

We have already observed, that the removal of the whole enlarged tonsil is unnecessary, and therefore injudicious. We may now notice, that a portion of the tumour may be cut away, without any just ground for fearing a dangerous bleeding. The application of a ligature occasionally produces a most perilous swelling of the diseased tonsil, attended with such hazard of suffocation, as to compel the surgeon to cut and remove it. Bertrandi, and many other eminent surgeons, have been in the habit of cutting away enlarged tonsils, without ever meeting with an instance of danger from the subsequent bleeding.

Default sometimes employed a flat sheath, made of silver, and

and having a notch in it for the reception of the base of the tonsil. The latter part being thus taken hold of, a spring was touched, when a concealed blade immediately moved across the notch, and made the requisite division, without any risk of injuring the adjacent parts in the mouth.

The operation may be done with a pair of scissors, constructed with short blades and long handles; or it may be performed with a bistoury, which, in general, must be the best instrument.

The hæmorrhage may usually be stopped by repeatedly washing the mouth with very cold water.

When the enlargement of the tonsil is really of a ferruginous nature, a case which is possible, though not common, an operation, performed so as to remove only a part of the indurated enlargement, would not be followed by success.

Calculous concretions have been known to form in the tonsils, occasioning troublesome coughing, sore-throats, &c. The propriety of extracting them, when their existence is clearly ascertained, is almost too obvious to require being mentioned. First Lines of the Practice of Surgery, by Samuel Cooper, edit. 3.

TONSTALL, or **TUNSTALL**, **CUTHBERT**, in *Biography*, an English prelate, was the natural son of a gentleman of good family, and born at Hatchford, in the ancient Richmondshire, about the year 1474. Having studied both at Oxford and Cambridge, he travelled for further improvement, and graduated doctor of laws at Padua. Recommended by his learning and character to archbishop Warham, he became his vicar-general, and was collated by the king to the rectory of Harrow, in Middlesex. Besides other preferments, he was appointed, in 1516, to the office of master of the rolls, and in this year accompanied sir Thomas More as ambassador to Charles V. at Brussels, where he formed an intimacy with Erasmus. After obtaining other preferments, and accomplishing another embassy to the emperor, he was promoted, in 1522, to the see of London, and in 1523, to the office of keeper of the privy seal. He was afterwards employed in several missions of importance on civil affairs; and whilst he was at Antwerp, he manifested his religious zeal by buying all the unfold copies of Tyndale's translation of the Bible, in order to burn them at St. Paul's Cross. His zeal was similarly engaged in urging Erasmus to write against Luther, and in instituting prosecutions against heresy. In 1530, Tonstall was promoted, in recompence of his services, to the see of Durham. Fluctuating in his disposition and politics, he first favoured and afterwards disapproved the divorce of Catharine of Arragon: he also defended Henry's assumed title of supreme head of the church, after having at first protested against it: and though he was not inattentive to the usurpations of the papal see, he was firmly attached to the doctrines of the church of Rome. Repenting, as we hope, of having burnt the Bible, he joined with Heath, bishop of Rochester, in revising an English translation of it in 1541. Under Edward VI. he conformed to all the ordinances relating to religion, whilst in parliament he protested against every change. At length his rich bishopric presented a temptation, which those who sought preferment could not resist, and therefore Tonstall was charged with misprison of treason, and a bill of attainder was brought into the house of lords, which, though opposed by Cranmer, passed that house, but was stopped in the commons, the evidence being thought insufficient. His enemies, however, determined to displace him, and a commission was appointed to examine him with regard to all conspiracies, &c.; and having been found guilty, he was deprived, and committed to the Tower, where he remained a prisoner to the end of this reign. The see of Durham was converted into a county palatine, and

granted to the duke of Northumberland. On the accession of Mary, he was restored to his see; and his temper being mild, he neither avenged himself on his enemies, nor were any persons brought to the stake in his diocese during this sanguinary reign. His whole conduct seems indeed to indicate a favourable change in his temper, for he discouraged persecution, and afforded an asylum to his nephew, Bernard Gilpin. (See his article.) When Elizabeth succeeded to the crown, hopes were entertained that his moderate principles would have led him to acquiesce in the reformation, but he preferred the surrender of his bishopric to compliances against which his conscience revolted. Refusing to take the oath of supremacy, he was deprived, and being committed to the custody of Parker, archbishop of Canterbury, he was treated with kindness, and by the prelate's reasoning induced to abandon some of the grosser errors of popery. He died in 1559, at the advanced age of eighty-five, and was interred, at the archbishop's expense, in the church of Lambeth. As to his general character, he was munificent and attentive to his episcopal duties; and in his private life, exemplary and amiable. He was author of several works, among which was a treatise on arithmetic. Some of his letters are preserved in Erasmus's collection. *Biog. Brit.*

TONSURE, formed from *tondere*, to shave, the art or act of cutting the hair, and shaving the head. See **HAIR**.

The tonsure was anciently a mark of infamy in France; inasmuch that, when they would render any prince incapable of succeeding to the crown, they cut off his hair and shaved him. See **BEARD**.

TONSURE, in the Roman church, is used for the entrance or admission into holy orders.

In propriety, tonsure is the first ceremony used for devoting a person to God and the church, by presenting him to the bishop, who gives him the first degree of the clericate, by cutting off part of his hair, with certain prayers and benedictions.

Some hold the tonsure a particular order; others, as Loyseau, only the mark and form of ecclesiastical orders in general.

The tonsure suffices to make a clerk; the rest is only to qualify him for the holding of benefices. A person is capable of the tonsure at seven years of age; thence a benefice of simple tonsure is such an one as may be enjoyed by a child of seven years old. The tonsure is the basis of all the other orders.

TONSURE is also used for the corona, which priests, &c. wear, as the mark of their order, and of the rank they hold in the church. See **CROWN**.

The barbers have the measures and dimensions of the different kinds of tonsure, or clerical crowns, to be practised according to the different degrees and orders. A clerk's tonsure, a subdeacon's tonsure, a deacon's tonsure, a priest's tonsure, are each successively bigger than the other.

TONTANEA, in *Botany*, a word left unexplained by Aublet, but evidently of barbarous origin.—Aubl. Guian. 108. t. 42. Juss. 199. Lamarck Illustr. t. 64. (Bellardia; Schreb. Gen. 790? Willd. Sp. Pl. v. 2. 626.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in four deep, ovate, acute, equal, spreading segments. *Cor.* of one petal, funnel-shaped; tube thrice as long as the calyx; limb in four deep, ovate, acute, equal, spreading segments. *Stam.* Filaments four, thread-shaped, inserted into the throat of the corolla, between the segments, and about equal to them in length; anthers roundish, of two cells. *Pist.* Germen roundish, inferior, crowned with an annular disk; style rather

rather longer than the corolla, thread-shaped, divided half way down; stigmas distant, obtuse. *Peric.* Berry ovate, crowned with the withered calyx, of two cells, easily separable. *Seeds* numerous, convex on one side, concave on the other, winged, inserted into the transverse partition.

Eff. Ch. Corolla of one petal, funnel-shaped, four-cleft, acute. Berry of two cells, with many winged seeds.

1. *T. guianensis*. Aubl. t. 42.—Native of moist woods in Guiana and Cayenne, flowering, and bearing ripe fruit, nearly all the year. A trailing herbaceous perennial plant, creeping by means of fibrous radicles; the stem and branches round, slightly downy. *Leaves* opposite, stalked, ovate, fleshy, entire, hairy, an inch and half long, with a pair of intrafoliaceous stipulas. *Flowers* white or blueish, three or four together, in little, axillary, stalked, solitary heads. *Berry* blue, with a viscid juice. Schreber's *Bellardia* was named in honour of Dr. Charles Louis Bellardi, the coadjutor of Allioni, and still living at Turin. His *Appendix ad Floram Pedemontanam*, and his *Observazioni Botaniche*, prove him an able and observing botanist. *Bellardia* ought to have been noticed by one of our predecessors in its proper place. We should adopt it here, in the place of the above faulty name, *Tontanea*, were there not much doubt of the identity of the plants. Schreber describes his as having linear unequal segments to the calyx, a hairy or villous obtuse corolla, very short stamens, linear anthers, and a nearly globose capsule, not a berry. Neither does he notice a wing to the seeds, which he describes as acutely angular, and dotted. Had he not cited Aublet, no one would have supposed their genera to belong to each other; nor does Schreber himself decidedly assert it. Of his *Bellardia* nothing is known, except from his own generic character, because he never published a *Species Plantarum*, to clear up the obscurities attendant on his new genera.

TONTAPILLY, in *Geography*, a town of Hindoostan, in the circuit of Rajamundry; 30 miles N.E. of Rajamundry.

TONTECO, a town of Africa, in Bambouk; 10 miles N. of Combregoudou.

TONTELEA, in *Botany*, Aubl. Guian. t. 10. See TONSELLA.

TONTI, or TONTW, in *Geography*, a river of Canada, which runs into lake Erie, nor far from the Orwell.

TONTINE, a loan raised on life-annuities, with the benefit of survivorship. Thus, an annuity after a certain rate of interest is granted to a number of subscribers, who are divided into classes according to their ages; and annually the whole fund of each class is shared among its survivors, till at last it falls to one, and on his death it reverts to the power that first established the tontine. The term is derived from the name of the inventor.

TON-TING, in *Geography*. See TONG-TIN-HOU.

TONTON, an African drum, which Pere Labat, in his voyage to Guinea, tom. ii. numbers among the musical instruments of the Negroes, and which is never used but upon the approach of an enemy, or on extraordinary occasions. It seems to surpass in force the Stenterophonic tube of Alexander the Great; as it is said that it can be heard at the distance of six or seven miles!

TONTORAL, CAPE, in *Geography*, a cape on the coast of Chili. S. lat. 27° 30'.

TONTRAVELLORE, a town of Hindoostan, in the circuit of Condapilly; 25 miles W.N.W. of Masulipatam.

TONVORE, a cape of Scotland, on the N.W. of the island of Ilay. N. lat. 55° 51'. W. long. 6° 27'.

TONYES, a town of Mexico, in the province of Cuiliacan; 60 miles N.E. of St. Miguel.

VOL. XXXVI.

TONYN'S ISLANDS, a cluster of small islands in the East Indian sea, near the S.W. coast of the island of Celebes. S. lat. 5° 31'. E. long. 119°.

TONZI, in *Ancient Geography*, a town of Thrace, on the coast of the Euxine sea, between Apollon and Peronticum. Ptol.

TONZOS, or TONZUS, a town in the interior of Thrace. Ptol.

TOOBIGAN, in *Geography*, a small island in the Sooloo Archipelago. N. lat. 6° 14'. E. long. 120° 44'.

TOOBOUAI ISLAND, one of the Society islands, in the South Pacific ocean. Its greatest extent, in any direction, exclusive of the reef, is not above five or six miles. Small as the island is, there are hills in it of a considerable elevation. At the foot of the hills is a narrow border of flat land, running quite round it, edged with a white sand beach. The hills are covered with grass, or some other herbage, except a few rocky cliffs at one part, with patches of trees interspersed to their summits; but the plantations are more numerous in some of the valleys, and the flat border is quite covered with high strong trees, whose different kinds could not be discerned, except some cocoa palms, and a few of the ctoa. According to the information of some men whom captain Cook saw in the canoes, their island is stocked with hogs and fowls, and produces the several fruits and roots that are found at the other islands in this part of the Pacific ocean. This island is populous, and the inhabitants are more sedate than the natives of the Society islands, as well as less hospitable. Fletcher Christian, with his companions, mutineer of the Bounty, attempted to form a settlement here in the year 1789. They had a dispute with the islanders, and a severe engagement, in which one or two of the mutineers were wounded, and many of the natives were killed. Christian, after this, left the island of Toobouai, and sailed to Otaheite, where some of the crew left him: nine only remaining on board, with some of the natives, men and women, with these Christian cut the cable, and put to sea, since which time he has not been heard of. The language is the same as that spoken at Otaheite. S. lat. 23° 25'. E. long. 210° 37'.

TOODAWAH, a town of Pegu; 35 miles S. of Lundfey.

TOODIGUNTLA, a town of Hindoostan, in Golconda; 25 miles E. of Damipetta.

TOODRY, a town of Hindoostan, in Canara, on the coast; 21 miles S. of Carwar.

TOOE, a town of Hindoostan, in Bahar; 12 miles E. of Bahar.

TOOFOA, one of the Friendly islands, visible from Annamooka, by means of its height, and a volcano, which almost constantly emitted smoke, and sometimes threw up stones. Its shores are steep, and covered with black sand. The rocks are hollow, and in some places of a columnar form. The mountain, except in spots that appear to have been recently burned, is covered with verdure, shrubs, and trees. The coast is about five leagues in circuit. To the north-east of this island, and about two miles distant, is another of much less extent, but of thrice its height, which is called Kaō; it is a mountainous rock of a conical form. Both these were discovered by Tasman, and have been seen by every subsequent navigator of this group. Captain Cook passed between them, and had no soundings in the channel by which they were separated. Each island was understood to be inhabited, but no European had landed upon either, at the time when the mutiny suddenly occurred in the Bounty two days after the departure of that vessel from Annamooka. Lieutenant Bligh was forced into a boat with eighteen of his people, when ten leagues S.W. from Toofoa: he attempted

E there

therefore to get an immediate supply of bread-fruit and water at that island, which, as he understood, afforded those articles. The next morning, 28th of April, 1789, they landed in a cove, on the south-west coast; they climbed the heights, but obtained only some cocoa-nuts and plantains, and a few gallons of water from holes in the rocks. The weather being too boisterous to proceed, they sheltered themselves by night in an adjacent cave. On the 1st of May, several of the inhabitants brought them a small supply, and retired peaceably in the evening. The next day their number greatly increased. Some principal persons also came round the north side of the island in canoes, and among them one of the chiefs whom captain Bligh had threatened to carry from Annamooka: they offered to accompany him to Tongataboo, when the weather should become moderate; but some symptoms appearing of a design to obtain by force the articles that he could not afford to barter with them, he determined to depart that evening, as they were not inclined to retire. They had previously sold to him some of their weapons, and they now allowed his people to carry their property into the boat; but they would not suffer him to embark, and a contest ensued, in which most of the English were wounded by stones, and one of them was killed. The rest escaped, and bore away towards New Holland, from whence they reached the East Indies in their boat, enduring extreme hardship, but no farther loss of lives:

TOOGAUM, a town of Hindoostan, in Baglana; 16 miles S. of Junere.

TOOK, a town of Persia, in the province of Cohestan; 40 miles E. of Tabaskili.

TOOKE, JOHN HORNE, in *Biography*, the third son of a poulterer in Newport-market, was born in Newport-street, Westminster, in June 1736, and having spent some years at Westminster and Eton schools, was admitted into St. John's college, Cambridge, in 1755, where he took the degree of B. A. After officiating for some time as an usher in a school at Blackheath, he took deacon's orders, in compliance with the wishes of his father, and served as a curate in Kent. But the law being the object of his choice, he entered in the Inner Temple in 1756. Nevertheless, in 1760, he was ordained as a priest, and inducted into the chapelry of New Brentford, purchased for him by his father. But as he entered very deeply and warmly into the political disputes of the period in which he lived, he ceased officiating as a clergyman, and took an active part in the transactions of that period. When Wilkes returned from his exile to France, and became a candidate for the representation of the county of Middlesex, Horne was his zealous adherent, and was thought to have contributed to the success of his election. It is said, that it was by his instigation that Mr. Beckford, lord mayor in 1770, made a verbal reply to his majesty's answer to a remonstrance from the city of London; and that he drew up that reply as inscribed on the pedestal of Mr. Beckford's statue in Guildhall. He is regarded also as the principal founder of the "Society for supporting the Bill of Rights," of which he was an active member; and by his exertions Bingley, a printer, who had been committed to prison by lord Mansfield for refusing to appear for the purpose of answering to interrogatories, was at length liberated. In the years 1770 and 1771, a quarrel took place between Wilkes and Horne, in the prosecution of which the latter lost popularity, without incurring any just charge against his political integrity. In 1771 he took his degree of M. A., though opposed by some members, among whom was Mr. Paley. To him it was owing, that the publication of the debates in the house of commons has been continued without interruption.

At this time he had a literary controversy with Junius, in which he was thought to have the advantage. In 1773 he threw off his clerical garb, and proposed to resume his legal studies with a view to the profession. But at this time an incident occurred, which was of material importance with respect to his future fortune. Mr. Tooke of Purley, in Surrey, had ineffectually opposed an inclosure bill, which was likely to be detrimental to his estate, and as this bill was passing rapidly through the commons, he applied to Horne for advice. After some deliberation he proposed to Mr. Tooke a remedy, which was to commence with a libel on the speaker, which he would undertake to write. Accordingly he stated the case, accompanying the statement with some severe reflections, and sent it to the Public Advertiser. When the paragraph was next day reported to the house and read, it occasioned great irritation, and a motion was made for calling the printer before the house. Mr. Horne, as the acknowledged writer, was called to the bar; he immediately obeyed the summons, and in a respectful manner confessed, that through hatred to oppression, and zeal to serve a friend, he had been urged beyond the bounds of discretion. After a long debate, he was remanded from the bar in custody of the serjeant at arms, and upon being brought up some days after, he was, by the good offices of some friends, discharged upon paying his fees. His purpose was answered: time was thus given for reconsidering the obnoxious bill, and the exceptionable clauses were either altered or withdrawn.

Mr. Horne was an ardent opposer of the American war; and when the news of the battle of Lexington arrived, the Constitutional Society voted 100*l.* to the widows and children of the Americans who had fallen in it; and the resolution to this purpose, printed in the public papers, was signed John Horne. In this resolution, the sufferers were denominated "Englishmen who, preferring death to slavery, were, for that reason only, inhumanly murdered by the king's troops at Lexington." For this paragraph he was prosecuted, and tried at Guildhall in July 1777, and pleaded his own cause. Notwithstanding the spirit and acuteness with which he defended himself, he was sentenced to twelve months' imprisonment, and to pay a fine of 200*l.* In the course of this trial he first appeared before the public as a grammatical critic; and in 1778, he printed a letter to Mr. Dunning, which discussed the force and meaning of certain conjunctions and prepositions employed in his indictment, and which was the foundation of a larger work afterwards published. In the following year, he was disappointed in his expectation of being called to the bar; for though he was eminently qualified for the profession to which he aspired, he was rejected under the pretext of his being still a clergyman. This he felt as a very grievous disappointment, and with a mind not a little exasperated he devoted himself to politics. Accordingly, in 1780, he published a pamphlet, entitled "Facts," keenly reviewing lord North's administration, and containing two chapters on Finance, supplied by Dr. Price. Soon after the termination of the American war, parliamentary reform became a popular topic; and in 1782, Horne published a letter to Mr. Dunning (lord Ashburton) under the title of "A Letter on Parliamentary Reform, containing the Sketch of a Plan;" of which we shall merely say, that he disapproved of universal suffrage. Mr. Pitt was at this time a fellow advocate in the same cause. Horne now avowed himself the friend of Mr. Pitt, in opposition to Mr. Fox, whose coalition with lord North he very much disapproved. In 1786 Mr. Horne, having assumed the name of his friend Mr. Tooke, published his "Epea Pterocenta, or Diversions of Purley," so called
from

from the country residence of his friend. Of this work, founded on his letter to Mr. Dunning, already mentioned, the most prominent subject of discussion was the derivation of conjunctions and prepositions from verbs and nouns, whence they acquired a determinate meaning, often different from that which has been arbitrarily imposed upon them. This work attracted the notice of philologists, and gave to the author a high rank among writers on the philology of language. (See GRAMMAR.) Politics, however, diverted his attention from subjects of this nature; and in 1788, he published "Two Pair of Portraits," the figures in which were the two Pitts, and the two Foxes, of the past and present generations. The first name was strongly illuminated, and the latter thrown into a dark shade. He might probably, however, at a later period, have adopted a different mode of colouring. In 1790 he opposed Mr. Fox and lord Hood at the election of representatives in parliament for Westminster; and professing himself unconnected with party, and determined neither to open a house nor to give away a single cockade, he polled near 1700, without solicitation or corruption. On occasion of his defeat, he presented a petition to the house, in support of which he freely indulged himself in very bitter sarcastic invective. In the year 1794 he was brought to a trial, under the charge of high treason. During the progress of this trial, he maintained the most perfect composure and self-possession; and as he had little to apprehend after the previous acquittal of Hardy, the jury brought in their verdict of "not guilty," after being only eight minutes out of court. In consequence, however, of this trial, he became more cautious in his conduct, and declined the visits at Wimbledon, where he resided, of persons known to be violent in their principles and conduct. Upon the death of Mr. Tooke of Purley, he inherited, in consequence of a previous agreement, half of the property left by that gentleman to his nephew. In 1796 he offered himself again as a candidate for Westminster, and suffered a second defeat, after having polled 2819 votes. He was chargeable, however, with some inconsistency in the acceptance of a seat, in 1801, for the noted borough of Old Sarum, on the nomination of lord Camelford. Some attempts were made to exclude him, under the plea of his being a clergyman; but a compromise being proposed by the minister, Mr. Addington, by determining the future ineligibility of persons in holy orders, he retained his seat till the dissolution of parliament. Having published by subscription a second edition in 4to. of his "Diversions of Purley," a second part in 4to. appeared in 1805, in which he chiefly adverted to etymology, and to adjectives and participles, and their formation, intermixing satirical strictures upon some literary characters of note. From this time his bodily infirmities, occasioned by a disorder to which he had been long subject, increased, though he retained his faculties in full vigour, and continued to enjoy life. His temper was little affected by mental or physical evil, and "no one more strenuously maintained," says one of his biographers, "the balance of good in human existence."—"His latter days," says the same writer, "were cheered by easy circumstances, and the attention of many friends, whom he entertained with great hospitality, and amused by his conversation, which was singularly pleasant and lively. With an unaltered brow, he could be either facetious or sarcastic, and his features seldom disclosed what was passing within. His manners were polished, and his appearance was that of a gentleman of the old school." His life at length terminated, by tedious and continued decay, in March 1812, in the 77th year of his age. As he was never married, his

property was bequeathed to his natural children. Stephens's Memoirs of John Horne Tooke.

TOOKOOK, in *Geography*, a town on the W. coast of Borneo. S. lat. $2^{\circ} 24'$. E. long. $109^{\circ} 46'$.

TOOLAJEE, a town of Hindoostan, in Guzerat; 20 miles S. of Gogo.

TOOLEN, or TULLEN, (*i. e.* the Isle of Seals,) a small island in the Caspian sea, near the W. coast. N. lat. $44^{\circ} 14'$.

TOOLIAPOUR, a town of Hindoostan, in the country of Dowlatabad; 45 miles E.S.E. of Perinda. N. lat. $18^{\circ} 20'$. E. long. $76^{\circ} 35'$.

TOOLLY, a town of Hindoostan, in Geondwana; 10 miles W. of Coomtah.

TOOLMEDIN, a town of Hindoostan, in the circar of Bopal; 25 miles S.W. of Bopaltol.

TOOLS, simple and popular instruments, used in the more obvious operations, and particularly in the making of other more complex instruments.

The term *tool* is particularly used by canal-makers, for a kind of strong curved spade or shovel employed in canal-works.

Tools are divided into *edge-tools*, *spring-tools*, *pointed-tools*, &c.

Mr. Parkes, in the fourth volume of his "Chemical Essays," has given a history of the origin and progressive improvement of edge-tools, and an account of the materials of which they were constructed. It appears from Goguet's "Origin of Laws," to which he refers, that as many of the ancient nations had no knowledge of iron, they used stones, flints, the horns and bones of various animals, the bones and shells of fish, reeds, and thorns for every purpose in which the moderns now use edge-tools of iron and steel. Spears and other instruments for exterminating wild beasts, and even implements of agriculture, were formerly made with gold and silver; and instead of these was afterwards substituted copper, as a metal more easily to be procured than malleable iron. The abundance of celts and other ancient instruments, found in various parts of the globe, shews that copper and brass were formerly in very general use. From the prodigious number of copper instruments of different kinds and sizes, which have been found in this country, such as axes, swords, spear-heads, arrow-heads, &c. known among antiquaries by the general name of celts, it is evident that our ancestors were well acquainted with the art of forming metallic copper in any way which they thought proper; whereas the use of metallic iron is comparatively of late introduction. At the time of the first Roman invasion, this metal was so rare, that the Britons fabricated their money with it, and even their ornamental trinkets. But the Romans having made themselves masters of the country, established imperial founderies for making iron, and constructed forges for manufacturing spears, lances, battle-axes, and implements of every kind, in different parts of the kingdom. (See Cæsar, de Bell. Gall. lib. v. c. 12. Henry's Hist. of Britain, vol. ii. p. 139, 140.) At the battle of Hamilton, in 1402, the repulse of the Scots appears to have been entirely owing to the excellent temper of the arrows which were employed by the English army. Swords also were then in use, and Sheffield was, even then, famous for its cutlery. Table-knives, it is said, were first made in London in 1563, by one Thomas Matthews of Fleet-bridge.

Good edge-tools cannot be made without steel; and of this there are various sorts (see STEEL); such as blistered, shear, spur, star, and cast steel; besides which there is a kind of German steel, made immediately from the iron ore, by simple fusions. (See also WOOTZ.) The cheapest

TOOLS.

edge-tools, and other less important articles, are usually made with the first-mentioned kind, united to a large proportion of bar-iron. Clothiers' shears, firmer chisels, plane-irons, coopers' adzes, scythes, reaping-hooks, and large knives, are commonly made with shear-steel: for the method of manufacturing it, see STEEL. The spur and star steel are used only for particular purposes, according to the fancy of the master cutler. Cast-steel is used for the best penknives, scissars, and razors; and fine saws, surgical instruments, and all edge-tools which require a fine polish, and various other implements employed in cutting iron, are all made with cast-steel. The superior beauty of instruments made with cast-steel would have occasioned a very great consumption of this article, if it had not been for the difficulty of welding, or uniting it properly with iron, and which occasioned its being used at first only for those smaller instruments, such as lancets and penknives, which are generally made entirely of steel. But since the discovery made by sir Thomas Frankland (for which see WELDING), cast-steel has been brought into more extensive use, and the instruments that are thus constructed, are much better than those which are made entirely of cast-steel. The circumstance of an instrument having its back made of iron, renders it not so apt to fly from the work to which the edge or steel part is applied, and eventually less liable to break.

Many articles, long after the invention of cast-steel, used to unite it to the iron by means of rivets. Hoes are still made by riveting or screwing the back, together with the eye, upon a blade made with cast-steel. We cannot minutely recite the various manipulations that are practised in the manufacture of different edge-tools. The reader will find information of a more ample kind in the work of Mr. Parkes, above cited. (See also our article CUTLERY.) We shall, however, select the following particulars: the cooper's adze and the carpenter's axe are first formed by the white-smith, in iron, together with the eye for the helve. The instrument is then heated again, and the edge of the cutting part is slit down with a chisel, and this slit is filled with a thin piece of steel, of a corresponding size and form. The iron, that has been slit upon, is folded down upon the steel, and the whole again heated to a welding heat, when the sledge-hammer quickly unites the iron and the steel into one compact mass. Scythes and such other large instruments are forged at the mill, by means of a large hammer, moved by water, and the process is called "skelping." Augers, gouges, large chisels, table-knives, razors, and other instruments of a similar bulk, are forged upon a large anvil by the principal workman, aided by an assistant called the "striker," who strikes occasionally with a sledge-hammer. Penknives, lancets, gravers, surgical instruments, and other small edge-tools, are generally forged on a small anvil firmly fixed within a large one, in order to give greater steadiness. These are usually fashioned out of steel only, and forged by one workman singly and alone. Scissars are also forged by a single hand; but the anvil on which they are fashioned is of a peculiar construction, having *bosses* or *dies*, and *beak* irons of various sizes occasionally adapted to it, so as to suit the different shapes and dimensions of the separate parts of these particular instruments.

It should have been noticed, that many other tools besides the axe and the adze are originally forged out of a piece of iron, with a little steel welded to it for the cutting part of the instrument.

The real Damascus sword-blades are said to be composed of slips or thin rods of iron and steel bound together with iron wire, and then firmly cemented together by welding.

It is well known that it is the circumstance of drawing

down the shear-steel under the tilt-hammer that gives it the superiority over common steel. (See TILT-Hammer, and TILTING of Steel.) Mr. Bingley therefore suggests in his patent, that, if he could roll out his steel much thinner than it had ever been done before, he should much improve its quality: and accordingly a very thin piece of steel is let into the face of a plane-iron made of cast-iron; and, as the steel for this particular purpose has to go through the rollers several times to make it sufficiently thin, it becomes of a peculiar texture, and the tool made with it is found to suit the joiner much better than the plane-irons heretofore in use.

In the manufacture of edge-tools, the process which immediately succeeds the forging is that of *hardening*. All these cutting instruments are therefore fashioned when the metal is in its original soft state; and when they have attained the intended forms, they are heated afresh to a particular temperature suitable to the article. When they have acquired that degree of heat, they are instantly plunged into cold water, which gives them great hardness, and renders them capable of cutting soft iron, or even steel. See TEMPERING.

TOOLS, *Draining*, in *Agriculture*, the various kinds of tools which are employed in performing this sort of work, such as *spades*, *shovels*, *scoops*, *draining augers*, *boring augers* or *rods*, *sod-knives*, &c. See these heads.

TOOLS, *Lopping* or *Pruning*, in *Rural Economy*, the various tools, such as hedge-bills, large knives, axes, saws, chisels, &c. used in taking off the side-shoots and branches of forest-trees. And lately an instrument uniting several of these properties has been invented, which is very convenient, and readily dispatches the business. It is described as below in the first volume of the "Memoirs of the Caledonian Horticultural Society," where a representation of it is also given. It is perfectly simple in its form, having merely two edged hooks, projecting from a socket-shank three inches in length, the breadth of which, where the hooks spring off, is two inches and two-tenths of an inch; the hooks themselves project from the shank three inches; between them, and on the top or upper side, is placed a strong chisel, four inches in breadth, and one inch in depth; the whole tool or instrument being about eight inches in width. The length of the wooden handle must, of course, be in proportion to the height and size of the trees to be lopped or pruned, as in different lengths, from six to eighteen feet, which last is, it is said, as long as a man can well and properly manage them. Where trees require lopping or pruning to a greater height than the above length of shaft or handle, a ladder is to be made use of for the purpose, and one of the short-handled tools or instruments.

It is noticed, that the hook part is what is principally made use of, which cuts the branch from the upper side: the chisel is only employed when snags are left, and where branches are too strong for the hooks; in which cases, the chisel is first made to strike the branch from below; but a mallet is never used.

It is observed that fir-trees will certainly be greatly improved by lopping and pruning with this tool, both as to growth and quality of timber; but that care should be had not to over-cut or prune them. Larches will, it is said, always shew when that is the case with them, by breaking out into numerous unnatural branches; but that it may not be so soon noticed in Scotch, spruce, and other firs, which, however, have generally a stunted appearance for some years afterwards, and that it sometimes occasions their death. Four or five tiers of branches should always, it is thought, be left, particularly on young trees; and that on larches there should be still more.

TOOLS, *Scraping*, in *Agriculture* and *Rural Economy*, the several

several sorts of tools and contrivances which are formed and made use of for cleaning and removing the mould, dirt, and other matters, that may adhere to different kinds of implements while they are in work, as those of the drill, roller, plough, and some other kinds; and to the surfaces in some other cases, as those of wheels, roads, &c.

In the drill and the roller, the scrapers mostly consist of thin bars of iron or wood, so constructed and fixed behind, as to take off the dirty or mouldy cloggy substances as they collect upon them. In ploughs it is usually done by a small sort of paddle, with a short handle used by the ploughman. The surfaces of wheels, in heavy carriages, are cleaned by tools of the scraping kind, properly contrived for the purpose. For tools of this sort, where the tires of the wheels, in such cases, are made concave, it has been advised that a small stem should be fixed to the body of the carriage, which may present a convex scraper; which, on account of the shifting of the wheel on its axis, sometimes a full inch or more at its perimeter, should be made to slide on the stem, having a kind of bracket to embrace the thickness of the felly: thus the thickness of the wheel having presented to it a convex scraper sliding on a square stem; which, allowing one or two inches of play, has at its outer end a bolt-head, the two arms of which forming a bracket, will always keep the scraper opposite to the groove, or hollow in the wheel.

It is suggested that the blade of the scraper should be very shallow, as it would otherwise operate as a lever upon the bar; and either wrench it, or ultimately round off the corners, so as to allow the tool to be turned out of its proper direction, which should be at an angle of five degrees under the horizon. But it is supposed that the tool for scraping the fore-wheel of a waggon will be more difficult to fix, with proper firmness, on account of its traversing. It might, however, it is thought, be effected by setting it on a segment attached to the body of the carriage; but the necessary length of stem would prove a formidable objection in such a case. The best mode would, it is thought, be to fasten it to the wooden axle, so as to move always with it, and consequently preserving its relative position to the edge of the wheel.

In other cases, other sorts of light iron plain scrapers may be fixed so as to allow them to act in removing the dirt from wheels where necessary.

In the scraping and cleaning of roads, tools of the cow-rake headed kind are used by the hand, and large machines in other shapes by horses. See *ROAD-Scraping Machine*.

TOOL, *Skimming*, in *Agriculture*, that sort which is employed in taking off the surface of the land in ploughing, in order to its being deposited in the bottom of the preceding furrow, and thus making neat clean tillage-work. Tools of this kind, with sharp paring and cutting edges, are differently formed, according to the purposes to which they are to be applied; but the mode of fixing them to a sort of fore-coulter in ploughs is considered by many as a great improvement, as they are found in that way to do the work much better than if attached to the common coulter, in which manner they sometimes do not work well. See **TILLAGE**.

TOOLUC, in *Geography*, a town of Hindoostan, in Mohurbunge; 36 miles N.W. of Harriopour.

TOOLUMBO, a town of Africa, in Bambarra. N. lat. 12° 55'. W. long. 5°.

TOOM, a river of Hindoostan, which runs into the Tungebadra, 15 miles S.E. of Sanore.

TOOMANUA. See **OPOUN**.

TOOMBEWADY, a town of Hindoostan, in the Carnatic; 8 miles S.W. of Caroor.

TOOMBUCK, a town of some note on the Persian gulf, between Congou or Kungoon, a large and populous town, and Tæhire or Tahirie.

TOOMCOUR, a town of Hindoostan, in Mysore; 20 miles S.S.E. of Sera.

TOOME-BRIDGE, a post-town of the county of Antrim, Ireland, situated at the northern extremity of Lough Neagh, where there is a bridge over the narrow channel which separates that lake from Lough Beg. It is 97 miles N. by W. from Dublin, and 13 miles W. from Antrim.

TOOMISH, a town of Ireland, in the county of Kerry; 14 miles S. of Tralee.

TOOMRY, a town of Hindoostan, in the circar of Hindia; 24 miles N. of Hurdah.

TOOMSIR, a town of Hindoostan, in Goondwana; 38 miles N.E. of Nagpour.

TOON, a town of Persia, in the province of Cohestan; 90 miles N. of Tabaskili. N. lat. 34° 32'. E. long. 57° 35'.

TOONDY, a town of Bengal; 38 miles S.S.E. of Curruckdeah. N. lat. 23° 58'. E. long. 86° 34'.

TOONE, a river of Ireland, which runs into the Lee, 15 miles W. of Cork.

TOONG, a town of Hindoostan, in Dowlatabad; 26 miles W. of Poonah.

TOORAMBADDY, a town of Hindoostan, in Mysore; 13 miles W.N.W. of Aravacourchy.

TOORATTEO, a town on the fourth coast of Celebes. N. lat. 5° 33'. E. long. 120° 4'.

TOORDA, a town of Africa, in Kaarta; 24 miles N. of Kemmoo.

TOORGOODY, a town of Hindoostan, in the Carnatic; 10 miles S.E. of Tritchinopoli.

TOORSHA, a river of Bengal, which, after its confluence with the Maunsi, assumes the name of Neelcoomar, and shaping its course through Baharbund, falls into the Berhampooter, properly (it is said) Brahmá pootra, offspring of Brahma.

TOOS, a town of Persia, in Khorassan; 25 miles S. of Meshid.

TOOSANG, a town on the west coast of Celebes. S. lat. 0° 30'. E. long. 119° 38'.

TOOSCHONDOLCH, an Indian village, on the west coast of North America; of importance in the fur trade. N. lat. 53° 2'.

TOOSHOOR, a town of Hindoostan, in Mysore; 5 miles E. of Nameul.

TOOSI, a town of Japan, on the fourth coast of the island of Nippon; 84 miles S.S.E. of Meaco. N. lat. 34° 35'. E. long. 137° 35'.

TOOSIMA, one of the small Japanese islands, near the N.W. coast of Nippon. N. lat. 40° 40'. E. long. 140° 40'.

TOOTH, DENS, in *Anatomy*. See **TEETH**.

TOOTH-Ache. See **TEETH, Diseases of**.

TOOTH-Drawing. See **TEETH**.

TOOTH, Wolf. See **WOLVES-Teeth**.

TOOTH, in the *Manege*. It is by a horse's teeth, chiefly, that his age is known. See **TEETH**, in *Rural Economy*.

TOOTH-Ache Tree, in *Botany*. See **ZANTHOXYLUM**.

TOOTH-Pick. See **DAUCUS**.

TOOTH-Wort, a name applied to several plants, on account of a resemblance in their roots to the human teeth.

This

This is very striking in *Lathraea Squamaria*, whose roots are furnished with smooth white scales, very accurately imitating, except in hardness, the *dentes incisores*, or fore-teeth. This resemblance is perceptible also, though less exact, in the roots of the various species of *DENTARIA*; see that article. *Ophrys Corallorrhiza* of Linnæus has, for a similar reason, been sometimes called *Dentaria*; which name, or *Dentillaria*, has also been given by Rondeletius to the *Plumbago*, because of the teeth of its corolla; a character found in many other genera. *DENTECLA*, see that article, owes its name to the last-mentioned circumstance. It is hardly necessary to advert to the reputed qualities of the above tooth-rooted plants, which were founded on the resemblance in question. On this subject more may be said when we come to speak of the *VIRTUES of Plants*.

TOOTHED, in *Botany and Vegetable Physiology*, *dentatus*, is properly applied to the margin of any leaf, petal, &c. when furnished with directly prominent teeth, which scarcely point either towards the base or the point of such leaf or petal, or of their segments. Yet this term is not always so strictly limited as it ought, being sometimes negligently used, when *ferrated* would be more proper. *Stamens* however are said to be toothed, when they have any lateral prominence, or notch whatever, as in *Alyssum*.

TOOTOOCH, in *Geography*, a small island in Nootka found, with an Indian village.

TOOTOONA. See *ERRONAN*.

TOP, or **TOPE**, in *Commerce*, a wine-measure at Breslau, and in other places of Germany. At Breslau, an eimer of wine contains 20 tops, 80 quarts, or 320 quarters, and is equal to 14½ English gallons.

Top, in *Geography*, a lake of Russia, in the government of Olonetz, about 44 miles in length, and 8 in breadth; 256 miles N.N.W. of Petrovodska. N. lat. 61°. E. long. 30° 14'.

Top of a Ship, a sort of platform, surrounding the lower mast-head, from which it projects on all sides like a scaffold. Its principal intention is to extend the topmast-shrouds, so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by the tressel-trees and cross-trees. The top is also convenient for containing the materials necessary for extending the small sails, and for fixing or repairing the rigging machinery. In ships of war it serves as a kind of redoubt, and is accordingly fortified for attack and defence, being furnished with swivels, musquetry, and other fire-arms, and guarded by a thick fence of corded hammocks. It is also used as a place for looking out, either in the day or night. The frame of the top is either close-planked like a platform, or open like a grating. In all ships of war, and in the largest merchantmen, the top is fenced on the aft-side by a rail about three feet high, stretching across and supported by stanchions, between which a netting is usually constructed.

The outside of this netting is generally covered with red bays, or red painted canvas, extended from the rail down to the edge of the top, and called the *top-armor*. By this name it seems to have been considered as a sort of blind, behind which the men may conceal themselves from the aims of the enemy's fire-arms in time of action, whilst they are charging their own muskets, carbines, or swivels. The dimensions of tops in the royal navy are as follow: the breadth of the top athwart-ships is one-third of the length of its corresponding top-mast; the length of all tops, from the foremost to the after-edge, is equal to three-fourths of their breadth athwart; and the square hole in the middle is five inches to

a foot of those dimensions. The tressel-trees and cross-trees extend nearly to the edge of the tops.

The aft-side of the top is straight, and the fore and aft sides square from thence to the aft-side of the foremost cross-tree; from thence the fore-part breaks in with an elliptical curve. Tops in the navy are separated in the middle by a fore and aft line, which makes them much more convenient to be gotten over head.

By a late order in the navy, the under sides of tops are to be planed, and the after-part of the fore and main tops is to be eighteen inches wider, and the after-part of the mizen top, one foot wider than at the chain-plate for the foremost-shroud: the inside of the tops on each side by the part called *lubber's-hole*, is to have a flap and hinges, so that a top-gallant yard, mast, or a top-fail, may pass inside of it.

Tops, to lay ropes from a six-thread ratline to the largest cables, are conical pieces of wood, with three or four grooves, or scores, from the butt to the end, for the strands to lie in, and form a triangle. If too broad at the butt, the rope will not close well, nor the strands work so close as they should. A hole is made through the centre of the top, one-third the length from the butt-end, for the staff or bolt to go through, round which are put pieces of old rope, called tails, for the layers to close the rope with, and lay it hard or slack, according to the use it is for. A hole is likewise made through the middle of the top lengthways, for laying ropes with a heart. A collar is put on to assist the layer when the work is too heavy, and to enable him to hold the tails, and close the rope well.

Tops, to lay ropes of three inches and upwards, have a staff under them, with a truck-wheel at the lower end. An iron bolt goes through the centre of the top, and is lashed down to the staff, on which the tails are put and rounded over the rope, being too heavy to be laid with the collar. A strap is put round the tails, with a woolder for the layer to close the rope with.

Tops, to lay cables, have a leg to support them, with a truck-wheel at the end to run on, besides the staff which the tails go over.

Tops, for laying lines of all sizes, are of box or hard wood, tapered at the after-part, that the line may close sharp. Those for fash-lines have four grooves, and for drum-lines eight grooves.

Top and Butt, in *Ship-Building*, a method of working English plank, so as to make good conversion. As the plank runs very narrow at the top, clear of sap, this is done by disposing the top-end of every plank within six feet of the butt-end of the plank above or below it, letting every plank work as broad as it will hold clear of sap, by which method only can every other seam produce a fair edge.

Top-Armour, in a *Ship of War*. See *TOP*, *supra*,

Top-Block. See *BLOCK*.

Top-Brim, a space in the middle of the foot of a top, sail, containing one-fifth of the number of its cloths. It is so called from its situation, being near the fore-part of the top when the sail is extended.

Top-Chain, a chain to sling the sail-yards in the time of battle, in order to prevent them from falling down, when the ropes by which they are hung happen to be shot away, or rendered incapable of service. Falconer.

Top-Hamper, any unnecessary weight aloft, either on the top-side of a ship, or about its tops and rigging.

Top-Lantern, a receptacle to hold three or more lights, made of tin and glass, placed in the aft-part of the top, in any ship where an admiral or commodore leads the van of a fleet,

TOP-Lining, the lining sewed on the aft-side of top-fails, to preserve the fail from the chafing of the top.

TOP-Mast, the second division of a mast, or that part which stands between the lower mast and the top-gallant mast. See **MAST-Making**.

By a late order in the navy, the blocks at the heels of top-masts (particularly in line-of-battle ships) are to be discontinued, and the top-masts made from as small sticks as possible: the sheave-hole is to be placed nearer the heel, by which means the several quarters will be brought nearer the butt, and the sizes of the sticks for making of top-masts diminished; and as some of the rough sticks will work one way larger than the other in the upper quarters, and thereby increase the circumference of the wood, where strength is so requisite, leave this additional wood, and make the mast oval: a hoop is to be placed below the sheave-hole, and above the fid-plate.

The caps of top-masts, also, are to have a semi-circle cut at the after-part, with an iron clamp to fit, so as to admit of getting a top-gallant-mast up abaft the top-mast, if necessary in chase.

The heels of jib-booms are also to be left square, to serve as substitutes for mizen-top-masts occasionally: and let the hearts be prepared conformable thereto.

TOP-Gallant-Masts, are two, *viz.* *main-top-gallant-mast*, and *fore-top-gallant-mast*, which are small round pieces of timber, set on their respective top-masts; on the top of which masts are set the flag-staffs, on which the colours, as flags, pendants, &c. hang.

TOP-Netting is fastened to the rail, shrouds, and top, to preserve the men from falling, &c.

TOP-Rope, a rope employed to sway up a top-mast, or top-gallant-mast, in order to fix it in its place, or to lower it in tempestuous weather, or when it is no longer necessary. The rope used on this occasion for the top-masts is furnished with an assemblage of pulleys at its lower end, called the *top-tackle*; the effort of which in erecting the top-mast is communicated from the head of the lower-mast to the foot of the top-mast; and the upper end of the latter is accordingly guided into, and conveyed up through the holes between the tressel-trees and the cap. For this purpose, the top-rope, passing through a block which is hooked on one side of the cap, and afterwards through the holes, furnished with a sheave or pulley, in the lower end of the top-mast, is again brought upwards on the other side of the mast, where it is at length fastened to an eye-bolt in the cap, which is always on the side opposite to the top-block. To the lower end of the top-rope is fixed the top-tackle, the effort of which being transmitted to the top-rope, and thence to the heel of the top-mast, necessarily lifts the latter upward, parallel to the lower-mast. When the top-mast is raised to its proper height, the lower end of it becomes firmly wedged in the square hole, between the tressel-trees. A bar of wood or iron, called the *fid*, is then thrust through a hole in the heel of it, across the tressel-trees, by which the whole weight of the top-mast is supported. In the same manner the top-gallant-mast is erected, and fixed at the head of the top-mast. Falconer.

TOP-Sail-Lifts. See **LIFTS**.

TOP-Sails, and *Top-gallant-fails*, in a *Ship*, are those belonging to the top-masts, and top-gallant-masts. The former are extended across the top-mast by the top-fail-yard above, and by the yard attached to the lower-mast beneath; being fastened to the former by *robands*, and to the latter by means of two blocks fixed on its extremities, through which the top-fail sheets are inserted, passing from thence to two other blocks fixed on the inner part of the yard, close by

the mast; and from these latter the sheets lead downward to the deck, where they may be slackened or extended at pleasure. The top-gallant-fails are expanded above the top-fail-yard in the same manner. Falconer. See **SAIL**.

Since the article *Sail-making* was printed, the following alterations concerning fails have been adopted in the navy: *viz.* top-fails are to be reduced by deducting four inches for every three feet in length of the top-mast, instead of three inches and an eighth, as at present.

Mizen-top-fails are to be hollowed in the foot a yard and a half, instead of twenty-seven inches, to prevent rubbing over the stay; and top-gallant-fails are to be hollowed two feet in the foot of the fail, for the above-mentioned purpose.

The main-top-mast-stay-fail is to have six inches gore in every cloth at the foot of the fail, and long gore at the clue.

Mizen-courses are not to be supplied to any ships under fifty guns, but two drivers in lieu.

Driver-booms, as used in 1806, are to be reduced two inches in every yard. The length of the gaff to be in proportion to the fail, and then three feet added thereto, to shew signals.

Drivers are to be cut with a deduction in length, to answer the reduction in length of the boom and gaff, as above. Drivers for line-of-battle ships, the leech is to be twice the length of the luff. For frigates, the length of the leech is to be once and two-thirds the depth of the luff.

Jib.—The after-leech rope is to be two inches and a half in ships of the line, and in forty-gun frigates two inches and a quarter: other ships above twenty guns two inches, and one inch and three-quarters all under.

White bolt-rope is to be used in making of fails, instead of the tarred rope at present in use.

Single clump-blocks of eight inches in size are to be strap-bound, clue-garnet fashion for reef-tackles in the leech of fails.

TOP-Side, a name given to all that part of a ship's side above the main-wales.

TOP-Timbers, the timbers which form the top-side of a ship. The first general tier which reach the top of the side are called the long top-timbers, and those the shift above are called the short top-timbers.

TOP-Timber Half-breadth, a section containing one-half of the ship, at the height of the top-timber line, perpendicular to the plane of elevation.

TOP-Timber Line, is the curve limiting the height of the sheer at the given breadth of the top-timbers.

TOP-Timber Sweep, is that which forms the hollow of the top-timber. This hollow is, however, very often formed by a mould, so placed as to touch the upper-breadth sweep, and pass through the point limiting the half-breadth of the top-timber.

TOP-a-Starboard, and *Top the Yard-arms*. See **TOPPING**.

TOP-Bank, signifies the level of the top of a canal's bank; as **BCIK**, *Plate I. Canals*, fig. 1. &c. This is generally about one foot higher than the surface of the water **DK**.

TOP-Soiling, the art of taking off the vegetable mould or top-soil before a canal is began, to be returned again upon the bank and new-made ground by the side of it.

TOP-Water is the level line of the water's surface, as **DH** (*Plate I. Canals*, figs. 14 and 15.) in a canal **CFG I**.

TOP-Draining, in *Agriculture*, a term sometimes applied to the practice of removing surface-wetness from land, either before it is to be prepared for the seed, or after that

has been put into the soil. In the latter of which cases, the furrows for the water are to be stricken with the plough, so as to terminate in the drains which have been formed, and take it away. This should be done daily, as the field is gone over by the harrow. See *SURFACE-Draining*.

This is an useful sort of draining for ploughed lands that are inclined to be wet.

Top-Dressing, a term applied to such sorts of reduced and other manure as is laid upon the surface of land without being turned into it; and also to the practice of dressing the surface of grass-land, or that of other kinds of land and crops, with some sorts of highly reduced or powdery manure, that can be evenly spread out or sown equally over them by the hand.

In the cultivation and management of lands of these kinds, a great variety of substances is in use for this purpose, such as foot, ashes, the dung of rabbits, pigeons, and other birds, rape-dust, gypsum, malt-dust, and several others; the nature, uses, and benefits of which, are more particularly noticed under their different respective heads, which see.

The advantages which the Hertfordshire farmers derive from the practice of spring or top-dressing their lands and crops, are fully shewn in the statements that have been given in the original report of the agriculture of that district: in which it is said, the spring or top-dressings of their lands are the leading features of the farming in that county, and consist of foot, ashes, malt-dust, and oil-cake dust, or pulverized oil-cake. The foot is generally used on the wheat-crops which have had no previous manure. It is laid in heaps on the crops in winter, and sown over them in the spring. But the other top-dressings are housed, and kept dry till used in this way at the proper time. See *SOOT*.

It has been observed in some of the early Essex agricultural reports, that the application of manure upon the surface, or what is generally called top-dressing, ought chiefly to be regulated by the following considerations: as, first, whether the soil is of such a nature as to require any correction in its temperament, to render it more or less tender, open, or friable: secondly, whether the manure proposed to be applied, is capable of operating to that end: thirdly, whether such manure is capable of affording nourishment to vegetables, unless it is brought into close and immediate contact with some other power or principle containing vegetable food in the soil: and, fourthly, whether the plant proposed to be fed by such manure, draws its nourishment principally from the ground, or in other ways.

It is said, that in the affirmative of all these cases it is plain the manure should only be slightly covered or lightly ploughed under. But that when the manure is of such a nature as to apply but lightly to such considerations; when it is capable of being dissolved on the surface, and conveyed by water downwards to the roots of the plants, or by conversion into vapour, to be absorbed by their stems or leaves, and that the plant is equally prone to receive its nourishment in both ways; the economy and effective operation of top-dressings are unquestionably the most highly beneficial and greatly to be preferred.

These top or spring-dressings are peculiarly applicable to poor light sandy and gravelly lands, and of course to the production of the specifically heaviest corn; and they put such lands more on an equality, in point of annual value, with stronger and richer soils.

And in the Corrected Agricultural Report of the same district, it is stated that ashes as top-dressings, though they open and loosen the soil, do not feed a crop. They are supposed to last two crops, and to be of such benefit to wheat-

crops, that when tenants quit farms, they are allowed half the expence of ashing or top-dressing the clovers, which has been laid out, that the in-coming tenants are to sow with wheat: some few instances too are met with of sowing them over or on wheats. The usual time is the middle of winter, if the season be mild or moist. Moss is destroyed by some with this sort of top-dressing on park grass-land, who think they do little good to the wheat that follows the clover on which they are spread, otherwise than by improving the clover. They are decidedly of opinion that it is better husbandry to use foot on barley than this kind of top-dressing; as the former will do much good to the following clover, whereas the latter are of no more utility to the wheat than by increasing the quantity of the clover crop. The farmers in these cases sow from ten to sixteen sacks on clover.

In other parts of the same district, these sorts of top-dressings are said to be very beneficial; and that on being spread out on clover, they do as much good to the following wheat, as that of a top-dressing of the foot kind or footing would do. On a comparison of them, as sown in November and February on clover, over exactly the same spaces of land, in the same quantities: those used at the former period produced the best crop by about a fourth part of a load of this sort of hay on the acre. Some, however, in other places, do not much approve of such top-dressings, except on clay, to sharpen the soil, as they term it: they are supposed to do little good on arable chalky lands.

Top-dressings composed of the dusts of different cakes are found very useful, but often too expensive for the purpose. Some think those of the linseed-cake kind the best dressing they have seen for wheat in top-folding, even so late as the month of May, with sheep fed on such cake in troughs. The dust of cakes of the rape kind has likewise been much employed in some places as top-dressings, even when the expence has been so high as twenty shillings the quarter. Mills are constructed for grinding it in the above district, and large quantities are imported from Ireland, and perhaps other places. Some have stones attached to threshing-mills for reducing it to dust as a manure, the use of which is greatly approved of in some cases. By some it has been found that it answers the best when spread on wheat. The quantity of this manure as a top-dressing is of from twelve to sixteen bushels on the acre, so as to add to the richness of the land or soil, already in a tolerable state of condition. It cannot be made use of for any crop better than for that of wheat. By having machinery for breaking and reducing it into a dusty state, the farmer is said to have the advantage not only of buying it in at any time of the year when it is the most reasonable, (for as the two seasons of using it come on, it often increases in price, and is again cheaper when they are past,) but of readily preparing it and keeping it free from any admixture of other matters. It is said that this substance is not now so good as formerly, as the manufacturers of oil from the seed of rape contrive to press it twice at present, whereas they formerly never pressed it more than once; and that, besides, they then only used horses, where they now use water, wind, and steam.

The two principal seasons for making use of these sorts of dusts as top-dressings, are in the very early spring, and in the early part of the autumn, when the weather is rather moist.

Top-dressings of the malt-dust kind, which chiefly consist of the infant sprouts of the grain, and probably contain saccharine matter, from the powerful nature of their effects

in some cases, should, as in the other dust-top-dressings, be made use of in as dry a condition as possible, and without undergoing any degree of fermentation. It is used in the first of the above counties for wheat, in nearly the same quantities as other such matters, in some places, at the rate of twelve shillings the quarter; and it works much the best, it is said, on lands that are inclined to be rather wet. See GRASS-Land, GYPSUM, SALT, &c.

Top-dressings of these kinds are often well suited to and admirably beneficial for recovering and restoring backward and stunted crops of different sorts, but particularly those of the grain and grass kinds.

Top-Folding, a term applied to the practice of feeding down some sorts of spring corn-crops with sheep, as those of the wheat, and occasionally the barley kinds, when too rank or luxuriant. It is a method of practice which is much in use in some parts of Hertfordshire, and which is said there to be very beneficial in its effects; it should, however, be employed with caution in most cases, and constantly in the early stages of growth of the grain, as in the more advanced ones it must always be hazardous, and often hurtful and destructive of such crops. The feeding down in these cases must, of course, be nicely regulated, so as never to suffer the crops to be too much or too little eaten by the sheep, as in either extreme the consequences will be injurious to them.

Top-Up, a term used to signify the making up or topping the roofs of hay or corn-stacks or ricks. It is likewise sometimes made use of, in feeding and fattening bullocks, to imply full feeding, or to finish highly, as with cake, oats, &c.

Top-Wood, in Rural Economy, the boughs or branches which form the tops of timber, or other trees, or the wood which they contain. See TIMBER and TREES.

TOPAN, in Ornithology, a name by which some have called the horned-beaked Indian raven, more usually known by the name of the rhinoceros-avis.

TOPARCHY, formed from *τοπος*, place, and *αρχη*, government, a little state, or signory; consisting only of a few cities, or towns; or a petty country, governed and possessed by a toparch, or lord.

Judæa was anciently divided into ten toparchies. See Pliny, lib. v. cap. 14. and Joseph. lib. iii. cap. 2. de Bel. Jud. & lib. v. &c.

Procopius only gives the quality of toparchy to the kingdom of Edeffa; to Abgarus, the toparch or lord of which, there is a tradition, that Jesus Christ sent his picture, with a letter.

TOPAYOS, in Geography, a river of Brasil, which runs into the river Amazon, with a fort at its mouth of the same name. S. lat. 2° 30'. W. long. 57° 6'.

TOPAYOS, a savage tribe in Brazil, the chief and most numerous of the kind. They are anthropophagi; and if a woman miscarry, will greedily devour the fœtus. Strangers to cultivation, they live upon fruits, and the animals they kill. The Topayan language is very widely diffused, and is divided into several dialects. Their nakedness, ferocity, vindictive spirit, war cries, and whole mode of existence, have been particularly described by Lery.

TOPAZ, in Mineralogy, a gem so called from Topazos, a small island in the Red sea, where the Romans formerly obtained a stone called by them the topaz, but which is the chrysolite of the moderns. The topaz is said to have been first found by Juba, king of Mauritania; but it was known to the Hebrews before, as appears from the 118th Psalm. The most valued topazes are those of Saxony, Siberia, and Brazil.

The principal colour of the topaz inclines to yellow, called by professor Jameson wine-yellow. The pale wine-yellow passes from various shades of yellowish and greenish-white to green. The dark wine-yellow passes from orange to cherry-red and even to blue, but the latter colour is very rare. The topaz sometimes occurs massive and in rolled pieces, but more frequently crystallized. The crystals are seldom very large. The primitive form of the crystal, according to Haiiy, is a rectangular octahedron. The common forms of the secondary crystals are varieties of the oblique four-sided prism, terminated by four planes. The sides of the prism are longitudinally streaked, but the terminating planes are smooth. When the edges of the crystals are truncated, the truncated planes are also smooth. The Brasilian and Siberian topazes are more deeply streaked than the Saxon. The external lustre of the topaz is splendid, the internal vitreous. The longitudinal fracture is small, and imperfectly conchoidal; the cross fracture is straight, and exhibits a lamellar structure. The topaz is translucent or transparent, and refracts double: it scratches glass, but is scratched by spinel: it is easily frangible. The specific gravity varies from 3.464 to 3.641.

The Saxon topaz becomes colourless by a gentle heat, and in this state is sometimes sold for the diamond. A strong heat deprives it of its lustre and transparency. The Brasilian topaz, by exposure to a strong heat, becomes red; and in a still higher temperature, violet-blue; it is then sometimes sold for the ruby, or for pale spinel. The topaz is infusible by the blowpipe, but melts with the addition of borax. The topazes of Brazil, Siberia, and Asia Minor, become electrical by heating. The constituent parts of this gem appear to vary considerably in different specimens.

	Saxon.	Brasilian.
Silex	35	29
Alumine	59	50
Fluoric acid	5	19

The topaz is found in various parts of Europe and Asia, and in South America. It occurs in large quantities in a rock denominated by Werner the topaz rock, which is an aggregate of massive topaz, quartz, and schorl, in which there are frequently small cavities lined with crystals of these three substances, and portions of lithomarge. This rock is situated at Schneckenstein, in Saxony.

It occurs also in veins of quartz at St. Michael's mount, in Cornwall, and with tin-stone at St. Anne's, in the same county. The topaz has recently been found, in large crystals and rolled pieces, in alluvial soil in the primitive country of the upper part of Aberdeenshire; indeed it is stated, in the first volume of the Wernerian Memoirs, that a specimen of topaz, weighing one pound three ounces eight drachms troy weight, has been obtained from that part of Scotland. The largest specimen of Brasilian topaz in the museum of natural history at Paris, weighs four ounces two gros. In this museum there is also a superb Indian Bacchus engraved on topaz. Tavernier mentions a topaz, in the possession of the great Mogul, weighing one hundred and fifty-seven carats, which cost 20,300l. sterling: and Boetius de Boot, in his treatise of precious stones, affirms to have seen in the cabinet of the emperor Rudolphus, whose physician he was, a topaz above three feet long, and six inches broad. Probably, it might be some other stone a little transparent, of a topaz colour. This gem was much prized by the ancients. Yellow-coloured rock-crystal has not been unfrequently imposed on the ignorant for topaz.

The oriental topazes, which have a deep rich orange-colour, are highly valued at present. The Brasilian topaz

has not so rich and fine a colour as the former. The Saxon topaz is distinguished by its wine-yellow colour, and when cut, often exhibits a lustre equal to that of the finest oriental varieties. The mountain-green varieties of topaz, which are found in Siberia, are included under the name of aqua marine. The Brazilian ruby and sapphire include the red and blue Brazilian topaz.

The topaz may generally be distinguished from all other minerals by the rhomboidal base of its crystals, the fracture, and cross lamellar structure, and by the longitudinal streaks on its side planes. It is less hard and heavy than yellow sapphire, and the latter does not become electric by heating. The same characters distinguish it from spinel: it is further distinguished from spinel by its double refraction. Green-coloured topaz is distinguished from beryl by its greater specific gravity, that of topaz being 3.5, and of beryl only 2.7. The latter cleaves in the direction of its lateral planes, which the topaz does not.

The following minerals have been denominated topazes, when colour was considered as affording the most certain character of precious stones.

- | | | |
|---------------------------------------|----------------|----------------------------------|
| 1. Yellowish-white sapphire | } mistaken for | Oriental topaz. |
| 2. Zircon | | Hyaline and yellowish-red topaz. |
| 3. Chrysolite | | Yellowish-green topaz. |
| 4. Yellowish beryl | | Siberian topaz. |
| 5. Yellow rock-crystal | | Bohemian or Occidental topaz. |
| 6. Clove-brown and brown rock-crystal | | Smoke topaz. |

Names given to varieties of the topaz.

- | | | |
|---------------------------------------|----------|---------------------------|
| 1. Mountain green topaz | } called | Aqua marine. |
| 2. Blue topaz | | Sapphire. |
| 3. Yellow topaz | | Chrysolite. |
| 4. Wine-yellow inclining to red topaz | | Rubicelle. |
| 5. Red topaz | | Brazilian or Balais ruby. |
| 6. Yellowish-green topaz | | Saxon chrysolite. |

See SAPPHIRE, RUBY, and GEMS.

A peculiar property of the topaz was discovered by Vauquelin, that the powder of this gem changes the syrup of violets to green if it remain in the liquor two or three hours, and this property is common to all the varieties of the topaz.

Mr. Canton, in 1760, found that the Brazil topaz has the electrical properties of the tourmalin.

The topaz is easily counterfeited; and there are factitious ones, which, to the eye, are not inferior to the natural ones.

To counterfeit the topaz in glass, see GLASS resembling Topaz.

To counterfeit the oriental topaz in paste: Take crystal prepared, two ounces; ordinary minium, or red lead, seven ounces: put these into a crucible luted, and bake them twenty-four hours in a potter's kiln. If the mass is not sufficiently clear and fine, cover it up again, and give a second baking, and it will come out of a fine topaz colour. See PASTE.

If we might believe the ancients, the topaz has very notable virtues; but those are now in discredit. See GEM.

TOPAZOS, or TOPAZIUS, in *Ancient Geography*, an island placed by Pliny in the Red sea, 300 stadia from the continent.

TOPDALS, in *Geography*, a town of Norway, in the province of Christiansand; 32 miles N. of Christianand.

TOPE, in *Ichthyology*, an English name for a species of the squalus, according to the Ardeian system, the *squalus galeus* of Linnæus, distinguished from the other squali by the nostrils being placed extremely near the mouth, and by certain foramina, or apertures, near the eyes. It is the fish called by the ancients γαλιος κορυς, *galeus canis* and *caniculata*. See SQUALUS.

TOPEL, or TAPL, in *Geography*, a town of Bohemia, in the circle of Pilsen; 56 miles W. of Prague. N. lat. 49° 58'. E. long. 12° 57'.—Also, a river of Bohemia, which runs into the Egra, near Carlsbad.

TOPERS HAT, a small island in a bay on the N. coast of New Guinea. S. lat. 3° 5'. E. long. 135° 33'.

TOPETINA, a town of Mexico, in the province of Mechoacan, at the mouth of a river near the Pacific ocean; 50 miles N.W. of Zacatula. N. lat. 18° 56'. W. long. 103° 44'.

TOPETRY, a town of Hindoostan, in the Carnatic; 50 miles S.E. of Tanjore.

TOPHATH, in *Ancient Geography*, a place in the Land of Paradise, near the Dead sea. Jothah destroyed this place on the abolition of idolatry.

TOPHUS, a kind of node, or swelling of the periosteum. Also, the sort of concretion found in the joints of gouty persons.

TOPHUS, in *Natural History*, is a species of sand-stone, called also *porus*, mostly of a grey colour; but it is also found of other colours, as whitish, brownish, &c. according to the soil in which it is imbedded. It much resembles the pumice in texture, being rough and brittle, and composed of a large angular grit, cemented by a very coarse terrene crystalline substance. It is too soft to strike fire with steel. It is common in Italy and in Germany, where it is used for building, chiefly for cellars and turning arches. Da Costa's Hist. Fossils, p. 136.

TOPI, in *Geography*, a small island in the Mediterranean, near the N. coast of the island of Elba. N. lat. 42° 51'. E. long. 11° 30'.

TOPIA, a town of Mexico, in the province of Culiacan; 80 miles N. of Culiacan. N. lat. 25° 44'. W. long. 108°.

TOPIA, the chief chain of mountains in Spanish North America, commencing in the neighbourhood of Guadalaxara, and extending north to New Mexico, a distance of 150 leagues, or, according to our maps, more than 700 British miles; while the breadth of all the ridges is, according to Alcedo, sometimes 40 leagues, or 160 miles. This chain is of such a height as to be comparable with the Andes of Peru, and abounds with precipices of the most profound and terrible aspect. It is almost universally densely clothed with large and lofty pines, and other trees which afford sustenance to birds of very variegated and beautiful appearance. On the summit the cold is intense, but the temperature on the sides varies according to climate and exposure. It is the source of many rivers flowing into the Atlantic and Pacific, and subject, on the melting of the snow, to very considerable inundations. During the rains, which last from June to September, the rivers become terrible in their devastations to the distance of two or three leagues, and the mosquitoes become intolerable. Among the animals in these regions, are bears, lions, and tigers, as well as squirrels of various kinds. This chain is prolific in silver, yielding about a mark for each quintal of earth. It received its name from a savage tribe, which was converted by the Jesuits in 1590; but the mines, on account of their distance from the capital, have been mostly abandoned. The ridge of Topia is also called the "Sierra Madre," or mother-chain, and embraces the singular province of Nayarit, which remained

remained Pagan till the year 1718. Towards the N. the extent of this chain has not been precisely ascertained; but the Moquis, on the W. of Santa Fé, and under the same parallel, are positively classed among its inhabitants; and it probably forms one chain with that of Nabajo, and the Sierra Azul, or Blue Ridge, of Alzete, and the stony mountains of North-west America, sending off a branch called Gemes on the W. of New Mexico, while on the E. of that province is the inferior ridge of Namli. In the vicereignty, the general distance of the Topian chain from the western shore is about 140 British miles, but in some parts not above half that space. Pinkerton.

TOPIARIA, in *Botany*, a name by which some authors have called the acanthus, or bear's-breech, a plant common in the gardens of the curious.

TOPIC, in *Rhetoric*, a probable argument, drawn from the several circumstances and places of a fact, &c. See ARGUMENT and LOCUS.

TOPICE, *τοπικα*, *Topica*, expresses the art or manner of inventing and managing all kinds of probable argumentations.

The word is formed from the Greek, *τοπικος*; of *τοπος*; place, its subject being the places, which Aristotle calls the *seats* of arguments.

Aristotle has written "Topics;" and Cicero a kind of comment on them, to his friend Trebatius, who, it seems, did not understand them. But the critics observe, that the "Topica" of Cicero agree so little with those eight books of Topics which pass under the name of Aristotle, that it follows necessarily, either that Cicero was much mistaken, which is not very probable; or that the books of Topics, now attributed to Aristotle, are not wholly his.

Cicero defines *topica*, or *topice*, to be the art of finding arguments, "disciplina inveniendorum argumentorum."

Rhetoric is sometimes divided into two parts; judgment, called also *dialektice*; and invention, called *topice*.

TOPICS, formed from *τοπος*, place, or *topical remedies*, in *Medicine*, are commonly used for what we otherwise call *external remedies*, i. e. such as are applied outwardly to some particular diseased and painful part.

Such are plasters, cataplasms, blisters, unguents, felves, collyriums, &c.

Topics are such medicines, as by the smallness and mobility of their particles, attended for the most part with gentle acrimony, are able to make their way into the substance of the parts to which they are applied, without eroding or wounding any of the solids; and thence are justly called *penetrating topics*.

It may be a question how topics in medicine act. It is commonly said, that this or that medicine penetrates the pores; but the ideas annexed to such expressions do not seem very distinct. Writers on this subject have seldom been at the pains to tell us what pores they mean. We have an essay on this subject in the Med. Ess. Edinb. vol. ii. art. 4. by Dr. Armstrong, who thinks that the effects of such medicines are not owing to the particles entering the orifices of the absorbent veins; nor to the opening of the exhalent vessels on the surface of the body by these medicines; nor will he allow the particles of penetrating topics to force their way through the coats of the vessels; but he supposes that subtle medicines are conveyed, by the exhalent vessels of the skin, to those parts of the smaller arteries, where the circulation is choked by obstruction.

The gout is never cured by topics; they may assuage the pain for a time; but for a cure, the source of the evil must be attacked with internals.

TOPINAM BARANAS, in *Geography*, a town of Brazil,

in the government of Para, on the river of the *Amazons*; 80 miles S.W. of Pauxis. S. lat. 2° 42'.

TOPINAMBOS, a considerable tribe of anthropophagi in Brazil.

TOPINO, a river of Italy, which runs into the Tiber, 5 miles S. of Perugia.

TOPIRIA, in *Ancient Geography*, a town situated in the interior of Thrace. Pliny and Ptolemy.

TOPLITZ, in *Geography*, a town of Bohemia, in the circle of Leitmeritz, near which the Austrians defeated the Prussians in the year 1762; 14 miles W.N.W. of Leitmeritz. N. lat. 50° 37'. E. long. 13° 51'.

TOPLIWODA, a town of Silesia, in the principality of Munsterberg; 7 miles N.W. of Munsterberg.

TOPLOCZA, a town of Hungary; 14 miles S.E. of St. Crot.

TOPLUC, a town of Hungary; 20 miles S.S.W. of Podolicz.

TOPOBEA, in *Botany*, Aubl. Guian. 476. t. 189. Juss. 329, is probably not generically distinct from MELASTOMA; see that article, and the natural order of MELASTOMÆ.

TOPODURTY, in *Geography*, a town of Hindoostan, in Myfore; 24 miles W. of Tadameri.

TOPOGRAPHY, formed from *τοπος*, place, and *γραφω*, I describe, a description or draught of some particular place, or small tract of land; as that of a city or town, manor or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

Topography differs from *chorography*, as a particular from a more general.

TOPOLEVA, in *Geography*, a fortress of Russia, in the government of Caucasus, on the Ural; 40 miles N. of Guriev.

TOPOLITZA, a town of European Turkey, in Moldavia; 12 miles S.W. of Niemeecz.

TOPOLTZAN, a town of Hungary; 52 miles N.E. of Presburg. N. lat. 48° 34'. E. long. 18° 25'.

TOPOLTZAN, (*Kis*,) a town and castle of Hungary; 12 miles N.W. of Bukans.

TOPOROW, a town of Austrian Poland, in Galicia; 35 miles N.E. of Lemberg.

TOPPARPOUR, a town of Hindoostan, in Oude; 25 miles E. of Bahraitch.

TOPPING of *Trees*, in *Rural Economy*, the practice of cutting or lopping off the heads of them, especially of the different sorts of hedge-row trees, which, in this last case, is a disgusting and disgraceful custom, now on the decline. See POLLARD *Trees*.

Where, however, this sort of work is to be performed, it should, in all cases, be executed in the autumn, or very early in the spring months.

In topping fallen trees, the different parts should be cut out and put together into separate lots, as the large arms into one, the smaller branches into another, and the small brush, or faggot-wood, into a third. Thus the whole may be readily disposed of, or converted to its proper use.

TOPPING the *Lifts*, aboard a *Ship*, the same as hauling the top-sail-lifts, by slackening one of them, and pulling upon the opposite one, so as to place the yard at a greater or less obliquity with the masts. See LIFTS.

TOPPING-*List*, a large and strong tackle, employed to suspend or top the outer end of a gaff, or of the boom of a main-sail and fore-sail; such as are used in brigs, sloops, or schooners. Falconer.

TOPRAK-KALA, in *Geography*, a town of Turkish Armenia; 6 miles S. of Kars.

TOPRAK-KALAH, a town of Asiatic Turkey, in the province of Diarbekir; 60 miles S. of Mosul.

TOPSAIL INLET, a channel between two small islands on the coast of North Carolina. N. lat. $34^{\circ} 18'$. W. long. $77^{\circ} 48'$.

TOPSFIELD, a township of Massachusetts, in the county of Essex, containing 815 inhabitants; 24 miles N.E. of Boston.

TOPSHAM, a market-town in the hundred of Wonford, and county of Devon, England; is situated at the confluence of the rivers Clyft and Exe, 3 miles S.E. from Exeter, and 170 miles W.S.W. from London. Leland, speaking of this town, says, "Here is the great trade and rode for shippes that usith this haven, and especially for the shippes and merchant-mannes goodes of Excester. Men of Excester contende to make the haven cum up to Excester self: at this time shippes cum not further up but to Apsam." The manor was the property of the Courtenays, earls of Exeter, one of whom procured for the town the privilege of a market, and an annual fair, which are still held; the market-day being Saturday. The town consists principally of one long street, of irregular breadth, chiefly extending north and south along the eastern bank of the Exe. Many of the houses are handsome, but the greatest number have but a mean appearance. The southern extremity, called the Strand, is the most pleasant, the river flowing within a short distance of the houses, and is chiefly inhabited by persons of fortune: the view from it is extensive and beautiful. The quay is spacious and convenient, and now belongs to the chamber of Exeter, who purchased it about the year 1778. Most of the inhabitants are employed in the shipping business; the total number, as returned under the act of the year 1811, was 2871; the number of houses was 620. The church stands near the centre of the town, on a high cliff, which affords an extensive view of a noble river, distant shipping, churches glimmering through groups of trees, a fertile vale, and a fine range of mountains, rising above each other in beautiful perspective, as far as the eye can reach.

In the vicinity of Topsham is Nutwell, the seat of lord Heathfield, nephew and successor to sir Francis Drake. According to Rifdon, the manor-house was a castle, till lord Dinham, about the time of Edward IV., converted it into a stately dwelling-house. Sir Francis Drake made many alterations; and it has been nearly rebuilt by the present possessor on a more ample scale, and at a very great expence.—*Beauties of England and Wales*, vol. iv. Devonshire, by J. Britton and E. W. Brayley, 1803. *Polwhele's History*, &c. of Devonshire, fol. 1797.

TOPSHAM, a township of the province of Maine, in the county of Lincoln, containing 1271 inhabitants; 156 miles N.E. of Boston.—Also, a town of Vermont, in the county of Orange, containing 814 inhabitants.

TOR, a sea-port of Arabia, on the coast of the Red sea, formerly a place of consequence, and strong, but at present in a ruinous state and without a garrison. Near it is a ruined castle, inhabited by the Arabs; the Greeks call this place "Raitho," which might have its name from being inhabited by some of those people called by Ptolemy "Raitheni," towards the mountains of Arabia Felix; it is inhabited by Arabs, and about twenty families of the Greek church. The monks of mount Sinai have a convent here, to which they have sometimes retired when they could not conveniently stay at mount Sinai; only one priest resides in it for the service of the church. About a league north of Tor is a well of very good water, and about it are a great number

of date-trees, and several springs of salt-water, especially to the south-east, where the monks have their garden. Near it are several springs, and a bath or two, which are called "the Baths of Moses;" the Greeks as well as some others are of opinion that this is Elim. The greatest curiosities of Tor are the productions of the Red sea; the shell-fish of it are different from those of the seas to the north of it; but what are most peculiar to it, are the several stone vegetables, the madreporæ, a sort of coral; the fungi, or mushrooms; and the red pipe coral. In 1540, Tor was taken by the Portuguese. N. lat. $28^{\circ} 10'$. E. long. $33^{\circ} 37'$.

TOR, a town of Africa, in the country of the Foulahs. N. lat. $16^{\circ} 30'$.

TOR *Alba*, a town of the island of Sardinia; 20 miles E.N.E. of Algeri.—Also, a town of the island of Sardinia; 13 miles S. of Oristagni.

TOR *di Cane*, a town of Naples, in the province of Bari; 9 miles S.E. of Monopoli.

TOR *Point*, or *Hope's Nose*, a cape of England, on the coast of Devonshire, forming the north point of Torbay.

TORA, a town of Egypt, on the Nile; 8 miles S. of Cairo.—Also, a town of Naples; 9 miles N.N.E. of Sezza.

TORACA, or BUTUA, a province of Africa, in the empire of Mocaranga.

TORADOR. See *BULL-Fighting*.

TORAITO, in *Geography*, a town of Thibet; 30 miles N.E. of Tchontori.

TORAL, EL, a sea-port of Chili. S. lat. $27^{\circ} 55'$.

TORALIBA, in *Ancient Geography*, an island of the Indian sea, near the mouth of the river Indus, and 9 miles from the island of Bybaga. Pliny.

TORAR, in *Geography*, a town of Hindoostan, in the circar of Surgooja; 30 miles E.S.E. of Surgooja.

TORBAY, is a commodious bay or sea-road, five miles from Dartmouth, on the coast of Devonshire, England. It is formed by two capes, that on the east called Bob's-Nose, that on the west, Berry-Head. Its general shape is semilunar, inclosing a circumference of about twelve miles. The winding shores on both sides are screened with great ramparts of rock; between which, in the central part, the ground from the country, forming a gentle vale, falls easily to the water's edge. Wood grows all round the bay, even on its rocky sides, where it can get footing and shelter; but in the central part with great luxuriance. This noble bay has often afforded protection to the fleets of England, which, in their full array, ride safely within its ample bosom. The prince of Orange, afterwards king William III., landed here on the 5th of November, 1688, to effect the ever memorable revolution. Near this bay is a remarkable place called Kent's-Hole, consisting of many caverns entered by subterraneous passages, but having only one external entrance.

Tor Abbey, the seat of George Cary, esq. is finely situated amidst some ancient and noble trees, and commands an interesting prospect of Torbay, and the rocky tors in the vicinity. The house is mostly modern; though some parts of the old abbey are still preserved. It consists of a centre and two wings; one of which is connected with a castellated gateway, having octagonal towers and battlements. Beyond this gateway is a large barn, which formerly belonged to the Abbey. It is overspread with a venerable mantle of ivy, and decorated with loop-holes, and numerous buttresses. The ancient religious house of this place was erected by William, lord Briwire, or Bruer, in the time of king John, and endowed by him with considerable revenues, which were afterwards much augmented by his son. It was appropriated for canons of the Premonstratensian order. After the Bruers, Tor

Abbey

Abbey came into the Mohun family, who were succeeded by the Ridgeways, and these by the Carys, who now enjoy it. At the dissolution, the revenues amounted to 396*l.* 11*s.*—Gilpin's Observations on the Western Counties, 8vo. Beauties of England and Wales, vol. iv. Devonshire, by J. Britton and E. W. Brayley, 1803.

TORBAY, a bay of the North Atlantic, on the east coast of Newfoundland. N. lat. 47° 48'. W. long. 52° 20'.—Also, a town and bay on the fourth coast of Nova Scotia. N. lat. 45° 8'. W. long. 61° 15'.

TORBEEK, a town on the fourth coast of Hispaniola; 9 miles N.W. of Vache island.

TORBIA, a town of France, in the department of the Maritime Alps, called by the Romans *Trophæa Augusti*, with an ancient Gothic tower. In the environs are found many remains of monuments erected by the Romans, trophies and fragments of a statue of Augustus; 7 miles E. of Nice.

TORBIDO, FRANCESCO, called *Il Moro*, in *Biography*, was born, about the year 1500, at Verona, and perhaps rather before it, as he is said to have had, for a short time, the advantage of receiving instruction from Giorgione. He afterwards became the pupil of Liberale, and his own style is a compound of those of his masters, partaking of the glow of the former, with the elaborate finish of the latter. His principal occupation was in portrait, yet he left several historical pictures of considerable merit. Amongst them are some frescoes, representing the life of the Virgin, in the cathedral at Verona; and a picture in oil of the Transfiguration, in the church of S. Maria Maggiore, at Venice. He died at the age of 81, but the exact date is unknown.

TORBIDO, in *Geography*, a river of Naples, which runs into the Crate, near Bisignano.

TORBISCON, a town of Spain, in the province of Grenada; 14 miles N.E. of Motril.

TORBOLE, a town of the Tyrol, on the north-east coast of lake Garda. In 1796, this town was taken by the French; 17 miles N. of Garda.

TORBUS. See TUBURBO.

TORC, a mountain of Ireland, in the county of Kerry, on the fourth side of Lough Lane, whence the southern part is called Lough Torc.

TORCELLO, a small island in the gulf of Venice, with a town of the same name, the see of a bishop, suffragan of Venice. The town of Torcello is in a flourishing state, which it owes to the inhabitants of Altino, who were driven out of that place by Attila, and fled hither; it has also been the see of the bishop of Altino, in consequence of the bishop Paolo having emigrated to the first-mentioned place. His successor, Mauro, or Maurizio, obtained from pope Severino the confirmation of his new see, and built here several churches, together with the elegant nunnery S. Giovanni di Torcello. More churches were built by his successor Giuliano; and Diadato, the fourth bishop, erected finally, in the year 697, the principal church of Santa Maria; which was rebuilt from the ground, in the eleventh century, by the bishop Orfo; 3 miles N. of Venice.

TORCH, TĀDA, a sort of luminary, properly a stick of fir, or other resinous and combustible matter, as pine, linden, &c. more or less thick, and long; encompassed at one end with six wax candles, which being lighted, yield a kind of gloomy brightness.

Torches are used in some church ceremonies, particularly at the processions of the holy sacrament in the Romish church, and at the interments of the poorer people.

Formerly they were used at the funerals of those of the first rank; but tapers and flambeaux are now introduced in their stead; and frequently also called by their name.

TORCH-*Thistle*, in *Botany*. See CEREUS.

TORCHENES, in the *Manege*, a long stick with a hole at the end of it, through which a strap of leather is run, the two ends of which being tied together, serve to straighten and closely tie up a horse's nose as long as the stick is stayed upon the halter or snaffle. This is done to keep the horse from being unruly when he is dressed, or upon any other occasion.

TORCHIARA ROCCA, in *Geography*, a town of the duchy of Parma; 5 miles S. of Parma.

TORCHILLI, JONAS, in *Biography*, the descendant of a respectable family in Iceland, was born in the district of Guldbringe in 1697, and sent in 1718 to the university of Copenhagen, from whence he proceeded to Holstein, completing his studies at the university of Kiel. In 1728 he returned to Iceland, and became rector of the school of Skalholt, which he resigned in 1736, quitting his country on account of some troubles which ensued from his speaking his sentiments too freely. At Copenhagen, whither he withdrew, he made some unfavourable reports of the clergy in Iceland, and was sent thither as secretary to Harboe, afterwards bishop of Zealand, who was deputed to examine the state of the Icelandic church. Having finished this business, Torchilli retired to Copenhagen, and died there in 1759. His works, besides some others, are, "The Augsborg Confession, translated into Icelandic," 1742, 12mo.; "Biblia Islandica ab eo Mendis Typographicis purgata," Havn. 1746; "An Appendix to Anderfon's Account of Iceland, in Danish," 1748, 8vo.; "Chryforis, five Descriptio Tractus Guldbringentis;" "A Supplement to Runolf Jonæ's Icelandic Grammar;" "Versio Latina Odæ Havamal Carmine Sapphice expressa;" "Lexicon Islandico-Latinum." Tiraboschi. Gen. Biog.

TORCOLA, in *Geography*, a small island in the Adriatic. N. lat. 43° 27'. E. long. 16° 54'.

TORCULAR, a bandage, or instrument, used to check hæmorrhage. See TOURNIQUET.

TORCULAR *Herophili*, in *Anatomy*, a name given to one of the sinuses of the brain. See VEIN.

TORCY le Grand, in *Geography*, a town of France, in the department of the Lower Seine; 3 miles S. of Arques.

TORDA, or TORENBURG, a town of Transylvania, famous for its salt-works. The Hungarian language is said to be spoken with the greatest purity in this town; 15 miles W.N.W. of Clausenburg. N. lat. 46° 42'. E. long. 23° 24'.

TORDEHUMOS, a town of Spain, in the province of Leon; 5 miles W.S.W. of Rio Seco.

TORDERA, a river of Spain, in Catalonia, which runs into the sea, near Blanes.

TORDESILLAS, a town of Spain, in the province of Leon, on the Duero; 13 miles S.W. of Valladolid.

TORDINO, a river of Naples, which crosses Abruzzo Ultra, passes by Teramo, and runs into the Adriatic, N. lat. 42° 40'. E. long. 14°.

TORDINO, in *Ornithology*, a name by which the Venetians call a bird of the lark kind, common in their markets, and called by authors *spinoletta*.

TORDO MARINO, the name of a bird of the starling kind, called also the *coliroffo maggiore*, or *ruticilla major*, and by the Austrians the *stein-reilling*. Aldrovandus has named it the *merula saxatilis*, or *rock-blackbird*. It is of the size of our starling, and much resembles it in figure; its breast is greyish, and has a black transverse streak, and behind that the whole is of a yellowish hue; its head and back are of a blackish hue, with some slight variegations of grey, from the tip

tip of the feathers being of that colour: the tail is long and of a reddish-orange colour, and the under-feathers of the wings are of the same hue; the females are of a less elegant colour than the males, viz. a mouse-colour, variegated with white on the back, and ash-colour on the belly: what is yellow in the male birds, is also very pale in the females: it is not uncommon in Germany, and may be taught, like the starling, to imitate the human voice. Ray.

TORDYLIUM, in *Botany*, τὸρδύλιον of the Greeks, probably the very plant of Dioscorides, is supposed by Linnæus to owe its name to the neat orbicular figure of its seeds, which seem as if artificially wrought, or *turned*. The same idea is hinted by Bodæus a Stapel, in his edition of Theophrastus, 1125; but Linnæus appears to have been more particularly led by Ambrosinus, to resolve the word into τρεῖς, a turning lathe, and ἄλλω, to turn. The latter seems superfluous. De Theis is dissatisfied with this etymology. We can only say, in its support, that those philologists who have not traced the word to its origin, nevertheless consider it as applying particularly to the *seed* of the plant.—Linn. Gen. 130. Schreb. 181. Willd. Sp. Pl. v. 1. 1381. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 294. Prodr. Fl. Græc. Sibth. v. 1. 180. Ait. Hort. Kew. v. 2. 124. Spreng. Prodr. Umbellif. 11. Jusf. 224. Tourn. t. 170. Lamarck Illustr. t. 193. Gærtn. t. 21.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellifera*.

Gen. Ch. *General Umbel* of many unequal rays; *partial* of many unequal very short ones, flat. *General involucrem* of several slender undivided leaves, mostly as long as the umbel; *partial* unequal, exceeding the partial umbel in length at its outside. *Perianth* of five teeth. *Cor.* *Universal* irregular, radiant; all the florets fertile; *partial of the disc* with five equal petals, whose inflexed points render them heart-shaped; *of the radius* similar, but its outermost petals are very large, and deeply divided. *Stam.* in all the florets, Filaments five, capillary; anthers simple, roundish. *Pistl.* in all the florets, Germen roundish, inferior; styles two, small, erect; stigmas obtuse. *Peric.* Fruit nearly orbicular, compressed, crenate at the edge, separable into two parts. *Seeds* two, nearly orbicular, almost flat, with a thickened, finely crenate, margin.

Eff. Ch. *Involucrem* long and undivided. *Corolla* radiant. Flowers all perfect. Fruit nearly orbicular, compressed almost flat, with a crenate margin.

Obs. Linnæus points out the presence of efficient stamens and pistils in all the florets as the most important difference between this genus and CAUCALIS, see that article. But the seeds of the latter being ovate, striated, and beset with rigid bristles, afford, as he afterwards justly thought, a more constant and satisfactory character.

1. *T. syriacum*. Syrian Hart-wort. Linn. Sp. Pl. 345. Willd. n. 1. Ait. n. 1. Jacq. Hort. Vind. v. 1. 21. t. 54. Rivin. Pentap. Irr. t. 3. (*T. minus syriacum, feminis limbo granulato*; Morif. sect. 9. t. 16. f. 7. *Gingidium latifolium*; Ger. Em. 1042.)—*Partial involucrem* many times longer than the nearly sessile flowers.—Native of Syria and Caria. A hardy annual in our botanic gardens, flowering in July. The whole herb is hoary with short close hairs, which render it soft to the touch. *Stem* twelve or eighteen inches high, angular, leafy, somewhat branched, zigzag, spreading. *Leaves* stalked, pinnate, of three or five broad, obtuse, rounded, notched leaflets; the odd one largest, slightly three-lobed, an inch and half long. *Umbels* lateral and terminal, on long, spreading, furrowed stalks. *Flowers* white, few and small; but the leaves of the *partial involucrem* are remarkable for being about an inch in length, obovato-lanceolate, leafy, exceeding those of the

general one in size. The *seeds* are bristly and viscid, with a crisped margin.

2. *T. officinale*. Official Hart-wort. Linn. Sp. Pl. 345. Willd. n. 2. Fl. Brit. n. 1. Engl. Bot. t. 2440. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 267, unpublished. (*Seseli creticum minus*; Bauh. Pin. 161. Ger. Em. 1050. *Caucalis minor, pulchro femine, five Bellonii*; Bauh. Hist. v. 3. p. 2. 84. *Small Hartwort*; Petiv. Herb. Brit. t. 24. f. 6.)—*Partial involucrem* full as long as the flowers. Leaflets ovate, cut, crenate. Radiant petals two together, unequally lobed.—Native of the south of France, Italy, Sicily, and the Levant. Dr. Sibthorp found this plant in various parts of Greece and the neighbouring islands. He judged it, with great probability, to be the identical τὸρδύλιον of Dioscorides. As a British plant it rests on the authority of Doody, who gathered specimens about Isleworth, and communicated them to Ray. The latter could not mistake the species, but he hints, in his *Synopsis*, ed. 2. 102, that the seeds probably escaped from some garden. This is an annual, more erect than the foregoing, but, like that, downy, not bristly. The leaflets are ovate, sometimes rather oblong, sometimes roundish-heart-shaped, from three to nine; stalked and lobed in the larger more luxuriant leaves, but generally unequally crenate only: the upper ones are lanceolate or oblong. *Flowers* large, white or pale flesh-coloured, numerous; the two outer petals, especially of the marginal flowers, remarkably radiant, one lobe of each being disproportionately large. *General and partial involucrem* of narrow awl-shaped leaves, the latter smallest. *Seeds* smooth, with an elegant, broad, thick crenate border. This plant was formerly cultivated for the sake of its seeds, supposed to promote urine and other excretions, but now out of use. The *T. apulum minimum*, Column. Ecphr. 122. t. 124. f. 1, seems to us a starved variety, different, as Jacquin well remarks, in Hort. Vind. v. 3. 2, from the following, though he errs in taking it for the true *apulum*, which is what he originally so called. See the next species.

3. *T. apulum*. Smaller Hart-wort. Linn. Sp. Pl. 345. Willd. n. 4. Ait. n. 4. Prodr. Fl. Græc. n. 631, excluding the synonyms. Rivin. Pentap. Irr. t. 2. Jacq. Hort. Vind. v. 1. 21. t. 53. Spreng. n. 3. (*T. humile*; Desfont. Atlant. v. 1. 235. t. 58.)—*Partial involucrem* shorter than the flowers. Leaflets lacinated; the upper ones narrow. Radiant petals solitary, of two equal lobes.—Native of cultivated fields in Italy, Barbary, and Greece. A smaller plant than the foregoing, annual like that, but with several stems, whose lower part, as well as the sheaths of each *footstalk*, is shaggy, with long white woolly hairs. The leaflets of the lower leaves, about seven, are rounded, variously jagged and notched; those of the upper still more various in figure, narrow, mostly wedge-shaped, often deeply, and very acutely, three-lobed. *Umbels* of usually five rays, sometimes more, four times as long as the *general involucrem*. *Flowers* white, radiant, but not in the manner of the foregoing, they having but one greatly enlarged petal, whose two obovate lobes are nearly equal. The *seeds* have a broader, striated, granulated disk, with a thick, but not so broad, border as in *T. officinale*. The synonyms of Bauhin, *Seseli creticum minimum*, as well as those of Tournefort, Ray and Morison, cited in Sp. Pl. and Hort. Cliff., all depending on Columna's plant mentioned under our last species, are to be transferred to that.

4. *T. sisifolium*. Red Dwarf Hart-wort. Scop. Carn. v. 1. 194. t. 8. Willd. n. 6. Spreng. Prodr. 11.—*General involucrem* of one or two leaves. Leaflets ovate, lobed and notched, nearly uniform. Radiant petals solitary, of two equal lobes. Fruit bristly.—Native of the alps of Carniola.

Carniola. This appears to be nearly related to the last, nor can we discern why professor Sprengel marks it as a doubtful species. We have seen no specimens. The faithful Scopoli describes it as about a foot high, with uniform leaves, composed of two pair of obliquely ovate, or half-heart-shaped, sessile, notched leaflets, and a terminal one, broader, deeply three-lobed. The flowers are red, or pink. Fruit oval, compressed, with a thick bristly border, not described as crenate, whence perhaps the doubts of professor Sprengel.

5. *T. maximum*. Great Hart-wort. Linn. Sp. Pl. 345. Willd. n. 5. Fl. Brit. n. 2. Engl. Bot. t. 1173. Jacq. Austr. t. 142. Scop. Carn. v. 1. 195. Tournef. Inst. 320. (Tordylium; Rivin. Pentap. Irr. t. 1. Sefeli creticum majus; Bauh. Pin. 161. Ger. Em. 1050. *Caucalis major*; Cluf. Hist. v. 2. 201. Ger. Em. 1021, bad. *Heraclium Tordylium*; Spreng. Prodr. 12.)—Umbels dense. Leaflets lanceolate, deeply serrated. Stem rough with deflexed bristles; umbels and fruit with erect ones.—Native of waste ground, banks and hedges, in Italy, Switzerland, Germany, and, though very rarely, England, flowering from June to August. It has long been observed under the hedge on the north side of the parks, at Oxford; and was gathered by Mr. Gotobed near Eton. Dr. Sibthorp met with this plant in Greece and about Constantinople. The root is annual, tapering. Stem three or four feet high, erect, branched, leafy, furrowed, clothed all over with short, rigid, pungent bristles, which point strongly downward; while the rays of the umbels, the involucreal leaves, which are all short and awl-shaped, and the germen, as well as fruit, are equally rough, with erect bristles. The lower leaves consist of about five broad, ovate leaflets, deeply and irregularly notched; the upper of about three elongated narrow ones, strongly serrated; all rough with close-pressed rigid hairs. Flowers small, reddish, with unequal petals, but not strikingly radiant. Calyx-teeth elongated, unequal. Fruit nearly orbicular, bristly, with a thick, pale, rugged border, less crisped than in the first three species, and a slightly tumid ribbed disk. The presence of a general as well as partial involucre, does not agree with Sprengel's character of *Heraclium*, nor do the seeds answer to his description of that genus.

6. *T. peregrinum*. Oriental Hart-wort. Linn. Mant. 55. Willd. n. 3. Ait. n. 3. (*Conium dichotomum*; Desfont. Atlant. v. 1. 246. t. 66. *Caucalis Hispanica*; Camer. Hort. 37. t. 11. *Cachrys peregrina*; Spreng. Prodr. n. 11, and *C. dichotoma*; *ibid.* n. 12.)—Leaves repeatedly compound, smooth, with linear decurrent segments. Fruit elliptical, furrowed, with crisped ribs and margin.—Native of the Levant. Herb annual, smooth, with a branched spreading stem, and very finely divided, thrice compound leaves. General umbels of scarcely more than three or four stout smooth rays; partial small and dense. General involucre of one or two small, ovate, pointed, white-edged leaves; partial of several similar unequal ones. Flowers small, scarcely, if at all, radiant, white, or slightly reddish. Fruit thick, almost sessile, more elliptical and acute than in the rest of the genus, having a thick, crisped edge, and three greatly elevated, less strongly corrugated, ribs at each side. The genus of this plant is certainly very ambiguous. It might perhaps be safely referred to *Conium*, with which its habit more accords, especially as the fruit answers but indifferently to the idea or definition of a *Tordylium*.

T. latifolium, *Autbriscus* and *nodosum* of Linnæus are now generally referred to *Caucalis*. Sprengel however has restored the genus TORILIS of Adanson and Gærtner; see that article, to which the two latter belong.

We shall have occasion to speak of the difficulties frequent

in the generic distribution of this tribe, when we come to the article UMBELLIFERÆ.

TORRE, TORUS, in *Architecture*, a large round moulding, used in the bases of columns.

Daviler derives the word from the Greek, *τορος*, a cable, to which it bears some resemblance; or from the Latin *torus*, a bed, as being supposed to represent the edge of a bed or quilt, swelled out with the weight of the incumbent column.

The tore is also called *gros baton*, and *tordin*. It is the bigness that distinguishes the torus from the astragal.

The bases of Tuscan and Doric columns have but one tore, which is between the plinth and the listel. In the Attic base there are two; the upper, which is the smaller; and an under, or bigger.

TORÉE, in *Geography*, a circar of Bengal, bounded on the north by Palamow, Koonda, and Ramgur; on the east by Ramgur; on the south by Chuta and Nagpour; and on the west by Palamow; about 32 miles long, and 24 broad. Torée is the capital.—Also, a town of Hindoostan, and capital of a circar of the same name, in Bengal; 210 miles W. of Calcutta. N. lat. 22° 37'. E. long. 84° 53'.

TORÉK, a town of Hungary, near the Theyffe; 40 miles S.W. of Debreczin.

TORRELLI, LELIO, in *Biography*, a learned jurist, was born at Fano in 1489. Having studied Greek and Latin at Ferrara, he graduated at Perugia, where he studied law. The last respectable office of magistracy which he occupied, was that of grand chancellor and first secretary to the dukes of Tuscany, Cosmo, and his son Francesco. He was also advanced to the rank of Florentine nobility, and the title of senator, and was consul to the academy of Florence, where he died in 1576, universally esteemed for his mental and moral qualities. He amused himself with polite literature, in which he was a proficient, and with writing Latin and Italian poetry; but the subject of his serious study was jurisprudence. He was the author of several works on the law; but he was principally engaged in preparing a new and correct edition of the Pandects, availing himself of the Pisan or Florentine MS. This magnificent edition appeared from the Torrentian press in 1553, in three large volumes folio. His son Francesco was his associate in the labour of this work; but the son died before the father. Gen. Biog.

TORRELLI, POMPONIO, a poet and man of letters, and count of Montechiarugola, was educated at Padua, where he resided eleven years. Upon his return to his native place he married, and in 1584 was sent on a mission to Spain; and having succeeded in the object of it, he afterwards employed himself chiefly in literary compositions. His works were numerous, among which we may reckon a treatise "De Debito del Cavaliero," 1596; five tragedies, viz. "La Me-rope," "Il Tancredi," "La Galatea," "La Vittoria," and "Il Polidoro." His MSS., which were also numerous, are preserved at Reggio. He died in 1608. Tiraboschi. Gen. Biog.

TORRELLI, GIUSEPPE, a native of Verona, member of the Philharmonic society, and principal violin of San Petronio, at Bologna. In 1701 he was concert-master at the court of Anspach, and his performance on the violin acquired him great reputation. He was a voluminous composer for that instrument. His productions, however, are so superannuated, as almost to cease to be music; for having little original melody, and no uncommon stock of harmony or modulation, there is nothing left to make amends for the want of novelty and elegance. This composer, besides the numerous works which he published for violins during his life,

life, of which the titles are recorded in Walther, left behind him an unedited work, which was published in 1709 by his brother, Felice Torelli, after the author's decease, under the title of "Concerti grossi con una pastorale per il fantissimo natale," consisting of twelve concertos in eight parts. These concertos have been thought the best of his productions, and the model of grand concertos for a numerous band. Quantz, *Arte de la Flute*.

TORELLO, in *Geography*, a town of Naples, in Principato Ultra; 3 miles W.N.W of Conza.—Also, a town of Spain, in Catalonia. In the year 1694, a battle was fought near this town between the French and Spaniards, in which the former were victorious; 6 miles N. of Vique.

TORENATE, a town of New Navarre; 100 miles S.S.E. of Casa Grande.

TORENIA, in *Botany*, was so called by Linnæus, after his pupil, the Rev. Olof Torén, or Toren, chaplain of a ship in the service of the Swedish East India Company, who studied at Upsal, in order the better to qualify himself, as a naturalist, for a voyage to China. He communicated to his great botanical preceptor many scarce plants, and addressed to him a series of letters, descriptive of the voyage, in which, though various other subjects are touched upon, natural history makes a principal figure. These were published at the end of Osbeck's *Voyage*, (see **OSBECKIA**), and translated with that work into English, by Dr. Forster. Soon after they were written, the author died, apparently at an early age, near Nafinge, in Sweden, Aug. 17, 1753.—Linn. Gen. 311. Schreb. 407. Willd. Sp. Pl. v. 3. 265. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 440? Juss. 122. Lamarek. Illustr. t. 523.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Personate*, Linn. *Scrophulariæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, permanent, two-lipped; the lips toothed, unequal. *Cor.* of one petal, ringent, twice the length of the calyx; its upper lip nearly entire; lower three-cleft, the middle segment most prominent. *Stam.* Filaments four; the two uppermost simple; two lowermost longest, with a lateral branch or tooth; anthers of two vertical, oblong, rather distant lobes, converging in pairs, their respective lobes closely contiguous. *Pist.* Germen superior, elliptic-oblong; style thread-shaped, swelling upwards; stigma of two parallel flat plates. *Peric.* Capsule elliptic-oblong, of two cells, and two undivided valves, with a parallel unconnected partition. *Seeds* numerous, roundish, attached to the partition.

Eff. Ch. Calyx tubular, angular, with two lips. Corolla ringent. Two of the filaments with a lateral branch. Anthers connected in pairs, by their opposite lobes. Capsule of two cells, with a parallel partition. Seeds numerous.

Obs. We take our characters of this genus principally from the original Linnæan species, and therefore hesitate to admit, after the example of our learned friend Mr. Brown, any species with a regular five-toothed calyx, such as *Capraria crustacea*, Linn. and *Torenia scabra* of Brown. We also omit *T. flaccida* of the last-mentioned author, and *Antirrhinum hexandrum* of Forster, because we have not seen them. The strange name of the latter probably alludes to the lateral branches of two of the filaments, by which therefore it should seem to be a good *Torenia*. Yet these appendages appear to be wanting in *T. cordifolia* of Roxburgh, if we may trust the figure, nor do we find them clearly in our *T. obtusifolia*. The two-lipped tubular calyx seems to us the most important mark.

1. *T. asiatica*. Smooth Creeping *Torenia*. Linn. Sp.

Pl. 862. Willd. n. 1. Osbeck's *Travels*, English edition, v. 1. 337. Lamarck f. 1. (*T. glabra*; Osbeck It. 210. "Kaka-pu; Rheede Hort. Mal. v. 9. 103. t. 53.")—Smooth, with a creeping stem. Leaves stalked, ovate, acute, ferrated.—Native of China, in watery places, flowering in September. The whole *herb* is smooth, except a few hairs about the joints, and at the insertion of the leaves. *Stem* a span long, branched, square, leafy, creeping by means of fibrous roots, which seem to be perennial. *Leaves* hardly an inch long, opposite, smooth, with shallow ferratures; on stalks about half their own length. *Flowers* axillary, solitary, opposite; on long simple stalks, purple, large and handsome, not unlike those of **MAURANDIA**; see that article. The small teeth, or points, of the *calyx* are narrow, close together, and its angles are winged.

2. *T. hirsuta*. Hairy *Torenia*. Willd. n. 2. Lamarck f. 2. Mart. Mill. Dict. n. 2.—Hairy, with an erect stem. Leaves ovate, ferrated, on short stalks.—Native of China. Linnæus thought it a variety of the first species, but it is much more hairy, with smaller flowers; the *calyx* scarcely winged, except at the very base. The teeth of that part appear to become more deeply separated as the capsule enlarges.

3. *T. ciliaris*. Fringed *Torenia*.—Leaves ovate, acute, slightly hairy, ferrated, on long stalks. Angles of the calyx broadly winged, fringed.—Native of the Nicobar islands. Communicated by the Right Hon. Sir Joseph Banks. The stem appears to be erect. The leaves are an inch and half long, strongly ferrated, slightly besprinkled with hairs, oblique at the base. *Footstalks* nearly half the length of the leaves, channelled, hairy. *Flowers* opposite, about as large as the first species. *Calyx* remarkable for its broad wings, fringed with short upright hairs; its teeth slender and hairy.

4. *T. cordifolia*. Heart-leaved *Torenia*. Roxb. Coromand. v. 2. 32. t. 161. Mart. Mill. Dict. n. 3.—Nearly smooth. Stem branched, spreading. Leaves ovate-heart-shaped, ferrated. Calyx without wings.—Native of the East Indies. Found by Dr. Roxburgh, in the moist pasture lands about Samulcotah, flowering during the cold season. The root is fibrous, simple, apparently annual. *Stem* erect, six inches high, square, leafy, bushy, with numerous cross branches. *Leaves* an inch long, paler beneath, on stalks half that length. *Flowers* about the tops of the branches, axillary, on long slender stalks. *Calyx* rather swelling, angular, but destitute of wings, two-lipped, with five small teeth. *Corolla* pale purple, twice the length of the calyx. *Stamens*, according to Roxburgh, without any lateral branch or tooth.

5. *T. obtusifolia*. Blunt-leaved *Torenia*.—Leaves roundish-ovate, obtuse, stalked, wavy, somewhat toothed, smooth. Stem creeping. Lips of the calyx unequal, abrupt.—Sent from Mexico by Mutis to Linnæus. The specimens were laid into the genus *Gratiola*, but seem never to have been described. The whole *herb* is smooth, branched, succulent, creeping; in habit not unlike *Veronica Beccabunga*, like which plant it seems to grow in swampy places. *Leaves* ribbed, broad, an inch long. *Flowers* axillary, stalked, solitary, the size of *T. cordifolia*. *Calyx* angular, not winged, oblique at the mouth; its upper lip prominent, obtuse, slightly emarginate; lower much shorter, abrupt, with three small distant teeth. *Corolla* twice the length of the calyx, white or yellowish; internally somewhat hairy. The insertion of two of the *stamens* into the upper part of the corolla agrees with *T. asiatica*; we are not sure whether the other pair has any lateral teeth, but there is some appearance of such appendages, conglutinated as it were

were with the corolla. The *anthers* are roundish, combined in pairs. *Germen* ovate, pointed. *Stigma* between the anthers, of two thin plates. The parts of the flower in our specimens scarcely admit of sufficient examination to determine the genus of this plant with certainty, but it appears to agree with *Torenia* better than with any other.

TORENTO, in *Geography*. See YORK.

TOREUMATOGRAPHY, a Greek term, signifying the knowledge, or rather description, of ancient sculptures, and basso-relievos.

The invention of toreumatography is owing to Phidias, and its perfection to Polyclethus: the Italian graveurs have let a great deal of light into the toreumatography.

TOREUTICE, *τορευτικη*, formed from the Greek *τορευοι*, *lath*, of *τορευω*, *terebro*, *perforo*, that part of sculpture called *turning*.

TORFÆUS, THORMODUS, or THORMOD TORVESEN, in *Biography*, an eminent historian, was born in a small island called Engoe, on the southern coast of Iceland; and having laid the foundation of his education at the school of Skalholt, he spent three years, from 1654 to 1657, in the university of Copenhagen. In the spring of 1659 he was captured, in a voyage from Christianland on board a Dutch vessel, by a Swedish cruizer, and carried to Jutland. Upon his release and arrival at Copenhagen, he was appointed the king's interpreter for Icelandic antiquities. In 1662 he visited Iceland, for the purpose of collecting old MSS.; and in the accomplishment of his object was much encouraged and assisted by the bishop of Skalholt. In 1663 he returned to Denmark with a variety of valuable materials; in 1664 he was made secretary to the district of Stavanger; and in the following year he married: but in 1667 he resigned his office, and was appointed antiquary to the king. Upon the death of his father and brother he made a voyage to Iceland, for the purpose of securing his property; and in the same year he went to Amsterdam; but on his return he was shipwrecked at Skagen, and obliged to travel to Aarhus by land. Embarking for Zealand, he encountered a storm near the island of Samsoe, and landed at Senas, where he was wantonly attacked by an Icelander, and in self-defence killed his antagonist. Upon this he was arrested, tried, and condemned to suffer death. Upon an appeal first to a superior court in 1672, and afterwards to the king, it was ultimately determined that he should pay a fine of 100 dollars, and be released. The king, however, was displeased, and deprived him of his salary and office; upon which he retired to Norway, where he lived without any employment till the year 1682, when he was appointed royal historiographer and assessor in the consistory, with a stipend of 600 dollars *per annum*. Thus circumstanced, he commenced his history of Norway; but in 1706 he was obliged to desist from the prosecution of it by a severe illness, after he had brought it down to the union of Calmar, and to resign the completion of it to professor Reitzer. Having lost his wife in 1695, he married a second in 1709; and in 1719 died without issue. Torfæus was a man of considerable learning, and particularly conversant with ancient history and antiquities; and he was much respected by the northern sovereigns, Frederick III., Christian V., and Frederick IV. His works, actually published and left in MS., were very numerous. The collection of his MSS., relating more especially to the history of Iceland, amounts to several volumes folio, and is preserved in the king's library at Copenhagen. Gen. Biog.

In connection with Torfæus, we shall here mention the learned and eminent Arnas Magnæus, the son of an obscure country priest in the western part of Iceland, and more con-

spicuous for his devotion to literary pursuits than Torfæus. Raised from a humble and obscure situation by extraordinary efforts of talent and industry, he attained, in 1694, at the age of 31 years, the honourable station of professor of philosophy in the university of Copenhagen; and a few years afterwards, he was invested with the offices of professor of northern antiquities and secretary of the royal archives. Incessant in his literary labours, he composed several important works, and collected at great expence a magnificent library, serving to illustrate the literature and antiquities of the North, and more especially the literature of his native island. The greater part of this library was unhappily consumed by the fire which happened at Copenhagen in 1728; and the unfortunate Magnæus was witness to the almost total destruction of the fruits of many years' labour. He died two years after this disastrous event, and bequeathed to the library of the university the remnant of his literary treasures. His friend and favourite pupil, Finnur Jenfon, was another of the eminent Icelanders, who, during the last century, have contributed to preserve unimpaired the character and respectability of their country. Created bishop of Skalholt in 1754, he retained this office during the remainder of a long life, wholly devoted to the improvement and happiness of his fellow-citizens. In his admirable work, the "Ecclesiastical History of Iceland," written in elegant Latin, and published at Copenhagen in 4 vols. 4to. he has bequeathed to his countrymen a monument of extensive erudition, genuine piety, and warm patriotic feelings, which will continue as one of the most illustrious monuments of their literature. Mackenzie's Travels in Iceland.

TORFVE, in *Geography*, a town of Sweden, in West Gothland; 75 miles N.E. of Uddevalla.

TORGA, a town of the principality of Georgia, in the province of Caket; 85 miles S.E. of Teflis.

TORGAW, or TORGAW, a town of Saxony, in the marggravate of Meissen, on the Elbe. It was anciently the head place of a peculiar seigniory, which passed in fief from the electors of Saxony, of the Ascanian line. In the year 1530, the seventeen articles of the Protestant doctrine were presented at this place, to the elector John; and in 1576, the Torgau writing was made here, out of the Swabian Concordat and the Maulbrun Formula; from which writing, the year following, the Formula Concordiæ was drawn up at Kloster Bergen. In the year 1745, the Prussians passed the Elbe here; in the year 1756, they fixed their military office at this place; and in the year 1757, they broke down the bridge thrown over the Elbe. In the year 1760, the Austrians, under marshal Daun, were defeated by the Prussians, commanded by the king in person. The Austrians lost 200 officers, and 7000 men prisoners. Marshal Daun himself was wounded. The Prussians had 2500 men killed, and 4000 wounded; 28 miles E.N.E. of Leipsic. N. lat. 51° 32'. E. long. 13° 3'.

TORGAW, *Convocation of*. See Form of CONCORD.

TORGEISKOI, in *Geography*, a town of Russia, in the government of Irkutsk; 24 miles N.N.W. of Nertchinsk.

TORGEL, a small island in the North sea, near the coast of Norway. N. lat. 65° 30'.

TORGELOW, a town of Anterior Pomerania, on the Ucker; 9 miles N. of Pasewalk.

TORGOCH, in *Ichthyology*. See CHARR.

TORGOTS, in *Geography*, a tribe of the Mongoles, who formed themselves into a distinct horde much later than the other Kalmuck branches. Removing at first from the restless Soongares, they marched westward till they came to the steppes on the Volga, where they finally settled, and

received from the Russians the name of the Volgaic Kalmucks. In 1616, this horde is said to have submitted to the Russian empire; and on crossing the Ural in 1662, their number amounted to 50,000 kubitkies. In 1761, the Russian government entered into an agreement with this opulent and powerful horde, which restricted the authority of the khans to narrower bounds, and excited such discontents, that they returned in the winter of 1770 and 1771, to the amount of between 55,000 and 60,000 kubitkies, over the ice of the river Ural, across the Kirghisian steppe, into the Soongarey. The greater part of the Soongares took part in this migration; only some few ainaks of the Torgots remained behind; but the Tartars in subjection to the horde refused to follow them. The fugitives were pursued by order of the Russian government; but most of them made their escape. Numbers indeed perished on their journey; many were taken prisoners by the Kirghises; and those who reached the place of their destination, put themselves under the protection of the Chinese government, who gave them a kind reception, but afterwards, for political reasons, treated them with great severity. The Torgots, with the Khofchotes and Soongares, who staid behind or were brought back from their flight, are distributed among the Derbets; and wander, with their flocks and herds, in the steppes between the Don and Volga, from the line of Tzeritzin as far as Caucasus, and between the Volga and the river Ural, from the Irghis quite to the Caspian; consequently in the governments of Saratof and Astrakhan, and in the seats of the Cossacks of the Don. Tooke's Russia, vol. i.

TORGOWITZA, a town of Russian Poland, in the palatinate of Braclaw; 20 miles E. of Human.

TORSAKER, a town of Sweden, in the province of Angermannland; 25 miles N. of Hernofand.

TORHOUT, a town of France, in the department of the Lys; 10 miles S. of Bruges.

TORIES, or TORYS, a party or faction in England, opposite to the Whigs.

These two celebrated parties, which have so long divided our country, will make a considerable article in the English history, nothing inferior, in many respects, to that of the Guelfs and Gibellins. The division has gone so deep, that it is presumed, no Englishman, who has any concern or principles at all, but inclines more to one side than the other; for which reason, we shall borrow our account of them from the mouths of foreigners, who may be supposed more impartial; and particularly from M. de Cize, a French officer, some time in the service of England, who has written the History of Whiggism and Toryism, printed at Leipsic, anno 1717; and M. Rapin, whose Dissertation sur les Weighs & les Torys, printed at the Hague the same year, is well known; and reprinted at the close of the second volume of his History of England, fol. ed.

During the unhappy war which brought king Charles I. to the scaffold, the adherents of that king were first called *Cavaliers*, and those of the parliament *Round-heads*; which two names were afterwards changed into those of *Tories* and *Whigs*, on the following occasion.

A kind of robbers, or banditti, in Ireland, who kept on the mountains, or in the islands formed by the vast bogs of that country, being called *Tories*, a name they still bear indifferently with that of *Rapparees*; the king's enemies accusing him of favouring the rebellion in Ireland, which broke out about that time, gave his partisans the name of *Tories*; and on the other hand, the *Tories*, to be even with their enemies, who were closely leagued with the Scots, gave them the name of *Whigs*, who living in the fields and

woods, fed much on milk; *whig* signifying *whay*. But for a more probable etymology of whig, see *WHIGS*.

The *Cavaliers*, or *Tories*, had then principally in view the political interests of the king, the crown, and the church of England; and the *Round-heads*, or *Whigs*, proposed chiefly the maintaining of the rights and interests of the people, and of Protestantism. Nor have the two factions yet lost their first views; though their first names, *Cavalier* and *Round-head*, be now entirely disused.

This is the most popular account; and yet it is certain the names *Whig* and *Tory* were but little known till about the middle of the reign of king Charles II. M. de Cize relates, that it was in the year 1678, that the whole nation was first observed to be divided into *Whigs* and *Tories*; and that on occasion of the famous deposition of Titus Oates, who accused the Catholics of having conspired against the king and the state,—the appellation *Whig* was given to such as believed the plot real; and *Tory* to those who held it fictitious.

When we compare, says Mr. Hume (Ess. ix.), the factions of *Whig* and *Tory* with those of *Round-head* and *Cavalier*, which were merely parties of principle, the most obvious difference that appears between them, consists in the principles of "passive obedience" and "indefeasible right," which were but little heard of among the *Cavaliers*, but became the Universal doctrine, and were esteemed the true characteristics of a *Tory*. If these principles were pushed into their most obvious consequences, they imply a formal renunciation of all our liberties, and an avowal of absolute monarchy; since nothing can be a greater absurdity than a limited power which must not be resisted, even when it exceeds its limitations. But as the most rational principles are often but a weak counterpoise to passion; it is no wonder that these absurd principles were found too weak for that effect. The *Tories*, as men, were enemies to oppression; and also as Englishmen, says Hume,—they were enemies to arbitrary power. Their zeal for liberty was, perhaps (says this partial writer), less fervent than that of their antagonists; but was sufficient to make them forget all their general principles, when they saw themselves openly threatened with a subversion of the ancient government. From these sentiments arose the Revolution; an event of mighty consequence, and the firmest foundation of British liberty. The conduct of the *Tories*, during that event and after it, will afford us a true insight into the nature of that party. In the *first* place, they appear to have had the genuine sentiments of Britons in their affection for liberty, and in their determined resolution not to sacrifice it to any abstract principle whatsoever, or to any imaginary rights of princes. This part of their character might justly have been doubted of before the Revolution, from the obvious tendency of their avowed principles, and from their compliances with a court, which seemed to make little secret of its arbitrary designs. The Revolution shewed them to have been, in this respect, nothing but a genuine "court party," such as might be expected in a *British* government; that is, "lovers of liberty, but greater lovers of monarchy." It must, however, be confessed, that they carried their monarchical principles further, even in practice, but more so in theory, than was in any degree consistent with a limited government. *Secondly*: Neither their principles nor affections concurred, entirely or heartily, with the settlement made at the Revolution, or with that which has since taken place. This part of their character may seem opposite to the former; since any other settlement in those circumstances of the nation, must probably have been dangerous, if not fatal, to liberty. But the heart

TORIES.

heart of man, says our author, is made to reconcile contradictions; and this contradiction is not greater than that between "passive obedience," and the resistance employed at the Revolution. A Tory, therefore, since the Revolution, may be defined in a few words to be "a lover of monarchy, though without abandoning liberty; and a partisan of the family of Stuart;" as a Whig may be defined to be "a lover of liberty, though without renouncing monarchy; and a friend to the settlement in the Protestant line."

Some, who will not venture to assert, that the *real* difference between Whig and Tory was lost at the Revolution, seem inclined to think, that the difference is now abolished, and that affairs are so far returned to their natural state, that there are at present no other parties among us but *Court* and *Country*; that is, men who, by interest or principle, are attached either to monarchy or liberty. The Tories have been so long obliged to talk in the republican style, that they seem to have made converts of themselves by their hypocrisy, and to have embraced the sentiments, as well as language of their adversaries. There are, however, very considerable remains of that party in England, with all their old prejudices.

The precise difference, says an anonymous writer (Edinb. Rev. N^o L.), between a moderate Tory and a moderate Whig is, "that a Tory is more influenced by loyalty, and a Whig by the love of liberty; that a Tory considers liberty as the second interest of society, while a Whig regards it as the first." Loyalty is denominated by Mr. Hume "that noble and generous principle, inferior only in excellence to the more enlightened affection towards a legal constitution."

We should here confine ourselves to the *Tories*; and for what regards the *Whigs*, refer to that article; but since, by comparing and confronting the two parties together, both the one and the other will appear in the stronger light, it would be imprudent to separate them; so that we rather choose to say the less under the word *Whigs*, and refer thence hither.

The factions we are speaking of, may be considered either with regard to the *state*, or to *religion*. The *state* Tories are either violent or moderate: the first would have the sovereign to be absolute in England, as in other countries, and his will to be a law. This party, which is not very numerous, has yet been considerable. 1. On account of its leaders, who have been lords of the first rank, and generally ministers and favourites. 2. In that, being thus in the ministry, it engaged the church Tories to maintain stiffly the doctrine of passive obedience. 3. Because they have been frequently supported by the crown.

The moderate Tories would not suffer the king to lose any of his prerogatives; but neither would they sacrifice those of the people.

The *state* Whigs, again, are republican or moderate: the first, according to our author, are the remains of the Long parliament, who took in hand to change the monarchy into a commonwealth: these make so slender a figure, that they only serve to strengthen the party of the other Whigs. The Tories would persuade the world, that all the Whigs are of this kind; as the Whigs would make us believe, that all the Tories are violent.

The moderate *state* Whigs are much in the same sentiments as the moderate Tories; and desire the government may be maintained on its ancient foundation, and that the king may be reduced to an incapacity of abusing his power, by leaving him the possession of his just rights: all the difference is, that the moderate Tories lean a little more

to the side of the king, and the moderate Whigs to that of the parliament and people.

Before we consider our two parties with regard to religion, it must be observed, that the Reformation, as carried on to a greater or less length, divided the English into Episcopalians and Presbyterians or Puritans: the first contended, that the episcopal jurisdiction should be continued on the same footing, and the church in the same form, as before the Reformation: the latter maintained, that all ministers or priests had equal authority; and that the church ought to be governed by presbyteries, or consistories of priests and lay-elders. See PURITANS.

After long disputes, the more moderate of each party relaxed a little of their stiffness; and thus formed two branches of moderate Whigs, and moderate Tories, with regard to religion; but there were others who kept to their principles with inconceivable firmness: and these constituted two branches of rigid Episcopalians and Presbyterians, comprised under the general names of Whigs and Tories; in regard, the first join the Tories, and the latter the Whigs.

The former consisted of rigid churchmen, who were against the least change in the discipline of the church, while the more moderate among the ecclesiastical Tories were less scrupulous and obstinate, and may be called the low or moderate churchmen. See HIGH CHURCH and NON-JURORS.

The latter were the rigid Presbyterians, who would be contented with nothing less than the destruction of the hierarchy, while the more moderate among them would have been satisfied with much less, and put up, says Mr. Rapin, with a bare toleration.

From what has been observed, we may conclude, that as the names *Tory* and *Whig* have a regard to two different objects, they are equivocal, and of consequence ought never to be applied without expressing in which sense it is done; for the same person may be, in different respects, both Whig and Tory.

For the rest, the general motives that have formed and kept up the two parties, appear in the main to be no other than the private motives of particular persons: self-interest is the *primum mobile* of their actions: ever since the rise of these factions, each has struggled earnestly to get the advantage over the other; inasmuch as from such superiority accrue places, and honours, and promotions, &c. which the prevailing party usually distributes among its own members, exclusive of the contrary party.

There are, however, men belonging to each of these parties, though the distinction is almost worn out, who act from conviction; some of whom are for the extension, and others for the limitation of royal prerogative, with a view to the good of the state, as their principles lead them to form different notions of the most effectual method of promoting it. The names, it is true, are almost sunk into oblivion; but the operation of the distinguishing sentiments of Whigs and Tories is discoverable in every period of the English history: and the true interest of a limited monarchy, always inseparably connected with the rights of the people, renders the distinction of importance, and should prevent its ever being disregarded.

It is with the Whigs and Tories on those points, which have discriminated the two parties, says Dr. Gregory Sharpe, as it is with all other sects of men under the agitation of hope and fear, ambition and interest; they tighten or relax their principles as suits best their convenience. When the Tories have had the exercise of the powers of the prerogative, they have been eager to extend those powers;

when the edge has been turned against them, they have been as eager in the defence of popular liberty: and in like manner the Whigs, who withstood the storm, have melted in the sun-shine, so that in point of court complaisance, the administrations of the one have differed very little from those of the other. Holberg's Int. to Universal History, by Sharpe, p. 260.

As to the characters commonly attributed to the Whigs and Tories; the Tories, says M. Rapin, appear fierce and haughty: they treat the Whigs with the greatest contempt, and even sometimes with rigour, when they have the advantage over them: they are very hot and vehement, and proceed with a rapidity, which yet is not always the effect of heat and transport, but has its foundation sometimes in good policy: they are very subject to change their principles, as their party prevails or is humbled.

If the rigid Presbyterians prevailed in the Whig party, it would not be less hot and zealous than that of the Tories; but it is said they have not the direction thereof; which gives room to affirm, that those at the head of the Whig party are much more moderate than the chiefs of the Tories: add, that they usually conduct themselves on fixed principles, proceed to their end gradually, and without violence; and their slowness is not less founded on good policy, than the hastiness and precipitation of the Tories. Thus much says our author may be said to the advantage of the moderate Whigs, that, in the general, they maintain a good cause, viz. the constitution of the government as by law established.

TORIESDALE HEAD, in *Geography*, a cape on the N. coast of Scotland. N. lat. $58^{\circ} 30'$. W. long. $4^{\circ} 10'$.

TORILIS, in *Botany*, a genus of Adanson's, whose name perhaps may have been fabricated from *τορεως*, *to carve* or *emboss*, in allusion to the seeds, which, however, answer less to this idea than those of many neighbouring genera.—Adans. Fam. v. 2. 99. Spreng. Prod. Umbellif. 24. Gært. t. 20.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferae*.

Adanson distinguishes this genus from CAUCALIS, (see that article,) by the want of a general involucre, and the slenderness of the leaves which compose the partial ones. These are principles of Artedi and Linnæus, but not generally reckoned among their best. Gærtner, and more recently Sprengel, distinguish *Torilis* by the bristles of the fruit being scattered equally over its whole surface; not, as in *Caucalis*, ranged along its ribs. As one of the species, *Anthriscus*, usually, if not constantly, is furnished with a general involucre, and another, *nodosa*, is not always destitute of one; and as the insertion of the bristles is a very obscure, if not precarious, character; which appears by the disagreement between Gærtner and Sprengel, concerning the species supposed to compose this genus, we prefer leaving our three British ones at least in *Caucalis*, where they are placed in the *Flora Britannica*.

TORIM, in *Geography*, a town of New Mexico, in the province of Hiaqui; 35 miles S.W. of Riochico.

TORIN ROCKS, a cluster of rocks near the S.W. coast of the island of Mull. N. lat. $56^{\circ} 16'$. W. long. $6^{\circ} 28'$.

TORISA, a river of European Turkey, which runs into the Mariza, at Adrianople.

TORKESEY, JOHN, in *Biography*, author of one of the most important tracts in the MS. of Waltham Holy Cross, at present in the possession of the marquis of Lansdowne. This tract, which is the fifth in the collection, has been already described. See POWER, LIONEL.

TORLA, in *Geography*, a town of Spain, in Aragon; 16 miles E. of Jaca.

TORM, ERIC OLAVIUS, in *Biography*, a Danish writer, was born in 1607, and educated in the school of Viborg. Having finished his education, and spent several years in the capacity of private tutor, he set out on his travels with a view to further improvement; and visited Oxford, Leyden, and Paris; and in 1736 he was appointed professor of mathematics in the university of Copenhagen, and afterwards librarian and preacher in one of the churches. He died in 1667. He was the author of many works, chiefly mathematical and historical. Gen. Biog.

TORME, in *Geography*, a town of Spain, in Old Castile; 15 miles N. of Frias.

TORMENT, CAPE, a cape on the coast of Canada; 24 miles below Quebec.

TORMENTILLA, in *Botany*, a diminutive of *tormentum*, a pain or griping, supposed to have been chosen to designate this little astringent plant, because it served to alleviate pains of the teeth, or of the bowels, *tormina*. But it may simply perhaps apply to that astringency, which, considering the primary sense of the above words, the name seems to indicate.—Linn. Gen. Pl. 256. Willd. Sp. Pl. v. 2. 1112. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 552. Juss. 337. Tourn. t. 153. Lamarck Illustr. t. 444.—Class and order, *Icosandria Polygynia*. Nat. Ord. *Senticose*, Linn. *Rosaceae*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, flat, cut half way down into eight segments, of which four alternate ones are smaller and more acute. Cor. Petals four, inversely heart-shaped, flat, spreading, their claws inserted into the calyx. Stam. Filaments sixteen, awl-shaped, half the length of the petals, inserted into the calyx; anthers roundish, simple. Pist. Germens eight, small, collected into a little round head; styles thread-shaped, the length of the stamens, inserted laterally into the germens; stigmas obtuse. Peric. none. Receptacle of the seeds dry, minute, covered entirely by them, and enclosed in the calyx. Seeds eight, roundish-oblong, corrugated, bluntly pointed.

Ess. Ch. Calyx inferior, in eight segments. Petals four. Seeds roundish, naked, wrinkled, attached to a small dry receptacle.

Obs. Linnæus remarks, that this genus differs from POTENTILLA, (see that article,) in characters founded on number only, and therefore they might be united. Schreber, and recently Dr. Nestler of Strasburgh, have adopted this measure, the latter uniting *Comarum* also to *Potentilla*. As the numerical differences are extended throughout the parts of fructification, though some of them are acknowledged to vary, and the two species of *Tormentilla* accord so well in habit, we are induced to follow Linnæus, Tournefort, and Jussieu, in retaining the genus; for if number were in this case entirely overlooked, we do not perceive how SIBBALDIA could be supported. (See that article, COMARUM, and ROSACEÆ.) It has been asserted, that botanists who retain such genera as this, viz. Ray, Tournefort, Linnæus, and Jussieu, will not gain much fame with posterity; but of this, we humbly presume, posterity will be the judge.

1. *T. officinalis*. Common Tormentil, or Septfoil. Curt. Lond. fasc. 5. t. 35. Fl. Brit. n. 1. Engl. Bot. t. 863. (*T. erecta*; Linn. Sp. Pl. 716. Willd. n. 1. Woodv. Med. Bot. t. 9. Fl. Dan. t. 589. Tormentilla; Ger. Em. 992. Camer. Epit. 685. Matth. Valgr. v. 2. 297. Brunf. Herb. v. 1. 85.)—Stem ascending, branched. Leaves sessile.—Common in dry barren pastures, especially on bushy heaths, throughout Europe, flowering in summer. The root is perennial, large, and woody, very astringent, used by the Laplanders to dye leather red. (See Linnæus's Tour to Lapland, v. 1. 155.) Stems weak, slender and wiry,

wiry, often procumbent. *Leaves* ternate, lanceolate, rather hairy, deeply serrated, with a pair of deeply cut *stipulas*. *Flowers* bright yellow, on long, simple, solitary, lateral stalks. The late Miss Johnes of Hafod found one plant in that romantic spot, whose flowers were double, a rare instance.

2. *T. reptans*. Trailing Tormentil. Linn. Sp. Pl. 716. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 864. (*Pentaphyllum reptans alatum, foliis profundius serratis*; Plot. Oxford. t. 9. f. 5.)—Stem prostrate. Leaves stalked.—Native of banks and shady places, in England and Germany, but not common. We once gathered it in a lane at Brighthouse, near Halifax, Yorkshire, in the middle of summer. The root, though perennial, is much smaller and slenderer than in the foregoing. *Stems* few, eighteen or twenty inches long, often simple, entirely prostrate, but not creeping. Whole herb finely hairy, of a light green. Radical leaves on long stalks, of five, obovate, deeply serrated leaflets; those on the stem of three only, on shorter stalks; the floral ones sessile, narrow, and often entire. *Stipulas* united to the base of the footstalks. *Flowers* twice as large as the foregoing, on very long stalks, opposite to the leaves.

TORMENTILLA, in the *Materia Medica*. The root of the common tormentil, or upright septfoil, *tormentilla erecta*, is the only part that is used in medicine. It is knotty, externally blackish, and internally reddish. It has a strong styptic taste, but imparts no peculiar sapid flavour. As a proof of its powerful astringency, it has been substituted for oak-bark in the tanning of skins for leather. Its active matter is therefore chiefly tannin; the infusion in boiling water being copiously precipitated by solution of isinglass, and striking a deep black with sulphate of iron. This root has been long held in high estimation by physicians, as a very useful astringent; and having little resin, it becomes peculiarly adapted to cases where the heating and stimulating medicines of this class are less proper, as pthical diarrhœas, diarrhœa cruenta, &c. Dr. Cullen thinks it has been justly commended for every virtue that is competent to astringents; and he adds, that he has found it, both by itself and as joined with gentian, cure intermittent fevers, when given in substance and in large quantities. It gives out its astringency both to water and rectified spirit, but most perfectly to the latter: the extracts, particularly the spirituous, obtained by inspissation, are intensely styptic. The root is generally given in powder, from half a drachm to one or more for a dose; but it is more generally given in decoction: an ounce and a half of the powdered root may be boiled in three pints of water to a quart, adding, toward the end of the boiling, a drachm of cinnamon: of the strained liquor, sweetened with an ounce of any agreeable syrup, two ounces or more may be taken four or five times a day. As a local remedy, it may be used with advantage in the form of gargle and lotion in ulcerations of the tongue and mouth, against spongy gums, and as an application to fœtid ill-conditioned sores; but it is seldom used. Lewis. Woodville.

TORMENTING, in *Agriculture*, a term signifying in tillage cultivation an imperfect sort of horse-hoeing or ploughing, or what is sometimes, in some districts, termed sub-hoeing or sub-ploughing. It is occasionally too used as a term of reproach for bad tillage of any kind.

TORMENTOR, an implement of the tillage kind, used for breaking down and reducing the parts of stiff soils. It is a powerful tool of this sort which is much employed in Devonshire, Cornwall, and some other counties; in the first of which for the purpose of cross-cutting the balks of whole

ground, left after the velling and skirting operations for beat-burning, or paring and burning the surface-turf. It is indeed useful in working lands in almost all cases of bringing them into cultivation, and into a fine state of mould. See SKIRTING, TILLAGE, and VELLING.

This sort of implement is constructed in different modes and forms, as in a kind of long triangular shape, the beam part being lengthened out before, in which is fastened, by a sort of shank, a small wheel, which is capable of being raised or let down at pleasure, so as to regulate the depth of working of the tool. At or near the extremity of the frame behind are fixed two large wheels, so as to allow the triangular pointed shares or hoes to work in the ground. The whole is strongly framed together in three pieces; the middle or beam, and the two outside pieces. The number of shares or hoes is usually about nine. The same tool is sometimes contrived with two wheels in the front, and with a crane neck, being the same in all other respects.

The spill of iron which passes through the beam in the front, and supports the fore-wheel, has a number of iron rings on it, by which the depth of stirring is regulated. The length of the beam is six feet nine inches. The breadth or width of the back-piece, where the large wheels are placed, is three feet seven inches. The large wheels are three feet in diameter. The small fore-wheel is ten inches in diameter. The side-pieces of wood of which the frame is made, are four inches square, and the beam thereabouts. The shares or hoes, which are fixed upon shanks, with smaller parts to pass through the frame parts and be fastened above, are fifteen inches in length.

The construction of the tool is consequently very simple, and easily accomplished by any common workman, so that the farmer need never be at a loss for so powerful and effective an implement in the cultivation of tillage land.

TORMES, in *Geography*, a river of Spain, which rises in Old Castile, and crossing the province of Leon, passes by Alva de Tormes, Salamanca, &c. and enters the Duero a few leagues below Miranda de Duero.

TORMINA, in *Medicine*, a term sometimes used to express pains in the general; but more particularly a species of pain, called *tormina ventris*, or *alvi*; in English, the gripes; which see. See also DYSENTERY.

Young children are very often troubled with gripes; it is upon this account that nurses, in order to prevent or remedy them, usually mix with their spoon-meats a little brandy, or some carminative seeds, as caraway-seeds, &c.

Some children breed their teeth with violent gripes, which are apt to bring on convulsions of the bowels.

In adults, the dry gripes are usually cured by the exhibition of warm cathartics, such as tincture of hiera picra, elixir salutis, tincture of rhubarb, &c. with the assistance of opiates.

TORMIS, TORMES, in *Ancient Geography*, a river of Hispania, in Lusitania, which united with the Durus. See TORMES.

TORNA, in *Geography*, a town of Hungary, and capital of a county; 14 miles S.W. of Cafchau.—Also, a town of Saxony; 3 miles S. of Pira.

TORNADO, or TURNADO, a sudden and violent gust of wind rising suddenly from the shore, and afterwards veering round all points of the compass like a hurricane; very frequent on the coast of Guinea. These winds frequently shift suddenly from one quarter of the horizon to another, and then come again to the former point. Before a tornado comes, it calms the constant easterly winds; and when they are past, the easterly wind gathers force again, and the weather clears up fair. See HURRICANE and WHIRLWIND.

TORNADOTUS, or **PHYSCUS**, in *Ancient Geography*, the same with the *Gorgus*, now *Odorneh*, a river of Asia, on the left of the Tigris, and near it, into which it discharged itself near the place where the town of Opis was situated. Xenophon called it *Phycus*, and Ptolemy *Gorgus*.

TORNARECCIO, in *Geography*, a town of Naples, in Abruzzo Citra; 13 miles N.N.E. of Civita Borello.

TORNARSUK, an island near the west coast of West Greenland. N. lat. $61^{\circ} 50'$. W. long. $47^{\circ} 30'$.

TORNAVA, a town of Sweden, in the government of Ulea; 15 miles S.S.E. of Ulea.

TORNEA, a river of Sweden, which rises from a lake in Lapland, and runs into the gulf of Bothnia, at Tornea.

TORNEA, or *Torne*, a town of Sweden, in West Bothnia, situated on a small island, formed by a river of the same name at its mouth, near the gulf of Bothnia, and said to be the oldest town in the country, and the farthest towards the north. It has three streets, running in parallel lines from north to south, which are intersected at right angles by fourteen cross-streets or lanes. Tornea, though built on an uniform plan, consists mostly of detached cottages, and contains only 600 inhabitants. The streets are very broad, and not being paved, are overgrown with grass, on which the cows regularly pasture. The inhabitants, being a mixture of Finns and Swedes, have the character of being idle, and addicted to drunkenness; yet the adjacent country, chiefly by the industry of the Finnish settlers, is rapidly improving; and the population of the province of Lapmark appears to have advanced much faster than that of any other part of Europe. In the year 1750, this, according to baron Hermelin, was 27,000; in 1777, it had increased to 31,000; but in 1801, it amounted to 52,000. The church is built with timber, and stands at a little distance from the other buildings, but within the palisades which inclose the town, and a pretty large piece of arable land. Divine service is performed here in the Swedish language, which is used by the burghers. There is another church, built with stone, on an island called *Bjorkhon*, which lies near the town, in which the service is performed in the Finnean language, for the benefit of the burgher servants, and the inhabitants of the adjacent country. A very considerable trade is carried on here, not only by the Swedes and Laplanders, but the Russians and Norwegians, who also resort to the trading and bartering places of Tornea, in order to traffic. In the year 1694, this town was honoured with the presence of king Charles XI. who, being accompanied by several persons of distinction and learning, took a view of the sun, at midnight, if it may be called so, from the church tower, at Tornea. In this town, and the adjacent country from hence to Kites, observations were made in 1736 by M. Maupertuis, and some other members of the Academy of Sciences at Paris, in order to determine the measure of a degree of, and consequently the figure of the earth, and its ratification and extension by Ivanborg in 1799. N. lat. $65^{\circ} 48'$. E. long. $24^{\circ} 2'$.

TORNEA Ofver, a town of Sweden, in West Bothnia; 3 miles N. of Tornea.

TORNESE, a cape on the coast of the Morea; 8 miles S.S.E. of Chiarenza.

TORNESOL. See **TURNESOL**.

TORNESS, a cape on the south coast of the island of Stronfa. N. lat. $58^{\circ} 56'$. W. long. $2^{\circ} 29'$.

TORNIELLI, **AGOSTINO**, in *Biography*, a learned ecclesiastic, was born at Novara in 1543, and having entered into the society of Barnabites, he became general of this society. He undertook to write an ecclesiastical history from the beginning of the world to the time of Christ, in the form of annals, and executed the work with very laudable saga-

city and correctness, furnishing the reader by his chronological and geographical observations, with a valuable commentary on the books of the Old Testament. It was first printed at Milan in 1610, and afterwards frequently reprinted. Father Negri published an enlarged edition, with valuable notes, in 1757, at Lucca, in four vols. folio. He declined the offer of the bishopric of Mantua, and chose to remain in the Barnabite college at Milan, where he died in 1622. Dupin.

TORNIT, in *Geography*, a town of Germany, in the principality of Anhalt Zerbst; 3 miles W. of Zerbst.

TORNOVO, a town of Italy; 18 miles S. of Venice.

TORO, an island in the Baltic, near the coast of Sweden. N. lat. $58^{\circ} 49'$. E. long. $17^{\circ} 40'$.—Also, a town of Naples, in the county of Molise; 15 miles S.E. of Molise.—Also, a town of Spain, in the province of Leon, situated on the summit of a hill above the Duero, over which is a bridge of twenty-two arches. It is the see of a bishop, and one of the most ancient in the kingdom. Here are the remains of an ancient Moorish castle, forming a square of 143 feet, with a round tower at each angle. In the year 1476, a battle was fought here, by which Ferdinand, prince of Aragon, obtained the kingdom of Castile from Alphonso, king of Portugal; 17 miles E. of Zamora. N. lat. $41^{\circ} 45'$. W. long. $5^{\circ} 37'$.—Also, a town of New Mexico, in the province of Cinaloa; 50 miles N. of Cinaloa.

TORO, II, a small island in the Mediterranean, near the south coast of Sardinia. N. lat. 39° . E. long. $8^{\circ} 34'$.

TOROCCA, in *Ancient Geography*, a town in the interior of European Sarmatia, near the river Carcinites. Ptol.

TOROLLA, in *Geography*, a town of Spain, in Aragon; 18 miles N.W. of Jaca.

TOROM, a river of Russia, which runs into the Oby; 24 miles E. of Surget.

TORON, a town of European Turkey, in Macedonia, situated on a neck of land which projects into the Archipelago, between the gulf of Monte Santo and the gulf of Cassandra; 60 miles S.E. of Saloniki. N. lat. 40° . E. long. $23^{\circ} 54'$.

TORONÆUS or **TORONÆICUS Sinus**, in *Ancient Geography*, a gulf of the Ægean sea, on the coast of Macedonia, and separated from the Singitic and Thermæan gulfs by two large peninsulæ. Tacitus. Pliny calls this gulf *Mecyberniensis*.

TORONE, a town of Macedonia, upon the Toronæic gulf, to which this gulf owes its name. Ptolemy places it in the Paraxia, and Thucydides fixes it in Chalcidia. About three stadia from this town was a temple of Castor and Pollux.—Also, a town of Epirus.

TORONTO, in *Geography*, a settlement of Canada, on the N.W. bank of lake Ontario, now called York. See **YORK**.

TOROPALCA, a town of Peru; 60 miles S. of Potofi.

TOROPETZ, a town of Russia, in the government of Pskov; 156 miles S.E. of Pskov. N. lat. $56^{\circ} 25'$. E. long. $32^{\circ} 24'$.

TOROSAY, a town on the island of Mull. N. lat. $56^{\circ} 35'$. W. long. $6^{\circ} 5'$.

TOROSKO, a town of Transylvania, in the environs of which are mines of iron and silver; 19 miles N. of Weifsemburg.

TOROSUS, in *Botany*, is sometimes used to express an inequality of surface, like the brawny swellings of a muscular limb; as in the capsule of *Papaver hybridum*.

TORP, in *Geography*, a town of Sweden, in West Gothland;

TORPEDO.

land; 11 miles N. of Uddevalla.—Alfo, a town of Sweden, in Warmeland; 11 miles N. of Carlstadt.

TORPEDO, *Cramp-Fish*, or *Electric Ray*, the *raja torpedo* of Linnæus, in *Ichthyology*, a sea-fish, famed, both among the ancient and modern naturalists, for a remarkable numbness with which it strikes the arm of such as touch it. See *RAIA Torpedo*.

This species is found in the Mediterranean, on the Atlantic coast of France, in the English seas, particularly at Torbay, near Waterford, on the coast of Ireland, and in other places. See Anfon's Voyage, p. 266.

It is generally taken with the trawl, but an instance occurs of its taking a bait, which vindicates a fine account which Oppian has left us of this fish. It commonly lies in water about the depth of forty fathoms, in company with the congenerous rays; but its more frequent and favourite situation is the sand, in which it will bury itself by flapping its extremities, and throwing the sand in a light shower over its back. In this situation the torpedo gives his most forcible shock, which throws down the astonished passenger who inadvertently treads upon him. The food of the torpedo is fish, and they probably stupefy their prey by the shock they give them; and yet the sea-leech and common sea-crab will venture to annoy them.

This fish is so far amphibious as to live in air twenty-four hours, and but little longer in fresh water. The best method of preserving them is in well-boats kept in salt-water, and not put into much motion.

Rondelet speaks unfavourably of the torpedo as food, and tells us, that at Venice the prefect of health forbids it to be sold in the market; but in deeming it wholesome food, we have the sanction of Hippocrates and Galen, and it is sold in the markets of France. The electrical organs, indeed, which make one half of the animal, though wholesome, are an insipid mucilage; but its muscular part is, at least, as palatable as the flesh of the other rays: among these, the old and overgrown are always in little request.

The torpedo brings forth its young at the autumnal equinox, as affirmed by Aristotle, though questioned by Lorenzini. In one dissected at La Rochelle, on the 10th of September, were found in the matrices several of the fœtuses quite formed, and nine eggs in no state of forwardness; superfetation seems to be, therefore, a property of this fish; the eggs seemed to be destined for the spring brood, as they produce about the vernal as well as the autumnal equinox. There may be also another production at midsummer, but it principally takes place at the two equinoxes.

Upon touching this fish with the fingers, it frequently, though not always, happens, that the person feels an unusual painful numbness, which suddenly seizes the arm up to the elbow, and sometimes to the very shoulder and head.

The pain is of a very particular species, and is not to be described by any words; yet MM. Lorenzini, Borelli, Redi, and Reaumur, who all felt it severely, observe it to bear some resemblance to that painful sensation felt in the arm, upon striking the elbow violently against a hard body: though M. Reaumur assures us, this gives but a very faint idea of it.

Its chief force is at the instant it begins; it lasts but a few moments, and then vanishes entirely. If a man do not actually touch the torpedo, how near soever he holds his hand, he feels nothing: if he touch it with a stick, he feels a feint effect: if he touch it through the interposition of any pretty thin body, the numbness is felt very considerably; if the hand be pressed very strong against it, the numbness is

the less, but still strong enough to oblige a man speedily to let go.

Oppian affirms, that it will benumb the astonished fisherman, even through the whole length of line and rod. See the passage cited and translated by Pennant, Brit. Zool. vol. iii. p. 39.

But great as are the powers of this fish when in vigour, they are impaired as it declines in strength, and totally cease when it expires. The shocks in water are apprehended to be near a fourth of the force of those at the surface of the water, and not much more than a fourth of those entirely in air. This strange power, with which the torpedo is endued, and which we shall presently explain, seems to have a double use; the one, when it is exerted as a means of defence against voracious fish, who are by a touch deprived of all power of seizing their prey; the other is well explained by Pliny, who tells us, that by the same powers it attains its end with respect to those fish which it wishes to ensnare; for, concealing itself in the mud, and numbing the fish that are carelessly swimming about, it makes a ready prey of them.

M. Reaumur, having no fishes alive to examine what the torpedo would do to them, shut up a drake in water with it, and after some time it was taken out dead. See *Electric Organs of FISH*.

We shall now proceed to give a brief recital of the different theories that have been adopted in order to account for the extraordinary effects of the torpedo. This fish was early known to the Greeks; it is mentioned, as an esculent fish, by Hippocrates, under the name *υζεξερ*, which shews that the ancients had some knowledge of its torporific qualities. Plato also was acquainted with them, as appears by the humorous comparison of Socrates to that animal, which he puts into the mouth of Menon. Aristotle likewise treats of the numbing or stupefying qualities of this fish, though he seems to have no idea of their being communicated by the intervention of a stick, rope, or water.

Theophrastus, according to Athenæus, observed that the torpedo conveyed the numbing sensation through sticks and spears into the hands of the fishermen that held them. Diphilus, of Laodicea, takes notice that the torpor was occasioned, not by the whole, but by certain parts of the body of this fish: and Hero of Alexandria mentions it as emitting effluvia through brass and iron, and other solid bodies.

Pliny's account, though partly true, is mingled with the marvellous and false. Plutarch is more full and just; for he represents the torpedo as not only numbing all that touch it, but striking a numbness through the net into the hands of the fishermen, and as even diminishing the feeling of those who poured water upon it, if it happened to be laid on the ground alive. He adds, that whilst the torpedo swims round his prey, he emits certain effluvia like darts, that first affect the water, and then the fishes in it, which are thus disabled from defending themselves or escaping.

Before the days of Galen the torpedo was placed alive to parts affected, and particularly for the cure of an obstinate head-ache, as appears from Scribonius Largus, who lived under Claudian, and from Dioscorides, who flourished soon after. Galen conceived that the torpedo acted by a frigorific principle, for as cold occasions a numbness in an animated body, so does the shock given by that animal. Paulus of Ægina, one of the Galenic school, recommends the oil of the dead fish for tempering the hot humour of the gout, and for other ailments that required cooling applications.

Such are the unsatisfactory accounts of the philologists and physicians of antiquity.

The Abyssinians, it is said, use torpedos for the cure of fevers,

TORPEDO.

fevers, by tying down the patient to a table, and applying the fish successively upon all his members, which puts him to cruel torment, but effectually removes his disease. Belonius assures us, that our own torpedos applied to the soles of the feet, have proved successful against fevers.

Oppian, like Diphilus, distinguishes the parts where the powers of the fish peculiarly reside; these he calls *λαγυνες*, the flanks, from which he imagined the animal had a faculty of darting upon other fishes certain substances, called by a name *κερυσις*, the meaning of which is obscure. In the sixteenth century, some members of the Academia del Cimento availed themselves of their vicinity to the sea to make experiments on the torpedo. Redi began, and was afterwards assisted by Borelli, and Steno the Dane; and Lorenzini, his scholar, engaged in the same pursuit, and published a curious treatise upon the subject. Redi, having endeavoured to distinguish between the real properties of the torpedo, and those erroneously ascribed to it, proceeded to the anatomy of it; and was the first who with any accuracy described those crooked substances lying on each side of the spine, near the head, which he considered as muscles (from thence named *musculi falcati*) that projected, according to him, certain effluvia, occasioning the sensation of numbness more or less, as the animal was excited to put these organs into action. This hypothesis of the transmission of effluvia was immediately embraced by Lorenzini, and afterwards by Claude Perrault. Borelli, not admitting the emission of benumbing particles, referred the sensation produced by this fish to a certain brisk undulation of the parts touched, which the animal could excite at will.

In 1714, M. Reaumur, being on the coast of Poitou, took an opportunity of making some experiments on the torpedo, which, with the result, he communicated to the Royal Academy of Sciences at Paris. His hypothesis, which was generally received by the ingenious naturalists over all Europe, is not very different from that of Borelli; for instead of the undefined vibrating parts of the latter, M. Reaumur substituted muscles (the *musculi falcati* of Redi and Lorenzini) which, by the vivacity of their action, impressed upon the hand, that touched these parts, a sensation of numbness, owing to the stoppage of the progression of the nervous fluid, or a repulsion of the same. But he denied that this impression of numbness could be communicated through water, a net, or any other soft and yielding substance; nay, through a stick, except a very short one; whereas, it is certain, that the shocks of the torpedo are not less conducted through such media than those from a charged electrical phial.

We have been lately furnished, by the experiments and observations of John Walfh, esq. with a theory, much more plausible and just than any above recited, which considers the electric fluid as the efficient cause of the amazing qualities of the torpedo. We shall be led to a brief account of the facts on which this theory is founded by the following preliminary remarks.

Soon after the discovery of the Leyden phial, the celebrated professor Allemand applied to M. s'Gravesande, governor of Essequibo, for an account of a fish in Surinam, resembling a conger-eel, and possessing properties similar to those of the torpedo; this account was received in 1754, and published in the second volume of the Transactions of the society at Haerlem. From this account it appears, that the shocks of the fish, which were so violent, when the fish was strong and lively, as to throw a person who touched it to the ground, were like those of the electrical fire, but unaccompanied with sparks of fire; and that the fish was a

species of the gymnotus of Artedi. In the sixth volume of the same work, we have a more ample relation of the exertions of this animal by M. Vander Lott, dated from Rio Essequibo, in 1761. M. Adanson, about the same time with the discovery of M. s'Gravesande in America, met with the same or a similar fish in the river of Senegal in Africa. The earliest account we have of this kind of eel is by M. Richer, recorded by M. du Hamel, in his History of the Royal Academy of Sciences for 1677. In the island of Cayenne, says M. du Hamel, there is a fish, not unlike a conger-eel, which, touched with the finger, or even with the end of a stick, affects the arm with a numbness, and the head with giddiness, and the eyes with a dimness of sight, which M. Richer had himself felt upon making the experiment. See GYMNOTUS.

We are indebted to Mr. Walfh for not only the first, but for a numerous series of experiments on the torpedo, in order to ascertain its electrical nature; together with some correct and elegant drawings of the entire animal, and of some of its principal organs that appeared upon dissection. These experiments were made in the year 1772, partly at the isle of Rhé, and partly at Rochelle, in the presence of the members of the Royal Academy of Sciences at that place. They were conducted in a scientific manner, and properly diversified, and the result of them satisfactorily established the torpedo in the rank of an electrician, furnished with a power over the electric matter; by means of which he can, without any foreign machinery, and almost in an instantaneous manner, collect, condense, and at his will dispense it to neighbouring bodies, through any of those substances that are known to be conductors of the electric fluid. The sensations occasioned by the torpedo and Leyden phial, in the human frame, are precisely similar: not only the shock, but the numbing sensation sometimes given by the animal, may be exactly imitated with the phial, by means of Lane's electrometer; the regulating rod of which, to produce the latter effect, must be brought almost into contact with the prime conductor which joins the phial. The first experiment of Mr. Walfh discovered the electrical quality of the torpedo, by his conveying its effects through the same conductors with his electricity, such as metals, water, and animal fluids, and by intercepting it by the same non-conductors, as glass and sealing-wax. Besides, one of the most brilliant of his discoveries was, that this animal not only could accumulate in one part a large quantity of electrical matter, but was furnished with a certain organization, disposed in the manner of the Leyden phial: thus, while one surface of the electrical part (e.g. that on the back) was charged with this matter, or in a positive state; the other surface (that on the belly) was deprived of it, or in a negative state: so that the equilibrium could be restored, by making a communication between the two surfaces by water, the fluids of the human body or metals, in the same manner as by forming a circuit between the inside and outside surfaces of the Leyden phial. A living torpedo was laid on a table, upon a wet napkin; round another table stood five persons insulated: and two brass wires, each thirteen feet long, were suspended from the ceiling by silken strings. One of the wires rested by one end upon the wet napkin, the other end was immersed in a basin full of water, placed on a second table, on which stood four other basins full of water. The first person put a finger of one hand into the water in which the wire was immersed, and a finger of the other hand into the second; and so on successively, till all the five persons communicated with one another by the water in the basins. In the

TORPEDO.

the last balon one end of the second wire was dipped, and with the other end Mr. Walsh touched the back of the torpedo, when the five persons felt a shock, differing in nothing from that of the Leyden experiment, except in being weaker. Mr. Walsh, who was not in the circuit, was not affected. This experiment was successfully repeated several times, even with eight persons. From this experiment it is evident, that the action of the torpedo is communicated through metals and water, or, in general, through the same media that transmit the electrical concussion. It follows, likewise, that the upper and under parts of the animal, like the upper and under surfaces of an electrified plate of glass, are in different states; for a person who touches only the upper or the under surface of the electric organs, will not receive the shock of the torpedo. This action evidently depends on the will of the animal, who, however, scarcely exhibits any other sensible motion or effort at the time of exerting it than a depression or winking of his eyes. The same motion is observed likewise to accompany its fruitless attempts to transmit a shock through non-conductors. The shock of electrical matter which the torpedo possesses appears to be very considerable: a torpedo, when insulated, has given to Mr. Walsh, insulated likewise, no less than fifty shocks in the space of a minute and a half.

Such are the operations performed by the torpedo in air. When a large fish, very liberal of his shocks, was held in water, with one hand on his breast and another on his back, he gave the operator shocks of the same kind as before, but about one-fourth of the strength of those given in air. At the very instant of raising him out of the water, he constantly gave a very violent shock, and another nearly as violent, when his lower surface first touched the water on dipping him into it. On briskly and alternately plunging him a foot deeper into water, and raising him an equal height into air, besides one or two shocks which he gave during the short time he was wholly in the water, and those which he gave at the surface, he constantly gave at least two when he was wholly in the air: so that Mr. Walsh estimates that he gave above one hundred shocks during the minute in which the experiment was performed. The conclusions drawn from Mr. Walsh's experiments were farther confirmed by some experiments made on the torpedo at Leghorn, by Dr. Ingenhousz, in 1773.

Mr. Walsh observes, that the electricity of the torpedo resides in those parts that are called his electric organs: the parts bordering on these acting, more or less, as conductors, either through their substance, or by their superficies: and of these, the parts which conduct the best are the two great lateral fins bounding the organs outwardly, and the space lying between the two organs inwardly. All below the double transverse cartilages scarcely conduct at all, unless when the fish is just taken out of water and is still wet, the mucus, with which he is lubricated, shewing itself, as it dries, to be of an insulating nature; and the organs themselves, when uncharged, appeared to be, not interiorly but rather exteriorly, as Mr. Walsh supposes, conductors of a shock. We are indebted to Mr. John Hunter for an accurate anatomical description of the torpedo, accompanied with two excellent drawings, who has thus supplied us with a valuable addition to the anatomical examination of this animal by Redi, Steno, and Lorenzini. For his account, we refer to *Electric Organs of Fish*.

Although Mr. Walsh's experiments leave little room to doubt, that the shock given by the torpedo is produced by the same agent that gives the shock in an electrical explosion, yet there are some circumstances which it is difficult to reconcile to the supposition that it is produced by the

electric fluid. One of these difficulties is, that the fish is able to give a shock when he is in the water, and consequently surrounded by a medium, through which the electric fluid is known to be transmitted with the greatest facility. It has likewise been difficult to conceive why the shock of the torpedo, supposing it to be produced by the electric fluid, should not, like that of an electrified jar, be accompanied with the appearance of light or sparks, or should not exhibit some signs of attraction or repulsion. But from Mr. Walsh's experiments it appears, that no light could possibly accompany the shock of the torpedo, because this shock could never be made to pass through the least sensible space of air, or the smallest interruption made by the circuit; not even through the imperceptible interval between the links of a slender brass chain, apparently in contact with each other, nor over an almost imperceptible interval or slit formed by cutting through a slip of tin-foil pasted on sealing-wax, which constituted part of the circuit; nor are the most delicate pith-balls, or other light bodies, in what manner soever applied, in the least degree affected at the time of the shock. Mr. Walsh observes, that, with respect to the pith-balls, it is not surprising that no motion could be discovered in them, as all his experiments fully shewed that there was no gradual accumulation of the electric fluid, as in the case of charged glass; but that it was collected or condensed in the very instant of the explosion, by a sudden energy of the animal. He also explains this and the other differences between the phenomena of the Leyden phial, and of the torpedo, or the absence of light and sound, in the experiments made with the latter, by the following considerations.

In a large fish, the number of columns above mentioned, contained in one electric organ, was found to be no less than eleven hundred and eighty-two. This immense collection of cylinders Mr. Walsh considers as somewhat analogous to a large number of jars in an electric battery, and as containing a very large area in consequence of the great number and extensive surface of the columns. Now it is known, from experiments made with artificial electricity, that though the electric matter violently condensed, or crowded into a very small phial highly charged, is capable of forcing a passage through an inch of air, and that it will afford, in a very conspicuous manner, the phenomena of light, sound, attraction, and repulsion; yet if the quantity thus condensed be expanded and rarefied, by communicating it to, or dividing it amongst a large number of jars, whose coated surfaces constitute a space, *e. g.* four hundred times larger than that of the phial: this same quantity of electric matter, thus dilated, will now yield only the fainter, or, if they may be so called, the negative phenomena of the torpedo. It will not now be capable of passing over the one hundredth part of that inch of air, which, in its condensed state, it before sprung through with ease; it will not now be able to jump over the little gap made in its track by the intersection of the tin-foil; no spark, sound, or attraction of light bodies, will now be perceived; and yet this portion of electric matter, in this dilated state, and with its elasticity thus diminished, will, like that of the torpedo, to effect its equilibrium, run through a considerable circuit of different conductors, perfectly continuous, and will communicate a sensible shock.

The Hon. Mr. Cavendish has endeavoured to remove the difficulties above stated, first, by some ingenious reasonings *à priori*, and afterwards by others drawn from the phenomena presented by an artificial torpedo which he constructed, and by means of which he has imitated the effects produced by the living animal. With respect to the diffi-

culty of conceiving how the torpedo can give a shock in water, he observes that those electricians are mistaken, who suppose that the electric fluid will only pass along the shortest and best conductors. When different circuits are made (e. g. by means of iron wire, and the human body) between the positive and negative sides of a charged jar, some parts of the electric fluid will pass along each of them; though the greater quantity will pass through those in which it meets with the least resistance. Thus, a person may receive a part of the shock given by the torpedo in water, by holding one hand on the lower surface of an electric organ, and the other on the upper, or by applying his hands to other parts of the fish, or by dipping them into the water, so that one hand is nearer to the upper surface of the electric organs than the other; yet the greater part of the shock or charge may pass at the same time in all directions over the surface of the fish, or through the substance of its body, or through the water contiguous to it. With respect to the other difficulties, he solves them by reasonings similar to those urged by Mr. Walsh, and by concurring experiments. Mr. Cavendish has confirmed these reasonings by means of his artificial torpedo, which is a piece of wood A B C F G D E (*Plate XV. Electricity, fig. 4.*) of which the part A B C D E is cut into the shape of the torpedo, and $16\frac{3}{4}$ inches long from A to D, and $10\frac{3}{4}$ inches broad from B to E: the part C F G D is forty inches long, and serves for a handle. M N n m is a glass tube let into a groove cut in the wood: W w is a piece of wire passing through the glass tube, and soldered at W to a thin piece of pewter, R r, lying flat on the wood, and intended to represent the upper surface of the electric organs: on the other side of the wood there is placed such another glass tube, with a wire passing through it, and soldered to another piece of pewter like R r, intended to represent the lower surface of those organs. The whole part A B C D E is covered with a piece of sheep-skin leather. In making experiments with this apparatus, after thoroughly soaking it in water of the saltness of the sea, made by dissolving one part of common salt in thirty of water, the end of one of the wires is fastened to the negative side of a large battery, and when it is sufficiently charged, the positive side is touched with the end of the other wire; by which means the battery will be discharged through the torpedo. In experiments with this torpedo under water, Mr. Cavendish uses a trough, A B C D E (*fig. 5.*), the length B C of which is nineteen inches, the depth A B fourteen inches, and the breadth thirteen inches. The battery which he used was composed of forty-five jars, of very thin glass, disposed in seven rows, and so contrived, that he could use any number of rows at pleasure. Mr. Cavendish was enabled, by means of this apparatus, when immersed in water, to give shocks much resembling those given by the living animal. He felt similar concussions likewise when he dipped his hands in the water, at the distance of two or three inches from it: and as it is affirmed, that a person accidentally treading on the living fish, when buried in the sand, is sometimes shocked by it, he imitated this experiment with his artificial torpedo, and received shocks from it. The events, indeed, in the greater part of his experiments, too numerous to be recited in this place, with this artificial fish, relative to the shock, seem to agree sufficiently with those made by Mr. Walsh with the living animal. The experiments which Mr. Cavendish made with this machine, relative to the circumstance of the shock of the real torpedo not being able to pass through any sensible space of air, appear likewise to correspond with Mr. Walsh's trials. A piece of sealing-wax covered with tin-foil freely conducted a shock from the

artificial torpedo; but on making as small a separation as possible through the metal with a penknife, the shock would not pass. See on the subject of this article for Mr. Walsh's papers, *Phil. Transf.* vol. lxxiii. part ii. p. 461. *Id.* vol. lxxiv. part ii. p. 464. For Mr. Hunter's paper, *Id.* vol. lxxiii. part ii. p. 481. For Dr. Ingenhouz's, *Id.* vol. lxxv. part i. p. 1. For Mr. Cavendish's, *Id.* vol. lxxvi. part i. p. 169. See also Sir John Pringle's *Six Discourses, &c.* by Dr. Kippis, p. 45, &c.

TORPEDO, a machine so called, invented by Mr. Fulton of the United States, and designed to blow up the largest ships. It is an apparatus of which the principal piece is a copper-box, inclosing a certain quantity of gunpowder, and prepared with an interior spring which sets fire to the powder, at the same time that the whole is inclosed in a covering of cork, or some other light wood, to make the torpedo float under the surface of the water. It is placed under the keel of the vessel to be destroyed, by means of an harpoon directed against the sides of the ship.

TORPEN, in *Geography*, a town of Transylvania; 4 miles S.S.W. of Bistriz.

TORPERLEY, a town of England, in the county of Chester; 10 miles S.E. of Chester.

TORPETCHIN, a town of Thibet; 100 miles S. of Haratoubé.

TORPHICHEN, a parish in the shire of Linlithgow; Scotland, is situated four miles S. by W. from the shire-town, and extends about nine miles in length, and two and a half in breadth. Its general appearance is hilly, particularly towards the E. end, where the hill called Cairn Naple is situate, which is elevated 1498 feet above the level of the sea. The greater part of the parish is inclosed; and where the land is unfit for cultivation, considerable plantations have been made. Coal is abundant; and here are large quarries of excellent free-stone; several seams of iron-stone, rich in metal; and a strong chalybeate spring. In the year 1811, the population was returned as 1131, occupying 236 houses. The hospital or preceptory of Torphichen, long the principal residence of the knights of St. John of Jerusalem, was founded, in 1120, by king David I. The choir and a square tower still remain, and are fine specimens of the elegance and beauty of the architecture. There are two wings, one on the S. and the other on the N. side; and evident marks of other two on the E. and W. This preceptory had the privilege of sanctuary, which is supposed to have extended a mile in every direction: there is a stone in the church-yard as a centre, and four others at the distance of a mile, E., W., N., and S., with St. John's cross upon them, which stand about two feet above the surface. At the Reformation, the vast estates of that opulent order were converted into a temporal lordship, in favour of Sir James Sandilands, lord St. John of Jerusalem; in which noble family the title of lord Torphichen still remains. Near Loch-Coat, in this parish, are the ruins of a castle, which still display baronial gloom and grandeur. About a mile to the E. of the village, is an altar of four great unpolished whin-stones, which is said to have been a druidical place of worship; and about a mile to the N.W., is Boudane Hill, upon which are evident marks of a military station.—*Beauties of Scotland*, vol. iii. Linlithgow. *Carlisle's Topographical Dictionary of Scotland.*

TORPON, a town of Little Bucharria; 20 miles S.W. of Acfu.

TORQUATA, in *Zoology*, a name given by many authors to the common or water-snake, from the remarkable ring it has about its neck. See NATRIX.

TORQUE, in *Heraldry*, a round roll of cloth twisted

and stuffed: such is the bandage frequently seen in armories about the heads of Moors, savages, &c.

It is always of the two principal colours of the coat. The torque is the least honourable of all the enrichments worn on the helmet by way of crest.

TORQUEMADA, JOHN DE, in *Biography*, a cardinal, was born at the place in Spain whence he took his name in 1388, and entered at the age of 15 into the Dominican order at Valladolid. He distinguished himself at home, in the university of Paris, and in various other places, and at length was promoted to the cardinalate, under the title of St. Sixtus, in 1439. After having been successively translated from one bishopric to another, he died in 1468, at the age of 80 years. He published a great number of works on theology, and in defence of the papal authority. Among other preferments which he enjoyed, he was confessor to Isabella of Castile from her infancy; and such was the intemperate zeal that actuated him, he extorted from her a promise, that if she ever came to a throne, she would make the chastisement and destruction of heretics her principal object.

Another person of the same name was provincial in New Spain, and published a Spanish work under the title of "Monarquia Indiana;" or, A History of the Wars, Discoveries, Conquests, &c. in the West Indies, in 22 books, 3 vols. fol. 1615. Dupin. Moreri.

TORQUEMADA, in *Geography*, a town of Spain, in the province of Leon, on the Arlanza; 12 miles E. of Palencia.

TORQUILLA, in *Ornithology*, the name of a species of wood-pecker, more commonly known by the name of *jynx*, and called in English the *wry-neck*.

TORQUINO, in *Geography*, a river of Cuba, which runs into the Spanish Main, N. lat. 20°. W. long. 76° 57'.

TORR, a town of Arabia, in the province of Yemen; 32 miles E. of Loheia.

TORRALBA, a town of Spain, in New Castile; 7 miles N.E. of Ciudad Real.

TORRALVA, a town of Spain, in Navarre, 15 miles from Estella.

TORRANO, a town of Spain, in Navarre; 15 miles W. of Pamplona.

TORRÉ, FILIPPO DEL, in *Biography*, an eminent antiquary, was born at Ciudad de Friuli in 1657, and having acquired an extensive knowledge of jurisprudence, mathematics, and anatomy at the university of Padua, he sought farther improvement at Rome in 1687, and became an academician of the college of the Propaganda. He was afterwards employed as auditor to cardinal Imperiali, in his legation to Ferrara, and accompanying him on his return to Rome, he devoted his attention to the great work on the antiquities of Antium, which he published in 1700. In 1702 he was nominated by pope Clement XI. to the bishopric of Adria, and there he presided with great reputation until his death, in 1717. Among his writings we may mention as the principal, his "Monumenta Veteris Antii," 4to.; besides which, he published several other dissertations on antiquities, natural history, &c. and left many more in MS. Gen. Biog.

TORRE, JOHN MARIA DE LA, a celebrated Italian philosopher, was born at Rome in 1710, studied at the Clementine college, and was elected professor of mathematics and philosophy in the college of Ciudad, in the Frioul; and afterwards removed to Naples, where he taught the same sciences in the archiepiscopal seminary. In 1754 he was appointed librarian to the king of Naples, superintendent

of the royal printing-house, and conservator of the museum. In the construction of microscopes he is said to have made considerable improvements. He was a member of the principal academies in Italy, and a correspondent of those of Paris and Berlin, and of the Royal Society of London. He died in March 1782. His works, besides a Treatise on Arithmetic, are, "The Science of Nature," Naples, 1749, 2 vols. 4to.; Venice, 1750, 4to.; "Elementa Physicæ," Naples, 1767, 8vo.; "History of the Phenomena of Vefuvius," *ibid.* 1755, 4to.; "Microscopic Observations," *ibid.* 1776.

TORRE, in *Geography*, a town of Spain, in Catalonia; 6 miles S. of Lerida.

TORRE del Acri, or *Agri*, a town of Naples, in Basilicata, on the coast of the gulf of Tarento; 25 miles S.S.E. of Matera.

TORRE del Annuntiata, a town of Naples, in Lavora; 9 miles S.E. of Capua.

TORRE Calença, a town of the island of Corfica; 15 miles N.E. of Ajazzo.

TORRE de Candelaro, a town of Naples, in Capitanata; 11 miles W.S.W. of Manfredonia.

TORRE Capigliola, a town of the island of Corfica; 10 miles N. of Ajazzo.

TORRE del Capo di Rosito, a town of Naples, in Calabria Citra; 18 miles N.E. of Cassano.

TORRE Garabese, a town of the island of Corfica; 10 miles W.S.W. of Vico.

TORRE di Cedagna, a town of Spain, in Catalonia; 9 miles N. of Puycerda.

TORRE di Francolisi, a town of Naples, in Lavora; 8 miles N.W. of Capua.

TORRE di Galeria, a town of the island of Corfica; 15 miles S. of Calvi.

TORRE la Gattarella, a town of Naples, in Capitanata; 2 miles S. of Vieste.

TORRE Girolata, a town of the island of Corfica; 20 miles S. of Calvi.

TORRE del Greco, a town of Naples, in Lavora. This town was destroyed by an eruption of Vefuvius; yet the inhabitants, after the eruption, returned and rebuilt the town on the same spot; 5 miles S.E. of Capua.

TORRE Maggiore, a town of Naples, in Capitanata; 5 miles S.W. of St. Serviero.

TORRE di Mare, a town of Naples, in Basilicata; 20 miles S.E. of Matera.

TORRE di Mezzo, a town of Italy, in the department of the Mincio; 16 miles E.S.E. of Mantua.

TORRE Molina, a town of Spain, in Grenada; 12 miles from Antequera.

TORRE de Moncorvo, a town of Portugal, in the province of Tras os Montes, surrounded with a wall, and defended by a bastion and a castle. The number of inhabitants is about 1300; 42 miles S.S.W. of Bragança. N. lat. 41°. W. long. 6° 44'.

TORRE di Neopoli, a town of the island of Sardinia; 5 miles N. of Oristagna.

TORRE di Nogaro, a town of Italy, in the department of the Mincio; 11 miles E. of Mantua.

TORRE d'Oglio, a town of Italy, in the department of the Mincio, near its union with the Po; 11 miles S.S.W. of Mantua.

TORRE del Penna, a town of Naples, in Abruzzo Citra, on a promontory, near the Adriatic; 15 miles E. of Lanciano.

TORRE Rosso, a town of Naples, in the province of Otranto; 10 miles N. of Tarento.

TORRE de St. Basilio, a town of Naples, in Basilicata, on the coast of the gulf of Tarento ; 8 miles S.E. of Turfi.

TORRE St. Sufanna, a town of Naples, in the province of Otranto ; 7 miles S.E. of Oria.

TORRE de las Salinas, a town of Spain, in Valentia, near the coast of the Mediterranean, which carries on a great trade in salt, with which it is furnished by a small lake, formed by saline springs ; and though the water be apparently weakened by rain, yet is salt made of it by the exhalations of the sun. The usual quantity thus produced, one year with another, is about 900,000 fanegas, each fanega being 150lbs. weight ; but when heavy rains are succeeded by excessive heat, it comes little short of 1,500,000. This is the most considerable salt-work in all Spain ; 20 miles S.E. of Origuela.

TORRE de Sanguinazzo, a town of the island of Candia ; 9 miles E. of Retimo.

TORRE della Saffine, a town of Naples, in Capitanata ; 3 miles N.E. of Salpe.

TORRE Sicura, a town of the Popedom, in the marquisate of Ancona, on the Tronto, opposite Ascoli.

TORRE Tavignano, a town of the island of Corfica ; 28 miles S.E. of Corte.

TORRE di Vacarella, a town of Naples, in Capitanata ; 10 miles N.E. of Troja.

TORRE di Varano, a town of Naples, in Capitanata ; 20 miles W. of Viefte.

TORRE la Vega, a town of Spain, in the province of Biscay ; 11 miles S.W. of Santander.

TORRECILLA, a town of Spain, in Old Castile ; 11 miles S.E. of Najera.

TORRECILLAS, a town of Spain, in Estremadura ; 6 miles E.N.E. of Truxillo.

TORRECUSO, a town of Naples ; 5 miles W. of Benevento.

TORREDAL, a river of Norway, which runs into the sea near Christianfand.

TORREFACTION, formed of *torrefacere*, to roast, in *Metallurgy*. See **ROASTING**.

TORREFACTION, in *Pharmacy*, a kind of roasting, or affation, in which a drug is laid to dry on a metalline plate placed over or before coals, till it become friable to the fingers.

Torrefaction is particularly used, when, after reducing some drug, as rhubarb, or myrobalan, into powder, it is laid on an iron or silver plate, and that placed over a moderate fire till the powder begins to assume a darkish hue ; which is a mark, that those remedies have lost their purgative virtue, and have acquired a more astrigent one.

Formerly they used to torrefy opium, to get out some malignant parts fancied to be in it, before they dared use it in medicine ; but the effect was, that its volatile spirits and sulphur, in which its greatest virtue consists, were hereby evaporated.

TORREFIED EARTH, in *Agriculture*, that which has undergone the action of fire, or been burnt. It has been observed by the writer of a paper on peat in the third volume of the "Transactions of the Highland Society of Scotland," that the uncommon fertility of torrefied earth can scarcely have escaped the notice of any one ; but that it is difficult to account for the cause. It is suggested that torrefaction, by destroying the cohesive power of clay, may in that way render a soil containing torrefied earth more permeable to the roots of plants. But brick-dust, or burnt clayey matters, even when strewed on the surface of grass-ground, consumes the mosses, or plants of that kind, and produces a deep verdure and lively vegetation of sweet

herbage. It is stated by the author of the "Elements of Agricultural Chemistry," that when clay or tenacious earths are burnt, their power of absorbing moisture is lessened, and they are brought nearer to a state analogous to that of sands. That in the manufacture of bricks, this general principle is well illustrated : as, if a piece of dry brick-earth be applied to the tongue, it will adhere to it very strongly, in consequence of its power to absorb water ; but that after it has been burnt, there will be scarcely a sensible adhesion. The process of torrefaction or burning may, therefore, render an earth less compact, less tenacious and retentive of moisture ; and, when properly applied, may convert a matter that was stiff, damp, and, in consequence, cold, into one that is powdery, dry, and warm ; and much more proper as a bed for vegetable life.

Dr. Darwin, in his "Phytologia," has supposed that clay, during torrefaction, may absorb some nutritive principles from the atmosphere that may afterwards be supplied to plants ; but the earths are pure metallic oxyds, saturated with oxygen ; and the tendency of torrefaction, or burning, is to expel any other volatile principles that they may contain in combination. If the oxyd of iron in earths be not saturated with oxygen, torrefaction tends to produce its further union with this principle ; and hence in burning, the colour of clays changes to red. The oxyd of iron which contains its full proportion of oxygen, has less attraction for acids than the other oxyd, and is consequently less likely to be dissolved by any fluid acids in the earthy parts of land ; and it appears in this state to act in the same manner as the earths. And though it has been suggested, that the oxyd of iron, when combined with carbonic acid, is poisonous to plants ; and that one use of torrefaction is to expel the carbonic acid from it ; yet the carbonate of iron is not soluble in water, and is a very inert substance ; besides, a luxuriant crop of cresses has been raised by the writer in a soil composed of one-fifth carbonate of iron, and four-fifths carbonate of lime. Carbonate of iron, too, abounds in some of the most fertile soils of this country, particularly the red hop-soil. And there is no theoretical ground, it is said, for supposing that carbonic acid, which is an essential food of plants, should, in any of its combinations, be poisonous to them ; besides, it is known that lime and magnesia are both noxious to vegetation, unless combined with this principle.

The first of the above writers has likewise found, that cohesive earth which has suffered torrefaction, such, for instance, as brick-dust, is one of the most powerful agents in promoting the solubility of peat, and, consequently, not only of assisting in the cultivation of land of that sort, but in expediting the preparation of that earth as a manure. And as it has this very powerful effect in exciting the fertility of peat, kilns might, perhaps, be constructed, in which cohesive earth might be burnt either with the refuse of coal or peat-fuel. After the peat had been somewhat mellowed by the first culture as proposed, into a soil, a quantity of this brick-dust material might be spread out on the surface, after being turned up, to be harrowed in with the seed. But although the torrefaction or burning of clay for this purpose should not be attainable at a moderate expence, if a sufficient quantity of earth be once mixed with the peat, it will not be difficult to reduce that earth to the state of brick-dust. As when the viscidty of peat is destroyed, and its parts separated by the intervention of earthy particles, it is very susceptible of combustion ; it might be lightly turned over in the beginning of summer, and fire be communicated to it as soon as

it became dry. The fire, it is thought, would eat along the surface without penetrating deep, when a body of moist unaltered peat lay below, and not only convert the earth within its reach into brick-duft, but confume many of the incorruptible elastic fibres by which the foil is kept too loofe. And by the mixture of incombustible earth checking the rapidity of the combustion, most of the peat would be converted into a fort of charcoal, not ashes. The residue might be mingled with the subfoil, and the field would then be in excellent condition, it is said, for any crop, particularly for turnips; and there is, perhaps, no plant better adapted to such a situation, from its power to resist the autumnal frosts, by which some other cultivated plants are often ruined. See the Paper.

The same writer has, indeed, proved the great disposition of this powdery substance to produce fertility in a variety of experiments, which he has recorded in an elementary work on agriculture, already before the public. See Naismith's Elements of Agriculture.

TORREJON, in *Geography*, a town of Spain, in New Castile; 13 miles S. of Madrid.

TORREJONCILLOS, a town of Spain, in New Castile; 20 miles S. of Huete.

TORRELAGUNA, a town of Spain, in New Castile; 17 miles N. of Guadalaxara.

TORRELLA *de Mongri*, a town of Spain, in Catalonia, on the north side of the Ter, near its mouth; remarkable for a battle fought here between the French and Spaniards in the year 1694, in which the latter were defeated; 18 miles E. of Gerona.

TORREMOCHA, a town of Spain, in New Castile; 6 miles W. of Melina.

TORRENT, TORRENS, in *Hydrography*, a temporary stream of water, falling suddenly from mountains in which there have been great rains, or an extraordinary thaw of snow; sometimes making great ravages in the plains.

TORRENTE, in *Geography*, a town of Spain, in the province of Valentia; 5 miles S. of Valentia.

TORRENUOVA, a town of Spain, in New Castile; 23 miles S.E. of Ciudad Real.

TORREPORA, a town of Hindoostan, in Lahore; 20 miles W. of Nagorcote.

TORRES, a town of Spain, in the province of Granada, on the coast of the Mediterranean; 9 miles E. of Velcz Malaga.

TORRES, a river of Sardinia, which runs into the sea, about 10 miles N. of Sassari.

TORRES, *Cape*, a cape of Spain, on the coast of Asturia. N. lat. $43^{\circ} 37'$. W. long. $5^{\circ} 44'$.

TORRES *Islands*, a cluster of islands in the Indian sea, near the coast of Siam. N. lat. $11^{\circ} 25'$ to $11^{\circ} 48'$. E. long. $96^{\circ} 50'$ to 97° .

TORRES *Novas*, a town of Portugal, in Estremadura; 12 miles E. of Santaren.

TORRES *Vedras*, a town of Portugal, in Estremadura, one of the oldest towns in the kingdom, and containing four churches, an hospital, a castle, four convents, and about 2250 inhabitants; 21 miles N. of Lisbon.

TORRESIA, in *Botany*, a genus so named in the *Flora Peruviana*, p. 114, in honour of Jerome de las Torres, under-gardener of the botanic garden at Madrid. *De Theis*.

TORREXIMENO, in *Geography*, a town of Spain, in the province of Jaen; 8 miles W.N.W. of Jaen.

TORRICELLA, a town of Naples, in Principato Citra; 4 miles S.W. of Amalfi.—Also, a town of Naples, in Abruzzo Citra; 6 miles N. of Lanciano.—Also, a town of Italy, in the department of the Mincio; 10 miles S.S.W.

of Mantua.—Also, a town of Italy, in the department of the Panaro; 8 miles W.S.W. of Modena.

TORRICELLI, EVANGELISTA, in *Biography*, a very distinguished mathematician and philosopher, was born at Faenza in 1608, and at the age of eighteen he went to Rome to complete his education, and particularly to extend his acquaintance with mathematics, under the instruction of Benedetto Castelli, who was professor of mathematics in that city. After the perusal of Galileo's "Treatise on Motion," he composed a work of a similar kind, which being shewn to Galileo by Castelli, excited his admiration, and induced him to invite the young author to his house. But as Galileo died three months after his arrival, he proposed to return to Rome; he was diverted, however, from his purpose, by being appointed mathematician and philosopher to the grand duke Ferdinand II., who also advanced him to the mathematical chair at Florence. In this honourable station he assiduously prosecuted his speculations and experiments, till death prematurely deprived the world of the benefit which could not fail to result from them, in the year 1647, at the age of 39 years. His "Treatise on Motion," already mentioned, was published in a "Collection of his Mathematical Works" in 1644. Of his dispute with Roberval concerning the *Cycloid*, we have already given a short account under that article. But Torricelli's fame is sufficiently established by his discovery of the true principle upon which the barometer is constructed. (See TORRICELLIAN.) Torricelli was no less celebrated for his mathematical knowledge, evinced by his improvement of the science of indivisibles discovered by Cavalieri, and for his acquaintance with the principles of optics, by which he was led to improve the construction of telescopes and microscopes. His discoveries, by which his name is immortalized among the promoters of useful sciences, are recorded in his "Lezioni Accademiche," published at Florence in 1715, 4to. by Buonaventuri, with the life of Torricelli prefixed. The style with which he wrote in his native language was pure and elegant, and his general character was such as to command the respect and esteem of all who knew him.

TORRICELLIAN, a term very frequent among physical writers, used in the phrases *Toricellian tube*, or *Toricellian experiment*, on account of the inventor, Torricelli, a disciple of the great Galileo.

TORRICELLIAN *Tube*, is a glass tube, open at one end, and hermetically sealed at the other, about three feet long, and one-tenth of an inch in diameter. See BAROMETER.

TORRICELLIAN *Experiment*, is performed by filling the Toricellian tube with mercury, then stopping the open orifice with the finger, inverting the tube, and plunging that orifice into a vessel of stagnant mercury. This done, the finger is removed, and the tube sustained perpendicular to the surface of the mercury in the vessel.

The consequence is, that part of the mercury falls out of the tube into the vessel, and there remains only enough in the tube to fill from twenty-eight to thirty-one inches of its capacity, above the surface of the stagnant mercury in the vessel.

Those twenty-eight, &c. inches of mercury are sustained in the tube by the pressure of the atmosphere on the surface of the stagnant mercury; and according as the atmosphere is more or less heavy, or as the winds, blowing upwards or downwards, heave up or depress the air, and to increase or diminish its weight and spring, more or less mercury is sustained from twenty-eight inches to thirty-one.

There is a case, however, first taken notice of by Huygens (*Journal de Sçavans*, 1672. p. 111.) in which, if a glass tube of a small bore seventy or eighty inches in length, be well cleaned, and filled with mercury well purged

of air, &c. in the manner described under BAROMETER, and then carefully inverted into a vessel of stagnant mercury, the mercury, instead of coming down to the height just mentioned, at which the pressure of the atmosphere is able to sustain it, will continue to fill the tube, and stand at the height of seventy-five inches: but by striking the tube, or gently shaking it, the mercury will descend and settle at its proper height, as in the common barometer. This phenomenon is explained on the principles of the attraction of cohesion, which acts most powerfully in contact: for when the tube is clean, and the mercury well purged of air, many parts of the mercury, which, by the interposition of small air-bubbles, would be kept from touching the tube, are brought into contact with it, and those particles that are in the middle of the column adhere to those that are next to the sides of the tube, and thus form a compact column. Besides, the increase of attracting surface at the arched top of the tube, by means of which a greater number of mercurial particles may come into contact with the glass than those that recede from the contact of one to another, will also give an advantage to the attraction of the glass, and cause the mercury, immediately in contact with it, to adhere to it. That the attraction of cohesion, as already explained, is the cause of this phenomenon is plain, because the experiment will not succeed when the mercury is not well purged of its air, nor even then if the bore of the tube is large.

The Torricellian experiment makes what we now call the *barometer*.

TORRICELLIAN Vacuum, is the vacuum produced by filling a tube with mercury, and allowing it to descend to such a height as is counterbalanced by the pressure of the atmosphere, as in the Torricellian experiment and barometer. For the method of rendering this vacuum luminous by electricity, see **ELECTRICAL**, Exp. 15.

TORRICELLO, in *Geography*, a town of the duchy of Parma, on the Po; 12 miles N.N.W. of Parma.

TORRID ZONE, See **ZONE**.

TORRIGIA, or **TORREGLIA**, in *Geography*, a town of the Ligurian republic; 15 miles N.N.E. of Genoa.

TORRIJOS, a town of Spain, in New Castile; 15 miles N.W. of Toledo.

TORRIMORE HEAD, a cape of Scotland, on the E. coast of the island of Skye. N. lat. 57° 22'. W. long. 6° 2'.

TORRIN-BEG, a rock on the S.W. of the island of Mull. N. lat. 56° 19'. W. long. 6° 20'.

TORRINGTON, or **GREAT TORRINGTON**, as it is generally called, to distinguish it from a village of the same name, is a market-town in the hundred of Fremington, and county of Devon, England; 36 miles N.W. from Exeter, and 197 miles W. by S. from London. The town is situated, partly on the summit, and partly on the declivity of an eminence which forms the eastern bank of the river Torridge. On the south side are some slight vestiges of an ancient castle, the origin of which is unknown; though, according to Risdon, it was the head of a notable barony, which continued from the Conquest to the time of Edward I. Its site is now used as a bowling-green, and commands a fine prospect. The river is here seen to flow in a graceful current along a narrow valley, inclosed by sloping ridges, and having a beautifully wooded back-ground. Torrington was formerly invested with the privilege of having representatives in parliament; but no return has been made since the reign of Henry VI. Its government is vested in a mayor, eight aldermen, and sixteen burgessees, who act under a charter granted by queen Mary. The town consists chiefly of one long street, "indifferently beautified," says Risdon, "with

buildings very populous, and flourishing with merchants and men of trade." The population return of the year 1811, states the number of houses to be 414; the number of inhabitants 2151: the chief employ of the latter arises from the woollen manufacture. A weekly market is held on Saturdays; and here are four annual fairs. The parish contains two churches, the most ancient of which is furnished with a library. In the town are some ancient alms-houses, possessing the right of commoage on an extensive piece of ground given by William Fitz-Robert, baron of Torrington, in the reign of Richard I. Here is likewise a charity-school for thirty-two boys. Margaret, countess of Richmond, mother of Henry VII., resided some time in Torrington, and was a considerable benefactress to it.

At Fritheltoke, a village opposite Torrington, on the W. side of the Torridge, are the ruins of a priory, founded by sir Roger Beauchamp, in the reign of Henry III., for secular Augustine canons. At the dissolution, the annual revenues were valued at 127*l.* 2*s.* 4*d.* The site of the priory is now a farm-yard. The chief remains of the buildings are the walls of two or three apartments, the west window of the conventual church, which still continues perfect, and the great gate.

Near Torrington is Crofs, late the seat of H. Stevens, esq., a handsome mansion, looking down on the romantic scenery which encompasses the bridge and the banks of the Torridge.

A few miles from Crofs, southward, are the ruins of an old mansion called Heanton, formerly a seat of the Rolles, afterwards of lord Orford, and lastly of lord Clinton, who, after its late demolition by fire, cut down the oaks which were in the park, forming woods and groups of the noblest trees in the county.—*Beauties of England and Wales*, vol. iv. Devonshire, by J. Britton and E.W. Brayley, 1803. *Pol-whele's History*, &c. of Devonshire, folio, 1797.

TORRINGTON, a town of the state of Connecticut; 22 miles W.N.W. of Hartford.

TORRINGTON Bay, or *Bedford's Bay*, a bay on the S. coast of Nova Scotia; 3 miles N. of Halifax.

TORRO, a river of Africa, which runs into the Scherbro.

TORROFF, a town of Bengal; 70 miles N.E. of Dacca. N. lat. 24° 20'. E. long. 85° 18'.

TORRUM, a town of Sweden, in the province of Blekingen; 10 miles S.E. of Carlscrona.

TORRYBURN, a seaport town of Scotland, in Fifeshire, on the Frith of Forth, with a good harbour, to which belong thirteen vessels, amounting to upwards of 1000 tons.

TORSAKER, a town of Sweden, in Angermanland; 27 miles N. of Hernosand.—Also, a town of Sweden, in the province of Gestricia; 15 miles S.W. of Gesle.

TORSANG, a town of Sweden, in the province of Dalecarlia; 10 miles S. of Fahlun.

TORSAS, a town of Sweden, in the province of Smaland; 18 miles S.S.W. of Calmar.—Also, a town of Sweden, in the province of Smaland; 16 miles S.W. of Wexio.

TORSEERA, a town of Hindooſtan, in the circar of Sumbulpour; 16 miles S. of Sumbulpour.

TORSHELLA, a town of Sweden, in Sudermanland, on a river which runs into the Mælar lake; 46 miles W. of Stockholm.

TORSHOK, a town of Russia, on the route from Peterburgh to Moscow, 71 versts distant from Vyshney-Voloshok, remarkable for a spring superstitiously venerated and attracting pilgrims from all parts. This town has no less than 20 churches, some of stone; and is in a thriving condition. See **TORZOK**.

TORSIANO,

TORSIANO, a town of the Popedom; 10 miles N. of Perugia.

TORSKOG, a town of Sweden, in West Gothland; 53 miles N. of Uddevalla.

TORSO, a small island on the E. side of the gulf of Bothnia. N. lat. $63^{\circ} 37'$. E. long. $22^{\circ} 14'$.

TORSSA, a town of Sweden, in Helsingland, on a river which runs into the gulf of Bothnia; 6 miles W. of Hudwickswall.

TORSUTATAK, a town of East Greenland. N. lat. $59^{\circ} 56'$. E. long. $43^{\circ} 15'$.

TORT, in *Law*, denotes injustice, or injury, as *de son tort même*, in his own wrong, &c.

Hence, also, *tort-feasor*, &c. The word is pure French, where it signifies the same.

Actions upon torts, or wrongs, are all personal actions for trespasses, nuisances, assaults, defamatory words, and the like.

TORT, *Executor de son*. See EXECUTOR.

TORTICOLLIS, from *torqueo*, to twist, and *collum*, the neck; the *Wryneck*; which see.

TORTO, in *Geography*, a small river of Spain, which runs into the Orbeza, in the province of Leon.—Also, a river of Sicily, which runs into the sea, 5 miles E. of Termini.

TORTOISE, in *Zoology*. See TESTUDO.

Dr. Parsons has remarked a singularity in the structure of the wind-pipe of the land-tortoise, which for a few inches from the epiglottis is single, but soon divides into two; and as it descends with the œsophagus, forms a folded ring outward on each side, and turns down again to enter the lungs; so that this animal has the advantage of a double aspera arteria, with a volution in each; which shews that this provision is intended to contain a greater portion of air than ordinary, while he is under-ground in winter. It has been observed likewise, that the principal use of the lungs in tortoises is to render them specifically lighter or heavier in the water, by their inflation and compression at pleasure, as fishes do by their swimming bladders; and such a power of long inspiration seems to be as necessary in the land-tortoise as in that of the sea; because, in many countries where they breed, they are known to go into the ground, and lie concealed for several months, and several species of land-tortoises go into ponds or canals in gardens, where they are kept, and remain long under water. *Phil. Transf.* vol. lvi. p. 213.

TORTOISE-Shell, the shell, or rather scales of the testaceous animal, called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c. Mr. Catesby observes, that the hard strong covering, which encloses all sorts of tortoises, is very improperly called a shell; being of a perfect bony contexture; but covered on the outside with scales, or rather plates, of an horny substance: which are what the workmen call tortoise-shell. *Phil. Transf.* N^o 438, p. 117.

It is the *testudo imbricata* of Linnæus alone, which furnishes that beautiful shell, so much admired in Europe. See TESTUDO *Imbricata*.

The lamellæ or plates of the shell of this tortoise, called the *hawk's-bill turtle*, are much stronger, thicker, and clearer than those of any other kind, and constitute the sole value of the animal. They are semi-transparent, and elegantly variegated with whitish, yellowish, reddish, and dark brown clouds and undulations, so as to constitute, when properly prepared and polished, one of the most elegant articles for ornamental purposes. These laminae form the external coating, and this is raised or separated from the bony part, which it covers, by placing fire beneath the shell; the heat soon

causing the plates to start, so as to be easily detached from the bone. These plates vary in thickness, according to the age and size of the animal, and measure from an eighth to a quarter of an inch in thickness. A large turtle is said to afford about eight pounds of tortoise-shell; or, according to M. Schoepf, from five to fifteen or twenty pounds; and unless the animal itself be about the weight of 150 pounds, the shell is not worth much.

“In order to bring tortoise-shell into the particular form required on the part of the artist,” says Dr. Shaw, “it is steeped in boiling water, till it has acquired a proper degree of softness, and immediately afterwards committed to the pressure of a strong metallic mould of the figure required; and where it is necessary that pieces should be joined so as to compose a surface of considerable extent, the edges of the respective pieces are first scraped or thinned, and being laid over each other during their heated state, are committed to a strong press, by which means they are effectually joined or agglutinated. These are the methods also by which the various ornaments of gold, silver, &c. are occasionally affixed to the tortoise-shell, which is not capable of being melted, as vulgarly supposed. The Greeks and Romans appear to have been peculiarly partial to this elegant ornamental article, with which it was customary to decorate the doors and pillars of their houses, their beds, &c. In the reign of Augustus, this species of luxury seems to have been at its height in Rome.” *Shaw's General Zoology*, vol. iii. pt. 1.

The Egyptians, says Mr. Bruce in his *Abyssinian Travels*, dealt very largely with the Romans in this elegant article of commerce. According to Pliny, the cutting of them for inlaying or inlating was first practised by Carvilius Pollio; and this circumstance leads us to presume, that the Romans were not acquainted with the art of separating the laminae by fire placed in the inside of the shell, when the meat is taken out; for these scales, though they appear perfectly distinct and separate, nevertheless adhere, and more frequently break than split, where the mark of separation may be distinctly seen. Martial says, that beds were inlaid with it. Juvenal and Apuleius mention, that the Indian bed was all-over shining with tortoise-shell on the outside, and swelling with stuffing down within. The immense use made of it at Rome may be inferred from what Velleius Paterculus says, who observes, that when Alexandria was taken by Julius Cæsar, the magazines were so full of this article, that he proposed to have made it the principal ornament of his triumph, as he used ivory afterwards, when triumphing for having happily finished the African war. This substance has been, in more modern times, a great article in the trade to China.

Tortoise-shell colour may be given to horn, by first pressing the horn into proper plates or scales, and tempering two parts of quick-lime and one of litharge to the consistence of a soft paste with soap-ley. Let this paste be laid over all the parts of the horn, except such as are proper to be left transparent, and thus let it remain till it be thoroughly dry; when the paste being brushed off, the horn will be found partly opaque and partly transparent, like tortoise-shell. Semi-transparent parts may be added, by mixing whitening with some of the paste to weaken its effect in particular places, by which means spots of a reddish-brown will be produced, which will increase the beauty of the work as well as its resemblance of real tortoise-shell. *Haudmaid to the Arts*, vol. i. p. 518.

TORTOISE, in the *Military Art*. See TESTUDO.

TORTOISE, *River of*, in *Geography*, a river of North America, in Louisiana and Florida, formed by the Mississippi.

TORTOLA.

TORTOLA, a town of Spain, in New Castile; 5 miles N.E. of Guadalaxara.—Also, a town of Spain, in New Castile; 8 miles S. of Cuenca.—Also, one of the Virgin islands in the West Indies, first settled by a party of Dutch Buccaneers, who built a fort for their protection; but who, in the year 1666, were driven out by another party of the same adventurers, calling themselves English, and pretending to take possession for the crown of England; and the English monarch, if he did not commission the enterprise, made no scruple to take the benefit of it: for Tortola and its dependencies were soon afterwards annexed to the Leeward island government, in a commission granted by king Charles II. to Sir William Stapleton. The Dutch had done little towards the cultivation of the island, when they were expelled; but the chief merit of its improvements was reserved for some English settlers from the little island of Anguilla, who, about a century and a quarter ago, embarked with their families and settled in the *Virgin Islands*; which see. Tortola is not more than 15 miles long and 6 miles broad. Its chief and almost only staple productions are sugar and cotton. N. lat. 18° 20'. E. long. 64° 20'.

TORTOLI, a town of the island of Sardinia, near the E. coast; 50 miles N.N.E. of Cagliari.

TORTONA, a town of France, in the department of Marengo, on the Scrivia; late the see of a bishop, suffragan of Milan, with a good citadel, situated on an eminence. This place has often been taken and retaken during the different wars in Italy. It gives name to a district called Tortonese; 9 miles E. of Alexandria. N. lat. 44° 53'. E. long. 8° 52'.

TORTORELLA, a town of Naples, in Principato Citra; 5 miles N.E. of Policastro.

TORTORICI, a town of Sicily, in the valley of Demona; 30 miles N.W. of Taormina. N. lat. 38° 9'. E. long. 15°.

TORTOSA, a town of Spain, in the province of Catalonia, situated near the Ebro, about 15 miles from its mouth; the see of a bishop, suffragan of Saragossa. It is said to have been founded 2000 years before the Christian æra, but the proofs of this illustrious origin are unfortunately lost. Scipio gave it the name of "Dordosa," and made it a municipal city. Among the numerous and trifling combats between the Spaniards and the Moors, there was one in which the women of Tortosa signalized themselves. They courageously mounted the ramparts of their city, and performed such prodigies of valour, that Raimond Berenger, the last count of Barcelona, instituted for them, in 1170, the military order of the hacha, or flambeau. They merited and obtained the same day several honourable privileges, which exist not at present; they have however preserved the right of precedence in matrimonial ceremonies, let the rank of the men be ever so distinguished. The most remarkable buildings are the cathedral and the castle; the latter of which is a mile square, and in a state of decay; and only serves as a place of residence for a governor; 81 miles S.E. of Saragossa. N. lat. 40° 47'. E. long. 0° 26'.—Also, a sea-port of Syria, in the pachalic of Tripoli, anciently called "Antaradus" and "Orthosia." This town appears to have been built about the fifth or sixth century; it is situated on the sea, and may be about three-quarters of a mile in circumference. The ancient walls are of large hewn stone; without them there are other lower walls, with a fosse round them. At the N.W. corner there are great remains of the castle, and the present town is within the walls of it, which are strong, and built of large hewn stone, rusticated. They are of a surprising height, being at least fifty feet high, and the whole is near half a mile in circuit. Within the castle there is a church. Towards the E. cor-

ner of the city there is also a very beautiful large church; it is built of hewn stone inside and out, and consists of three naves; it does not seem to have been finished, and probably is a building of the sixth century; it is of the Corinthian order; and the arches, which are executed with the plain olive leaf, are built on square pillars, covered on the four sides with semi-circular pilasters. The pulpit was fixed to one of the pillars, and over it there is an inscription in the Syriac language. When Jerusalem was in the hands of the Christians, Tortosa was the see of a bishop, suffragan of Tyre; 35 miles N. of Tripoli. N. lat. 34° 55'. E. long. 35° 58'.—Also, a river of Syria, which runs into the Mediterranean, between Antioch and Tripoli.—Also, a cape of Spain, on the coast of Catalonia. N. lat. 40° 40'. E. long. 0° 47'.

TORTUE, a river of America, which runs into the Wabash, N. lat. 39° 30'. W. long. 87° 55'.

TORTUES, a river of Louisiana, which runs into the Missouri, N. lat. 38° 26'. W. long. 94° 24'.

TORTUGA SALADA, an island in the Caribbean sea, about 36 miles in circumference; the east end is full of rugged and broken rocks, which stretch themselves a little way out to sea. At the south-east part is an indifferent good road for shipping, and much frequented in peaceable times by merchantmen, which come hither to lade salt, from May to August: for at the east end is a large salt-pond, within 200 paces of the sea. Near the west extremity of the island, on the south side, there is a small harbour, and some fresh water. The end of the island is full of shrubby trees; but the east end is rocky, and bare of trees, producing only coarse grass. Upon it are some goats, but not many. The turtles or tortoises come into the sandy bays to lay their eggs, and from hence the island has its name. There is no anchoring any where but in the road where the salt-ponds are, or in the harbour. N. lat. 11° 7'. W. long. 64° 30'.

TORTUGA, an island about six miles from the north coast of the island of Hispaniola, about 40 miles in circumference. N. lat. 20° 5'. W. long. 72° 40'.

TORTUGAS POINT, a cape of South America, on the coast of Chili, near Coquimbo.—Also, the south point of the port of Coquimbo, on the coast of Chili. The road or harbour is well sheltered, but will not contain above 20 or 30 vessels safely. S. lat. 29° 37'.

TORTUGAS Shoals, shoals and rocks in the gulf of Mexico, near the coast of East Florida. N. lat. 24° 36'. W. long. 82° 50'.

TORTUGAS, *Dry*, shoals in the Florida streams, at the entrance of the gulf of Mexico. N. lat. 24° 40'. W. long. 82° 25'.

TORTUGILLA, a small island in the Spanish Main, near the coast of South America. N. lat. 8° 45'. W. long. 76° 20'.

TORTULA, in *Botany*, Screw-moss, an Hedwigian genus of Mosses, whose essential character, of the spiral fringe, is expressed in the name, derived from *tortus*, twisted. The same appellation was subsequently bestowed on a genus of the *Didymania*, in allusion to its twisted corolla, by the late Dr. Roxburgh, who not being conversant with cryptogamic botany, was not perhaps aware of the preoccupation of the name. (See **STREPTIUM**.)—Hedw. Fund. v. 2. 92. t. 8. f. 38, 39. Sp. Musc. 122. Schreb. Gen. 760. Mart. Mill. Dict. v. 4. Sm. Engl. Bot. 1101. Fl. Brit. 1249. Compend. 171. Prodr. Fl. Græc. Sibth. v. 2. 283. Swartz Musc. Suec. 38. Turn. Musc. Hib. 43. (Barbula; Hedw. Fund. v. 2. 92. v. 1. t. 6. f. 29—32. Sp. Musc. 115.)—Clafs and order, *Cryptogamia Musci*, Nat. Ord. *Musci*.

TORTULA.

Eff. Ch. Capsule oblong. Fringe simple, of numerous capillary teeth, spirally and repeatedly twisted together.

This is a most natural genus, the character of whose fringe cannot be mistaken. *Barbula* of Hedwig differs only in having round-headed male flowers, on a separate plant from the female, instead of axillary bud-like ones, on the same individual. This is a difficult and obscure distinction, without any natural difference. Of *Barbula* Hedwig defines twelve species, of *Tortula* three. Of the two genera united, nineteen are now enumerated as natives of Britain and Ireland only, exclusive of five of Hedwig's, not as yet discovered among us, so that twenty-four are known in all.

The habit of the genus here described is rather dwarf; the stems erect, sometimes short or nearly wanting; root fibrous, mostly perennial; leaves entire; fruit-stalks terminal or lateral; capsule nearly erect, generally even, rarely furrowed; lid conical or awl-shaped; fringe long, brown, or deep red, elegantly twisted, its points rather loose and spreading.

The species are, in many cases, difficult to ascertain, and probably some of the smaller ones are too much multiplied. All our native ones are figured in *English Botany*. We shall here select some of the principal, in order to exhibit, as in other instances, a compendious view of the genus.

T. rigida. Rigid Screw-moss. Fl. Brit. n. 1. Engl. Bot. t. 180. (*Barbula rigida*; Hedw. Crypt. v. 1. 65. t. 25. *Bryum rigidum*; Hudf. 477. *B. acaulon*, *erica tenuifolia* Gerardi folio; Dill. Musc. 388. t. 49. f. 55.)—Stem very short. Leaves spreading, rigid, involute, obtuse, ribless. Capsule cylindrical. Lid conical.—Found on rocks, walls, chalky banks and cliffs, bearing capsules in the winter and early spring, not only in England, but in various parts of Europe, from Sweden to Greece. The writer of the present article first discovered and distinguished this humble moss, since the time of Dillenius, on a bank on the right hand of the road from Norwich towards Yarmouth, a little beyond Thorpe. It agrees in size with the most common of mosses, *T. muralis*, hereafter mentioned, but differs in the thickness and dark colour of its almost linear leaves, which have no hair at the point. The fruit-stalk is solitary, red, half an inch to an inch high. Capsule inclining, cylindrical, smooth, dark brown, with a slender veil and lid. Fringe brown, of thirty-two fine teeth. The foliage is incurved when dry.

T. convoluta. Convoluted Screw-moss. Fl. Brit. n. 5. Engl. Bot. t. 2382. (*Barbula convoluta*; Hedw. Crypt. v. 1. 86. t. 32, excluding the *Mnium setaceum* of Linnæus. *Bryum convolutum*; Dickf. Crypt. fasc. 2. 6. H. succ. fasc. 1. 20. *B. stellare nitidum pallidum*, *capulis tenuifimis*; Dill. Musc. 381. t. 48. f. 44.)—Branches short. Stem-leaves lanceolate, keeled; those of the sheath obtuse, convoluted and ribless. Lid taper, oblique.—Native of sandy heaths, dry banks and walls, in England, Ireland, Sweden, and Germany, bearing fruit in winter and spring. The perennial roots bear broad, dense patches of very low leafy stems, whose branches are extremely short. Leaves short, imbricated, of a full bright green, spreading, ovato-lanceolate, pointless, single-ribbed. Sheaths at the base of the fruit-stalks very large, solitary between the branches, conspicuous for the pale green hue of their convoluted ribless scales. Fruit-stalks slender, wavy, of a pale lemon-colour, an inch high. Capsule slender, incurved, pale brown, smooth, with a slender oblique lid, half as long as itself.

T. nervosa. Rib-sheathed Screw-moss. Compend. n. 6. Engl. Bot. t. 2383. (*T. convoluta*; Swartz Musc. Succ.

41. Schrad. Spicil. 66.)—Stem much branched. Leaves all ovate, acute, keeled, with a midrib. Sheaths between the branches, imbricated.—More common than the last, in England, Sweden, and Germany, bearing capsules in March. The tufts of this are much higher, the branches being longer and more numerous. Leaves more ovate and pointed; those of the sheath more numerous, ribbed, imbricated, not rolled together, differing little from the proper foliage. Fruit-stalks tawny, or red. Capsule erect, somewhat ovate, smooth, with a shorter thicker lid than that of *T. convoluta*, with which the present species has usually been confounded.

T. stellata. Starry Furrowed Screw-moss. Fl. Brit. n. 6. Engl. Bot. t. 2384. (*Bryum stellatum*; Dickf. Crypt. fasc. 2. 6, excluding the synonyms.)—Stem none. Leaves ovate, keeled, incurved. Capsule erect, ovate, somewhat cylindrical, furrowed. Lid oblique.—Hitherto gathered only by our great English cryptogamist Mr. Dickson, about Banks, and by the sides of rivers, in Scotland. The synonyms he has applied to it are justly pointed out by Hedwig as erroneous, and belong in fact to three different species. But Hedwig himself errs far more unaccountably, in asserting Mr. Dickson's moss to be merely *T. convoluta*. The want of a stem, smaller size of the whole plant, and, above all, the strongly furrowed capsule, singular perhaps in the whole genus, afford sufficient distinctions. The fringe and lid are as long as the capsule; veil much longer. There appears to be no sheath to the solitary fruit-stalk, whose height is half an inch.

T. ruralis. Great Hairy Screw-moss. Ehrh. Crypt. n. 184. Fl. Brit. n. 7. Engl. Bot. t. 2070. (*Barbula ruralis*; Hedw. Sp. Musc. 121. *Bryum rurale*; Linn. Sp. Pl. 1581. *B. rurale unguiculatum hirsutum*, *elatius et ramosius*; Dill. Musc. 352. t. 45. f. 12.)—Stem branched. Leaves obtuse, recurved, hair-pointed; the uppermost stellated. Capsule cylindrical, somewhat ovate.—Common on walls, roofs, and the trunks of trees, throughout Europe from Sweden to Greece, bearing fruit from January to April. This is much larger than any of the foregoing, the stems, mostly about two inches high, composing broad cushion-like patches, of a dirty hoary aspect in dry weather; dark green in wet; bearing abundance of upright capsules, on long red stalks, in winter and spring. The leaves, recurved in every direction, are very abrupt, with a strong rib, ending in a long, roughish, wavy hair. Capsule slender, the teeth of its fringe united at the bottom into a firm, partly perforated, tube, which last character in this, the *subulata*, and a few other *Tortula*, has given occasion to Mohr to establish a genus by the name of *Syntrichia*; but it seems to us better avoided.

T. subulata. Awl-shaped Screw-moss. Hedw. Sp. Musc. 122. t. 27. Fl. Brit. n. 8. Engl. Bot. t. 1101. (*Bryum subulatum*; Linn. Sp. Pl. 1581. Curt. Lond. fasc. 3. t. 66. *B. capulis longis subulatis*; Dill. Musc. 350. t. 45. f. 10.)—Stem nearly simple, short. Leaves ovato-lanceolate, pointed. Capsule cylindrical. Lid awl-shaped, straight.—Common in damp shady places, in the southern and middle countries of Europe; rare in Sweden, and even in Scotland. It forms dense perennial tufts, of a fine deep green, bearing capsules in March and April. The leaves are broad, nearly obovate, tipped with a point, sometimes elongated into a hair, when it becomes the *T. pilosa* of Schrader's *Spicilegium*, 66. The fruit-stalks are terminal, an inch or more in height, rather stout, but seldom straight. Capsule almost erect, long and slender, with a long taper lid and veil. Fringe united into a spiral tube for three quarters of its length.

T. muralis. Wall Screw-moss. Hedw. Sp. Musc. 123. Fl. Brit. n. 9. Engl. Bot. t. 2033. *Bryum murale*; Linn. Sp. Pl. 1581. *B. tegulare humile, pilosum et incanum*; Dill. Musc. 355. t. 45. f. 14.)—Stem mostly simple, very short. Leaves ovate, acute, hair-pointed. Capsule cylindrical, slightly elliptical. Lid conical.—This is perhaps the most universal of all mosses throughout Europe. Every wall and bank is covered with it, and the abundant capsules, produced in winter and spring, remain in a dry and empty state almost throughout the year. The roots are perennial. Stems very short, though sometimes divided, composing broad dark-green patches, not dense elevated tufts, and rendered hoary by the terminal white hairs of the leaves. These hairs, however, vary in length, and are sometimes scarcely discernible. Fruit-stalk terminal, straight, reddish-brown, near an inch high. Old capsule a little curved when the fringe falls off. The latter is not so much twisted as in most other species, the teeth, all separate and parallel, making hardly more than one turn. Lid red, not half so long as the capsule, slightly oblique. Veil as long as both together, slender, brownish.

T. cuneifolia. Wedge-shaped Screw-moss. Fl. Brit. n. 10. Engl. Bot. t. 1510. (*Bryum cuneifolium*; Dickf. Crypt. fasc. 3. 7. *B. murale* ♂; Hudf. 477. *B. humile, pilis carens, viride et pellucidum*; Dill. Musc. 356. t. 45. f. 15.)—Stem very short, mostly simple. Leaves obovate, reticulated, pellucid, slightly pointed. Capsule cylindrical. Lid conical.—Found on banks and sandy ground, at Streatham, Surrey, and abundantly about Oxford, according to Dillenius. Mr. D. Turner gathered the specimens figured in Engl. Bot. on some old banks at Hopton, near Yarmouth. This moss is said to be biennial, bearing capsules in the early spring, and composing broad indeterminate patches. When carefully examined, it cannot be confounded with any variety of the last. The leaves are of a brighter green, strongly reticulated, pointless. Capsule more oval, with a longer, more awl-shaped, lid; its fringe bright red, or crimson, repeatedly and closely twisted together, which alone would distinguish this species from the preceding.

T. tortuosa. Frizzled Mountain Screw-moss. Hedw. Sp. Musc. 124. Fl. Brit. n. 12. Engl. Bot. t. 1708. (*Bryum tortuosum*; Linn. Sp. Pl. 1583. Dickf. Dr. Pl. 48. *B. cirratum, fetis et capsulis longioribus*; Dill. Musc. 377. t. 48. f. 40.)—Stem branched, level-topped. Leaves linear inclining to lanceolate, keeled; twisted and undulated when dry. Capsule cylindrical, slightly ovate. Fringe lax.—Plentiful on the mountains of Wales, Scotland, and the north of England, Derbyshire, &c. as well as in Sweden, Switzerland, Germany, Italy, and, according to Dillenius, in Virginia. It bears capsules in summer, but not very constantly. A large and handsome species, whose stems, from two to four inches high, compose broad and soft tufts, of a most beautiful green, the leaves being long and taper, frizzled when dry, especially at the rough, or minutely crenate, edges. Fruit-stalks an inch and a half or two inches high, bright crimson; pale yellow at the summit. Capsule inclining, slender, smooth, light brown, crimson at the mouth; finally erect. Lid taper, half as long as the capsule. Fringe long, crimson, gradually unrolled, and partly spreading or straight, approaching the character of a *TRICHOSTOMUM*. See that article hereafter.

T. barbata. Bearded Lateral Screw-moss. Fl. Brit. n. 14. Engl. Bot. t. 2391. (*Bryum barbatum*; Curt. Lond. fasc. 4. t. 65. *B. unguiculatum et barbatum, tenuius et stellatum*; Dill. Musc. 384. t. 48. f. 48.)—Stem

branched from the base. Leaves elliptic-lanceolate, spreading, somewhat revolute. Fruit-stalks lateral. Capsule ovate.—Native of walls and barren heaths, in the winter and spring, said to be not unfrequent about London, particularly at Charlton, where nevertheless we have many a time sought it in vain. Mr. Hudson is reported to have confounded this species with *T. convoluta*, or perhaps *neruosa*, above described, though certainly none of the genus can be more essentially unlike. The stems are level-topped, branched from the base, clothed with dark-green, single-ribbed, beardless leaves, recurved when dry; the uppermost forming a kind of star at the top of each branch. The fruit-stalks seem to spring from the base of each branch; yet the flower, to which each owes its origin, perhaps terminated the shoot of the preceding season. Capsule small, erect, ovate, polished. Fringe red, not very much twisted, more than half the length of the capsule. The lid is represented by Curtis nearly as long as the capsule, awl-shaped, and oblique. The specific name was meant to contrast this moss with the following, supposed to have no fringe; so that few names can be more exceptionable than either.

T. imberbis. Deciduous Screw-moss. Fl. Brit. n. 15. Engl. Bot. t. 2392. (*Bryum imberbe*; Linn. Mant. 309. *B. tenue, imberbe et pallidum, foliis crebrioribus*; Dill. Musc. 382. t. 48. f. 46.)—Stem branched. Leaves awl-shaped, spreading; ovate at their base. Stalks about the upper part of the branches. Capsules cylindrical, somewhat elliptical.—Found on dry banks, walls, and amongst grass, perfecting its capsules very early in the spring. This has much the habit of the last, but its leaves are of a paler yellowish-green, more tapering and channelled, turning inward in drying. Fruit-stalks purplish, an inch high. Capsule more cylindrical and longer, while the lid is shorter than in *T. barbata*. Fringe light brown, very soon deciduous, whence Dillenius thought it to be wanting, and his definition led Linnæus to apply the faulty name, which still sticks to this species.

T. arislata. Short-pointed Screw-moss. Fl. Brit. n. 16. Engl. Bot. t. 2393. (*Bryum aristatum*; Dickf. Crypt. fasc. 4. 12. t. 11. f. 7.)—Stem branched, level-topped. Leaves oblong, obtuse, with a minute point; curved inward and twisted when dry. Capsule cylindrical.—Found on walls at Croydon, Surrey, by Mr. Dickson, who first described this moss, and to whom we are indebted for specimens. The stems are perennial, branched and level-topped, much in the manner of the two foregoing. Leaves rather abrupt, with a very small terminal point: by drying they become twisted, enfolding the branch in a spiral order, and are neither recurved nor inflexed. Fruit-stalks terminal, crimson, scarcely an inch high. Capsule cylindrical, of a light shining brown, thin and semi-pellucid. Lid incurved, tapering, tawny, almost equal in length to the capsule. Fringe soon falling off.

TORTURA, or TANTUR, in *Geography*, a town of Palestine, on the coast of the Mediterranean, called in the scripture *Dor, Dora*, and *Nepbath*. Joshua took it from the Canaanites, and it fell to the tribe of Manasseh. Tryphon, tyrant of Syria, after the murder of Antiochus VI. fled to this place for shelter; but he was soon compelled to abandon it, and shortly after lost his life. In the times of Christianity it was erected into a bishopric under the archbishop of Cæsarea. It is at present a village only. The environs abound in grain, cotton, and fruit: wheat in particular is abundant, and of a quality superior to the other parts of Palestine and Syria; 15 miles S. of Acre. N. lat. 32° 35'. E. long. 34° 2'.

TORTURA, a word appropriated by many medical writers, to express only the distortions of the face, and particularly of the mouth, in convulsions.

TORTURE, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

The forms of torture are different in different countries. In some they use water, in others iron, in some the wheel or rack, in some the boot, thumbkins, &c. See **RACK**, **BOOT**, &c.

Torture, says archdeacon Paley, (*Principles of Mor. and Pol. Philos.* vol. ii.) is applied, either to obtain confessions of guilt, or to exasperate or prolong the pains of death. No bodily punishment, however excruciating or long continued, receives the name of torture, unless it be designed to kill the criminal by a more lingering death, or to extort from him the discovery of some secret, which is supposed to lie concealed in his breast. The *question by torture* appears to be equivocal in its effects; for since extremity of pain, and not any consciousness of remorse in the mind, produces those effects, an innocent man may sink under the torture, as soon as the guilty. The latter has as much to fear from yielding as the former. The instant and almost irresistible desire of relief may draw from one sufferer false accusations of himself or others, as it may sometimes extract the truth out of another. This ambiguity renders the use of torture, as a means of procuring information in criminal proceedings, liable to the risk of grievous and irreparable injustice. For which reason, though recommended by ancient and general example, it has been properly exploded from the mild and cautious system of penal jurisprudence established in this country. The enlightened and liberal spirit of modern times has excluded torture from most other countries in Europe; and the revival of it in any nation reflects indelible reproach on the government which countenances it.

The torture, says M. Bruyere, is a sure expedient to destroy an innocent person of a weak complexion, and to save a criminal of a robust one. It was a noble saying of an ancient, "They who can bear the torture will die, and also they who cannot bear it."

The marquis Beccaria (chap. 16.) with exquisite raillery proposes this problem: the force of the muscles and the sensibility of the nerves of an innocent person being given, it is required to find the degree of pain necessary to make him confess himself guilty of a given crime.

TORTYRA, in *Ancient Geography*, the name of one of the seven towns which Cyrus gave to his favourite Pythæus, supposed to be in the environs of Asia Minor. Athenæus.

TORUP, in *Geography*, a town of Sweden, in the province of Halland; 12 miles N.N.E. of Halmstad.

TORUS, in *Architecture*. See **TORRE**.

Torus, in *Botany* and *Vegetable Physiology*, a name applied by Mr. Salisbury to what is termed by Linnæus either the receptacle of the flower, or a glandular nectary surrounding the base of the germen. Jussieu and his followers call *idiscus hypogynus*, alluding to its form, as well as situation. The word *torus* is very descriptive, as expressing the frequent resemblance of the part in question to what usually sustains an architectural column, and it is certainly preferable to the compound appellation just mentioned. A very curious lobed and plaited *torus* may be seen in *Cobæa*, but we believe it to be strictly a glandular nectary. Mr. Brown's natural order of *Epacrideæ* contains some genera with five separate glands, of a like nature, indubitably (in our opinion) nectariferous; and others with an uninterrupted annular nectiferous disk, or *torus*, under the germen. It does not

follow, because Linnæus has sometimes misapplied the term *nectarium*, that there is no such thing in nature; but his opponents have wished to obscure and invalidate that term, because he has in general, with so much originality and success, employed it for the clear and concise discrimination of genera. This displays a want of candour, unbecoming disinterested students and admirers of Nature.

TORUS, in *Ancient Geography*, a mountain of Sicily, between Heraclea and Agrigentum.

TORUSCULA, a word used by some medical writers to express a drop.

TORY. See **TORIES**.

TORY Island, in *Geography*, an island lying north of Bloody Farland Point, in the county of Donegal, about 61 miles from the main land. It is said to be extremely fertile.

TORYNE, in *Pharmacy*, the name of a kind of spatula intended for stirring up the ingredients of decoctions while boiling.

TORYNETOS, a name given by some to a mixture of bread and water boiled together, whether meant as a kind of a panada, or for a poultice.

TORZA, in *Geography*, a town of Persia, in the province of Irak; 40 miles E. of Hamadan.

TORZOK, a town of Russia, in the government of Tver, on the Tvertza; 40 miles W.N.W. of Tver. N. lat. 57°. E. long. 35° 14'. See **TORSHOK**.

TOSA, a sea-port town of Spain, in the province of Catalonia; 23 miles S.S.E. of Gerona. N. lat. 41° 43'. E. long. 2° 48'.—Also, a river of Italy, which runs into lake Maggiore; 4 miles N.E. of Omegna.—Also, a town of Japan, capital of a province of the island of Xicoco, on the south coast. N. lat. 33° 40'. E. long. 134° 50'.

TOSALE, in *Ancient Geography*, a town of India, on the other side of the Ganges, and near it, which had the title of metropolis. Ptolemy.

TOSANLU, in *Geography*, a river of Natolia, which waters the city of Tocat, and afterwards joins the Jekilernak. It was anciently called *Lycus*.

TOSARCAN, a town of Persia, in the province of Irak; 21 miles S. of Hamadan.

TOSCANELLA, a town of the Popedom, in the Patrimonio, the see of a bishop, suffragan of Viterbo; 9 miles W.S.W. of Viterbo. N. lat. 42° 24'. E. long. 11° 52'.

TOSCANELLI, PAOLO, in *Biography*, an eminent astronomer, was born at Florence in 1397. Declining the profession of his father, who was a physician, he devoted himself to the study of geometry and astronomy, and also of the Latin and Greek languages. He was one of the curators of Niccoli's library, and conversant with the solar motions. He corrected the astronomical tables of Alphonso and the Arabians. Of his astronomical tables he left a memorial in the great dial fixed upon the metropolitan church at Florence, erected about the year 1468. He died in 1482, at the age of 85.

TOSCOLANO, in *Geography*, a town of Italy, in the department of the Benaco, on a small river which runs into lake Garda. Here is a manufacture of cloth, with some paper and iron-mills; 6 miles E.N.E. of Salo.

TOSENA, a town of Sweden, in West Gothland; 20 miles W.N.W. of Uddevalla.

TOSI, GIUSEPPE FELICE, of Bologna, in *Biography*, maestro di capella at Venice the latter end of the 17th century, and composer of five operas for that city between the years 1684 and 1690. (*Gloria della Poësia*.) Beside these dramas, he composed others for Bologna. His name,

however, will be longer remembered by the merit of his son, than by his musical productions, which have been long lost and forgotten. See the next article.

TOSI, PIER FRANCESCO, *Accademico Filarmonico di Bologna*, and not only an eminent opera singer, in soprano, during his youth, but a composer of cantatas, in which the recitatives were particularly impassioned, energetic, and impressive, and author of an excellent treatise on singing, well known in England, by the late Mr. Galliard's admirable translation.

The author of this treatise seems to have had no partiality for rapid execution. His own favourite style of singing was the pathetic, which he describes and recommends by excellent precepts. Though this elementary tract has been written more than fourcore years, no work of the same kind has been produced in Europe since its publication, but upon Tosi's model, and in confirmation of his precepts. The excellent composer of the old school, Galliard, a profound and experienced judge of every species of musical merit, not only recommended its perusal to the first musical professors, instrumental as well as vocal, by an admirable translation and notes in 1740, but by his encomiums instantly exalted it into a classical work.

In 1757, Agricola, opera composer to Frederic II., king of Prussia, and the best singing-master in Berlin, published a translation of it with useful and instructive notes, which made the work well-known in Germany; a knowledge which Hiller of Leipzig much increased by frequent extracts from it, in his musical journals.

And in 1774, Mancini, singing-master to the archduchesses at Vienna, published a treatise on singing of great merit, founded on the work, and confirming the principles of Tosi, of whom he speaks with the highest respect in his chapter on "Intonation." "Gioverá non poco si ogni scolare leggera' nel libro tanto stimato di Pier Francesco Tosi. A carte 12, la spiegazione, che esso fa sopra il femituoono maggiore, e minore, appunto per sapere la quantità degl' intervalli, o sia delle comme, che li compone."—"It will be of no small service to students in singing, if they read in the work of P. F. Tosi, (p. 12. of the original,) the explanation which he gives of major and minor semitones, that they may know precisely the quantity of the several intervals, or rather commas, of which they are composed." See **MANCINI**, for the original title and further account of his book.

Of Tosi's life but little is known, except from Galliard's prefatory discourse to his translation; who tells us that he was a singer of great esteem and reputation. He sung on the stage at Venice in 1707, in the opera of "Olibrio," written by Apostolo Zeno, and set by Gasparini, where he is styled Virtuoso di S. A. Elettorole Palatina. He spent the chief part of his time, according to Galliard, in travelling, and by that means heard the most eminent singers in Europe; whence, by the help of his refined taste, he made the observations which are contained in his book. Among many excursions, his curiosity was excited to visit England, where he resided for some time in the reigns of king James II., king William, George I., and beginning of George II. He was very much esteemed by persons of rank wherever he went: among whom, in England, was the late earl of Peterborough, whom he had often met in his travels on the continent, to whom he had dedicated his book, though it was printed at Bologna in 1723, some time after he had quitted England. The emperor Joseph I. gave him an honourable employment in some part of Italy, and the archduchess, a church retirement in Flanders, where he died.

The original title of his book, which is now become scarce, is, "Opinione de' Cantori Antichi e Moderni o' Sieno Osservazioni sopra il Canto figurato:" 8vo.

The earl of Peterborough, to whom he dedicates his book, was one of the best informed judges of dramatic music and performance in his time. He married the amiable and accomplished Mrs. Anastasia Robinson, after a very long courtship. (See her article.) Tosi used to meet Bononcini, and all the first opera singers of the time, at the earl's villa, at Parson's Green; and we remember hearing Monticelli, Reginelli, and Manzoli, speaking with great respect of the "Trattato di Tosi."

TOSIA, in *Geography*, a neat town of Asiatic Turkey, in Natolia, built on the side of a hill, at the foot of which is a fine fertile country; 70 miles S.S.W. of Sinob.

POSICCIA, a town of Naples, in Abruzzo Ultra; 7 miles S. of Teramo.

TOSINO, a river which crosses the marquisate of Ancona, and runs into the Adriatic, N. lat. 42° 57'. E. long. 13° 55'.

TOSMUANASSA, in *Ancient Geography*, a town of Asia, in Bactriana. Ptolemy.

TOSNA, in *Geography*, a river of Russia, which runs into the Neva, near Pella, in the government of Petersburg.

TOSNITZPACH, a river of Austria, which runs into the river Erlebach, 2 miles below Scheibs.

TOSOLIC, a town of Thibet; 35 miles S. of Tourfan.

TOSON-HOTOC, a town of Chinese Tartary; 88 miles S.S.W. of Haratoubé.

TOSPITES, in *Ancient Geography*, a country of Asia, in Greater Armenia, S. of the sources of the Euphrates and Tigris. Ptolemy.

TOSQUIATOSSY CREEK, in *Geography*, one of the branches of the Allegany river.

TOSS, a river of Switzerland, which runs into the Rhine, 2 miles S.E. of Eglisau, in the canton of Zurich.

TOSSAQUA, a town of Peru, in the audience of Quito; 110 miles W. of Quito.

TOSSE, a town of France, in the department of the Landes; 12 miles W. of Dax.

TOSSIAT, a town of France, in the department of the Ain; 7 miles S.E. of Bourg-en-Bresse.

TOSSIGNANO, a town of Italy, in the department of the Amona; 13 miles W. of Ferrara.

TOSSO, a town of Sweden, in West Gothland; 42 miles N.N.E. of Uddevalla.

TOST, or **TOSCHEK**, a town of Silesia, in the principality of Oppeln; 26 miles S.E. of Oppeln.

TOSTA, a river of Mexico, which runs into the Pacific ocean, N. lat. 12° 30'.

TOSTAR, or **SUSTER**. See **SHUS**, **SHUSTER**, and **SUSA**.

POSTERYD, a town of Sweden, in Smaland; 22 miles S. of Jonkioping.

TOSTES, a town of France, in the department of the Lower Seine; 12 miles S.W. of Arques.

TOSTO, **CAPE**, a cape on the N. coast of Spain. N. lat. 43° 13'. W. long. 9° 10'.

TOSUN HOTUN, a town of Thibet; 508 miles W.S.W. of Tourfan. N. lat. 41° 55'. E. long. 99° 10'.

TOT VARADIN, a town of Hungary; 24 miles S.E. of Boros Jenó.

TOTA ISLAND, or *Island of Plantains*, an island of the Atlantic, near the coast of Africa, at the mouth of the Scherbro.

TOTANA, a town of Spain, in the province of Murcia; 11 miles N.E. of Lorca.

TOTANO,

TOTANO, or **TOTANUS**, in *Ornithology*, the name of a bird common in the Italian markets, and more usually known by the name of *Vetola*; which see.

The totanus of Linnæus is a species of *Scolopax*, (which see,) and the *crex* of other authors. See **RAIL**.

TOTANUS is also used by some for the *Limosa*; which see.

TOTAQUESTAC, in *Ornithology*, the name of a beautiful American bird, described by Nieremberg from Antonius Herrera. It is said to be something smaller than a pigeon, and all over of a most beautiful green; its tail-feathers are of a very great length, and are greatly esteemed. The Indians value the bird so highly, that it is death by their laws to kill it, so that when it is caught they only strip it and let it go again. Ray.

TOTEN, in *Geography*, a town of Norway, in the province of Aggerhuus; 47 miles N. of Christiania.

TOTES, a town of France, in the department of the Lower Seine; 14 miles N. of Rouen.

TOTEZVA, a town of Hungary, on the river Bodrog; 5 miles S.W. of Patak.

TOTFALU, a town of Hungary; 1 mile N. of Siclos.—Also, a town of Hungary; 8 miles W. of Podolicz.

TOTILA, in *Biography*, king of the Ostrogoths in Italy, was a commander of the Gothic garrison at Treviso, and upon the deposition and murder of his uncle Eraric, was chosen to succeed him A.D. 541. After several successful conflicts with the Romans, and the capture of their chief cities, he advanced to Tibur, within eighteen miles of the capital. In every step of his progress his conduct was conciliatory; he restrained his soldiers, in the career of victory, from all acts of licentiousness; and by the exercise of humanity and liberality, he attached to his service and cause his vanquished enemies. Upon his approach to the capital, the emperor Justinian was alarmed, and recalling Belisarius from the Persian war, sent him, already renowned for his character and exploits, to its relief. Failing in his attempts to throw succours into the city, he withdrew, and abandoned it to the distress of famine; so that those inhabitants who could make their escape deserted it, and those that remained importunately solicited the governor to capitulate. At length the Roman garrison retired, and one of the gates was opened to the Gothic troops, by which Totila entered the city December 17, A.D. 546. Although the conqueror spared the lives of the inhabitants, he allowed his soldiers to pillage the city, and by so doing reduced the wealthy senators and their families to absolute beggary. Having convened those few of this rank that remained, he reprehended and threatened them; but pacified by the intercession of Pelagius, he sent a respectful message to Justinian, offering to live with him upon amicable terms; and yet intimating, that on the rejection of his proposal he would utterly destroy Rome, and remove the seat of war to Illyricum. The emperor referred him for an answer to Belisarius, upon which slight he began to demolish the city. As he was proceeding in the work of destruction, Belisarius remonstrated with him on the barbarity of his conduct, and so far succeeded as to induce Totila to desist, and to march off, with his troops and the senators, to Lucania. The remaining inhabitants were dispersed in exile, and Rome was for forty days in a state of total depopulation. Belisarius seized the opportunity of taking possession of the city, repairing the fortifications to the utmost of his power, and recalling the inhabitants. Upon receiving this intelligence, the Gothic sovereign returned, and having made many unsuccessful attempts for regaining possession of the city, and sacrificed, in repeated assaults, the choicest of his troops, he was under a necessity of decamping, and of marching, with degraded

reputation, and a discontented army, to the siege of Perugia. He contrived, however, to regain the confidence of his troops, and after obtaining a reinforcement, marched again for Rome, and by the treachery of some Italian centinels, became master of the city. Experience had now taught him wisdom; and he adopted every measure which sound policy dictated for conciliating his enemies. He not only repaired the walls and edifices which he had demolished, but recalled the senators, and restored them to their rank, and at the same time invited the citizens to take possession of their property, supplying them in the mean while with provisions. He also exhibited the Circensian games, and presided at them with the dignity of a Roman emperor. Totila renewed his embassy to Justinian, making an offer of peace and alliance; but the emperor would not admit the Gothic ambassadors to an audience. The Gothic sovereign was incensed by this treatment; and fitting out a powerful fleet, took Rhegium and Tarentum, and passed over to Sicily, which he speedily reduced and pillaged; and having made himself master of Sardinia and Corsica, and ravaged the whole sea-coast of Greece, whilst his troops were besieging Ancona, his fleet was defeated, so that he was obliged to raise the siege, and soon after he lost Sicily. Justinian, encouraged by these fortunate events, determined to preserve Italy from the power of Totila; and having recalled Belisarius, devolved the command of his army on Narfes, who marched directly to Rome, and meeting Totila in his progress, presented to him the emperor's message, which was merely an offer of pardon. Totila seemed to regard it as an insult, and replied, that he would conquer or die. In the furious combat between the hostile armies that ensued, the Goths were driven from the field of battle, and Totila fled with no more than five attendants. In his flight he was overtaken by Asbad, a leader of the Gepidæ, who pierced him through the body with a lance. His faithful companions hurried him away seven miles beyond the scene of action, and had his wound dressed; but he soon after expired. A private burial terminated the glory of this conqueror of Rome, whom his eulogists have celebrated for valour tempered by humanity and moderation, and for a government conducted with a regard to justice and equity. With this battle, fought in July 552, the 11th year of Totila's reign, the triumph and dominion of the Goths in Italy also terminated. *Anc. Un. Hist.* Gibbon's Rom. Emp.

TOTMA, in *Geography*, a town of Russia, in the government of Vologda. In the environs are several salt-pits; 92 miles N.E. of Vologda. N. lat. 60° 10'. E. long. 42° 34'.

TOTNESS, an ancient borough and market-town in the hundred of Coleridge, and county of Devon, England; is situated on the banks of the river Dart, 22 miles S.S.W. from Exeter, and 195 miles W.S.W. from London. It ranks among the most ancient towns in the kingdom; and if credit could be given to Geoffrey of Monmouth, would assume an origin coeval with the first; for here, according to this author, Brute first landed; and the inhabitants, to corroborate the tale, still point out a stone near the spot where the east gate stood, as the very one on which he first set his foot. It is certainly, however, of remote antiquity; for Leland mentions that the Roman fofs-way, extending through Devonshire and Somersetshire, began here; and Riddou quotes a passage from Bede, which notices the arrival of Ambrosius and Uther-Pendragon at Totness, when they returned from Bretagne to oppose the tyranny of Vortigern. The site of the town is peculiarly fine: from the margin of the Dart it climes the steep acclivity of a hill, and stretches itself along its brow; commanding a view of the winding stream and the country in its vicinity; but sheltered by

by higher grounds on every side. The piazzas in front of the houses in some parts of the town, and the higher stories projecting over the lower, are manifest proofs of its antiquity; a claim which is strengthened by the keep of its castle, a large circular building, turretted, rising from an immense artificial mound. This castle, according to Brown Willis, was erected by Judhael de Totnais (to whom the manor was given by the Conqueror), and made the head of his barony. During his residence here, he founded a priory for Benedictines, which continued till the dissolution, when its annual revenues were estimated at 124*l.* 10*s.* 2*d.* The manor was granted in the reign of Henry VII. to Richard Edgecumbe, whose son, or grandson, in the second year of Elizabeth, conveyed it to the corporation, reserving the right of a burgessship to his heirs for ever. Totness was incorporated by charter of king John; and has had its privileges confirmed by several succeeding sovereigns. The corporation is vested in a mayor, recorder, thirteen burgo-masters, and twenty common-councilmen. The borough first sent representatives to parliament in the 23d of Edward I.: the right of election is in the corporation. At the period of the Norman survey, Totness had immunity from taxation, excepting at those times when Exeter was rated. The parish-church is a handsome edifice, having a well proportioned tower at the west end. The date of its foundation was unknown till the year 1799, when the south-east pinnacle was struck by lightning, and in its fall beat in the roof of a small room over the porch. In this room were two chests of old records, which becoming exposed by this accident, among them was found a grant of indulgence from bishop Lacey, "to those people who had or might contribute to the rebuilding of the church at Totness." This was dated at Chudleigh, where the bishops of Exeter had a residence in 1432. The chancel is separated from the body of the church by an elegant screen of ornamental tracery in stone-work; but the altar-piece, instead of corresponding with the rest of the building, is of Grecian design, having a semi-dome supported by Corinthian pillars. Totness consists principally of one street, about three-quarters of a mile in length, terminated on the E. by a bridge over the Dart: the town was formerly surrounded by a wall, and had four gates: the east and north gate-houses are now standing. By the population return of the year 1811, the houses were estimated at 327, the number of inhabitants at 2725. Many of the labouring class derive employment from the woollen trade, which is rapidly increasing. Five fairs are held annually, and a market weekly, on Saturday.

Edward Lye, the learned author of the Anglo-Saxon and Gothic Dictionary, published in 1772, was a native of Totness; as was also Dr. Benjamin Kennicott, well known for his collection of Hebrew MSS. The former died in 1769, the latter in 1783.

About two miles below Totness, on the brow of a thickly wooded declivity which rises from the margin of the Dart, is Sharpham, the seat of Edmund Bastard, esq. The mansion, an elegant building of freestone, was erected by captain Pownall, who lost his life at the moment of victory in a naval engagement during the American war. The daughter of that gentleman married Mr. Bastard.

On the eastern shore is Greenaway, a seat for many generations possessed by, and a residence of the family of Gilbert. Of this family, and born here, was sir Humphrey Gilbert, a celebrated voyager in the reign of Elizabeth: to him this kingdom is indebted for the discovery and settlement of Newfoundland.—Warner's Walk through the Western Counties, 8vo. 1800. Beauties of England and Wales, vol. iv. Devonshire: by J. Britton and E. W. Brayley, 1803. Polwhele's History, &c. of Devonshire, folio, 1797.

TOTOMINA, a bay on the fourth coast of the island of Nippon. N. lat. 35° 10'.

TOTOO, a town of Bengal; 7 miles N.N.E. of Toree.

TOTAL, a town of South America, in the province of Cordova; 54 miles N. of Cordova.—Also, a small island in the Pacific ocean, near the coast of Chili. S. lat. 29° 20'.

TOTOWA, a town of New Jersey, on the Passaic; 15 miles N. of Newark.

TOTSKAIA, a fortress of Russia, in the government of Upha; 20 miles S.E. of Buzulatsk.

TOTTAIUM, in *Ancient Geography*, a place of Asia, in Bithynia, on the route from Constantinople to Antioch, between Oriens-Medio and Dahlis. Anton. Itin.

TOTTAVILLA, in *Ornithology*, a name by which some authors have called the *alauda arborca*, or common wood-lark. See ALAUDA.

TOTTED. A good debt to the king is, by the foreign apposer, or other officer, in the exchequer, noted for such by writing the word *tot*, q. d. *tot pecunie regi debentur*; whence it is said to be *totted*. Also that which is paid is to be totted.

TOTTENHAM, or TOTTENHAM HIGH-CROSS, in *Geography*, in ancient records called *Totbam*, is a village and parish in the hundred of Edmonton, and county of Middlesex, England. The village is situated about five miles to the N. of London: the parish is about fifteen miles in circumference, and is bounded on the E. by the river Lea; on the N. by Edmonton; on the W. by Hornsey and Friars Barnet; and on the S. by Hackney and Stoke-Newington. It contains about 4000 acres of land, of which nearly one-eighth part is arable, the remainder grass. It is divided into four districts, named the Middle, Lower, High-Cross, and Wood-Green wards. There are an overseer and a constable for each ward, and two churchwardens for the whole parish. The New River passes with a very circuitous course through the western part of the parish. On the east side of the high road, nearly in the centre of the village, stood an ancient wooden cross, whence the place is said to have obtained the appellation of Tottenham High-Cross. About the year 1580, Bedwell described it as "a column of wood, covered with a square sheet of lead." This, being decayed, was taken down, and an octangular brick column raised in its place. The manor of Tottenham, in the reign of Edward the Confessor, was the property of earl Waltheof, son to the famous Siward, earl of Northumberland, who defeated Macbeth, the usurper of the crown of Scotland. Waltheof's widow, Judith, niece of William the Conqueror, was in possession of this manor at the time of the Domesday survey. From her it passed through a succession of royal and noble possessors till the year 1254, when, having been the property of John, earl of Chester, it was divided between Robert de Brus, John de Baliol, and Henry de Hastings, as coheirs, by marriage, of the said earl. The manor, being thus divided into three portions, formed as many distinct manors, some of which were subdivided, and acquired also the name of manors. Through various descents, they all devolved to, and concentrated in, John Gedeney, alderman of London, who died possessed of the whole in 1449. In 1792 it was sold to Thomas Smith, esq. of Gray's Inn, who is now the lord. Bruce castle, which may be considered as the manor-house of Tottenham, is a large brick mansion: it was probably rebuilt by sir William Compton, at the beginning of the sixteenth century, as we read that in the year 1516, king Henry VIII. met his sister Margaret, queen of Scots, at "Maister Compton's house befidis Tottnam." Bruce castle was repaired and altered by Henry, lord Colerane, in the latter part

part of the last century. The parish-church is built of hewn stone, flints, and pebbles, and consists of a chancel, nave, two aisles, and a square embattled tower. On the south side of the church is a large brick porch, built, as appears by the architecture, about the beginning of the sixteenth century. At the east end of the north aisle is the vestry, erected in 1696, by Henry, lord Colerane, and repaired, pursuant to his will, in 1790. The building is semi-circular at the east end; its roof is in the shape of a dome. The font is octagonal, richly ornamented with tracery, and the devices of a mermaid, pelican, &c. Monuments and other sepulchral memorials abound in every part of the church. David, king of Scotland, gave this church, in the twelfth century, to the canons of the Holy Trinity in London; after the dissolution of that monastery, the rectorial manor and the advowson of the vicarage were granted, in 1544, to the dean and chapter of St. Paul's, in whom they are still vested. There is a considerable Quakers' meeting in this parish, and a chapel belonging to the Methodists. An alms-house for four men and four women was founded and endowed, in 1600, by Balthasar Sanchez, a Spaniard. A similar establishment for six men and six women was built in 1736, pursuant to the will of Nicholas Reynardson, esq.; who also made provision for a school, for twenty poor children. By the bequests of Sarah, duchess dowager of Somerset, the school-house was enlarged, and the benefits extended to all the children of such inhabitants of this parish as were not possessed of an estate of 20*l.* per annum. A charity-school for girls was established in the year 1735: also a Sunday-school for boys, and a school of industry for girls, in the year 1790. According to the return made to the population act in 1811, the number of houses in this parish was 873; of inhabitants 4571.—Lysons's *Environs of London*, vol. iii. quarto, 1792, 1811. Dyson's *History of Tottenham High-Cross*, octavo, 1792.

TOTTIUM, a town of Hindoostan, in the Carnatic; 24 miles W.N.W. of Tritchinopoly.

TOTTWEIL, a town of Switzerland, in the county of Baden; 4 miles S.W. of Baden.

TOVALEY, a town of Hindoostan; 16 miles S.E. of Travancore.

TOUCAN, otherwise called *anser Americanus*, in *Astronomy*, a modern constellation of the southern hemisphere, consisting of nine small stars. See **CONSTELLATION**.

TOUCAN, in *Ornithology*. See **RAMPHASTOS**.

TOUCH, or **TOUQUE**, in *Coinage*, the manner of expressing the fineness of gold and silver in China, by dividing it into 100 parts, so called: thus, if it be 93 touch, it contains seven parts of alloy in 100. The Chinese in general take French silver coin at 95 touch (the better informed taking it only at 93), and English silver at 94 ditto; Spanish dollars at about 92; Siam ticals, and Madras rupees, at 98; and Rajamole rupees at 99 ditto.—Also, a method of trying the fineness of gold and silver in many places, by means of a stone called touch-stone.

TOUCH, in *Music*. An organ is said to have a good touch, or stop, when the keys close, and lie down well, being neither too loose, nor too stiff.

TOUCH, in *Ship-Building*, the broadest part of plank worked top and butt, which place is six feet from the butt-end; or, the middle of a plank worked anchor-stock fashion. Also, the angles of the stern-timbers at the counters, &c.

TOUCH the Wind, in *Sea Language*, is when the steerfiner at the helm is bid to keep the ship as near the wind as may be. See **TOUCHING**.

TOUCH-Me-Not, in *Botany*. See **IMPATIENS** and **MORMORDICA**.

TOUCH-Hole, or *Vent*, in *Gunnery*, is the small hole at the end of the cylinder of a gun or musket, by which the fire is conveyed to the powder in the chamber.

In a fire-lock, carabine, or pistol, it is called the touch-hole; but in a piece of cannon, it is more properly called the vent.

TOUCH-Needles, small masses of gold, silver, and copper, each pure and simple, and in all the different combinations, proportions, and degrees of mixture, prepared for the trying of gold and silver by the touch-stone; by comparison with the mark they leave on it.

The metals usually tried by the touch-stone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions by fusion. In order to find out the purity or quantity of baser metal in these various admixtures, when they are to be examined, they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates one-twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the mixture in it.

The manner of making the touch-needles is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into sixteen half-ounces, the half-ounces each into four drachms, the drachm into four pennyweights, and this into two half-pennyweights.

TOUCH-Needles, Silver: these must be only tempered with copper, and the proportion determined by the mark divided into half-ounces and grains.

You must use therefore for this purpose one mark of such a weight, that it may constitute a sufficient mass of metal for the making of one needle; let it weigh, for instance, one drachm, then weigh such a mark of the purest silver, wrap it up in a small paper, and upon this write sixteen half-ounces, which will signify that the whole mark of this metal is the purest silver, and make the first needles of this mass.

Next weigh fifteen half-ounces of pure silver, and one half-ounce of pure copper; wrap these both in a paper, and write on it fifteen half-ounces, which will signify that there are in that small mass fifteen parts of pure silver, and one part of pure copper; make of this the second needle. In the same manner go on with the rest, add two half-ounces of copper to fourteen half-ounces of silver, mark it fourteen half-ounces, make the third needle of this; and in the same manner proportion the small masses of silver and copper for making the other needles, and put inscriptions upon every one in the following manner.

For the needle	{	1 — 16	}	half oz. of silver.	{	0	}	} half oz. copper.
		2 — 15				1		
		3 — 14				2		
		4 — 13				3		
		5 — 12				4		
		6 — 11				5		
		7 — 10				6		
		8 — 9				7		
		9 — 8				8		
		10 — 7				9		
		11 — 6				10		
		12 — 5				11		
		13 — 4				12		
		14 — 3				13		
		15 — 2				14		
		16 — 1				15		

When you have the metals in each of their due proportions, each being wrapped up in its separate paper ; put each separately into a new crucible never used for any operation, and, adding a little borax, melt them together in a very quick fire, which must be well kindled before with bellows ; or, what is yet better, throw them suddenly into a hot crucible, and as soon as they melt, stir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot. When this is done, wrap up each mass, when cold, in its own paper again, and weigh them singly, in a nice balance ; if they still weigh a whole mark, they are good ; but if there is any considerable deficiency in their weight, it is a sign that your fire, having been too weak, or of too long duration, has consumed as much copper as is wanting in the weight ; therefore this mass must be esteemed useless, and another made in its place in the same proportion.

When this is all finished, make with the hammer out of each of these small masses, a needle, making them a little hot ; then engrave on each of these needles the number of half-ounces it contains, as before marked on its paper ; that is, upon the first sixteen, upon the second fifteen, and so on ; and then pierce them at one end, and running a silver wire through their eyes, collect them in order according to their different numbers. These are the silver touch-needles, made of the different alloys of silver and copper.

In Holland they make use of the mint mark, divided into grains, for the making of their needles. The first needle made of pure silver is said to be of twelve pennyweights. The second is made of eleven pennyweights, and eighteen grains, by the addition of six grains of copper. The third is made of eleven pennyweights and twelve grains, by the addition of twelve grains of copper ; and so on, the proportion of silver decreasing always six grains, that is, one quarter of a pennyweight at a time, and that of the copper being always increased in the same proportion, till at last the weight of the silver is reduced to one pennyweight, and that of the copper increased to eleven pennyweights, which proportion constitutes the last needle.

It is needless, however, to go through the whole series of the needles, by so small progressions to the very last, for very delicate proportions cannot be very accurately distinguished in the operation.

Touch-Needles, Gold. These must be mixed either with silver alone, or with silver and copper variously intermixed. This mixture is called allowing or carating, and is determined with a mark divided into twenty-four carats, or weights of two-sixth parts of an ounce. There is nothing to be observed about the making of these needles, beside what has been already said in regard to the silver needles ; except that the proportions of the weights are determined in another manner. These needles are made according to the following division and order ; and they all weigh one mark.

The first is entirely of pure gold, or of 24 carats.

2. 23 car. 6 gr.	} pure gold.	6 gr.	} pure silver.
3. 23 car.		1 car.	
4. 22 car. 6 gr.		1 car. 6 gr.	
5. 22 car.		2 car.	
6. 21 car. 6 gr.		2 car. 6 gr.	
7. 21 car.		3 car.	
8. 20 car. 6 gr.		3 car. 6 gr.	
9. 20 car.		4 car.	
10. 19 car.		5 car.	
11. 18 car.		6 car.	

The decrease goes on thus, by whole carats, till the weight of the gold is arrived at one carat, and that of the silver at

twenty-three ; for after the ninth needle, you cannot make so exact a distinction of the half-carats.

N. B. The carat is divided into twelve grains.

This mixture of the gold and silver is called the white alloy ; but when copper together with silver enters into the mixture of the gold, then it is called a mixt alloy. The needles for trial of pieces thus debased, are made of mixtures analogous to the former, except only that those portions, which in the first case were pure silver, here consist of copper and silver mixt. Therefore you have a double series ; for the mixture is either of two parts of silver and one of copper, or of two parts of copper and one of silver. For instance,

The first is of pure gold.

2	} of pure gold.	23 car. 6 gr.	} of pure silver.	4 gr.	} of pure copper.	2 gr.
3		23 car.		8 gr.		4 gr.
4		22 car. 6 gr.		1 car.		6 gr.
5		22 car.		1 car. 4 gr.		8 gr.
6		21 car. 6 gr.		1 car. 8 gr.		10 gr.
7		21 car.		2 car.		1 car.
8		20 car. 6 gr.		2 car. 4 gr.		1 car. 2 gr.

and so on as in the foregoing.

If in this table you take pure copper instead of pure silver, and silver instead of copper, this gives you a third series of golden needles. And you may have a fourth by mixing with gold equal quantities of silver and copper in the same proportion. These alloys of gold are much in use, but workmen may easily employ a number of other variations, which, compared with those already mentioned, will be distinguished into a thousand different ways by an experienced person, so that it is neither possible, nor necessary to imitate them all.

But that these golden needles may not be too expensive, they may be made much shorter than those of silver, and afterwards folded to plates of copper, that may be sufficiently long for use.

The use of these needles is by means of the touch-stone ; and arises hence, that every metal when pure must have its specific colour, that distinguishes it from the rest : but metals being the most opaque of all known bodies, the specific colour of every one appears most distinctly when you rub it against a very black hard stone ; and if the colours of two or more metals are expressed by large lively spots, made near each other on the same plane, by rubbing them against the surface of the stone, you will by that means easily discern their difference, or their likeness.

The stone adapted to this use, and called from its office the touch-stone, must have the following qualities. It must be of the deepest black, lest the tincture of the metal should be altered by spurious rays of light shining among it : it must be capable of being pretty well polished, for when too rough, the colours of the metals rubbed against it cannot be nearly or regularly distinguished ; and if it is too smooth, the metals are but faintly, and too slowly abraded or scraped by it, especially when gold is tried. It must also be neither too hard nor too soft. Tripoli, coal-dust, and tin-ashes, are used in rubbing off the thin metalline crusts, and in a short time the stone when very hard is apt to acquire too smooth a surface ; and when it is too soft it easily wears, throws off a dust, and contracts furrows.

The stone is made in the form of a quadrangular prism, about an inch thick, and two or three inches long.

If the proper stone cannot be procured, moderately smooth pieces of flint are the best substitutes ; and the more they approach in colour to the other the better.

The method of using your needles and the stone is this: the piece of gold to be examined, being well cleaned in some convenient part of its surface, a stroke is to be made with it on the stone; and another, close by it, with such of the touch-needles as appear to come the nearest to it in colour. If the colour of both, upon the stone, is exactly the same, it is judged that the given mass is of the same fineness with the needle: if different, another and another needle must be tried, till such a one is found as exactly corresponds to it. To do this readily, practice only can teach.

In making the strokes, both the given piece, and the needle of comparison, are to be rubbed several times backwards and forwards upon the stone, that the marks may be strong and full, not less than a quarter of an inch long, and about a tenth or an eighth of an inch broad: both marks are to be wetted before the examination of them, their colours being thus rendered more distinct. A stroke, which has been drawn some days, is never to be compared with a fresh one, as the colour may have suffered an alteration from the air; the fine atoms, left upon the touch-stone, being much more susceptible of such alterations than the metal in the mass. If the piece is supposed to be superficially heightened by art in its colour, that part of it, which the stroke is designed to be made with, should be previously rubbed on another part of the stone, or rather on a rougher kind of stone than the common touch-stones, that a fresh surface of the metal may be exposed. If it is suspected to be gilt with a thick coat of metal finer than the internal part, it should be raised with a graver, to some depth, that the exterior coat may be broken through: cutting the piece in two is a less certain way of discovering this abuse; the outer coat being frequently drawn along by the sheers or chisel, so as to cover the divided parts.

The metallic compositions, made to resemble gold in colour, are readily known by means of a drop or two of aqua fortis, which has no effect upon gold, but dissolves or discharges the marks made by all its known imitations.

If gold is debased by an admixture of any considerable quantity of these compositions, aqua fortis will, in this case, also discharge so much of the mark as was made by the base metal, and leave only that of the gold, which will now appear discontinued or in specks. Silver and copper are in like manner eaten out from gold on the touch-stone, and hence some judgment may thus be formed of the fineness of the metal from the proportion of the remaining gold to the vacuities.

Ereker observes, that hard gold appears on the touch-stone less fine than it really is. It may be presumed that this difference does not proceed from the simple hardness; but from the hardness being occasioned by an admixture of such metallic bodies, as debase the colour in a greater degree than an equal quantity of the common alloy. Silver and copper are the only metals usually found mixed with gold, whether in bullion or in coins; and the only ones, whose quantity is attempted to be judged of by this method of trial.

The Chinese are said to be extremely expert in the use of the touch-stone, so as to distinguish by it so small a difference in the fineness as half a touch, or a two hundredth part of the mixt. The touch-stone, says Dr. Lewis, is the only test by which they regulate the sale of their gold to the European merchants; and in those countries it is subject to fewer difficulties than among us, on account of the uniformity of the alloy, where there is almost always silver; the least appearance of copper being used in the alloy gives a suspicion of fraud. As an assay of the gold is rarely permitted in that commerce, it behoves the European trader to be well prac-

Vol. XXXVI.

tised in this way of examination: by carefully attending to the above directions, and by accustoming himself to compare the colours of a good set of touch-needles, it is presumed he will be able to avoid being imposed on, either in the touch itself, or by the abuses said to be sometimes committed, of covering the bar or ingot with a thick coat of finer metal than the interior part, or of including masses of base metal within it. A set of needles may be prepared, for this use, with silver alloy, in the series of the Chinese touches; or the needles of the European account may be easily accommodated to the Chinese, by means of a table formed for that purpose on the principles already explained. It may be observed, that the gold shoes of China have a depression in the middle, from the shrinking of the metal in its cooling, with a number of circular rings, like those on the balls of the fingers, but larger: Dr. Lewis says, that when any other metallic mass is included within, the fraud is discoverable at sight, by the middle being elevated instead of depressed, and the sides being uneven and knobby; but that the same kind of fraud is sometimes practised in the gold bars, where it is not discoverable by any external mark. See Cramer's Art of Assaying, p. 116, &c. Lewis's Com. of Arts, p. 122, &c. See also ASSAYING.

TOUCH-STONE, a black, smooth, glossy stone, used to try metals upon.

The ancients called it *lapis Lydius*, the Lydian stone, from Lydia, a country of Asia Minor, whence it was brought. See **TOUCH-NEEDLES**.

TOUCH-STONE, Irish, called *basanus Hibernicus* by Molyneux and some others, is a black stone, found in the county of Antrim, in that kingdom, in angular columns, forming that amazing pile called by the vulgar the Giant's Causeway. See **BASALTES** and **MARMARO-PROSERA**.

The basaltis being an excellent touch-stone, authors have confounded it with the touch-stone of the ancient Greeks, called by them *basanos*, *basanites*, *lapis Lydius* or *Heraclius*, &c. which were, probably, only black jaspers; and they have derived *basanos* and *basaltis* from the same Greek word, *βασανίζω*, to try or prove: but the basaltis was not known to the Greeks, and Pliny expressly tells us, that it is an Ethiopic or Egyptian name: whence it is probable that basaltis is a corruption of the Hebrew word *ברזל*, *barzel*, which signifies iron, a very proper name for a stone, which they describe to be of the colour and hardness of iron. Many authors affirm, that the touch-stone is a kind of black marble, or that most black marbles may serve for touch-stones: black marbles, it is true, take the colours of metals, and may be used as touch-stones in the ancient manner mentioned by Theophrastus and Pliny; i. e. by touching them with needles of different alloys; which manner is still practised in Germany and other countries: but in the manner of trying them with aqua fortis, it is absurd to use any calcareous substances, as the acid will immediately destroy the substance of the stone, and consequently affect and somewhat deface the strokes of the metals. For a good touch-stone, choice should be made of a black stone of the genus of *marmaro-prospera*, or of the jasper genus, on which the aqua fortis will only dissolve the copper, silver, &c. without touching the gold, or affecting the stone. The first genus should be preferred, as a nice touch-stone should only have a certain degree of polish, and should be of a compact fine texture, and neither too hard nor too soft; whereas the jaspers are too hard, and do not shew with sufficient exactness the different degrees of alloy; for the touches of the metal give them a higher lustre than their natural polish, and that lustre injures the distinctness of the strokes made upon it. Costa's Hist. Foss. p. 264. See **TOUCH-NEEDLES**.

TOUCH-WOOD, in *Botany*, a name given to spunk or agaric of the oak, on account of its readily taking fire.

TOU-CHAN, in *Geography*, a city of China, of the second rank, in Koei-tcheou; 987 miles S.S.W. of Peking. N. lat. $25^{\circ} 46'$. E. long. $107^{\circ} 3'$.—Also, a lake of China, in Chan-tong, 52 miles in circumference; 15 miles S. of Tei-ngan.

TOU-CHANG-TAO, a small island near the coast of China. N. lat. $36^{\circ} 55'$. E. long. 121° .

TOUCHE, CLAUDE GUIMOND DE LA, in *Biography*, a French poet, was born in 1719, and entered among the Jesuits; but a comedy, acted in 1748, occasioned his alienation from their fraternity. The slight of this body was repented by him in a poetical epistle published in 1766, and entitled "Les Soupirs du Cloître, ou le Triomphe du Fanatisme," in which he has exhibited the Jesuits in the blackest colours. Upon abandoning their society, he attached himself to the theatre; and in 1757 introduced on the stage his tragedy "Iphigénie en Tauride," the subject of which he borrowed from Euripides. This play, though chargeable with many defects, was well received, and has retained its reputation. Whilst he was preparing another tragedy on the story of Regulus, he fell a sacrifice to a pulmonary disorder in 1760. Among his MSS. was found his "Épître à l'Amitié," which has been read with pleasure. *Nouv. Dict. Hist.*

TOUCHE, in *Geography*, a town of France, in the department of the Saône and Loire; 7 miles N.W. of Châlons sur Saône.

TOUCHING is sometimes used for the sense of feeling. This sense may be injured by any thing that obstructs the nervous influence, or prevents its being regularly conveyed to the organs of touching, as pressure, extreme cold, &c. also by too great a degree of sensibility, when the nerve is not sufficiently covered with the scarf-skin, or where there is too great tension, or it is too delicate. Whatever disorders the functions of the brain and nerves, hurts the sense of touching; and as it proceeds from the same general causes, as palsy and apoplexy, it requires nearly the same method of treatment. In a defect of touching, which arises from an obstruction of the cutaneous nerves, the patient must be first purged, and then such medicines as excite the action of the nerves or stimulate the system may be used; for which purpose spirit of hartshorn, sal volatile oleosum, horse-radish, &c. may be taken inwardly; and the disordered parts often rubbed with fresh nettles or spirit of sal ammoniac.

Blistering plasters and sinapisms applied to the parts will likewise be of use, as also warm bathing, especially in the natural hot baths.

TOUCHING, in *Geometry*. See **TANGENT**.

TOUCHING, in *Sea Language*, denotes the state of a ship's sails when they first begin to shiver, with their edges in the direction of the wind. It is either occasioned by a sudden alteration of the ship's course, or by a change of the wind, in which it blows more obliquely along the surface of the sails, instead of falling into their cavities from behind, according to its usual direction. *Falconer*. See **FULL-and-by**.

TOUCHING-AT, denotes the circumstance of stopping, or anchoring occasionally, at some intermediate port, in the course of a voyage.

TOUCHIROA, in *Botany*, formed by Aublet, out of the Caribbean appellation *Moutouchiraou*, which belongs to an aromatic tree of Guiana. See **CRUDIA**.

TOUCQUES, in *Geography*, a sea-port town of France,

in the department of the Calvados, taken by the English in 1427; 6 miles S.W. of Honfleur.

TOUCQUES, *La*, a river of France, which runs into the sea, about 8 miles N. from the town of Touques.

TOUCY, a town of France, in the department of the Yonne; 12 miles W.S.W. of Auxerre.

TOUDARGA, a town of Asiatic Turkey, in Natolia; 26 miles W.S.W. of Boli.

TOUDSONG, a town of Thibet; 92 miles S.S.W. of Lassa. N. lat. $29^{\circ} 6'$. E. long. $90^{\circ} 42'$.

TOUERY, a town of Hindoostan, in the circle of Nagore; 40 miles S.W. of Nagore.

TOUET, in *Rural Economy*, a term used provincially in some districts to signify a measure of half a bushel. It is sometimes written *tofet* in books on agriculture and rural economy.

TOU-FANS, in *Geography*. See **SI-FANS**.

TOUGITO-HOTOC, a town of Chinese Tartary. N. lat. $44^{\circ} 48'$. E. long. $116^{\circ} 54'$.

TOUING, a town of Croatia; 24 miles S.S.W. of Carlstadt.

TOUINTCHOSE, a Tartarian standard of Chinese Tartary. N. lat. $41^{\circ} 40'$. E. long. $111^{\circ} 14'$.

TOUJOO, a small island near the W. coast of Sumatra. S. lat. $0^{\circ} 38'$. E. long. $99^{\circ} 25'$.

TOUI-YUEN, a town of Corea; 50 miles N.E. of King-ki-tao.

TOU-KIE, a city of China, of the second rank, in Quang-si; 1137 miles S.S.W. of Peking. N. lat. $23^{\circ} 10'$. E. long. $106^{\circ} 49'$.

TOUL, a town of France, and principal place of a district, in the department of the Meurte, on the Moselle, over which is a stone bridge, and regularly fortified. Before the revolution it was the principal town of a government, and the see of a bishop. It was formerly imperial, and the bishop a prince of the empire, and suffragan of Treves. The Toulinois, with the city of Toul, and the two bishoprics of Metz and Verdun, in the year 1552, put themselves under the protection of France; and, in 1648, became a part of that country; 12 miles W. of Nancy. N. lat. $48^{\circ} 41'$. E. long. $5^{\circ} 59'$.

TOULA, a river of Tartary, in that part inhabited by the Kalkas, and called *Kalka-pira*, which takes its course from E. to W., and is often broader, deeper, and more rapid than the Kerlon, another river of the same country, which runs from W. to E., and discharges itself into the lake Koulon-nor, the waters of which again flow into the river Saghalién by that of Ergone; and the banks of which afford the best pastures in Tartary. The banks of the Toula are covered with woods and beautiful meadows. The mountains which hang over it on the northern side are covered with forests of aged firs, and present to the view a kind of amphitheatre. This river, after having received the waters of the Selingué, loses itself in the lake of Pai-cal, which is the largest lake in Tartary, and lies in the territories of the Muscovites. The Russians are also masters of the lower part of the Selingué, where they have built a small city called the Selingeskoï.

TOULICIA, in *Botany*, from the Caribbean name of the same plant *Toulici*. See **PONÆA**.

TOULOMBA, in *Geography*, a town and fortress of Hindoostan, in the subah of Moultan, on the Rauvec. This town was taken and plundered by Timur Bec; 50 miles N.E. of Moultan. N. lat. $30^{\circ} 59'$. E. long. $72^{\circ} 25'$.

TOULON, a city and seaport of France, and capital of the department of the Var, strongly fortified. Before the revolution, it was the see of a bishop, and, besides the

cathedral

cathedral and other parish-churches, contained nine convents, a seminary, and a college. The old and new harbour lie contiguous, and, by means of a canal, communicate with one another, both having an outlet into the spacious outer harbour, which is naturally almost of a circular figure, and very large, being surrounded with hills. The entrance on both sides is defended by a fort, with strong batteries. The new harbour, which is a work of Louis XIV., is well defended by batteries, and round it stands the arsenal, where every man-of-war has its own particular storehouse, but the guns and cordage are laid up separate. In it are spacious working houses for blacksmiths, joiners, carpenters, locksmiths, carvers, &c. The rope-house is built wholly of freestone, being 320 toises in length, with three arched walks, in which as many parties of rope-makers may work at the same time. The general magazine here, which supplies whatever may be wanting in the particular storehouses for single ships, contains an immense quantity of all kinds of stores, disposed in the greatest order and conveniency. In the month of August, 1793, the people of Toulon, and the French vice-admiral Trugoff, entered into a negotiation with the English admiral lord Hood, who was then cruising in the Mediterranean, and he took possession both of the town and of the shipping, in the name of Louis XVII., and under the express and positive stipulation, that he was to assist in restoring the constitution of 1789. Great expectations were formed on this occasion; and general O'Hara was sent with troops from Gibraltar, being appointed, under the king of England's commission, governor and commander-in-chief: the republicans were not negligent in attempting to recover a place of so much consequence, and soon succeeded. General O'Hara was wounded, and taken prisoner, and the city and port abandoned. On the 19th of December, the town was bombarded from noon till ten o'clock in the evening; when the allies, and part of the inhabitants, having set fire to the town and shipping, precipitated their flight. Two chaloupes, filled with fugitives, were sunk to the bottom by the batteries. The precipitation with which the evacuation was effected, caused a great part of the ships and property to fall into the hands of the French, and was attended with the most melancholy consequences to the wretched inhabitants. Of thirty-one ships of the line, which the English found at Toulon, thirteen were left behind, nine were burned at Toulon, and one at Leghorn, and four lord Hood had previously sent away to the French ports, Brest and Rochefort, with 5000 republican seamen, whom he was afraid to trust; $7\frac{1}{2}$ posts E. of Marseilles. N. lat. $43^{\circ} 7'$. E. long. 6° .

T O U L O N, a township of New York, near lake Ontario.

T O U L O N en Charollois, a town of France, in the department of the Saône and Loire, near the Arroux river; 16 miles N.W. of Charolles. N. lat. $46^{\circ} 41'$. E. long. $4^{\circ} 13'$.

T O U L O U S E, a town of France, and capital of the department of the Upper Garonne, on the Garonne. In the sixth century, it was the capital of the kingdom of the Goths. Before the revolution, it was the capital of Languedoc, see of an archbishop, and second parliament of France: it is recognized for size next to Paris; the streets are mostly broad, and the houses are built of brick. The number of inhabitants, by a late enumeration, is said to be 50,171. Though so finely situated, its trade is inconsiderable, the principal article being Spanish wool. The university here was founded in 1228. The town-house is a spacious building, and called the capitoul, whence the aldermen are termed capitouls; and amongst other curiosities preserved here, are fifteen large parchment folios, delicately written and illuminated,

being annals of the city, commencing from the year 1288, and annually continued by the eldest capitoul. These were drawn up originally in Latin, but under Francis I. were altered to French. The three first volumes are principally filled with the portraits and names of the capitouls, and the following contain all the memorable events and transactions throughout the whole kingdom. Here is also an academy of the sciences and liberal arts. At half an hour's distance below the city, the celebrated canal of Languedoc joins the Garonne, which here becomes navigable. In this city are made carpets, but of little value; together with some slight silk and woollen stuffs; 34 posts S.E. of Bourdeaux. N. lat. $43^{\circ} 35'$. E. long. $1^{\circ} 32'$.

T O U M, a town of Syria; 6 miles N.E. of Damascus.

T O U M A N D I, a town of Asiatic Turkey, in Natolia; 32 miles W. of Kiutaja.

T O U M A N D I Daghi, a mountain of Natolia, part of the ancient Olympus; 20 miles S.E. of Bursa.

T O U M A N U G G R E E, a town of Hindoostan, in the circle of Kitchwaja; 12 miles S. of Budawar.

T O U M E N, a town of Chinese Tartary; 608 miles E.N.E. of Peking. N. lat. $42^{\circ} 27'$. E. long. $128^{\circ} 51'$.—Also, a river of Corea, which rises lat. $42^{\circ} 8'$, long. $127^{\circ} 34'$, and runs into the sea of Japan, N. lat. $42^{\circ} 30'$. E. long. $130^{\circ} 34'$.

T O U M E T, a Tartarian standard of Chinese Tartary. N. lat. $41^{\circ} 7'$. E. long. $110^{\circ} 49'$.

T O U N, a town of Persia, in the province of Khorassan; 90 miles N.W. of Herat.

T O U N A, or *Shrik Abdallah*, a small island of Egypt, in lake Menzaleh, on which are the ruins of an ancient town; 3 miles W. of Tennis.

T O U N A T E A, in *Botany*, somewhat arbitrarily constructed by Aublet, out of the Guiana name *Tounou*. See **S W A R T Z I A**.

T O U N S E, in *Geography*, a river of Hindoostan, which rises about 20 miles S.W. of Mahur, in the circle of Gurrah, and runs into the Ganges, about 20 miles below Allahabad.

T O V O M I T A, in *Botany*, an untenable name, altered by Aublet, from the Caribbean *Votomite*. Jussieu has, we presume, according to his declared intention, afforded it merely a temporary adoption, till the genus is fully understood. With the same view we here admit this name, for the present only.—Juss. Gen. 256. Aubl. Guian. 956. Poir. in Lamarck's Dict. v. 7. 717.—Class and order, *Polypandria Monogynia*. Nat. Ord. *Guttiferae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of two roundish, concave leaves. *Cor.* Petals four, rather longer, ovate, acute, concave, equal, inserted into the receptacle of the flower. *Stam.* Filaments numerous, twenty to twenty-five, inserted into the same receptacle, erect, linear, shorter than the corolla; anthers of two distinct ovate cells. *Pist.* Germen superior, sessile, ovate, with four furrows; style none; stigma cruciform, in four depressed, rounded lobes. *Fruit* unknown.

Ess. Ch. Petals four. Calyx of two leaves. Stigma sessile, four-lobed.

1. *T. guianensis*. Aubl. t. 364.—The only species, found in the inland forests of Guiana, flowering in September. This is a tree, whose trunk rises to the height of ten feet, and is a foot in diameter, with a branching head. The wood is compact and hard. Bark reddish, exuding drops of a yellow transparent resin. Leaves on the young branches only, opposite, stalked, smooth, three inches long, elliptical, pointed, entire; green above; whitish, with red parallel veins, beneath. Flowers in little terminal three-forked pa-

nicles, with a pair of small scales, or *bractæas*, at the base of each partial stalk. They are small, with a green *corolla*, as well as *calyx*. Nothing having been observed by Aublet respecting the *fruit*, the character of the genus remains incomplete. Of its natural order there can be no doubt, from its near affinity to *Clusia*, *Garcinia*, &c.

TOUP, JONATHAN, in *Biography*, a learned critic, was born at St. Ives, in Cornwall, in the year 1713, and entered at Exeter college, Oxford, where he took a bachelor's degree. After being presented to the rectory of St. Martin, Cornwall, he took the degree of M.A. at Cambridge, in 1756. His "Emendationes in Suidam" introduced him to the learned world: it was published successively in three parts, the first in 1760, the second in 1764, and the third in 1766. The learning of this writer recommended him to the notice and patronage of bishop Warburton, whose positive and contemptuous manner he too much resembles; and for which he received merited castigation. In 1769 he published "Epistola Critica ad Virum celeberrimum Gul. Episc. Glocestr.," which contains remarks on Greek writers. Warton's edition of Theocritus, which appeared in 1770, was accompanied with valuable corrections and annotations by Toup; and in 1772 he published, in a separate work, "Curæ posteriores, five Appendicula Notarum atque Emendationum in Theocritum, Oxonii nuperrime publicatum," 4to. His treatment of Reiske, on account of his edition of Theocritus, drew upon him the very severe animadversion of that learned writer. By the recommendation of Warburton to Keppel, bishop of Exeter, Mr. Toup obtained a prebend in the church of Exeter, and the vicarage of St. Martin. In 1775, he printed "Appendicula Notarum in Suidam;" and in 1778, his "Longini omnia quæ extant; Gr. et Lat., &c." This latter work was well received, and a second edition was printed in 8vo.

Notwithstanding the asperity which Mr. Toup manifested as a critic, and which is too common among learned men of this description, he is said in private life to have been kind and affectionate, and singularly humane towards the brutal creation. As a theologian, he drew his sentiments from the Scriptures; and he was respected as a liberal and tolerant divine. He was never married, but left considerable property among the three daughters of a half-sister, who lived with him. He died in January 1785, in his 72d year. Nicholl's Anecd. Gen. Biog.

TOUPOUR, in *Geography*, a lake of Thibet, 27 miles in circumference; 10 miles N. of Souc.

TOUR, TURN, a French term, often used among English writers for a journey. Thus we say the tour of Paris, or Rome, &c.

Tour of Hair, a tress or border of hair, going round the head, which, mingled dexterously with the natural hair, lengthens and thickens it.

These tours are for men. The women likewise use tours, and false hair, either to hide their age, or to supply the thinness of their natural hair on the forehead and temples.

The form is different according to the mode, sometimes raised and curled, sometimes straight, and laid flat along the forehead.

TOUR, in *Geography*, a town of France, in the department of the Calvados; 3 miles W.N.W. of Bayeux.

TOUR, La, a town of France, in the department of the Puy-de-Dôme; 12 miles W. of Besse.

TOUR la Blanch, a town of France, in the department of the Dordogne; 9 miles N. of Riberaç.

TOUR de Cordovan, a fort on the coast of France, in the department of the Gironde, at the mouth of the Garonne,

whose summit is 300 feet above the level of the sea. N. lat. 44° 35'. W. long. 1° 4'.

TOUR de France, La, a town of France, in the department of the Eastern Pyrenées; 12 miles W.N.W. of Perpignan.

TOUR d' Aigues, La, a town of France, in the department of the Mouths of the Rhône; 12 miles N.N.E. of Apt.

TOUR Landry, La, a town of France, in the department of the Mayne and Loire; 6 miles W. of Vihiers.

TOUR de Peil, La, a town of Switzerland, in the Pays de Vaud, on the lake of Geneva; 1 mile S. of Vevay.

TOUR du Pin, La, a town of France, and principal place of a district, in the department of the Isere, situated on a small river of the same name, which runs into the Rhône; 27 miles S.E. of Lyons. N. lat. 45° 34'. E. long. 5° 32'.

TOUR de Rosel, a cape of the island of Jersey; 5 miles N.N.E. of St. Helier.

TOUR de Rouffillon, La, a town of France, in the department of the Eastern Pyrenées, on the Tet; situated on a spot where once stood a city called Rufcino, which was destroyed in the ninth century; 3 miles E. of Perpignan.

TOUR de Treme, a town of Switzerland, in the canton of Friburg; 2 miles N. of Gruyeres.

TOUR la Ville, a town of France, in the department of the Channel, celebrated for its manufacture of glass: almost joining to Cherbourg.

TOURAINÉ, before the revolution a province of France, bounded on the E. by Orleannois, on the S. by Berry and Poitou, on the W. by Anjou, and on the N. by Maine; about 60 miles in length, and 54 in breadth: the river Loire runs through it, and divides it into Higher and Lower Touraine. Tours is the capital. This province had formerly counts of its own. In the year 1044, it was taken by the counts of Anjou; in 1202, united with the crown; and in 1356, raised to a dukedom and peerage. It has frequently been granted to the royal children; and after the death of Francis, duke of Alençon, brother to Henry III., was again united to the crown, since which it has never been alienated. It was governed by laws of its own, but with a right of appeal to the parliament of Paris.

TOURAK, a river of Turkish Armenia, which runs into the Batoun; 20 miles E.N.E. of Ipiria.

TOURAN, *Kingdoms of*, an appellation given to the vast regions of Grand Tartary, extending from Russia to China, and from Siberia to the Caspian sea.

TOURACO, in *Ornithology*. See CUCULUS.

TOURANCOURCHY, in *Geography*, a town of Hindoostan, in the Carnatic; 35 miles S.S.W. of Trichinopoly.

TOURCALL, a town of Hindoostan, in Bahar; 9 miles S. of Arrah.

TOURCHENGADA, a town of Hindoostan, in Baramaul; 18 miles N.N.W. of Namacul.

TOURETTE, a town of France, in the department of the Var; 3 miles N.W. of St. Paul.

TOURFAN HOTUN, a town of Little Bucharia, and capital of a province; 180 miles W.N.W. of Hami. N. lat. 43° 33'. E. long. 107° 17'.

TOURINA, CAPE, a cape of Spain, on the W. coast of Galicia. N. lat. 43° 3'. W. long. 9° 20'.

TOURMALINE, in *Mineralogy*, a stone sometimes used as a gem by jewellers, and particularly remarkable for exhibiting electricity by heat or friction. It almost always occurs in long prisms which are deeply striated. The common form of the crystal is a six-sided prism, terminated by three principal planes, which on one extremity are set on the sides of the prism, and on the other on the edges.

TOURMALINE.

The edges of the prism are frequently truncated, and thus form prisms with nine or twelve sides. The primitive form of the crystal, according to Haüy, is an obtuse rhomb. The fracture of tourmaline is perfectly conchoidal; the internal lustre is vitreous. It is harder than hornblende, but less hard than quartz: it scratches glass, and is brittle. The principal colours are dark green and brown, but it occurs also red and blue, of various shades and degrees of intensity. It is sometimes nearly opaque, but more frequently translucent or transparent. The crystals of tourmaline possess the peculiar property of being transparent when the light passes perpendicular to the axis of the prism, and opaque when it passes in the direction of the axis. It is always opaque when the height of the prism is less than its breadth. The principal form of the crystal has been before stated; but the most common of the fourteen or fifteen different varieties, is the prism with nine sides terminated by six planes at one end, and by three at the other; or by seven planes at one end, and three at the other. The end which has the smallest number of planes exhibits negative electricity, and that which has the greatest number, positive. This difference in the form of the electric poles is a general law of all crystallized minerals that are electric by heat. Before the blowpipe, the tourmaline melts into a greyish-white porous enamel, but the red Siberian tourmaline is infusible. The constituent parts of tourmaline are given by Vauquelin and Klaproth as under.

According to Vauquelin :

	Green Tourmaline from Brazil.	Violet Tourmaline from Siberia.
Silex - - -	40	42
Alumine - -	39	40
Soda - - -		10
Lime - - -	3.84	
Oxyd of iron -	12.5	
Oxyd of manganese	2	7

According to Klaproth :

	Red Tourmaline from Rosene.	Black Tourmaline.
Silex - - -	43.5	35
Alumine - -	42.25	40
Soda - - -	9	
Oxyd of manganese	1.5	
Oxyd of iron -		22
Lime - - -	0.1	
Water - - -	1.25	

The tourmaline is a name given, as Dr. Watson has evinced, to the *lyncurium* of the ancients. See *LYNCURIUS Lapis*.

This stone is very common in several parts of the East Indies, particularly in the island of Ceylon, where it is called *tourmalal*. Pliny mentions a red or purple stone which attracted light bodies. This is supposed to be the tourmaline. The first account of this stone, that occurs of late years, is in the History of the Royal Academy of Sciences at Paris for 1717, where we are told that M. Lemery exhibited an uncommon stone brought from Ceylon, which attracted and repelled small light bodies. Linnæus, in his *Flora Zeylanica*, calls this stone *lapis electricus*, and takes notice of Lemery's experiments. M. Æpinus, having been informed of the attractive power of the tourmaline by Mr. Lechman, and furnished by him with two stones, made many experiments, the result of which was published in the History of the Academy of Sciences and Belles Lettres at Berlin, for 1756. The substance of his memoir is as follows: the tourmaline has always, at the same time, a positive

and a negative electricity; the one of its sides being in one state, and the other in the opposite; and this does not depend on the external form of the stone. These electricities he could excite in the strongest degree by plunging the stone in boiling water.

The proper degree of heat for manifesting the electricity of the tourmaline, is from 100° Fahrenheit to 212°. If we raise the temperature above 212°, it loses its electricity, but regains it in cooling; but if we continue to raise the temperature, we arrive at a point in which the mineral again becomes electric, but has its poles reversed to what they were before. Haüy observed, that we may also change the position of the poles, by heating it unequally in the focus of a lens or mirror. If an electrified tourmaline be broken, the fragments immediately present electric poles, situated in the same direction as that of the large crystal.

If one side of the tourmaline be heated more than the other (as if it had lain upon a hot cake of metal), each of the sides acquires an electricity opposite to that which is natural to it; but if left to itself, it will return to its natural state.

If one of the sides of the tourmaline be rubbed, while the other is in contact with some conductor communicating with the ground; the rubbed side is always positive, and the other negative. If neither side be in contact with a conductor, both become positive. If, in the former of these cases, the tourmaline be rubbed so as to acquire a sensible heat, and the side which is naturally positive be made negative, it will, upon standing to cool, return to its natural state; but if it have acquired no sensible heat, it will not return to its natural state while any kind of electricity remains. If it be heated, even when it is rubbed and insulated (in which case both sides become positive), it will still return to its natural state upon cooling.

The Duc de Noya, who, in 1758, procured two of these stones in Holland, and made a number of experiments with them, an account of which he published, mentions the experiments of M. Æpinus, but does not admit of a *plus* and *minus* electricity belonging to the tourmaline when heated. On the contrary, he says that both the sides are electrified *plus*, but one of them more than the other. The tourmaline was introduced to the notice of the English philosophers by Dr. Heberden, who procured one (and, indeed, the only one known in England at that time) for Mr. Wilson; whose experiments confirmed the opinion of its positive and negative power, advanced by M. Æpinus. Dr. Franklin, likewise, in a letter to Dr. Heberden, in 1759, informs him of experiments on one of these stones, sufficient for establishing the same theory. About this time Dr. Heberden procured some of these stones from Holland, and put them into the hands of Mr. Wilson and Mr. Canton, gentlemen particularly conversant with the subject of electricity, and capable of using them with the greatest advantage to this branch of science. Mr. Wilson's experiments and observations are very numerous; the result of which was, in the main, the same with that of M. Æpinus, establishing the opinion of the two different powers of this stone; but he differs from him in asserting, that when the sides of the tourmaline are unequally heated, it exhibits that species of electricity which is natural to the hotter side; *i. e.* the tourmaline is *plus* on both sides, when the *plus* side is the hottest; and *minus* on both sides, when the *minus* side is the hottest. Both these gentlemen repeated their experiments, and each retained his own opinion; but Mr. Wilson's apparatus was better calculated for the purpose of accurate experiments than that of M. Æpinus, and he used a greater variety of methods

TOURMALINE.

methods for communicating heat to his tourmaline. Mr. Wilson imagined that this stone, as well as glass, was permeable to the electric fluid, and that the resistance to its entering the substance of it was less on what he calls the negative than on the positive side; for rubbing the positive side of the stone strongly, he found both sides electrified *plus*; by rubbing the negative side in the same manner, both sides were electrified *plus*, more strongly than before. Several experiments led Mr. Wilson to conclude, that the tourmaline resisted the exit and entrance of the electric fluid considerably less than glass, or even than amber; and he infers, upon the whole, that this stone differs in nothing from other electric bodies but in acquiring electricity by heat. Mr. Wilson also conceived, that the tourmaline suffered the electric fluid to pass through it only in one direction, bearing in this respect some analogy to the load-stone, and having as it were two electric poles, which are not easily destroyed or altered. He also apprehended, that the electric fluid, flowing through all the stones and gems which resemble the tourmaline in their electrical properties, moves in that direction in which the grain happens to lie; the resistance, as he supposes, which the fluid meets with, being less in that direction than in any other.

Notwithstanding the attention given to this subject by M. *Æpinus* and Mr. Wilson, the most important discovery relating to the electricity of the tourmaline was reserved for Mr. Canton, who, in a paper read before the Royal Society in December 1759, observes, that the tourmaline emits and absorbs the electric fluid only by the increase or diminution of its heat; for if the tourmaline, he says, be placed on a plain piece of heated glass or metal, so that each side of it, by being perpendicular to the surface of the heated body, may be equally heated; it will while heating have the electricity of one of its sides positive, and that of the other negative. This will likewise be the case, when it is taken out of boiling water, and suffered to cool; but the side which was positive while it was heating, will be negative while it is cooling; and the side which was negative will be positive. In the *Gentleman's Magazine* for September 1759, (vol. xxix. p. 424.) he published the result of some experiments which he had made on a tourmaline procured from Holland, in a series of propositions, comprising the principal part of what is known on this subject. They are as follow: 1. When the tourmaline is not electrical or attractive, heating it, without friction, will make it so; and the electricity of one side of it (distinguished by A) will be positive, and that of the other side (B) will be negative. 2. The tourmaline not being electrical, will become so by cooling; but with this difference, that the side A will be negative, and the side B positive. 3. If the tourmaline, in a non-electrical state, be heated, and suffered to cool again, without either of its sides being touched; A will be positive and B negative, during the whole time of the increase and decrease of its heat. 4. Either side of the tourmaline will be positive by friction, and both may be so made at the same time. He suggests that, if air be endued with similar properties, or be capable of becoming electrical by the increase or diminution of its heat (as is probable by attending to its state before and after a thunder-storm), thunder-clouds, both positive and negative, as well as thunder-gusts, may be easily accounted for. Mr. Canton, with the tourmaline which he received from Dr. Heberden, made other new and curious experiments, first published by Dr. Priestley. He put one of them, which was of the common colour, into the flame from a blowpipe, and burnt it white; when he found that its electrical property was entirely destroyed. The electricity of another was only in part destroyed by fire.

He joined two others, made soft by fire, without destroying their electrical property. The virtue of another was improved by being melted at one end; and he found (contrary to what Mr. Wilson had observed of another tourmaline, heated in the same manner) that one tourmaline retained its electrical property, after it had been frequently made red-hot, and in that state put into cold water. But the most curious experiment was made on a large irregular tourmaline, about half an inch long, which he cut into three pieces; taking one part from the positive and another from the negative end. Trying these pieces separately, he found the outer side of the piece cut from the end that was negative when cooling, was likewise negative when cooling; and that the outer side of that piece which was cut from the end that was positive when cooling, was likewise positive when cooling; the opposite sides of both pieces being, according to the general law of the electricity of the tourmaline, in a contrary state. The middle part of the same stone was affected as it had been when it was entire; the positive end remaining positive, and the negative end negative.

Dr. Priestley, about the close of the year 1766, directed his attention to the tourmaline: being in possession of Dr. Heberden's large polished one, which weighed one hundred and twenty grains, of an oval form, plane on one side and convex on the other, and which had passed through the hands of Mr. Wilson and Mr. Canton, he pursued his investigation of the properties of this stone in a variety of experiments. Several of them were undertaken with a view of determining, whether the tourmaline collected its electricity from the neighbouring air: he was led to this conjecture from the consideration of Mr. Wilcke's experiments on the production of spontaneous electricity, by melting one substance within another; and his experiments seem to prove that his conjecture was just. He also discovered a method of reversing all the experiments made upon the tourmaline, making that side which is positive in heating or cooling to be negative; and that which is negative to be positive: so that the kind of electricity shall be just what the operator shall direct, by the application of proper substances to the stone. Dr. Priestley not only tried how the tourmaline would be affected by being heated or cooled in contact with various substances, to which only one of its sides was exposed at once, but he also made other experiments, in which the stone was entirely surrounded by them. Having covered the stone to the thickness of about a crown-piece with sealing-wax, he found it to act nearly, if not quite as well, through this coating of wax, as if it had been exposed to the air: hence, if a tourmaline be concealed in a stick of sealing-wax, the wax will seem to have acquired the properties of the tourmaline. See on this article *Phil. Trans.* vol. li. p. 308, &c. p. 394, &c. vol. liii. p. 436, &c. *Franklin's Letters*, &c. p. 376. *Priestley's Electricity*, vol. i. p. 347, &c. vol. ii. p. 308, &c. 8vo. ed.

The tourmaline, according to Mr. Kirwan, is a siliceous earth, imperfectly united with from 1.05 to 1.47 of its weight of argil, from 0.3 to 0.4 of its weight of mild calcareous earth, and from 0.15 to 0.243 of its weight of iron. This stone has been found in Ceylon, Brazil, and the Tyrol: a specimen of each has been examined by Mr. Bergman; that of Ceylon is of a dark-brown or yellowish colour; its specific gravity 3.065 or 3.295: that of Brazil is green, blue, red, or yellow, and its specific gravity 3.07 or 3.18: that of the Tyrol, by reflected light, is of a blackish-brown, but by refracted light, yellowish, or in thin pieces, green; its specific gravity 3.05. In fire, none of them decrepitate: but those of Ceylon and

and the Tyrol melt *per se* into a black frothy slag. That of Brazil forms only a brittle scoria. Bergman's Ess. by Cullen, vol. ii. p. 120, &c. 1784. Kirwan's Elem. Mineral, p. 131.

The red-coloured tourmaline from Siberia is regarded by some mineralogists as a distinct species; it differs from other tourmalines in being infusible: it has been denominated *rubellite*, (which see.) The indigo-blue variety of tourmaline has been called by Karsten and Dendrada an *indicolite*.

The tourmaline occurs imbedded in gneiss, mica-slate, talcous slate, and talc. It is sometimes found in granite. It is found in rolled pieces in alluvial ground: it was first discovered in the island of Ceylon in the 16th century. It has since been found in various alpine districts of Europe and Asia, in the island of Madagascar, and in North and South America.

The tourmaline may be distinguished from common schorl by its colour; the latter is always black. The fracture in common schorl is small-grained and uneven, that of tourmaline conchoidal. The opacity of common schorl is always greater than that of tourmaline. It differs from common and basaltic hornblende in its structure, that of the latter being distinctly foliated. The following names have been given to different varieties of tourmaline.

Green tourmaline	named	Brasilian emerald
Berlin blue	-	Brasilian sapphire.
Indigo-blue	-	Indicolite.
Honey-yellow	-	Peridot of Ceylon.
Red	-	{ Rubellite, fiberite, and tourmaline apyre.

In the Memoirs of the Royal Academy of Sciences at Berlin for 1780, we have the following directions by Mr. Margraaf, for forming a composition similar to the tourmaline. Take magnesia, or that earth which is the basis of the sal catharticus amarus; mix it with chalk, which has been dissolved in spirit of nitre, and precipitated from thence by a solution of salt of tartar, and then well edulcorated; add to this mixture equal quantities of flint and clay (taking a scruple of each of the four ingredients), and four grains of the precipitate of sublimat of fusible spar, or what is here called the fluor crust, *i. e.* the earth, which is not only sublimed from the fluor or Derbyshire spar, on heating it with oil of vitriol, but may also be precipitated from thence, and from the acid liquor in the receiver, by the addition of a solution of salt of tartar.

To two drachms of the above mixture add five grains of crocus martis, calcined according to the method of Kunckel, during four months, in a glass-house furnace, and the result will be the formation of a vitreous stone, similar to the tourmaline.

TOURMENTINE, in *Geography*, a town of France, in the department of the Maine and Loire; 6 miles N.N.E. of Chollet.

TOURN, in *Law*. See **TURN**.

TOURNAMENT. See **TURNAMENT**.

TOURNAN, in *Geography*, a town of France, in the department of the Seine and Marne; 13 miles N. of Melun.

TOURNAY, a city of France, in the department of Jemappe, on the Scheld, considered as the most ancient town of Belgic Gaul, being founded 600 years B.C., and anciently the capital of the Nervii. It was lately the capital of a district to which it gave name, and the see of a bishop, erected in the fifth century. This city has often been taken and laid waste in the different wars between the

French, English, and Flemings. By the peace of Aix-la-Chapelle it was ceded to France, and made one of the best fortified towns in Flanders. In 1709, prince Eugene and the duke of Marlborough invested Tournay, and besieged it in form. The town capitulated, being in want of provisions. The citadel held out till the 3d of September, when the garrison surrendered prisoners of war. By the peace of Utrecht, in the year 1713, the States-General remained masters of the military, and the emperor of the civil government. In 1745, after the battle of Fontenoy, it was taken by the French, but ceded to the Austrians, by the peace of Aix-la-Chapelle, in 1748. The late emperor Joseph ordered the fortifications to be destroyed. In 1792 an action took place between the Austrians and the French near Tournay, in which M. Dillon commanded the latter; and being suspected of treachery, was murdered at Lille by the soldiers. On the 10th of May, 1794, the duke of York was assailed near Tournay by the republican forces, in different columns, to the amount of 30,000 men; but they were compelled to retreat. In 1794, on the general evacuation of Flanders by the allies, the French entered Tournay, where they found 20 guns spiked, 10,000 musket-balls, a large quantity of gunpowder, several magazines, and 14 barges laden with ammunition; 3 posts E. of Lille. N. lat. 50° 35'. E. long. 3° 25'.

TOURNAY, a town of France, in the department of the Pyrenées; 9 miles S.E. of Tarbes.

TOURNE-COUPÉ-EN-BIGORRE, a town of France, in the department of the Gers; 9 miles S.E. of Lectoure.

TOURNEFORT, JOSEPH PITTON DE, in *Biography*, the great leader of the French school of botany, of whom we have spoken (see RIVINUS) as one of the three most distinguished systematic writers of the age preceding Linnæus, was born of a gentleman's family at Aix, in Provence, June 5th, 1656. His mother, Ademara Fagouë, was of a Parisian family, likewise, in the French sense, noble. Being destined by his parents for the church, he was educated at the Jesuits' college of his native town; but he soon imbibed a taste for natural knowledge, which led him at the age of 21, on the death of his father, to change his original destination, for the profession of physic. This latter indeed was but subservient to a most ardent devotion for botanic science, which ever after made the object and the happiness of his life. Not that his education, in other respects, was neglected; for he proved a good scholar, well grounded in the studies necessary to his medical profession, particularly anatomy and chemistry, and no less versed in historical and critical knowledge; inasmuch that he became an elegant writer and lecturer, as happy in his powers of communicating, as of acquiring, information. His personal character, manners, and address were also such as to prove a general recommendation in his favour through life.

Having soon exhausted the botanical riches of a physic-garden at Aix, and of the circumjacent fields, he extended his researches to the neighbouring Alps, and afterwards to the Pyrenées, where his hardy frame of body, and his observing enterprising mind, rendered easy to him the acquisition of the principal vegetable stores of those romantic and fertile regions. Even the thievish and lawless borders, which so often infest the borders of kingdoms, and which then abounded in the Pyrenean fastnesses, were scarcely formidable to a traveller, whose only riches were dried plants, and whose ostentible provision for his journey consisted of a little black bread, in which he concealed his money. The intermediate winters between his several visits to Dauphiny, Savoy, Catalonia, the Pyrenées, &c.

TOURNEFORT.

were spent in the university of Montpellier, where he first entered in 1679; but he is said to have taken his doctor's degree at Orange. At Montpellier he enjoyed the intimacy of the excellent MAGNOL, of whom we have given an account in his proper place, and to whom the long-established botanical fame of that university is chiefly owing. Yet this able man narrowly escaped being hunted from his seat; as his no less eminent successor, professor Decandolle, has lately, in 1816, been, because he was a Protestant; nor could the appointment of his king protect the latter from that king's worst enemies. Tournefort was in no danger of this kind. He was nevertheless a liberal Catholic, whose subsequent animadversions on the depraved superstitions that occurred in his travels, prove him to have been by no means the slave of any church or priesthood.

The merits of Tournefort, as a botanist, soon became conspicuous at Paris, and, aided by a fortunate introduction, procured him the especial favour of professor Fagon, then chief physician to the queen, (see FAGONIA,) who resigned in his favour the superintendance of the royal garden. In this school he was soon attended by a numerous throng of students, eager to follow him in his herborizations round Paris, and to profit by his practical remarks. We have already, in our account of WILLIAM SHERARD, mentioned that illustrious botanist as among his assiduous pupils. The subject of our memoir now became desirous of further examining the productions of other countries than his own, in their native situations. For this purpose he travelled in 1688 to Spain and Portugal, afterwards into Holland and England; enriching by these means his own collection of dried plants, as well as the living collections of the Parisian garden, and procuring the acquaintance and correspondence of all the most eminent cultivators of the science in which he excelled. Hence the great herbarium of Sherard became supplied with all Tournefort's acquisitions, not only at that time, but after his subsequent voyage to the East, the fruits of which were transmitted to England with more particular care and exactness, than perhaps to any other country, as appears by what are still preserved at Oxford. The studies and labours of Tournefort were facilitated and encouraged by a royal pension, which could certainly not come under the opprobrious denomination of a sinecure. In 1692 he became a member of the Academy of Sciences, and in 1694 published in French his *Elements de Botanique*, making three octavo volumes, dedicated to Louis XIV.—This was but a prelude to his immortal work, the *Institutiones Rei Herbarie*, of which the first edition, in three quarto volumes, with 476 plates, appeared in 1700. The second, which, with a reference to the "*Elements*," is called the third, was published by Anthony de Jussieu, at Lyons, in 1719, with the *Curollarium*, composed of the author's Oriental discoveries. In 1698, when he was admitted a member of the Medical Faculty at Paris, he published a little duodecimo volume, *Histoire des Plantes qui naissent aux Environs de Paris*, afterwards translated by professor Martyn into English. The reputed virtues of the plants are subjoined to their synonyms and descriptions. The arrangement is alphabetical, the style desultory, nor is this one of the best books of its kind.

We know not at what period Tournefort received the order of St. Michael, but that he was decorated therewith appears by his portrait, published by Dr. Thornton, from an original picture; and the circumstance is alluded to by Haller, *Bibl. Bot.* v. 2, 3.

At the earnest recommendation of his friend Fagon, Tournefort was dispatched, under royal patronage, on a voyage to the Levant, the avowed object of which was to

investigate the plants of ancient writers, as well as to make new discoveries. He was accompanied by a German physician, named Andrew Gundelsheimer, (see GUNDELIA,) and by Claude Aubriet, one of the most exquisite botanical painters that the world ever saw. These travellers left Paris on the 9th of March, 1700, and embarking at Marseilles the 23d of April, anchored nine days afterwards in Crete. The investigation of the Archipelago, Greece, the shores of the Euxine, the countries of Bithynia, Cappadocia, Iberia, Armenia, Georgia, Galatia, Lydia, &c. occupied two years, and our adventurers returned in safety to Marseilles, on the 3d of June, 1702. Tournefort's account of this expedition, written in French, and published soon after his decease, is one of the most agreeable, intelligent, and valuable books of travels extant. De Theis justly reverts the censure of the Abbate Sestini, that it is written with the *furia francese*, or rage for every thing French. To the mode of its composition indeed something may be objected. The work is addressed, in the form of letters, to the comte de Pontchartrain, secretary of state, &c. &c.; and as the etiquette of the French court required that so illustrious a personage should of course be endued with all human erudition and knowledge, the writer is obliged to treat him accordingly. We are therefore told nothing without the impertinence of "vous sçavez Monseigneur;" except perhaps the harmless description of a new plant, in writing which the author's love of science made him slip, for a moment, the collar of patronage. The reader indeed soon forgets every thing but the delightful company of the narrator, who takes us along with him to every spot; details with equal intelligence the manners, dresses, and information of the people he visits; or carries us into the profoundest researches of ancient history and geography; tracing the fate of empires, countries, and cities, with the same grace and facility with which he makes us enamoured with a new plant, or exposes the impositions or the ignorance of empirics of the soul or body. This work is illustrated with a very large number of plates, of which the botanical ones are peculiarly excellent. We have a good English edition, and Haller mentions one in Dutch. The curious grotto of Antiparos afforded the author an opportunity of detailing his favourite theory of the vegetation of stones, which is now refuted by more accurate chemical enquiries. (See STONES.) His travels were to have extended into Africa, but the plague raging in Egypt, he returned home directly from Smyrna. On arriving at Paris, it was his design to have turned to advantage the connections and reputation he had acquired, by devoting himself to the practice of physic. But whatever prospect he might formerly have had of success in this line, was defeated by his long absence; nor did the duties of his botanical appointments leave him sufficient leisure to court or to pursue his more lucrative profession. His time however was incessantly occupied; and the preparation of his *Voyage du Levant* for publication, which, considering the books necessary to be consulted, was no light or speedy task, led him too often to encroach on the night, after the superabundant labours of the day. His health became impaired, but this could not relax his ardour. His fate however was precipitated by the accident of a carriage in the street, which crushed his breast, and even threatened him with instant death, from which he was rescued by the exertions of a friend near at hand. He languished for a few months only after this event, and died December 28, 1708, in the fifty-third year of his age. We find no mention of his place of burial, nor of any monument erected to his memory. He was never married. He left his collection of plants to the king, who bestowed a pension of a thousand

TOURNEFORT.

thousand livres on his nephew, as an avowed return for this legacy, and a testimony of royal esteem for the deceased. The first volume only of his *Voyage* was printed at the time of its author's death. A second edition appeared at Amsterdam in 1718, to which are prefixed the *elogé* of Tournefort, delivered by Fontenelle to the Academy of Sciences, April 10, 1709; and a more ample composition of the same kind by Lauthier, in a letter to M. Begon, the patron of Plumier, and the friend of Tournefort. This last account, in particular, is written with the affection and respect of a person intimately acquainted with the private character, as well as public merits, of the subject of his narrative. Tournefort is described by him as of the most simple though engaging manners, devoid alike of ostentation and of jealousy, as amiable and exemplary in private life, as he was zealous and exact to fulfil his public duties. Besides his knowledge of Latin and Greek, he was versed in the Italian and Spanish languages. The abundant riches of his mind were readily communicated, with clearness and facility, but without parade, in his conversation as well as in his lectures.

Of the principal works of this eminent man, we have already spoken, and it chiefly remains for us to offer some remarks upon his merits as a systematic botanist. He is said to have left several works in manuscript. One of these was entitled *Topographie Botanique*, containing the precise places of growth of the plants collected by himself in the south of France, as well as in Spain and Portugal, between the years 1676 and 1690. He also composed an universal critical history of plants, in alphabetical order, under the title of *Plantarum Adversaria*, in which the remarks of preceding writers were collected and compared, and his own opinions subjoined. The *Schola Botanica* a catalogue of the Paris garden, we have already mentioned in the biographical article of WILLIAM SHERARD. M. Lauthier removes all doubt respecting the real author of that little volume, by informing us he had seen a copy, with manuscript additions and corrections in Tournefort's own hand, where Sherard was named as the writer of the book.

Tournefort was led, by the philosophy of his time, to search for the medical qualities of plants by a chemical analysis. On this subject he is recorded to have left a volume of manuscripts. That it has never been published is no loss to the world; the work of Geoffroy, undertaken, and laboriously accomplished, with the same view, having proved that no real knowledge is to be acquired by this means, and having therefore set the question for ever at rest. Our readers will find the principles of Tournefort's system of botanical arrangement, under the article CLASSIFICATION. According to this, his *Institutiones Rei Herbariæ* are disposed; and the same system was adopted by several compilers of local *Floras*, or of garden Catalogues, in the early part of the eighteenth century. Even Linnæus's earliest work, entitled *Spolia Botanica, sive Plantæ Rariores per Smolandiam, Scaniam et Roslagiam observatæ et enumeratæ*, the unpublished manuscript of which, dated Upsal, 1729, and illustrated with drawings, is now before us, is classed after Tournefort's method. Nor did any great difficulties attend the application of that method to any tribes of plants with which its author had been conversant. But when the productions of new continents came to be examined, it necessarily fell short; as we have remarked in the biographical article of DR. ALEXANDER GARDEN. No system of botanical classification, except the artificial sexual one of Linnæus, has ever proved universally applicable to the vegetables of all countries, because no other depends on parts essential to the very being of every plant.

Tournefort's method, however, by its apparent facility,
VOL. XXXVI.

the elegance of the parts on which it chiefly rested, and its great conformity, in many respects, to the evident order of nature, though in others it as remarkably infringes on that order; became, by all these attractions, very popular. If the more abstruse and philosophical principles of Cæsalpinus, Ray, Hermann, &c. educated founder theoretical botanists; the method of Tournefort made a great number of practical ones. Yet it is not upon his system of classification that the fame of this great naturalist depends. His discrimination of the genera of plants must alone immortalize his memory. His labours in this department of the science are the principal foundation of all that has been done since his time, and of all that can ever be attempted in future. If he did not, like Linnæus, invent a clear mode of defining each genus by words, no one can deny that he had a most comprehensive, and, for the chief part, distinct idea of the whole subject. He has caused each genus to be figured in so able a manner, that his exquisite plates supply, as much as possible, all verbal deficiencies. Haller indeed complains, not unjustly, that Tournefort's figures are more instructive than his definitions, as exhibiting characters respecting the stamens, styles, and other parts of flowers, which, though affording the best generic distinctions, are not taken into his descriptions. Such defects seem to have arisen from his disappointment, bordering on contempt, of the doctrine of the sexes of plants. He thought the anthers served merely to discharge an excrementitious matter, or to separate impurities from the embryo; though it could not escape him that these two parts were often very distant from each other; and he was therefore not much satisfied with his own hypothesis. Such dissatisfaction would naturally lead him farther from dwelling with pleasure on the parts in question, for any purposes of arrangement. He rather delighted to persist in the disgraceful blunder of the old authors, who spoke of the male and female plants of Nettle, Mercury, Hemp, &c. as distinct species, and called the female the male, because of the form of the seed-vessel. It is indeed one of the most remarkable facts in the philosophy of botany, if it may here deserve so honourable an appellation, that when the most ancient writers, as well as their early followers among the moderns, distinguished plants by the names of male and female, they meant to designate them, in general, as different species. Tournefort, from inadvertency surely, followed them in this error, as well as in every other, relating to the species of plants. To that subject he never gave any philosophical attention. The plan of his work was to dispose all the known plants, under genera, whose leading principles of distinction were, with some exceptions, taken from the fructification. This great undertaking he accomplished in a masterly manner, as well as the arrangement of those genera, according to a philosophical system. But he was content to collect under each genus all the reputed species of Caspar Bauhin and others, judging of their generic character only, and not taking into the least consideration their specific differences. Hence double flowers, varieties of colour, flavour, &c. stand as species in Tournefort's *Institutiones*. It is unfair to blame him for imperfections in what he never undertook to amend; but if genuine specific distinctions be, as Linnæus declared, the perfection of botanical science, as they are, in fact, the only permanent and indisputable ground of the whole; we cannot claim for Tournefort the highest rank as a practical botanical philosopher. That he was deeply and learnedly versed in the theory of the science, appears from all parts of his writings, and from none more than his masterly *Isagoge in Rem Herbariam*, where the subject is treated historically as well as systematically. Whatever this illustrious botanist has done, or whatever he has

left undone, he is the father of the French school of botany, and the traces of his principles, either confirmed, improved, or superseded by the labours of other teachers, are conspicuous in the works of his distinguished followers Vaillant, Lamarck, and the Jussieus. With the feelings of the first of these, as Vaillant could not but be sensible that, in some important points, he had the advantage of his great predecessor, somewhat of conscious superiority, not inconsistent with jealousy, was often intermixed, and too often betrayed. But the others, living at too remote a period from their idol to consider him otherwise than as the glory of their country, have made him ample amends in identifying his fame with that of France itself. The most valuable improvements, not only in classification, but in nomenclature, were, for a long time, not permitted to encroach even on the negligences or errors of Tournefort. The national spirit of the French still renders this illiberal principle sacred. The homage long given to Tournefort is now transferred to Jussieu. The term of *l'èze-nature* is applied to the Linnæan system, as if his own were entirely a natural one, and as if what the great Swedish botanist modestly called fragments of a natural scheme of arrangement, were not, in fact, the basis of the best part of Jussieu's. The mischief of these exclusive partialities is, that the really valuable improvements in science, which originate in other schools, are too much neglected by the pupils of the Parisian one. In clear discrimination, and concise definition, in lucid order, elegant and classical terminology and nomenclature, in judicious combination, as opposed to fastidious and indiscriminate distinction, they generally, and sometimes very remarkably, fail. If any of them should deign to peruse this criticism, may they disarm it by correcting the imperfections to which it alludes! Rivalship in science or philosophy ought only to lead to mutual improvement; for he who will learn nothing from an adversary, does but render apparent one discreditable cause of his own imperfections. Tournefort's Works. Hall. Bibl. Bot. S.

TOURNEFORTIA, in *Botany*, bears that name in commemoration of the great French botanist, of whom we have given an account in the preceding article. This genus, founded by Plumier, was called by him *Pittonia*, after the family name of the person commemorated. Linnæus altered it, according to his own rule, of retaining the appellation by which that person was most known. So he preferred *Hippocratea* to the *Coa* of Plumier, and *Theophrasta* to his *Eresia*. French writers have subsequently acceded to this decision.—Linn. Gen. 78. Schreb. 104. Willd. Sp. Pl. v. 1. 791. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 303. Brown Prodr. Nov. Holl. v. 1. 496. Juss. 129. Lamarck Illustr. t. 95. Poiret in Lam. Dict. v. 5. 355. Gært. t. 76. (*Pittonia*; Plum. Gen. 5. t. 3.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifoliae*, Linn. *Borraginæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, in five deep, awl-shaped, permanent segments. *Cor.* of one petal, funnel-shaped; tube cylindrical, globose at the bottom; limb spreading, divided half way down into five pointed, horizontal segments. *Stam.* Filaments five, awl-shaped, in the throat of the corolla; anthers simple, within the orifice of the tube, converging, pointed. *Pist.* Germen superior, globose; style simple, the length of the stamens, club-shaped; stigma bare, umbonate. *Peric.* Berry globose, of two cells, perforated by two pores at the summit. *Seeds* four, nearly ovate, separated by pulp.

Ess. Ch. Corolla funnel-shaped, with a naked throat. Stamens in the tube. Stigma umbonate. Berry superior, of two cells. Seeds two in each cell.

A tropical genus of erect or twining shrubs, with simple, undivided, alternate, rough, hairy, or silky, rarely smooth, leaves. The flowers are numerous, mostly white or blueish, in dense, recurved, unilateral, often cymose, spikes, without bractæas. Berries white, blueish or black. In habit, this genus comes nearest to *HELIOTROPIMUM*; *MESSERSCHMIDIA* is united to it by Mr. Brown. (See those articles.) In the true *Tournefortia*, according to that learned botanist, the berry has only two seeds, or nuts, each with two cells. To these belong the *Messerschmidia*, and *Heliotropium gnaphalodes* of Linnæus. In *T. hirsutissima*, the berry has four simple, or single-kernelled, seeds, and a straight embryo. In *T. volubilis* of Linnæus, and *scandens* of Solander, to which we may add *sericea* of Vahl, the segments of the corolla are awl-shaped, the berry with four simple seeds, of which two or three are often abortive, and a curved embryo. Mr. Brown would separate all these from *Tournefortia*, but whether the *hirsutissima* should form a distinct genus from the species with awl-shaped segments of the corolla, he is doubtful. A consideration of the genera *Onosma* and *Cerinth*, to say nothing of others of this same order, makes us doubtful whether the number of parts, or cells, in the fruit, or rather the greater or less union of those parts, can here make a generic distinction. We submit it to the re-consideration of our learned friend; and in the meanwhile we shall attempt a display of all the species of *Tournefortia*, of which Linnæus and Willdenow have given but a very incomplete list. Poiret in Lamarck's Dict. has added several to the number, but we possess some, even from Commerçon's collection, which are not to be referred to any of his. Some of the described ones have not come under our inspection, and the history of others is much confused, but we hope to leave the subject, if not fully elucidated, at least in a clearer state than we find it.—*T. humilis*, Linn. Sp. Pl. 202, belongs, according to Mr. Brown, to *HELIOTROPIMUM*. See that article.

1. *T. ferrata*. Greater Serrated Tournefortia. Linn. Sp. Pl. 201. Willd. n. 1. (*Pittonia arborescens*, *chamædrifolia major*; Plum. Ic. 224. t. 228. f. 1. *Varronia mirabiloides*; Poiret in Lam. Dict. v. 4. 262.)—Leaves ovate, serrated, on spinescent footstalks. Spikes recurved, on axillary stalks, longer than the leaves.—Native of the West Indies, where it was found by Plumier, from whose figure alone it is known to us. The stem is said to be arborescent, with round zigzag branches. Leaves about two inches long, strongly serrated, on stalks nearly an inch in length, each with a joint about the middle, where the stalk seems finally to separate, the lower part hardening into a spine. Flower-stalks axillary, solitary, each bearing three recurved spikes, of numerous, large sessile flowers, the limb of whose corolla is undulated, an inch in diameter. Berry the size of a pea, globose, undivided. Poiret says it is red. If his plant from Hispaniola be the same, this species must be removed to *Varronia*, which is rendered probable by the aspect of its corolla.

2. *T. chamædrifolia*. Lesser Serrated Tournefortia—(*T. ferrata* β; Linn. Sp. Pl. 201. Willd. n. 1. *Pittonia arborescens*, *chamædrifolia minor*; Plum. Ic. 224. t. 228. f. 2.)—Leaves oblong, serrated, on recurved spinescent footstalks. Spikes capital, terminal.—For this also our only authority is Plumier, who gathered it in some part of the West Indies. It appears to differ essentially from the former, in the characters above given, as well as its much smaller size. The flowers however are nearly as large, but much fewer, with partial stalks, which become very conspicuous as the fruit ripens. Their corolla is represented very regularly crenate, rather than undulated, but indicates a *Varronia*, as well as that of the foregoing.

TOURNEFORTIA.

3. *T. hirsutissima*. Hairy Tournefortia. Linn. Sp. Pl. 201. Willd. n. 2. Poir. n. 1. Swartz Obf. 56. (*Pittonia hirsutissima et ramifoliosa, baccis albis*; Plum. Ic. 226. t. 228. *Heliotropii flore, frutex baccifer racemosus, folio rugoso foetido maximo subrotundo hirsuto, fructu albo*; Sloane Jam. v. 2. 108. t. 212. f. 1.)—Native of bushy places in Jamaica, and other West Indian islands, as well as of Mexico, from whence it was sent by Mutis to Linnæus. This is a *shrub*, three or four feet high, somewhat twining, its branches, stalks, foliage, and *calyx* clothed with rusty down. The *corolla* is still more densely covered externally with silky hairs. *Leaves* foetid, stalked, elliptical, entire, pointed at each end, transversely ribbed, three inches long, and an inch and half broad; most hairy, and rather silky, at the back. *Spikes* aggregate, on long, hairy, axillary and terminal stalks, about the ends of the branches. *Flowers*, as well as *berries*, white; the latter rough and hairy, Swartz says of two cells, with two seeds in each, which does not agree with Mr. Brown's account, given above.

4. *T. fatidissima*. Tobacco-leaved Tournefortia. Linn. Sp. Pl. 201. Willd. n. 5. Ait. n. 2. Swartz Obf. 58. (*Pittonia racemosa, nicotianæ foliis, foetidissima*; Plum. Ic. 226. t. 230.)—Leaves ovate-lanceolate, rough; downy and paler beneath. Flower-stalks branched. Spikes pendulous. *Calyx* shorter than the style.—Native of Jamaica. Dr. Wright. The leaves vary in size; but are not unlike those of *T. hirsutissima* in shape. Their upper surface is more minutely rough than in that species, and their under one more softly and densely downy. The *spikes* are very remarkable for their extremely long linear form, and pendulous position. They measure frequently eight or ten inches, and are from six to eight on each axillary forked stalk. The *flowers* are small, sessile, in a simple unilateral line. *Calyx* hairy, with lanceolate upright segments. Tube of the *corolla* hairy upwards, about thrice as long as the *calyx*; its limb in five ovate, obtuse, keeled, reflexed segments. *Style* projecting beyond the permanent *calyx*, after the *corolla* is fallen, with a very large pulley-shaped pointed stigma. This is united, by Lamarck and Poir. to the following, under the name of *macrophylla*; Poir. n. 2.

5. *T. cymosa*. Drooping Cymose Tournefortia. Linn. Sp. Pl. 202. Willd. n. 8. Ait. n. 4. Jacq. Coll. v. 1. 96. Ic. Rar. t. 31. (*Heliotropii flore, frutex, folio maximo oblongo acuminato glabro*; Sloane Jam. v. 2. 109. t. 212. f. 2.)—Leaves elliptic-lanceolate, pointed, smooth. Flower-stalks much branched. Spikes drooping. *Calyx* as long as the style.—Native of the West Indies. This is certainly, as Linnæus observes, nearly related to the foregoing, but differs in the smoothness, and more elongated points, of the leaves, as well as in its more numerous, shorter, and less directly pendulous, *spikes*. The *flowers* are similar, but the style in our specimens does not project beyond the *calyx*. The *corolla*, at first white, turns tawny, and dark red, before it falls. *Berry* the size of a small pea, white, with black dots.

6. *T. syringæfolia*. Lilac-leaved Tournefortia. Vahl Symb. v. 3. 23. Willd. n. 4. Poir. n. 17.—Leaves ovate, somewhat heart-shaped, pointed, smooth. Spikes terminal, divaricated, hairy, as well as the stalks.—Native of Cayenne, and, if we mistake not, of Jamaica, where our specimen, precisely answering to Vahl's description, was gathered by Dr. Wright. The young branches, as well as the *footstalks*, the main rib of the leaves on both sides, and the transverse ribs underneath, are all more or less hairy, like the *flower-stalks*, *spikes*, *calyx*, and outside of the *corolla*. *Leaves* two inches long, destitute of fine intermediate veins,

quite smooth, except the ribs. *Flower-stalk* terminal, erect, forked, with spreading *spikes* above an inch long. *Flowers* alternate. Segments of the *corolla* with long taper points.

7. *T. bicolor*. Pale-backed Tournefortia. Swartz Ind. Occ. v. 1. 344. Willd. n. 7. (*T. lævigata*; Poir. n. 3?)—Leaves elliptical, pointed, smooth; slightly rugged on the upper side. Spikes terminal, cymose, crowded, erect, recurved, somewhat hairy.—Native of bushy places in Jamaica. A *shrub* six feet high, with smooth branches. *Leaves* three or four inches long, elliptical rather than ovate, acute at each end, finely reticulated with veins between the ribs, occasionally minutely hairy, as well as the branches and *footstalks*; paler beneath. *Flower-stalks* several, terminal, alternate, rather hairy, erect, each bearing six or eight subdivided, cymose, dense *spikes*. Segments of the *calyx* ovate, scarcely hairy, except when the leaves are so. *Corolla* greenish-white, externally covered with silky hairs. *T. glabra*, Linn. Sp. Pl. ed. 1. 141, is perhaps a variety of this.

8. *T. maculata*. Four-dotted Tournefortia. Jacq. Amer. 47. Poir. n. 4.—Leaves ovate, pointed, smooth on both sides. Spikes much branched, pendulous, lax, recurved. Stalks slightly hairy.—Native of thickets in South America. Jacquin found it near Carthage. He describes it as a *shrub*, with weak branches. *Leaves* stalked, entire, scentless. *Berry* yellow, with four round black dots at the base. Poir. says the leaves are at least four inches long, and two broad. *Corolla* yellow, with a long narrow tube, and five acute segments.

9. *T. orientalis*. Twining Oriental Tournefortia. Br. n. 1.—Stem twining. Leaves broadly ovate, somewhat pointed, smooth. Cymes forked. Limb of the *corolla* five-cleft, with plaited sinuses. Nuts cellular.—Gathered by Sir Joseph Banks, in the tropical part of New Holland.

10. *T. sarmentosa*. Trailing Tournefortia. Poir. n. 5.—Leaves ovate-oblong, acute. Spikes branched, very short, two-ranked. Stem twining.—Native of the Mauritius. Sonnerat. A specimen gathered by Commerçon in the Philippine islands, answers very nearly to the following description of Poir. The stems are climbing, with long, distant, trailing shoots, striated, nearly cylindrical, clothed with short whitish hairs. *Leaves* alternate; downy, and whitish beneath, especially when young; rounded and dilated at the base; almost smooth on the upper surface; three or four inches long, and an inch and half wide. *Footstalks* short, very downy. *Flowers* terminal, in short, close, branched, downy spikes, and disposed in two rows, sessile. *Calyx* short, with blunt segments.

11. *T. brasiliensis*. Brasil Tournefortia. Poir. n. 6.—Leaves ovate-lanceolate, harsh, somewhat sinuated; whitish beneath. Stem round, acutely striated.—Sent to Lamarck from Brasil. Allied to the last, but the leaves are of a different shape, and the whole plant nearly destitute of pubescence. *Leaves* two or three inches long, an inch or more in breadth, contracted at their base, harsh on both sides, whitish and downy beneath when young. *Flowers* in short, reflexed, downy, hoary, branched *spikes*, composing a terminal cyme. Segments of the *calyx* downy, very acute, slightly recurved. Poir.

12. *T. arborescens*. Arborecent Tournefortia. Poir. n. 7.—Leaves ovate-lanceolate; somewhat downy when young. Spikes branched, very short. Stem arborescent.—Gathered by Sonnerat, in the East Indies. Branches woody, angular, rough and rugged, particularly the young shoots. *Leaves* oval-lanceolate, contracted at each end, veiny, ribbed, harsh, four or five inches long, an inch and half broad, white and downy beneath when young. We have nothing

TOURNEFORTIA.

answering to this description, nor is the specific character such as to afford much assistance in determining the plant.

13. *T. velutina*. Velvet-leaved Tournefortia. — Leaves elliptic-lanceolate, acute, silky on both sides. Spikes dense, aggregate, cymose, from the forks of the branches, silky. Stigma slightly two-lobed. — Gathered by Commerçon in mountainous woods of the isle of Bourbon. The *branches*, *stalks*, *leaves*, *calyx* and *corolla* are entirely clothed with fine silky silvery pubescence, the globose base, and obtuse limb of the latter, on its upper side, being the only smooth parts, except the *berries*, which are snow-white. The *leaves* are four or five inches long, somewhat undulated, various in breadth. We have from the Mauritius what may possibly be a variety, with very narrow, and nearly smooth, *leaves*. Its *inflorescence* betrays no difference.

14. *T. argentea*. Blunt-leaved Silvery Tournefortia. Linn. Suppl. 133. Willd. n. 9. Poiret n. 8. Brown n. 2. (Buglossum lanuginosum; Rumph. Amboin. v. 4. 119. t. 55.) — Leaves obovate, bluntish, silky on both sides. Spikes in repeatedly compound cymes. Tube of the corolla very short. — Native of the sea-coast, in Ceylon, Amboyna, Banda, and other parts of the East Indies. This *shrub* is hardly so tall as a man; its main *stem* very short, the *bark* full of deep fissures; the *branches* widely spreading, hairy. *Leaves* crowded about the ends of the branches, alternate, stalked, about three inches long, entire; tapering at the base; rather fleshy, beautifully clothed all over with the finest silky pubescence, which appears to vary in degree, and in one of our specimens, from the isle of Bourbon, excels in splendour every plant of our acquaintance. The *flower-stalks*, longer than the leaves, are at first terminal, but the branch is soon protruded at each side beyond them. They are subdivided into tufts of dense recurved *spikes*, above an inch in length. All the *stalks*, like the broad obtuse *calyx*, are silky. *Corolla* white, with a short tube, and a recurved limb, altogether not extending beyond the calyx. Mr. Brown describes the *stigma* as sessile and two-lobed. Rumphius says the *leaves* are eatable, and much esteemed in Amboyna for their falcish flavour.

15. *T. gnaphaloides*. Cud-weed Tournefortia. See Brown 496. (Heliotropium gnaphaloides; Linn. Sp. Pl. 188. Willd. Sp. Pl. v. 1. 745. H. gnaphaloides litoreum frutescens americanum; Pluk. Phyt. t. 193. f. 5.) — Leaves linear, obtuse, densely downy on both sides. Spikes dense, downy, recurved, on cymose stalks. — Native of the sea-coast in the West Indies. We follow Mr. Brown in removing to the present genus this elegant *shrub*, whose snow-white downy covering is rather more cottony than silky, and yet partakes of the silvery beauty of the last described. The *leaves* are crowded, thick, about two or three inches long, and hardly a quarter of an inch wide. *Flowers* small, white, in short, thick, woolly, solitary or twin, recurved spikes. *Berries* smooth, the size of a currant.

16. *T. suffruticosa*. Hoary-leaved Tournefortia. Linn. Sp. Pl. 202. Willd. n. 11. Ait. n. 5. (*T. subfruticosa*, foliis subincanis oblongis, fronde comosa; Browne Jam. 170, excluding the synonym of Sloane, which belongs to *Suriana maritima*. *T. incana*; Poiret n. 9? Lamarck Illustr. n. 1880. t. 95. f. 3?) — “Leaves nearly lanceolate, hoary. Stem somewhat shrubby.” — Native of Jamaica, by the sea-side, near the borough of St. James’s. Seldom rises above three or four feet from the ground. *Browne*. This is a very uncertain species, for which Dr. Browne seems the only authority, nor is there any specimen to represent it in the Linnæan herbarium. The *Thymelæa facie frutes*, Sloane Jam. v. 2. 29. t. 162. f. 4, is certainly *Suriana maritima*, for which it was subsequently quoted by Linnæus. Confe-

quently Willdenow cites it under both. It is sufficient to read Sloane, to see that his plant can be no *Tournefortia*. Possibly it may, nevertheless, have been what Browne intended. If so, the plant of Lamarck and Poiret has nothing to do with it, and may perhaps be the *sericea* of Vahl, hereafter described. Miller is recorded as having cultivated the *T. suffruticosa*, whence it has found a place in Mr. Aiton’s work, but apparently without being known at the present day.

17. *T. volubilis*. Climbing Rough Tournefortia. Linn. Sp. Pl. 201. Willd. n. 3. Ait. n. 1. Poiret n. 10. Lamarck Illustr. n. 1884. t. 95. f. 2. Gärtn. t. 75. Bryonia nigra fruticosa, racemi ramulis variè implicitis, atque caudæ scorpionis instar in se contortis, baccis albis unâ vel alterâ nigra maculâ notatis; Sloane Jam. v. 1. 234. t. 143. f. 2. Virga aurea americana frutescens glabra, foliis subtus cæsiis, &c.; Pluk. Phyt. t. 235. f. 6.) — Leaves deflexed, ovate, acute, rough with minute points on both sides. Stem twining. Segments of the corolla awl-shaped. — Native of South America and the West Indies. It flowered with Linnæus in the Upsal garden, and is preserved occasionally in our English stoves. Sloane says the *trunk* near the ground is as thick as one’s arm, twining round any thing it comes near, rising to the height of seven or eight feet. The *branches* are slender, round, somewhat zigzag, repeatedly subdivided, minutely downy, or rather silky, with close-pressed hairs. *Leaves* scattered, an inch or inch and half long, on slender, downy, deflexed *stalks*, about half an inch in length, single-ribbed, entire, flat and even, clothed on both sides with very minute, white, callous prickles, but no hairiness. *Flowers* numerous, small, greenish, in lateral, or somewhat terminal, slender, divaricated, downy, cymose *panicles*, of lax *spikes*, or rather *clusters*. *Calyx* in five deep, hairy, narrow segments. Tube of the *corolla* silky, hardly thrice the length of the calyx; limb in five narrow, awl-shaped, spreading segments, above half the length of the tube. *Style* slender, with a large long-beaked *stigma*. *Berry* half the size of a pea, globose, often two-lobed, white, with black dots.

18. *T. lævigata*. Climbing Smooth Tournefortia. — Leaves spreading, ovate, acute; smooth above; rough with minute points beneath. Stem twining. Segments of the corolla awl-shaped. — Native of Jamaica. Dr. Wright. This has altogether the habit of the last, of which it may possibly be a variety. The chief difference discoverable in the dried specimens is the upper surface of the *leaves* being perfectly destitute of the innumerable callous points which cover their backs, and which are found on both sides of the foliage of the foregoing. The *leaves* of the present are also perhaps less deflexed. The *inflorescence* and *flowers* afford no marks of distinction. The *berries* are most frequently of three globular lobes.

19. *T. sericea*. Climbing Hoary Tournefortia. Vahl Eclog. fasc. i. 17. Willd. n. 10. Poiret n. 11. (*T. incana*; Poiret n. 9. Lamarck Illustr. n. 1880. t. 95. f. 3. Frutex; Marcgr. Brasil. 78, excellent as to the leaves, but though cited by Vahl, without any exception, the description shews it to be a syngeneis plant.) — Leaves spreading, ovate, acute; rough with minute points above; downy and hoary beneath. Stem twining. Segments of the corolla awl-shaped. — Native of Hispaniola, and other parts of the West Indies. Like the two last in size and general habit; but the *footstalks* are rather shorter; *leaves* more rounded, and often somewhat heart-shaped, at the base; their upper surface covered with much more numerous and minute, hair-pointed, white, callous tubercles, which produce somewhat of a hoary appearance; while the under

TOURNEFORTIA.

is white with fine clove down, and furnished with very prominent ribs. *Inflorescence, flowers, and fruit*, much like the two foregoing. The *stigma* in all has a long conical point.

20. *T. tomentosa*. Climbing Downy Tournefortia. Mill. Dict. ed. 8. n. 5. Poir. n. 12.—Leaves heart-shaped; downy beneath. Stem twining. Segments of the corolla awl-shaped?—Discovered by Mr. Robert Millar, near Carthage, in South America. The twining *stems* reach to the height of ten or twelve feet. *Leaves* two inches long, and one and a quarter broad near their base, very downy beneath, on very short *footstalks*. *Inflorescence* apparently like the last. *Flowers* small, dirty-white. *Berries* juicy, with two, three, or four seeds. We gather from Miller's account, our only authority, that this plant comes very near our last, of which it may possibly be a variety; yet the *leaves* seem to be of a broader figure, and their *footstalks* shorter.

21. *T. ferruginea*. Climbing Rusty Tournefortia. Lamarck Illustr. n. 1882. Poir. n. 13.—“Leaves somewhat heart-shaped, acute; villous beneath. Stem somewhat climbing. Young branches very hairy.”—Native of Hispaniola, where it is known by the name of *Kallaba*. Allied to *T. volubilis*, but its *branches* are less elongated and trailing; its *leaves* and young shoots very much more hairy, or shaggy, with stiff, straight, rusty-coloured hairs, equally remarkable on the *footstalks*, and ribs at the backs of the *leaves*. The latter are pointed, thick, harsh above, downy beneath, a little fringed at the margin, dark green, two or three inches long and one broad. Their *footstalks* straight, very short. *Flower-stalks* much branched, hairy, divided into short *spikes*. *Flowers* small, unilateral, with a rough hairy *calyx*, and a short tubular *corolla*. Poir.

22. *T. scabra*. Rough Small-leaved Tournefortia. Lamarck Illustr. n. 1883. Poir. n. 14.—“Leaves reflexed, oblong, obtuse; very rough above; wrinkled and downy beneath. Flower-stalks branched, terminal. Berries conical.”—Gathered in Hispaniola, by Joseph Martin. *Branches* slender and flexible, striated, somewhat downy. *Leaves* stalked, slightly toothed, an inch long and four lines broad, rounded at the base, blunt at the extremity. *Calyx* hairy, rough, widely spreading, acute. *Berry* reddish, oval, almost conical. Poir. whose description is our only guide, mentions a supposed variety, with *leaves* twice as long, but narrower, of which, however, he had seen neither *flowers* nor *fruit*.

23. *T. scandens*. Climbing Brown-flowered Tournefortia. Mill. Dict. ed. 8. n. 4. Poir. n. 18.—“Leaves heart-shaped, hairy. Spikes branched, reflexed. Stem twining. Segments of the corolla awl-shaped.”—Found in Jamaica by Houstoun, who sent seeds to Miller. We presume it to be the same with what Mr. Brown mentions as *T. scandens* of Solander's manuscripts, and therefore we adopt from him the character of the *corolla*; though our *lavigata* was marked by Dr. Wright, with doubt indeed, as the plant of Solander; but it does not at all answer to the description. The present has shrubby branching *stems*, ten or twelve feet high. *Leaves* near three inches long, one and a half broad near the base, acutely pointed, on short *footstalks*. *Flowers* in very slender, branching, terminal *spikes*, small, unilateral, of a dirty brown. *Berries* pulpy, with four seeds. Miller.

24. *T. sessilifolia*. Sessile-leaved Tournefortia. Poir. n. 19.—“Leaves sessile, linear-lanceolate, villous. Flowers in roundish dense terminal spikes. Stem hispid.”—Gathered by Commerçon at Buenos Ayres. *Branches* shrubby, round, clothed with stiff hairs. *Leaves* obtuse at each end,

though a little contracted at the base, half clasping the stem an inch and a half long, three lines broad, downy on both sides. *Flowers* at the ends of the branches, on a common stalk, which divides into two parts, each bearing several very dense crowded *spikes*. Limb of the *corolla* dilated, with five short blunt segments. *Stalks* and *calyx* clothed with numerous, stiff, glandular hairs. Poir.

25. *T. carnosa*. Flethy-leaved Tournefortia. Mill. Dict. ed. 8. n. 6. Poir. n. 20. (*Pittonia frutescens*, folio carnosio, hirsuto et obtuso; Plum. Gen. 5.)—“Leaves stalked, ovate; rugose and very rough above; paler and smoother beneath. Spikes branched, axillary. Stem shrubby.”—Gathered by Robert Millar, near Carthage in South America. *Stem* woody, near 20 feet high, with strong rough branches. *Leaves* thick, oval, four inches long and three broad, on pretty long *footstalks*. *Flowers* small, white. *Berries* small, with two or three oblong seeds. Miller.

Besides all the above species, Poir. has a *T. bifida*, n. 16. Of this we find a specimen, gathered by Commerçon in the island of Mauritius; but it appears to us totally foreign to this genus. The *stem* is shrubby, with opposite, bluntly quadrangular, rugged branches. *Leaves* likewise opposite, though Poir. says alternate, on downy channelled *footstalks*, ovate, about two inches long, entire, even, smooth, pale green, with a yellow mid-rib, slender lateral ribs hairy at their origin, and innumerable, excessively minute, reticulated veins. *Stipulas* opposite, between the *footstalks*, and half as long, broad at the base, pointed, silky, deciduous. *Flower-stalks* axillary, solitary, opposite, round, downy, longer than the *footstalks*, each bearing two, horizontally divaricated, simple, unilateral *spikes*, of numerous, small, sessile *flowers*, in two rows. *Germen* inferior, oblong, silky, crowned with a *calyx* of five deep, round, silky segments. *Corolla* funnel-shaped, white or yellowish, twice as long as the *calyx* and *germen* together, a little silky externally. *Stamens* within the tube; their *anthers* large, oblong, obtuse. Of the *style, stigma*, or *fruit*, we can give no account. This shrub appears to belong to the natural order of *Rubiaceae*, but we have not sufficient materials to determine its genus.

TOURNEFORTIA, in *Gardening*, contains plants of the shrubby exotic kind, among which the species cultivated are, the hairy Tournefortia (*T. hirsutissima*); the climbing Tournefortia (*T. volubilis*); the fetid Tournefortia (*T. foetidissima*); the dwarf Tournefortia (*T. humilis*); the broad-leaved Tournefortia (*T. cymosa*); the silvery Tournefortia (*T. argentea*); and the hoary-leaved Tournefortia (*T. suffruticosa*).

Method of Culture.—These plants may all be increased by seeds, which should be procured from the countries where they grow naturally, and be sown in small pots filled with light earth, and plunged into a hot-bed of tanners'-bark. They sometimes grow the first year, but often remain in the ground a whole year: therefore, when the plants do not come up the same season, the pots should be plunged in autumn into a tan-bed in the stove, where they should remain all the winter, and in the spring be removed and plunged into a fresh tan-bed, which will soon bring up the plants, if the seeds were good. When these are fit to remove, they should be each planted in a small pot, and plunged into a tan-bed, where they must be shaded from the sun till they have taken new root, and then be treated in the same way as other tender plants from the same countries, which require to be kept constantly in the bark-stove. They may also sometimes be increased by cuttings, which should be planted in pots, and plunged into the bark-bed.

These

These are all plants of the tender kind, which constantly stand in need of the heat of the stove in this climate.

They afford variety in stove collections, among others in pots, mostly retaining their leaves the year round.

TOURNEHEM, in *Geography*, a town of France, in the department of the Straits of Calais; 9 miles N.W. of St. Omer.

TOURNEMINE, RENÉ-JOSEPH DE, in *Biography*, a learned Jesuit, was born at Rennes in 1661, entered among the Jesuits in 1680, and took all the vows of their order in 1695. In 1701 he resided in the Jesuits college at Paris, for the convenience of conducting and superintending the journal of Trevoux, or "Memoires pour servir à l'Histoire des Sciences et des beaux Arts," printed at Trevoux, and periodically published from 1701 to 1767, when it fell with the society. In 1718, Tournemine was made librarian of the Jesuits library, in the professed house of the society, where he died in 1739, at the age of seventy-eight years. Tournemine published some other works of less note. Moreri.

TOURNEUR, PETER LE, born at Valogne, in Normandy, in 1736, gained prizes at Montauban and Befançon for his literary pieces, which were reprinted at Paris, and admired on account of their philosophic spirit and eloquence. But he was brought more into notice by his free translation of Young's "Night Thoughts," which being favourably received, was followed with translations of "Hervy's Meditations;" "The Life of Savage;" "Ossian and other Gaelic Poems;" a great part of the "Universal History;" "Shakspeare;" "Clarissa;" and other works. These translations are introduced by prefaces, abounding with bold and interesting ideas. His praises of Shakspeare provoked various attacks, and particularly from Voltaire. Le Tourneur, who died in 1788, is represented as one of the mildest and most amiable of men. *Nouv. Dict. Hist.*

TOURNIQUET, Fr. from *tourner*, to *turn*, a machine, or instrument, employed in the practice of *Surgery*, in order to stop bleeding. It is only applicable, however, to the limbs, and its use is merely intended to be temporary, that is to say, until some more permanent method of checking the hemorrhage can be practised. Thus, in the operation of amputation, the tourniquet is applied with a view of preventing the loss of blood, which would otherwise happen before the surgeon had done with the knife and the saw, and before he could possibly devote his attention to the ligature of the arteries. But it is never put on tightly with the design of being left any considerable time in this way, as the constriction produced would inevitably bring on mortification. Sometimes, after amputations, operations for aneurisms, and in cases of wounds, it is left loosely upon the limb, so that, in the event of a sudden hemorrhage, it may be tightened in an instant. Here, however, the surgeon does not regard it as the principal means by which the bleeding is to be stopped; but simply as a temporary assistance, until an opportunity has been afforded of securing the bleeding vessels in another way.

When hemorrhage takes place from a large artery in one of the limbs, where the vessel can be conveniently compressed above the wound in it, a tourniquet, judiciously applied, never fails in putting an immediate stop to the bleeding.

Before the invention of this instrument, which did not take place till the latter part of the seventeenth century, surgery was really a very defective art. No important operation could be undertaken on the extremities without placing the patient in the most imminent peril; and the want of the aid afforded by the tourniquet made many wounds mortal which

otherwise would not have been attended with the least danger.

Perhaps we are not justified in stating that the tourniquet was not invented till the late period above specified; and it might be more correct to say, that it has been used in a rude and imperfect manner ever since surgeons have known that the flow of blood through a limb may be commanded by pressure. For when a simple band was tightly applied round a limb, in order to stop bleeding, it was, in fact, a kind of tourniquet. The records of surgery, indeed, inform us, that the old surgeons used to surround the limb with a band, with which they made such a degree of constriction, that the circulation was quite stopped. These practitioners also believed, that the pressure of the band was advantageous in benumbing the limb, and moderating the pain of operations.

The violent pain and confusion, however, which this sort of tourniquet occasioned, were frequently followed by sloughing and abscesses, and therefore surgeons endeavoured to devise some other method of checking hemorrhage. The application of the circular band was first improved, so that it caused less pain and less mischief to the skin. The limb was surrounded with a very thick compress, over which the band was placed. Two small sticks were next put under the band, one on the inside, the other on the outside of the limb; and they were twisted till the band was rendered sufficiently tight. It is in this manner, says Dionis, in his *Treatise on the Operations of Surgery*, that carriers tighten the cords which fasten the bales of goods in their carts. A French surgeon named Morel is said to have made this first improvement in the application of tourniquets.

Although in the *Armamentarium Chirurgicum* of Scultetus, there is an engraving of a machine invented by this author for compressing the radial artery by means of a screw, M. Petit is universally allowed to be the first who brought the tourniquet to perfection, by combining the circular band with a screw, in such a manner, that the greatest pressure operates on the principal artery. It was in 1718 that he presented his improved instrument to the Academy of Sciences. It consists of two pieces of wood, one of which is superior, the other inferior. The inferior piece is about four inches and a half long, and nearly two broad. Its under surface is somewhat concave, while its upper one is a little convex; and the ends are hollowed out. From its middle part rises a round eminence, about seven lines high, and eight and a half broad. The superior piece is almost the same as the inferior, but rather shorter. The eminence which ascends from its middle part is six lines high, and an inch and a half in diameter. This eminence is hollow within, and calculated to receive a wooden screw, the top of which is a sort of button for turning the screw. The grooves of Petit's screw were about four or five, and each of them four lines in diameter, in order that a half-turn might produce the necessary effect. Lastly, all the pieces of the instrument were fastened together with an iron pin, which went through the middle of the two pieces of wood, and through the whole length of the screw. This iron pin was rivetted under the inferior piece, and at the top of the button; in such a manner, however, that the screw was capable of turning on it as on a pivot.

In order to apply this tourniquet, the limb is to be surrounded with a double strap, about four finger-breadths wide, and made of chamois leather, which is the softest material that can be used. To one end of the strap a small double cushion is fastened, of the same length and breadth as the lower piece of the tourniquet. A narrow compress, or cylindrical pad, is also requisite, for the purpose of compressing

pressing the track of the vessels. This compress consists of a very firm roll of linen, covered with chamois leather. The ends of a piece of tape are sewed to the outer part of the pad, and thus the tape leaves a passage for the leather strap. By this artifice, the pad can be moved to any situation on the strap which may be most convenient, according to the bulk of the limb. The middle of the tape is to be fastened to the outside of the leather strap. The cylindrical compress, or pad, is to be put over the course of the vessels. The double cushion is to be placed on the opposite side of the member, while the leather strap is to surround the limb in a circular manner. All the different pieces of the apparatus are next to be retained by the tape, which is to be tied at the side of the cushion.

The tourniquet is now to be put over the cushion, on that side of the limb which is furthest from the track of the large vessels, and is to be fastened in this situation by a double band, with a hole in it for the reception of the upper part of the screw.

In order to make proper compression, the screw is to be half turned round from the right to the left. The upper piece of the tourniquet becoming now further from the lower one, the double band draws the pad, and presses it against the vessels, so as to make the due degree of compression for stopping the flow of blood through the main arteries.

The following are the advantages attending the use of Petit's tourniquet. 1. It compresses the lateral parts of the limb less than the tourniquet previously in use. 2. It requires the aid of no assistant either to hold, tighten, or loosen it. 3. The operator is able of himself to stop the flow of blood through the artery by means of the screw. 4. When there is any danger of hemorrhage after an operation, this kind of tourniquet may be left on the limb; and in case of bleeding coming on, the patient, if no one be at hand, can tighten the instrument himself as much as necessary. 5. The constriction which this tourniquet produces may be continued longer than that of the old method, without hazard of sloughing, because it does not altogether stop the flow of blood through the collateral arteries.

The tourniquet just described is certainly very complex, when compared with what is now used by the best modern practitioners; but still it is the original of the latter, and both are constructed on the same principles. The several pieces of a modern tourniquet are always kept connected together, and, instead of two pieces of wood, used by Petit, there is contrived a brass bridge, which is capable of being elevated or depressed by means of a screw of the same metal. Over this bridge a very strong band proceeds, and by passing under two little rollers at the ends of the bridge, it always remains connected with the instrument. A convex firm pad is sewed to the band, and put immediately over the artery when the instrument is applied. There are no cushions for the opposite side of the limb under the screw; but a thick piece of leather, through which the band proceeds in two places, is sometimes put under the lower surface of the brass, and serves to prevent any bad effects of its pressure on the skin. It is usual, also, for the surgeon to fold some rag, and put it in this situation at the time of applying the instrument. Cooper's Dict. of Pract. Surgery.

In the army, surgeons are provided with what are named *field* tourniquets, in addition to such as are always found in cases of amputating instruments. A field tourniquet is most simple in its construction, and is particularly intended for use on the field of battle, where numerous soldiers frequently stand in need of temporary compression of their bleeding limbs, until the surgeon has time to pay their accidents further attention. It consists merely of a strong band, a pad

fixed to this band, and a buckle. It admits of being applied in an instant. Every military surgeon is commonly furnished with two or three dozen field tourniquets, and the plan is undoubtedly good, as the preservation of many lives by it has confirmed.

The reader will have a better idea of the nature of a tourniquet, by referring to engravings of the instrument; but a sight of the thing itself will be still more useful.

Some tourniquets of different constructions are represented in *Plate I.* of the *Surgical Instruments*, where *fig. 1.* shews a tourniquet of the most simple kind, which is tightened by twisting the band *D* with the piece of wood *B*. *C* is the pad which is to be placed upon the main artery, and *A* is a sort of metallic or wooden guard, for preventing the twisted part of the band from hurting the skin. *Fig. 2.* a tourniquet of a more modern and improved make. *D* the screw. *C, C,* the two pieces of the frame or bridge of the tourniquet, which tighten the band *B*, when the upper piece is raised by turning the screw. *A* is the pad. *Fig. 3.* represents another kind of tourniquet, which is tightened by a contrivance resembling a windlass in principle; *C* the handle by which it is turned; *E* a steel branch, which serves to prevent the handle from turning back again; *B* a short bit of chain, which fixes itself in the notches of the circle, and by carrying the band with it when moved round, tightens the band *D*; *A* the basis of the tourniquet. *Fig. 4.* another kind of screw-tourniquet.

TOURNOIS, in *Coinage*, the name applied to French money in the old system, as sterling is to English money.

TOURNON, in *Geography*, a town of France, in the department of the Lot and Garonne; 12 miles E. of Villeneuve d'Agen.—Also, a town of France, situated on the river Creuse, one part in the department of the Indre, and the other in the department of the Indre and Loire; 7 miles S. of Preuilly.—Also, a town of France, in the department of the Ardèche, on the Rhône; 22 miles N.N.E. of Privas. N. lat. $45^{\circ} 4'$. E. long. $4^{\circ} 54'$.—Also, a town of France, in the department of Mont Blanc; 15 miles E. of Chambéry.

TOURNUS, a town of France, in the department of the Saône and Loire, on the Saône; 3 posts S. of Châlons sur Saône. N. lat. $46^{\circ} 34'$. E. long. $5^{\circ} 0'$.

TOURO, a town of Portugal, in the province of Beira; 13 miles W.S.W. of Alfayates.

TOURONE, a town of Persia, in the province of Cohestan; 80 miles S.W. of Neifabur.

TOUROULIA, in *Botany*, a Caribbean name, used by Aublet, but absolutely inadmissible into any classical work.—Aubl. Guian. v. 1. 492. Juss. 434. Lamarek Illustr. t. 424. Poiret in Lam. Dict. v. 7. 718.—Schreber and Willdenow, after Scopoli, have called this genus *ROBINSONIA*, which may be found in its proper place.

TOUROUMANG, in *Geography*, a town on the west coast of Sumatra. N. lat. $2^{\circ} 50'$. E. long. $97^{\circ} 6'$.

TOUROUVRE, a town of France, in the department of the Orne; 6 miles N.E. of Mortagne.

TOURRETTE, MARK-ANTHONY-LEWIS-CLARKE DE, in *Biography*, was born at Lyons in 1729, and having studied at the college de Harcourt, at Paris, settled in his native place, where for twenty years he occupied an important post in the magistracy. Strongly attached to the study of natural history, he formed, in 1763, a large collection of insects, and a series of specimens in mineralogy. In 1766 he introduced into a large park near the town of Arbrisse all the foreign trees and shrubs that could bear that climate, and in his own garden at Lyons, he cultivated more than 3000 species of rare plants. He was a companion of J. J. Rousseau,

seau, in his botanical excursions; and he maintained a correspondence with Linnæus, Haller, Adanson, Jussieu, and other celebrated botanists of Europe. At length, overcome by fatigue at the siege of Lyons in 1793, he sunk under a disorder of the lungs, and died in his 64th year. His principal works are, "Demonstrations Elementaires de Botanique," 1766, 2 vols. 8vo.; "Voyage à Mont Pilè," 1770, 8vo.; "Chloris Lugdunensis," 1785, 8vo.; "Conjectures sur l'Origine des Belemnites;" "Memoire sur les Montres Vegetaux," and "Memoire sur l'Helminthocoron Physique."

TOURRETTIA, in Botany, was so named by its discoverer, the unfortunate Dombey, in honour of his countryman M. de la Tourrette, author of the *Chloris Lugdunensis*, and lecturer on botany in the Veterinary school at Lyons. Whether M. l'Heritier thought but moderately of the claims of this gentleman, we know not; but he chose the name of *Dombeya* for the plant in question, on account of its beauty and singularity. That appellation indeed is now bestowed on a much nobler genus, see *DOMBEYA* and *DOMBEY*, and we trust it will so remain, for the *Dombeya* of Cavendish, like most of that author's monadelphous genera, is too ill-defined to be the guardian of such a name.—Schreb. Gen. 406. Willd. Sp. Pl. v. 3. 263. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 19. Juss. 139. Fougeroux in Mem. de l'Acad. des Sciences for 1784. 200. t. 1. Lamarck Illustr. t. 527. Poiret in Lam. Dict. v. 7. 719. (*Dombeya*; l'Herit. Stirp. Nov. 33. Salisb. Stirp. Rar. 5.)—Class and order, *Didymia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Bignoniæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, two-lipped, coloured in the bud, deciduous; its upper lip acute; lower obscurely four-toothed, furnished with an accessory membrane at the inside. Cor. of one petal; tube compressed, the length of the calyx; upper lip vaulted, compressed, its edges converging; lower lip none, except a pair of minute teeth. Stam. Filaments four, thread-shaped, concealed under the upper lip, two of them shorter than the rest; anthers two-lobed. Pist. Germen superior, oblong, obsolete quadrangular, granulated; style thread-shaped, the length of the lip, parallel to the stamens; stigma divided. Peric. Capsule oblong, coriaceous, more or less beset with prickles that are occasionally hooked, of four cells and two valves. Seeds from four to six in each cell, ovate, somewhat triangular, surrounded with a membranous notched border divided at its base.

Ess. Ch. Calyx two-lipped. Corolla with two minute teeth in the place of a lower lip. Capsule with four cells and two valves. Seeds bordered.

1. *T. lappacea*. Scarlet-flowered Tourrettia. Willd. n. 1. Ait. n. 1. (*Dombeya lappacea*; l'Herit. Stirp. Nov. t. 17. Salisb. Stirp. Rar. t. 3.)—Found by Dombey in Peru. First raised in England by Mr. Salisbury, at Chapel Allerton, near Leeds, in 1788, from seeds communicated by M. l'Heritier. The plant is annual, of very luxuriant growth, filling a moderate-sized stove, so that few cultivators can be induced to allow it a place in their collections; the flowers, which are produced in abundance from Midsummer till the end of autumn, being, though elegant and curious, less tawdry and glaring than many popular favourites. The stem is square, much branched in a forked manner, climbing, pale green, smooth, tender and pellucid, as well as the leaves, which are opposite, stalked, ternate or quinate, in pairs on a common stalk, which terminates in a very delicate, spiral, adhesive, compound tendril: leaflets ovate, acute, strongly and unequally serrated, about an inch long, shining, with one rib, and many oblique parallel veins.

Flowers from the forks of the branches, in solitary, simple, lax, ascending spikes rather than clusters, each flower with a small awl-shaped bractea at its base. The lower ones only are perfect and fertile, having a green calyx, clothed with fine viscid hairs, and a violet corolla; several of the uppermost consist chiefly of a dilated scarlet calyx, on which much of the beauty of the plant depends, and which emulates the coloured bracteas of the *Bartia* and *Ajuga*. The capsule, though usually mucronated with hooked prickles, is sometimes smooth and bare, a variation similar to what is seen in *Datura*, and by no means indicating a specific distinction.

TOURS, in Geography, a city of France, and capital of the department of the Indre and Loire, on the Loire. Before the revolution the capital of Touraine, and see of an archbishop. The number of inhabitants is about 33,000. In 732, the Saracens were defeated by Charles Martel, near this town, with the loss of 10,000 men; 47 posts N.E. of Bourdeaux. N. lat. 47° 25'. E. long. 0° 16'.—Also, a town of France, in the department of the Puy de Dôme; 12 miles E.S.E. of Billon.

TOURTERELLES, a cluster of small islands in the Indian sea, near the coast of Africa. N. lat. 11° 50'.

TOURVACORA, a town of Hindoostan, in Mysore; 32 miles N. of Seringapatam.

TOURVES, a town of France, in the department of the Var; 4 miles S.E. of St. Maximin.

TOURVILLE, a town of France, in the department of the Eure; 10 miles W. of Louviers.

TOURY, a town of France, in the department of the Loiret; 12 miles W. of Pithiviers.

TOUSERA, a town of Africa, in the country of Biledulgerid, depending on Tunis. N. lat. 32° 30'. E. long. 10° 44'.

TOUSIEH, a town of Asiatic Turkey, in Natolia; 21 miles N.N.E. of Kiangari.

TOUT *temps prêt et encore est*, that is, always ready, and so at the present time: a kind of plea in way of excuse or defence for him that is sued for any debt or duty belonging to the plaintiff.

TOU *Ensemble*, in the Arts. See ENSEMBLE.

TOU, *per my et per*. See PER MY.

TOUTERON, in Geography, a town of France, in the department of the Ardennes; 13 miles S. of Mezières.

TOUTSI-TCHAMSLIA-LING, a town of Thibet; 30 miles N.W. of Tankersong.

TOUTTI, a town of Nubia, on the left bank of the Nile; 90 miles N. of Sennaar.

TOUVRE, a river of France, which runs into the Charente, about half a mile above Angoulesme.

TOUY, a river of Tartary, in the country of the Kalkas, the waters of which are equally pure and salubrious with those of the Toula, (which see,) and waters plains as fertile as those adjacent to this river; and, after having traversed several very extensive cantons, suddenly loses itself in the bosom of the earth, and never appears again.

TOU-YANG, a city of China, of the first rank, in Quang-si; 1127 miles S.S.W. of Peking. N. lat. 23° 18'. E. long. 107° 4'.

TOU-YUN, a city of China, of the first rank, in Koeitcheou. The jurisdiction of this city is but small, and comprehends only two cities of the second order, and two of the third. It is in the neighbourhood of mountains, which are inhabited by the Seng-miao-se, a people whom the Chinese could never subdue, and who have their particular government. It is separated from them only by a river,

and some steep mountains; 955 miles S.S.W. of Peking. N. lat. $26^{\circ} 12'$. E. long. $107^{\circ} 2'$.

TOW, To, derived from the Saxon *teon*, or *teohan*, to draw, in *Sea Language*, is to draw a ship forward in the water, by means of a rope attached to another vessel or boat which advances by the effort of rowing or sailing. Towing is practised either when a ship is disabled, and rendered incapable of carrying sail at sea; or when her sails are not fixed upon the masts, as in a harbour; or when they are deprived of their force of action by cessation of the wind. When a ship of war is dismasted, or otherwise disabled from carrying sail at sea, she is usually towed by a cable reaching from her bow to another ship a-head. In a harbour, towing is practised by one or more boats, wherein the force of all the oars is exerted to make her advance. Falconer.

Tow-Chain, in *Husbandry*, a name given by our farmers to a chain, that makes a part of the structure of the plough, fastening the plough-tail to what they call the plough-head. See **Plough**.

Tow-Line, in *Sea Language*, a small hawser generally used to remove a ship from one part of a harbour or road to another, by means of anchors, capsterns, &c. It is also employed occasionally to moor a small vessel in a harbour, conveniently sheltered from the wind and sea.

Tow-Rope is the name given to any cable or rope used in towing.

TOWA, in *Geography*, a river of Wales, in the county of Caermarthen, which runs into the Tave, at St. Clare. See **St. Clare**.

TOWACZOW. See **TOBITSCHAU**.

TOWAGE, is a term used for money, or other recompence given by bargemen to the owner of the ground next the river where they tow a barge, or other vessel, for the liberty of passing along the side of it.

TOWAMENCING, in *Geography*, a township of Pennsylvania, in the county of Montgomery, containing 488 inhabitants.

TOWAMENSING, a township of Pennsylvania, in the county of Northampton, containing 593 inhabitants.

TOWAN HEAD, a cape of England, on the N.W. coast of Cornwall. N. lat. $50^{\circ} 26'$. W. long. $4^{\circ} 57'$.

TOWANDY, a township of Pennsylvania, in the county of Luzerne, containing 788 inhabitants.

TOWAR, a small island near the north coast of Celebes, in the East Indian sea. N. lat. $1^{\circ} 18'$. E. long. $124^{\circ} 25'$.

TOWCESTER, commonly called *Töfeter*, and in the Domesday book *Towcester*, a market-town in the hundred of the same name, and county of Northampton, England; is situated on a plain near the banks of a small river named Tove, 10 miles S.W. by S. from the county-town, and 60 miles N.W. from London. Numerous Roman coins have been found here, particularly about Berry-mount Hill, an artificial mount, composed of earth and gravel, on the N.E. side of the town. It is flat on the top, about twenty-four feet in height, and the diameter one hundred and two. This hill was surrounded by a moat capable of being filled with water from the adjoining brook, and has every appearance of having been of Roman formation. Horsley places here the station *Lactodorum* with great probability of correctness. Mr. Camden and Dr. Gale have fixed it at Stony Stratford, deriving its British name from the two British words, *lach*, a stone, and *dour*, water. On the N.W. side of the town are vestiges of a foss, and the ruins of a castle or tower, probably a Saxon work; for in that period Towcester appears to have been a place of considerable strength, and is said to have been so well fortified, that the Danes who besieged it were unable to take possession. It must, however, have suffered severely

VOL. XXXVI.

from them, for in the year 921, king Edward issued his mandate for rebuilding and fortifying Towcester. The Danes of Northampton and Leicester, who had previously made a truce with the Saxons, suddenly broke their engagement; and marching to this place, carried on an assault for a whole day; but by the vigorous resistance of the inhabitants, and the aid of a Saxon army, the Danes were obliged to retreat; Edward having fortified the town, and encompassed it with a stone wall. Towcester, in its present state, consists principally of one long street, in general well-built: and being a great thoroughfare, there are several good inns. In the windows of one, the Talbot, are the arms and name of William Sponne, archdeacon of Norfolk, and rector of the parish, who, in the twenty-ninth year of Henry VI., gave this inn and certain lands to the town; the revenues to be applied to repairing and paving the streets. A monument in the church commemorates his benefaction. He is represented in a loose robe, which descends beneath his feet, with an ermine hood and sleeves. By the returns under the population act of the year 1811, the number of houses in Towcester are stated to be 485; the inhabitants 2245. The principal manufactures are those of silk and lace; of the latter article great quantities are made in the town and in the adjacent villages. Four fairs are held annually; and a market weekly on Tuesdays.

Sir Richard Empson, famous as the favourite of king Henry VII., and one of the instruments of his avarice and oppression, was the son of a sieve-maker in this town. By a rigorous enforcement of the penal statutes through the kingdom, he and his associate Edmund Dudley incensed the people to such a degree, that Henry VIII. was constrained to submit to popular remonstrance, and sign his hand for their execution. Empson was tried at Northampton, and beheaded August 16, 1510.—*Beauties of England and Wales*, vol. xi. Northamptonshire; by J. Britton, F.S.A. *History, &c. of Northamptonshire*, by the Rev. — Brydges, 2 vols.

TOWER, TURRIS, a high building, consisting of several stories, and usually of a round form, though sometimes square or polygonal.

Before the invention of guns, they used to fortify places with towers, and to attack them with moveable towers of wood, mounted on wheels, to set the besiegers on a level with the walls, and drive the besieged from under the same.

These towers were sometimes twenty stories, and thirty fathoms high: they were covered with raw skins, and a hundred men were employed to move them; and they were assisted by the capstern and other mechanical contrivances.

The moveable towers of the ancients were of an astonishing magnitude. Hero distinguishes three kinds: the smallest were, he says, of sixty cubits and ten stories; the base, which was square, measured seventeen cubits on each side. The larger were ninety cubits high, and had fifteen stories: the greatest, called double, were of twenty stages: they were largest at bottom, and decreased every story: the dimensions of the timber used for the uprights, the traverses, and other principal pieces, were proportioned to each of their three sizes. The strength and thickness of the wheels bore proportion also to the weight which they were to carry; the number of the wheels was proportioned to the squares of their bases: they had at least six, and sometimes eight. The towers or belfreys, as they were called, of more modern times, were not so large: they rarely exceeded three or four stages or stories, and were covered with raw hides to protect them from fire; in these was a bridge to let down on the parapet, when the works were to be stormed. The lower stage or ground-floor was occupied by a ram; the upper stories accommodated archers and

M

cross.

cross-bow men. A moveable tower was constructed by the royalists so late as the troubles under king Charles I., which was surpris'd and taken by the parliamentary forces. It was misnamed a *few* ; which see.

Towers are also built to enable people, by their elevation, to view to a great distance. These are of all figures, as square, round, pentagonal, &c. (See PHAROS.) In China is a famous tower of porcelain, of which the Dutch relate wonders.

Towers are also built for fortresses, prisons, &c. as the Tower of London, the towers of the late Bastille, &c.

The Tower of London is not only a citadel to defend and command the city, river, &c. but also a royal palace, where our kings with their courts have sometimes lodged.

It contains a royal arsenal, in which are arms and ammunition for 80,000 soldiers ; the offices of ordnance ; a treasury for the jewels and ornaments of the crown ; formerly a mint for coining of money ; the great archive, in which are preserved all the ancient records of the courts of Westminster, &c. and is the chief prison for state criminals.

In the midst of it is the great square white tower, built by William the Conqueror, about the year 1079. Within the Tower is a parochial church, founded by king Edward III. and dedicated in the name of St. Peter in Chains, exempt from all jurisdiction of the archbishop, and a royal chapel, now difused.

The chief officer of the Tower is a constable, or chief governor, under whom is the lieutenant-governor, who acts by his direction, and in his absence. He had, by grant of several of our kings, *unam lagenam*, two gallons and a pint of wine before, and as much behind the mast of all wine ships that come to London ; and a certain quantity out of every boat laden with lobsters, oysters, and other shell-fish, and double the quantity out of every alien's boat passing by the Tower. Under the constable, besides the lieutenant, are a deputy-lieutenant, a tower-major, a chaplain, a physician, gentleman-porter, gentleman-gaoler, surgeon, and forty warders. The gentleman-porter has charge of the gates to lock and unlock them, and deliver the keys every night to the constable or lieutenant, and receive them of him the next morning : he commands the warders in waiting, and at the entrance of a prisoner has for his fee *vestimenta superiora*, or else a composition for the same.

For the yeomen warders of the Tower, see WARDER.

In the Tower is likewise kept a court of record by prescription for the liberty of the Tower, of debt, trespass, and other actions of any sum.

The Tower liberty, subject to no jurisdiction but that of the Tower itself, includes both the Tower-hills, part of East Smithfield, Rosemary-lane, Wellclose-square, Little Minories, Artillery-street, French-alley, Duke-street, Steward-street, Gun-street, Fore-street, and the other courts and alleys within their compass, in Spitalfields.

TOWER, in *Glass-making*. See LEER.

TOWER-Bastions, in *Fortification*, are small towers, made in the form of bastions by M. Vauban in his second and third method ; with rooms or cellars underneath, for accommodating men and guns. See FORTIFICATION.

TOWER, *Hollow*. See HOLLOW Tower.

TOWERS, *Inclined*, are those whose tops hang so far over, as to appear in danger to people walking below. Such is that of Pisa, 138 feet high, whose top overhangs the base 15 feet ; and that of Bologna, 130 feet high, whose top overhangs the base 9 feet ; and the reason why they do not fall is, that their centres of gravity are supported, or the lines of direction in them fall within their base. But if towers of this kind, that incline, were to be elevated in height by any additional weight on their tops ; in that case

the centres of gravity would be raised, and their lines of direction fall without the base, so that the towers themselves must fall.

TOWER *Mustard*, and *Bastard Tower Mustard*, in *Botany*. See MUSTARD.

TOWER *Pound*, an old English weight for coins. This tower or moneyers' pound, with which gold and silver were weighed in England before the reign of Henry VIII. and which is still occasionally referred to on the subject of coins, was lighter than the pound troy by fifteen penny-weights troy.

TOWER-Hill, in *Geography*, a town of the state of Rhode island, with a post-office ; 17 miles S. of Providence.—Also, a town of North Carolina, on the Neufe ; 30 miles W. of Newbern.

TOWER *Island*, a small island in the East Indian sea, near the S. coast of the island of Flores. S. lat. 9° 2'. E. long. 124° 44'.

TOWIACHES, called *Panis* by the French, a tribe of Indians in Louisiana, who live on the S. bank of the Red river, by the course of the river upward of 800 miles above Natchitoches, and by the nearest land distance about 340 miles. They have two towns near one another : the lower town, where the chief lives, is called Nitchera, and the other is called Towaahach. Their present chief is denominated the Great Bear. They are at war with the Spaniards, but friendly to those French and American hunters who have lately been among them, according to the statement of Mr. Jefferson in the year 1806. They are likewise at war with the Osages, as is every other nation. For many hundreds of miles round them, the country is a rich prairie, covered with luxuriant grass, which is green summer and winter, with skirts of wood on the river bank, by the springs and creeks. They have many horses and mules. They raise more corn, pumpkins, beans and tobacco than they want for their own consumption, so that some of these commodities furnish articles of trade. They have but few guns, and very little ammunition, which they keep for war, and hunt with the bow. Their meat is principally buffalo, and they seldom kill a deer, though plentiful. They have also elk, bears, wolves, antelopes, and wild hogs in abundance, and white rabbits and hares, as well as the common rabbits. The men are generally altogether naked, and the women nearly so, with the exception of a small flap of a piece of skin. They have many Spaniards among them, taken from the settlement of Santa Fé, when they were children. Their language differs from that of every other nation, the Towakanoes excepted. Mr. Jefferson states the number of men at about 400 ; a great number of them having been swept away, about four years before, by the small-pox.

TOWING-PATH, the road or path which is formed along on the borders of navigable rivers and canals, for the purpose of drawing different sorts of materials for farm and other uses, in some kind of small vessels, on them, either by men or horses. (See E.C, *fig.* 16. *Plate I. Canals*, and *fig.* 40. *Plate V.*) These paths constitute one of the great improvements in this sort of navigation, by removing the inconvenience and disgust afforded by the mode of hauling the barges by means of men instead of horses, where they are formed with that intention.

In speaking of the inland navigation of the river Severn, and the county, in the Shropshire agricultural report, Mr. Felford observes, that with regard to adopting the mode of hauling barges by means of horses, instead of the present barbarous and expensive custom of performing this slave-like office by men, it is only necessary that a good towing-path for horses should be formed along the banks of the river, and which will no doubt take place, if any scheme of general

ral improvements should ever be adopted. That in the mean time, a laudable example has been shewn by Mr. W. Reynolds, of Ketley, who has formed a towing-path for horses near to the new manufactories at Coalport, and has carried it on through his father's property to the iron bridge, a distance of about two miles: this being along some rugged banks, and over some of the worst fords which are on the river, proves, beyond contradiction, it is thought, that this sort of towing-path is practicable at no very extravagant expence, and besides, that it completely destroys the common objection of horse towing-paths where many rapids or fords intervene.

In constructing all sorts of towing-paths, they should be formed as much on the level as possible, and be well and firmly laid with some convenient sort of hard materials.

Where they are for men or small animals, they need not be of such breadths or depths of hard substances, as where large and many horses are in use. In carrying them over fords or runs of water, an experienced workman will mostly be necessary.

TOWING-Path Wall, is a wall under the bridges, A B C D, (*Plate V. Canals, fig. 40.*) for keeping up the towing-path.

TOWLGAW, in *Geography*, a town of Hindoostan, in Dowlatabad; 6 miles W. of Tooliapour.

TOWN, a place inhabited by a considerable number of people, of an intermediate magnitude and degree between a city and a village, &c.

It is hard to give a tolerable definition of a town, because the idea is a little arbitrary and unfixed. A town is generally without walls, which is the character which usually distinguishes it from a city; but this does not hold universally.

Tithings, towns, and villages, have the same signification in law; and are said to have had, each of them, originally a church, and celebration of divine service, sacraments, and burials; though that seems to be rather an ecclesiastical than a civil distinction. The word town or vill is, indeed, by the alteration of times and language, now become a general term, comprehending under it the several species of cities, boroughs, and common towns. A city is a town incorporated, which is or hath been the see of a bishop: a borough is now understood to be a town, either corporate or not, that sends burgesses to parliament: other towns there are, to the number, according to sir Edward Coke, of 8803, which are neither cities nor boroughs; some of which have the privileges of markets, and others not; but both are equally towns in law. To several of these towns there are small appendages belonging, called hamlets.

Entire vills, sir H. Spelman conjectures, consisted of ten freemen, or frank-pledges, demi-vills of five, and hamlets of less than five. These little collections of houses are sometimes under the same administration as the town itself, sometimes governed by separate officers; in which last case they are, to some purposes in law, looked upon as distinct townships. These towns contained each originally but one parish and one tithing, though many of them now, by the increase of inhabitants, are divided into several parishes and tithings; and sometimes there is but one parish where there are two or more vills or tithings. Blackst. Com. b. i.

We have several kinds of towns; borough-towns, market-towns, county-towns, &c. See *BOROUGH*, &c.

TOWN, Freedom of a. See *FREEDOM*.

TOWNS, Hanse. See *HANSE*.

TOWN-Clerk, or *Common Clerk*, an officer in the city of London, who keeps the original charters of the city, the books, rolls, and other records, wherein are registered the

acts and proceedings of the city. He is to attend the lord mayor and aldermen at their courts.

TOWN-Dung or *Manure*, in *Agriculture*, that sort which is scraped up and collected from the streets and other places of large towns. This kind of manure is used in large quantities in some districts near the metropolis, as in Essex and some others, with great success and advantage, though at very considerable expence. Mr. Hardy, near Bradfield, in the above county, uses to the amount, it is said, of one waggon-load to every acre of summer fallow, at the expence, for the charge of the dung or manure only, of one guinea the load: it is then mixed with his own yard-dung in heaps for the purpose of exciting fermentation, from a notion that it has this effect, and that having it, the benefit will be in proportion. In several other parts of the same district, the usual mode of manuring *per acre*, is one waggon-load of town-muck with about five times the quantity of fresh soil collected from road-sides and hedge-greens.

TOWN-House. See *HOUSE*.

TOWN-Adjutant, in *Military Language*, is an assistant to the town-major.

TOWN-Major. See *MAJOR*.

TOWN, Cape, in *Geography*, a town agreeably situated somewhat above 30 miles from the Cape of Good Hope, in a valley, between the Table and Lion mountains. It contains about 200 houses, many of which are magnificent; its streets are broad, but ill-paved. Provisions of every kind are very reasonable, and the town is well supplied with springs of excellent water, sufficient for the ships which recur to this port. S. lat. 34° 29'. E. long. 18° 23'.

TOWNSEND, a town of the state of Massachusetts; 36 miles N.W. of Boston.

TOWNSHEND, a township of the state of Vermont, in the county of Windham, containing 1115 inhabitants; 25 miles S. of Windsor.

TOWNSHEND, Cape, a cape on the N.E. coast of New Holland. S. lat. 22° 15'. W. long. 209° 43'. See also *VERMILION Point*.

TOWPAAL, a town of Meckley; 12 miles S.E. of Munnypour.

TOWRIDGE, a river of England, which passes by Biddeford, and joins the Taw near Appledore, in Devonshire.

TOWY, a river of Wales, which rises in the county of Cardigan, and runs into the bay of Caermarthen, 6 miles below Caermarthen.

TOWYN, or *TŴYN*, a small town in the hundred of Yftumaner, and county of Merioneth, North Wales, is 12 miles W. by S. from Machynlleth, and 223 miles W.N.W. from London. It is built of coarse schistose stone, commands an unbounded view of the ocean, and is backed by a range of high mountains. During the bathing season, it is frequented by several genteel families. The town is surrounded by several populous hamlets, and respectable farm-houses. In the population return of the year 1811, the parish is stated to contain 1941 inhabitants, occupying 482 houses. Though the soil is rocky, and exposed to the influence of the western gales, yet industry has surmounted these obstacles; the marsh is converted into meadows and pastures; and corn overspreads the sterile rock and bleak shore. The church contains several ancient monuments. Gwenddydd, daughter of Brychan, and wife of Cadell, prince of Powys, about the middle of the fifth century, was buried here. In the cemetery are two rude pillars: one of them, called St. Cadfan's stone, is shaped like a wedge, about seven feet in height, with a cross, and an inscription on each side in old British characters. St. Cadfan is supposed to have been interred in this church about the year

250; and this stone is preserved as a fragment of his tomb.

About a mile north-east of Towyn is Ynys Maen Gwyn, the seat of Edward Corbet, esq.

In the vicinity of the town is a vast rock, called Craig-y-Deryn, or the Rock of Birds, so called from the numbers of cormorants, rock-pigeons, and hawks which breed on it. At its verge is a prodigious mass or stream of stones, which extends some hundreds of yards from the bottom of the rock, and is formed by the continual accumulation of fragments. The vale of Towyn extends two miles further. Near its end is a long and high rock, narrow on the top. Here stood the castle of Teberri, which extended lengthways over the whole surface of the summit, and was a fortress of great strength. One apartment was thirty-six feet broad, and was cut out of the rock on two sides. The remaining walls are well built: the stones squared; the mortar, shells, and gravel are at present very rotten.—Pennant's Tour through Wales, 4to. 1783. Beauties of England and Wales, vol. xvii. North Wales, by the Rev. J. Evans.

TOWYNMYN, a river of Wales, in the county of Montgomery, which runs into the Dowy, 5 miles N.E. of Machynlleth.

TOXANDRI, in *Ancient Geography*, the name of a people beyond the Scheldt, or beyond the limits of Belgium, according to Pliny. The centre of their possessions is said to have been in the environs of Maestricht. In the time of Julian the Franks had an establishment in a place called by Ammianus Marcellinus "Toxandria Locus."

TOXICODENDRUM, in *Botany*, from τοξικος, *poison*, and δένδρον, *a tree*, because the fruit is used at the Cape of Good Hope to poison hyænas. The same name has been employed in botany before, particularly for some very poisonous shrubs, reduced by Linnæus to Rhus; see that article.—Thunb. in Stockh. Transf. for 1796, 188. Willd. Sp. Pl. v. 4. 821. (Hyænanche; Correa in Lambert's Cinchon. 52. Ait. Hort. Kew. v. 5. 402.)—Class and order, *Diœcia Polyandria*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of from five to seven small, ovate, acute, hairy leaves. *Cor.* none. *Stam.* Filaments from ten to twenty, very short, crowded together at the base; anthers oval, of two cells, separated by a furrow at each side.

Female, *Cal.* Perianth inferior, of seven or eight ovate, acute, erect, imbricated silky leaves, deciduous. *Cor.* none. *Pist.* Germen superior, sessile, ovate; style solitary, the length of the germen, triangular, cloven at the top; stigmas three, oblong, reflexed, fringed, glandular. *Peric.* Capsule coated, nearly globular, three-lobed, three-celled, with six furrows and six valves. *Seeds* two in each cell, obovate, compressed, smooth, with a lateral tumid scar.

Eff. Ch. Male, Calyx of several leaves. Corolla none. Stamens from ten to twenty, very short.

Female, Calyx of several imbricated leaves. Corolla none. Style one. Stigmas three. Capsule of three cells and six valves. Seeds two in each cell.

Obf. The stigmas, and cells of the fruit, often vary to four.

1. *T. capense*. Hyæna Poison. Thunb. as above, 189. t. 7. Willd. n. 1. (Hyænanche globosa; Lamb. as above, t. 10. *Jatropha globosa*; Gærtn. t. 109. *Croton*; Burm. *Afric.* 122. t. 45.)—Found about two hundred miles from the Cape of Good Hope, in a rocky soil, on a single spot, on Wind-Hoek mountains, near Elephant's river. It was introduced into the green-house at Kew, by Mr. Francis Maffon, in 1783, and it blossoms there from April to Sep-

tember, as well as in the earl of Tankerville's collection. Mr. Lambert was informed by Mr. Maffon, that a farmer who lived near the native place of this shrub, gained about 20l. a year by gathering the fruit, which being beaten to powder, is used to poison the carcases of lambs, &c. By feeding on these, the hyænas are infallibly destroyed. This is a *shrub*, or small *tree*, six or seven feet high, with spreading branches, which appear jointed, from the scars where the footstalks have been inserted. *Leaves* three or four in a whorl, stalked, spreading, about three inches in length, obovate or oblong, entire, emarginate, coriaceous, smooth, opaque, with one red rib, and many branching lateral veins. *Footstalks* thick, channelled, about half an inch long. *Male flowers* in axillary, branched, yellowish panicles, shorter than the leaves; *female* ones on a separate plant, in simple, axillary, green tufts. *Fruit* smooth, about the size and shape of a Hickory-nut.

It has been debated between Mr. Miller and Mr. Ellis, whether our poison-ash, or winged-leaf American toxicodendron, be the true Japan varnish-tree: Mr. Miller maintains the affirmative, and Mr. Ellis the negative: for the arguments on both sides, see Phil. Transf. vol. xlix. p. 160, p. 866. vol. l. p. 430, p. 441. See VARNISH.

TOXICUM, τοξικον, a word particularly used to express a sort of poison, said to be used by the Indians to their arrows, in order to render wounds made by them incurable.

The word, in a more general sense, signifies any poison. The Indians are supposed to poison their arrows, daggers, &c. with the virus of vipers, the mischievous effects of which continue a long time after the matter is quite dried up.

TOXICUS, in *Botany*, a name by which some authors have called the *arundo furca*, of which walking-canes are made.

TOXILI, TAXILI, or *Taxile*, in *Ancient Geography*, a people of India, in the number of those who inhabited territories near the rivers Cophes, Indus, Hydaspes and Auhini.

TOXOTÆ, τοξοται, among the Athenians, bowmen, a sort of inferior officers, or rather servants, who attended the lexiarchi.

They were much like the Roman lictors: there were a thousand of them in the city of Athens, that lived in tents, erected first in the forum and afterwards in the areopagus. See LEXIARCHI.

TOZER, in *Geography*, a town of Africa, in the country of Sahara; 50 miles S.S.W. of Gafsa. N. lat. 33° 30'. E. long. 8° 15'.

TOZZETTIA, in *Botany*, was so called by professor Savi of Pisa, in honour of his learned friend Dr. Octavian Targioni Tozzetti, the present possessor of the library and manuscripts of the celebrated MICHELI, at Florence, and son of the botanist after whom TARGIONIA was named, who afterwards took the name of Tozzetti; see the articles just indicated. Savi in Ust. Annal. v. 24. 50.—Unfortunately the plant thus denominated is a genuine species of *Alopecurus*; as professor Schrader has made it, in Fl. Germ. v. 1. 174; and as the writer of the present article has long ago shewn, in Tr. of Linn. Soc. v. 7. 245, as well as in Prodr. Fl. Græc. v. 1. 43; it being not only the *Phalaris utriculata* of Linnæus, but likewise his *Cornucopia alopecuroides*. We find it difficult to account for the mistake of Linnæus in referring this grass to *Phalaris*, of which genus it has neither the habit nor characters.

TOZZI, ANTONIO, in *Biography*, a member of the Philharmonic society at Bologna, where he was born, and where he was a disciple of Padre Martini. In 1765 he was appointed

appointed maestro di capella to the duke of Brunswick, for whose court he first composed "Andromache," and in 1775 "Rinaldo." His subsequent productions were unknown to Gerber. In Italy, Tozzi has two operas recorded; "Tigrane" in 1762, and "L'Innocenza vindicata" in 1763.

TOZZIA, in *Botany*, received its name from Micheli, in honour of the reverend father Bruno Tozzi, abbot of Vallumbrosa, who found this rare and curious plant, on the alpine heights of Tuscany, above the celebrated and romantic solitude, where his abbey is situated. This learned ecclesiastic, unlike many of his monkish brethren, delighted to adore his Creator through his works, and was the cheerful and welcome companion of Micheli, in many of his botanical excursions, over the Italian alps, as well as along the shores of the Mediterranean. He was a fellow of the Royal Society of London, and of the Botanical Society of Florence. A number of figures of rare Tuscan *Orchideæ*, drawn by him, may be seen in Petiver's Works, vol. 1. t. 128.—Linn. Gen. 306. Schreb. 403. Willd. Sp. Pl. v. 3. 202. Mart. Mill. Dict. v. 4. Mich. Gen. 19. t. 16. Juss. 97. Lamarck Illustr. t. 522.—Class and order, *Didynamia Angiosperma*. Nat. Ord. *Personate*, Linn. *Lysimachiis affine*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, very short, five-toothed, permanent. Cor. of one petal, ringent; tube cylindrical, longer than the calyx; limb spreading; its upper lip in two, lower in three, segments, all nearly equal and roundish. Stam. Filaments four, concealed beneath the upper lip, unequal; anthers roundish, of two lobes, each with a spur at the base. Pist. Germen superior, ovate; style thread-shaped, agreeing with the stamens in length and situation; stigma capitate. Peric. Capsule globose, of one cell and two valves. Seed solitary, ovate.

Ess. Ch. Calyx tubular, five-toothed. Corolla ringent, with five rounded segments. Capsule globose, of one cell, and two valves. Seed solitary.

Obs. Surely the affinity of this genus to *Euphrasia*, *Lathræa*, &c. is apparently, even without the character of the spurred anthers, indicated by Jacquin. The fruit, which in this tribe affords such admirable distinctions, is here peculiarly marked. *Melampyrum* alone approaches it, by the fewness, size and shape of its seeds. *Tozzia* is erroneously described by Linnæus, with a single-valved capsule. We would presume to remove this genus to the *Pedicularis* of Jussieu.

1. *T. alpina*. Alpine Tozzia. Linn. Sp. Pl. 844. Willd. n. 1. Savi Etrusc. v. 2. 164. Jacq. Austr. t. 165. (*T. alpina lutea*, alfine folio, radice squamatâ; Mich. Gen. 20. t. 16. *Euphrasia lutea* alfinefolia, radice squamatâ; Bauh. Pin. 234. Prodr. 111. *Anonyma fratris Gregorii*, radice dentariæ; Column. Ecphr. v. 2. 49. t. 50. *Dentaria buguloides*, &c.; Mentz. Pugil. t. 9. f. 3, 4.)—Native of moist stony alpine places, in Austria, Switzerland, Dauphiny, Italy, and the Pyrenees, flowering in May. Mentzelius gives an interesting account of his gathering it among the melting snows, on a lofty precipitous mountain, near the source of the Iser, in 1654. The perennial root consists of numerous, fleshy, imbricated scales, and bears a solitary, herbaceous, erect, branched, square, juicy stem, about a foot high, slightly downy at the angles only. Leaves opposite, sessile, ovate, ribbed, succulent, smooth, slightly but coarsely notched, an inch long at most; the numerous floral ones much smaller. Flowers axillary, solitary, on simple slender stalks, shorter than the leaves, bright yellow, a little drooping, perfectly two-lipped, and rather more irregular than Micheli represents them. Calyx oblique, smooth,

brownish. We know of no attempt to cultivate this plant, nor would it perhaps be possible.

TRAABURG, in *Geography*. See DRAABURG.

TRAARBACH, a town of France, in the department of the Sarre. Its neighbourhood is a fine wine country. Opposite the town, on the other side of the Moselle, France, after the treaty of Nimeguen, erected a fort, called Mont Royal; but the demolition of it was made an article of the peace of Ryfwick; 34 miles S.W. of Coblenz. N. lat. 50° 0'. E. long. 7° 5'.

TRABAY, a river of Spain, in the province of Grenada, which runs into the sea near Muxacra.

TRABEATION, TRABEATIO, in the *Ancient Architecture*, the same with *entablature*; which see.

TRABENKA, in *Geography*, a town of Sweden, in the island of Aland.

TRABIA, a town of Sicily, in the valley of Mazara; 2 miles W. of Termini.

TRABUNACTUM, in *Ancient Geography*, a town of Africa Propria, on the route from Tacapæ to Leptis Major, between Adaugmadun and Tramudufis. Anton. Itin.

TRACANA, a town in the interior of European Sarmatia, in the vicinity of the river Carcinites. Ptolemy.

TRACE, a mark or impression which any thing leaves behind it in passing over another.

TRACES of the Brain, among the Cartesian philosophers, are those impressions, more or less deep, which, they say, sensible objects make on the fine fibres of the brain, by means of the organs of sense.

These impressions are also called *traces of the object*; the course of the animal spirits, they say, serves to keep them up, and to renew them.

The vivacity of the imagination, they say, arises from the prodigious quantity of traces of different objects in the brain; which are so linked together, that the spirits cannot be sent into one of them, but they run into all the rest; by which means the ideas occasioned by the application of the spirits to those several traces, are all excited, as it were, at once.

Memory, according to the same, consists in the traces which the animal spirits have impressed.

TRACE of a Hare, among Hunters, is her footing in the snow; distinct from other treadings, called *doubling* and *pricking*, &c.

TRACES also denote the tracks of ravenous beasts, as wolves, wild beasts, &c.

TRACES, Lady's, in *Botany*. See OPHRYS.

TRACHÆ, in *Ancient Geography*, a name which Ovid gives to Anxur.

TRACHEA, in *Anatomy*, the wind-pipe, (from *τραχίτις αετησις*), a rough tube containing air, (rough from its cartilaginous rings,) whence the Latin *aspera arteria*. It is the tube conveying air into the lungs, and commencing at the root of the tongue. See LUNGS.

TRACHEA, Wounds of. See WOUNDS.

TRACHEÆ, in *Vegetable Physiology*, is the appellation given by Malpighi, Grew, &c. to the large spiral-coated vessels of plants; which, being generally found filled with air only, are likewise termed air-vessels. The discoveries of Dr. Darwin, Mr. Knight, and others, have shewn them rather to be sap-vessels, and that the empty state in which they are usually found, is owing to their contents having been expelled on dissection, by the elasticity and irritability of their coats. Such is known to be the fact with regard to the arteries of animals. We have explained the nature of these vessels, and their functions, under the articles

CIRCULATION of Sap, LEAF, and SPIRAL Vessels, the latter being now their most usual denomination. It is preferable to any of the above, as not involving any theoretical opinion.

TRACHEAL ARTERY, in *Anatomy*, a branch of the right subclavian, running up from it in a winding course, along the *aspera arteria*, to the glandulæ thyroideæ and larynx, detaching small arteries to both sides; one of which runs to the upper part of the scapula. The tracheal artery may likewise be called *gutturæ inferior*. See ARTERY, and LUNGS.

TRACHELAGRA, formed of τραχηλος, *neck*, and αγγελ, *seizure*, a term used by some medical writers to express the gout in the neck.

TRACHELIUM, in *Botany*, is not derived, as De Theis supposes, from τραχυς, *rough*, however applicable that sense may be to the plants to which the name was originally applied, our larger *Campanula*. The word comes from τραχηλος, *the neck*, being synonymous with the Latin *Cervicaria*, and the English Throatwort. Old writers tell us, the plants so denominated were believed to be useful in complaints of the neck, or throat; whence also originated another of their synonyms, *Uvularia*. Tournefort, alluding to these reputed virtues, derives the above name from *trachea arteria*, or *aspera arteria*, the wind-pipe, which is certainly not its real source. Being superfluous as a synonym to *Campanula*, he, as well as Linnæus, retain *Trachelium* for a neighbouring genus, distinguished by the long tube, or neck, of its corolla.—Linn. Gen. 89. Schreb. 119. Willd. Sp. Pl. v. 1. 926. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 355. Thunb. Prodr. 38. Juss. 165. Tourn. t. 50. Lamarck Illustr. t. 126. Gært. t. 31.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Campanulaceæ*, Juss.

Gen. Ch. Cal. Perianth superior, very small, in five deep segments, permanent. Cor. of one petal, funnel-shaped; tube cylindrical, very long and slender; limb small, spreading, in five deep, ovate, concave segments. Stam. Filaments five, capillary, nearly the length of the corolla; anthers simple, oblong. Pist. Germen inferior, roundish, with three angles; style thread-shaped, twice as long as the corolla, rather swelling upward; stigma capitate, globose, slightly three-lobed. Peric. Capsule roundish, bluntly three-lobed angular, of three cells, bursting by pores at the base. Seeds numerous, minute.

Eff. Ch. Corolla funnel-shaped. Stigma globose. Capsule inferior, of three cells, bursting by pores at the base.

Obs. Linnæus himself corrected in his *Systema Naturæ* the error in his *Genera*, of the single-celled capsule. The remark subjoined in the last-mentioned work, of some bilocular species, properly belongs to the preceding genus, *Phyteuma*.

1. *T. cæruleum*. Blue Throatwort. Linn. Sp. Pl. 243. Suppl. 143. Willd. n. 1. Ait. n. 1. (*Trachelis azuro umbellifero*; Pon. Bald. 44. *Valeriana cærulea*, *urticæ folio*; Barr. Ic. t. 683, 684.)—Leaves ovate, serrated. Corymbs compound.—Native of shady stony places, in Italy, Spain, and Barbary. Frequent on the ancient walls of Rome, flowering in the spring and summer. It may be kept for many years with us in a greenhouse, though usually considered as a hardy biennial. The root is tapering, white, with many fibres. Herbage smooth, dark green, about two feet high. Stem roundish, often branched, leafy. Leaves alternate, ovate, acute, veiny, an inch or two long, and full half as broad, sharply, and sometimes very deeply, serrated. Footstalks linear; the upper ones half the length of the leaves; lower longer. Flowers very numerous, of a fine

blue, in a terminal, corymbose, level-topped tuft, or panicle, with awlshaped bractæas, in aspect, though not in colour, resembling a *Valerian*.

2. *T. diffusum*. Slender Shrubby Throatwort. Linn. Suppl. 143. Willd. n. 2. Thunb. Prodr. 38.—Leaves awlshaped, erect. Stem panicled, with divaricated branches.—Found by Thunberg, at the Cape of Good Hope. Mr. Masson sent it in 1787 to Kew, where it is a greenhouse plant, flowering in August. Stem a foot or more in height, woody, much branched in the lower part, the branches erect, straight, round, leafy, smooth, or very minutely downy. Leaves scattered, slender, an inch long, very narrow, revolute, entire, sharp-pointed, nearly or quite smooth. Flowers blue, with a pale tube, small, solitary at the ends of the numerous, widely spreading or deflexed, branches of the slender, rigid, smooth panicle.

3. *T. tenuifolium*. Slender Fringed Throatwort. Linn. Suppl. 143. Willd. n. 3. Thunb. Prodr. 38.—Leaves linear, flat, recurved, fringed. Stem branched. Flowers lateral.—Brought by Thunberg likewise from the Cape, but as yet a stranger to our gardens. The long woody root bears a bushy woody stem, a few inches high, divided from the bottom into many branches, clothed with crowded, narrow, recurved, sharp-pointed leaves, half an inch long; strongly fringed at the margin; flat above; keeled beneath; often somewhat downy. Flowers numerous, axillary, solitary, sessile, slender, apparently white or yellowish, except the tips of the corolla. We must rely on the authors cited for the determination of the genus. The style does not project out of the flower. The germen is inferior.

TRACHELIUM, in *Gardening*, contains a hardy herbaceous plant of the perennial kind, of which the species cultivated is the blue throatwort (*T. cæruleum*). It is a plant that is perennial in its nature, being very lasting in soils which are dry and not of a rich quality, but not so in the contrary sort.

Method of Culture.—It is raised from seeds, which should be sown in the autumn when well ripened, or in the spring, in a bed or border of light mould. And when the plants are two or three inches in height, they should be set out in nursery-rows six inches apart, to remain till the following autumn, when they should be planted out where they are to remain.

These are flowering perennials which may have their seeds sown in the crevices of old walls, ruins, and rock-work with much effect and advantage, as the plants continue several years, and display many flowers.

They afford ornament in the above sort of works, and other situations where the earth is poor.

TRACHELO-MASTOIDEUS, in *Anatomy*, complexus minor; a small narrow muscle, situated at the posterior and lateral part of the neck, and extending from the mastoid process to the transverse processes of the vertebræ. Behind, it is covered by the splenius, and the transversalis colli, to which it is connected: in front, it covers the complexus, the obliqui capitis, the posterior extremity of the digastricus, and the occipital artery. Its inner edge is close to the complexus, and is sometimes united by a muscular slip to the longissimus dorsi. The outer edge is fixed by small tendinous and fleshy slips to the transverse processes of the four last cervical vertebræ; and is unattached above. The inferior extremity of the trachelo-mastoideus is slender and pointed, and fixed to the transverse process of the seventh cervical vertebra, or sometimes of the first dorsal; thence it ascends perpendicularly, growing thicker and broader to its upper end, which is fixed to the back of the mastoid process in front of the splenius. It is attached to the

the vertebral processes by small tendons, which produce muscular slips united in the body of the muscle: a flattened tendon is the medium of insertion in the head. When the right and left muscle act together, they restore the head, after it has been bent forwards, and they carry it backwards. The muscle of one side inclines the head and neck laterally.

TRACHELOPHYMA, a swelling of the thyroid gland. See **BRONCHOCELE**, and **THYROID Gland**.

TRACHELOS, a word used by some anatomical authors to express the neck.

TRACHENBERG, or **DRACHENBERG**, in *Geography*, a principality of Silesia, bounded on the N. by Poland, on the E. and S. by the principality of Oels, and on the W. by Wohlau. It was formerly a part of Oels, but erected into a distinct principality, in the year 1741, by the king of Prussia, in favour of the count of Hatzfeld and Gleichen, who was made a prince of the empire, by the emperor Francis, in 1748.

TRACHENBERG, or *Straburck*, a town of Silesia, and capital of the principality of the same name; 14 miles W.S.W. of Militsch. N. lat. $51^{\circ} 28'$. E. long. $16^{\circ} 50'$.

TRACHEOCELE, an enlargement of the thyroid gland. See **BRONCHOCELE**, and **THYROID Gland**.

TRACHEOTOMY, (from *τραχεια*, the *wind-pipe*, and *τομή*, to cut,) in *Surgery*, denotes the operation of making an opening into the wind-pipe.

When a foreign body has entered the trachea, the only means of relief consists in making a longitudinal incision through the skin and cellular substance of the neck, in order to expose the wind-pipe, and slit it open in the same direction. Several of the old practitioners conceived the propriety of this operation, which Junkers, in his "*Conspectus Medicinæ Chirurgicæ*," proscribed in the most positive terms. How, indeed, would it be otherwise possible to put an end to the suffocation and convulsive cough, which the extraneous substance produces? Few practitioners, however, have ventured to do the operation. In the year 1650, the performance of it was recommended by Bonnet, upon a child seven years of age, who, in eating some rice-soup, swallowed a small bone, which passed into the trachea. The young patient pointed out with his finger the place where the foreign body had stopped, and which was exactly opposite the middle of the throat. A physician, who was consulted, gave it as his opinion, that the operation was improper, either because he was not convinced of the presence of the bone in the trachea, or because he thought that it could not be taken out without exposing the child to a certain death. At the end of five days the boy died, and the trachea having been opened, the extraneous substance was taken out of it with the greatest ease. Raw and Heister also successfully extracted foreign bodies from the trachea; the former, a piece of mufhroom, which had been swallowed with some soup; the latter, a bean, which had fallen into the wind-pipe.

Louis was not equally fortunate, in a case where the operation would have infallibly saved the patient's life. A child seven years old, like that of Bonnet, was amusing herself with throwing up small dry beans, and catching them in her mouth. She supposed she had swallowed one of them; but was instantly seized with a difficulty of breathing, and a most fatiguing convulsive cough. It was suspected that the bean had stopped in the throat, and every thing was tried, which was thought to be likely to make it descend into the stomach, or cause it to be ejected from the mouth. The symptoms, however, recurred from time to time, with the addition of convulsions of the limbs. The

case had gone on in this manner two days, when Louis was consulted. He found the child sitting up in bed, leaning upon her two arms, and breathing with difficulty. When he asked her where she felt any thing the matter, she placed her left fore-finger upon the trachea, betwixt the larynx and the sternum. The consideration of the various circumstances of the case made him conclude, that the bean had passed into the wind-pipe, and that the practice of bronchotomy was indispensably necessary for its extraction. Others, who were called into consultation, entertained a different sentiment. M. Louis could not bring them over to his opinion. The opposition which they made even increased, as the child appeared for a time a little better. But at length a new symptom occurred, which no one had yet observed, and which two hours previously did not exist. The child was evidently affected with an emphysematous swelling on each side of the neck above the clavicle. She took an emetic, which only had the effect of disturbing her. The third day she seemed more tranquil, though her respiration was always difficult. In the evening she died. When the trachea was opened, the bean was seen lodged at the upper part of this tube, whence it admitted of being most easily extracted with a pair of forceps.

The long intervals of ease which the patient had, contributed particularly to throw doubts on the presence of the extraneous body in the trachea. It was supposed, that it would necessarily have kept up there a continual irritation, which could not have allowed of the alternations of suffering and ease which took place. But the fact is, the body was smooth, and it had descended below the glottis, the sensibility of which is doubtless greater than that of the trachea, so that it only produced urgent symptoms, when it was forced by the action of respiration against the lower part of the glottis, whose ligaments it hurt, and whose aperture it closed in such a manner, that the air was no longer capable of passing through it with its wonted freedom. It is to this cause that the emphysema, which has been spoken of, must be imputed; for the air being urged back into the lungs, must have ruptured some of the bronchial cells, insinuating itself into the cellular texture of this viscus, and extending from below upward to the lower part of the neck, the integuments of which were elevated by it. This symptom is truly pathognomonic. It was also imagined, that if the extraneous substance had been in the trachea, it would have caused more quickly a fatal suffocation; but there are many cases on record, proving that patients have survived the accident a long while. Bonnet's child, and another mentioned by Marcellus Donatus, did not die until the fifth day. The only symptom which the last experienced, was a slight cough, with a little irritation. The cough which occurred before death was attended with efforts, in which the child turned livid, as if it had been strangled with a rope. Other children also, who have swallowed beans, and whose cases are related by Louis, died; one on the eighth or ninth day after the accident; the other at the end of three weeks, and after having in the interim followed the amusements of their age.

Perhaps it may be apprehended, that a foreign body, after its entrance into the trachea, will descend by its weight to the bottom of this tube; or, that after the proper incisions are made, its extraction will be attended with too much difficulty; but to these two objections, experience gives the most decisive answer. In almost all cases of this sort, the foreign body has been found opposite that part of the trachea which would have been opened, if tracheotomy had been performed; and the experiments relating to this operation which have been made upon living animals, for the purpose

TRACHEOTOMY.

purpose of judging of the facility or difficulty of extracting foreign bodies from the trachea, have shewn, not only that they remain at the upper part of the trachea, (whither they are forced by the air which endeavours to find a way out from the lungs,) but that they even of themselves come out of this tube, and are thrown out to a distance by the same cause, immediately a sufficient opening for their escape has been practised by the surgeon. We are indebted for such experiments to M. Favier, then a student in surgery at the Hotel des Invalides, and since member of the college of surgery at Paris. A large dog, which was muzzled, had an incision made under his jaw, capacious enough to let the tongue be drawn out through it. M. Favier took an opportunity, when the animal was in the act of inspiration, of introducing into the glottis an extraneous substance of an irregularly spherical shape. The dog was seized with convulsive motions, which gave reason for apprehending immediate suffocation; but symptoms abated sufficiently, to allow the operation of tracheotomy to be deferred six hours. The wind-pipe was then opened by a longitudinal incision, which divided three of its cartilaginous rings. Scarcely was the bistoury withdrawn, when a strong expiration propelled the foreign body out of the wound; and as soon as it was a second time introduced, it was expelled again.

The experiment was repeated ten times with the same result. M. Sabatier informs us, that he had seen M. Favier introduce into the wind-pipes of other dogs, extraneous substances of every description and figure, and amongst other things nails and small leaden balls. These were even pushed very far down with instruments; but notwithstanding this, they were thrown out with force as soon as they were left to themselves.

The difficulty of finding and extracting foreign bodies which are lodged in the trachea, must therefore be no longer urged as a pretext for omitting the performance of tracheotomy in all cases in which there is imminent danger of suffocation, in consequence of the presence of those bodies. If, after the integuments and trachea have been divided, they should neither make their escape nor present themselves at the opening, the surgeon should at once endeavour to find them with a pair of forceps, or any other instrument calculated to facilitate their extraction. All that now remains to be done, is to dress the wound in the most simple manner, and to promote its cicatrization by the usual means. The operation which we have been speaking of, may be successfully resorted to in some other cases. When the function of respiration is materially impeded in inflammatory quinies, or by the pressure which a foreign body in the œsophagus makes on the trachea, and which foreign body cannot possibly be extracted, nor pushed down into the stomach, the patient's life may be saved by making an opening into the trachea or larynx. The necessity for such an operation was recognized in the very infancy of the art. With the same view, Hippocrates advised the introduction of a tube into the throat. This bad practice prevailed until Aesclepiades, who proposed the method of making an incision into the larynx of patients who were in danger of suffocation. This operation, however, met with opposition. Cælius Aurelianus considered it as fabulous and absurd. But it met with advocates in several other skilful practitioners, such as Antilus, Oribasius, Ætius, and especially Paulus Ægineta, who describes it in the following terms.

“The incision must be made into the trachea, under the larynx, about the third or fourth ring. This situation is the most proper, because it is not covered with flesh, and the vessels are not near it. The patient's head is to be carried backward, so that the wind-pipe may project more

forward. We make a transverse section between two rings, so that the cartilages may not be wounded, but only the membrane which joins them together.”

The Arabians, who succeeded the Greeks, were also advocates for tracheotomy. It does not appear, however, that they often practised the operation, on account of the dangers by which they supposed it was liable to be followed. Since the revival of learning, the possibility of doing it has been more generally admitted. The subsequent frequent examples of wounds of the throat, where the trachea has likewise been divided, have now produced a conviction, that this canal may be successfully opened in such cases as require it. Fabricius ab Aquapendente was the first who proposed the operation in strong terms. He judiciously examined and considered every part of it, and was fully aware of its advantages. The cannula which has been employed for placing in the opening made in the wind-pipe, seems to have been invented by him. He recommends it to be introduced between two of the rings; to have a straight shape; and to be furnished with wings, by means of which it may be fastened in its place. Its length should not be great, lest it should reach too far, and hurt the back part of the wind-pipe. Lastly; Fabricius advises it to be worn only during the impediment to respiration, since as a foreign body it may do harm, and cause pain and coughing.

Casseri, his pupil, also carefully treats of bronchotomy. He describes the manner of performing it. By the first incision, the skin is to be opened longitudinally over the trachea. By the second, which is to be made betwixt the muscles going up to the larynx, the wind-pipe itself is to be brought into view. A transverse opening is then to be made in it below the thyroid gland. Morgagni gives much credit to this author for having first noticed this gland, which in its enlarged state may materially increase the difficulty of the operation. Casseri approves of the cannula recommended by Fabricius, which he thinks ought to be made of silver, of a flat form, curved, every where pierced with small holes, and fastened to the neck with a ribband. He was quite apprized of all the inconveniences, which Fabricius points out as being liable to attend the employment of this instrument.

While these two skilful practitioners professed themselves to be in favour of bronchotomy in cases where the necessity for it exists, a French surgeon, M. Habcot, endeavoured to bring the operation into repute. The treatise which he has published upon this subject, is entitled, “*Question Chirurgicale, par laquelle il est démontré que le Chirurgien doit assurément pratiquer l'Opération de la Bronchotomie, vulgairement dite Laryngotomie, ou Perforation de la Flûte, ou Tuyau.*” This tract made its appearance in 1620. Besides the reasons upon which this author supports his observations, he relates several cases in which bronchotomy saved the patients' lives. The first is that of a young girl, who was shot in the throat. The ball, after having broken the larynx, and particularly the left side of the thyroid cartilage, made its exit below the inferior angle of the scapula. So considerable a degree of swelling followed, that the patient was almost suffocated. Habcot introduced into the trachea a leaden tube, which was worn three weeks, until the inflammation had subsided. The patient got well. The second person upon whom he performed tracheotomy, was a young man, who had received twenty-two wounds in the head, face, throat, hands, arms, chest, back, yard, and thighs. These were done with a sword, knife, and penknife. In the evening of the same day, Habcot perceived that the patient was nearly suffocated in consequence of the inflammation and swelling of the throat. He was therefore de-

TRACHEOTOMY.

terminated to make an opening in the trachea, below the wound, opposite the upper part of the larynx. The respiration was immediately established again, and the wound was kept open with a grooved tent, until the tumefaction of the larynx was diminished. The cure was complete in three months. M. Louis was of opinion, that, in these two cases, the cannula only served to keep the lips of the wound in the skin apart, because, in the first, the thyroid cartilage was broken so extensively, that it could hardly be supposed to form an obstacle to the passage of the air; and because, in the second, the wound of the trachea had allowed the air to enter and come out again with ease, without the assistance of any tube.

We find in Habcot's essay a third instance in which tracheotomy was successfully performed. "A lad, fourteen years of age, who had heard that gold, when swallowed, did no harm, having sold some merchandize at Paris, for which he had received about nine pistoles, wrapped them up in a piece of cloth and swallowed them, for fear of being robbed. But as they could not pass through the narrow part of the pharynx or œsophagus, his face became so frightful and deformed with swelling and blackness, that his companions could not recollect him. Hence, having caused him to be brought to my house, and not being able to make him void, nor get the obstacle into his stomach, so closely was it fixed by the swelling of the throat; and considering that he would be suffocated, I first made a favourable prognosis, and then performed bronchotomy, which being finished, he revived so rapidly from the violence of the air, that the bystanders were alarmed; but the tumour and unfavourable colour of the face having disappeared, I assured them that he would recover," &c. The foreign bodies were then pushed down into the stomach with a leaden probe, and these were discharged about a week afterwards at different times with the stools. As the patient was so promptly relieved, probably Habcot never thought of keeping the wound open with a cannula, but endeavoured to heal it as expeditiously as possible. In the two other cases, he employed this instrument, which he has described in the last chapter of his treatise.

Since Habcot, and before the end of the seventeenth century, the testimonies to be found in favour of tracheotomy are very numerous; but no one did any thing to perfect the operation until Decker, who, in 1675, proposed to practise it with a small trocar, armed with a cannula. The method is more simple, more easy, and subject, as some have conceived, to fewer inconveniences, if the trachea be not pierced until this tube is exposed by an incision made in the anterior and inferior part of the neck, betwixt the muscles destined to depress the os hyoides and larynx. Paulus, in his notes on Van Horne, imputes the preceding method to Sanctörins, who recommends the trachea to be pierced in the operation of tracheotomy, with the same instrument which he had invented for the paracentesis of the abdomen. By this means the trachea is opened, and the cannula placed, at the same time, a circumstance which prevents the bleeding, which might otherwise escape from the edges of the wound, and occasion an inconvenient and perhaps fatal cough. Dionis, who only proposes bronchotomy in the case of inflammatory quinsy, thinks that it may be done in a more expeditious manner, with less pain, and in a way more calculated to procure a speedy cure, than the mode which was previously in use. This plan consists in performing the operation by one puncture, so that the lancet at once opens the integuments and the interspace of the cartilages of the trachea, and the instrument is not withdrawn before the introduction of the probe, which is to serve as a conductor for the cannula. The advantages which Dionis ascribes to this method

would merit the greatest attention, were they not counterbalanced by the inconveniences which result from it. There are not many subjects, whose necks are so entirely destitute of fat, that the interspace of the rings of the trachea can be felt. This tube, whose figure is cylindrical, easily slips under the fingers, and the change of position may render Dionis's manner of operating extremely difficult. The operation is not without danger of wounding the posterior parietes of the trachea, because one cannot penetrate into its cavity, through the thickness of the integuments and cellular substance, without using a degree of force which it is difficult to regulate with precision. Lastly, when the cannula is put into the wind-pipe, this canal rises, and descends so considerably in various circumstances, and especially in the action of deglutition, that the instrument must be liable to slip out of it. Verduc, before Dionis, had made some remarks on the posture of the patient during the operation. His head was extended back, and the integuments were pinched up into a transverse fold before being divided. Verduc observed, that by inclining the head back, the difficulty of breathing would probably be increased, and that when this position was adopted, the integuments of the neck could not easily be pinched up into a fold. For such reasons, he thinks that posture best, in which the patient breathes with most freedom.

Tracheotomy had been practised only with a view of relieving the suffocation arising from the quinsy, and that which is produced by the pressure of a foreign body in the œsophagus upon the trachea. Detharding, professor of medicine at Rostock, published in 1714 a dissertation, entitled "De Methodo subveniendi submersis per Laryngotomium;" the object of which was to prove, that this operation is necessary in order to restore drowned persons. The principle with which he sets out is, that drowned persons cannot breathe when taken out of the water, because the epiglottis is in contact with the glottis, and closes this opening so closely, as to leave no passage at all for the air. But some observations, carefully drawn up by M. Louis, have proved that the glottis is open and free in drowned persons, as well as in persons who have perished of any other kind of death, and that their death is caused by the water which they have forcibly inspired, and which mixing with the air and mucus with which the bronchiæ and bronchial cells are naturally filled, obstructs and blocks up these organs, so that the air can no longer enter them. But if Detharding has been mistaken upon this point, he has not been deceived in regard to the advantages of tracheotomy in every other circumstance, and the little risk there is in practising it. He states, that the integuments, and the membrane which unites the rings of the trachea, being the only parts which ought to be cut, no vessels nor nerves of importance need be wounded.

Though there are no nerves of considerable size in the track which the incision must necessarily follow, the same observation cannot be made in respect to the blood-vessels. The thyroid gland sends down, to the left subclavian, veins which, after having ramified on its anterior surface, unite into two trunks, the left of which most commonly passes in front of the trachea, at the lower part of the interspace, which lies between the sterno-hyoidæi muscles. In the greater number of subjects, these trunks only form one at the place of their insertion. Sometimes they continue separate. Sometimes, also, one of them terminates in the left subclavian vein, and the other in the right. The left may be injured in dividing the cellular substance which covers the trachea. This canal itself has likewise its own vessels, which may be cut, and bleed a good deal. This was

TRACHEOTOMY.

what happened in a case inserted by Hevin, in his memoir on foreign bodies lodged in the œsophagus and trachea, in the first volume of the *Mémoires de l'Acad. de Chirurgie*. A Spanish soldier, twenty-three years of age, was nearly dying of suffocation from quinsy. Tracheotomy was deemed the only means by which his life could be saved. The wind-pipe having been exposed by a longitudinal incision, an opening was made between two of its cartilaginous rings; but the patient derived no benefit from it, because the blood entered it, and occasioned a convulsive cough, which hindered the cannula from keeping in its place. The case appeared so urgent, that M. Virgili determined to divide the trachea longitudinally down to the sixth ring; and he then made the patient lean forward. The blood soon ceased, and the surgeon was enabled to place in the wound a plate of lead, pierced with several holes, and provided with two shoulders, very much like what Belloste employed in the treatment of the wound after trepanning. The next day the fever was diminished, and deglutition easier. M. Virgili suspected that the patient would be able to breathe without the assistance of the plate, and he therefore removed it. His hopes were not deceived. The only thing which remained to be done, was to bring the edges of the wound together, and endeavour to heal it, which was accomplished in a few days.

Garengot states, that in separating the sterno-thyroidei muscles, the thyroid glands are separated, a circumstance which produces a risk of cutting them in the centre, and of wounding a great many of the vessels which are either distributed upon them or the adjacent parts, so that the blood running into the trachea, the operation must be useless. He allows that it is necessary to operate thus upon persons who are inclined to be fat; but in order to avoid so great an inconvenience, when the patients are thin, and the interspace betwixt the third and fourth ring of the trachea has been felt with the index-finger of the left hand, and the place marked, Garengot recommends introducing a lancet into the trachea at once, before the finger has been removed. The lancet is then to be moved gently towards each side, so as to enlarge the opening. A flat tube is afterwards to be introduced, the sides of which are furnished with narrow ribbands. In this manner, the vessels of the trachea are alone cut, and these are small and of no consequence, so that there is less danger of blood falling into the wind-pipe: Garengot adds, that tracheotomy was in his days accounted a dangerous operation, and that there were few who had practised it, or who mentioned their having done it with success. This want of success appeared to him to be less ascribable to the operation itself, than to its having been undertaken too late. Such was also the sentiment of M. Louis, who insists upon the necessity of having recourse to it as soon as the suffocation appears at all urgent, so as to prevent the effusions in the lungs and brain, always brought on by an extreme difficulty of respiration.

Garengot's method was not original, since it had been described by Dionis. It has also some resemblance to Decker's mode of operating, which consisted in opening the trachea through the integuments, without exposing this canal by a longitudinal incision, in the usual way. Sharp records a case, which confirms the inconveniences which have been attributed to it. A patient, who was in great danger of dying suffocated, was operated upon in the preceding manner. The motion of the wind-pipe in respiration soon separated the opening in the trachea from that in the skin, and occasioned the utmost difficulty in introducing the cannula, and keeping it in its place. Sharp rightly infers

from this fact, that it is absolutely necessary to practise a longitudinal incision, and make it of sufficient size. Platner likewise recommends this incision of the skin, after which, he says, the trachea may be opened with a lancet, or with an instrument analogous to what is employed for tapping. But though this method seemed to him the most expeditious, he deemed it less safe.

It does not appear to Sabatier, however, in what it is more objectionable than the other. On the contrary, he thinks that it has the advantage of preventing bleeding into the trachea, because the cannula immediately fills the opening made in this tube. Platner cites a case, which is recorded in the *Philosophical Transactions*, and which the celebrated commentator upon Boerhaave has also quoted. Authors who had mentioned the cannula which was to be introduced into the trachea, had contented themselves with stating, that it ought not to be too long, lest it should injure the posterior side of that canal. Garengot conceived, that the dimensions of the instrument might be determined with more precision, and he calculated that its length should be about twenty-seven millimetres. Dr. G. Martin, the author of the case to which we have alluded, found this length insufficient, and he was even obliged to use the cannula of a trocar for the paracentesis of the abdomen, instead of what he was first about to employ; but as it was too long, he was under the necessity of making it pass through an aperture made in a thick linen compress.

It has been apprehended, that the extraneous substances in the air may pass through the cannula into the lungs, and, consequently, it has been recommended to cover the mouth of the instrument with a bit of sponge, cotton, or gauze. But Dr. Martin did not find this precaution necessary. He thinks it more useful to warm the air which the patient breathes, so that the lungs may not be hurt by it. There is one serious inconvenience which experience taught him, and which arises from the mucus discharged from the lungs. By this the cannula becomes so obstructed, that its presence affords no assistance. Dr. Martin was several times compelled to take out the tube in order to clean it. He received a suggestion, that he might employ a double cannula, that is to say, two cannulae, one within the other, so that the internal one might be withdrawn as often as necessary, without disturbing the outer one, into which it could be easily put again. In this manner, a free respiration would be assured; but Sabatier conceives, that so thick a tube would be difficult of introduction. He also doubts whether the tube, of which all practitioners have spoken, is indispensably requisite. When the trachea, or larynx, is opened in wounds of the neck, the air makes its escape with force, and the circumstance needs to be checked by inclining the patient's head forward, and confining it in this posture with bandages. Meyffonnier, who wrote towards the conclusion of the seventeenth century, and who practised tracheotomy three times, put no leaden cannula in the wound. He contented himself with applying dry lint, a pledget, and bandage. Sabatier notices, that these cases are detailed too briefly. They prove, however, that the cannula may be dispensed with, and that the making of an opening in the trachea will enable the patient to breathe.

Van Swieten, as well as Platner, rejects the plan of opening the trachea with a trocar. His reason was, because the point of this instrument being thick and short, it was difficult to make it penetrate without using a great deal of force, especially in consequence of the great moveableness of the part on which it has to act. The trials which he made of this method, both on the dead subject and on living animals, convinced him that it was difficult, and that there was danger

in the event of the trocar slipping. This risk may be avoided by fixing the trachea well, and particularly by using some instruments, which were invented by Bauchot, an old surgeon-major of the French navy. They consist of a cutting blade mounted on a handle, to which is adapted a flat cannula, the opening of which has a rim furnished with two small rings, and of a kind of steel crescent, which served to fix the trachea, and as a conductor to the first instrument, which was called the *bronchotome*. Bauchot employed these instruments successfully upon two persons attacked with quinsy, and threatened with suffocation.

It may be concluded from all which has been said, that the operation of tracheotomy, which is also named bronchotomy, and laryngotomy, may be successfully practised, when patients are in danger of suffocation in cases of inflammatory quinsy; when respiration is obstructed by the lodgment of a foreign body in the œsophagus, which body can neither be extracted, nor pushed down into the stomach; and when an extraneous substance has fallen into the wind-pipe. In quinsies, and in cases of foreign bodies lodged in the œsophagus, the operation consists in making an opening, through which the air can enter to the lungs. In the case of a foreign body in the trachea, an incision is required, which divides longitudinally several of the cartilaginous rings of this tube, which is of a size proportioned to that of the substance to be extracted.

When merely an opening is required for the passage of the air, the surgeon may proceed in several different ways. In the oldest method, the patient was placed in the recumbent posture, with his head supported on pillows, so that the skin of the front and lower part of the neck could be pinched up into a transverse fold, of which one end was held by an assistant, the other by the surgeon himself with his left hand. This fold was divided from above downwards, and the incision was continued from the lower part of the larynx to the front of the upper edge of the sternum. The cellular substance between the sterno-hyoidei and sterno-thyroidei muscles, was next divided down to the fore-part of the thyroid gland and trachea. This canal being exposed, the surgeon puts his left-hand index-finger between two of the cartilaginous rings, and then passing along his nail the instrument of which he has made choice, he makes a transverse incision in it. When he judges a cannula indispensable, Bauchot's instrument is the best, the perforating part of which should be taken out immediately the trachea is divided, so as to leave only the tube, which is to be fixed in its place with suitable ribbands passed through the little rings. In this manner, there is no risk of blood falling into the trachea, because the wound is filled by the instrument with which it is made. If, on the contrary, the tube be considered useless, the surgeon should use a lancet with rather a long point.

Instead of practising tracheotomy, or bronchotomy, surgeons have been recommended to perform the operation of laryngotomy, as more safe and easy. The lower edge of the thyroid cartilage, and the upper edge of the cricoid cartilage, are connected together by a thick ligamentous membrane, covered in front merely by the integuments. This anterior part of the crico-thyroid membrane is also immediately opposite the highest and broadest portion of the cavity of the larynx, directly below the glottis, so that it is not only easy to bring it into view by a superficial small cut through the skin and cellular substance, but the incision may be made longitudinally, by which its union will be facilitated, and there can be no risk of hurting the opposite side of the larynx. In France, this mode of operating has had several distinguished advocates, and the celebrated Vic-d'Azyr com-

municated to the Société de Médecine some observations concerning it.

In whatever manner the operation may have been practised, some attention must be paid to the dressing of the wound. If the sole object has been to restore respiration during the short period of time necessary for the removal of a foreign body lodged in the œsophagus, there is no reason why the wound should not be speedily healed. Supposing the trachea, or larynx, to have been opened by a transverse incision, the patient's head must be inclined forwards, and the edges of the longitudinal wound of the skin brought together. When the operation has been practised to relieve the suffocation caused by quinsy, the passage of the air through the wound must be promoted, until the diminution of the inflammation of the parts about the throat allows the air to pass the natural way. The cannula which is used must be covered with gauze, in order to prevent the entrance of extraneous substances in the atmosphere, or bits of the dressings. The wound should be covered with pledgets and compresses, and the whole supported with a suitable bandage. Such are at least the means recommended by methodical writers; but Sabatier observes, that experience has not confirmed their propriety. To some practitioners she has proved, that it is difficult to keep the cannula in its place; to others she has shewn, that the tube becomes filled with mucus, by which it is rendered useless. Sabatier even thinks, that it might be better to omit altogether the employment of the cannula, and nothing would be more easy, were laryngotomy performed as above explained. The superficial small wound required in this operation, may be left uncovered with dressings, and no inconvenience will follow. Sabatier's *Médecine Opératoire*, tom. iii. p. 25, &c. edit. 2.

TRACHICHTHYS, in *Ichthyology*, a genus of fishes, first described by Dr. Shaw in the "Naturalist's Miscellany," the characters of which are as follow: head rounded in front; eye large, mouth wide, toothless, descending. Gill-membrane furnished with eight rays, of which the four lowermost are rough on the edges. Scales rough; abdomen mailed with large carinated scales. There is one species; *viz.*

T. AUSTRALIS, or *Southern Tr.* With mailed abdomen; a native of the coast of New Holland. Its colour is a bright pink-ferruginous, or fair reddish-brown. The middle part of all the fins of a deeper colour than the rest of the animal, and the edges lighter, or of a yellowish tinge.

TRACHIDNA, a name given by Jovius and some others to the *draco marinus* of the old authors, called by us the *weever*.

TRACHINIA, in *Ancient Geography*, a canton of Theffaly, in the Phthiotide, near mount Oeta. It is also called Melide. In this country was the town of Heraclea, since called Heraclea Trachiniæ. Thucydides.

TRACHINIÆ PETRÆ, high and inaccessible rocks which bordered a plain near the Maliac gulf. They surrounded the Melide. Between these rocks and the sea flowed the river Melas, whence the territory had its name.

TRACHINUS, in the Linnæan system of *Ichthyology*, the name of a genus of fish of the order of the *Jugulares*: the characters are, that the head is compressed and not smooth: the membrane of the gills has six rays, and the lower lamina of the opercula is serrated; and the anus is near the breast. Linnæus mentions one species, *viz.* the *Draco*. Artedi refers the *Uranoscope* also to this genus.

The name is originally Greek, the word *τραχίνος* signifying rough, sharp, or prickly. It was given to this fish from

the rays of its back-fin being remarkably rigid, and sharp like prickles.

TRACHINUS Lapis, in *Natural History*, a stone mentioned by the writers of the middle ages, as possessing many great medicinal virtues. It seems to have been a kind of *lapis nephriticus*, being described as bright, but not transparent, and being of two kinds, the one blackish, and the other green.

TRACHIS, in *Ancient Geography*, a town of Thessaly, said to have been built by Hercules at the foot of mount Oeta, towards the mouth of the river Afopus. It derived its name from its mountainous and rugged situation. On the site of this town, which is mentioned by Homer, the Lacedæmonians built another, to which they gave the name of Heraclea.

TRACHOMA, (from *τραχυς*, *rough*,) a roughness of the inner surface of the eyelids, caused by hardened mucus and scabs. It implies the same sort of disease as the *Pforophthalmia*; which see.

TRACHON, in *Ancient Geography*, a plain which bounded the territory of the king of the Cimberian Bosphorus, on the side of Scythia.

TRACHONES, the name of two hills situated beyond the town of Damascus, in Syria. Strabo.

TRACHONITÆ ARABES, Arabs who inhabited Sacæa, at the foot of mount Alfadamus. Ptolemy.

TRACHT, or **TRACHTIN**, in *Geography*, a town of Moravia, in the circle of Brunn; 21 miles S. of Brunn.

TRACHURUS, in *Ichthyology*, the name of a fish of the scomber kind, called in English a *scad*, and by several authors, *furo*, *saurus*, and *acertus marinus*. See **SCOMBER**.

TRACHURUS Brasiliensis, a name given by Mr. Ray to a fish of the scomber kind, the *scomber cordyla* of Linnæus, known among writers on these subjects by its Brazilian name *guaraterêba*.

TRACHYNOTIA, in *Botany*, a genus of grasses, so named by Michaux, from *τραχυς*, *rough*, and *ωτος*, *the back*, because the glumes are rough in that part.—Michaux *BoREALI-AMER.* v. 1. 63.—This is the same with *Limnetis* of Richard and Perfoon, adopted by Pursh, v. 1. 25 and 59, referred to *Triandria Monogynia*, and thus defined.

Eff. Ch. Spike lateral-flowered; flowers imbricated in two ranks. Calyx of two valves; one smaller than the other. Corolla of two valves, pointless, compressed, keeled. Style elongated.—Three species are described.

1. *T. juncea*. Michaux v. 1. 64. (*Limnetis juncea*; Pursh n. 1. *Dactylis patens*; Ait. Hort. Kew. v. 1. 160. Donn. Cant. ed. 5. 20.)—"Leaves two-ranked, shortish, convolute and tapering. Spikes few, remote, spreading. Calyx pointed; its keels rough."—Common in dry salt meadows of North America. Perennial, flowering in July. *Pursh.*

2. *T. cynosuroides*. Michaux *ibid.* (*Limnetis cynosuroides*; Pursh n. 2.)—"Somewhat glaucous. Leaves very long. Spikes numerous, alternate, turned one way. Calyx pointed, awned; its keels prickly."—Frequent on rocky sea-shores of North America. Perennial, flowering in July. *Pursh.*

3. *T. polystachya*. Michaux *ibid.* (*Limnetis polystachya*; Pursh n. 3. *Dactylis cynosuroides*; Linn. Sp. Pl. 104, excluding the synonyms of Loefling and Ray. Willd. Sp. Pl. v. 1. 407. Linn. fil. fasc. 1. t. 9.)—"Leaves broad, flat. Spikes several, spreading in every direction, long and linear. Keels prickly."—Common in salt marshes, from Canada to Florida. Perennial, flowering in August. *Pursh.*

These are very coarse harsh grasses; the last is said by Clayton to have a rancid smell. We mention them here, because *Limnetis* is accidentally omitted in its proper alphabetical order. Which of the two above names is to be preferred, might require consideration; but we have already declared under **DACTYLIS** that we do not see the necessity of dividing that genus. If otherwise, our British *D. stricta*, Fl. Brit. 110. Engl. Bot. t. 380. Knapp Gram. t. 63, must be associated with the above three American species.

TRACHYS MONS, in *Ancient Geography*, a mountain of the Peloponnesus, in Arcadia. Pausanias.

TRACING, in *Husbandry*, a term used by our planters for the method of preserving the maize, or Indian corn. This being a large grain, is apt to spoil, if not carefully preserved.

Some thresh out the corn as soon as the ears are gathered, and lay it up in holes of the earth, which are their granaries; but those who have not opportunities of doing this, trace it, that is, they leave it in the ear, and weave, or fasten together a great number of ears by the ends of the husks: these traces of corn they hang up within doors, on such supports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own, of burying the clean corn, was at least as good, and was the same practised by the Egyptians of old, and by all the wisest nations of the East at this time. But whether we have improved their husbandry in this particular, or not, it is certain that we have greatly assisted them in the planting of this corn, which we do by the plough, instead of the troublesome method they had of doing it with the hoe. The manner of our planting it is this: we plough single furrows the whole length of the field, and at about six feet distance one from another; we then plough others across at the same distance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by running another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plough the spaces again, and by this means destroy and turn in all the weeds, and give the earth a stirring, that greatly assists vegetation.

The famous method of horse-hoeing husbandry, so celebrated by Mr. Tull, in a book written on that subject, is no other than the bringing home this method of our American planters, on the culture of the maize, and applying it to our European corn. The Indians, and our planters, join in the method of raising a hill of earth round every stalk of the maize; and when the ground is poor, or out of heart, they bury two or three fish, of a kind called by them the *aloofe*, under every hill, and by this means they have a crop double to what would otherwise have been produced. The English have learned this manure from the Indians; and in New England, where they are near the fishing-stages, they bury the heads and garbage of the cods, which succeed as well as the aloofe, and cost nothing but the carriage.

The lands on which the maize or Indian corn has grown, are as well fitted for our European corn as if they had been laid fallow. The reason of this is, that the plants of the Indian corn standing at six feet distance from each other, the far greater part of the ground has remained unoccupied, and at the same time has had the advantage of often ploughing to kill the weeds, which is a benefit equal to that of dung and rest. All this, though it tends to prove the doctrine of horse-hoeing husbandry not new, yet it strengthens the system greatly. Phil. Trans. No. 142.

TRACING, among *Miners*. See **TRAINING**.

TRACING-Line, in *Sea Language*, a small cord generally passing

passing through a block or thimble, and used to hoist up any object to a higher station, in order to render it less inconvenient. Such are the tracing-lines of the awnings, and those of the yard-tackles, which, by hanging down in a cavity or bight, would be awkward and incommodious. Falconer.

TRACK, in *Geography*, one of the Nicobar islands. N. lat. $7^{\circ} 30'$. E. long. $94^{\circ} 6'$.

TRACK of a Ship. See **WAKE**.

TRACK-Road, the same as *Towing-path*; which see.

TRACK-Scout, a vessel employed to carry goods or passengers up and down the rivers or canals in Holland, and the countries bordering on the Baltic sea. It is usually tracked by a horse, who trots along the margin to a limited distance, after which he is relieved by another. Falconer.

TRACKING, denotes the art of pulling any vessel or floating body along the stream of a canal or river, by means of a rope extending from the vessel, &c. to the adjacent shore, and drawn along the banks of the river by men or horses. Whence **TRACK-Scout**; which see.

TRACONITIS, in *Ancient Geography*, a rude and mountainous country of Palestine, on the other side of Jordan. M. d'Anville places it at the bottom of Anti-Libanus, inclosed within several branches of this mountain, extending towards the S.E. among which is found mount Hermon: the principal place was *Ænos*.

TRACOSSOZ, in *Geography*, a town of Spain, in the province of Leon; 30 miles W. of Zamora.

TRACT, **TRACTUS**, properly denotes an extent of ground, or a portion of the surface of the terraqueous globe.

TRACT, *Traçate*, or *Traçatus*, does also signify a small treatise or written discourse upon any subject.

TRACT, in *Hunting*, denotes the trace or footing of a wild beast.

TRACTION, **DRAWING**, the act of a moving power, by which the moveable is brought nearer to the mover, called also *attraction*.

TRACTION, *Line of*, in *Mechanics*. See **WHEELS**.

TRACTORIÆ, among the Romans, were diplomas or tickets given by the emperor to such as he sent into, or called out of, the provinces; by which they were entitled to the use of the public post, and to be maintained at the expence of the government.

TRACTRIX, in *Geometry*, a curved line, called also *satenaria*; which see.

TRADE, *Traffic*, *Commerce*, the act, or art, of dealing, buying, selling, exchanging, &c. of commodities, bills, money, &c.

For the origin, progress, &c. of trade, see **COMMERCE** and **NAVIGATION**.

It is observed by Dr. Smith, that all wholesale trade, all buying in order to sell again by wholesale, may be reduced to three different sorts; *viz.* the home trade, the foreign trade of consumption, and the carrying trade. The home trade is employed in purchasing in one part of the same country, and selling in another, the produce of the industry of that country; and it comprehends both the inland and the coasting trade. The foreign trade of consumption is employed in purchasing foreign goods for home consumption. The carrying trade is employed in transacting the commerce of foreign countries, or in carrying the surplus produce of one to another.

The capital that is employed in the first kind of trade generally replaces, by every such operation, two distinct capitals, that had both been employed in the agriculture or manufactures of that country, and thereby enables them to

continue that employment. When it sends out from the residence of the merchant a certain value of commodities, it generally brings back in return at least an equal value of other commodities. When both are the produce of domestic industry, it necessarily replaces, by every such operation, two distinct capitals, which had both been employed in supporting productive labour, and thereby enables them to continue that support.

The capital employed in purchasing foreign goods for home consumption, when this purchase is made with the produce of domestic industry, replaces, too, by every such operation, two distinct capitals; one of which only is employed in supporting domestic industry. Though the returns of the foreign trade should be as quick as those of the home trade, the capital employed in it will give but one-half the encouragement to the industry or productive labour of the country. But, in fact, the returns of the foreign trade are very seldom so quick as those of the home trade; the former coming in before the end of the year, and sometimes three or four times in the year; and the latter seldom coming in before the end of the year, and sometimes not till after two or three years. The capital, therefore, in the home trade will sometimes make twelve operations, before a capital employed in the foreign trade of consumption has made one. If the capitals are equal, therefore, the one will give twenty-four times more encouragement and support to the industry of the country than the other.

That part of the capital of any country which is employed in the carrying trade, is altogether withdrawn from supporting the productive labour of that particular country, to support that of some foreign countries. And though it may replace, by every operation, two distinct capitals, yet neither of them belongs to that particular country. See the illustration of these principles in Smith's *Wealth of Nations*, vol. ii. p. 60, &c. See **CAPITAL**.

The offences against trade, considered in a legal view, are *owling*, or the offence of transporting wool or sheep out of this kingdom, to the detriment of its staple manufacture, (see **OWLER**,) *smuggling*, fraudulent *bankruptcy*, *usury*, *cheating*, (see **CHEATS**,) *forestalling*, *regrating*, (see **REGRATOR**,) *engrossing*, *monopoly*, exercising a trade in any town, without having previously served as an *apprentice* for seven years, punishable by statute 5 Eliz. c. 4. with the forfeiture of 40s. per month; and transporting and seducing our *artificers* and *manufacturers* to settle abroad. See each head.

TRADE, *Balance of*. See **BALANCE**.

TRADE, *Board of*. See **BOARD**.

TRADING Society. See **SOCIETY**.

TRADE-Winds, denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their great use in navigation, and the Indian commerce.

The trade-winds are of different kinds, some blowing three or six months of the year one way, and then the like space of time the opposite way: these are very common in the Indian seas, and are called *monsoons*; which see.

Others blow constantly the same way: such is that general wind between the tropics, which off at sea is found to blow all day long from east to west. For the phenomena of each, with their physical causes, see **WIND**.

Dr. Lister has a conjecture in the *Philosophical Transactions*, N^o 156, that the tropical or trade-winds arise, in great part, from the daily and constant exhalations of a sea-plant, called the *sargossa*, or *lenticula marina*, which grows in vast quantities from 36° to 18° north latitude, and elsewhere upon the deepest seas. For the matter of wind,

coming from the breath of one only plant, must needs be constant and uniform; whereas the great variety of trees and plants at land furnishes a confused matter of winds. Hence, he adds, it is, that these winds are briskest about noon; the sun quickening the plant most then, and causing it to breathe faster, and more vigorously. Lastly, the direction of this wind of east to west, he attributes to the general current of the sea; for a gentle air is observed to be constantly led along with the stream of the river: nor must it be omitted, that every plant is, in some measure, an heliotrope, and bends itself, and moves after the sun, and consequently emits its vapour thitherward; so that the direction of the trade-wind is, in some measure, also owing to the course of the sun.

Dr. Gordon has another hypothesis: the atmosphere, which furrounds the earth, and moves along with it in its diurnal motion, he supposes to keep pace with it; that part of it, at least, which is near the earth, if the remoter part should be judged to lose ground.

If, then, there were no changes in the atmosphere's gravity, he supposes it would always go along with the earth from west to east in an uniform motion, altogether insensible to us: but the portion of the atmosphere under the line being extremely rarefied, its spring expanded, and so its gravity and pressure much less than the neighbouring parts of the atmosphere, it is incapable of the uniform motion towards the east, and must, therefore, be pressed westwards, and make the continual breeze from east to west, between the tropics.

TRADESCANT, JOHN, in *Biography*, one of the fathers of natural history in England, having been the first who made any considerable collection of natural productions, (see MUSEUM,) as well as one of the earliest cultivators of exotic plants in this country, is reported by Anthony Wood to have been a Dutchman. His name nevertheless appears to be English, and was originally of two syllables, *Trade-scant*, though it subsequently became *Tra-des-cant*, as appears by a line in his family epitaph,

“————— beneath this stone,
Lie John Tradescant, grandfire, father, son.”

Dr. Pulteney thinks he was not settled in England during the life of Gerarde, though often mentioned in the second edition of that author's *Herbal*, by its editor Johnson, as well as in Parkinson's *Works*. He is recorded to have been for a considerable time in the service of the lord-treasurer Salisbury, and lord Wooton. He travelled into various parts of Europe, even as far Russia, and was on board a fleet sent against the Algerines in 1620. He brought home plants and other curiosities from these various excursions, but it does not appear what was their primary object. About the year 1629, he obtained the title of gardener to king Charles I., and about that time, or before, was settled at Lambeth, where his own garden was situated. Some remains of this were traced out by sir William Watson 120 years afterwards. Tradescant's Ark, or Museum, became very famous as a collection of natural rarities. It was much visited by the great, and even by the royal family, all of whom took pleasure in enriching it, as in later times their descendants have done to other such collections. A catalogue of the *Museum Tradescantianum*, in 12mo., appeared in 1656, with portraits of the owner and his son, engraved by Hollar; of which however most of the copies are plundered by mere print collectors, careless of the value of any thing beyond their own object. By this catalogue, the museum appears to have been furnished, not only with birds, quadrupeds, fish, shells, insects, minerals,

fruits, &c. but also with warlike instruments, habits, utensils, coins, and medals. There is annexed a catalogue in English and Latin of the plants cultivated in the author's garden. His portrait represents him as greatly advanced in age at this period, but the time of his death is not known. His son, of the same name, visited Virginia, and returned with several new plants; amongst others the original TRADESCANTIA, hereafter mentioned. This son inherited his father's collections, and dying in 1662, bequeathed them to Mr. Elias Ashmole, so that they may be said to have laid the foundation of the Ashmolean Museum at Oxford, in which they, like the name of their original owner, are now sunk. The widow of the younger Tradescant, the mother probably of the grandson mentioned in the epitaph, is said to have erected the curious and rather splendid tomb, remarkable for its allusive decorations, which still exists in Lambeth church-yard. See Dr. Ducarrel's account of this monument, in the sixty-third volume of the Philosophical Transactions. Pulteney's Sketches of Botany.

TRADESCANTIA, in *Botany*, was so named by Ruppian, in Fl. Jen. 55, and Linnæus in Hort Cliff. 127, after the two John Tradescants, father and son, commemorated in the preceding article.—Linn. Gen. 159. Schreb. 213. Willd. Sp. Pl. v. 2. 16. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 204. Pursh 218. Muhlenb. Cat. 34. Juss. 45. Lamarck Dict. v. 2. 370. Illustr. t. 226. Kunth Nov. Gen. et Sp. v. 1. 261. Gærtner. t. 15. (Ephemery; Tourn. t. 193.)—Class and order, *Hexandria Monogynia*. Nat. Ord. *Ensatæ*, Linn. *Junci*, Juss. *Commelineæ*, Brown. See his Prodr. Nov. Holl. v. 1. 269.

Gen. Ch. Cal. Perianth inferior, of three ovate, concave, equal, spreading, permanent leaves. Cor. Petals three, ovate, flat, equal, widely spreading, their claws sometimes combined. Stam. Filaments six, thread-shaped, the length of the calyx, erect, more or less clothed with jointed or beaded hairs; rarely smooth; anthers kidney-shaped, of two, somewhat separated, cells. Pist. Germen superior, ovate, with three blunt angles; style thread-shaped, the length of the stamens; stigma triangular, obtuse. Peric. Capsule ovate, inclosed in the calyx, of three cells and three valves, with partitions from their centres. Seeds few, angular, inserted into the inner angle of each cell, with a papillary protuberance over the transverse, constricted, imberbed embryo.

Eff. Ch. Calyx of three leaves. Petals three, equal. Filaments erect, bearing jointed hairs. Capsule of three cells. Seeds with a protuberance over the embryo.

Obf. Mr. Brown, by whose and Gærtner's observations we have endeavoured to improve the above generic characters, has most justly established a natural order of *Commelineæ*, as distinct from Jussieu's *Junci*, from which they are, as he says, very different in habit as well as structure. Indeed we were never able to conceive how any professed natural system could allow of so strange an assemblage, of plants that have so little in common, as the above-named order of the great French teacher. Nor are we less surprised at the arbitrary assumption which will still call the beautiful delicate and transient corolla of these plants, a calyx, though as different and distinct from the real external perianth, as in any flower whatever. But it is decreed that monocotyledonous plants can have but one integument to their flowers, and that this one must be a calyx; though here they have manifestly two, of which the internal one is, as usual, a self-evident corolla. Mr. Brown indeed feels the necessity of calling these internal parts petals with Linnæus, though such phraseology oversets the Jussieuan hypothesis.

The genus before us consists of various species of herba-
ceous

TRADESCANTIA.

aceous plants, some annual, others perennial, none of them natives of Europe. Their *leaves* are alternate, sheathing, simple, entire, with parallel ribs. *Flowers* clustered, short-lived, usually purplish, differing from those of *COMMELINA*, (see that article,) in being regular, with almost universally six perfect *anthers*. Mr. Brown proposes to separate, into a distinct genus, certain species, the claws of whose *petals* are united, and whose two *seeds*, in each cell, are directed in a contrary manner, one upward, the other downward. The scar of these *seeds*, moreover, is said to be at the base, their embryo at the opposite extremity. In this predicament are *T. axillaris*, *crifata*, and some unpublished species. We proceed to augment Willdenow's list with some new species, most of them recently published by Mr. Kunth, among the discoveries of those illustrious travellers Baron Humboldt and M. Bonpland.

1. *T. virginica*. Common Virginian Spider-wort. Linn. Sp. Pl. 411. Willd. n. 1. Ait. n. 1. Pursh n. 1. Curt. Mag. t. 105. Sowerb. Drawing-book t. 6. Redout. Liliac. t. 95. (Phalangium ephemerum virginianum; Park. Parad. 152. t. 151. f. 4.)—Stem erect. Leaves lanceolate, smooth. Flowers numerous, in a sort of terminal sessile umbel. Calyx hairy.—This, the original species of its genus, was brought from Virginia by the younger TRADESCANT, (see that article,) before the year 1629, as appears by Parkinson's *Paradisus*; and is now one of the most common hardy perennials of every country garden, blossoming copiously throughout summer and autumn. Pursh says it occurs in shady woods, from Pennsylvania to Carolina, flowering in May and June. The plant is readily increased, by parting its long fibrous roots, and thrives particularly well in shade and moisture. The stems are eighteen inches high, round, leafy, scarcely branched. Leaves sheathing, concave, taper-pointed, of a dark shining green. Flowers large, of a rich violet blue, each lasting but a day, or rather a few hours in the early part of a day, after which they roll up into a liquefying pulpy mass; but there being a great number in each umbel, or tuft, there is a long succession. The six golden *anthers* are brilliantly contrasted with the dark purple shaggy filaments.

2. *T. rosea*. Rosy-flowered Spider-wort. Venten. Hort. Celf. t. 24. Ait. n. 2. Pursh n. 2. Redout. Liliac. t. 94.—Stem erect. Leaves linear-lanceolate, elongated. Umbels stalked, of few flowers. Calyx smooth.—Native of wet sandy fields, in Carolina and Georgia, flowering in June and July. Root perennial. Flowers rose-coloured, small, but very handsome. Pursh. The whole plant is of a much more slender habit than the last. Leaves grassy, fringed. Umbels on long stalks, often rising above the uppermost leaves.

3. *T. subaspera*. Roughish Spider-wort. Curt. Mag. t. 1597. Ait. Epit. 375. (*T. cristata*; Walt. Carol. 119.)—Stem erect. Leaves ovato-lanceolate, recurved, rough-edged. Umbels lateral and terminal, many-flowered. Calyx hairy.—Native of North America, from whence it is reported to have been brought by Mr. Lyon in 1812. The plant is a hardy perennial with us, flowering from June to September, but has little superiority to claim over *T. virginica*, except what arises from novelty. The foliage is broader, and more divaricated, than in that species, as well as wavy and roughish, especially at the edge. Flower-stalks reddish or purple, becoming wrinkled as the flowers fade.

4. *T. crassifolia*. Thick-leaved Spider-wort. Cavan. Ic. v. 1. 54. t. 75. Willd. n. 2. Kunth. n. 5. Curt. Mag. t. 1598.—Stem erect, woolly. Leaves ovate, coriaceous; silky at the margin and under side; with very short sheaths. Umbels terminal, hairy.—Native of New Spain,

flowering in September. A stove plant in England, introduced by the late marchioness of Bute. The root is tuberous, perennial. Mr. Ker Bellenden describes the stem as procumbent, but by every other account it is erect. The broad thick ovate leaves, densely silky with white hairs at the margin, as well as beneath, distinguish this species from all the foregoing. The flowers are of a pale violet, expanded but for three or four hours in a morning; their size equal to our first and third species. Calyx hairy.

5. *T. speciosa*. Beautiful Mexican Spider-wort. Kunth n. 6.—“Stem erect, branched. Leaves oblong, acute, smooth on both sides; woolly at the margin. Umbels terminal and axillary, sessile, many-flowered. Calyx woolly.”—Native of the elevated plains of Mexico, near Chapultepec, flowering in May. Perennial. Stem striated, sparingly clothed with white woolly pubescence. Leaves lanceolate-oblong, membranous, somewhat channelled, three inches long, hardly one broad. Sheaths short, lax, striated, woolly at the edge. Umbels of about twenty flowers, whose stalks are divaricated, round, hairy, near an inch long. Calyx tipped with purple. Petals thrice its length, purple, combined at the base. Germen woolly. Style purplish, smooth. Kunth.

6. *T. erecta*. Upright Racemose Spider-wort. Cavan. Ic. v. 1. 53. t. 74. Willd. n. 3. Ait. n. 4. Jacq. Ic. Rar. t. 354. Redout. Liliac. t. 239. (*T. bifida*; Roth Catal. v. 1. 42.)—Stem erect, smooth. Leaves elliptical, acute at each end, smooth. Clusters terminal.—Native of Mexico. A hardy annual in our gardens, introduced by sir Joseph Banks, in 1794, flowering in July and August. Stem a yard high, or more, branched, leafy. Leaves three or four inches long, pale or glaucous beneath, each tapering at the base into a short sheath. Clusters solitary or in pairs, gradually elongated, of many sky-blue flowers, scarcely half the size of *T. virginica*.

7. *T. undata*. Wavy Racemose Spider-wort. Kunth n. 7. Willd. Enum. 347.—Stem erect, with a hairy lateral line. Leaves oblong, acute at each end, wavy, rough on the upper side and margin, with fringed sheaths. Clusters terminal, in pairs.—Native of the sloping sides of hills in Cunana, flowering in September. An annual plant, very nearly related to the last, but more tender, and with reddish-purple flowers.

8. *T. Zanoniana*. Gentian-leaved Spider-wort. Swartz Ind. Occ. v. 1. 604. Willd. n. 4. Ait. n. 5. (Commelina Zanoniana; Linn. Sp. Pl. 61. Redout. Liliac. t. 192. Campelia Zanoniana; Kunth 264. Zanoniana graminea perfoliata; Plum. Gen. 38. t. 38. Periclymenum rectum herbaceum, gentiane folio, folii pediculo caulem ambiente; Sloane Jam. v. 1. 243. t. 147. f. 1.)—Stem erect. Leaves elliptical, tapering at each end. Flowers capitate, on long, lateral, solitary stalks, jointed in the middle, with a pair of bracteas. Capsule clothed with the permanent pulpy corolla.—Native of woods in the West Indies and South America, flowering in autumn. A not unfrequent stove-plant in Europe, though less remarkable for the beauty of its flowers, which are small and white, than for the peculiarity of its dark-purple juicy fruit, formed of the thickened and enlarged corolla, which completely invests the capsule. The root is perennial. Stem two or three feet high, mostly branched, smooth, juicy, leafy in the upper part. Leaves near a foot long, downy beneath, fringed at the base, often red at the edges; their sheaths tumid, doubly fringed. Flower-stalks opposite to each leaf, and nearly as long, with a sheath in the middle, and two ovate, spreading, leafy bracteas at the top, accompanying a head of eight or ten flowers.

TRADESCANTIA.

9. *T. discolor*. Purple-leaved Spider-wort. L'Herit. Sert. Angl. 8. t. 12. Willd. n. 5. Ait. n. 6. Swartz Ind. Occ. v. 1. 607. Sm. Ic. Piët. t. 10. Curt. Mag. t. 1102. Redout. Liliac. t. 168.—Smooth, with scarcely any stem. Bractæas compressed, embracing each other. Leaves lanceolate, coloured on the under side.—Native of South America, about the gulf of Mexico. Naturalized in Jamaica, and now very common in our stoves, flowering early in the day throughout the summer. The leaves, forming a large tuft, are very conspicuous and handsome, in consequence of the rich violet hue of their under side, contrasted with the fine green of the upper. Flowers very copious, small, white, in stalked axillary umbels, much shorter than the leaves, and subtended by a pair of strongly compressed and keeled purple bractæas.

10. *T. malabarica*. Grass-leaved Spider-wort. Linn. Sp. Pl. 412. Willd. n. 6. Ait. n. 7. (Tali pullu; Rheede Hort. Mal. v. 9. 123. t. 63.)—Stems erect, angular; hairy at one side. Leaves linear, channelled, recurved, clasping the stem. Flower-stalks lateral and terminal, hairy, two or three together.—Native of the East Indies. Perennial, flowering in our stoves in June and July. About a foot high, with many slender, slightly branched stems, most leafy in their lower part, and small flowers. The calyx is hairy. Capsule exquisitely polished, as if varnished.

11. *T. divaricata*. Spreading Spider-wort. "Vahl Eclog. v. 1. 34." Willd. n. 8. (Commelina hexandra; Aubl. Guian. 35. t. 12.)—Stem branched, trailing. Leaves ovate, somewhat stalked, smooth, with bearded sheaths. Panicles terminal. Filaments naked.—Found by Aublet about rivers in Cayenne and Guiana, flowering almost all the year. Root perennial. Stems rising to the height of ten feet, supporting themselves upon the neighbouring bushes. Leaves two or three inches long. Flowers blue, in compound clusters, or panicles. Their stamens are said to be smooth, white, and fleshy.

12. *T. geniculata*. Knotted Spider-wort. Linn. Sp. Pl. 412. Willd. n. 9. Ait. n. 8. Jacq. Amer. 94. t. 64. (Ranunculus aut Damasonium repens, parnassæ foliis villosis; Plum. Ic. 106. t. 116. f. 2.)—Stem decumbent, with a hairy lateral line. Leaves ovate, shaggy at the base and sheath. Panicles terminal, compound, capillary, nearly smooth.—Native of the West Indies, in shady moist places, flowering in our stoves about July and August. Root perennial. Stems weak; decumbent and creeping at the bottom; branched and leafy above. Leaves rather above an inch in length, pointed, hairy, especially at the margin and base; their sheaths tumid, membranous, densely shaggy at the border. Flowers small, white, in loose divaricated panicles. Calyx smooth. Capsule pellucid, polished.

13. *T. monandra*. Small Monandrous Spider-wort. Swartz Ind. Occ. v. 1. 597. Willd. n. 10.—Stems diffuse, with a hairy lateral line. Leaves ovate-heart-shaped, smooth. Stalks axillary, many-flowered. Stamen solitary.—Discovered by the scrutinizing eyes of Dr. Swartz in bushy places on hills in the western part of Hispaniola, flowering from June to March. A delicate perennial herb, creeping by means of long fibrous radicles. The leaves are not an inch long, very smooth, pointed, finely reticulated when dry, with pale fringed sheaths. Flowers minute, white, in little axillary umbels. Calyx hairy. Stamen but one, slender, smooth.

14. *T. multiflora*. Many-flowered White Spider-wort. Swartz Ind. Occ. v. 1. 599. Willd. n. 11.—"Stem erect, branched. Leaves heart-shaped, fringed at the margin and

sheaths. Flower-stalks axillary, crowded, many-flowered. Stamens three."—Found in shady woods on the mountains of Jamaica. Stem one or two feet high, round, striated, smooth. Leaves an inch long, acute, with short sheaths. Flowers small, white, short-lived, in little stalked umbels, from the sheaths of two or three of the upper leaves.

15. *T. cordifolia*. Heart-leaved White Spider-wort. Swartz Ind. Occ. v. 1. 601. Willd. n. 12.—"Stem creeping, thread-shaped. Leaves heart-shaped. Stalks terminal, solitary, many-flowered."—Native of moist, shady, grassy spots, on the lofty mountains of Jamaica; annual, flowering in autumn. A very small herb, with numerous, white, capillary roots, and slender, branched, decumbent, creeping stems. Leaves small, nearly sessile, pellucid. Flowers minute, white, transient, with six short, uniform, naked stamens.

16. *T. procumbens*. Procumbent White Spider-wort. Willd. n. 13. (T. multiflora; Jacq. Coll. v. 3. 226. Ic. Rar. t. 355.)—Stem procumbent, creeping. Leaves ovate, fringed at the base. Stalks axillary, cymose, many-flowered. Three of the stamens short and beardless.—Found in moist situations at the Caraccas. It flowers in the stove from August to December, and is perennial. Jacquin. This appears to be a much larger and stouter plant than the preceding, the stems being four feet long; their numerous flowering branches ascending. Leaves an inch and half or two inches in length, dark green, with ribbed sheaths. Flowers in many axillary, as well as terminal cymose tufts, small and white; their three longer stamens only bearded at the summit.

17. *T. axillaris*. Grass-leaved Axillary Spider-wort. Linn. Syst. Veg. ed. 13. 260. Willd. n. 14. (Commelina axillaris; Linn. Sp. Pl. 61. Ephemenum phalangoides maderaspatanum minimum, secundum caulem quasi ex utriculis floridum; Pluk. Phyt. t. 174. f. 3. "Nir-pullu; Rheede Hort. Mal. v. 10. t. 28. f. 13.")—Stem branched, decumbent. Leaves linear, acute; with short, fringed, tumid sheaths, which are longer than the axillary flower-stalks.—Native of the East Indies. Root small, fibrous, annual. Stem much branched, decumbent, taking root at the joints, leafy, smooth, a foot long or more. Leaves grassy, smooth, from three to six inches in length, and one-third of an inch in breadth: their sheaths coloured, smooth, but strongly fringed. Flowers rather small, blue, slightly stalked, scarcely projecting beyond the sheaths of the leaves, not always solitary in our specimens. Calyx-leaves lanceolate, but half as long as the tube formed by the united bases of the petals. Stamens, according to Koenig, six, with jointed hairs.

18. *T. cristata*. Crested Spider-wort. Willd. n. 16. Ait. n. 9. Jacq. Hort. Vind. v. 2. 64. t. 137. (Commelina cristata; Linn. Sp. Pl. 62. Burm. Ind. 18. t. 7. f. 4. Ephemenum zeylanicum procumbens cristatum; Herm. Parad. 148.)—Stem branched, decumbent. Leaves lanceolate, reflexed. Spikes terminal, recurved, with imbricated crescent-shaped bractæas.—Native of Ceylon; introduced at Kew in 1770 by M. Richard. It is annual, flowering in the stove from July to September, and is remarkable for its long-stalked bracteated recurved spikes, of pretty little bright blue flowers, whose six stamens are all bearded at the summit. The habit of the herb is like the last, but with shorter, broader and blunter, deflexed leaves.

19. *T. papilionacea*. Papilionaceous Spider-wort. Linn. Mant. 61. 513. Willd. n. 17. Vahl Symb. v. 1. 27? (Commelina papilionacea; Burm. Ind. 17. t. 7. f. 1.)—Stem branched, decumbent. Leaves linear, recurved. Spikes

Spikes terminal, with three clasping bracteas.—Native of the East Indies. Burmann's figure indicates a very distinct species from the last, with longer and linear leaves. Each spike moreover seems completely enfolded in one large external bractea. Yet the Linnæan specimen, from the Upsal garden, appears scarcely different from *T. cristata*, as Linnæus himself suspected. He says the flowers are violet, not sky-blue. Those who possess both plants, in a living state, can alone clear up the uncertainty which envelopes these species.

20. *T. gracilis*. Slender Purple-veined Spider-wort. Kunth n. 1. — "Stem branched, procumbent. Leaves ovate, acute, fringed as well as their lax sheaths. Umbels terminal, aggregate, on downy stalks. Calyx coloured, rather downy." — Native of the cooler regions of Quito, near Tarqui and Chillo; perennial, flowering in February. Stems smooth, a foot long. Leaves thickish, eight or nine lines in length. Umbels three or four together, with about seven flowers in each, whose corolla is white, veined with purple. Stamens hairy at the base. Cells of the anthers widely separated.

21. *T. debilis*. Weak White Spider-wort. Kunth n. 2. — "Stem erect, weak, nearly simple. Leaves ovate-oblong, acute, fringed as well as their lax sheaths. Umbels solitary or in pairs, on smooth stalks. Calyx hairy at the summit." — Found with the last, to which it is confessedly nearly akin; but the leaves differ somewhat in shape, and the umbels consist of ten or twelve flowers, whose calyx is green, and their petals pure white.

22. *T. pulchella*. Dwarf Purple Spider-wort. Kunth n. 3. — "Stem procumbent, branched. Leaves ovate-oblong, pointed, smooth; rough with minute serratures at the margin. Sheaths lax. Umbels in pairs, on smoothish stalks. Calyx gibbous at the base, smooth." — Native of a temperate climate, on the Mexican mountains, between Guanaxuato and Santa Rosa de la Sierra, flowering in September. — Root perennial. Stem six inches or more in length, round, smooth, sometimes simple. Leaves an inch and a half long, membranous, with about thirteen ribs. Umbels terminal, of about nine purple flowers. Calyx-leaves linear-lanceolate, bluntish, gibbous at the base. Capsule oblong, smooth, of only two cells, with solitary seeds, rough with dots.

23. *T. hirsuta*. Hairy Procumbent Spider-wort. Kunth n. 4. — "Stem procumbent, branched. Leaves oblong-lanceolate, pointed, rough-edged, waved, beneath hairy, as well as their lax sheaths. Stalks three or four-flowered, terminal, in pairs, hairy like the slightly coloured calyx." — Native of the cooler mountains of New Granada, near San Miguel on the banks of the river Putès, Teindala, and the village of La Cruz, flowering in November. The root is perennial. Stem two or three feet long, round, striated, smooth. Leaves rounded at the base, flat, with about nine ribs, an inch and a half or more in length, four lines broad; their upper surface nearly smooth. Sheaths pellucid, striated, half an inch long. Calyx-leaves lanceolate, acute, purplish-green. Petals twice as long, purple. Filaments red, hairy at the base.

24. *T. formosa*. Tall Cape Spider-wort. Willd. n. 15. (*T. speciosa*; Linn. Suppl. 192. Lamarck n. 9. *T. nodiflora*; Lamarck n. 6, according to Willdenow. *Commelina speciosa*; Thunb. Prodr. 58.) — Stem erect, zigzag. Leaves opposite, combined at the base. — Found by Thunberg at the Cape of Good Hope. The stem is two feet, or more, in height, round, smooth, except a little woolly line at each side, running down from the joints. Stem-leaves opposite, awl-shaped, keeled, from two to four inches long,

Vol. XXXVI.

rather woolly at the margin, inserted in pairs into a tumid, entire, woolly or hairy sheath, about half an inch in length. Flowers in dense, axillary, aggregate heads, with lanceolate bracteas; the lower heads stalked. Leaves of the calyx lanceolate, keeled, combined at the base. Filaments very hairy. Style bearded at the upper part. Willdenow seems, in transferring from the *Supplementum*, to have written the name *formosa* by mistake for *speciosa*. The latter being now applied to a different species, see n. 5, we retain the former here. Lamarck may possibly have inserted the same plant twice, once after Linnæus, without seeing a specimen.

The most singular circumstance in the botanical history of *Tradescantia* relates to what Linnæus has named *T. nervosa*, Mant. 223. Willd. n. 7. This proves, by the original specimen from Mutis, accompanied with a drawing, to be a very curious plant of the Orchis family. Mutis justly remonstrated with Linnæus against making it a *Tradescantia*, and called it an *Epidendrum*. Mr. Kunth, who has seen our specimen, informs us it belongs to a new genus, and is named by him *Thelypogon angustifolius*. The style, or column, is excessively hairy, or rather bristly. The lip is very little broader than the two petals, all of them being marked with numerous parallel ribs. The whole flower is above an inch wide, and seems to be very handsome.

TRADESCANTIA, in Gardening, furnishes a plant of the hardy herbaceous perennial kind, the species of which that is chiefly cultivated, is the common Virginian spider-wort, or flower of a day; but there are other species that may be cultivated.

And there are varieties with pale blue flowers, with deep blue flowers, with white flowers, with red flowers, and with purple flowers.

Method of Culture.—They are readily increased by parting the roots, and planting them out in the autumn, or early in the spring, in a bed or border of common earth.

And also by seeds sown at the same seasons in similar situations, the plants being pricked out into other beds in the summer, and removed in the autumn to the places where they are to grow.

These plants are durable in the roots, but the stalks decay annually; they mostly send forth a new flower every day, hence the common name, during some weeks in the summer season, and are proper for planting out in various places in pleasure-grounds.

They afford ornament in the common borders among other flower-plants.

TRADEWATER, in Geography, a river of Kentucky, which runs into the Ohio, N. lat. 37° 17'. W. long. 88° 30'.

TRADITA NEXU. See ABALIENATION.

TRADITION, TRADITIO, the act of delivering a thing into the hands of another. The sale of a moveable is completed by a simple tradition.

TRADITION, in Matters of Religion, is applied to those laws, doctrines, relations, &c. which have been handed down to us from our forefathers, without being written.

Taking tradition in this sense, for every thing relating to faith, or the rites and ceremonies of religion thus derived down to us from the primitive church, there are two kinds, viz. apostolical and ecclesiastical tradition.

TRADITION, Apostolical, which is what we properly call tradition, is defined by the Romanists to be the unwritten word of God, descended from the apostles to us, through a continual succession of the faithful.

By this tradition, say they, it is, that the Holy Scriptures have been kept entire, both as to the letter, i. e. the text, and as to the spirit or sense thereof. This tradition the

council of Trent declares to have the same authority with the Holy Scripture itself, and pronounces every one who rejects it an heretic.

It is a question of some difficulty, when the church of Rome began to derogate from the authority of the Scriptures, and to raise these traditions to an equality with them. It is generally supposed, that pope Nicholas ordained, that the decretal epistles of the popes should be of the same authority as the Scriptures, about the year 855. Du Plessis (Myst. Iniq. Progreff. 31.), indeed says, that pope Agatho had, 170 years before, pronounced openly, "that all decrees made by the see apostolic, ought to be received as if they had proceeded from St. Peter's own mouth." But as this doctrine had gained no canonical authority in the pontificate of Nicholas, it ought not at so early a period be placed to the account of the church. Nor did that diligent inquirer find any formal decree to such effect till the year 1415, when the council of Constance, in the condemnation of the 38th article of Wickliffe's heresy, ordained, that such of the decretal epistles as should be found upon examination to be rightly ascribed to the popes whose names they bore, should be of equal authority with the epistles of the apostles. (L'Enfant's Hist. Council of Constance, vol. i. p. 229.) From this period, the sufficiency of the Scriptures alone to salvation became a formal heresy, as appears by the 12th of the interrogatories exhibited to Lambert with Fox's Martyrology in the year 1538. Hitherto, however, the Scriptures stood upon even ground with papal constitutions; and the inconsistencies between them were kept sufficiently out of sight, by depriving the people of the ordinary means of studying the sacred oracles, and entertaining them only with the ignorant and mystical comments of the monks upon them. When these would no longer pass upon mankind, it then became necessary to degrade the Scriptures to an inferior class.

TRADITIONS, *Ecclesiastical*, are certain statutes and regulations regarding the rites, customs, and circumstances of religion, introduced since the time of the apostles, by councils, popes, &c. and continued to our time through a constant observance of the church.

The Romanists make another division of tradition, *viz.* into *written* and *unwritten*.

TRADITION, *Written*, is that of which we find some traces in the ancient fathers and doctors.

TRADITION, *Unwritten*, is that of which there appear no signs or steps in any of the fathers extant.

The church of Rome pretends to be the depositary of each kind; tradition she holds to be absolutely necessary in the church, grounding this necessity on the promise of infallibility which Jesus Christ is pretended to have made her.

Yet others of that communion deny tradition, how excellent soever it may be for the reclaiming of heretics, to be absolutely necessary; maintaining, that the church would not be less infallible, nor less the rule of doctrine, &c. if the fathers had never written at all.

TRADITIONARY, TRADITIONARIUS, a name given among the Jews to such of them as acknowledge tradition, follow it, and explain the Scriptures by it: in opposition to the Caraites, who refuse any thing but the pure Scriptures themselves.

The traditionaries are what we more usually call rabbins, and rabbinites, or talmudists. Hillel shone among the traditionaries, and Shammai among the textuaries.

TRADITORES, a name given in the first ages of the church to such Christians as, in times of persecution, to avoid death and martyrdom, delivered up the sacred writings to the persecutors.

The enemies of religion, even under the old law, made their utmost efforts to deprive the world of the Holy Scriptures: in that cruel persecution which Antiochus raised against the Jews, the books of the law were very solicitously sought after, torn, and burnt, and such as kept them were put to death; as we read in the first book of Maccab. ch. i. v. 56, 57.

Dioclesian renewed the same impiety, by an edict published in the nineteenth year of his empire, commanding all the sacred books to be brought to the magistrates, and burnt.

Many weak Christians, and even some bishops, overcome with the fear of punishment, carried in their books to the persecutors: which the church detesting, made very severe laws against them, and gave them the infamous names of *traditores*, from *trado*, *I deliver*, *betray*.

As the great pretence of the schism of the Donatists was, that the Catholics tolerated the traditores, it was decreed in the council of Arles, held in 314, that such as should be found guilty of having delivered up any of the holy books or vessels, should be deposed from the order of the clergy, &c.

TRADUCIAN, TRADUCIANI, a name which the Pelagians anciently gave the Catholics, because of their teaching that original sin was transmitted from father to children, or that it was communicated to the children by the father in the way of generation.

The word is formed of the Latin *tradux*, which was made use of to express that communication; and which comes from *traduco*, *I transmit*, or *propagate* from one to another.

At present, some give the appellation *traduciani*, to such as hold, that the souls are transmitted to the children by the father.

TRADUCTION, formed of *trans*, *beyond*, and *duco*, *I lead*, *draw*; the act of translating, or turning out of one language into another. See TRANSLATION.

TRAETH BUCHAN, in *Geography*, a bay of the Irish sea, on the west coast of Wales, in the county of Merioneth; 2 miles N. of Harlech.

TRAETH Coch. See REDWHARF Bay.

TRAETH Mawr, a bay of the Irish sea, on the west coast of Wales, between the counties of Merioneth and Caernarvon; 4 miles N. of Harlech.

TRAETTA, TOMASO, in *Biography*, a Neapolitan composer of the first class during the last century. We have a very spirited and accurate account of the rapid progress of this master to the temple of Fame, in M. Laborde's "Essai sur la Musique," drawn up, we believe, by the animated and discriminative pen of count Benincasa; who says that, "Traetta, one of the last disciples of Durante, quitted the conservatorio at the age of twenty-one, and two years after he was chosen to compose an opera for the great theatre royal of San Carlo, at Naples, entitled 'Farnace.' His success in this first attempt was so great, that he was employed in the same city to compose six other operas, serious and comic, successively.

"The reputation of this young composer soon reached Rome, whither he was invited, and composed for the Aliberti theatre 'Ezio;' which, though it had been previously set by so many great masters, that of Traetta was, and is still, the most esteemed. All the great theatres of Italy now wished to engage him, and he composed for them all more than once, till he was fixed in the service of the court of Parma, in the splendid reign of Don Philip, where he had the honour of instructing in music the late archduchess, consort of the emperor Joseph II., and the princefs of Asturias.

rias, her sister. The operas which he then composed at Parma were entirely in the French taste, which was that of the court. The choruses and the ballets are not yet forgotten. It is this totality that unites the charms of all the fine arts together. The Italians have long known and applauded such splendid spectacles, and often exhibited them successfully in the last and preceding century; but with them the occasions cannot be frequent. A great capital, like Paris, is necessary, which constantly furnishes an audience and spectators able to pay for their amusements all the year round; or magnificent courts, such as those of the princes of the house of Este, Medici, Farnese, and Parma, in former times.

"The first of the six operas which Traetta composed in this style, was 'Ipolito and Aricia,' written by the famous poet, the abate Frugoni, in 1759. At this period Traetta was twice called to Vienna to compose 'Armida' and 'Ifigenia,' two grand operas with choruses and ballets, which were crowned with the greatest success. (This was five years previous to the performance of Gluck's "Orfeo" at Vienna.)

"These two operas were afterwards represented at Milan, Florence, Mantua, and Naples. After the decease of the infant Don Philip, Traetta was called to Venice, where he was appointed maestro to the conservatorio of l' Ospidaleto; but he could not there resist the proposals made to him from all parts of Europe. After two years' residence at Venice, he suffered himself to be attracted to Petersburg, where he was engaged for five years; at the end of which period he was detained two years longer, during which periods he composed seven operas, and many cantatas."

England wished to have him in its turn; but he arrived there too late; his health was so impaired, that he seemed never to have enjoyed a day's ease and comfort while he was here. And Sacchini, who was still in London, had taken such possession of our hearts, and so firmly established himself in the favour of the public, that he was not to be supplanted by a composer in the same style, neither so young, so graceful, nor so fanciful as himself.

Sacchini's person and address had contributed towards endearing him to the English; but, on the contrary, Traetta's countenance and general appearance were so chilling as to be almost frightful. A skin extremely austere, a settled gravity, discontent and gloom covered his visage so constantly, as to make a beholder shrink at the sight of him, and imagine it impossible that any thing pleasing, even to rapture, should flow from its master. But all this only proves that Horace, who says, "Fronti nulla fides," was a much better physiognomist than Lavater.

Though many excellent songs and scenes of his composition had been introduced in pasticcio operas on our stage, yet we can remember but two entire dramas of this master that were executed here, "Germondo," a serious opera; and "La Serva rivale," a burletta. But the dramas which he composed in and for different parts of Europe, must amount to more than fifty.

On quitting England, he returned to Italy in an alarming state of health; however, we find that, in 1778, he produced two operas there: "La Disfatta di Dario," and "Il Cavaliere Mante;" but 1779 was the last year of this admirable musician's existence.

TRAFAGNOL, in *Geography*, a river of Germany, in the county of Tyrol, which runs into the Lavis, 4 miles N. of Casteller.

TRAFALGAR, CAPE, a cape of Spain, on the coast of Andalusia; about 60 miles E. of Cadiz. N. lat.

36° 10'. W. long. 6° 8'. This cape has been rendered famous by the complete victory obtained October 21, 1805, by the British fleet, commanded by Lord Nelson, over the combined fleets of France and Spain off this cape. (See the biographical article of NELSON.) Among the Arabians there is a tradition, that the province of El Garb, in Morocco (see GARB), was originally united to Trafalgar and Gibraltar, shutting up the Mediterranean sea, the waters from which passed into the Western ocean by a subterraneous passage: and at this day they call Trafalgar *Traf-el-garb*, i. e. the piece or part of El Garb; and Gibraltar, *Jibbel-traf*, i. e. the mountain of the piece, or part of El Garb.

TRAFARIA, a fort of Portugal, in the province of Estremadura, on the south side of the Tagus; 6 miles S. W. of Lisbon.

TRAFFICK. See TRADE and COMMERCE.

The word is formed from the French, *traffic*, and that from the Italian, *traffico*, which is again borrowed from the Arabic.

The principal traffic in Muscovy and the North is in furs and skins: the great traffic of the Dutch in the East is in spices: the traffic of money is mostly carried on at the Exchange.

TRAFINE. See TREPAN.

TRAGACANTHA, in *Botany*, *τραγακάνθα* of Dioscorides, book 3, chap. 23, is so called from *τραγός*, a goat, and *κανθα*, a thorn, probably because of its growing in mountainous situations, frequented by goats; or perhaps from being the food of those animals, to whom its thorny footstalks may scarcely prove any impediment. There are several species, almost all confounded by Linnæus under his *Astragalus Tragacantha*, but distinguished by Tournefort, as well as more recently by Willdenow, Lamarck, and others. Three of them are destined to appear in the *Flora Græca*. They all produce more or less of the mucilaginous substance called Gum-Tragacanth, or Gum-Dragon, and are remarkable for their dense bushy thorny habit, and copious, not inelegant, flowers. Tournefort, in his *Corolla*, p. 29, 30, has added nineteen Oriental species to the four mentioned in his *Institutiones*, p. 417; but these, though for the most part truly distinct, are some of them probably mere varieties, and are so considered by Lamarck; see his *Dictionnaire de Botanique*, v. 1. 320; where these plants compose a section of the genus *Astragalus*, characterized by the permanent, finally spinous, common footstalks of the leaves.

TRAGACANTHA, in the *Materia Medica*. The naked hillocks of mount Ida, in Candia, M. Tournefort tells us, produce much of the plant tragacantha, or goat's thorn, which gives the gum spontaneously towards the end of June, and in the following month; when the nutritious juice of the plant, thickened by the heat, bursts most of the vessels in which it is contained.

This juice coagulates in threads, which make their way into the pores of the bark, where being pushed forward by new juice, they get through the bark, and are at length hardened in the air, either into little lumps, or into twisted pieces in form of little worms, more or less long, according to the quantity of the matter of which they are formed.

It should seem, too, that the contraction of the fibres contributes to the expression of the gum; those fine fibres, like the fibres of hemp, laid bare and trampled under foot by men and horses, contract themselves, and facilitate the expression of the extravasated juice. The plant grows also in several places of the Levant, particularly about Aleppo.

M. de la Billardiere's account of the manner in which this gum is produced, differs in some respects from that of Tournefort. Having visited mount Lebanon in August, 1786, the season when this gum is collected, he found the species which afforded it to be different from that figured and described by Tournefort, and consequently not the tragacantha of Linnæus. The stem of the Cretan atragalus is blackish, that of Lebanon is yellow: the leaves of the first are downy, of the second smooth: the flowers of one are red, those of the other are of a pale yellow. Hence he infers that there are several species of atragalus which produce gum-tragacanth. He also contradicts the statement of Tournefort, who attributes the flowing of the gum to the contraction of the fibres of the bark, occasioned by the intensity of the solar heat; observing, that it is only during the night, or when the sun is obscured by clouds, that the gum issues from the plant, and that the same has been remarked at Crete.

The gum is of different colours and qualities, some being white, some greyish, some reddish, and some almost black. The white is the best: it must be chosen clear, smooth, and twisted, or vermicular. It is dry, and yet somewhat soft to the touch.

Gum-tragacanth differs from all the other known gums in giving a thick consistence to a much larger quantity of water: and in being much more difficultly soluble, or rather dissolving only imperfectly. Ruttly asserts, that in five or six hours it will dissolve in cold water. Put into water, it slowly imbibes a great quantity of the liquid, swells into a large volume, and forms a soft but not fluid mucilage; with the addition of more water, a fluid solution may be obtained by agitation, but the liquor appears turbid and wheyish, and on standing the mucilage subsides.

It is smooth and softening, and is therefore good to obtund the acrimony of any humours; which makes it of service in such coughs as proceed from catarrhs, and defluxions of rheum. It is also very strengthening in some seminal weakesses, and is prevalent against the whites in women.

Tragacanth is usually preferred to the other gums for making up troches, and other such purposes, and is supposed likewise to be the most effectual as a medicine; but on account of its imperfect solubility, is unfit for liquid forms. The dose is grs. x to ʒj, or more. It is commonly given in powder, with the addition of other materials of similar intention.

The mucilage of tragacanth of the Edinb. Ph. is prepared by macerating one ounce of gum-tragacanth in powder, in eight ounces of boiling water for 24 hours, and triturating the gum so that it may be dissolved, and straining the mucilage through linen. The mucilage of gum-tragacanth of the Dubl. Ph. is obtained by macerating two drachms of gum-tragacanth in powder, in eight fluid-ounces of water, in a covered vessel, until the gum be dissolved, and straining the mucilage through linen. The compound powder of tragacanth of the Lond. Ph. is formed by taking of tragacanth powdered, acacia gum powdered, and starch, of each an ounce and a half; and of refined sugar three ounces. Rub the starch and sugar together to a powder; then add the tragacanth and the acacia gum, and mix the whole together. This powder is used with effect as a demulcent in hectic fever, and to allay the tickling cough of catarrh; in gonorrhœa and strangury it is given combined with nitre, and in dysentery with ipecacuanha powder. The dose is from ʒss to ʒiij, mixed in water or any bland fluid.

TRAGACANTHUM *Venereum Indicum*, in *Natural History*, a name given by some writers to the bird's-nests so famous in soups in China, and in some parts of Europe, for

their cordial, restorative, and provocative virtues. They are the nests of a kind of Indian sea-swallow, and are made up of a substance resembling gum-tragacanth, and, like it, melting in a jelly in any warm liquor.

TRAGÆA, in *Ancient Geography*, a town of the island of Naxos, in which particular worship was paid to Apollo Trajan.

TRAGAN, in *Geography*, a town of Africa, in Fezzan; 100 miles N. of Mourzouk.

TRAGARTH, a river of Wales, in the county of Brecknock, which runs into the Neath.

TRAGASÆ SALINÆ, in *Ancient Geography*, salt-pits of Asia Minor, in the Troade, near Hamaxitum. Strabo.

TRAGASIAN SALT, a term used among the ancients for a sort of sea-salt, very little different from the common kind, being made by the evaporation of the water of some salt-ponds near the sea-shores.

TRAGEA, in *Pharmacy*, an aromatic powder grossly beaten and mixed with sugar; taken by way of carminative.

TRAGEA, or *Tragia*, in *Ancient Geography*, an island situated in the vicinity of the Cyclades.

TRAGEÆ, islands situated on the coast of Ionia, but they were joined to the continent by the depositions of the Meander. They served as a retreat for pirates, according to Strabo, and lay N. of the promontory Posidium, S.E. of that of Trogilium, and W. of the town of Miletus.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, and which has generally a fatal issue or end.

Accordingly, it has been always reckoned a more dignified entertainment than comedy. The former directs our attention to the high passions, the virtues, crimes, and sufferings of mankind; the latter to their humours, follies, and pleasures. Terror and pity are the great instruments of tragedy; and ridicule is the sole instrument of comedy.

Tragedy exhibits the characters and actions of men, says Dr. Blair, in some of the most trying and critical situations of life, and serves as a direct imitation of human manners and actions. It differs from the epic poem, in which the poet narrates and describes characters, by excluding the poet, and setting before us the personages themselves, acting and speaking what is suitable to their characters. As no kind of writing affords so great a trial of the author's profound knowledge of the human heart, none, when duly executed, has so much power to raise the strongest emotions. It is, or ought to be, a mirror, in which we behold ourselves, and the evils to which we are exposed; a faithful copy of the human passions, with all their direful effects, when they are suffered to become extravagant.

Aristotle scientifically defines tragedy, the imitation of one grave and entire action, of a just length, and which, without the assistance of narration, by raising of terror and compassion, refines and purges our passions.

This definition has given the critics some perplexity; and Corneille declares he cannot reconcile Aristotle with himself; the instances Aristotle cites, he thinks, defeat his own definition. He even denies the purging of our passions to be the end of tragedy.

Our English authors are more favourable to the definition; by the purging of our passions, they understand not the extirpating of them, but the reducing them to just bounds; for by shewing the miseries that attend a subjection to them, they say it teaches us to watch them more narrowly; and by seeing the great misfortunes of others, it lessens the sense of our own.

TRAGEDY.

The ingenious writer already cited, disapproving the statement of Aristotle with regard to the design of tragedy as somewhat obscure, thinks its intention may be more shortly and clearly defined, "to improve our virtuous sensibility." If an author interests us in behalf of virtue, forms us to compassion for the distressed, inspires us with proper sentiments, on beholding the vicissitudes of life, and by means of the concern which he raises for the misfortunes of others, leads us to guard against errors in our own conduct, he accomplishes all the purposes of tragedy. Tragedy is, therefore, a moral species of composition; and the impressions left by it on the mind are, upon the whole, favourable to virtue and good dispositions. In order to produce this beneficial effect, it is necessary that the author should choose some interesting and moving story, and then conduct it in a natural and probable manner. The end of tragedy is not like that of epic poetry, to elevate the imagination by the marvellous, but to affect the heart by a stricter imitation of the life and actions of men. This principle, duly regarded, excludes from tragedy all machinery, or fabulous intervention of the gods; and, therefore, the mixture of machinery with the tragic action, is a blemish in the ancient theatre. Hence some critics have required, that in order to produce and maintain the impression of probability upon which the success of tragedy depends, the subject should not be a pure fiction, but founded on real history, or known facts. This, however, seems to be an extreme; as a fictitious tale may affect the heart as much as a true history, provided that the events related be such as might easily have happened in the ordinary course of nature. Some of the most pathetic tragedies are altogether fictitious as to their subject; such as Voltaire's *Zaire* and *Alzire*, the *Orphan*, *Douglas*, the *Fair Penitent*, &c. For the regulation of the conduct of a tragedy, critics have established the famous rule of the three unities, to which we shall presently advert.

Tragedy, in its original, M. Hedelin observes, was only an hymn sung in honour of Bacchus by several persons, who, together, made a chorus of music with dances and instruments. A goat was the sacrifice offered to that god; and from *τράγος*, a goat, and *ὤδῆ*, a song, was formed the appellation tragedy.

As this was long, and might fatigue the fingers, as well as tire the audience, they bethought themselves to divide the singing of the chorus into several parts, and to have certain recitations in the intervals.

Accordingly, Thespis (see his article) first introduced a person to speak upon the stage with this view.

Phrynichus, the disciple of Thespis, selected that kind of verse which is most suitable to the drama, and introduced some other changes, but left tragedy in its infancy. He, it is said, introduced women's parts on the stage.

Æschylus, the father of tragedy, as he has been called, finding one person insufficient, introduced a second to entertain the audience more agreeably by a kind of dialogue: he also clothed his persons more decently, and first put on them the buskin. For his other improvements in this species of drama, see his article *ÆSCHYLUS*.

The persons who made their recitations on the scene, were called *actors*; so that tragedy at first was without many actors. And what they thus rehearsed, being things added to the singing of the chorus, of which they were no necessary part, were called *episodes*.

Sophocles found that two persons were not enough for the variety of incidents; and accordingly he introduced a third: and here the Greeks seem to have stopped; at least,

it is very rare that they introduce four speakers in the same scene.

The progress of the art under the culture of Æschylus, and his immediate successors, was extremely rapid. He had for contemporaries and competitors, Chœrilus, Pratinas, and Phrynichus already mentioned, whose glory he eclipsed; and Sophocles, who rivalled his own. Sophocles censured in Æschylus three defects: the excessive elevation of his ideas, the gigantic style of his expressions, and the difficult conduct of his plots; and these faults he flattered himself for having avoided. By reducing heroism to its just standard, Sophocles lowered the style of tragedy, and banished those expressions which a wild imagination had dictated to Æschylus, and which diffused terror through the souls of his spectators. His style, like that of Homer, is full of strength, magnificence, sublimity, and mildness. Even in depicting the most violent passions, he happily suits his style to the dignity of his personages. See the article *SOPHOCLES*.

Euripides, at an early age, emulated the fame of Sophocles, and aspired to the sovereignty of the stage. See the biographical article *EURIPIDES*.

Notwithstanding the prejudices and hatred of Aristophanes against Euripides, his decision in assigning the first place to Æschylus, the second to Sophocles, and the third to Euripides, was conformable to the opinion of the greater part of the Athenians. Æschylus, it is said, painted men greater than they can be, Sophocles as they ought to be, and Euripides as they are. The two former had neglected passions and situations, which the latter thought capable of producing great effects. He sometimes represented princesses inflamed with love, and respiring only adultery and crime; and sometimes kings debased by calamity to such poverty, as to be covered with rags, and solicit a wretched alms. These scenes, in which no resemblance was discernible of the manner of Æschylus or Sophocles, at first disgusted the spectators. It was said, that under no pretext ought the character and rank of the heroes of the stage to be so degraded; that it was highly reprehensible to portray with so much art images so shameful, and dangerous to supply vice with the authority of great examples. But at this time the Athenians in general were less offended at the attacks which the pieces of Euripides made on received ideas, than hurried away by the sentiments with which he had animated them; for this great poet, capable of managing at pleasure all the passions of the soul, is especially admirable when he paints the furies of love, or excites the emotions of pity; then, surpassing himself, he sometimes attains the sublime, for which he seems not to have been intended by nature. While he was accused of enervating tragedy, he had proposed to render it the school of wisdom. Euripides, whose eloquence sometimes degenerated into a redundant profusion of words, and whose rhetorical phrases, learned digressions, and idle disputes reduced him much below Sophocles, who has said nothing which has not its utility, is nevertheless said to have fixed the language of tragedy. He retained scarcely any expressions that are especially appropriated to poetry; but he so judiciously selected and employed those of ordinary language, that, under their happy combination, the feebleness of the thought seemed to disappear, and the most common word to become ennobled. Such was the magic of that enchanting style, which, preserving a just medium between meanness and inflation, is almost always eloquent, clear, harmonious, flowing, and so flexible, that it seems to adapt itself without effort to every feeling of the soul. Whilst Sophocles admitted into his choruses the Phrygian

TRAGEDY.

Phrygian harmony, the object of which was to moderate and attemper the passions, and which was adapted to the worship of the gods; Euripides, favouring the innovations made by Timotheus in the ancient music, employed almost all the modes, and especially those, the sweetness and softness of which accorded with the genius of his poetry. Accordingly the audience were astonished to hear in the theatre effeminate tones, and sometimes divisions on a single syllable. Hence the author was represented as a feeble artist, who, incapable of raising himself to the sublimity of tragedy, had depressed tragedy to the level of his own inferior abilities.

Euripides rarely succeeded in the disposition of his subjects; sometimes he offends against probability, sometimes the incidents are forced, and sometimes the action wants unity; almost always the complications and developments of his plots are in some respect imperfect; and his choruses have frequently only an indirect relation to the action.

He invented the method of explaining his subject in a prologue, or long preface, almost entirely detached from the piece, in which usually one of the persons of the drama comes forward, and frigidly details all the events antecedent or relative to the action, gives his own genealogy, or that of one of the principal characters, informs us of the occasion of his descent from heaven, if he is a deity, or who has called him forth from the tomb, if a mortal; and announces himself to the spectators by declaring his name.

It is hardly necessary in this connection to mention Dionysius the elder, king of Syracuse; who was aided in the composition of his tragedies by some men of genius, but was indebted to their assistance for the victory he obtained in this species of literature. Æschylus, Sophocles, and Euripides were, and ever will be, placed at the head of those who in ancient times rendered the stage illustrious. Nevertheless, though the number of pieces they presented in the theatrical competitions was very great, the first obtained the crown only thirteen times, the second but eighteen, and the last only five times; because the victory was decided by the multitude, which had patrons whose passions it espoused, and favourites whose interests it supported. It is remarkable, in how short a space of time tragedy grew up among the Greeks, from the modest beginning to the most perfect state. For Sophocles, the greatest and most correct of all the tragic poets, flourished only twenty-two years after Æschylus, and was little more than seventy years posterior to Theſpis. The chorus was the basis of the ancient tragedy, and the dramatic dialogue was superadded to it. In process of time, the chorus, from being the principal, became only the accessory in tragedy; till at last, in modern tragedy, it has disappeared altogether; which forms the chief distinction between the ancient and the modern stage.

Each tragedy required three actors for the three leading parts; and the same actors sometimes performed both in tragedy and comedy; but persons very rarely excelled in both. Actors who had acquired great celebrity received considerable pay; not less than a talent (or 225*l.* sterling) in two days. The kind of verse generally employed in tragedy was the iambic, a species of measure that frequently occurred in conversation. The actors had habits and symbols suited to their several parts; and tragedy almost from its earliest invention employed the mask, which was completed under the hands of Æschylus. In tragedy the stature of the actors was frequently increased to four cubits (six English feet and nearly half an inch); which was effected by buskins, that raised them four or five inches;

gauntlets also lengthened their arms; and their breasts, sides, and every part of the body, were rendered apparently thicker in proportion. The subject, in the composition of the Greek tragedy, was diversified by variety in the fable, which was simple or complex; by variety in the incidents, which excites terror and pity; by variety in the discoveries, which are one of the most copious sources of the pathetic, especially when they produce a sudden revolution in the condition of the persons of the drama; by variety in the characters, and by variety in the catastrophe, in which latter respect some dramatic pieces conclude happily, and others disastrously; and there are some, in which, by a double revolution, both the virtuous and the wicked experience a change of fortune. The first of these terminations, however, seems only suitable to comedy. The manners in this species of drama, as well as in others of a similar kind, teach the exact conformity of the actions, sentiments, thoughts, and language of the personage with his character; and it is, therefore, necessary, that from the very first scenes, we should be able to discover, from what he does and what he says, the nature of his present inclinations, and his ultimate designs. Accordingly, the manners should be proper and uniform; suitable to the age and dignity of the person; neither contrary to the idea of the hero delivered down to us by ancient tradition, nor inconsistent in any part of the piece. The writers of tragedy should, like our actors, inspire spectators and judges with pity, terror, or indignation; and like them, demonstrate a truth, or refute an objection, aggrandize or diminish an object. In many of the ancient tragedies we perceive beauty of thought and elevation of sentiment in all their lustre, triumph in the language of truth, and the eloquence of the unfortunate. With this view behold Merope, Hecuba, Electra, Antigone, Philoctetes, succeeded sometimes by the horrors of death, and sometimes plunged in shame or despair, or listen to those accents of grief, those piercing exclamations, those passionate expressions, which, from one end of the theatre to the other, make the voice of nature resound in every heart, and compel all eyes to dissolve in tears. The style of tragedy, though not pompous, should nevertheless be suitable to the dignity of the ideas. All mean expressions should be avoided. See Travels of Anacharsis the younger, in Greece, vol. vi.

Tragedy and comedy were at first confounded with each other; but they were afterwards separated; and the poets in general applied themselves to the cultivating of tragedy, neglecting comedy.

When tragedy was got into a better form, they changed the measure of its verse, and endeavoured to bring the action within the compass of a day, or of a revolution of the sun.

We now proceed to give some account of the three unities of action, place, and time, which have been considered as essential to the proper conduct of the dramatic fable. The first of these is the most important, and it consists in a relation which all the incidents introduced bear to some design or effect, so as to combine naturally into one whole. This unity of subject is more essential to tragedy than to epic poetry; for a multiplicity of plots or actions, crowded into so short a space as tragedy allows, must necessarily distract the attention, and prevent passion from rising to any height. (See ACTION and EPIC Poem.) All under-plots should be rendered subservient to the main action. Addison's "Cato" is defective in this respect. The subject of the tragedy is the death of Cato, which the author supports with dignity; but all the love-scenes in the play are mere episodes, unconnected with the principal action.

Unity

TRAGEDY.

Unity of the action should not be confounded with the simplicity of the plot. The plot is simple, when a small number of incidents are introduced into it; but it may be complex, in the language of critics, or include a considerable number of persons and events, and yet not be deficient in unity, if all the incidents tend towards the principal object of the play, and be properly connected with it. Congreve's "Mourning Bride" is adduced as an instance which stands in perfect opposition to the simplicity of the ancient plots. The incidents succeed one another too rapidly, and the play is too full of business. Unity of action must not only be regarded in the construction of the fable, or plot, but it must also regulate the several acts and scenes into which the play is divided. The division of the play into five acts is altogether arbitrary, and rests merely on common practice, and the authority of Horace, *De Art. Poet.* (See *ACTS*, in *Poetry*.) The pauses between the acts should be duly adjusted; so that there are corresponding pauses in the action. The fifth act is the seat of the *Catastrophe*; which see. For the several parts of tragedy, see *ACT, ACTION, CHARACTER, FABLE, PLOT, MANNERS, and SCENE*.

It has been a question much agitated among philosophical critics, how it comes to pass that those emotions of sorrow which tragedy excites afford any gratification to the mind? Sorrow, it is said, is a painful passion: scenes of misery exhibited in tragedies excite a degree of sympathy and agitation that occasions anguish and distress. The spectators cannot suppress their feelings; they are indicated by their tears: and yet they applaud such exhibitions, and recur to them with satisfaction and pleasure. That such exhibitions should draw such crowds of spectators, and that they should be so highly gratified by them, appears to be somewhat mysterious. The fact is acknowledged, and many hypotheses have been proposed for the satisfactory explanation of it. In order to account for it, we can by no means recur to an innate principle of malice, which prompts us to extract delight from the sufferings of others, and as it were to enjoy their calamities. Dr. Campbell, in his "Philosophy of Rhetoric," (vol. i. chap. 11.) has detailed and examined the various hypotheses that have been devised by ingenious men for the solution of this difficulty. The theory of the abbé du Bos, in his "Reflections on Poetry and Painting," is as follows. Few things, according to him, are more disagreeable to the mind, than that listlessness into which it falls, when it has nothing to occupy it, or to awake the passions. In order to get rid of this most painful situation, it seeks with avidity every amusement and pursuit; business, gaming, news, shows, public executions, romances; in short, whatever will rouse the passions, and take off the mind's attention from itself. It matters not what the emotion be, only the stronger it is, so much the better. And for this reason, those passions which, considered in themselves, are the most afflicting and disagreeable, are preferable to the pleasant, inasmuch as they most effectually relieve the soul from that oppressive languor which preys upon it in a state of inactivity. They afford it ample occupation, and by giving play to its latent movements and springs of action, convey a pleasure which more than counterbalances the pain.

Mr. Hume, in reference to this theory, observes, that the same object of distress which pleases in a tragedy, were it really set before us, would, without doubt, give the most unassigned uneasiness, though it should be the most effectual cure of languor and indolence; and Dr. Campbell says, that the most which can be concluded from the abbé's premises is, the utility of exciting passion of some kind or other,

but nothing that can evince the superior fitness of the distressful affections.

The next hypothesis is that of M. Fontenelle, in his "Reflexions sur la Poétique." According to this writer, pleasure and pain, which are two sentiments so different in themselves, differ not so much in their cause. From the instance of tickling it appears, that the movement of pleasure, pushed a little too far, becomes pain; and that the movement of pain, a little moderated, becomes pleasure. Hence it proceeds, that there is such a thing as a sorrow, soft and agreeable. It is a pain weakened and diminished. The heart likes naturally to be moved and affected. Melancholy objects suit it, and even disastrous and sorrowful, provided they are softened by some circumstance. It is certain that, on the theatre, the representation has almost the effect of reality; but yet it has not altogether that effect. However we may be hurried away by the spectacle, whatever dominion the senses and imagination may usurp over the reason, there still lurks at the bottom a certain idea of falsehood in the whole of what we see. This idea, though weak and disguised, suffices to diminish the pain which we suffer from the misfortunes of those whom we love, and to reduce that affliction to such a pitch as converts it into a pleasure. We weep for the misfortunes of a hero to whom we are attached. In the same instant we comfort ourselves by reflecting, that it is nothing but a fiction: and it is precisely that mixture of sentiments which composes an agreeable sorrow, and tears that delight us. But as that affliction which is caused by exterior and sensible objects, is stronger than the consolation which arises from an internal reflection, they are the effects and symptoms of sorrow, which ought to prevail in the composition. To Mr. Hume this solution appeared just and convincing; but to Dr. Campbell it appeared unsatisfactory. The ingenious author begins with laying it down as a general principle, that however different the feelings of pleasure and of pain are in themselves, they differ not much in their cause; that the movement of pleasure, pushed a little too far, becomes pain; and that the movement of pain, a little moderated, becomes pleasure. Dr. Campbell has shewn, that on this principle, exemplified in a few instances, and not warranted by others more immediately connected with the subject in question, we are not justified in founding a general theory. "The only truth," says our author, "which I can discover in the preceding hypothesis is, that the mind, in certain cases, avails itself of the notion of falsehood, in order to prevent the representation or narrative from producing too strong an effect upon the imagination, and consequently to relieve itself from such an excess of passion, as could not otherwise fail to be painful. But let it be observed, that this notion is not a necessary concomitant of the pleasure that results from pity, and other such affections, but is merely accidental. It was remarked above, that if the pathetic exceeds a certain measure, from being very pleasant it becomes very painful. Then the mind recurs to every expedient, and to disbelief amongst others, by which it may be enabled to disburden itself of what distresseth it. And, indeed, whenever this recourse is had by any, it is a sure indication that, with regard to such, the poet, orator, or historian, hath exceeded the proper measure.

"But that this only holds when we are too deeply interested by the sympathetic sorrow, will appear from the following considerations: first, from the great pains often taken by writers (whose design is certainly not to shock, but to please their readers) to make the most moving stories they relate, be firmly believed: secondly, from the tendency, nay fondness of the generality of mankind, to believe
what

TRAGEDY.

what moves them, and their averfenes to be convinced that it is a fiction. This can result only from the confcioufnefs that, in ordinary cafes, difbelief, by weakening their pity, would diminish, inftead of increafing, their pleafure. They muft be very far then from entertaining Fontenelle's notion, that it is neceffary to the producing of that pleafure; for we cannot well fufpect them of a plot againft their own enjoyment: thirdly, and laftly, from the delight which we take in reading or hearing the moft tragical narrations of orators and hiftorians, of the reality of which we entertain no doubt; I might add, in revolving in our own minds, and in relating to others, difaftrous incidents, which have fallen within the compafs of our own knowledge, and as to which, confequently, we have an abfolute affurance of the fact."

The third hypothefis produced and examined by Dr. Campbell is Mr. Hume's, which he propofes as a fupplement to the former two, in the doctrine of both which he, in a great meafure, acquiefces. "What is it then," fays Mr. Hume, "which in this cafe (that is, when the forrow is not foftened by fiction) raifes a pleafure from the bofom of uneafinefs, fo to fpeak; and a pleafure, which ftill retains all the features and outward fymptoms of diftreff and forrow? I anfwer: This extraordinary effect proceeds from that very eloquence, with which the melancholy fcene is reprefented. The genius required to paint objects in a lively manner, the art employed in collecting all the pathetic circumftances, the judgment difplayed in difpofing them; the exercife, I fay, of thefe noble talents, together with the force of expreffion, and beauty of oratorical numbers, diffufe the higheft fatisfaction on the audience, and excite the moft delightful movements. By this means, the uneafinefs of the melancholy paffions is not only overpowered and effaced by fomething ftonger of an oppofite kind, but the whole movement of thofe paffions is converted into pleafure, and fwells the delight which the eloquence raifes in us. The fame force of oratory employed on an uninterefting fubject, would not pleafe half fo much, or rather would appear altogether ridiculous; and the mind, being left in abfolute calmnefs and indifference, would relifh none of thofe beauties of imagination or expreffion, which, if joined to paffion, give it fuch exquisite entertainment. The impulfion or vehemence arifing from forrow, compaffion, indignation, receives a new direction from the fentiments of beauty. The latter being the predominant emotion, feize the whole mind, and convert the former into themfelves, or at leaft tincture them fo ftongly, as totally to alter their nature: and the foul, being at the fame time roused by paffion, and charmed by eloquence, feels on the whole a ftong movement, which is altogether delightful."

The infufficiency of this hypothefis is very fatisfactorily evinced by Dr. Campbell; and he has fhewn, that inftead of being fupplementary to M. Fontenelle's, as he intended it to be, it is fubverfive of the principles on which the French critic's theory is founded. The effect, according to the latter, results from moderating, weakening, foftening, and diminishing the paffion: according to the former, it results from what is directly oppofite, from the arts employed by the orator for the purpofe of exaggerating, ftrengthening, heightening, and inflaming the paffion. Indeed, neither of thefe writers feems to have attended fufficiently to one particular, which of itfelf might have fhewn the infufficiency of their fystems. The particular alluded to is, that pity, if it exceed not a certain degree, gives pleafure to the mind, when excited by the original objects in diftreff, as well as by the representations made by poets, painters, and orators: and, on the contrary, if it exceed a certain degree, it is on the

whole painful, whether awakened by the real objects of pity, or roused by the exhibitions of the hiftorian or of the poet. Indeed, as fenfe operates much more ftongly on the mind than imagination does, the excefs is much more frequent in the former cafe than in the latter. But our limits will not allow our enlarging.

A fourth hypothefis is that of thofe who maintain that compaffion is "an example of unmixed selfishnefs and malignity," and may be "refolved into that power of imagination, by which we apply the misfortunes of others to ourfelves;" that we are faid "to pity no longer than we fancy ourfelves to fuffer, and to be pleafed only by reflecting that our fufferings are not real; thus indulging a dream of diftreff, from which we can awake whenever we pleafe, to exult in our fecurity, and enjoy the comparifon of the fiction with truth."

This is no other, as Dr. Campbell obferves, than the antiquated doctrine of the philofopher of Malmefbury refcued from oblivion, to which it had been faft defcending, and re-published with improvements. Hobbes, indeed, thought it a fufficient ftretch, in order to render the fym pathetic forrow purely selfish, to define it "imagination or fiction of future calamity to ourfelves, proceeding from the fenfe of another man's calamity." This paradoxical conceit, as our author has denominated it, has been adopted by Hawkefworth in the "Adventurer." In the selfish fystem, it appears to be a great objection, that in pity we are affected with a real forrow for the fufferings of others, or at leaft that men have univerfally underftood this to be the cafe, as appears from the very words and phrafes expreffive of this emotion to be found in all known languages. But to one who has thoroughly imbibed the principles and fpirit of a philofophic feft, which hath commonly as violent an appetite for myftery (though under a different name, for with the philofopher it is paradox) as any religious feft whatever; how paltry muft an objection appear, which hath nothing to fupport it but the conviction of all mankind, thofe only excepted whose minds have been perverted by fcholastic fophiftry?

It is remarkable, that though it has been contended by a great number of perfons, that fome fiction of the imagination is abfolutely neceffary to the production of pity, and though the examples of this emotion are fo frequent, as to give ample fcope for examination, they difagree with regard to their fiction. Some contend only, that in witnessing tragedy, one is under a fort of momentary deception, which a very little reflection can correct, and imagines that he is actually witnessing thofe diftreffes and miferies which are only reprefented in borrowed characters, and that the actors are the very perfons whom they exhibit.

Others, who refer every thing to felf, maintain, that by a fiction of the mind, we inftantly conceive fome future and fimilar calamity as coming upon ourfelves; and that it is folety this conception, and this dread, which call forth all our forrow and our tears. Others, not fatisfied with this, maintain boldly, that we conceive ourfelves to be the perfons fuffering the miferies related or reprefented, at the very inftant that our pity is raifed. When nature is deserted by us, it is no wonder that we fhould lofe our way in the devious tracks of imagination, and not know where to fettle.

Dr. Campbell's hypothefis is illuftrated by the following general obfervations, of which the following detail is an abfttract. He obferves, firft, that almoft all the fimple paffions, of which the mind is fufceptible, may be divided into two claffes, *viz.* the pleafant and the painful, differing confiderably both in kind and degree. 2dly. Among the paffions,

TRAGEDY.

passions, as well as among the ideas of the mind, there is an attraction or association. 3dly. Pain of every kind generally makes a deeper impression on the imagination than pleasure does, and is longer retained by the memory. 4thly. From a group of passions associated together, and having the same object, some of them pleasant, and others painful; if the pleasant predominate, there arises often a greater and a more durable pleasure to the mind, than would result from these, if alone and unmixed. 5thly. Under the name *pity* may be included all the emotions excited by tragedy. It has been usual, however, to comprehend pity and terror under the class of passions that are moved by tragedy; but our author observes, that this enumeration is more popular than philosophical, though adopted by the Stagyrite himself. For what is pity but a participation by sympathy in the woes of others, and the feelings naturally consequent upon them, of whatever kind they be, their fears as well as sorrows: whereas, this way of contradictistinguishing terror from pity, would make one, who knew nothing of tragedy but from the definition, imagine, that it were intended to make us compassionate others in trouble, and dread mischief to ourselves. If this were really the case, Dr. Campbell thinks there are few or none who would find any pleasure in this species of entertainment. If all the sympathetic affections excited by theatrical representations were enumerated, our author cannot see why hope, indignation, love and hatred, gratitude and resentment, should not be included as well as fear. 6thly. Pity is not a simple passion, but a group of passions strictly united by association, and as it were blended, by centering in the same object. Of these, some are pleasant, some painful, but commonly the pleasant preponderate. In pity there are three different emotions: *first*, commiseration, purely painful; *secondly*, benevolence, or a desire of the relief and happiness of the object pitied, a passion, as was already observed, of the intermediate kind; *thirdly*, love, in which is always implied one of the noblest and most exquisite pleasures whereof the soul is susceptible, and which is itself, in most cases, sufficient to give a counterpoise of pleasure to the whole.

The principal pleasure in pity arises from its own nature, or from the nature of those passions of which it is compounded, and not from any thing extrinsic or adventitious. Nevertheless, certain adventitious circumstances may contribute to heighten the effect; but they cannot be regarded as essential to the passion. Of this sort is the satisfaction which arises from a sense of our own ease and security, compared with the calamity and the danger of another.

“ ’Tis pleasant, safely to behold from shore
The rowling ship, and hear the tempest roar:
Not that another’s pain is our delight;
But pains unfelt produce the pleasing fight.
’Tis pleasant also to behold from far
The moving legions mingled in the war.”

Another adventitious source of pleasure is, the satisfaction that results from the conscious exercise of the humane affections, which it is our duty to cherish and improve. Sense, as we have frequent occasion to observe, invariably makes a stronger impression than memory, and memory a stronger than imagination; yet there are particular circumstances which appear to form an exception, and to give an efficacy to the ideas of imagination, beyond what either memory or sense can boast. So great is the anomaly which sometimes displays itself in human characters, that it is not impossible to find persons who are quickly made to cry at seeing a tragedy, or reading a romance, which they know to be fictitious, and yet are both inattentive and unfeeling in

respect of the actual objects of compassion who live in their neighbourhood, and are daily under their eye.

Men, says our author, may be of a selfish, contracted, and even avaricious disposition, who are not what we should denominate hard-hearted, or insusceptible of sympathetic feeling. Such will gladly enjoy the luxury of pity, (as Hawkesworth terms it,) when it nowise interferes with their more powerful passions; that is, when it comes unaccompanied with a demand upon their pockets. With the tragic or the romantic hero or heroine they most cordially sympathise, because the only tribute which wretches of their dignity exact from them is sighs and tears. And of these their consciences inform them, to their inexpressible consolation, that they are no niggards. But the case is totally different with living objects. Barren tears and sighs will not satisfy these. Hence it is that people’s avarice, a most formidable adversary to the unhappy, is interested to prevent their being moved by such, and to make them avoid, as much as possible, every opportunity of knowing or seeing them. See this observation admirably exemplified in the parable of the compassionate Samaritan, Luke, x. 30. Our author concludes with observing, that compassion alone, especially that displayed on occasion of witnessing public spectacles, is at best but a very weak evidence of philanthropy.

Dr. Blair, agreeing in the main with the hypothesis of Dr. Campbell, introduces the following observations on this subject, which we cannot forbear transcribing. “ By the wife and gracious constitution of our nature, the exercise of all the social passions is attended with pleasure. Nothing is more pleasing and grateful than love and friendship. Wherever man takes a strong interest in the concerns of his fellow-creatures, an internal satisfaction is made to accompany the feeling. Pity, or compassion, in particular, is, for wife ends, appointed to be one of the strongest instincts of our frame, and is attended with a peculiar attractive power. It is an affection which cannot but be productive of some distress, on account of the sympathy with the sufferers, which it necessarily involves. But, as it includes benevolence and friendship, it partakes, at the same time, of the agreeable and pleasing nature of those affections. The heart is warmed by kindness and humanity, at the same moment at which it is afflicted by the distresses of those with whom it sympathises: and the pleasure arising from those kind emotions prevails so much in the mixture, and so far counterbalances the pain, as to render the state of the mind, upon the whole, agreeable. At the same time, the immediate pleasure, which always goes along with the operation of the benevolent and sympathetic affections, derives an addition from the approbation of our own minds. We are pleased with ourselves for feeling as we ought, and for entering, with proper sorrow, into the concerns of the afflicted. In tragedy, besides, other adventitious circumstances concur to diminish the painful part of sympathy, and to increase the satisfaction attending it. We are, in some measure, relieved, by thinking that the cause of our distress is feigned, not real; and we are also gratified by the charms of poetry, the propriety of sentiment and language, and the beauty of action. From the concurrence of these causes, the pleasure which we receive from tragedy, notwithstanding the distress it occasions, seems to me to be accounted for in a satisfactory manner. At the same time, it is to be observed, that, as there is always a mixture of pain in the pleasure, that pain is capable of being so much heightened, by the representation of incidents extremely direful, as to shock our feelings, and to render us averse, either to the reading of such tragedies, or to the beholding of them upon the stage.”

Under the general head of the unity of action, to which

TRAGEDY.

after a long digression we now return, it may not be improper to make a few remarks on the conduct of the several scenes which make up the acts of a play. See SCENE.

The entrance of a new personage upon the stage forms, what is called, a new scene. These scenes, or successive conversations, should be closely linked and connected with each other. For this purpose, two rules should be regarded. The *first* is, that, during the course of one act, the stage should never be left vacant; for whenever the stage is evacuated, the act is closed. This rule is very generally observed by the French tragedians; but the English writers, both of comedy and tragedy, seldom pay any regard to it. The *second* rule, little better regarded by English writers than the former, is, that no person should come upon the stage, or leave it, without a reason appearing to us, both for the one and the other.

In order to render the unity of action more complete, critics have added the other two unities of time and place. The unity of place requires, that the scene should never be shifted; but that the action of the play should be continued to the end, in the same place where it is supposed to begin. The unity of time, strictly taken, requires, that the time of the action be no longer than the time that is allowed for the representation of the play; though Aristotle seems to have given the poet a little more liberty, and permitted the action to comprehend the whole time of one day. During the course of each act, the unities of time and place ought to be strictly observed; that is, during each act the scene should continue the same, and no more time should be supposed to pass, than is employed in the representation of that act. This is a rule which the French tragedians regularly observe. To violate this rule, as is too often done by the English; to change the place, and shift the scene in the midst of one act; shews great incorrectness, and destroys the whole intention of the division of a play into acts. Mr. Addison's "Cato" is remarkable beyond most English tragedies for regularity of conduct. The author has limited himself, in time, to a single day; and in place, has maintained a most rigorous unity. The scene is never changed; and the whole action passes in the hall of Cato's house, at Utica.

The *characters* most proper to be exhibited in tragedy have been usually considered by writers on this subject. (See CHARACTER.) Several critics require that the principal personages should be of high or princely rank, because their misfortunes and sufferings interest the imagination, and impress the heart more forcibly, than those of persons in humbler condition or more private life. But this observation is more specious than solid, and is refuted by facts. The distresses of Desdemona, Monimia, and Belvidera, affect us as much as if they had been princeesses or queens. The moral characters of the persons represented are much more important than the external circumstances in which they are exhibited. The personages presented to view, and the incidents relating to them, should be so described, as to leave upon the spectators impressions favourable to virtue, and to the administration of Providence. Mixed characters, such as occur in the world, afford the most proper field for displaying, without any bad effect on morals, the vicissitudes of life; and they interest us the more deeply, as they display emotions and passions, of which we have all been conscious. The subjects of the ancient Greek tragedies were too often founded on mere destiny, and inevitable misfortunes; and though in the course of the drama, many moral sentiments occurred, the instruction conveyed by the fable of the play was seldom any more than that reverence was owing to the gods, and submission due to the decrees of destiny. Besides, their tales about oracles, and the vengeance of the gods, led to many incidents more melancholy and tragical than moral

and useful. Modern tragedy has aimed at a higher object. An Othello, hurried by jealousy to murder his innocent wife; a Jaffier, ensnared by resentment and want to engage in a conspiracy, and then stung with remorse, and involved in ruin; a Siffredi, through the deceit which he employs for public-spirited ends, bringing destruction on all whom he loved; a Calista, seduced into a criminal intrigue, which overwhelms herself, her father, and all her friends in misery these, and such as these, are the examples which tragedy now displays to public view; and by means of which, it inculcates on men the proper government of their passions.

The *sentiments* of a tragedy should be suited to the characters of the persons to whom they are attributed, and to the situations in which they are placed. Moral sentiments and reflections should not occur too often, because they would thus lose their effect, and they would render the play pedantic and declamatory. This is the character, in a great degree, of Seneca's tragedies. Nevertheless, moral reflections, properly introduced, give dignity to a composition, and, on many occasions, are extremely natural. Much of the merit of Addison's Cato depends upon that moral turn of thought which distinguishes it. The *style and versification* of tragedy should be free, easy, and varied. Our blank verse is happily suited to this purpose. The style of tragedy ought always to possess force and dignity, but at the same time that ease and briskness, which are adapted to the freedom of dialogue, and the fluctuations of passion.

Of the Greek tragedy and tragedians we have already given some account. In the compositions of some of the French dramatic writers, particularly Corneille, Racine, and Voltaire, tragedy has appeared with much lustre and dignity. But though they have improved upon the ancients; though they are attentive to all the unities, and to all the decorums of sentiment and morality; and though their style is generally very poetical and elegant; yet they want fervour, strength, and the natural language of passion: too declamatory, when they should be passionate; and too refined, when they should be simple. These defects of the French theatre are freely acknowledged by Voltaire. (See their respective biographical articles.) The general character of tragedy in Great Britain is, that it is more animated and passionate than French tragedy, but more irregular and incorrect, and less attentive to decorum and to elegance. See the biographical articles of SHAKESPEARE, DRYDEN, OTWAY, ROWE, YOUNG, CONGREVE, THOMSON.

We shall close this account of tragic compositions with the following extract from Dr. Blair's Lectures, vol. iii. "A Greek tragedy is the relation of any distressful or melancholy incident; sometimes the effect of passion or crime, oftener of the decree of the gods, simply exposed; without much variety of parts or events, but naturally and beautifully set before us; heightened by the poetry of the chorus. A French tragedy is a series of artful and refined conversations, founded upon a variety of tragical and interesting situations; carried on with little action and vehemence; but with much poetical beauty, and high propriety and decorum. An English tragedy is the combat of strong passions, set before us in all their violence; producing deep disasters; often irregularly conducted; abounding in action; and filling the spectators with grief. The ancient tragedies were more natural and simple; the modern are more artful and complex. Among the French, there is more correctness; among the English, more fire. Andromaque and Zayre, soften; Othello and Venice Preserved, rend the heart. It deserves remark, that three of the greatest masterpieces of the French tragic theatre turn wholly upon religious subjects: the Athalie of Racine, the Polyucte of Corneille, and the Zayre of Voltaire. The first is founded upon an historical

istorical passage of the Old Testament; in the other two, the distress arises from the zeal and attachment of the principal personages to the Christian faith: and in all the three, the authors have, with much propriety, availed themselves of the majesty which may be derived from religious ideas."

The English received the first plan of their drama from the French, among whom it had its first rise towards the end of the reign of Charles V. under the title of the *chant-royal*; which consisted of pieces in verse, composed in honour of the Virgin, or some of the saints, and sung on the stage: they were called by the title *chant-royal*, because the subject was given by the king of the year, or the person who had borne away the prize the year preceding.

The humour of these pieces took wonderfully among the people, inasmuch, that in a little time there were formed several societies, who began to vie with each other in them: and one of these, to engage the town from the rest, began to intermix various incidents or episodes, which they distributed into *acts* and *scenes*, and had as many different persons as were necessary for the representation.

Their first essay was in the Bourg St. Maur, and their subject the passion of our Saviour. The prévot of Paris prohibiting their continuing of it, they made application to court; and to render it the more favourable to them, erected themselves into a friary, or fraternity, under the title of "Brothers of the Passion;" which title has given some occasion to suspect them to have been an order of religious.

The king, on seeing and approving some of their pieces, granted them letters of establishment in 1402, upon which they built a theatre, and for an age and a half acted none but grave pieces, which they called *moralities*; till the people growing weary of them, they began to intermix farces or interludes taken from profane subjects. This mixture of farce and religion displeasing many, they were re-established by an arret of parliament in 1548, on condition of their acting none but profane, yet lawful and decent subjects, without intermeddling with any of the mysteries of religion; and thus were the Brothers of the Passion despoiled of their religious character; upon which they mounted the stage no more in person, but brought up a new set of comedians, who acted under their direction.

Thus was the drama established, and on this foundation arrived in England. In process of time, as it was improved, it became divided into two branches, agreeable to the practice of the ancients, and the nature of things, *viz.* into tragedy and comedy properly so called; and this last again was subdivided into pure comedy and farce. See each under its proper head, COMEDY, &c.

TRAGEDY, *Hilaro*. See HILARO-*tragædia*.

TRAGEIN, in *Geography*, a town of Austria; 10 miles E.N.E. of Steyregg.

TRAGELAPHUS, in *Zoology*. See CERVUS and OVIS.

TRAGEN, in *Geography*, a town of Africa, in Fezzan; 25 miles E. of Mourzouk.

TRAGIA, in *Botany*, received its name from Plumier, in memory of Hieronymus Tragus, or Jerome Bock, a famous old German botanist, who was both a divine and a physician, and discovered a number of rare plants in Germany, which Haller enumerates, *Bibl. Bot.* v. 1. 266. He is chiefly known to us by the Latin edition of his herbal, published in quarto by David Kyber in 1552, with a learned historical preface, by his illustrious friend Conrad Gesner. Some of the cuts, often coloured, give a ludicrous exhibition of the medical qualities of the plants, or of some particulars in their history. Tragus died in 1554, aged 56.

Adanson always called him Le Bouc, as if we were to say in English Mr. He-goat; and would not retain the Linnæan name of the present genus, preferring that used in the Hortus Malabaricus, *Schorigenam*, spelling it, by a fatality incident in orthography to many of his countrymen, *Schorigeram*, which blunder he seems to have copied from Linnæus. Nobody has attended to this erudite alteration. — *Linn. Gen.* 483. *Schreb.* 627. *Willd. Sp. Pl.* v. 4. 322. *Mart. Mill. Dict.* v. 4. *Ait. Hort. Kew.* v. 5. 255. *Pursh* 604. *Juss.* 390. *Plum. Gen.* 14. t. 12. *Lamarck Dict.* v. 7. 722. *Illustr. t.* 754. — Class and order, *Monoecia Triandria*. *Nat. Ord.* *Tricocceæ*, *Linn. Euphorbia*, *Juss.*

Gen. Ch. Male, *Cal.* Perianth in three deep, ovate, acute, flat, spreading segments. *Cor.* none. *Stam.* Filaments three, the length of the calyx; anthers roundish.

Obf. Linnæus remarks, that Plumier took this calyx for a funnel-shaped monopetalous corolla.

Female, on the same plant, *Cal.* Perianth inferior, in five, sometimes six, deep, ovate, concave, acute, permanent segments. *Cor.* none. *Pist.* Germen superior, roundish, with three furrows; style one, erect, longer than the calyx; stigma in three spreading segments. *Peric.* Capsule of three globular lobes and three cells, bristly, each cell marked at the base externally with a pair of dots. *Seeds* solitary, globose.

Ess. Ch. Male, Calyx in three deep segments. Corolla none.

Female, Calyx in five deep segments. Corolla none. Stigmas three. Capsule three-lobed, of three cells. Seeds solitary.

Obf. Some species have the style more or less deeply split into three parts.

Tragia is an unsightly genus, with the aspect of a nettle, or a *Croton*. The flowers are green and inconspicuous; the herbage mostly hispid or hairy; the stem either twining, often shrubby and perennial; or erect, herbaceous, with an annual root,

Sect. 1. *Stem climbing.*

1. *T. volubilis*. Twining *Tragia*. *Linn. Sp. Pl.* 1390. *Willd. n.* 1. *Ait. n.* 1. "Trew *Pl. Rar.* v. 2. 7. t. 15." *Lamarck f.* 1. (*T. alia scandens, urticæ folio*; *Plum. Ic.* 251. t. 252. f. 2.) — Leaves ovate, somewhat heart-shaped, pointed, strongly ferrated, rather hairy. Foot-stalks bristly above. Segments of the female calyx undivided. Stem twining. — Native of dry, calcareous situations in the West Indies, blossoming in our stoves in June and July, provided it be admitted there. The stem is round, hairy, leafy, branched, twining from west to east. Leaves alternate, about two inches long; paler beneath. Flowers axillary; the males in long bracteated clusters; the females solitary, on a long stalk at the base of each cluster. Capsule the size of a large pea. Browne's specimen has the leaves more soft and downy beneath than in the original one from the Upsal garden. Whether the β of Linnæus, *Plum. Ic.* t. 252. f. 1, be a variety, or a distinct species, we have no means of determining.

2. *T. cordata*. Heart-leaved *Tragia*. *Vahl Symb.* v. 1. 76. *Willd. n.* 2. (*Jatropha pungens*; *Forst. Ægypt.-Arab.* 163.) — "Leaves heart-shaped, pointed, ferrated; bristly beneath. Segments of the female calyx pinnatifid, hairy. Stem twining." — Gathered by Forskall near Yemen, in Arabia Felix, where it is called *Hôrekrek*, *Meberkaka*, or *Humja*. *Vahl* says the stem is shrubby, twining, and, like the whole plant, bristly. Leaves paler beneath. Spikes terminal.

3. *T. hispida*. Bristly *Tragia*. *Willd. n.* 3. — "Leaves lanceolate,

lanceolate, pointed, hispid, nearly entire; heart-shaped at the base. Segments of the female calyx pinnatifid, rough with bristles. Stem climbing."—Native of the East Indies. *Leaves* on very short, very hispid footstalks, most bristly beneath, two inches long, occasionally furnished with an obsolete tooth at the base, or near the point. *Spike* axillary, stalked. *Calyx* densely covered with white bristles.

4. *T. macrocarpa*. Large-fruited Tragia. Willd. n. 4. Pursh n. 3. (*T. cordata*; Michaux Boreal.-Amer. v. 2. 176.)—"Leaves ovate, sharply toothed, hispid; deeply heart-shaped at the base. Stem twining."—Found by Michaux in Kentucky. Annual, flowering in July. *Pursh*. Each lobe of the *capsule* is said to be the size of a large pea.

5. *T. villosa*. Shaggy Tragia. Thunb. Prodr. 14. Willd. n. 5.—"Leaves heart-shaped, crenate; hairy beneath. Stem climbing."—Gathered at the Cape of Good Hope by Thunberg, who alone appears to have seen this or the next species.

6. *T. capensis*. Cape Tragia. Thunb. Prodr. 14. Willd. n. 6.—"Leaves heart-shaped-ovate, toothed, hispid. Stem twining. Segments of the female calyx pectinate. From the same country.

7. *T. involucreta*. Calycine Tragia. Linn. Sp. Pl. 1391. Willd. n. 7. Ait. n. 2. Lamarck n. 3. Jacq. Misc. v. 2. 372. Ic. Rar. t. 190. (*Ricinokarpus zeylanica hirsuta, foliis lanceolatis ferratis*; Burm. Zeyl. 202. t. 92. Schorigenam; Rheede Hort. Mal. v. 2. 72. t. 39.)—Leaves ovate, pointed, ferrated, hispid. Stem climbing. Segments of the female calyx pinnatifid, bristly.—Native of the East Indies, in sandy ground. The *root* is annual. *Stem* twining, rising to the height of ten feet, much branched, leafy, round, densely covered with pale bristly hairs. *Leaves* about three inches long, ribbed and veiny, paler beneath, on short hispid stalks. *Clusters* lateral, stalked, short and simple, each of several little green male flowers, with a foliary female one at the base. *Capsule* woody, hairy, enveloped in the large, very bristly, strongly pinnatifid, or pectinate, permanent *calyx*.

SECT. 2. *Stem erect, herbaceous.*

8. *T. nepetifolia*. Nep-leaved Tragia. Cavan. Ic. v. 6. 37. t. 557. f. 1. Willd. n. 8. Lamarck n. 6.—Leaves oblong-heart-shaped, strongly ferrated, hispid. Stem erect, much branched.—Native of New Spain, flowering in August. An annual herbaceous plant, a foot high, very much branched. *Leaves* about an inch long, alternate, stalked; glaucous beneath. *Clusters* axillary and terminal, capillary, rather shorter than the leaves. Female *calyx* with entire segments.

9. *T. urticifolia*. Nettle-leaved Tragia. Michaux Boreal.-Amer. v. 2. 176. Willd. n. 9. Pursh n. 2. (*Croton foliis cordatis ferratis petiolatis alternis, floribus spicatis*; Gron. Virg. ed. 2. 153.)—"Leaves heart-shaped, ovate, ferrated. Stem erect, very hairy."—In fields, from Virginia to Georgia; annual, flowering in July. *Pursh*.

10. *T. Mercurialis*. Mercury-leaved Tragia. Linn. Sp. Pl. 1391, excluding the reference to Gronovius. Willd. n. 10. Lamarck n. 7. (*Mercurialis maderaspatensis triccocos, acetabulis destituta*; Pluk. Phyt. t. 205. f. 4. "Pee-cupameni; Rheede Hort. Mal. v. 10. t. 82.")—"Leaves heart-shaped, ovate, pointed, ferrated. Spikes paniced. Stem erect."—Native of the East Indies. Apparently annual, with the aspect of a *Mercurialis*. We have examined no specimens.

11. *T. corniculata*. Horned Tragia. Vahl Eclog. v. 2. 55. Willd. n. 11. Lamarck n. 8.—Leaves ovate, somewhat heart-shaped, pointed, nearly entire. Stem erect,

branched, hairy. Each valve of the capsule with two horns.—Native of Trinidad and Guiana. *Root* annual. *Leaves* occasionally furnished with a tooth or two near the base, with slender downy veins. *Spikes* axillary. *Capsule* depressed, its valves two-horned at each extremity. *Vahl*.

12. *T. urens*. Stinging Tragia. Linn. Sp. Pl. 1391. Willd. n. 12. Ait. n. 3. Pursh n. 1. Lamarck n. 12. (*Ricinus parvus urens, foliis quercinis, virginianus*; Pluk. Phyt. t. 107. f. 5.)—Leaves oblong-lanceolate, sessile, obtuse, more or less toothed towards the extremity, downy, as well as the upright branched stem.—In cultivated and waste ground, and by road-sides, from Virginia to Carolina; annual, flowering from June to August. *Pursh*. The name of *urens* seems to have remained with this species on the authority of Plukenet. Its pubescence appears to be of a very fine kind; nor has any recent botanist attributed to it any stinging property. The habit of the herb is like a *Mercurialis*. The *leaves* are from one to two inches long, very variable in breadth; usually deeply toothed, or almost sinuated; rarely linear and entire. *Clusters* axillary; longer than the leaves. *Capsules* slightly hairy.

13. *T. Chamælea*. Lance-leaved Tragia. Linn. Sp. Pl. 1391. Willd. n. 13. Ait. n. 4. Lamarck n. 13.—(*Chamælea foliis linearibus, flosculis spicatis, echinato fructu*; Burm. Zeyl. 59. t. 25. Codi avanaçu; Rheede Hort. Mal. v. 2. 63. t. 34.)—Leaves linear-lanceolate, stalked, obtuse, fringed with close bristles. Stem branched, diffuse. Lobes of the capsule toothed at the back.—Native of the East Indies, in grassy places; rare on the coast of Malabar. It was sent in 1793 by Dr. Roxburgh to Sir Joseph Banks, and flowered in the stove at Kew, in the middle of summer. The *root* is annual. *Herb* twelve or eighteen inches high, nearly smooth, and somewhat glaucous. *Stems* slender, angular, diffuse. *Leaves* very variable in length and breadth, undivided, entire, curiously fringed with dense, close, white, callous, bristly teeth. *Clusters* small, simple, axillary. The lowest *leaves* are sometimes nearly orbicular.

14. *T. cannabina*. Hemp-leaved Tragia. Linn. Suppl. 415. Willd. n. 14. Ait. n. 5. Lamarck n. 14. (*Croton hastatum*; Linn. Sp. Pl. 1427. Burm. Ind. 305. t. 63. f. 1. *Ricinus asperior, alceæ venetæ foliis aliquatenus accedens maderaspatanus*; Pluk. Phyt. t. 220. f. 2.)

β. *Croton urens*; Linn. Sp. Pl. 1428. (*Ricinus urens, cannabinis foliis triphyllis*; Pluk. Phyt. t. 120. f. 6.)

Leaves deeply three-lobed, or ternate, toothed; the middle lobe longest; ribs most bristly beneath. Stem erect.—Native of the coast of Malabar, in grassy places. A perennial herb, whose *foliage* bears a considerable resemblance to the Venice Mallow, *Hibiscus Trionum*. The lobes of the *leaves* are obtuse, jagged and toothed, bristly on both sides, but particularly along the ribs and veins beneath. The *footstalks* and *branches* are also bristly. *Clusters* on long, axillary, very bristly, stalks. *Calyx* of the fruit pinnatifid, thickly covered, as well as the *capsule*, with pale rigid bristles. When the lobes of the *leaves* are quite separate to the very base, the plant becomes *Croton urens* of Linnæus; but this affords no permanent specific distinction. Plukenet's figures of both varieties are infinitely preferable to Burmann's plate.

SECT. 3. *Stem erect, shrubby.*

15. *T. colorata*. Red-leaved Tragia. Lamarck n. 9. ("Gagana, seu Valli-vara; Rheede Hort. Mal. v. 12. 59. t. 36? foliis acutis." *Lam.*)—Leaves lanceolate, obtuse, smooth, with shallow ferratures; somewhat heart-shaped at the base. Stem erect. Male flowers in sessile cylindrical spikes; female separate, solitary; both axillary. *Capsule* prickly.

prickly.—Native of the East Indies. Commerſon gathered it in the Mauritius. The *ſtem* is ſhrubby or perhaps arbo- reous, with angular *branches*, finely downy when young. *Leaves* ſtalked, two or three inches long; their midrib and margin ſtained with a vinous red, as are ſometimes the fine tranſverſe veins. *Stipules* rounded. *Flowers* all axillary; the males in denſe ſpiral ſpikes, ſometimes compound, half the length of the leaves; females ſolitary, ſeſſile, ſeparate from the males, though ſometimes on the ſame branch. *Capsule* beſet with ſtout ſpines.

16. *T. marginata*. Pale-bordered Tragia. Lamarck n. 10.—Leaves ovato-lanceolate, acute, toothed; finely downy on both ſides. Stem erect. Male flowers in axillary cylindrical ſpikes. Capsule hairy.—Gathered by Commerſon in the iſle of Bourbon. The young *branches* are finely downy, as well as the *footſtalks*, *ſpikes*, and *ſoliage*. *Leaves* three or four inches long, ſometimes more, diſtinguiſhed by a pale marginal diſcoloration, more or leſs dilated or limited. Male *ſpikes* ſomewhat ſtalked, two inches in length. The female *flowers* we have not ſeen. The *capsule* is ſaid to be hairy; its *calyx* deciduous.

17. *T. reticulata*. Reticulated Tragia. Lamarck n. 11.—Leaves ovate, obtuſe, ſmooth; reticulated with fine veins beneath. Stem erect. Male flowers in lax, ſlightly downy cluſters.—Gathered in the iſle of Bourbon, by Commerſon, whoſe ſpecimen is before us, agreeing in every point with the deſcription of M. Poiret in Lamarck, except that the *leaves* are not crenate, but quite entire. They are an inch or two long, thin, not coriaceous, obtuſe at the baſe, pale and ſhining at the back. The *branches* are woody, much divided, round, ſmooth, ſcarred with pale warts. Male *cluſters* about the ends of ſmall lateral ſhoots, ſomewhat ſtalked, an inch and half long. *Flowers* on ſhort, diſtant, partial ſtalks, with a little *bractea* at the baſe of each. We know nothing of the female *flowers*, or the *capsules*.

18. *T. virgata*. Wand-like Tragia. Lamarck n. 15. Illuſtr. t. 754. f. 2.—Leaves on ſhort ſtalks, ovato-lanceolate, acute, ferrated, ſmooth. Stem erect. Male ſpikes axillary, as long as the leaves.—The native country of this ſpecies has not been aſcertained. We know it only from the materials above cited. The *leaves* are delineated about an inch long, ſtrongly ferrated. If the plate be exact, the *female flowers* compoſe a long lax terminal ſpike, and the ſegments of their *calyx* are finely pinnatifid. But of this nothing is ſaid in the deſcription. The *male ſpikes* are like thoſe of ſeveral preceding ſpecies in the preſent ſection, axillary, ſolitary, ſlightly ſtalked.

19. *T. filiformis*. Thread-shaped Tragia. Lamarck n. 16.—Leaves ovato-lanceolate, pointed, ſmooth, diſtantly toothed. Stem erect. Spikes thread-shaped. Bractees of the female flowers rounded, very large.—Deſcribed by Poiret from Lamarck's herbarium. We have ſeen no ſpecimen. The *ſtem* is ſhrubby, with ſmooth, cylindrical, ſtriated *branches*. *Leaves* thin, an inch or two long, pale green, blunt with a point, ſmooth on both ſides, on almoſt capillary ſmooth *footſtalks*, half an inch long, accompanied by ſetaceous *bractees*. *Flowers* in very ſlender axillary ſpikes; the males minute, greeniſh, ſeſſile; females in the lower part of the ſame ſpike, accompanied by very large, roundiſh, ſmooth, ſomewhat crenate *bractees*, which give this plant the aſpect of an *Acalypha*. Poiret.

We are poſſeſſed of ſeveral incomplete and undetermined ſpecimens, which by their habit ſhould ſeem probably to belong to this laſt ſection, but there being no poſitive certainty of their genus, we muſt leave them undeſcribed.

TRAGIC DANCE. See EMMELIA.

TRAGI-COMEDY, a kind of dramatic piece, repreſenting ſome action paſſed among eminent perſons, the

event of which is not unhappy or bloody, and in which is ſometimes admitted a mixture of leſs ſerious characters.

The ancients, M. Dacier obſerves, knew nothing of ſuch compoſitions, in which the ſerious and comic are blended; nor does the epithet M. Corneille give them, of heroic comedies, excuſe their irregularity.

Their foundation is certainly bad; for, endeavouring both to make us laugh and cry in their turns, they endeavour at contrary emotions, which the heart can never undergo; every thing that diſpoſes for the one, indiſpoſing for the other.

The tragi-comedy was formerly very common on the Engliſh ſtage; there was ſcarcely ſuch a thing in the ſeventeenth century as a pure tragedy, without a ſpice of comedy or farce to make the people laugh. Now that the ſtage and our taſte are brought nearer to the model of nature and the ancients, the tragi-comedy is diſuſed.

Tragi-comedy is the only caſe wherein comedy is allowed to introduce kings and heroes.

TRAGICUS, in *Anatomy*, a muſcle of the external ear. See EAR.

TRAGILUS, in *Ancient Geography*, a town of Thrace, between the Cheronneſus and Macedonia. Steph. Byz.

TRAGIUM, in *Botany*, a new umbelliferous genus of Sprengel's, ſeparated by him from PIMPINELLA; ſee that article. The name is borrowed from Dioſcorides, whoſe *τραγιον* appears to belong to our *Pimpinella*, and to have been ſo denominated from *τραγος*, a goat; becauſe when the wild goats fed upon it, the arrows with which they were wounded would drop out; as Ælian relates of the Cretan Dittany.—Sprengel Prodr. Umbellif. 26.—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatae*, Linn. Sect 5. *fructu armato*, Sprengel.

The learned author whom we have juſt quoted, in his new mode of arranging the UMBELLIFERÆ, of which, as well as of other attempts of the ſame kind, we propoſe to treat hereafter in its proper place, lays conſiderable ſtreſs on the hairy or briftly clothing of the ſeeds in ſome ſpecies. Such are all ſeparated by him from thoſe with ſmooth ſeeds, and diſpoſed in different genera, compoſing by themſelves a particular ſection characterized "*fructus armati*." Among them is *Tragium*, diſtinguiſhed from *Pimpinella* chiefly by the circumſtance juſt mentioned, and the moſt total abſence of ribs to the ſeeds.

Eff. Ch. Fruit ovate-oblong, downy, with ſcarcely any ribs. Seam flattiſh. Skin rather looſe. No general or partial involucreum.

Obf. The ſeam, *commiſſura*, is the line by which the two ſeeds touch each other.

The ſpecies enumerated by profeſſor Sprengel are

1. *T. Columba*. (*Pimpinella* Tragium of Villars. See our PIMPINELLA, ſp. 4, where notice is taken of the importance of the downineſs of the ſeeds, as a *ſpecific* diſtinction; and where for *Columba* read *Columna*.)

2. *T. peregrinum*. (*P. peregrina*; Linn. Sp. Pl. 378. Marſch. a Bieberſt. Taur.-Caucas. v. 1. 241; ſee ſp. 7.)

3. *T. aromaticum*. (*P. aromatica*; Marſch. a Bieberſt. Taur.-Caucas. v. 1. 241.)—"Hoary with down. Leaves pinnate; leaflets all wedge-shaped, lineated; with deep ferratures at the extremity."—Native of the borders of woods, and banks of torrents, on the eaſt ſide of mount Caucasus, flowering in July. Root biennial. Akin to *Pimpinella Aniſum*, with which it exactly agrees in the taſte and ſmell of its ſeeds. But the preſent plant has all the *leaves* pinnate and glaucous, more ſlightly ſtriated, or ribbed, and the *ſeeds* are downy.

4. *T. villoſum*. (*Pimpinella villoſa* of Schouboe; unknown to us.)

5. *T. Broteri*. (*P. bubonoides*; n. 5.)

The fruit of this last is much more hairy than that of the first species. On a review of the whole genus of *Pimpinella*, there appears to us not the slightest difference in the form of the seeds, nor in the distinctness of the ribs in the several species, except that the latter are concealed by the hairs in *P. bubonoides*, though this is by no means the case in *P. Tragium*, whose ribs are more prominent than in any other under our inspection. There seems to be no reason for changing the specific name *bubonoides*, which is singularly expressive of the habit of the plant.

TRAGIUM Germanicum, a name given by some authors to the *atriplex olida*, or stinking orach.

TRAGOI, in *Geography*, a town of Bulgaria; 24 miles E. of Ternova.

TRAGOLLES, a town of Africa, in the kingdom of Bambouk.

TRAGONERA. See *DRAGONERA*.

TRAGONICE, in *Ancient Geography*, a town of Asia, in the interior of the Perside, according to Ptolemy and Ammianus Marcellinus.

TRAGONISI, or *DRAGONISI*, in *Geography*, an island in the Grecian Archipelago, so called from the number of goats, which are almost its only inhabitants; 2 miles W. of Myconi. N. lat. 37° 27'. E. long. 25° 30'.

TRAGOPOGON, in *Botany*, Goat's-beard, from *τραγος*, a goat, and *παγων*, a beard, a name adopted from Dioscorides, whose *τραγοπωγων* may very well belong to the genus which now bears it. His description answers in every particular to our *T. porrifolius*, except the shortness of the stem. He says it is "an eatable herb, with leaves like Garlic or Saffron, a short stem, a long sweet root, with a large flower-cup on the top of the stalk, and a black, or dark, seed," according to some readings, "from whence," it is observed, "the name is derived." But Saracenus, the best commentator on this ancient author, instead of *καλυξ μεγας*, and *καρπος μελεις*, would read *καλυξ μελεις* and *παππος μεγας*; for he justly remarks that "a black seed could never have given rise to the name of Goat's-beard." With this explanation, the dark calyx, and the large *pappus*, or seed-down, are intelligible enough, as describing the deep purple florets lining the calyx, and the feathery seed-down, of *T. porrifolius*. So Matthioli likewise understands the matter. Dr. Sibthorp indeed did not meet with this plant in Greece, and it finds a place in his *Prodr. Fl. Græc.* merely as having been observed by the abbatte Sestini, near Constantinople; but it might have been cultivated in Greece, as well as elsewhere.—Linn. Gen. 398. Schreb. 525. Willd. Sp. Pl. v. 3. 1492. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 812. Prodr. Fl. Græc. Sibth. v. 2. 120. Ait. Hort. Kew. v. 4. 432. Juss. 170. Lamarck Illustr. t. 646. f. 1. Gært. t. 159, *T. pratensis*.—Class and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ semistipulosa*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* simple, of about eight, (from five to twelve,) lanceolate equal leaves, four of which are interior when closed. *Cor.* compound, imbricated, uniform. Florets numerous, all perfect, of one petal, ligulate, abrupt, with five teeth, the outermost rather the longest. *Stam.* Filaments, in each floret, five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen, in each floret, oblong; style thread-shaped, the length of the stamens; stigmas two, revolute. *Peric.* none, except the converging pointed calyx, the length of the seeds and their down, slightly tumid, finally reflexed. *Seeds* solitary, oblong, tapering at each end, angular, rough, each terminating in a long awl-shaped stalk, bearing the flat, feathery seed-down, consisting of about thirty horizontally spreading rays. *Recept.* naked, flat, rough.

Obf. Vaillant distinguished his *Tragopogon* by having straight seeds, and a calyx longer than the corolla; while his *Tragopogonoides* has incurved seeds, and a calyx shorter than the corolla. Linnæus makes no such distinction. Jussieu, and after him Willdenow, have adopted the latter genus of Vaillant, though by a different character and name, referring thereto such species as have a turbinate simple-leaved calyx, in eight segments only, not eight leaves. Of this we shall treat at the end of the present article, describing first the genuine species of *Tragopogon*, all caulescent, from which are to be removed what constitute the *Troximon* of Gærtner, to be described in its proper place.

Eff. Ch. Receptacle naked. Calyx of several leaves in a simple series. Seed-down stalked, feathery.

1. *T. pratensis*. Common Goat's-beard. Linn. Sp. Pl. 1109. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 434. Fl. Dan. t. 906. Bulliard. t. 209. (*Tragopogon*; Fuchf. Hist. 821. Matth. Valgr. v. 1. 490. *T. luteum*; Ger. Em. 735.)—Calyx nearly as long as the corolla. Leaves keeled, pointed; dilated at the base. Flower-stalk round.—Native of dry grassy pastures, in England, and other parts of Europe, flowering in June. The root is biennial, tapering, milky and sweet. Whole herb perfectly smooth, and destitute of hairiness, branched, erect, eighteen inches or more in height; the stem leafy, often purplish. Leaves alternate, undivided and entire, tapering; flaccid at the point; clasping the stem with their tumid and somewhat undulated base. Stalks terminal, solitary, precisely cylindrical, each bearing one very large bright-yellow flower, opening in a morning, and closing at noon, except in cloudy weather. Anthers brownish. Seeds rough, with a broad feathery crown.—The character of "*foliis integris*" is now needlessly retained by Willdenow, as contrasting only with species that he himself has removed to his genus *ARNOPOGON*, hereafter described.

2. *T. mutabilis*. Changeable Goat's-beard. Jacq. Misc. v. 2. 316. Ic. Rar. t. 157. Willd. n. 2.—Calyx as long as the corolla. Leaves lanceolate, rough-edged; recurved at the point; somewhat ovate at the base.—Supposed to be a native of Siberia, the seeds having been sent to Jacquin by Pallas. We have seen no specimen. The leaves appear to be broader at the base, and less sheathing, than in the foregoing, and their points rather revolute than flaccid. The flowers, which open at sun-rise, and close about ten in the forenoon, for three successive days, are usually whitish; in some individuals rose-coloured, with red streaks; in others yellow, with purple ones; but these varieties are not constant from seed.

3. *T. undulatus*. Wave-leaved Goat's-beard. Jacq. Misc. v. 2. 317. Ic. Rar. t. 158. Willd. n. 3. Ait. n. 2. Marsch. von Bieberst. Taur.-Caucas. v. 2. 232.—Calyx as long as the corolla. Leaves nearly linear; those of the stem very much waved, revolute at the point.—Found in the meadows of Tauria, along with *T. pratensis*, of which some think it a variety; but the flowers are much smaller and paler, and the strongly undulated leaves are remarkable.

4. *T. orientalis*. Oriental Goat's-beard. Linn. Sp. Pl. 1109. Willd. n. 4. Ait. n. 3. (*Barbula hirci*; Camer. Epit. 312.)—Calyx shorter than the corolla. Leaves tapering, somewhat wavy, with spiral points.—Found by Tournefort in the Levant, and by Camerarius, as it seems, in Germany. M. Thouin sent seeds to Kew garden in 1787. It is a hardy biennial, flowering, like all the foregoing, in June and July, nor does the plant seem to differ much from the first, or most common, kind, except in the greater size of its golden flowers, whose marginal florets extend far beyond the calyx.

5. *T. canus*. Hoary-stalked Goat's-beard. Willd. n. 5. Waldf.

TRAGOPOGON.

Waldst. et Kitaib. Hung. t. . . .—“Calyx nearly equal to the corolla. Flower-stalks woolly. Leaves linear, straight.”—Found in meadows in Hungary. Biennial. Stem much branched and divaricated. Leaves ribbed, not undulated. Calyx, flower-stalks, and younger branches, clothed with white woolly down. Corolla pale yellow. Willdenow.

6. *T. major*. Great Goat's-beard. Jacq. Austr. v. 1. 19. t. 29. Willd. n. 6. Ait. n. 4. Marfch. von Bieberst. Taur.-Caucas. v. 2. 233.—Calyx longer than the corolla. Leaves tapering, straight. Flower-stalks swelling upward. Florets rounded at the tip.—Native of meadows, vineyards, &c. in Germany and Austria, as well as near Branson, in Switzerland, where it was found flowering in August, by the late Mr. Davall, who sent its seeds to Kew in 1788, and whose own specimen is now before us. The gradual dilatation of the flower-stalks upward, the great size of the flowers, at least of their calyx, which extends much beyond the corolla, and consists of a greater number of leaves than the generic character requires, even as many as twelve or thirteen; these circumstances led Jacquin to consider the present plant as a distinct species from *T. pratensis*, or at least as a remarkable variety. We believe it remains constant from seed. Some of the preceding are but too nearly akin, or this ought to stand next to the *pratensis*.

7. *T. porrifolius*. Purple Goat's-beard, or Salsafie. Linn. Sp. Pl. 1110. Willd. n. 7. Fl. Brit. n. 2. Engl. Bot. t. 638. Jacq. Ic. Rar. t. 159. Fl. Dan. t. 797. (T. purpureum; Ger. Em. 735. T. alterum; Matth. Valgr. v. 1. 491.)—Calyx almost twice as long as the corolla. Florets tapering, abrupt. Leaves straight. Flower-stalks swelling upwards.—Native of meadows in Switzerland, Germany, England, and about Constantinople, flowering in May and June. Cultivated in the kitchen gardens of the more opulent, the roots being esteemed a delicacy, and known by the name of Salsafie. They resemble *Scorzonera hispanica*, and have a sweetish delicate flavour, when dressed with cream, but are esteemed chiefly for the sake of variety. This plant having been perhaps more cultivated when esculent vegetables were fewer in England, has become naturalized in various situations, chiefly of a low or moist description. We have alluded to it above as the *τραγοπογών* of the Greeks. The herb is biennial, erect, glaucous, smooth, four or five feet high. Leaves slightly, or not at all, wavy. Flowers of a violet-purple, with black anthers; they close before noon. Linnæus, in his Dissertation on the Sexes of Plants, English ed. 54, relates that he obtained a mule plant, by sprinkling the stigmas of *T. pratensis* with the pollen of the present species. The progeny of the seeds had purple flowers, yellow at the base, evidently of an intermediate nature between the two parents; nor can any thing, as Linnæus observes, more decidedly evince the generation of plants.

8. *T. angustifolius*. Narrow-leaved Goat's-beard. “Belardi MSS.” Willd. n. 8.—“Calyx of eight leaves, longer than the corolla. Leaves straight, smooth.”—Found near Nice. Biennial. Like *T. crocifolius*, but the calyx consists of eight leaves, and the foliage is entirely smooth at the base. The stem is but four inches high. Willdenow. We are not sure whether one of our specimens from Dauphiny be referrible to this species. It is hardly three inches high; the foliage quite smooth and naked throughout; but the calyx has only six leaves. Another from the same country seems intermediate between it and *crocifolius*. The species of few genera are less satisfactorily defined than those of *Tragopogon*.

9. *T. crocifolius*. Crocus-leaved Goat's-beard. Linn.

Sp. Pl. 1110. Willd. n. 9. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 779, unpublished. (*T. crocifolium montanum*, flore nigro-purpureo; Column. Ecphr. v. 1. t. 230.)—Calyx longer than the corolla. Leaves tapering; loosely woolly at the base on the upper side.—Native of Italy, the south of France, and the isle of Cyprus. Miller is said to have cultivated this species, but we do not remember to have met with it in gardens. The root is tapering and biennial, like all the rest of this section. The stem is scarcely above a foot high, branched, nearly or quite smooth, clothed with numerous, narrow, spreading, drooping, white-ribbed leaves, very remarkable for a quantity of loose, shaggy, cottony wool, about their base on the upper side, which is sometimes found also on the branches and flower-stalks. Flowers of a violet-purple, with yellow stigmas and blackish anthers; their florets more spreading than in *T. porrifolius*, and their calyx greatly deflexed, twice as long as the corolla, consisting of from five to eight acute leaves. Columna represents five broad ones only; Dr. Sibthorp found eight, which are narrower. The humble stature of the plant, and its woolly leaves, afford its most striking distinctions. The seeds are beautifully adorned with ascending scales, which prevent their escaping, when once lodged in the earth, the agitation of their feathery wings, by the wind, serving only to force them further down, till each wing shrivels at its base, and easily breaks off. The same economy is apparent in other species of this and similar genera, but peculiarly admirable in that before us. It is analogous to what has been observed in the first species of *STIPA*; see that article.

10. *T. villosus*. Hairy-Goat's-beard. Linn. Sp. Pl. 1110. Willd. n. 10. Ait. n. 433.—Calyx longer than the corolla. Stem much branched, corymbose, clothed, like the bases of the ovato-lanceolate leaves, with shaggy wool.—Native of Spain and Siberia; introduced at Kew, in 1794, by Mr. Hunnemann. Root biennial. Herb as tall as *T. porrifolius*, but the stem is very much more branched, and more slender, clothed with loose, scattered, cottony wool, as well as with numerous, short, ovato-lanceolate, pointed leaves, those about the corymbose upper part of the stem measuring from one and a half to two inches in length. Flowers a little drooping, pale yellow, rather smaller than those of *porrifolius*, on cylindrical striated stalks. Calyx of about nine leaves, nearly half as long again as the corolla. Anthers brownish. Rays of the seed-down rough, very woolly, with long, naked, taper points. This, at least, is an unquestionably distinct species.

For *Tragopogon virginicum*, Linn. Sp. Pl. 1111. (*Hysferis prenanthoides* of Willd. Sp. Pl. v. 3. 1615.), as well as the two stemless species of Linnæus and Willdenow, see *Troximon*.

Other Linnæan species are separated, as we have already said, into a no less distinct and natural genus, for which we here retain Willdenow's name.

ARNOPOGON. This word is composed of *αρν*, *agnos*, a lamb, and *πογών*, a beard, alluding to the peculiarly white, soft, and dense woolliness which crowns the seeds.—Willd. Sp. Pl. v. 3. 1496. Ait. Hort. Kew. v. 4. 433. Sm. Prodr. Fl. Græc. Sibth. v. 2. 121. (*Urosperrum*; Juss. 170. *Tragopogon pteroides* et *Dalechampii*; Gærtn. t. 159. *Tragopogon*; Lamarek Illustr. t. 646. f. 2. 3.)—Class and order, *Syngenesia Polygamia-aequalis*. Nat. Ord. *Compositæ semisfosculese*, Linn. *Cichoraceæ*, Juss.

Gen. Ch. *Cymose* Calyx simple, of one leaf, ovate, tumid at the base, deeply divided into eight equal, lanceolate segments. Cor. compound, imbricated, uniform. Florets numerous, all perfect, of one petal, ligulate, abrupt, with five teeth; their tubes about the length of the calyx. Stem Filaments,

TRAGOPOGON.

Filaments, in each floret, five, capillary, short; anthers united into a cylindrical tube, projecting out of the tube of the floret. *Pist.* Germen in each floret obovate; style tumid and oblique at the base, with a kind of joint, then thread-shaped, straight, the length of the stamens; stigmas two, revolute. *Peric.* none, except the permanent closed turbinate calyx, shorter than the seed-down, finally reflexed. *Seeds* solitary, obovate, oblique, angular, rough, each crowned, at an obtuse angle, with a stalk, various in length, tumid and inflated at the base, bearing the spreading feathery seed-down. *Recept.* naked, flat, roughish.

Eff. Ch. Receptacle naked. Calyx turbinate, of one leaf, in eight deep segments. Seed-down feathery, on an oblique inflated stalk.

1. *A. Dalechampii.* Great-flowered Sheep's-beard. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 780, unpublished. (*Tragopogon Dalechampii*; Linn. Sp. Pl. 1110. *Hieracium magnum*; Dalech. Hist. 569, bad. *H. purpureum, incisifoliis, montanum*; Barrel. Ic. t. 209.)—Calyx finely downy, without bristles. Leaves runcinate, toothed.—Native of Spain, the south of France, Italy, and the Levant. We have seen it, adorning sunny hills about Genoa, in the early part of a summer's day, when its copious large flowers, of a delicate sulphur-colour, purple underneath, make a fine appearance, intermixed with the blue *Catananche*, and other handsome plants, while the great *Myrmeleon libelluloides* is seen softly fluttering over their blossoms. Miller appears to have cultivated this plant, which is a tolerably hardy perennial in warm dry situations, flowering from June to October, but not often seen in gardens. The stem is from two inches to a foot high, purplish at the base, leafy, roughish, as well as the alternate, clasping, runcinate leaves, of which the upper ones are oblong, and nearly entire. Flowers two inches wide, solitary, on very long, simple, terminal, round, rough, furrowed stalks. Calyx even, covered with peculiarly soft short down. *Flowers* hairy at the back. Stalk of the seed-down tapering, hollow throughout, nearly vertical, about thrice the length of the seed.

2. *A. picroides.* Prickly-cupped Sheep's-beard. Willd. n. 2. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 781, unpublished. (*Tragopogon picroides*; Linn. Sp. Pl. 1111. *Sonchus asper laciniatus creticus*; Bauh. Prodr. 60.)—Calyx hispid, with prominent bristles. Leaves toothed; the upper ones jagged; dilated at the base, clasping the stem.—Native of the south of France, and the shores of Italy, Sicily, Crete, &c. Dr. Sibthorp found it frequent in Greece and the Archipelago, especially among rubbish near the sea. He suspected it might be the Greater Hawkweed, *Ἰσρακίον το μέγα*, of Dioscorides. Curious cultivators have often raised the plant in England, where it proves a hardy annual, but is too like a common Sow-thistle to be much cherished. The herb varies in luxuriance and roughness, but is not at all hoary. Lower leaves obovate, tapering much at the base, where they clasp the stem; upper greatly dilated in the same part, and furnished throughout with many sharp segments and teeth; their mid-rib prickly beneath. Flowers several, bright yellow, not half the size of the former, on long, terminal, solitary, bristly stalks. Calyx tumid, clothed with tawny, rigid, projecting bristles. Seeds dark-brown, depressed, scaly, as is the tumid base of the otherwise slender, longish, and white stalk which sustains the snow-white feathery down.

3. *A. asper.* Rough Sheep's-beard. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 782, unpublished. (*Tragopogon asperum*; Linn. Sp. Pl. 1111. *Sonchus asper, subrotundo folio*; Bauh. Prodr. 60, no figure.)—Calyx

hispid, with prominent bristles. Leaves undivided, toothed; those of the stem oblong, contracted towards the rounded clasping base.—Found on the shores of Montpellier, Italy, and Asia Minor. Sent to Kew by M. Richard in 1774. Annual, with the habit and flowers of the last, but the leaves are very different, at least those of the stem, which, instead of being dilated and deeply jagged, are merely oblong and toothed. The stalk of the seed-down moreover seems much shorter, though equally tumid at the base.

4. *A. capensis.* Cape Sheep's-beard. Willd. n. 4. (*Tragopogon capensis*; Jacq. Coll. v. 2. 320. Ic. Rar. t. 577.)—Calyx hispid, with prominent bristles, and deeply channelled. Leaves runcinate, toothed; the upper ones arrow-shaped at the base, nearly entire. The seeds were received by Jacquin from the Cape of Good Hope, and produced biennial plants, three or four feet high, branched, having much of the appearance of a Sow-thistle, like our second species. But the leaves are much less dilated at the base, and the calyx is more deeply channelled, having eight tumid ribs, or angles. The slender and elongated stalk of the seed-down is very like that species, of which it is possible the present may be but a variety. We know it only from Jacquin's works.

TRAGOPOGON, in Gardening, contains plants of the hardy, herbaceous, biennial, and perennial kinds, among which the species mostly cultivated are, the purple goat's-beard, or falfafie (*T. porrifolius*); the common yellow goat's-beard (*T. pratensis*); the crocus-leaved goat's-beard (*T. crocifolius*); and the great-flowered goat's-beard (*T. Dalechampii*).

The first sort is cultivated in gardens under the name of falfafie principally for the use of the root parts of the plant and the young shoots. The roots, when boiled or stewed, have a mild sweetish flavour. The stalks are also cut in the spring, when they are four or five inches high, and dressed like asparagus, in which way they eat very tender and well.

Method of Culture.—The first sort is only raised from seed, which should be sown in the spring, in an open situation to remain, either broad-cast and raked in, or in shallow drills eight or nine inches asunder, scattering the seeds thinly, and covering them half an inch deep; and when the plants are come up two or three inches in height, they should be thinned and weeded by hand or the hoe, leaving them eight or ten inches asunder, repeating the weeding as required during the summer, which is all the culture they require, and they will have large roots by the autumn, as September or October, when they may be begun taking up for use; and in November, when the leaves begin to decay, a quantity be preserved in sand for use in time of severe frost, when those in the ground cannot be got up.

In the spring, when those remaining in the ground begin to shoot, the shoots, when a few inches high, may be cut for use, which, when quite young and tender, on being boiled, are excellent eating. A few plants should be suffered to run up to stalk every spring, to produce seeds.

The shoots are brought to market in bunches during the autumnal and winter seasons.

The two following sorts may also be raised from seed in the same way, and the plants, when a little advanced in growth, be planted out if they are required for variety in any particular part.

The third sort may also be propagated by parting the roots in autumn and spring, and planting them where they are to remain.

The first is cultivated wholly as a culinary plant, but the others afford variety in the borders of pleasure-grounds, &c.

TRAGORCHIS, in *Botany*, from *τραγος*, a goat, and **ORCHIS**, see that article, has been used by several old authors to designate certain species of that beautiful and curious tribe, whose flowers were thought to have a goat-like scent. Two in particular have thus been called; the *Satyrion hircinum* of Linnæus, now *Orchis hircina*, and his *Orchis coriophora*.

TRAGORIGANUM, from *τραγος*, a goat, and *οριγανος*, *marjoram*, a name applied by the older botanists to several plants, mostly belonging to our present genus **ORIGANUM**, which may be found in its proper place, or to some aromatic plants allied thereto. The original meaning of the word was founded in the idea of Marjoram being agreeable to goats, and especially of the Cretan Marjoram, or Dittany, being a sovereign remedy for such as were wounded by arrows. *Tragoriganum nothum*, Bastard Goat-marjoram, Dalechamp Hist. 889, has indeed no connexion or affinity with other plants that bear this name, being the *Lithospermum fruticosum*, whose leaves only possess a slight resemblance to the ringent plants, without any of their flavour or qualities.

TRAGOSELINUM, from *τραγος*, a goat, and *σελινον*, *parsley*, a name first used by Tabernæmontanus for the *Pimpinella saxifraga* of Linnæus, which some have called **TRAGIUM**; see that article and **TRAGUS**.

TRAGULA, among the Romans, a strong kind of javelin, with a barbed head.

TRAGUM, in *Ichthyology*, the name given by Aristotle, and others of the old Greek writers, to the *trugum* of Ælian, Athenæus, and Oppian. Both names are used to express the fish called by authors the *psalinacha marina*, and by us the *fire-flaw*, or *fire-flaire*.

TRAGURIUM, in *Ancient Geography*, a town of Dalmatia, famous for its marble. Ptolemy.

TRAGUS, a river of the Peloponnesus, in Arcadia. Pausanias.

TRAGUS, in *Anatomy*, an eminence of the external ear. See **EAR**.

TRAGUS, in *Botany*, a name which has been variously applied. One *Τραγος* of Dioscorides, book 2. chap. 115, appears to be a kind of meal or flour. Hence perhaps Haller was led to use this name for a genus of grasses, now denominated **LAPPAGO**; see that article. Such an application is like the old derivation of *lucus*, "a non lucendo;" few of the tribe being likely to yield less meal. Another *τραγος* of the above Greek author, book 4. chap. 51, is described by him as "a maritime shrub, of humble growth, without leaves, whose branches are beset with a kind of reddish berries, the size of grains of wheat, pointed, and very atringent." Whether this may be the *Ephedra*, or any thing else, it is difficult to determine. Valerius Cordus thought it *Sedum album*, which is a common Greek plant. We might rather indicate *S. anglicum*, were that found in Greece, the leaves, in both cases, being taken for berries. Camerarius gives *Salsola Kali* for the plant of Dioscorides, annexing an abstract of his description of its form and qualities, the former of which, at least, does not agree with this *Salsola*; any more than with *S. Tragus*, so called by Linnæus, apparently because the name was at hand when he was intent on distinguishing it from *S. Kali*; see *Amoen. Acad.* v. 4. 310. We collect these particulars to shew the difficulty of the enquiry, as well as its utility. Dioscorides is amusing enough, as a botanical riddle-book, because, while some of his descriptions are elaborate and precise, others are just sufficiently vague to afford room for conjecture. Theophrastus, though far more philosophical, is in but a few instances clearly intelligible. The greater number of his plants are merely

named, as being supposed well-known to his readers, and therefore he scarcely affords matter to found any conjectures upon.

TRAHINA, in *Geography*, a town of Sicily, in the valley of Demona; 28 miles N.W. of Catania. N. lat. 37° 40'. E. long. 14° 40'.

TRAHONA, a town of Italy, in the Valteline, on a small river which runs into the Adda, 2 miles N. of Morbegno.

TRAJAN, M. **ULPIUS TRAJANUS**, in *Biography*, a Roman emperor, the son of a distinguished commander under Vespasian in the Jewish wars, was born at Italica in the Spanish province of Bœtica, entered betimes into the army, and accompanied his father in several military expeditions; acquiring the hardiness, submitting to the discipline, and uniformly practising the duties of a soldier. In the career of public honour, he was first made prætor A.D. 86, consul A.D. 91, and raised by Nerva to the rank of Cæsar A.D. 97, being at this time in the 42d or 45th year of his age, according to the statements of different writers, and possessing a majestic stature, manly features, and dignified aspect. Upon the death of Nerva in the following year, Trajan succeeded, without opposition, to the imperial throne. He was at this time at Cologne, and remained for some time in Germany. In 99 he set out for Rome, and entered the city on foot, preceded by the lictors as an ordinary magistrate, and followed by a few soldiers exhibiting the demeanour of citizens. Affable in his manners, bountiful in his largesse to the Roman people, and anxious to procure a supply of corn by allowing free importation from the colonies, Trajan acquired and maintained a very great degree of popularity. He likewise very much contributed to the tranquillity and good order of the city, by removing to exile the infamous tribe of delators, who had been encouraged by the tyranny of Domitian, and not sufficiently repressed by the lenity of Nerva, and by issuing an edict with some penalties against all false accusers. He also reduced the tax of the twentieth upon collateral successions, imposed by Augustus, and formed a fund for the exercise of liberality by his own economy and frugality. He encouraged merit, and advanced to posts of trust men distinguished by their integrity and talents. He associated on the most condescending terms with persons of various rank and condition, and treated the citizens of Rome in general more as friends than as subjects. Although his military education and employments allowed him no leisure for acquiring the accomplishments of literature, he was the patron of learned men, and by founding libraries and other methods, he promoted the diffusion of learning. As he was moderate and frugal in his own habits, and in the entertainments he provided for his guests, he checked and restrained the prevalence of luxury and extravagant expenditure in others. By pursuing various methods for rendering the people happy, he obtained, by the unanimous voice of the senate, the title of "Optimus," which glorious distinction he retained through life and transmitted to posterity. In the third year of his reign he was honoured with a third consulate; and during his exercise of this office, Pliny pronounced that panegyric which is still extant, and which presents to view a finished portrait of a perfect prince. In the following year, when he was again consul, he was engaged in a war with Decebalus, king of the Dacians, from which he returned victorious, and obtained a triumph with the surname of "Dacicus." Having spent the two following years in an attention to objects that contributed to the improvement of the empire, one of which was the establishment of a port at Centumcella, now Civita-Vecchia, the close of the latter of these years was rendered

dered important and interesting, by the appointment of Pliny, A.D. 103, as governor of Pontus and Bithynia, and by the correspondence to which this appointment gave occasion, and which pours in the most pleasing characters the enlightened and benignant spirit by which he was actuated. (See CHRISTIAN RELIGION and PLINY.) In the following year the war with Decebalus was renewed, and on this occasion Trajan constructed a bridge over the Danube, which was long admired as one of the most considerable relics of antiquity. When Decebalus had dispatched himself after the loss of his capital, Dacia was constituted a Roman province, and colonized from other parts of the empire. (See DACIA.) Upon his return to Rome, he employed himself in carrying on some works of public magnificence and utility: but success in his military expeditions unfortunately cherished the innate propensity of war, which seems to have been his most censurable foible; and accordingly the subsequent period of his reign was too ardently devoted to the gratification of his ambition, in extending the boundaries of the Roman empire. In the year 107, he reduced Armenia into a Roman province; the whole of Mesopotamia was also subdued; Arabia Petraea was likewise made a Roman province; and all the barbarous tribes situated north of Armenia, between the Euxine and Caspian seas, were reduced to submission. After the lapse of some years, of which no regular account remains, we find Trajan, A.D. 114, dedicating the magnificent forum, which he had constructed at Rome, and erecting the column on which his exploits are sculptured (see COLUMN and FORUM); and also renewing the war with the Parthians. In 115 he crossed the Tigris on a bridge of boats, and subdued Adiabene and the whole of Assyria; and having captured Ctesiphon and Susa, he descended the Tigris with his fleet, and had the honour of being the first and last Roman general who navigated the Indian ocean, ravaging the coast of Arabia Felix. He even indulged the ambition of visiting India. On his return he laid siege to Atræ, the capital of an Arabian tribe, which he was obliged to raise and to withdraw to Syria. In the year 117 he was attacked with a paralytic disorder, attended with dropsy, and he therefore hastened his return to Italy. At Selinus in Cilicia he had another attack, which proved fatal. In his last moments, the empress Plotina secured the adoption of Adrian for his successor. Trajan died in the sixty-fourth year of his age, after a reign of nineteen years and a half, and his remains were deposited under his own column. This emperor's virtues were shaded by weaknesses and vices. His passion for war has been already mentioned; he was also addicted to sensual indulgences, of which intemperance in drinking was the least scandalous. Notwithstanding the blemishes of his character, his memory was long held in veneration, inasmuch that 250 years after his death, the senators, in their acclamations on the choice of a new emperor, vociferated the wish that he might be "more fortunate than Augustus, and better than Trajan." Anc. Un. Hist. Crevier's Rom. Emp.

TRAJAN Column, a famous historical column, erected in Rome, in honour of the emperor Trajan. See COLUMN, *Colossal*.

TRAJAN, in *Geography*, a town of European Turkey, in Moldavia, on the Pruth; 16 miles N. of Galatz.

TRAJANA, or **TREA**, in *Ancient Geography*, a town of Italy, in the interior of Picenum. Ptol. and Itin. Anton.

TRAJANOPOLI, in *Geography*, a town of European Turkey, in the province of Romania, on the Mariza. This is an ancient town, and took its name from the emperor Trajan, who repaired and adorned it: it afterwards became very considerable, and now, though much reduced from its

ancient splendour, is still the see of a Greek archbishop; 40 miles S. of Adrianople.

TRAJANOPOLIS, in *Ancient Geography*, a town in the interior of Thrace, upon the banks of the river Hebrus. In the Itin. Anton. this town is placed between Bricizes and Cypsela.—Also, a town of Mysia, near the sea, between Antandrus and Adramyttium.—Also, a town of Asia, in Cilicia Trachea, where the emperor Trajan died: the same with Selinunte.

TRAJANOPOLIS, or *Tranopolis*, a town of Asia, in Phrygia Pacatiana.

TRAJANUS PORTUS, a port of Italy, on the coast of Etruria, at the mouth of the Tiber; constructed by the emperor Claudius, and repaired by Trajan, who rendered it more secure and commodious, and gave it his name.

TRAJECTORY of a comet, is its path or orbit, or the line it describes in its motion.

This, Hevelius, in his *Cometographia*, will have to be very nearly a right line; but Dr. Halley concludes it to be a very eccentric ellipse.

Sir Isaac Newton, in prop. xli. of his third book, shews how to determine the trajectory of a comet from three observations; and, in his last proposition, how to correct a trajectory graphically described. See COMET.

This term is often used, in general, for the path of any body moving either in a void, or in a medium that resists its motion; or even for any curve passing through a given number of points. Thus Newton, Princip. lib. i. prop. 22. proposes to describe a trajectory that shall pass through five given points.

TRAJECTUM, in *Ancient Geography, a town of the Batavi upon the Rhine. Trajectum is thought to be one of the fifty mansions erected by Drusus in this country, to ascertain the course of its rivers. This place sustained a variety of vicissitudes, till at length it was established by the Romans. It had the name of Trajectum Ulpium, in honour of Ulpian Trajan. In its environs are found many ancient remains. See UTRECHT.*

TRAJECTUS, a place in the isle of Albion, upon the route from Calvea to Isca, between Abone and Aquæ Solis. Anton. Itin. Antiquaries are generally of opinion, that Trajectus should have been placed before Abone, and that it was situated at Oldbury, where, as they suppose, was a ferry over the Severn; but Mr. Horsley imagines that Trajectus was situated at the passage over the Avon, near Henham, 9 miles from Bath.

TRAJETTO, in *Geography*, a town of Naples, in Lavora, near the mouth of the Garigliano, the see of a bishop, built on the ruins of the ancient Minturnæ; 6 miles S.W. of Sezza.

TRAIGUERA, a town of Spain, in Valencia; 12 miles N.W. of Peniscola.

TRAIL-BOARDS, in *Ship-Building*, a term for the carved work between the cheeks of the head, at the heel of the figure.

TRAILING ARBUTUS, in *Gardening*, the common name of a curious ornamental plant. See EPIGÆA.

TRAIN, the attendance of a great person, or the trail of a gown, or robe of state.

In *Falconry*, it denotes the tail of a hawk.

TRAIN is likewise used for the number of beats which a watch makes in an hour, or any other certain time. See WATCH-work, &c.

TRAIN is also used for a line of gunpowder laid to give fire to a quantity thereof, in order to do execution, by blowing up earth, works, buildings, &c.

TRAIN or **TRAIL** of *Artillery*. See ARTILLERY.

TRAIN-

TRAIN-Bands, or **TRAINED-Bands**, a name given to the militia of England, particularly to those of the city of London.

TRAIN-Oil, the oil procured from the blubber of whales, by boiling. See **WHALE** and **Whale-FISHERY**.

TRAIN-Roads, a slight kind of rail-ways for small waggons, used in mines.

TRAIN-Scent, in the *Manege*, a method of trying the speed and goodness of the horses destined to the sport of hunting, so denominated because the scent which the hounds hunted, proceeded from some animal which had previously been trained along the fields and over hedges and ditches, according to the pleasure of the person who trained or dragged it after him. The rival horses were to follow the hounds which hunted this scent, and give proofs of their speed and merit, in competition with one another. Of all chases this was reckoned the swiftest and most trying, because the scent lies the hottest; so that the hounds run all the time at the utmost stretch, and the horses must have been exerted to their utmost powers to keep pace with them. Besides, in this manner of hunting, the sport was always ready when a fox or hare might not easily be found; and this mode of matching and running hunters, in order to try their speed against one another, while they followed the dogs, was thought to be more cheering both to the riders and horses, than to make them run simply against one another, or against *time*, as the present practice is. When neither the hunting of the hare, nor the running of train-scents, could not decide which horse is the best, recourse was had to another kind of chase, called by horsemen the *wild-goose* chase or chase. See **CHASE**.

TRAIN, in *Geography*, a river of France, which runs into the Dyle, about 9 miles S. of Lovain.—Also, a town of Bavaria, on the Ambs; 5 miles S. of Abensperg.

TRAINA, a town of Sicily, in the valley of Demona, on a river of the same name; 56 miles S.E. of Cefalu.

TRAINED TREES, in *Gardening*, such young fruit-trees as are designed for walls and espaliers, being trained in the nursery to the intended form, by planting them against any kind of walls, pales, reed-hedges, or other close fences; when a year old from the grafting or budding, training them in the manner of wall or espalier trees, for two, three, or more years, till they obtain a good spread of branches, and are arrived to a fruitful state, in order that those who are in haste to have their walls or espaliers covered at once with bearing trees, may have it accomplished in one season. The trees thus trained in the nursery, &c. on being planted out in autumn or spring to the places intended, cover the wall or espalier in some manner at once, and often bear fruit the ensuing summer, when the season proves favourable for the purpose.

In the public nurseries, large quantities of these sorts of trees are always kept ready trained for sale, particularly peaches, nectarines, and apricots for walls; in many places also, cherries and plums, &c. likewise apples, pears, and other fruit-trees, for espaliers; and are proper to furnish the walls and espaliers of new gardens, and occasionally those of old ones, to bear fruit till younger trees, planted untrained, become fruitful, or for supplying the places of old trees that fail, or bear bad fruit. In all cases of this sort, this mode of planting may often be adopted with great propriety and benefit, and besides much time and trouble be saved by it, in waiting for the trees to become in a bearing state, as well as the expence which is constantly incurred in carrying on the operations and processes of preparing young fruit-trees. The difference in the prices of trained trees over those of untrained ones is a mere trifle, and of no consideration in such

undertakings. Therefore, in all nurseries some of the best sorts of these trained fruit-trees, both for walls and espaliers, may be kept ready for these purposes with great utility and advantage.

When, of course, it is intended to raise trained fruit-trees for walls and espaliers, a quantity of the best young plants of the respective sorts, dwarfs and half-standards, of one year old, with the first shoots from the budding and grafting entire, should be planted out in autumn against some kind of fence in a free open situation, not less than four or five feet high, placing them from five or six to eight or ten feet distant, to remain for training. These in the spring following, just as they begin to make an effort for shooting, should be headed down, with a clean sloping cut upward, to within four, five, or six eyes or buds of their origin, or place of insertion in the stock, especially those intended for dwarfs, and the half-standards, if worked on tall stocks; which prevents their running up too high with a single naked stem, and causes them to throw out lateral shoots from the lower part to fill the wall or espalier regularly with branches quite from the bottom upward; as they soon after push forth strong shoots from all the remaining lower buds, sufficient to give the tree its first proper formation as a wall-tree, &c.; which shoots, when advanced in length in summer, should be trained along to the fence equally to the right and left, in a somewhat slanting or inclined position at full length till next spring, when these shoots may also be cut down to the length of six or eight inches, to force out a further supply of more branches near the bottom, as it is proper that they should be well furnished with branches below, in order to cover the wall, &c. at the bottom part, that none of it may be lost or left in an uncovered state.

The summer's shoots should be shortened in this manner; more or less the two or three first springs, as may be necessary, in order to obtain a proper spread of lower branches to give the tree its intended form; though this work of cutting in short to obtain laterals, may also be performed occasionally in summer, in May or early in June, on the strong young shoots of the year, cutting or pinching them down to a few eyes; but the first is the best mode. This last mode, by forcing out lateral shoots the same year, often saves time.

As the supply of branches thus obtained arrive at proper lengths, in the summer they should be all trained in along close to the wall, and if any fore-right or back shoots come out, they should be rubbed off close, leaving all the well-placed side and terminal shoots in every part, and letting the whole, or as many as possible, be trained in during this season, to have a plenty to choose from in the general pruning seasons of winter and spring, laying them in close to the wall, &c. equally to the right and left, on each side of the tree, in a spreading somewhat horizontal or fan-like manner, no where crossing one another but at parallel distances, and mostly all at full length during the summer's growth, to remain till the general winter or spring pruning.

In the winter pruning, where more wood was trained up in summer than appears necessary, or that can be trained in with due regularity, it should be retrenched, as well as any remaining fore-right or back shoots and other irregular growths omitted in the summer, be now all pruned out, cutting them quite close to their origin. The whole should then be close-nailed to the wall, in somewhat the fan manner, removing in the first place all the irregular side and other shoots of the different branches before they are laid in and nailed. See **PRUNING**.

Having thus procured proper heads, they should afterwards be pruned or cut in according to the method peculiar

to each respective sort, as directed under the culture, some requiring the branches to be shortened annually, others to be mostly trained at full length. See DWARF and ESPALIER TREES, PRUNING, &c.

The training of espalier trees is effected exactly in the same manner, only these may be trained as they stand in the nursery lines, in the open quarters or borders, &c. by ranging some stout stakes in the ground along one side of each tree, not in a continued straight range immediately the way of the row, but those of each tree ranged separate and obliquely, somewhat crossways the row as it were, that the branches of the different trees may range beside one another, and thereby have more room to extend the branches both ways, than the common distance in the nursery lines would admit, if ranged directly the way of the row.

It may be noticed, that occasionally it may happen that some particular trained trees of both the wall and espalier kinds may assume in the course of their training a state of extremely vigorous and luxuriant shooting and growth either in the whole of them, or in some particular parts, by which very strong rampant, rude shoots that have a peculiar unfruitful-like nature and appearance are sent forth, which in all such cases and circumstances should be ordered and directed in a particular manner, according to their nature and situation, until they have in a great measure exhausted their too great abundance or redundancy of sap which caused their excessive luxuriance, and they begin to take on a more moderate state of shooting and growth. In consequence of which, therefore, wherever there appears to prevail a general luxuriance and excess of growth in the whole trees, or parts of them, while under the course of training, or afterwards, it will be advisable to use proper and necessary caution in the work of pruning, employing the knife in rather a moderate manner in the way of thinning out and shortening the branches, and in some degree humouring, as it were, the trees in their natural tendency of shooting and growth, by leaving the young shoots and branches thicker and closer together than what is the common rule in all such cases, the whole being left at their full lengths particularly during their summer's growth: and to all those which are usually shortened in their winter pruning, as in the peach, nectarine, and other similar sorts of trees, they should be shortened much less in proportion than the other kinds; but those of the apple, pear, plum, cherry, and others of the same sorts, should always be continued at their whole lengths; that, on the whole, by thus dividing the sap-juice among a greater number, as well as larger extent of branches, that luxuriance may be checked which would take place in the case of a smaller number and less extent of growth. As, in general, the more wood can be cut out of a vigorous shooting tree, and the more the shoots are shortened, practices which are erroneously too frequently had recourse to, the more vigorously it will continue to shoot, without ever becoming properly fruitful; and if severe cutting-in be repeatedly practised and continued, the tree will often exhaust itself so greatly by its luxuriant shooting, that it suddenly becomes in a weak, imperfect, and decayed state of growth. But, on the contrary, if the natural inclination of the very vigorous-shooting young trees be somewhat consulted and indulged, in the first instance, by training in as many branches as can be conveniently had for the purpose, and those which require shortening, be cut in moderately only, or some which are very luxuriant hardly at all, and these methods continued to be practised for two or three years with proper discretion, the trees will be gradually reduced to a moderate state of growth, and good condition of bearing, after which they

may be managed and directed in the common way which is proper for each of the different sorts.

And, on the other hand, such trees as are only vigorous in particular shoots, may, in some cases, have such shoots radically retrenched, but in others reserved; and if a very vigorous shoot runs considerably stronger than all the rest, and seems to support its vigour at the expence of the others in its vicinity, it should be retrenched to its very origin as early in the summer as it is perceived: in other cases, if a luxuriant shoot arises in any vacant space, especially towards the bottom part, where a supply of more wood is wanted, it may be retained, and pinched off or topped down to a few eyes in the late spring or beginning summer months, when it will send out several lateral shoots below, the same season, and instead of one rude luxuriant shoot, there will probably be four, five, or more of a moderate growth to fill the vacancy in a more effectual manner, and which will much sooner attain the state of fruitfulness.

The trees having been thus in training in the nurseries for the space of three, four, or five years, they will have obtained a handsome spread of fruitful branches fanned in the regular proper and necessary forms for the different purposes which are intended, so as that when planted out, they may at once cover a large space, and become quickly fruitful and productive. The particular method of culture which is proper for each of the sorts, is more fully given in speaking of them individually under their several heads.

But it may be remarked that, in general, unless good trained trees can be readily obtained, of from three or four to five or six years old, of a clean free growth, it will be better to plant entire young untrained trees of one or two years old, immediately from the nursery, putting them at once where they are to remain, managing them afterwards as the trained trees, to give them the proper form of head.

Some, in order to have as great a chance as possible, plant young untrained trees to remain, and trained trees of a bearing state, dwarfs and half-standards between, to cover the wall more effectually at once, and furnish a supply of fruit, until the young ones are trained and arrive at the bearing state; then, according as the trees of both sorts advance in that state of growth, those which appear the most prosperous are retained, and the others are gradually cut away, leaving the more thriving trees to occupy the wall wholly at last.

In most of the public nurseries, they raise trained trees for sale, which occupy all their close fences of walls, pales, &c. where they may be procured of almost any size, differing in price from three to five or ten shillings or more *per* tree, according to the sorts, age, and goodness of growth.

TRAINEL, in *Geography*, a town of France, in the department of the Aube; 6 miles S. of Nogent sur Seine.

TRAINING, in *Planting and Gardening*, the practice of regulating the forms and growth of forest and fruit trees, by the proper lopping and retrenching of their side or other branches in the first kind, and by the cutting-in and distribution of their shoots and branches in the latter. What is principally necessary in the management of the former of these sorts of trees, in this respect, has been already pointed out under the heads to which it properly belongs. See PRUNING and TIMBER.

And in regard to the latter, or garden kinds of trees, it has been remarked, that when by fixtures it is properly a practice much connected with that of pruning, and which is employed, either for the purposes of protecting exotics of the tender fruit-tree kinds from the wind, for improving their climate by spreading them in a regular manner upon a wall or fence, or for supporting climbing or trailing

trailing plants. In the first case, it is performed in a great variety of modes and manners, according to the nature and kind of support which is made use of for the purpose. In the second intention too, it is done differently, as the circumstances may be, and mostly against walls, as in the fan and horizontal modes; the former of which is said to be calculated for soonest covering the walls, and to be likewise the most proper for such kinds of trees as do not abound in superfluous wood, as the cherry, peach, and apricot. The latter mode, however, is said to fill the walls more completely, though longer in accomplishing the business; and to be the best suited for such trees as run much to wood, as is the case with many apple and pear trees. See these different sorts of trees.

In the work of training for the support of climbing plants, nature should, it is supposed, be imitated as nearly as possible. That with the kinds which twine round other trees or supports, or that fasten themselves to walls, nothing more is thought necessary, than to put them on similar objects which are within their reach; but that with others, which support themselves by clasps or tendrils, it is requisite to fasten them by art when these clasps fail; which, in nature, is commonly the second year; when the whole twining shrub or climber falls down, or hangs by its last-formed tendrils in such a manner, as that its shoots are bent, twisted, or inclined in almost every direction. This is the case with many sorts of tree plants, such as vines, passion-flowers, and others, and strongly suggests the advantage of training such kinds in a twisted or serpentine manner; as nothing can be more unnatural than to train them in an upright mode, as is too commonly done with the first of these sorts, where set against the back walls of hot-houses, &c. In training them along a trellis, under the sloping glass of such houses, they are said to be in a more natural situation, and are more likely to send out shoots, or to *break*, as it is often termed, at every joint; but still experience has, it is thought, proved the vast advantage of training in a serpentine or twining direction in every situation. In a great many houses of the above sort in all parts of the country, nearly two-thirds of the crops which might annually be produced, are, it is supposed, lost for want of attention to this circumstance. And, that as the practice is natural, uniformly successful, so far as it has been yet tried, and without injury, it ought to be more generally had recourse to in the business.

Great uses and benefits are capable of being taken of the same principle in the training of other sorts of trees; as whenever the sap is constrained by twisting a shoot or branch, it is sure at such places as are most bent, or which have most of the angle of the curve, to send out a shoot, as has been well noticed, illustrated, and taken advantage of by both ancient and modern writers on horticulture. See Hitt's and Forfyth's *Treatises on Fruit-Trees*, &c.

In the training of fruit-trees, few who have been engaged in the work have, it is supposed, fully understood or sufficiently availed themselves of the advantages which might be taken of this general law in vegetable economy, that the extreme branches bent downward, or the extreme roots turned upward and exposed to the air, throw the tree more or less into a fruiting state. It has lately, however, been done by turning the branches of such trees over the tops of walls, or in other modes, with astonishing effects in the production of fruit. The great effects of this sort of training are evident too in many other instances, where binds, twists, and downward directions are given to shoots and branches by different circumstances in the objects to which they are trained. The powerful and excellent effects of cutting the

roots of trees either at some distance from or near to the chief stem, as well as those of cutting the stem itself, in order to throw them into a fruiting condition, have, it is said, been fully recorded by former writers on gardening, and been recently practised with complete success. See *ESPALIER Trees*, *PRUNING*, *TRAINED Trees*, and *WALL-Trees*.

TRAINING, or **TRACING**, in *Mineralogy*, a term used by our miners to express the tracing up of the mineral appearances on the surface of the earth to their head or original place, and there finding a mine of the metal they contain: or, training or tracing a lode, denotes the same with backing of it; that is, laying open the bryle, and discovering the back of the lode, by many pits for several fathoms in length, east and west. The bryle of a lode, is that mineralized substance which lies loosely upon the top of it under the loose mould and rubbish of the earth.

The principle on which this practice depends, is the change wrought in the face of the earth by the deluge, of the effects of which these remains are a very great proof. The superficial or upper part of veins, or lodes of ore, is always the poorest, the richer ores lying deeper down, the poor ones only serving to lead the way. These poor ores, or stones impregnated with the metalline matter of the mine, and called by our workmen *shoad-stones*, were, probably, at the creation of the earth, brought regularly up to the surface, and shewed the place of the metals below. But at the time of the covering of the earth by the waters of the deluge, they were, with the rest of the surface, washed off, and carried with the descent of the water down into the plains, or into the beds of rivers, and there carried many miles down the stream. This being an allowed truth, the art of training a mine is easy; for though this carrying of the *shoad-stones* and poor ore was done so many ages ago, yet all the way that some pieces were carried on, others would be deposited by the way, and the heaviest and richest falling first, the lightest would always be carried farthest, and there would be always left a stream of the matter all the way from the place where it was first produced, that is, where the mine now is: for the breaking of the surface of the earth at this great catastrophe was not so deep as to reach that, and this stream or train of matter will be found richer and richer as it approaches the mine, and finally will stop at the place where it is.

Where there is supposed to be a mine of any metal, the hills and country all about are diligently searched; the situations and descent of the lands, and the earth, stones, and other fossile bodies, are examined, particularly the colour and nature of the various sorts of earths and stones which are found on the hills where the mine is suspected to lie, that they may be readily known again if any of them are found in the neighbouring valleys. The stones which denote the lodes, and are called *shoad-stones*, are found two, three, four, or even five miles from the hills where they originally lay; but if the same sort of stones are remembered on the hills, the train is to be made out. After any great land-flood, in which it is supposed there are usually some new frets made in the banks of the rivers, these are carefully examined, to see whether any metalline stones may be found in their sides and bottoms, all being then so clean, that the smallest *shoad-stone* may usually be seen. If no stones of this kind are found, it sometimes is of use, in order to farther researches, to examine whether any pieces of earth, of a different colour and nature from that of the rest of the bank, be found; for these being, if any such are found, washed also from the neighbouring hills, afford a great direction which side of the hill to search into.

If no shoad-stone or grewt of a different nature from the rest be found in these frets or newly worn banks, the miners leave the place for the present. For though the bed of the river afford many metalline stones, they never regard them, the continual change of place they receive from the current of the water rendering them only tokens that there is metal somewhere in the country; but they confound and perplex rather than instruct in the search after the places where it is.

If there be found indeed stones of the shoad-kind, full of protuberances, or having sharp angles, as if newly broken, it may be worth while to see whether they are not washed out of some part of the neighbouring banks by the late floods; as this sort of appearance is a token of their having been newly taken into the bed of the river. But if they are rounded and smooth, it may be concluded they have been long subject to the action of the water, and brought, perhaps, many miles from the places where they were originally lodged in the earth, and where only they could have been of any use to the tracers of the mine.

When the frets in the sides of rivers have been traced in vain, the searcher after a mine goes up to the sides of the hills most suspected to have mines in them, and there seeks for a convenience of bringing a little stream of water to run down. When this is found, he cuts a trench about two feet over, and as deep as the shelf. The water is turned into this cut, and after two or three days running in it, all the filth will be washed away, and the loose part of the earth cleared off; and if any shoad-stones are lodged within the whole course of this cut, they will be found. If any such are found, it is an unquestionable proof that there is ore in the higher parts of the hill; this encourages the work, and there is always found a mine, or at least a squat, which will, without much danger, repay the expence and trouble. The squats are flat parcels of the ore, lying in different and distinct places of the hills, and not communicating with one another.

Sometimes a great deal of this labour is saved, and the shoad-stones are found on the surface of the ground, either turned up by the plough, or thrown up in small quantities in mole-hills, or raised by some other accident, for they are seldom found naturally lying on the very surface of the earth; for the putrid remains of vegetable and animal substances, and other adventitious matter, has raised the surface of the earth in all places, since the time of the flood, and made indeed a sort of new surface. These stones were certainly laid bare on the surface of the ground, at the time of their being carried down from the mines; but this adventitious matter has buried them in this long tract of time, and they are generally found under about a foot of a sort of vegetable mould. If, by any of these searches, a shoad is found, the miners have nothing to do but to follow it to its head, and there make the opening; but if no such direction can be had, nor any shoad found, and there is yet suspicion that there is a mine in the hill, the method is to make an *essay-hatch*, as it is called: this is sunk near the foot or bottom of the hill, and is an opening of about six feet long, and four feet broad, made in search of a vein as deep as the shelf: this is a caution that must be always carefully observed, for if they are made less deep than this, they may miss of the vein, though there is one. And the sinking thus deep is always attended with certainty, for if no shoad is found on this, it may be concluded there is none there; except that sometimes it is found that the shoad has been washed clean away, within two or three feet from the land; and then the lode or vein is two feet farther or thereabouts up in the hill. If any shoad is found in the

essay-hatch, there is a certainty of a vein of ore; neither doth it add a little toward the making of a conjecture how high up the hill, or how far off the vein-fringe, or bonny, is, carefully to mark how deep from the surface of the earth the shoad lies, for this is held an infallible rule, that the nearer the shoad lies to the shelf, or fast ground, the nearer the vein itself is, and *vice versa*.

When there is no shoad or appearance of a mine found in the first *essay-hatch*, if the conjecture of a mine being in the hill has any tolerable foundation, the tracing it does not end here; but they go ten or twelve fathoms up the hill, and there open a second *essay-hatch*, and if no ore or shoad-stone is found in this, they go as many fathoms on each hand at the same height with the second hatch, and there open a third and a fourth hatch, of the same depth and dimensions with the first: if in neither of these there is found any shoad-stone, they ascend proportionably with three more hatches, if the space of ground require, at every ten or twelve fathoms, and in this manner open them three abreast, at twelve fathoms distance up to the top of the hill. If no shoad is found in any of these, it is concluded then that there is no tracing of a mine there, and the hill is left.

If any shoad is found in any of these hatches or openings, the ascending hatches from this are kept on in a direct line, and the deeper the shoad lies the nearer the vein is. The shoad grows gradually deeper from the surface, but nigher the shelf as they approach the mine; as suppose it to be but half a foot from the shelf, and seven feet from the surface, the vein is then concluded to be within a fathom or two; and on this the first proportion of twelve fathoms between every hatch is lessened to six, four, two, one, or even less than that, as the vein is conjectured to be more and more near.

It often happens, for want of a good guess in this matter, that the diggers over-shoot the lode; that is, they open their next hatch too high up the hill, or above the lode or vein: this is a mistake easily discovered, and easily rectified. If a shoad is found lying near the shelf in one hatch, and in the hatch above there is no shoad at all, it is a proof that the hatch is too high, and the remedy is only to sink a hatch at a middle distance between the last two, which will probably fall upon the very point of the lode, and finish the work of tracing.

Sometimes it happens, that in continuing the tracing of the first shoad, a second or new one is found: it is not uncommon for two shoads to be thus found in one hatch, and this is easily discovered without any danger of mistake; for suppose in the last hatch the shoad which they trace lay at eight feet deep, and in this it lies at ten feet, and besides this there is a shoad found at two feet depth: it is very certain that the shoad at ten feet deep is the same they were before tracing, and this is a new one pointing to another vein or lode, which is now first discovered so near the surface of the earth. This has generally gravel or earth mixed with it, and is to be carefully examined: when the higher hatches are opened, this is continually found as well as the old lode; and when the first is traced to the point of the vein, this second is to be continued in the same manner, by other hatches opened at the same distances above: it often happens, that in tracing this second shoad, the hatches dug for it discover another new one, or a third shoad; all these are to be traced one over the other by the same hatches, and will all be found worth the seeking after.

The old writers on mineralogy agree with us in this observation, and tell us, it is not uncommon in some places to find as far as seven lodes lying parallel to one another in the same hill. In these cases, however, there is usually one master-lode, or a grand vein; the other six, that is, three or each

each side, being the lesser or concomitant veins. Five in the same manner sometimes lie in this order, the grand lode in the middle and two on each side; but the more common method is three, a large one, and two smaller.

Every lode has a peculiar coloured earth or grewt about it, which is found also with the shoad, and this always in a greater quantity the nearer the shoad lies to the lode, and becomes lessened by degrees to the distance of about a quarter of a mile, farther than which that peculiar grewt is never found in any quantity with the shoad; so that this is a proof that the lode or vein is near, when it is found in any quantity.

A valley may chance to lie at the foot of three several hills, in such a manner as to contain three several grewts, or that earth which was moved with the shoad in the concussion of the strata at the deluge, with as many different shoads or trains of shoad-stones in the midst of each: in this case it will be very necessary to know the cast of the country, and of each hill in respect to its grewt, for the surer training of them one after another as they lie in order: according to the foregoing rules of essay-hatching, the uppermost in this case always directs which hill to begin with first.

It sometimes happens, that after having trained the shoad found in a valley up to the upper parts of a hill, there is only a squat, or bonny, found instead of a right vein of ore; for these detached parcels of ore have their shoads as well as the right veins. These are usually about two or three fathoms long, and a fathom broad, few of them are larger, most less, and they never communicate with any other lode or vein, nor ever fend forth any of their own. The extremities of these beds of ore terminate without sending out any strings, not lying within walls as the lodes; but though they are in the shelf or fast ground, not moved by the flood, their surface is equal every where with that of the imaginary shelly one, and they go down five or six fathoms deep, and there terminate at once. The ore contained in these is rich, and they are always wrought out to the considerable advantage of the owners.

These are the general rules of tracing mines, and though somewhat tedious and expensive, they are certain, and never subject to the error and disappointment the other shorter ways, as they are called, are liable to. These short ways are by the *virgula divinatoria*, or the hazel-wand, whose bending in certain places without any external visible force, is to point out where the place the vein of ore lies: the waters thought to issue from the particular lodes, are also used by some as a short means of finding the veins; other of these ways are also by mineral streams and effluvia, by the barrenness of the soil, and the pitching of nocturnal lights on the supposed orifices of mines. But these methods are too extravagant or too uncertain to be used in cases of so much consequence.

Another way of discovering lodes, is by working drifts across the country, as it is called, that is, from north and south, and *vice versa*.

When the mine is found by the more certain rules of tracing, the digging of it is a matter of less difficulty. Phil. Trans. No. 69. See MINERALOGY, and Pryce's Mineral. Cornub. book iii. cap. 1.

TRAINING of Cattle, in *Agriculture*, the practice of taming and breaking in oxen and other neat cattle for the purpose of team-labour. It is performed in many different ways in different districts and places; but principally by first gradually accustoming them to be led by means of a halter or rope, and then using them to travel in other sorts of teams after the yoke or harness has been put on and rendered familiar to them; when afterwards they may be wrought in the plough-teams with the old labouring oxen, being placed between

them both before and behind, and with such as are not too free workers. See TEAM, YOKE, and YOKING.

TRAISENDORF, in *Geography*, a town of Germany, in the principality of Culmbach; 5 miles N.E. of Bayreuth.

TRAIT, Fr. *Traïus*, is the name of an ancient musical character, called likewise in old Latin treatises, *plica*; which see.

TRAIT, or *Tedia*, in *Geography*, a town of Romania, on the Mariza; 12 miles S.W. of Filippopoli.

TRAITOR. See TRAYTOR.

TRAITOR'S Cove, in *Geography*, a harbour on the west coast of the island of Revilla Gigedo, in the North Pacific ocean; so called by captain Vancouver, from the circumstance of being attacked, and two of his men wounded, by the natives of this place. N. lat. $55^{\circ} 40'$. E. long. $228^{\circ} 31'$.

TRAITOR'S Head, the north-east point of Erromango, one of the New Hebrides, so called by captain Cook in 1774, from the treacherous conduct of its inhabitants. S. lat. $18^{\circ} 43'$. E. long. $169^{\circ} 28'$.

TRAITOR'S Islands, a cluster of small islands, in a bay of the Pacific ocean, on the coast of New Guinea. S. lat. $1^{\circ} 12'$. E. long. 137° .

TRAITOR'S Island, an island in the Pacific ocean, discovered by Le Maire and Schouten in 1616, and so called from an attempt made by the natives to seize the vessel. M. Perouse discovered this island to be divided into two parts, by a channel about 150 toises wide. It belongs to the Friendly islands, and is called by the natives Neoota-bootaboo; 16 miles from mount Cocos. N. lat. $15^{\circ} 55'$. W. long. $173^{\circ} 48'$.

TRAITOR'S Island. See KEPPEL'S Island.

TRAITTE. See FOREIGN *Traite*.

TRALEE, in *Geography*, a post-town in the county of Kerry, Ireland, pleasantly situated at the bottom of Tralee bay, on the banks of the river Lee. It is the shire and assizes town of the county; was incorporated in 1612 by James I.; and sends one member to the imperial parliament. There were formerly four strong castles erected in this town, of which only one remains, which was the chief residence of the Desmond family, in which they exercised their jurisdiction during the continuance of the Palatinate. Tralee bay is shallow and unsafe, and therefore not much frequented. Near the town is a chalybeate spring, which is drunk medicinally with success. Tralee is $14\frac{1}{2}$ miles S.W. by W. from Dublin, and 48 S.W. from Limerick.

TRALLEBORG, a sea-port town of Sweden, in the province of Skone, near the Baltic; 19 miles S. of Lund. N. lat. $55^{\circ} 20'$. E. long. $12^{\circ} 54'$.

TRALLES, BALTHASAR-LEWIS, in *Biography*, an eminent physician, was born at Bressau in 1708, and having studied medicine at Hall under Frederic Hoffman, settled in his native city, where he gained great reputation. His works were numerous and valuable, and caused him to be admitted into the Imperial Academy at Vienna, and the Royal Society of Berlin. But his most celebrated work was that on opium, entitled "Ufus Opii salubris et noxius in Morborum Medela, solidis et certis principijs superstructus," 1757-1762, 2 vols. 4to. He also published a treatise against the materialism of La Mettrie. He declined, in 1767, accepting the offer of first physician at Warsaw to Stanislaus, king of Poland, partly on account of his advanced age, and principally from his attachment to the reformed religion. Haller. Eloy.

TRALLIA, called also *Troalida*, in *Ancient Geography*, a country of Illyria.

TRALLIANA, in *Botany*, was so named by Loureiro, from whom alone we have any knowledge of this genus, in memory of Alexander Trallianus, a celebrated physician and naturalist, whose works are said by De Theis to have been published at Paris in 1548, and republished by Haller in 1748. He wrote a letter on intestinal worms, which is mentioned in Dryander's *Bibl. Banks.* v. 2. 356; but we find no traces of his botanical information. Loureir. *Cochinch.* 157.—Class and order, *Pentandria Monogynia.* Nat. Ord. *Menispermata*. Juss.?

Gen. Ch. *Cal.* Perianth inferior, of five short, rounded, permanent leaves. *Cor.* Petals five, oblong, spreading, reflexed, longer than the calyx. Nectary large, erect, with ten notches. *Stam.* Filaments five, short, inserted into the receptacle; anthers roundish, of two cells. *Pist.* Germen superior, roundish; style the length of the stamens; stigma (simple?) *Peric.* Berry roundish, of two cells, with two seeds, which are angular on the inside, rounded externally.

Eff. Ch. Petals five, oblong, reflexed. Nectary with ten notches. Calyx inferior, of five leaves. Berry of two cells, with two seeds.

1. *T. scandens.* Cây rác of the Cochinchinese.—Found running up all kinds of trees in Cochinchina. *Stems* numerous, shrubby, long, climbing, without thorns or prickles; their branches copious, jointed. *Leaves* alternate, roundish-heart-shaped, pointed, crenate, smooth. *Clusters* lateral, forked, each on a long common stalk. *Flowers* of a whitish green.

TRALLIANUS, in *Biography*. See **ALEXANDER TRALLIAN.**

TRALLICON, in *Ancient Geography*, a town of Asia Minor, in the vicinity of Caria, watered by the river Harpafus.

TRALLIS, or **TRALLES**, a town of Asia Minor, in the interior of Lydia, which, according to Strabo, was rich and populous, and strongly fortified by nature. According to Plutarch, here was a temple of Victory. The town had been denominated Antheia, Euanthia, Seleucia, and Antiochia.

TRA-LOS-MONTES, in *Geography*. See **TRAS-OS-MONTES.**

TRAM, in the *Silk Trade*. See **SILK.**

TRAM-Road, the same with **RAIL-Road**; which see.

TRAMACASTREL, in *Geography*, a town of Spain, in Aragon; 12 miles S.S.E. of Albarazin.

TRAMANDI, a town of Brasil, on a river of the same name, which runs into the Atlantic, S. lat. 27° 15'.

TRAMARICIUM, in *Ancient Geography*, a place of Africa Propria, upon the route from Carthage to Alexandria, between Scina and Aubureum. Ant. Itin.

TRAMAYE, in *Geography*, a town of France, in the department of the Saone and Loire; 9 miles W. of Mâcon.

TRAMAZA, a town of Sardinia; 8 miles from Oristagni.

TRAMBLING of *Tin-Ore*, among *Miners*, is the washing of it very clean: which is done with a shovel, and in a frame of boards. See **TIN.**

TRAMIN, in *Geography*, a town of the county of Tyrol, on a small river which runs into the Adige, 8 miles S.S.W. of Bolzano.

TRAMIS, a word used by some medical writers, to express the line running along the middle of the scrotum from the penis to the anus.

TRAMMEL, an instrument or device, sometimes of leather, more usually of rope, fitted to a horse's legs, to regulate his motion, and form him to an amble.

It is also taken in many places for an iron moveable instrument in chimneys, to hang pots over the fire.

TRAMMEL-Net, or **TRAMEL**, is a long net with which to take fowl by night in champaign countries, much like the net used for the low-bell both in shape, size, and meshes.

The word comes from the French *tremail*, formed of the Latin *tremaculum* or *tremaculum*; of *tres* and *macula*, because it is composed of three rows of meshes.

To use it, they spread it on the ground, so as the nether or farther end, fitted with small plumbets, may lie loose thereon: then the other part being borne up by men placed at the fore-ends, it is thus trailed along the ground. At each side are carried great blazing lights, by which the birds are raised; and as they rise under the net, they are taken. See **LARK.**

TRAMMELLED, in the *Manege*. A horse is said to be trammelled, that has blazes or white marks upon the fore and hind-foot of one side; as the far foot before and behind. He is so called, from the resemblance the white foot bears to a half-trammel.

TRAMMELLED-Horse, *Crofs*, is one that has white marks in two of his feet that stand cross-ways, like St. Andrew's cross; as in the far fore-foot and the near hind-foot, or in the near-foot before and the far-foot behind.

TRAMMELS, in *Mechanics*, an instrument so called by the joiners, and used by them for drawing ovals upon boards. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins which slide in those grooves, and also the describing pencil. All the engines for turning ovals are constructed upon the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it: in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a Demonstration of the principal properties of these instruments, by Mr. Ludlam, in *Phil. Transf.* vol. lxx. part ii. p. 378, &c.

TRAMONNEL, in *Geography*, a town of France, in the department of Mont Blanc; 14 miles W. of Chambéry.

TRAMONTANE, or **TRAMONTAIN**, formed from the Italian *tra*, of the Latin *trans*, which signify *beyond*; and *mons* or *mont*, *mountain*; something beyond, or on the farther side, the mountains.

The term is particularly applied, by the Italian painters, to all such as live on the other side the Alps, *i. e.* all out of Italy; as the Germans, Flemish, French, &c.

The French lawyers give the same title of *tramontane*, or *ultramontane* doctors, to the Italian canonists, Gomez, Hostiensis, Panorm, &c. who go upon rules and maxims too favourable to the court of Rome, and contrary to those of France, &c. On the Mediterranean, and in Italy, a north wind is called *tramontane*, a *tramontane wind*.

Some also call the pole-star, *tramontana*. Hence the proverb, *to lose the tramontane*, that is, to be out of one's aim, to be disconcerted.

TRAMORE, in *Geography*, a small post-town of the county of Waterford, on a bay of the same name, where there is a very fine strand, from which it takes its appellation. It has a handsome market-house and assembly-room, and is much frequented for sea-bathing. It is 82 miles S.S.W. from Dublin, and about 6 S. from Waterford.

TRAMUTUL, a town of Naples, in Basilicata; 13 miles S.S.E. of Potenza.

TRANADUCTA, in *Ancient Geography*, a town of Hispania, in Bœtica, in the country of the Betuli, between Menralia and Barbefola. Ptolemy.

TRANCAULT, in *Geography*, a town of France, in the department of the Aube; 9 miles S. of Nogent sur Seine.

TRANCHE',

TRANCHE!, or **TRENCHÉ**, is used by the French armorists, to express that manner of partition called among us, *party per bend dexter*.

A scutcheon is said to be *tranché* cut, when it is divided in two diagonally, the division coming from the dexter angle of the chief to the sinister angle of the point. When it is divided contrariwise, it is said to be *taillé*, or *party per bend sinister*.

TRANCHEFILE, in the *Manege*, the cross chain of a bridle, that runs along the bit-mouth, from one branch to the other.

TRANCOSO, in *Geography*, a town of Portugal, in the province of Tra-los-Montes. In the beginning of the 12th century, Alboazan, a Moorish king of Badajoz, laid siege to this town, and persevered with great obstinacy, till the inhabitants were driven to the last extremity, but were relieved by king Alphonso Henriquez, who defeated the Moors with great slaughter; 9 miles W. of Pinhel.

TRANE, a town of Sweden, in the province of Skone; 9 miles W. of Christianstadt.

TRANEKIAR, an ancient fortress of Denmark, in the island of Langeland.

TRANEMO, a town of Sweden, in West Gothland; 46 miles E.S.E. of Gotheborg.

TRANENT, a market-town in the presbytery and shire of Haddington, Scotland, is situated on the eastern side of a narrow valley, 10 miles E. from Edinburgh, and 380 miles N. by W. from London. It was anciently called Tree-ar-Nent and Travernent, signifying the habitation in the vale. The church is an ancient incommodious fabric, of a very peculiar form. On the outside, it appears to consist of three separate oblong houses; but when entered, is found to be only one building. A square tower rises from the centre, supported by the side-walls of the middle building, and by cross arches. Two weekly markets are well supplied with butcher's meat. The parish of Tranent extends about six miles in length, and three miles in breadth, and is divided by the great east road into two nearly equal parts. It comprises the villages of Cockenzie, Port Seaton, Seaton, St. Clement's Wells, and Wester Falside. The surface is level and well cultivated. The coast abounds with oyster-beds, but they are nearly exhausted by over-dredging. Coal is abundant, and is worked at three collieries to a great extent. At Cockenzie is a great manufactory of common salt; and at St. Clement's Wells is the most considerable distillery in Scotland. According to the population return of the year 1811, the inhabitants of this parish were 3036, occupying 640 houses. Here is a parochial school, with a salary to the master of 300 merks and perquisites: here are also seven other schools. After the reformation, the parish of Seaton was annexed to that of Tranent; but it was reduced in 1606, by making the baronies of Preston-Grange and Preston-Pans a new parish, under the name of Preston. In 1695, the parish of Tranent was further diminished, by the north-east corner of it being annexed to the new parish of Glades-Muir. In 1493, a collegiate church was founded in the village of Seaton, by George, lord Seaton, which is still nearly entire. The most ancient edifice in the parish is that of St. Germans, now the seat of David Anderson, esq. where an hospital was founded previous to the year 1296. It was afterwards possessed by the Knights Templars; and after its suppression, was granted in 1494, with most of its revenues, by king James IV., to the King's College of Aberdeen. The battle of Preston, in 1745, was fought partly in this parish.—*Beauties of Scotland*, vol. i. 1805. *Chalmers's Caledonia*, vol. ii. 1810. *Carlisle's Topographical Dictionary of Scotland*, 1812.

VOL. XXXVI.

TRANFRANT, a town of Algiers, near the coast; 30 miles S.W. of Oran.

TRANG, a river of Lower Siam, which runs into the Indian sea, N. lat. 7°. E. long. 99° 33'.

TRANGANO, a town of Asia, in the kingdom of Johore, near the sea, on the side of a river, which has a shallow bar and several rocks scattered about. There are about 1000 houses; 110 miles N. of Pahang. N. lat. 5° 30'. E. long. 103° 5'.

TRANGARDE, a town of Hindoostan, in the county of Calicut; 8 miles N.E. of Paniany.

TRANGLE, in *Heraldry*, the diminutive of a fesse, commonly called a *bar*.

TRANI, in *Geography*, a city of Naples, and capital of the province of Bari; the see of an archbishop, and residence of the governor; 21 miles W. of Bari. N. lat. 41° 19'. E. long. 16° 28'.

TRANKEY, a name given in the island of Carrick, near the Persian shore, to a vessel about the size of a Peter-boat, sharp at both ends. It is built of very rough pieces of wood, rudely put together, and covered over with a thick coat of bitumen, with which the country abounds. These vessels sail with great speed with either end foremost, having no distinction of head from stern. The island of Carrick is about twelve miles long and seven broad, and contains between 600 and 700 inhabitants. It abounds with goats, but has very few cows, and no beasts of prey; nor are there any fowls, tame or wild, except stork and turtle-doves. It produces few vegetables, but has wheat, rice, and barley, though not in sufficient quantity for the inhabitants, whose food is fish, with which they are plentifully supplied from the vicinity of the island. Here is also very fine turtle, but not eaten by the natives.

TRANQUEBAR, in *Geography, a sea-port town of Hindoostan, in the country of Tanjore, situated on the coast of Coromandel, with a harbour, at the mouth of one of the branches of the Cauvery, defended by a fortress, erected by the Danes in the year 1621, who had obtained a grant of the town, and a fertile territory, from the rajah of Tanjore, for an annual rent of about 720*l*. In the beginning of the present century, the prince of Tanjore attempted to seize on Tranquebar, and began a regular siege; but by the assistance of the English, he was compelled to give over the attempt, and make peace. The town is between two and three miles in circumference, and surrounded with a wall and several bastions, well provided with artillery: within the walls are three Christian churches, one of which is for Roman Catholics, descendants of Portuguese in possession of the town before the Danes; a large mosque for the Mahometans, and several pagodas for the Gentoos. The territory belonging to the town is considerable, and is full of populous villages; 56 miles S. of Pondicherry. N. lat. 11° 1'. E. long. 79° 54'.*

TRANQUILLITY, a town of New Jersey; 8 miles S. of Newtown.

TRANQUILLO, a cape at the south end of the island of Rhodes. N. lat. 36° 2'. E. long. 27° 28'.

TRANS, a town of France, in the department of the Ille and Vilaine; 6 miles S.E. of Dole.

TRANSACCO, a town of Naples, in Abruzzo Ultra; 8 miles S. of Celano.

TRANSACTION, **TRANSACTIO**, in the *Civil Law*, an accommodation of some business or dispute between two parties, by a mutual and voluntary agreement or contract between them.

TRANSACTIONS, *Philosophical*, are a kind of journal of the

the principal things that come before the Royal Society of London. The Transactions contain the several discoveries and histories of nature and art, made by the members of the Society, or communicated by them from their correspondents, with the several experiments, observations, &c. made by them, or transmitted to them, &c.

They were first set on foot in 1665, by Mr. Oldenburg, secretary of the Society, and were continued by him till the year 1677. Upon his death, they were discontinued till January 1678, when Dr. Grew resumed the publication of them, and continued it for the months of December 1678, and January and February 1679, after which they were intermitted till January 1683. During this last interval, they were supplied in some measure by Dr. Hooke's Philosophical Collections. They were also interrupted for three years, from December 1687 to January 1691, beside other smaller interruptions amounting to near one year and a half more, before October 1695, since which time the Transactions have been regularly carried on.

They were for many years published in numbers, and the printing of them was always, from time to time, the single acts of the respective secretaries, till the year 1752, when the Society thought fit that a committee should be appointed to reconsider the papers read before them, and to select out of them such as they should judge most proper for publication in the future Transactions. The members of the council constitute a standing committee for this purpose. They meet on the first Thursday of every month, and no less than seven members of the committee (of which number the president, or, in his absence, a vice-president, is always to be one) are allowed to be a *quorum*, capable of acting in relation to such papers. The question, with regard to the publication of any paper, is always decided by the majority of votes taken by ballot.

They are published annually in two parts, at the expence of the Society, and each fellow is entitled to receive one copy *gratis*, of every volume published after his admission into the Society.

The Philosophical Transactions, to the end of the year 1700, were abridged in three volumes, by Mr. John Lowthorp; those from the year 1700 to 1720 were abridged in two volumes, by Mr. Henry Jones; those from 1719 to 1733 were abridged in two volumes, by Mr. John Eames and Mr. John Martyn. Mr. Martyn continued the abridgment of those from 1732 to 1744, in two volumes; and those from 1743 to 1750, in two volumes.

TRANSCELLENSIS MONS, in *Ancient Geography*, a mountain of Africa, near the municipium; called by Ammianus Marcellinus, Sugabarritanum. This town was situated in Mauritania Cæsariensis, south of the town of Zucchabbari, and near the river Chinalaph.

TRANSCENDENT, or TRANSCENDENTAL, something raised or elevated beyond other things; or which passes or transcends the nature and circumstances of other inferior beings, so as not to be intimately and essentially included under them.

The term is particularly applied to the object of metaphysics, which considers beings in general, or transcendental beings, as God and angels, and truths consisting in pure speculation.

Logicians and metaphysicians give the name of transcendental terms to those which are so general, and of a signification so extensive and universal, that they pass through all the categories, and agree to all kinds of things. Such are the terms *ens, unum, verum, bonum, res*. See *ENS*, &c.

TRANSCENDENTAL Art. See *ART*.

TRANSCENDENTAL Perfection. See *PERFECTION*.

TRANSCENDENTAL Quantities, among *Schoolmen*. See *QUANTITY*.

TRANSCENDENTAL Quantities, among *Geometricians*, are indeterminate ones; or such as cannot be expressed or fixed to any constant equation. Such is a transcendental curve, or the like.

M. Leibnitz has a dissertation in the *Acta Erud. Lipf.* in which he endeavours to shew the origin of such quantities; *viz.* why some problems are neither plain, solid, nor sur-solid, nor of any certain degree, but do transcend all algebraical equations.

He also shews how it may be demonstrated without calculus, that an algebraic quadratrix for the circle or hyperbola is impossible: for if such a quadratrix could be found, it would follow, that, by means of it, any angle, ratio, or logarithm, might be divided in a given proportion of one right line to another, and this by one universal construction; and consequently the problem of the section of an angle, or the invention of any number of mean proportionals, would be of a certain finite degree.

Whereas the different degrees of algebraical equations, and therefore the problem, understood in general of any number of parts of an angle, or mean proportionals, is of an indefinite degree, and transcends all algebraical equations.

TRANSCENDENTAL Curve, in the *Higher Geometry*, is such a one as cannot be defined by any algebraical equation; or of which, when it is expressed by an equation, one of the terms is a variable quantity. See *CURVE*.

These curves are the same with what Descartes, and, after his example, several others, call *mechanical curves*, and which they would have excluded out of geometry; but sir Isaac Newton and M. Leibnitz are of another sentiment. For, in effect, in the construction of geometrical problems, one curve is not to be preferred to another, as it is defined by a more simple equation, but as it is more easily described than that other. See *GEOMETRICAL Line*.

And some of these transcendental or mechanical curves are found of greater use than all the algebraical ones together, except the circle.

Add, that M. Leibnitz, in the *Acta Eruditor. Lipf.* gives us a kind of transcendental equations, by which these transcendental curves are actually defined, and which are of an indefinite degree; that is, are not always the same in all the points of the curve.

Whereas algebraists use to assume some general letters or numbers of the quantities sought, in these transcendental problems; M. Leibnitz assumes general or indefinite equations for the lines sought; *e. gr.* putting *x* and *y* for the absciss and ordinate, the equation he uses for a line sought is $a + bx + cy + exy + fxx + gyy$, &c. = 0. By the help of which indefinite equation, which in reality is finite, for it may always be determined how far soever it is necessary to raise it, he seeks the tangent; and comparing that which results, with the given property of tangents, he finds the value of the assumed letters *a, b, c*, and thus defines the equations of the line sought.

If the comparison above mentioned do not proceed, he pronounces the line sought not to be an algebraical, but a transcendental one.

This supposed, he goes on to find the species of transcendency; for some transcendentials depend on the general division or section of a ratio, or upon the logarithms, others upon the arcs of a circle, and others on more indefinite and compound inquiries.

Here, therefore, besides the symbols *x* and *y*, he assumes a third, as *v*, which denotes the transcendental quantity; and

and of these three forms a general equation of the line sought, from which he finds the tangent according to the differential method, which succeeds even in transcendental quantities. What he finds he compares with the given properties of the tangent, and so discovers not only the value of a , b , c , &c. but also the particular nature of the transcendental quantity.

And though it may sometimes happen that the several transcendentals are so to be made use of, and these of different natures, too, one from another; also, though there be algebraically impossible, or transcendentals, and a progression of these *in infinitum*; yet we may be satisfied with the most easy and useful one, and for the most part may have recourse to some peculiar artifices for shortening the calculus, and reducing the problem to as simple terms as may be.

This method being applied to the business of quadratures, or to the invention of quadratrices, in which the property of the tangent is always given, it is manifest not only how it may be discovered, whether the indefinite quadrature may be algebraically impossible, but also how, when this impossibility is discovered, a transcendental quadratrix may be found; which is a thing which had not before been shewn. So that it seems that geometry is by this method carried infinitely beyond the bounds to which Vieta and Descartes brought it; since, by this means, a certain and general analysis is established, which extends to all the problems which are of no certain degree, and consequently not comprehended within algebraical equations.

Again, in order to manage transcendental problems (wherever the business of tangents or quadratures occurs) by a calculus, there is hardly any that can be imagined shorter, more advantageous or universal, than the differential calculus, or analysis of indivisibles and infinities.

By this method we may explain the nature of transcendental lines by an equation; *e. g.* Let a be the arc of a circle, and x the versed sine; then will $a = \frac{fdx}{\sqrt{2x - xx}}$:

and if the ordinate of the cycloid be y , then will $y = \sqrt{2x - xx} + \frac{fdx}{\sqrt{2x - xx}}$, which equation perfectly expresses the relation between the ordinate y and the absciss x ; and from it all the properties of the cycloid may be demonstrated.

Thus is the analytical calculus extended to those lines which have hitherto been excluded, for no other cause but that they were thought incapable of it.

TRANSCOLATION, in *Pharmacy*, the same with filtration, or percolation.

TRANSCRIPT, a copy of any original writing, particularly that of an act, or instrument, inserted in the body of another.

In this sense we say, *transcript of a fine, &c.* See FINE and DUPLICATE.

TRANSCRIPTO recognitionis factæ coram justitiariis itinerantibus, &c. in *Law*, is a writ for certifying a recognition into chancery, taken before the justice in eyre.

TRANSCRIPTO pedis finis levati mittendo in cancellarium, is a writ for certifying the foot of a fine levied before justices in eyre, &c. into chancery.

TRANSEAT, in the *Schools*, &c. a term purely Latin, signifying, *let it pass*, or suppose a proposition to be true, without granting it.

Hence the proverb, *transeat, Græcum est, non legitur*: the phrase is said to have taken its rise from some ancient commentators, or glossographers of the civil law, who, not

understanding Greek, passed over all the words that occurred in that language, without explaining them.

In the Roman chancery, a *nil transeat* is a kind of opposition made to the sealing of a bull, or to the delivery of some other instrument, till the parties, against whose interest it is directed, have been heard against it.

TRANSELEMENTATION, a change of the elements or principles of one body into those of another.

Such is that which Roman Catholics contend for in the eucharist, where the elements of bread and wine, they say, are changed into those of flesh and blood. See TRANSUBSTANTIATION.

Transelementation, wherever it happens, is always allowed miraculous, or an effect beyond the ordinary powers of nature.

TRANSEPT, the cross aisle, extending from north to south across the nave and main aisles of our ancient churches. In some churches, as in the cathedral of Salisbury, there is a double transept, which makes it resemble an archiepiscopal cross in its ichnography.

TRANSFER, in *Commerce*, &c. an act by which a person surrenders his right, interest, or property, in any thing moveable or immoveable, to another.

The sale or donation of an inheritance, &c. transfers the property, rights, &c. of it.

The term is principally used, in the commerce of stocks, for the assigning and making over of subscriptions or shares therein to such as purchase them of the proprietors. In the South Sea Company, the Bank, East India, &c. transfers are made by entering the stock under the name of the purchaser under his proper letter of the alphabet.

A counterfeit, in this case, is by act of parliament made a capital crime.

TRANSFIGURATION, among *Divines*, that miraculous change wrought by Jesus Christ, in presence of St. Peter, St. James, and St. John, on mount Thabor, where he appeared in his glory, in company with Moses and Elias. See the description of it in St. Matthew, chap. xvii.

The term is also applied to a feast held in the Romish church on the 6th of August, in commemoration of that miracle.

TRANSFORMATION, a metamorphosis, or change of form.

The chemists have been a long time seeking the transformation of metals, that is, their transmutation, or the manner of changing them into gold.

Among the mystics, by transformation is understood a change of the contemplative soul, by which it is in some measure deified, or converted into the substance of God, and in which it is, as it were, lost and swallowed up in the divinity, so as not to perceive its own distinction from God.

The word transformation is very liable to be abused: but many of the mystics use it innocently enough; meaning no other by it than what St. Paul did, *Vivo ego, jam non ego, vivit vero in me Christus*.

TRANSFORMATION is also sometimes used for what we more properly call *transubstantiation*.

TRANSFORMATION of Equations, in *Algebra*, is a method of changing equations into others of a different form, but of equal value. This operation is necessary in order to prepare equations for a more easy solution. We shall subjoin some examples of the most common and useful kind under this head. The affirmative roots of an equation are changed into negative roots of the same value, and *vice versa*, by only changing the signs of the terms alternately, beginning with the second.

Thus, the roots of the equation $x^4 - x^2 - 19x^2 + 49x - 30 = 0$, are $+1, +2, +3, -5$; whereas the roots of the same equation having only the signs of the second and fourth terms changed, viz $x^4 + x^2 - 19x^2 - 49x - 30 = 0$, are $-1, -2, -3, +5$.

If it be required to transform an equation into another that shall have its roots greater or less than the roots of the proposed equation by some given difference, the method is as follows. Let the proposed equation be the cubic $x^3 - px^2 + qx - r = 0$; and let it be required to transform it into another, whose roots shall be less than the roots of this equation by some given difference (e), i. e. suppose $y = x - e$, and consequently $x = y + e$; then, instead of x and its powers, substitute $y + e$ and its powers, there will arise this new equation.

$$(A) \left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ - py^2 - 2pey - pe^2 \\ + qy + qe \\ - r \end{aligned} \right\} = 0;$$

whose roots are less than the roots of the preceding equation by the difference (e).

To find an equation whose roots shall be greater than those of the proposed equation by the quantity (e), suppose $y = x + e$, and $x = y - e$, and the equation will have this form.

$$(B) \left. \begin{aligned} y^3 - 3ey^2 + 3e^2y - e^3 \\ - py^2 + 2pey - pe^2 \\ + qy - qe \\ - r \end{aligned} \right\} = 0.$$

If the proposed equation be in this form, $x^3 + px^2 + qx + r = 0$, then by supposing $x + e = y$, there will arise an equation agreeing in all respects with the equation (A), but that the second and fourth terms will have contrary signs.

$$(C) \left. \begin{aligned} y^3 - 3ey^2 + 3e^2y - e^3 \\ + py^2 - 2pey + pe^2 \\ + qy - qe \\ + r \end{aligned} \right\} = 0.$$

By supposing $x - e = y$, there will arise an equation agreeing with (B) in all respects, but that the second and fourth terms will have contrary signs to what they have in (B): as

$$(D) \left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ + py^2 + 2pey + pe^2 \\ + qy + qe \\ + r \end{aligned} \right\} = 0.$$

Hence we see how the second or other intermediate term may be taken away out of an equation; for, in the equation

(A), whose second term is $3e - p \times y^2$, if we suppose $e = \frac{1}{3}p$, and consequently $3e - p = 0$, the second term will vanish. In the equation (C), whose second term is $-3e + p \times y^2$, supposing $e = \frac{1}{3}p$, the second term also vanishes. But the equation (A) was deduced from $x^3 - px^2 + qx - r = 0$, by supposing $y = x - e$, and the equation (C) was deduced from $x^3 + px^2 + qx + r = 0$, by supposing $y = x + e$; whence may be deduced the following rule for exterminating the second term out of any cubic equation; viz. add to the unknown quantity of the given equation the third part of the co-efficient of the second term with its proper sign, viz. $\mp \frac{1}{3}p$, and suppose this aggregate equal to a new unknown quantity y . From this value of y find a value of x by transposition, and substitute the value of x and its powers in the given equation

tion, and there will arise a new equation wanting the second term. E. g. Let the equation be $x^3 - 9x^2 + 26x - 34 = 0$; suppose $x - 3 = y$, or $y + 3 = x$, and substituting according to the rule, we shall have,

$$\left. \begin{aligned} y^3 + 9y^2 + 27y + 27 \\ - 9y^2 - 54y - 81 \\ + 26y + 78 \\ - 34 \end{aligned} \right\} = 0$$

wanting the second term.

If the equation proposed be of any number of dimensions (n), and the co-efficient of the second term with its sign prefixed be $-p$, then supposing $x - \frac{p}{n} = y$, and $x = y + \frac{p}{n}$, and substituting this value for x in the given

equation, there will arise a new equation that shall want the second term; whence the second term may be exterminated out of any given equation by the following rule. Divide the co-efficient of the second term of the proposed equation by the number of dimensions of the equation; and assuming a new unknown quantity y , add to it the quotient having its sign changed: then suppose this aggregate equal to x , the unknown quantity in the proposed equation; and for x and its powers, substitute the aggregate and its powers, and the new equation will want its second term.

Let the proposed equation be a quadratic, as $x^2 - px + q = 0$, then suppose $y + \frac{1}{2}p = x$ according to the rule, and substituting this value for x , we shall have,

$$\left. \begin{aligned} y^2 + py + \frac{1}{4}p^2 \\ - py - \frac{1}{2}p^2 \\ + q \end{aligned} \right\} = 0$$

$$y^2 * - \frac{1}{4}p^2 + q = 0$$

Having found the value of y , that of x may be had by means of $y + \frac{1}{2}p = x$: e. gr. since $y^2 + q - \frac{1}{4}p^2 = 0$, $y^2 = \frac{1}{4}p^2 - q$, and $y = \pm \sqrt{\frac{1}{4}p^2 - q}$, and therefore $x = y + \frac{1}{2}p = \frac{1}{2}p \pm \sqrt{\frac{1}{4}p^2 - q}$.

If the proposed equation is a biquadratic, as $x^4 - px^3 + qx^2 - rx + s = 0$, then by supposing $x - \frac{1}{4}p = y$, or $x = y + \frac{1}{4}p$, an equation shall arise having no second term. And if the proposed equation is of five dimensions, we must suppose $x = y \pm \frac{1}{5}p$, &c. It is plain, that in a quadratic equation wanting the second term, there must be one root affirmative and one negative, and these must be equal to one another. In a cubic equation wanting the second term, there must be either two affirmative roots equal, taken together, to a third root that must be positive.

Let an equation $x^3 - px^2 + qx - r = 0$ be proposed, and let it be required to exterminate the third term. By supposing $y = x - e$, the co-efficient of the third term in the equation of y is found (see equation A supra) to be $3e^2 - 2pe + q$. Suppose that co-efficient equal to nothing, and by resolving the quadratic equation $3e^2 - 2pe + q = 0$, you will find the value of e , which substituted for it in the equation $y = x - e$, will shew how to transform the proposed equation into one that shall want the third term.

The quadratic $3e^2 - 2pe + q = 0$, gives $e = \frac{p \pm \sqrt{p^2 - 3q}}{3}$;

so that the proposed cubic will be transformed into an equation

equation wanting the third term, by supposing $y = x - \frac{p - \sqrt{p^2 - 3q}}{3}$, or $y = x - \frac{p + \sqrt{p^2 - 3q}}{3}$.

If the proposed equation is of n dimensions, the value of e , by which the third term may be taken away, is had by resolving the quadratic equation $e^2 + \frac{2p}{n} \times e + \frac{2b}{n \times n - 1} = 0$, supposing $-p$ and $+q$ to be the co-efficients of the second and third terms of the proposed equation. The fourth term of any equation may be taken away by solving a cubic equation, which is the co-efficient of the fourth term in the equation when transformed. The fifth term may be taken away by solving a biquadratic, &c.

There are other transmutations of equations that on some occasions are useful. An equation, as $x^3 - px^2 + qx - r = 0$, may be transformed into another that shall have its roots equal to the roots of this equation multiplied by a given quantity, as f , by supposing $y = fx$, and $x = \frac{y}{f}$; and substituting this value for x in the proposed equation, there will arise $\frac{y^3}{f^3} - \frac{py^2}{f^2} + \frac{qy}{f} - r = 0$, and multiplying all by f^3 , $y^3 - fpy^2 + f^2qy - f^3r = 0$, where the co-efficient of the second term of the proposed equation, multiplied into f , makes the co-efficient of the second term of the transformed equation; and the following co-efficients are produced by the following co-efficients of the proposed equation (as $q, r, \&c.$) multiplied into the powers of f ($f^2, f^3, \&c.$) Therefore, to transform any equation into another whose roots shall be equal to the roots of the proposed equation multiplied by a given quantity f , you need only multiply the terms of the proposed equation, beginning at the second term, by $f, f^2, f^3, \&c.$ and putting y instead of x , there will arise an equation having its roots equal to the roots of the proposed equation multiplied by f as required. Let it be required to transform an equation, the highest term of which has a co-efficient different from unity, into one that shall have the co-efficient of the highest term unit. If the equation proposed is $ax^3 - px^2 + qx - r = 0$, then transform it into one whose roots are equal to the roots of the proposed equation, multiplied by a :

i. e. suppose $y = ax$, or $x = \frac{y}{a}$, and there will arise $\frac{ay^3}{a^3} - \frac{py^2}{a^2} + \frac{qy}{a} - r = 0$; so that $y^3 - py^2 + qay - ra^2 = 0$: whence we deduce the following rule; change the unknown quantity x into another y , prefix no co-efficient to the highest term, pass the second, multiply the following terms, beginning with the third, by $a, a^2, a^3, \&c.$ the powers of the co-efficient of the highest term of the proposed equation, respectively. Thus, the equation $3x^3 - 13x^2 + 14x + 16 = 0$, is transformed into the equation $y^3 - 13y^2 + 14 \times 3 \times y + 16 \times 9 = 0$, or $y^3 - 13y^2 + 42y + 144 = 0$. Then finding the roots of this equation, it will easily be discovered what are the roots of the proposed equation; since $3x = y$, or $x = \frac{1}{3}y$: and therefore, since one of the values of y is -2 , it follows that one of the values of x is $-\frac{2}{3}$. By this rule an equation is easily cleared of fractions.

Suppose the equation proposed is $x^3 - \frac{p}{m}x^2 + \frac{q}{m}x - \frac{r}{e} = 0$. Multiply all the terms by the product of the de-

nominator, you find $mne \times x^3 - nep \times x^2 + meb \times x - mnr = 0$. Then transforming the equation into one that shall have unit for the co-efficient of the highest term, you find $y^3 - nep \times y^2 + m^2enq \times y - m^3n^3e^2r = c$. Or, neglecting the denominator of the last term $\frac{r}{e}$, you need only multiply all the equation by mu , which will give $mn \times x^3 - np \times x^2 + m q x - \frac{mnr}{e} = 0$, and then, $y^3 - np \times y^2 + m^2nq \times y - \frac{m^3n^3r}{e} = 0$. After the values of y are found, it will be easy to discover the values of x ; since, in the first case, $x = \frac{y}{mne}$; in the second, $x = \frac{y}{m n}$.

E. g. The equation $x^3 - 4x - \frac{146}{27} = 0$ is first reduced to this form $3x^3 - 4x - \frac{146}{9} = 0$, and then transformed into $y^3 - 12y - 146 = 0$.

Sometimes, by these transformations, surds are taken away. E. g. The equation $x^3 - p\sqrt{a} \times x^2 + qx - r\sqrt{a} = 0$, by putting $y = \sqrt{a} \times x$, or $x = \frac{y}{\sqrt{a}}$, is transformed into this equation $\frac{y^3}{a\sqrt{a}} - p\sqrt{a} \times \frac{y^2}{a} + q \times \frac{y}{\sqrt{a}} - r\sqrt{a} = 0$; which, by multiplying all the terms by $a\sqrt{a}$, becomes $y^3 - pa y^2 + qay - ra^2 = 0$, an equation free of surds.

An equation, as $x^3 - px^3 + qx - r = 0$, may be transformed into one whose roots shall be the quantities reciprocal of x , by supposing $y = \frac{1}{x}$, and $y = \frac{z}{r}$, or by one supposition $x = \frac{r}{z}$, become $z^3 - qz^2 + prz - r^2 = 0$.

By this transformation, the greatest root in the one is transformed into the least root in the other: for since $x = \frac{1}{y}$, and $y = \frac{1}{x}$, it is plain that when the value of x is greatest, the value of y is least, and conversely. See on this subject Maclaurin's Algeb. part ii. chap. iii. iv. Saunderfon's Algeb. vol. ii. p. 687, &c. See REDUCTION OF EQUATIONS.

TRANSFUGA, in Antiquity, a deserter. Among the Romans, deserters were commonly punished by cutting off their hands, it being thought that living in such a miserable truncated condition would strike more terror than death itself. We find, however, that deserters were likewise crucified, burnt alive, thrown from the Tarpeian rock, or exposed to wild beasts at public shows.

TRANSFUSION, TRANSFUSIO, compounded of the preposition *trans*, beyond, farther, and *fundo*, I pour, the act of pouring a liquor out of one vessel into another.

In the preparations of chemistry and pharmacy there are frequent transfusions of liquors, syrups, &c.

TRANSFUSION of the Blood, in Physiology, the transfer of the blood of one animal into the vascular system of another, by means of a tube connected with a vein of the receiving animal, and an artery of the other. A vein is first opened, to allow the efflux of the animal's own blood, and thus to make room for the fresh supply. This preliminary evacuation produces syncope; the animal ceases to move, and appears dead: but when the end of the tube connected with the artery of the other animal is introduced into the vein, and the stop-cock is turned, the current of arterial blood produces reanimation; the power of motion and the former strength are restored.

The experiments on this subject were first tried in England, where T. Clarke failed in his attempts in the year 1657; Phil. Transf. N^o 35. Lower succeeded in 1665, and communicated his success to the Royal Society; Phil. Transf. N^o 30. This was on dogs: Th. Coxe did it on pigeons; Birch, vol. ii. p. 50. Coxe and King exhibited the experiment on dogs before the Society, transfusing the blood from vein to vein; *ibid.* p. 123; Phil. Transf. N^o 19, 20. 25. 27. It was again performed from a sheep to a dog; Birch, p. 133; and the experiment was afterwards frequently repeated; Birch, vol. ii. pp. 162. 179. 190. 191. It was also performed in France and other countries.

The first proceedings in this matter seem to have been instigated merely by curiosity, or at least by a disposition to inquire into the powers of the animal economy. But higher views soon opened themselves: it was conceived that inveterate diseases, such as epilepsy, gout, and others, supposed to reside in the blood, might be expelled with that fluid, while, with the blood of a sheep or calf, the health and strength of the animal might be transferred to the patient. The most sanguine anticipations were indulged on the occasion, and the new process was almost expected to realize the alchemical reveries of an elixir of life and immortality. The experiment was first tried in France, where the blood of a sheep was transfused into the veins of a stupid youth, with the effect, as was asserted, of sharpening his wits. (Phil. Transf. 27. 32.) And a similar experiment was made without injury in a healthy man. (*Ibid.*) Lower and King transferred blood from a sheep into the system of a literary man, who had offered himself for the experiment, at first without inconvenience, but afterwards with a less favourable result; the Royal Society still recommending perseverance in the trials. Birch, vol. ii. pp. 216. 225. 227. 312. Phil. Transf. N^o 30.

These events were not calculated to keep up the expectations that had been raised, of brilliant results; and other occurrences produced still more severe disappointment. The French youth first mentioned died lethargic soon after the second transfusion: the physicians incurred great disgrace, and were judicially prosecuted by the relations. (Phil. Transf. 28. 32. 36. 37. 54.) Not however discouraged by this unlucky case, they soon after transfused the blood of a calf into a youth related to the royal family, who died soon after with the intestines inflamed. (Phil. Transf. 28. 30.) The parliament of Paris now interfered, and proscribed the practice. (Du Hamel, Hist. Acad. Reg. Societ. p. 21, 22.) Two persons having died after transfusion at Rome, the pope also issued a prohibitory edict. (Eph. Nat. Cur. Dec. 1, ann. 1, obs. 149. Merclin de Transfus. Sanguinis, p. 25. 85.) From this time the practice has not been repeated in the human subject; although it has been repeatedly done, as a matter of philosophical curiosity, on animals who have suffered no interruption of their health and strength. Haller, Elementa Physiologiae, lib. iii. sect. 3. § 15—29.

TRANSGRESSION, TRANSGRESSIO, compounded of *trans, beyond, and gradire, to go*, an offence against some law, or a breach or violation of it.

The term is chiefly used in respect of the laws of God. In the doctrine of original sin, all mankind are supposed to share with Adam in the guilt of his first transgression. See *Original Sin*.

Moses threatens the transgressors of his law with a variety of temporal punishments.

TRANSGRESSIONE, in our *Law*, a writ, usually called a *writ*, or *action of trespass*.

Of this Fitzherbert has two sorts; one *vicountiel*, thus called because directed to the sheriff, and not returnable, but to be determined in the country. Its form differs from that of the other, as wanting the words *quare vi et armis*, &c. See *VICOUNTIEL*.

The other is termed a *writ of trespass*, and to be sued in the common pleas and king's bench. See *TRESPASS*.

TRANSIENT ACTION. See *ACTION*.

TRANSIENT Air. See *AIR*.

TRANSIRE, in stat. 14 Car. II. c. 11. is used for a custom-house warrant, or let pass; from the verb *transseo, I pass forth*.

TRANSIT, TRANSITUS, from *transire, to pass over*, formed of *trans* and *eo, I go beyond*, in *Astronomy*, signifies the passage of any heavenly body over the meridian, or of one body over another having the same apparent declination. When the smaller body is behind the larger, it is said to suffer an *occultation*; but when it passes before, it is said to transit the other. Thus a *star* behind the moon suffers an occultation, but a planet passing over the sun's disc is said to transit him.

Mercury and Venus, &c. in their transits over the sun, appear like dark specks. See *MERIDIAN* and *PARRALLAX*.

TRANSIT-Instrument, or Transit-Telescope, is an *astronomical instrument*, by which the *transits* or meridian passages of the heavenly bodies are taken. Before telescopic sights were introduced into the practice of astronomy, the instruments for finding a meridian line, and for observing meridian passages, were very different from what they are at the present day. So early as about the year 1700, Sir Christopher Wren, Mr. Gray, and Dr. Derham (see Phil. Transf.) had contrived instruments for this purpose; the last and best of which we shall briefly notice, by way of contrast with the modern transit-instrument, to shew the improvements that have taken place within the last century. In fig. 11. Plate XXXII. of *Astronomical Instruments*, A B is a horizontal bar of hard wood or metal, turning stiffly on the central stem of a tripod, and carrying two upright bars, C D and E F, which are bent a little near the lower extremity, and turned to a right angle at top; where there is a horizontal joint, as seen in the figure. From each of these upright bars are suspended a plumb-line, so as to come close to the ends of the horizontal bar A B respectively. At the ends A and B are two vanes, or sight-holes, from the former of which the sun, S, may be seen through a smoked glass, and from the latter the pole-star, P, with the plumb-line interposed. The portions of the horizontal bar A C and B E are moveable round the joints at C and E, and the plumb-lines are long enough to be tangents to the angles of elevation required to the radius A B, which therefore will be proportional in any given latitude, whatever the dimensions may be. The use of this meridian instrument may be thus explained: when P is the pole-star, the whole instrument must be turned round till the eye at A sees the pole-star

TRANSIT-INSTRUMENT.

very nearly in contact with the suspended line; and the contact or bisection may then more conveniently be effected by turning the vane a little round the joint E: in this situation, if the star be at the moment on the true meridian by calculation, the direction of sight will be in the meridian line, and bodies passing to the north, may be seen passing the plumb-line BF at any altitude below the pole. Suspend now the plumb-line AD from D, and turn the horizontal part on its joint, till this line bisects the vane at A, and move the vane at B gently round its joint E, till it is also intersected by the other plumb-line DA, and the two lines will be both suspended in the meridian line; consequently, an eye looking through the vane at B, will see any body to the south transit the line DA, provided it be below the ecliptic.

The condition to be attended to in the construction of a modern transit-instrument is, that while the telescope, through which the object is viewed, undergoes a change of elevation, its line of collimation shall move exactly in the plane of the meridian circle of the place of observation, after it has been once adjusted accurately into a line that lies truly parallel with the north and south line. To effect this purpose, it was found necessary that the axis of motion should lie exactly horizontal, in the direction of a line that joins the east and west points; that it should not bend by the superincumbent weight in any position whatever; and that the line of collimation should always cut the line of the axis at right angles, without the least perceptible deviation; for it is only while these conditions are fulfilled, that the line of collimation will ascend from the horizon in a truly vertical line, during an increase of altitude; and that this vertical line will continue also in the meridian. The first person, we believe, who used an astronomical instrument possessing the essential properties which we have described, was Dr. Halley at Greenwich Observatory, soon after the year 1719, which was the year in which he succeeded Flamsteed as astronomer-royal. According to Dr. Smith, the tube of Halley's telescope was five feet and a half long, and its axis of motion about an ell: it had also cross-hairs with the requisite adjustments in the eye-piece, with Y supports for the pivots of the axis, likewise adjustable, and the axis was levelled by a spirit-level, so that but little room remained for subsequent improvement, except in what relates to the achromatic object-glasses, and the method of illuminating the hairs, and of limiting the quantity of light necessary for particular observations. In the older instruments, the reflected light of a lamp or candle was received at the aperture of the telescope, as shewn in *fig. 15. Plate XXIX. of Astronomical Instruments*; but this mode of illuminating the hairs was found inconvenient, on account of the change of elevation of the telescope in successive observations, which required as many new adjustments of the lamp; and it was not till about the year 1787, that Dr. Usher of Dublin contrived the new method of transmitting light through one end of the horizontal axis to a diagonal perforated reflector, in the body of the tube, which brings it to the hairs after reflection, whatever the altitude may be to which the telescope is pointed. In our description of the different transit-instruments, it will not be necessary to repeat what we have already said of the theory and construction of either object-glasses or eye-pieces, under our article TELESCOPE, to which therefore our readers are referred on these essential points.

Transit-instruments, as they are now constructed, may be considered either as they are *stationary* or *portable*; the former of which was the original construction, and continues to be used in fixed observatories, for the purpose of

determining, in conjunction with a good astronomical clock, the right ascensions of the heavenly bodies; but the latter may be used in any place, for ascertaining the rate of a clock or chronometer, and when nicely brought into the meridian, for determining also the right ascensions with considerable accuracy.

Fig. 1. Plate XXXII. of Astronomical Instruments, represents a transit-instrument of the most approved stationary construction, which may be made of any dimensions that the aperture and focal length of the object-glasses will allow; but is usually made with a tube of from 30 to 120 inches long, and of proportional thickness, according to the degree of accuracy that is required. A and B are either a pair of solid stones firmly fixed in the ground, or a pair of pillars of firm masonry, sufficiently high to allow the eye of the observer to reach the eye-piece when the angle of elevation is about 45° . *Fig. 2.* exhibits a lateral view of the same, except that only one of the pillars is seen, in the direction of its breadth; while *fig. 3.* is an enlarged representation of the eye-end of the telescope; and *figs. 4. and 5.* are appendages attached to the superior end of the pillars; all which we shall describe in due succession. The tube of the telescope *a b* is usually of brass, of which the eye-end is at *a*, and the object-end at *b*: in the instrument before us it is five feet long; *c* and *d*, which appear to be two cones, are united to the central part of the tube, and form the axis of motion about three feet long; they are of brass also, and hollow, but are rendered very strong by circular pieces of metal, of different diameters, that are forced into the hollow space one after another at equal intervals; so that this axis has all the strength without the weight of solid metal. The pivots at the extreme ends of the axis are of bell-metal, and turned in the lathe to precisely the same dimensions, so that they may at any time have their positions reversed without affecting the horizontal line. The pieces, shewn by *figs. 4* and *5*, are made fast to the upper extremities of the pillars, and receive the pivots of the axis, each having an angular notch, called a Y, which are adjustable by proper screws, one in a vertical, and the other in a horizontal direction. The situation of each of these screws is seen by the handle inserted on the axis of the screw to which it belongs; and the manner in which the moving parts are made to slide by the action of the screws, between the parallel cheeks of the small frames, requires no particular description. When the weight of the telescope and of its axis is considerable, some part of this weight is supported by a loaded lever, as seen in *fig. 1*, which, by acting on the ponderous matter at some distance from the pivots, relieves them from a portion of the stress that would otherwise be laid on them by the whole weight. Hence the pivots have their friction diminished; and consequently their dimensions, as well as those of the Ys, remain unaltered. When the weight is small, such appendage may be dispensed with, provided the Ys and pivots be rectified occasionally, when they are a little altered by attrition. At a small distance from one end of the axis a graduated circle is made fast, which moving with the axis, shews the degree and minute of elevation, that the telescope has in any position, on two opposite adjustable verniers, which carry a spirit-level, and are clamped in a horizontal position, as seen in *fig. 2*. The extreme end of the axis, which is remote from the graduated circle, has a lens screwed into it, through which the light of a lamp is made to pass in its way to the diagonal reflector, contained between the two conical portions of the axis, within the tube; and by the light thus transmitted and reflected, the spider's lines, substituted for hairs or wires, are illuminated; without which illumination they would be invisible by night, except when the Moon or Venus

TRANSIT-INSTRUMENT.

Venus is observed. The spirit-level, which hangs on two vertical rods over the axis, is capable of being reversed in position, and is used, in the first place, for placing the axis of the telescope perfectly horizontal, and in the next, for watching the permanence of such position by the situation of its bubble. As the ends of the brass tube that contains the level revolve on two opposite pins, projecting from the rods of suspension respectively, the bubble will always occupy the upper part of the glass tube in every state of the telescope's elevation; but in the reversed position of the axis *c d*, the level will be underneath it, though the bubble will retain its place. The inside of the tube is ground to such a long radius, that *single seconds* of deviation from a true horizontal position may be read on an ivory scale by the end of the bubble. When, however, the telescope is large, and the axis consequently bulky, a spirit-level cannot be so well applied, as with telescopes of ordinary size; and when this is the case, a basin of pure mercury may be substituted with great advantage: for when the pole-star is on the meridian, and shines brightly, its reflected image, and also the star itself, will both pass together over the central vertical spider's line, at corresponding degrees of elevation and depression of the telescope, provided the axis be truly horizontal, and as little time as possible be suffered to elapse between the superior and inferior observations: but to render this operation easy, stops may be clamped to the graduated circle, to limit the space that is necessary to be described by the object-end of the telescope. There is in the instrument before us, moreover, a plumb-line apparatus for levelling the axis, which is seen in *fig. 2*, and partially on a larger scale in *fig. 3*. At *a* is a pin, from which a fine silver wire may be suspended; and at *e* is a horizontal screw, between two threads of which the wire rests, so as to be capable of adjustment in a lateral direction: the long narrow tube, which lies parallel with the main tube of the telescope, then receives the wire, and is put into a perpendicular direction, so that the suspended plummet may be immersed in a vessel of water; the microscope at *f*, next the eye-piece, now uppermost, views the image of a transparent dot, as a point to which the wire is referred, and to cover which it is now brought by the screw *e*: at the opposite end of the main tube, near *b*, is a similar microscope with a point of suspension and adjusting screw; so that when the object-end of the telescope is placed uppermost, the same adjustment is required to bring the stretched wire over its luminous image; and when this is done, the wire will bisect the lower luminous image also, if the axis be perfectly level, but not otherwise. To produce this coincidence, it will usually be necessary to adjust partly by the vertical screw of the proper Y, and partly by the screws of the plumb-line apparatus after each inversion of the tube.

When the achromatic object-glass does not produce a round and well-defined point, as the image of a *large* star, in any observation, it will be advantageous to diminish the aperture till this appearance takes place, which will generally be the case when the central part of the object-glass only transmits the light of such a star; but for small stars, it will always be better to allow the whole aperture to be open; not only because more light is thus admitted, but also because the image of a *small* star is always a point free from luminous irradiations, even in inferior achromatic telescopes. In the ten-feet telescope which Mr. Troughton has lately converted into a magnificent transit-instrument at Greenwich (*viz.* in 1816), he has ingeniously contrived a species of *iris*, that will contract or enlarge the effective part of the aperture by the simple turning of a milled nut, within reach of the hand, while the eye is at its place for making

the observation; so that the proper quantity of light can at any time be proportioned to what the nature of the observation may require. There are lastly screws of adjustment of the spider's lines in the eye-piece both for horizontal and vertical motion, and, in the best instruments, the eye-piece itself has a sliding horizontal motion, which enables the observer to keep the celestial body, though in motion, at the centre of the field of view during the whole passage over the five lines.

The best construction of a *portable* transit-instrument which we have yet seen, is that represented by *figs. 6* and *7*, which exhibit all the parts that are necessary for description, and which was one of the numerous inventions which we have had occasion to notice as the offspring of Troughton's ingenuity. The telescope of this instrument is 20 inches long, and magnifies from 20 to 35 times, according to the eye-pieces that are used; two of which are usually of the prismatic or diagonal kind, to be used in high altitudes; the aperture is 1.75 inch, and the power is competent to see the pole-star by clear day-light. The construction of the tube and axis is similar to that of the stationary instrument, except that the graduated circle and double vernier, with the level, lie beyond the Y of the support, and the iris is wanting: otherwise it has all the adjustments for levelling the axis, and bringing the line of collimation to a meridian mark that the larger instrument possesses, as well as those that rectify the position of the spider's lines in the focus of the negative eye-piece. The base of the stand is a thick ring or rim of brass, that receives three equi-distant screws for feet, besides the four screws that fix the two vertical frames thereto, which constitute the supports of the axis; one of which is seen entire in *fig. 7*. These supports are kept perpendicular by the interior bracing-bars, of which two are discoverable in *fig. 6*, attached by thumb-screws at both ends to the ring and upright frames respectively. The circular figure of the base is not only firm, but preserves its shape in all degrees of temperature; and when the parts are detached by loosening the thumb-screws, they will all pack into a box that is of a convenient size for carriage. The diameter of the circular base, and the consequent length of the axis, is a foot within, and the height of the supports thirteen inches. The graduated circle being of six inches diameter, admits of readings by each of the two opposite verniers to the accuracy of one minute, which is sufficient for finding the meridian altitude of any celestial body, of which the declination is known when the latitude is given; or for determining the latitude, when unknown, to the accuracy of one minute. If the circle were made a little larger, and three verniers substituted for two, a longer level might be used, and the readings might be accurate to 20" or 25"; but as the instrument was never meant to be used as an altitude-instrument, the inventor considered only what dimensions are requisite for constituting a useful transit-instrument in a portable form. The level of this instrument is entirely detached, and equal in length to the axis itself; its shape is delineated in the upper part of *fig. 9*, and the notches of its end-pieces stand upon the pivots of the axis, so that the reversion of the ends is performed without the least impediment. It is however necessary to remove the level from the axis, when the horizontal adjustment is finished, to avoid its being displaced and broken by an alteration in the elevation of the telescope. There are usually three studs of brass included, with the darkening-glasses, lantern, and other appendages; two of which studs have conical holes, to receive the points of the screws, or feet of the circular base: and for this purpose, all the studs must be made fast to the slab or pillar which supports the instrument, by plaster of Paris or putty inserted into as many holes in the plane of the marble or stone,

TRANSIT-INSTRUMENT.

stone, care being taken that the line which joins the two conical points be in the direction of the meridian, or so nearly so, that the adjusting screw of one of the Ys will bring it into that situation.

Mr. Thomas Jones, of Charing-Cross, has made several 30 and 42-inch transit-instruments of the portable sort, supported by oblong frames of cast-iron, which look very neat, and answer the purpose very well, a drawing of which construction we should have introduced into our plate, if it would have admitted of such addition. These instruments have all the properties of the instrument we last described, and have of course greater powers in their telescopes, and are also cheaper in proportion to their size. He has also made some of them with telescopes of only twenty inches, for the sake of greater portability.

Before any useful observation can be made with a transit-instrument of either the stationary or portable construction, it is necessary that all the adjustments be nicely made, and also that they be examined occasionally after a few observations are finished, in order to prevent errors that cannot be detected, or at least appreciated, at a subsequent period. These adjustments are nearly the same for all the common transit-instruments, and may be explained under eight heads, as follow; *viz.*

1. *To adjust the Spirit-Level.*—When the level hangs on, or is made fast to the axis, put the telescope in its place, and see to which end of the level the bubble runs, which will always be the more elevated end; bring it back to the middle by the Y screw for vertical motion, or by the foot-screw under the end of the axis, if it be a portable instrument, and then invert the axis, end for end; then, if the bubble is again found in the middle, the level is already parallel to the axis; but if not, adjust one half of the error by the adjusting-screw of the level, and the other half by the Y screw, or foot of the support, as the case may be; and let the operation of reversing and adjusting by halves be repeated, until the bubble will remain stationary in either position of the axis, in which case the level will be right. When the detached level is used, that notch must be made a little deeper, by scraping with a penknife, which has the bubble resting over it, instead of using an adjusting-screw, with which it is not usually provided; and when the notches that rest on the pivots are once made right, they will seldom require a second rectification. In the hanging level there are side-screws also, which adjust for parallelism of the level, as it regards a line joining the pivots of the telescope's axis; and this adjustment is known to be truly made, when the bubble does not run to one end, when the level is moved some degrees by a rotatory motion round its pivots, or central pins of suspension.

2. *To place the Axis of the Telescope truly horizontal.*—If the *spirit-level* is made use of, which is generally the case in instruments of ordinary dimensions, the same operation which we have just described will put the axis level, at the same time that it puts the level parallel to the axis; for unless both these conditions are fulfilled, the adjustment of the level will be deranged by reversion, and when this is not the case, it is a proof that both the level and the axis are truly horizontal. Hence, when the level is previously adjusted, it will be sufficient to bring the bubble to the middle of the level by the Y screw, or foot-screw alone, as the construction may require.

This adjustment may also be made, in the larger instruments particularly, by means of a *plumb-line*, either applied to a frame, suspended by the pivots of the axis, that will reverse in position according to Ramfden's method; or hang-

ing on the tube of the telescope parallel to the line of collimation, as we have described Troughton's in *figs. 2 and 3*: in either case, a dot is bisected by the plumb-line near the point of suspension, and another near the lower end of the line, in both the reversed positions of the axis, when the adjustment is truly made by the proper screws, as above directed.

But the most accurate, as well as probably the most convenient method of levelling the axis of a large instrument, is by *reflection*, by the aid of a basin of pure quicksilver, as we have already intimated; and the pole-star, being slow in its apparent motion, particularly at the time of its greatest elongation, is the most proper object by which to make the adjustment in question; for when the axis is level, and the star is made to cover any one of the spider's lines, its image reflected from the surface of the mercury will cover the same line, provided the depression of the telescope is effected instantaneously; and if this is not the case, the proper screws must be used for effecting this purpose without any reversion of the axis; for by this experiment, the line of sight of the telescope is proved to have a motion truly vertical, which is what the horizontal position of the axis is intended to produce. Hence, if the exact coincidence of the places of the star and of its reflected image takes place in an instrument both before and after the reversion of its axis, this is a proof that both the pivots and Ys are respectively similar. This method of adjusting the axis of the large transit-instrument at Greenwich has been lately adopted, after a trial had been made by the astronomer-royal, of the application of a plumb-line, suspended in a detached state from a point of considerable elevation.

3. *To produce distinct Vision.*—Before the subsequent adjustments can be made, it is necessary that the telescope should be put into a state of perfect vision; *viz.* that the object fixed upon should be seen well defined. This may be accomplished by sliding either the object-glass or the eye-piece within the tube, till the desired effect is produced; but when wires, hairs, or lines of any kind are made fast in the common focus of these glasses, a motion given to the eye-piece will make those lines disappear, and a motion given to the object-glass is in danger of deranging its best position: therefore, when a *meridian mark* is necessarily at so short a distance, that the same adjustment of the eye-piece will not suit it that has been made for a celestial object, by which the parallel lines have been fixed in the focus, an auxiliary object-glass, or glass of long focus to be added to the proper object-glass, is provided to remedy these inconveniences, whenever the meridian mark is the object viewed. The method of determining the focus of such additional glass, as shall shorten the compound focus of the object-glasses agreeably to what is requisite for a given distance, is explained under our article TELESCOPE.

4. *To put the Wires, Hairs, or Spider's Lins perpendicular to the Axis.*—The parallel lines in the eye-piece of the telescope are usually attached to a circular piece of brass that turns tight within the interior end of the tube, and if, when the telescope changes its elevation, a point in the meridian, or other mark, travels along one of these lines, so as to be bisected by it through the whole field of view, the said line will be perpendicular to the axis of motion; or if a long plumb-line be suspended at a distance, and a vertical line in the eye-piece is found to coincide with it while the telescope alters its angle of elevation, this will not only be a proof of the same thing, but will moreover shew that the axis is level; and when this is not the case, the piece holding the lines must be turned till they are found by trial to be truly vertical. The similarity of the intervals between the lines, and

also the angle measured by each, may be ascertained by a graduated staff, and the tables which we published under TELESCOPE.

5. *To make the Line of Collimation perpendicular to the Axis.*—After having adjusted for distinct vision to some distant known object, make the middle line in the eye-piece bisect some well-defined point in it, and, having reversed the ends of the axis, observe if the same line again bisects the same point exactly; if it does, the line of collimation is right; but if not, the error may arise either from the situation of the point observed, or of the centre of the object-glass, as they respectively regard the vertical line in the eye-piece; that is, one or other of those lines may deviate a little from a true perpendicular to the line of the axis of motion, or both may be erroneous in their respective degrees; therefore, when reversion has taken place, bring the vertical line one half way towards coincidence with the observed point, by the horizontal screw at the end of the axis, which alters the azimuth, and the other half by the side-screws of the eye-piece, which move the plate of the parallel lines, releasing one screw and tightening the other, so as to leave the said plate fast; then reverse again, and repeat the operation, till the same point is bisected in both positions of the axis.

6. *To illuminate the Wires, Hairs, or Spider's Lines.*—Before an observation of a star or planet can be taken, the parallel lines must be rendered visible to the eye of the observer, and the quantity of light to be admitted will depend on the magnitude of the body to be observed. A lantern containing a lamp must be fixed opposite that end of the axis which has its aperture closed by a lens, and so much of the light must be excluded as is superfluous for the observation; for when a small star is the object, much light will render it invisible, and yet it is necessary to have light enough to render the parallel lines visible; hence observations on very small stars require management of the quantity, and sometimes of the quality too of the extraneous light; on which account prisms of different coloured glass have been interposed between the lamp and the end of the axis, with sliding motions, to produce various modifications in the illumination, according to the exigencies of the moment.

7. *To adjust the horizontal Wire or Hair for taking Altitudes.*—When the altitude of an object is to be accurately taken, bring the bubble of the double vernier to the middle of the level, and turn the telescope on its axis of motion, till vernier 1 has its zero at 0 in the circle, or at 90° , if the circle is graduated for zenith distances, as is mostly the case; then notice what distant point is cut by the horizontal wire; reverse then the axis, and bisect the same point again, and in this situation see what quantity is read by the same vernier; or, which will be still better, half the sum of the readings of both verniers 1 and 2 may be taken at both times, and the difference of the two average readings may be considerable; then one half of this difference, + or —, is the real error of each observation, accordingly as the axis is situated in position; and if this error is not obviated by a proper adjustment, it must be allowed for in the reading of every observation. But this error may be owing partly to the unadjusted state of the vernier level, and partly to the situation which the horizontal wire occupies in the eye-piece; therefore the screws which elevate and depress the horizontal wire, which, however, are not in all instruments, may correct one half of the error, and the screws of the vernier level the other, in each reversed position till the error disappears; *i. e.* till there is no difference perceived in altitudes of the same object taken in reversed positions of the axis of the telescope's motion. But it is usual with astronomers,

who take altitudes in reversed positions of a circle, to ascertain the error arising from want of true collimation in altitude, from a repetition of observations, and to apply it to each observation as a correction, rather than attempt an exact adjustment in this respect, when the error is inconsiderable.

8. *To make the Line of Collimation move in the Plane of the Meridian.*—In order to fix a transit-instrument well in the meridian of any given place, it is necessary that the pole-star be exposed to its view; for as the polar point is situated in the centre of its diurnal circle, this circle must be bisected by the middle wire, or spider's line, that passes through the zenith, before it will move in the plane of the true meridian. Formerly it was usual to place the instrument, by double altitudes of the sun, or by a knowledge of the solar time gained by observation of his altitude on a given day, *nearly* in the meridian of the place, and then to observe which of the two semicircles, to the right and left of the approximate meridian line, were passed through in the shorter time, by means of taking both the upper and lower transits of the pole-star successively; after which an allowance was made for the deviation from the meridian, and the observations were repeated till both semicircles were performed in the same time. But by this method of finding the centre of the circle surrounding the pole, the accuracy of the result depended on the rate of the clock that was used, during the whole time that the successive observations were employed; consequently some uncertainty remained as to the comparative times intervening between the successive transits, and the true polar point was, therefore, not easily ascertained: but this difficulty has recently been obviated, by fixing on two stars nearly at opposite sides of the circle, so that their difference of right ascension may be very nearly 12^h ; for, when the two semicircles are alike, the time that elapses between the superior transit of one, and the inferior one of the other, will not be altered by a change of situation; the difference of the times will remain the same, whichever of the two stars makes the upper transit; but if the semicircles are unequal, the intervals of time will differ accordingly; so that if one star precede the other two minutes at its upper transit, and only one at its lower, half of this quantity will be the time corresponding to the deviation in position from the true meridian, which may be rectified by repeated observations of the short intervals, according to which the two stars follow one another, in transiting first above and then below the pole respectively; and all that the clock has to do, according to this method, is to count the *seconds* in each of those short intervals. When an instrument that is adjusted to have its line of collimation pass through the zenith by means of the horizontal position of its axis of motion, is thus made to bisect a polar circle, it will also pass through the pole, and will consequently move in the plane of the true meridian of the place. Various other methods of placing a common transit-instrument truly in the meridian have been recommended, but this is not only the easiest, but the best; and if the right ascensions of Dr. Maskelyne's or Mr. Pond's stars come right, when observed after the final verification, it may safely be concluded that the position of the instrument is in the true meridian.

When a transit-instrument is well constructed, and properly adjusted in all respects, it is one of the most useful instruments in astronomy, for without it the right ascensions of the heavenly bodies would not be accurately taken by direct observation, neither could the time, either solar or sidereal, be ascertained with that degree of precision which

TRANSIT-INSTRUMENT.

may be done by its aid. Indeed a perfect transit-instrument and a good sidereal clock are the indispensable furniture of every fixed observatory, and as companions, that mutually assist each other, they ought never to be separated.

We might now proceed to illustrate the use of the transit-instrument by real examples in practice, if we had not anticipated this part of our article under the heads ASCENSION and CHRONOMETER; in one or other of which articles we have explained both the method of determining the *right ascension* of any body, and also of ascertaining, without much calculation, the *rate* of a *chronometer* or *astronomical clock*. See the respective *problems* under CHRONOMETER.

The transit-instruments which we have above described are necessarily expensive, even in the portable form; and encouragement has been held out, by the Adelphi Society, for further improvements in the portable kind, so that they may become more common. And the frequent enquiries that have been made for a cheap portable instrument, induced sir H. C. Englefield, bart. to contrive a very simple one, which was first made by Mr. Thomas Jones, mathematical instrument-maker in London, and is now sold at his house at Charing-Crofs. A description of this instrument, called a *side transit-instrument*, written by the contriver, is sold along with it, from which it appears, that it is not to be considered an original instrument, but an improvement on an old transit-instrument formerly belonging to Mr. Aubert, and purchased at his sale by the late Mr. W. Walker. We propose to copy the description nearly as it has been published. "It is well known," says the ingenious author, "that the transit-instrument, in its usual form, is liable to great injuries from blows, or other violence affecting the perpendicularity of the telescope to the axis; that it necessarily takes up much room in package; that, unless of a very small size, it is not easily fixed in a window or other opening in a common dwelling-house; and that it is quite impossible, except in fixed observations, to make it sweep the entire arc between the southern and northern points of the horizon. In windy weather its use is also very difficult and inconvenient. In the instrument now offered, all these inconveniences are avoided. It may be fixed almost any where; in many places it may be made to describe the entire semicircle of the meridian; the observer is put to no difficulties by change of place, as he always looks directly along the axis; it is packed in one-eighth of the space requisite to pack a common transit-instrument of the same real size; its weight is not more than a sixth of the other; from its simplicity it will be afforded at half the price; and its verifications and adjustments are easy and simple. It has also another advantage, that the mark by which it is placed in the meridian may be either in the meridian or at right angles to it; or, if convenient, two marks may be erected, one to the south or north, the other east or west; and if so used, it will be always seen, by inspection only, whether the mirror needs adjustment or not. In many confined situations, such as occur in cities, the power of having a mark at right angles to the meridian may be eminently useful. The general description of the instrument is as follows: The telescope is included in a brass cylinder, having a small cylinder at each end, turned true in the usual manner, and resting in Ys of the usual construction. These smaller cylinders are both pierced. In one is the eye-piece of the telescope, with its wires, &c. The other is open, for the purpose of seeing through it, if necessary, the eastern or western mark; and for adjusting by direct vision the line of collimation of the instrument. It also serves for the illumination of the wires. The object-glass of the telescope is placed so near this cylinder, as only to allow room for an

unsilvered plane glass mirror to be placed before it at an angle of 45° . It is obvious, that as the telescope revolves on its axis in the Ys, every celestial object at right angles to it may successively be seen by reflection from the mirror; and of course, if the axis be placed due east and west, the transits of all celestial bodies over the meridian will be observed with the utmost accuracy and convenience. The aperture in the axis beyond the object-glass is not only of use for the adjustment of the instrument to an eastern or western mark, or for the illumination of the wires, but affords a means of seeing the mark at the same time with the body whose meridian passage is to be observed, and of thereby being certain of the true adjustments of the instrument at the very moment of observation; which is impossible in any other construction of the transit-instrument, and seems to be a very material advantage. I am convinced that transit-instruments of the largest size might, with very great advantage, be constructed on this principle. It is true, that where very much light is wanted, as in observations of stars in the day-time, the loss by reflection will be some disadvantage; but the loss of light from an unsilvered mirror is very small: and the convenient and simple form of the instrument; by its lightness less subject to flexure; by its position much less liable to errors from unequal change of temperature; and so extremely commodious in its use; present advantages of a very important nature, and such as might introduce it into the most extensive observatories with profit. The advantages may perhaps be even greater than in small transit-instruments. When in the present construction the telescope is long, as its whole weight rests on the most disadvantageous point of the axis, this is of necessity made very large towards its centre, to avoid flexure; and the whole instrument is so heavy, that an additional apparatus of counterpoise must be added to the pivots, lest they should wear away the Ys, and the reversing the instrument becomes a work of some difficulty and danger: whereas in the construction proposed, the small comparative weight of the object-glasses and eye-glasses lies very near the pivots, and the middle of the tube is the lightest part of it. The operation of reversing is performed with great ease, both from the form and lightness of the instrument; and it may be added, that the comparative facility of observations is of greater advantage the larger the instrument. Having so far explained the general principles of this transit-telescope, which was executed very much to my satisfaction by Mr. Thomas Jones, it will be proper to describe more particularly its construction. The transit-stand is represented by either the upper or lower part of *fig. 10*.

"The first is constructed for being placed or fixed on a vertical surface; the second for a horizontal one, A B; in both are the Ys, or supports for receiving the axis of the telescope. The end A, intended to be always next the eye, is furnished with both the horizontal and vertical adjustments, such as are usual to transit-instruments. The telescope's axis is represented by the lower part of *fig. 9*. The eye-end being at C, the object-end at D turns round in the Ys; A B upon its cylinders *n, n*: the screw-head *r*, at the object-end D, is for the purpose of adjusting the parallel glass. The telescope is adjusted to distinct vision by means of the head or knob at P. The wires of the telescope are adjusted by means of the four capstan head-screws at the eye-end *t t*. The circle R is divided on the surface next to the eye. The eye-tube has a sliding motion for viewing the wires distinctly: the short piece of tube at the object-end turns round on the telescope's tube, and serves as a cover for the object-glass. The upper part of *fig. 9* is the riding level, and is placed upon the axis in the Ys, and adjusted

TRANSIT-INSTRUMENT.

justed by means of the fore S. *Fig. 8.* represents the stand, telescope, and level, displaying the position in which they are used; *fig. 12.* for placing the transit in the meridian. Of the verifications of this instrument, two are common to every construction; one only is peculiar to this. The line of collimation is adjusted by looking direct at some distant small point (the cover being turned over the lateral aperture), and turning the telescope gradually round on its axis, and moving the screw of the wires, if necessary, till the spot is in every position covered by the intersection of the wires. The axis is brought to a horizontal position, and the level is in the same mode adjusted by reversing the telescope or level, and correcting half the error by the level-screw, and half by the vertical screw of the Y, in the usual mode. The verification peculiar to this instrument is that of the mirror, and perhaps the best mode of doing this is by the pole-star, when nearly in an eastern or western position from the pole; its motion in azimuth is then so slow as to give ample time for the adjustment. Bring the pole-star to the vertical wire (the line of collimation having been previously adjusted); then reverse the telescope in its Ys; and if the star is still on the wire, the mirror is in adjustment: if not, correct half the difference by the mirror-screw, and half by the horizontal of the Y, till the error vanishes. This adjustment may also be performed, by setting up a board with two parallel perpendicular lines drawn on it, distant from each other exactly the space between the positions of the mirror when the telescope is reversed in its Ys. If the vertical wire be brought to cover one of the marks, and on being reversed, the wire covers the other mark, it is right: if not, the error must be made to vanish by correcting it half and half, as before directed, for the adjustment by the pole-star. The following method of placing the instrument correctly in the meridian, is equal if not superior to any that has yet been devised. Let Z (*fig. 12.*) be the zenith; P, the pole; H O, the horizon; Z P I, the meridian circle; Z K, a circle of altitude, distant from the meridian by a small quantity I K (suppose a degree); 1, 2, 3, 4, the diurnal circle of the pole-star, whose radius is $1^{\circ} 45'$ nearly; and let the altitude of the pole be $51^{\circ} 30'$. Then when the pole-star is on the northern meridian, its altitude 3 I will be $49^{\circ} 45'$, and its zenith distance Z 3 = $40^{\circ} 15'$; and A C D be a part of the diurnal arc of a star whose polar distance is $46^{\circ} 30'$, and N. meridian altitude 5° . Now suppose the transit-instrument, whose axis is accurately levelled, and of course in the meridian at Z, to point, at the horizon to K (it is obvious from its construction the telescope's axis will be at right angles to the meridian line) instead of I, the true meridian; then at 3 (the altitude of the pole-star under the pole) it will point at B, and the arc 3 B will be to I K, as the cosine of the altitude 3 I to radius; but 3 B, measured on the diurnal circle of the pole-star, will be the sine of its distance from the meridian to the radius P 3 or P B: and, as in small arcs, the arc of a great circle, or of a small circle, or their sines, are nearly coincident, we shall have very nearly, as Z 3 (the zenith distance) is to P 3 (the polar distance), so is the value of 3 B, in degrees of the pole-star circle, to its value in degrees of a circle whose radius is Z 3. And as the radius Z 3 is to P 3 very nearly as 23 to 1, the error of the transit-telescope at the altitude 3 I, will be measured by a scale (if it may be so called) 23 times as great as itself. Now, let there be another star A, whose northern meridian altitude is as small as it conveniently can be, for example 5° , whose polar distance is, therefore, $46^{\circ} 30'$, and whose right ascension is the same as that of the polar star; then, if the transit-telescope be in the meridian, both these stars

will pass through it at the same time; but if it be out of the meridian by the quantity I K, the star A will pass through it when it comes to C, but the polar star not till it comes to B, when the star A has got to D, in its diurnal circle. The value of A C being therefore found, by multiplying I K by the cosine of its altitude A I, that value, being reduced to the angular value from the radius P A, will give the time of the star A passing through the transit-telescope, after the time of its passing the meridian; and the same operation being performed for the pole-star as before directed, the difference of these times will be the error in time of the transits, answering to the given deviation I K of the transit-telescope. And tables having been previously constructed for such stars as shall be thought convenient, the transit-telescope may, in a very short space of time, be set to the meridian, with a degree of precision unattainable by any other method. If the star A precedes the pole-star in its passage under the pole, no tables are requisite, nor any thing necessary to be known but the exact difference of the right ascension between the two stars; for having observed the transit of the star A, (the instrument being previously brought near the meridian, suppose half a degree,) then elevate the telescope to the pole-star, by moving the horizontal adjustment of the axis; keep the pole-star on the middle wire, till the due interval of time between their transit is elapsed; the instrument will then be extremely near its true position; and, by repeating the observation once more, will be brought to a perfect exactness. Or, if another star, following the pole-star in its passage, be observed on the same evening, if the times elapsed between their transits are equal to the tabular difference or their right ascensions, which will probably be the case, the accuracy of the first placing the instrument will be immediately ascertained. Other stars near the pole may be made use of in the same manner as is here described for the pole-star, but with proportionally less advantage as the polar distance is increased. It is also obvious from the figure, that the transit of the pole-star above the pole may be also used, and that with nearly, though not quite, the same advantage as the transit below the pole. The same method may also be applied with equal ease, if the second star A pass the southern meridian instead of the northern.

"The slowness of the pole-star's motion, though it renders its transit uncertain to a few seconds, cannot materially affect the accuracy of this method, as an error of ten seconds in time, in the estimation of its passage, which is certainly more than can be committed, would not cause an error of a third of a second of time in the passage of stars near the equator.

"Example of the computation with the numbers given above.

Star A.		Pole-star.	
Sin. I K	8.241855	Sin. I K	8.241855
Sin. Z A	9.998844	Sin. A C	8.240199
Sin. Z 3	9.810316	Sin. 3 B	8.052171
Sin. P A	9.860562	Sin. P 3	8.484848
Sin. A P C	8.379663	Sin. 3 P B	9.567328
	$1^{\circ} 22' 20''$	3 P B	$21^{\circ} 40' 10''$
In time	$5^m 29^{\frac{2}{3}}s$	In time	$1^h 26^m 40^{\frac{2}{3}}s$

"The error of a degree, therefore, in the position of the transit-telescope at the horizon, causes the star A to pass through it $5^m 29^{\frac{2}{3}}s$ in time later than it ought; whereas the same error causes the transit of the pole-star to be $1^h 26^m 40^{\frac{2}{3}}s$ later than it ought; and the difference between these

these two times, *viz.* $1^h 21^m 11\frac{1}{4}^s$, will be the difference of the observed time of their transits, owing to the error of the position of the transit-telescope, their real right ascension being supposed the same." After having thus given Sir H. Englefield's own words, we shall only add on this subject, that on enquiry of Mr. Thomas Jones, we learn that several of these instruments have been made and sold, and one on an enlarged scale; but that stars smaller than those of the third magnitude cannot be seen by a telescope in which the reflection precedes the refraction.

TRANSIT-CIRCLE, is an astronomical instrument, by which, with the aid of an astronomical clock, both the right ascension and declination of a heavenly body are determined at the same time. This instrument is of modern date, and differs from a transit-instrument of the best construction, only as it has a graduated circle of larger dimensions than the latter, and, by means of microscopes, reads the angle observed to the accuracy of a *single second*; whoever, therefore, has a good transit-circle, and a superior astronomical clock, has an observatory for determining the exact place of any heavenly body. Under our article CIRCLE, we have described the *mural transit-circle* by Troughton, which has been usefully employed by Mr. S. Groombridge at Blackheath, and which has proved itself to be an instrument of the first class; and we there stated a report, that a large one was in contemplation for Greenwich, which we said we might possibly have occasion to describe. That instrument has been finished by Troughton in his best manner, and though the plan of the construction is unique, and the mode of using it novel, its application to the purposes for which it was intended answers the most sanguine expectation of the maker, and in the hands of the present astronomer-royal, affords the means of making more accurate and at the same time more numerous observations in a given time, than ever were effected by any other instrument. Though this instrument has a long axis passing through a solid pier of masonry, and is capable of being used for transits, it has hitherto been principally used for determining polar distances, by actual measurement from the polar point; according to which mode, the uncertainty in the results, which commonly arises from variable refraction in ordinary measurements, is almost entirely obviated, and a repetition of any series of observations may be made on any part of the circle *ad libitum*, and with any number of readings to the number of six at the same time; so that a single observation is made with as much accuracy, as can be obtained from an average of several successive observations taken with a repeating-circle of the same dimensions; and yet there is the power of repeating any observation in various positions. Mr. Pond has already published one volume of observations taken with this instrument, which completely verifies our assertions, and in this first volume he has given a plan and section of this instrument, the circle of which is six feet two inches in diameter; but as Mr. Troughton intends to give a complete description thereof himself, as a paper suitable for the Philosophical Transactions, which, to be published therein, must be an original communication, Mr. Pond was not at liberty to describe the drawing which he has given as a frontispiece to his first volume; and as the description in question is not yet finished, we are in the same predicament with the astronomer-royal, and must consequently for the present forego the pleasure we had promised ourselves, of introducing this magnificent instrument to the notice of the public.

TRANSITION, in *Music*, is nearly synonymous with modulation: it implies little more, in its technical use, than a *change*; and, in general, a change of key, from major to

minor, or the contrary; or, indeed, from any one genus or key to another. Luckily no laws were laid down by our forefathers for transition, as for modulation, which we so long feared to violate.

TRANSITION, in *Rhetoric*, a kind of connection in discourse, by which the several different parts and members of it are joined, so as to constitute one regular whole: or, as Vossius defines it, it is a form of speech, by which the speaker, in a few words, tells his hearers both what he has said already, and what he next designs to say. Sometimes, however, in passing from one thing to another, a general hint of it is thought sufficient to prepare the hearers, without particularly specifying what has been said, or is next to follow.

Some place transition in the number of figures; others, with Quintilian, exclude it from that rank.

F. de Colonia makes two kinds of transitions, the one *perfecta*, and the other *imperfecta*.

TRANSITION, *Perfecta*, is that in which we briefly intimate what is said, and what remains to be said. As, *Nunc that we have spoken of war, there remains something to be said of peace. Satis multa de turpitudine: dicam deinceps, quod proposui, de periculo. Uni epistolæ respondi: venio ad alteram. Sed hæc vetera; illud recens: Cæsarem meo consilio interfecit.*

TRANSITION, *Imperfecta*, is that in which only one of these is expressed. As, *Let us now consider the consequences of, &c. Postularet hic locus, ut dicerem de — sed finis sit; neque enim præ lacrymis jam loqui possum; et hic se lacrymis negat.*

TRANSITION Rocks, in *Geology*, a name introduced by Werner to designate those rocks which, on account of their containing few organic remains, and lying immediately over other rocks which contain none, are supposed by him to have been formed when the world was passing from an uninhabitable to a habitable state. According to the same geologist, transition rocks are of more recent formation than the lower or primary rocks, and older than the stætz or stratified rocks, and are intermediate between both, being partly of mechanical and partly of chemical formation. The rocks which are enumerated in this class by Werner, are transition lime-stone, transition trap, greywacke, and stinty slate. It is now, however, admitted, that the distinction made between transition rocks and the lower stratified or stætz rocks, has little or no foundation in nature, as these rocks are not unfrequently observed to alternate with each other. (See Rocks.) Nor is the absence of organic remains in the lower rocks, called *primary*, a decisive proof that they were formed previously to the existence of organic life upon our planet; for in a series of stratified rocks containing organic remains, we frequently meet with other beds interposed, in which no vestige whatever of such remains can be traced. Hence we may infer, that the process by which the latter was consolidated, has destroyed the organic matter which they may have once contained. The absence of organic remains in siliceous beds that have a crystalline granitic structure, is, we conceive, owing to the peculiar mode by which they were crystallized, as such beds sometimes repose on other beds abounding in marine shells. Nor can we be certain, that the lowest rocks of granite were formed before the existence of animal life on our planet. The more extensively modern geologists have carried their observations, the more numerous are the instances found of marine shells or vegetables occurring in alpine districts formerly regarded as primary; and if granitic rocks, wherever they occur, are invariably destitute of extraneous fossils, we must attribute it to the peculiar mode of their formation, rather than to their priority of age.

The

The only circumstance which makes it probable, that the rocks classed as transition rocks, are the lowest in which the remains of organic substances have ever been imbedded, is, that the fossils found in such rocks belong almost exclusively to different species of zoophytes and shell-fish, which may be regarded as the first or lowest links in the chain of animated beings. It is only in the upper strata that we meet with remains of animals possessing the faculties of vision and locomotion, and a more complex organization. See ROCK, STRATA, and SYSTEMS of *Geology*.

TRANSITIVE, in *Grammar*, an epithet given to such verbs as signify an action which passes from the subject that does it, to, or upon, another subject which receives it. Under the head of verbs transitive, come what we usually call verbs active and passive: other verbs, whose action does not pass out of themselves, are called *neuters*, and by some grammarians *intransitives*.

In the Hebrew, the verb בָּיַב , *bajab*, in the Greek $\epsilon\upsilon\iota\varsigma$, and in the Latin *sum*, are verbs purely neuter, or intransitive; or, as the Latin and Greek grammarians more usually express it, verbs substantive, signifying the mere existence of the thing, without the active or transitive conjugations.

TRANSITORY, in *Common Law*, stands opposite to local. See ACTION.

TRANSITORY *Chose*. See CHOSE.

TRANSITORY *Trespas*. See TRESPASS.

TRANSLATION, formed of *trans*, *beyond*, and *latio*, of *ferre*, to carry; the act of transferring or removing a thing from one place to another.

We say, the translation of a bishop's see, a council, a feat of justice, a parliament; the translation of the relics of a saint, the translation of the empire, &c.

The translations of bishops from one see to another are prohibited by the council of Nice, which declares them null, and appoints the translated bishop to return to his former church. The council of Sardica excludes translated bishops from communion. It has been observed, that no bishop was ever removed from a greater church to a lesser; and that those who thus quitted their churches, only did it out of ambition or avarice.

This discipline was generally observed for nine hundred years; and the first instance of any translation of note, was that of pope Formosus, who was bishop of Porto. One of his successors took hold of this pretence to have him dug out of his grave; and a council, held soon after, forbade this translation to be made a precedent.

However, the same church allowed of some legitimate causes of translations; as the apparent advantage of the church; under which pretence, translations soon became so frequent, that for 500 or 600 years last past, they have been esteemed a kind of common law.

The translation of a religious from one order to another cannot be effected without the consent of the pope; it is added, that it is not allowed to translate from a severer rule to a laxer one.

TRANSLATION is also used for the version of a book or writing out of one language into another. See VERSION.

TRANSMARINE, TRANSMARINUS, something that comes from, or belongs to, the parts beyond sea.

TRANSMARISCA, in *Ancient Geography*, a town of Lower or Second Mæsia, upon the route from Viminacium to Nicomedia; between Appiaria and Candidiana. Anton. Itin.

TRANSMIGRATION, the removal or translation of a whole people into another country, by the power of a conqueror. See MIGRATION.

TRANSMIGRATION is particularly used for the passage of a soul out of one body into another; the same with what we otherwise call *metempsychosis*; which see.

The Siamese, F. Tachard informs us, from a belief of the transmigration of souls into other bodies, forbear killing any beasts; lest, by that means, they should dispossess the souls of their deceased relations.

TRANSMIGRATION, *Ionic*. See IONIC.

TRANSMISSION, in *Optics*, &c. denotes the property of a transparent body, by which it suffers the rays of light to pass through its substance; in which sense, the word stands opposed to reflection.

Transmission is also frequently used in the same sense with refraction, because most bodies, in transmitting the rays, do also refract them.

For the cause of transmission, or the reason why some bodies transmit, and others reflect, the rays, see TRANSPARENCY and OPACITY.

The rays of light, sir Isaac Newton observes, are subject to fits of easy transmission and reflection. See LIGHT and REFLECTION.

TRANSMUTATION, the act of transforming or changing one nature into another.

The term is chiefly used in chemistry and medicine. It has been greatly questioned, whether the transmutation of silver into gold, and of tin into silver, so much sought by the chemists, be possible or not.

The purest and subtlest parts of the food are transmuted or assimilated into the proper substance of the body. See NUTRITION.

Nature, sir Isaac Newton observes, seems delighted with transmutations: he goes on to enumerate several kinds of natural transmutations; gross bodies and light, he suspects, may be mutually transmuted into each other; and adds, that all bodies receive their active force from the particles of light which enter their composition.

For all fixed bodies, when well heated, emit light as long as they continue so; and, again, light intermingles itself and inheres in bodies as often as its rays fall on the solid particles of those bodies.

Again, water, which is a fluid, volatile, tasteless salt, is by heat transmuted into vapour, which is a kind of air; and by cold into ice, which is a cold, transparent, brittle stone, easily dissolvable; and this stone is convertible again into water by heat, as vapour is by cold.

Earth by heat becomes fire, and by cold is turned into earth again: dense bodies are rarefied into various kinds of air, and that air reverts into gross bodies.

Quicksilver sometimes puts on the form of a fluid metal; sometimes it appears in the shape of a pellucid, fragile salt, called *sublimata*; sometimes of a pellucid, volatile, white, tasteless earth, called *mercurius dulcis*: by distillation, it becomes vapour; and by agitation *in vacuo*, it shines like fire, &c.

All bodies, beasts, fishes, insects, plants, &c. with all their various parts, grow and increase out of water, and aqueous and saline tinctures; and, by putrefaction, all of them revert into water, or an aqueous liquor, again.

Farther, water exposed awhile to the open air, puts on a tincture, which, in process of time, has a sediment and a spirit; and, before putrefaction, yields nourishment both for animals and vegetables.

TRANSMUTATION, in *Alchemy*, denotes the act of changing or exalting imperfect metals into gold or silver.

This is also called the *grand operation*; and, they say, it is to be effected with the philosopher's stone.

The trick of transmuting cinnabar into silver is thus; the

the cinnabar, being bruised grossly, is stratified in a crucible with granulated silver, and the crucible placed in a great fire; and, after a due time for calcination, taken off; then the matter being poured out, is found to be cinnabar turned into real silver, though the silver grains appear in the same number and form as when they were put into the crucible; but the mischief is, coming to handle the grains of silver, you find them nothing but light friable bladders, which will crumble to pieces between the fingers.

Mr. Boyle, in his *Sceptical Chemist*, tells us, that two friends of his did, by urging mercury in a skilfully managed fire, turn it, almost weight for weight, into water; but he does not say what was the specific gravity of the produced water, nor of the remaining untransmuted mass of mercury. He likewise assures us, that rain-water, being distilled and re-distilled, by a friend of his, nearly two hundred times, did, after distillation, leave at the bottom of the glass body, a considerable quantity of a white earth; and that more plentifully in the latter distillations, than the former.

This he believed to be a certain quantity of water actually transmuted into earth, adding, that it was above twice as heavy specifically as common water, and of so fixed a nature, that it lay a considerable time, in a red-hot crucible, without losing any thing of its weight, or even emitting any smoke.

For the transmutation of iron into copper, see COPPER and VITRIOL.

TRANSMUTATION, in *Geometry*, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parallelepiped, &c.

TRANSMUTATION, in the *Higher Geometry*, is used for the converting of a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit the same tangents, &c.

If a rectilinear figure be to be transmuted into another, it is sufficient that the intersections of the lines which compose it be transferred, and lines drawn through the same in the new figure.

If the figure to be transmuted be curvilinear, the points, tangents, and other right lines, by means of which the curved line is to be defined, must be transferred.

TRANSMUTATION of Colours. The change of colour of a decoction of the nephritic wood, according to the different lights it was viewed in, long perplexed those who attempted to account for it; but Wolfius has carried the experiments on this decoction much farther, and found a way of giving it its colours again, after taking them wholly away. If this decoction be held between the eye and the light, it appears of a blue colour; but if the eye be placed between it and the light, it appears then of a yellowish or a red colour. If a few drops of oil of vitriol be dropped into it, it will appear of a gold yellow in whatever light it is viewed; but if too much of this oil be added, the whole becomes foul and obscure; and if a few drops do not produce the effect, it is a sign that the decoction is too strong, and that it must be diluted with water. See COLOURS.

Oil of vitriol has the same effect upon many other decoctions of the woods, particularly on that of Brazil wood, which is of a fine red, but immediately becomes yellow on dropping a small quantity of this acid into it. And as in the other instance, so in this, it is necessary to the success of the experiment, that the tincture be not over strong. A few drops of oil of tartar added to this yellow liquor turn it red again as at first; and if more oil of tartar be added, the colour becomes blueish, with a tinge of red, much stronger than the colour of the nephritic wood at first, when held

between the eye and the light. In all experiments of this kind, the weakness of the tincture produces the greatest beauty; and therefore it is best, instead of making a decoction, to make only a cold infusion, by putting a small quantity of the chips of the wood into water, and letting this stand cold for some time.

A tincture of red roses, made with common water and oil of vitriol, is well known to be of a very beautiful red colour, yet when the water has stood ever so long on the roses alone, it has scarcely any colour; if it be strained off in this colourless state, and the oil of vitriol then added, the red colour is produced as strongly as if this acid had been dropped into the water, while the roses were yet in it. When the liquor is of this fine red colour, a small quantity of oil of tartar makes it immediately green; and if more oil of vitriol be added to this green liquor, it becomes red again, but is muddy, and not so well coloured as before. If a few drops of a solution of corrosive sublimate be added to this, it does not at all change colour; and on adding more water, with salt of tartar dissolved in it, the liquor became red again, but of a very different red from what it was before in its muddy state, being now clear and deeper. When the tincture of roses has scarcely any colour, a small quantity of salt of tartar makes it green, but a large quantity makes it yellow. A few drops of oil of vitriol added to this yellow liquor, turned it to a pale red, and this could never be made green again by oil of tartar. Alum-water, added to a solution of salt of tartar, makes a white and opaque fluid, though they are both separately pellucid.

What is most observable in these experiments on the infusion of woods is, that oil of tartar, and a solution of salt of tartar in water, have a very different effect. Thus an infusion of Brazil wood is red, and on dropping into it a few drops of oil of vitriol, it becomes yellow. If oil of tartar be added to this liquor, it only makes it yet more yellow; but if a solution of salt of tartar in water be added to this, it makes it red again. *Act. Erudit. ann. 1718. p. 322.*

The solution of verdigris, which is green, becomes colourless by the affusion of spirit of nitre or spirit of vitriol, and by the affusion of the oil of tartar it becomes green again. The spirit of sal ammoniac gives it a purple colour, and oil of vitriol makes it pellucid. The solution of galls with vitriol gives black, the affusion of oil of vitriol destroys the blackness, and it becomes pellucid as before.

M. Muschenbroeck thought it to be universally true, that yellow vegetables, dissolved in spirit of wine, gave yellow tinctures, which are either not at all, or very little changed by acid, alkaline, or any other salts; but he thought there were some exceptions, and says, that when oil of vitriol is put to yellow paint, called *orleon*, it becomes of a beautiful blue, which is destroyed by water or any salt. A small quantity of an astrigent substance, with iron, gives a black colour; a greater quantity of the astrigent produces blue, more of it makes a violet, and more still produces purple.

There are some tinctures, the colours of which depend upon the external air: such is the red tincture made of Canarian lichen, called *orseille*, and water, a diluted spirit of wine, with lime and an urinous salt. For, if this tincture be put into a glass tube, hermetically sealed, in a few days it becomes colourless; and when the tube is opened the colour returns. The abbé Nollet made a variety of experiments with this tincture. To the same class may be referred the sympathetic inks.

Colours may be produced in liquors which originally have no colour; thus, spirit of wine with red roses, upon which, whilst it is yet white, any saline acid spirit is poured, in to small a quantity that the acid can hardly be perceived, produces

duces a florid red. Many other red flowers hardly give any colour to spirit of wine in a short time, yet give a red colour by the addition of any of the acids. A solution of mercury and oil of tartar gives orange; a solution of sublimate and lime-water produces yellow. The tincture of red roses with oil of tartar per deliquium, or with spirit of sal ammoniac, gives green. In like manner, the tincture of many red flowers it changes into green by an alkali. The tincture of red roses and spirit of wine gives blue. The solution of copper and spirit of sal ammoniac gives purple. The solution of sublimate and spirit of sal ammoniac gives white. The solution of saccharum saturni and that of vitriol, also the tincture of red roses, or many other red flowers, and the solution of copperas in water, and likewise the solution of galls and copperas, produce black. The following table exhibits the colours arising from different mixtures.

			Produce
1.	{ Yellow } Tincture of red roses	}	green.
	{ Red } Tincture of crocus		
2.	{ Green } Tincture of violets	}	carmine.
	{ Brown } Spirit of sulphur		
3.	{ Red } Tincture of red roses	}	blue.
	{ Brown } Spirit of hartshorn		
4.	{ Blue } Tincture of violets	}	violet.
	{ Blue } Solution of copper		
5.	{ Blue } Tincture of violets	}	purple.
	{ Blue } Solution of Hungarian vitriol		
6.	{ Blue } Tincture of cyanus	}	green.
	{ White } Spirit of sal ammoniac		
7.	{ Blue } Solution of Hungarian vitriol	}	yellow.
	{ Brown } Lixivium		
8.	{ Blue } Solution of Hungarian vitriol	}	black.
	{ Red } Tincture of red roses		
9.	{ Blue } Tincture of cyanus	}	red.
	{ Green } Solution of copper		
10.	{ Violet } Tincture of dipfacum, or iris, or	}	blue.
	{ Trans- } any other flowers that give a		
	{ parent. } violet colour in water		
	{ } Alum dissolved in water.		

Muschenbroeck's *Introd. ad Phil. Nat.* tom. ii. p. 738, &c. The result of a variety of mixtures to produce colours, was recited before the Royal Society by Dr. Goddard in 1661, and may be seen in Birch's *History*, vol. i. p. 11.

Mr. Melville has made many observations on the transmutation of colours by means of the light of different burning bodies. Bodies of all the principal colours, *viz.* red, yellow, green, and blue, are very little altered, he observes, when they are seen by the light of burning spirits; but if salts be continually mixed with them, during the burning, different changes ensue. When sal ammoniac, potash, or alum, are infused, the colour of red bodies appears somewhat faded and dirty. Green and blue appear much the same as in candle-light, both being faint, and hardly distinguishable. White and yellow are hardly at all affected.

When nitre, or sea-salt, is plentifully mixed with the burning spirits, and the whole is stirred about briskly, the brightest red bodies, seen by the light then emitted, are reduced to a dirty tawny brown, which seems to have nothing of redness in it. Green is transformed into another sort of brown, only distinguishable from the former by a certain inclination to a livid olive colour. When nitre is mixed with the spirits, one may still see some remains of greenish colour, unless it be poured in very plentifully. Dark blue is hardly to be known from black, except that it appears the deeper black of the two. Light blue is changed into a very light

brown, of a peculiar kind. White assumes a livid yellowish cast; and yellow alone appears unaltered, and extremely luminous.

These experiments he made with different sorts of richly coloured bodies, as silks, cloths, and paints. Polished copper, which had contracted from the air a high flaming colour, was reduced, by the same light, to the appearance of yellow brass. The faces and hands of the spectators appeared like those of a dead corpse; and other mixed colours, which had red or green in their composition, underwent the like changes.

Having placed a pasteboard, with a circular hole in it, between his eye and the flame of the spirits, in order to diminish and circumscribe this object, he examined the constitution of those different lights with a prism, holding the refracting angle upwards; and found that, in the first case, *viz.* when sal ammoniac, alum, or potash fell into the spirits, rays of all kinds were emitted, but not in equal quantities, the yellow being much more copious than all the rest put together, and the red being more faint than the green and blue.

In the light of spirits mixed with nitre, or sea-salt, he could observe some blue, though exceedingly weak and diluted. With the latter the green was equally faint, but with the former pretty copious. But when either of these salts was used, he could hardly perceive any trace of red, especially when they were mixed in great plenty, and the spirits constantly agitated. At every little intermission, indeed, the red rays would shew themselves very manifestly below the hole, and red bodies seen by that light resumed somewhat of their ordinary colour; and it was entertaining to observe how both would vanish again at once, when the salting and stirring were renewed.

The proportion in which the bright yellow exceeded the other colours in this light, was still more extraordinary than in the former: inasmuch that the hole, seen through the prism, appeared uniformly of that yellow, and as distinctly terminated as through a plane glass; except that there was adjoining to it, on the upper side, a very faint streak of green and blue. White bodies illuminated with it, appeared also through the prism perfectly well defined, both which, he says, are very surprising phenomena to those who have been accustomed to the use of the prism in heterogeneous lights, where it never fails to throw confusion on the extremities of all visible objects.

Upon examining bubbles of soap and water in the same light, he could only observe luminous streaks, separated by dark ones, the green and blue being too weak to affect his eye. *Edinb. Essays*, vol. ii. p. 32.

TRANSMUTATION of Plants. See SEEDS and DEGENERATION.

TRANSOM, among *Builders*, the piece that is framed across a double light window.

TRANSOM, among *Mathematicians*, denotes the vane of a cross-staff; or a wooden member fixed across it, with a square whereon it slides, &c.

TRANSOMS, in a *Ship*, are beams and timbers extended across the stern-post of a ship, to fortify her after-part, and give it the figure most suitable to the service for which she is calculated. See SHIP-BUILDING.

The general figure or curve given to the ship by the disposition of the arms of the transoms, which are gradually closer in proportion to their distance from the wing-transom downwards, in consequence of which it becomes extremely narrow from the counter towards the keel, is called the *figh* of the transoms. Although these pieces are extremely different in their figures, according to the extent of the angles formed

formed by their branches or horns, each of them has nevertheless a double curve, which is partly vertical, and partly horizontal, with regard to its situation in the ship. The former of these is called, by the artificers, the *round-up*, and the latter the *round-aft*.

As the transoms fill up the whole space comprehended between the head of the stern-post above, and the aft-most floor-timbers below, it is necessary to distinguish them by particular names. Thus, the highest is called the *wing-transom*; the next, the *deck-transom*; and afterwards follow the first, second, and third transoms, together with the intermediate ones.

The highest transoms are connected to the ship's quarter by knees, which are bolted to those pieces, and to the after-timbers. See SLEEPERS. Falconer.

TRANSPARENCY, DIAPHANEITY, in *Physics*, a quality in certain bodies, by which they give passage to the rays of light.

The transparency of natural bodies, as glass, water, air, &c. some have imputed to the great number and size of the pores or interstices between the particles of those bodies: but this account is exceedingly defective; for the most solid and opaque body in nature, we know, contains a great deal more pores than it does matter; a great deal more, surely, than is necessary for the passage of so infinitely fine and subtle a body as light.

Aristotle, Descartes, &c. place transparency in the rectitude or straightness of the pores; by means of which, say they, the rays are enabled to make their way through without striking against the solid parts, and being reflected back again: but this account, sir Isaac Newton shews, is imperfect; the quantity of pores, in all bodies, being sufficient to transmit all the rays that fall on them, however those pores be situated with respect to each other.

The cause, then, why all bodies are not transparent, must not be ascribed to their wanting rectilinear pores; but either to the unequal density of the parts, or to the pores being filled with some foreign matters, or to their being quite empty, by means of which the rays, in passing through, undergoing a great variety of reflections and refractions, are perpetually diverted this way and that, till, at length, falling on some of the solid parts of the body, they are extinguished and absorbed.

Thus cork, paper, wood, &c. are opaque; whereas glass, diamonds, &c. are transparent: the reason is, that in the neighbourhood of parts equal in density, such as those of glass, water, diamonds, &c. are with respect to each other, the attraction being equal on every side, no reflection or refraction ensues: but the rays, which entered the first surface of the bodies, proceed, without interruption, quite through the body, those few only excepted which chance to meet with the solid parts: but in the neighbourhood of parts that differ much in density, such as the parts of wood and paper are, both in respect of themselves, and of the air, or the empty space in their pores; as the attraction will be very unequal, the reflections and refractions must be very great; and therefore the rays will not be able to make their way through such bodies, but will be properly deflected, and at last quite stopped. See OPACITY.

TRANSPARENT, we think, would be as useful a term in music, as in painting. We know that visibility and audibility are objects of two different senses; but clearness, *chiarezza*, is a favourite excellence with musicians, in speaking of counterpoint: and in compositions of many different parts carrying on different designs, that clearness in their texture and arrangement, which enables the hearer to dis-

entangle them, and to distinguish the several parts through each other, but particularly in vocal music, and to hear the principal melody through all the accompaniments, we think might with some degree of propriety be termed *transparency*.

TRANSPARENT Column. See COLUMN.

TRANSPIRATION, in *Physiology*, an expression derived from the French, for the cutaneous exhalation. See INTEGUMENTS.

TRANSPLANTATION, in *Natural Magic*, was used for a ridiculous supposed method of curing diseases by transferring them from one subject to another; and was much in vogue among certain chemical, or rather sympathetic physicians, some ages ago.

This transplantation was effected, either by the use of a certain medium, called on that account a *magnet*; or, without that, only by simple contact.

Transplantation, by means of the magnet, was of five kinds, *viz.* *infemination*, *implantation*, *imposition*, *irrotation*, and *infection*; but the whole practice is now deservedly exploded.

TRANSPLANTATION, or *Transplanting*, in *Agriculture* and *Gardening*, the operation of removing plants and trees of various kinds from the situations and places in which they were originally sown, set, or raised, and replanting them in others which are more convenient and suitable. It is practised with a great number of each of these different sorts of vegetable productions.

With the former, for field crops, it is had recourse to with many of the cabbage tribe, and some other such sorts of plants, for wheat, and lately for potatoes. The transplanting of all the different sorts of plants of the first of these kinds, should always be performed, as much as possible, when the weather is in rather a moist state, the ground having previously been put into a suitable state of preparation, by proper ploughing and other means. The plants are placed out, in such cases, at different distances, as from two to three feet or more, as the nature of the land and circumstances may direct.

In transplanting wheat plants, which is sometimes the case, it has been noticed to be a practice which is not likely to become general for whole fields, but that circumstances may not unfrequently occur where it may be attended with much benefit when employed in a partial manner; as in those cases where some accidental failures may have happened to the parts of fields, which on a careful examination may be found to have wholly misled, or to be thinner than the others. In all such instances, whatever may have been the cause of the deficiency,—whether from the wheat plants having been destroyed by wetness during the winter, or any other cause,—some parts of the same fields will mostly be found, from which plants may be drawn for this purpose, without injury; and if attention be paid to good and neat cultivation, the vacancies may be usefully filled up by transplanting from such spots, where it may sometimes happen that the plants are so thick as to do harm to each other, and, of course, service be done to the crops in such parts, while the vacant land is filling with them in other places, and by such means the whole be rendered more perfect, uniform, and regular, improving the appearance as well as the abundance of the crops.

The practice of transplanting wheat in the early spring months, in these and other cases, has long been advised by different writers, and lately had recourse to, with great success, in the parish of Bocking in Essex, to some considerable extent. It was there performed with the common dibble at the distance of twelve inches, but nine would have been preferred,

TRANSPLANTATION.

ferred, had it not been apprehended that the plants which could be collected would be insufficient.

It is thought capable of being more generally introduced with great advantage not only in the abundance of the crops and the saving of seed, but in the vast increase of employment which it furnishes for the labouring poor of different descriptions, as well as in some other respects, as may be seen in the first volume of the Corrected Agricultural Survey of the above county.

In regard to the transplanting of potatoes, it has been shewn by the trials of the Rev. Mr. Cartwright, which are described in a paper in the fifth volume of Communications to the Board of Agriculture, that there is no plant which admits of being transplanted with more complete success. It is suggested as a practice which, besides affording hints to the farmer for the improvement of the field-crops of this sort, may throw in the way of the cottager some useful information, as it may teach him, that after he has had crops of spring and early summer vegetables in his garden, he may procure from it, by being provided with a small bed of the nursery kind for potatoe plants, a valuable supply of useful food for his winter consumption and advantage.

The crops in these transplantings were after tares of the winter kind, and only top-dressed for, which is a considerable saving of manure.

In garden culture, transplanting is essentially necessary for a great variety of different plants of the esculent and other kinds, as has been seen under their different heads. And it has lately been found to be a considerable improvement in the culture of the onion, both in the garden and the field. When transplanted in moist weather into small shallow drills, eight or nine inches apart on beds, having the whole roots first well dipped in a thick puddle liquid, composed of one part foot, and three parts earth, with a sufficient quantity of water to form the mixture, they are said to succeed perfectly. It is a method too which has the advantage of being less expensive, and of course more profitable, than the common one, as the work can be cheaply done by boys or girls; it admits of clearing the plants of weeds better, which is highly beneficial to their growth; a few small beds thickly sown will furnish plants for as many acres; the ground which is to be planted may be under winter or spring crops, it being sufficient to clear it of them by the end of April, or the beginning of the following month, when the transplanting of the onions is to take place, and those contained in the seed-beds will, in the mean time, afford the necessary supplies for family use or the market. It has besides the benefit of having the onions better in quality and larger in size, and the crops wholly free from worms and the rot. See a paper on this subject in the first volume of the Memoirs of the Caledonian Horticultural Society.

With the latter, or plants of the tree-kind, transplanting is performed both for those of the forest and fruit sorts in a great number of cases. It is a practice which is much had recourse to in nursery-grounds for raising the different kinds while in their early growths, as the first two or three years. But for providing timber-wood, especially with some sorts of trees, as the oak and a few others, it is probably better not to transplant at all, as the produce is said to be firmer, more durable, and better for many uses, where it is not done. See **TIMBER**.

Though the work of transplanting be mostly practised while the trees are in this young state, it is capable of being effected, by proper management and attention, with perfect success, when they are of considerably larger growth. Mr.

Amos, in his work on "Agriculture and Planting," has observed that, as in forming various sorts of ornamental undertakings with trees, as those of extensive lawns and fields interspersedly filled with large collections of such as are of the forest kind, and flowering shrubs placed out in the wilderness manner, with serpentine walks and paths running through the whole, the designs often become defective and unsatisfactory, from the want of various sorts of proper large-sized trees: to supply the defect in such cases, plenty of different proper-sized trees should always be at command, for the purpose of transplanting into bare fields, parks, and about naked new buildings, or into other situations where they may be most capable of imitating that charming tasteful negligence of nature which is so ravishingly pleasing to the senses. And that, in order to prepare the young trees for being thus transplanted when large, they should, it is said, be continued in the *seed-beds* for the space of two years and a half, and then be set out at greater distances, reducing the tap-roots considerably, but those of the lateral kind only sparingly. That as in such young trees the root grows faster than the stem, (as an oak-plant a foot and a half in height has sometimes a root four feet in length,) the necessity of mutilating the root, especially the tap one, in such cases, is clearly shewn, the plants then emitting radicles in every direction, grow faster than if the roots had remained perfect. And that if a plant, or tree, be transplanted in this state, it succeeds with greater certainty the more absorbent radicles are preserved to the root. When such trees have remained two years in the *nursery-beds*, they should be again removed, dressing their roots as before, and increasing the distance between them, when they may continue three or four years more. After which they may be put out in collections, where they are to remain for good, or until wanted for transplanting. That as in transplanting large trees, some large fibres of the roots are unavoidably broken and mutilated, and consequently the absorption of nutriment in the plant diminished, it is necessary that boughs answering to the destroyed roots should be cut away, in order to lessen the transpiration in proportion to the quantity of food that may be taken up.

The most proper and desirable sorts of trees for transplanting in this large state, are, it is conceived, the different sorts of elms, of which the English is the best, as it is most aspiring, and soonest recovers its wounds. The lime, too, will bear to be removed at a great size, as its wounds soon heal, and it may be formed into any shape desired. The oak, the beech, and the ash, will likewise bear to be removed when rather large, but they require more care in the work than the former: on the whole, those trees, the bark of which is the thinnest and smoothest, will be the most proper for this purpose. The hornbeam, the fycamore, the large-leaved maple, the sweet and horse-chestnut, and the laburnum, will all bear transplanting and removing, if they do not exceed fifteen or sixteen years' growth, and from twenty to twenty-five feet in height: if they are older and larger when this is done, they do not recover their wounds so perfectly as to become handsome trees. The larch and mountain-ash also bear transplanting and removing when large, but they should not exceed twelve years' growth. The balsam poplar of Canada, too, is a fine plant of the tree-kind, which is raised with much ease, is hardy, quick in its growth, and will bear to be transplanted and removed at a great size. And the crab-tree and white-thorn will suffer themselves to be transplanted at a large growth, when in a healthy and growing state; and that as few trees exceed them in beauty or fragrance in the spring season, or their rich

TRANSPLANTATION.

rich glow of fruit in the autumn, they may be transplanted out singly into lawns, fields, and parks, where, when judiciously interperfed with other trees, they may highly decorate fuch situations. The elevation of ftately trees in clumps, parks, lawns, or fields, is confidered, on the whole, as having a moft agreeable effect, but that in new defigns they cannot often be had without waiting many years, and incurring much labour, difficulty, and expence. However, by means of the directions which have been given above, and the ufe of the tranfplanter for large trees, it is thought the difficulty may be greatly removed, and a figure be foon made, even in bare fields, parks, and about new-built houfes, without fuffering fuch inconveniences, which muft be a great inducement to fuch perfons as are advanced in life to have recourfe to the practice. See *TRANSPLANTER, Tree.*

In the work of preparing for the removal and tranfplanting of large tall foreft-trees, it is recommended as proper to dig a circular trench all round them two or three feet deep, as early as poffible in the fpring; by which many new roots will fhoot from thofe which have their ends cut off, and by which the balls of earth will be better held together, when the trees are removed in the fucceeding autumn; and, by their having previoufly produced fo many more fine radicles of the absorbent kind, be more certain of growing in their new fituations. After which, the firft ftep to be taken in the following autumn, is to mark out the places where the trees are to be removed and tranfplanted to, and there to dig pits three, four, five, or fix feet wide, having the depth of from twenty-four to thirty-fix inches, as the fize of the roots and balls of earth which hang about them may be. The top-foil in thefe diggings is to be thrown to the fides of the pits where the trees are to come, and the bottom or poor foil to the other fides. It this ftate the pits are to remain until the trees are nearly ready for removal, which is to be effected in this manner, and is the next ftep in the bufinefs. It is carefully to raife the trees which are to be the moft healthy, and fuch as are of the pyramidical form, with as many roots, herby fibres, and as much earth about them as poffible. This is to be accomplished by digging trenches round about them, two, three, or four feet from the bodies of the trees, as their fizes may be, and about three or four feet deep, floping them on the fides where the tranfplanter is to receive the trees. Then to bend the trees fo far to one fide, by the affiftance of ropes, that the bottom roots may be eafily got at, when they may be cut acrofs with a fharp hatchet, and the extremities smoothed, which have been fcattered, by a fharp hedging-bill, when rearing them upright again, bend them to the contrary fide, and drefs the roots in the fame way, then raife them up a fecond time, when they will be ready for tranfplanting. In which cafe, it is directed that one fet of hands, as one, two, or three men, fhould fill the pits half full of water, the top-foil and other fresh mould being mixed with it to the confiftence of a thin puddle. That another fet of men, as two, four, fix, or eight hands, as the fizes of the trees may be, fhould rear up the tranfplanter of the trees againft them by means of the rope for the purpofe, balancing them properly by the machine, and leaving the fore-carriage part of it upon the ground, taking care to furround the places well with ftraw, where they reft upon the bars and bolts, in order to prevent the bark from being galled and rubbed off, which would greatly injure the trees. The whole fhould then be pulled and brought down together, in a gentle manner, by the rope for the purpofe; three or four men and a horfe being employed in the bufinefs, where neceffary, ftayding well the motion downwards, and at the

fame time a man or two are to guide the bolt of the machine into the fore-carriage, into which the horfes are then to be put, and the trees conveyed to the pits, which by this time will be ready for their reception. The carriage is then to be drawn up along that fide of the pits on which the top-foil was laid, backing it until it gets into fuch a pofition, that by rearing the machine and trees upright, as in loading, the root parts with the balls of earth about them, may be dropped exactly into the centres of the pits, amidft the puddle, which will fo run among and into the cavities of the balls hanging to the roots, as to furround and cover every fibre. The pits are then to be filled completely up, and a mound of earth raifed about a foot higher than the furface all round each of the trees to two or three feet diftant from the centres, hollowing it towards the trees, for the better reception and retention of moifture. After this, it is fuppofed the trees will be able to brave and defy the rudeft affaults of the winds, without any fupports, even at the firft tranfplanting out. In this manner, the whole bufinefs of tranfplanting large foreft-trees is to be proceeded in, and which has been found very fucceffful in a variety of trials.

In garden management, too, large old fruit-trees of both the wall, efpalier, and ftandard kinds have lately been found capable of being tranfplanted with great fuccefs and advantage, when performed fomewhat in this fimple manner. When for large wall-trees, it is to be done by forming a half-circle for each in extent equal to the fize of the trees, as feven or eight feet for fuch as cover a large fpace, meafuring from the trunks of them; digging a trench round that three feet in width, and fix inches below the roots, carefully preferving the whole, and working out the earth from among them with a blunt tool, and cafting out the loofe mould by the fpade. Proceeding thus until got fully under the trees to be raifed. The roots are then to be tied loofely together, and the branches freed from the walls, and put in parcels to prevent their being injured. The trees are now to be conveyed to the places into which they are to be tranfplanted; where proper-fized pits, for allowing the roots to be fpread out and extended, are to be provided, placing them upright in them, uſing fresh earth alone or mixed with dung, and difpofing them, fo as that the furface roots may be equal with the top of the border in which they are put; then packing in the well-broken earth underneath, and for about a foot round the bottoms of the trunks, to fill all vacancies where the roots proceed from. After which, the whole of the perfect roots are to be attentively fpread out at full length, cutting off any dead, bruifed, or knotty parts; the ends of the remaining ones being smoothed and preferved at different lengths, keeping fome at full length, others at five, four, and three feet, and a few even at one foot long, taking care to fave as many of the fmall fibres attached to the leading roots as poffible; beginning by laying the whole out in fets or layers from the bottom at the wall-fide of the half-circle, in the fan manner, until the top be reached, arranging the fmall fibres in regular order, and covering the different layers of roots with two or three inches in thicknefs of mould, packing it in well by the hand, and never fetting the foot on the roots which have been covered. Proceeding in this way with each fide of the half-circle, until they meet in the middle part of it, raifing the whole with earth to the height of two inches above the level of the border; and above all applying three inches thick of good rotten dung. A full watering is then to be given, to fettle the earth about the roots. Boards are to be laid to prevent the roots being trodden upon in nail-

ing up the trees, the principal branches being only first secured, the whole being completed when the ground has fully settled.

The transplanting of espalier and standard trees only differs in this, that a full circle is to be dug round them.

The most proper seasons for transplanting large fruit-trees, are either in the beginning of the autumn, or just before the spring, in mild weather.

A great number of such large trees has been transplanted in this manner with complete success, some of which have borne half crops the first year afterwards, and others more, the fruit in most cases being greatly improved, as may be fully seen by consulting different papers on the subject in the volume of Horticultural Transactions already noticed.

For fruit-grounds, the young stocks for apple-tree plants are mostly in a proper state for transplanting out the second or third year of their growth. See STOCKS, APPLE, &c.

The transplantation of the blossom-buds of fruit and other trees has lately also been tried, by transferring the abundant buds of this sort, of one tree to the barren branches of others, which is said to be capable of being performed with facility, and perhaps considerable advantage, in some cases. Such buds of pear-trees, when inserted into the strong young shoots of old ones, may afford abundant crops of very fine pears, and be gained with little trouble. The buds of those pear-trees are the best which have been formed upon the bases of the abortive bunches of blossoms of the preceding year; and that, instead of taking out the wood of the bud wholly, as is usual, it is most advantageous to let it remain in small quantities, only paring it very thin. See a Paper in the London Horticultural Transactions, vol. ii.

TRANSPLANTATION of *Flower-Plants*, among *Florists*, the means of putting out and managing the different sorts of young plants of this kind. Work of this sort should always be performed according to the particular nature and habits of growth of the several kinds of these plants. In the auricula, the polyanthus, and different other similar kinds, the transplanting is often done early in the spring season by some; while others perform it annually about the beginning of the autumnal season, especially for the first of these sorts; but probably the most suitable period is that about the beginning of the first of the above seasons, when the weather is rather showery, though it may often be performed later with good success. Those plants designed for very strong blooming, should, however, never be transplanted, either early in the spring or too late in the summer, as they always require to get well-rooted before the winter season sets in. But notwithstanding the young offsets and other plants are to be transplanted in the above manner into their small pots, the large strong-blowing roots are not to be transplanted or removed more frequently than once in every two or three years, as the risk of having fine strong flowers is otherwise very great, as plants of this sort never thrive in a right manner, until their roots have reached the sides of the pots, which rarely happens in so short a time as twelve months; but a difference is to be made, in performing this sort of work, between the plants which throw out suckers or offsets in great abundance, and such as do not; as the former require more frequent transplanting, all or most of such parts being carefully pared off and removed at the time; while in the latter it need not be so often. Where plants of strong superior bloom for increase are wanted, it is of material consequence to keep all such suckers and offsets from growing on the stocks of the old plants *without* fibres, they being kept constantly well rubbed off while of very small

fizes, but those that rise from below the surface of the earth need not be so much regarded.

It is thought by some, that the large healthy strong blooming plants of this sort need not be removed or transplanted, and have the earth shaken wholly from their roots every year, as is the usual practice; as they have been found to do better without, by having occasional fresh earthings without removing them from the pots in some late trials. They should not, however, remain longer in this way than the third year. Florists in general have, it is supposed, been too fond of frequently transplanting or removing the large blooming plants of this sort, as once in two, or not more than three years, will be found sufficient, and more beneficial. The plants of this large blooming kind are not by any means to be transplanted or removed in dry hot times, as by shaking the mould cleanly from the roots of the plants, fresh fibres will not be freely drawn, unless the season be inclined to be showery, and there be what is termed a cool moist state of the air. Fine young maiden plants may, however, sometimes be transplanted into small pots in such dry weather, being slipped out of the pots with the whole balls of earth about them, and then immediately replanted in full-sized blooming pots for the ensuing season. In short, in transplanting these as well as many other sorts of flower-plants, much must always depend upon the state and condition in which the plants are found.

Where the plants of this kind have not been transplanted for some length of time, as two or three years, the small roots having filled the pots, the large, the tap, or the carrot root, as it is often termed, may have become so long as to stand in need of shortening by taking it out of the pot, shaking the earth away from it, and doing what is necessary, as by remaining too long it either gets rotten at the end, and constantly keeps the plant weak, or becomes too long for a common pot; besides, it wants shifting or transplanting every year, and never produces fine strong flowers. The small roots are to be reduced to about a dozen, those nearest the leaves being left for supporting the plants. Where there is any canker or rottenness in the root, it is to be cut to the quick or quite sound parts, and the wounded part secured by the use of a composition made of bees-wax, turpentine, and white resin, and be made to crust over by exposure to the sun. Where large blooming or other plants of this sort to be removed have been in the pots only one year since the last transplanting, they are to be slipped out of the pots, with all the earth about them; and as the roots will be small and but little matted, it need not be shaken from them, only cutting it and the fibres of the roots down to a small ball in each plant, according to their ages and sizes. Some, however, do not like this method, but remove all the earth in transplanting them.

Different other fine flower-plants are to be managed somewhat in the manner which has been thus laid down in transplanting them, as the differences of their nature and habits may direct, only they will, for the most part, seldom require so many transplantations; indeed once or twice will almost always be as many as are necessary for them.

TRANSPLANTED or *Ground Onion*, in *Gardening*, a new sort of root of this kind lately brought from Egypt, and introduced into the northern parts of this island by Mr. J. Burn, captain in the royal navy, whence it is sometimes called by that name.

The manner of its cultivation, uses, and advantages, are thus described in a paper in the Scotch Horticultural Memoirs. The roots, being separated from the branches in which they grow, should be put out or transplanted into
any

any ground that is considered suitable for the common root of this sort, the soil being first well prepared and enriched by the use of horse-dung in a reduced state; the plants or roots are then to be covered with only about one inch in depth of earth. The best and most proper time for the putting them out or transplanting them is during the month of April. They should be put about a foot or eighteen inches asunder. They grow and are produced in clusters, somewhat in the manner of the bunches of grapes or currants; some growing in a round, others in a conical form or shape; those on the surface being the largest, while those in the centre are usually the soonest ripe. It is necessary that they should be taken up as they ripen, and when they are intended for keeping, they may be taken up rather before they are completely ripe.

It was found that two roots, the tops of which had begun to decay in the beginning of August, and which had been raised from the ground in the beginning of the following month, produced, in one case, nine onions, and in the other twelve. The onions in these cases were of very different sizes, but the whole, when taken together, weighed more than a pound. Twenty-three onions of this sort, when planted out, are however said, in another instance, to have produced upwards of six hundred fine plants at the same time.

The circumstance in which this sort chiefly differs from the common Deptford and Strasburgh seed-kinds is, that it is larger, as in taste the quality is much the same. But it has, it is said, a material advantage over the feed-onion in this particular, that if planted about the middle of April, it will be fully ripe about the same time in the following September. Besides, it is not liable to accidents from any badness, imperfection, or too moist or too dry seasons, as is often the case in the common feed-onion. Another great advantage the transplanted or ground onion has over the seed sort is, that no instance has yet occurred where it has been injured by vermin or insects, which is frequently the case with the feed-kind.

This sort of onion would seem on several accounts to deserve further attention to its cultivation and growth in this very uncertain climate for the common crops of such roots.

TRANSPLANTER, TREE, in *Agriculture and Gardening*, a machine or contrivance constructed for the purpose of assisting and facilitating the means of transplanting and removing trees of large growths and sizes.

A very simple and useful contrivance or machine of this kind has been given by Mr. Amos in his practical work on "Agriculture and Planting," with a correct representation of the same. It is simply composed of the two hind and the two fore-wheels and carriage part of a farm-waggon, with a platform, and diagonal frame raised and erected upon them so as to be capable of receiving the tree, and of retaining it in a firm, steady position, until it be conveyed to the place where it is wanted to be replanted, when it can be let down with great ease and readiness into the hole where it is to be set and grow.

Much facility and dispatch are given in replanting large trees by machinery of this kind for ornament or other uses. See **TRANSPLANTATION**.

TRANSPORT-SHIP, is a vessel used to convey provisions, warlike stores, soldiers, &c. from one place to another; also convicts over the seas.

TRANSPORTATION, the act of conveying or carrying a thing from one place or country to another.

In matters of commerce, transportation is of equal import with re-exportation, *viz.* the taking up of commodities in

one foreign state or kingdom, bringing them hither, and paying duties for them; and then conveying them into some other foreign state: by which it is distinguished from importation and exportation; where the commodities are either carried originally out of, or brought finally into, our own kingdom.

TRANSPORTATION, in *Law*, is also a kind of punishment, or, more properly, an alleviation or commutation of punishment, for criminals convicted of felony; who, for the first offence, unless it be an extraordinary one, are ordinarily transported to some foreign country for a term of years, or for life; within which, if they return, they are executed without farther trial than ascertaining their identity.

This is made felony without benefit of clergy by statutes 4 Geo. I. cap. 11. 6 Geo. I. cap. 23. 16 Geo. II. cap. 15. and 8 Geo. III. cap. 15; as is also the assisting transports to escape from such as are conveying them to the port of transportation.

Exile and transportation are punishments at present unknown to the common law; and whenever the latter is now inflicted, it is either by the choice of the criminal himself, to escape a capital punishment, or else by the express direction of some modern act of parliament. Accordingly, it was enacted by the statutes 4 Geo. I. cap. 11, and 6 Geo. I. cap. 23, that when any persons shall be convicted of any larceny or felony, who by the law shall be entitled to the benefit of clergy, and liable only to the penalties of burning in the hand or whipping, the court in their discretion, instead of such burning in the hand or whipping, may direct such offenders to be transported to America (or, by statute 19 Geo. III. cap. 74, to any other parts beyond the seas) for seven years. And by the subsequent statutes 16 Geo. II. cap. 15, and 8 Geo. III. cap. 15, many wise provisions are made for the more speedy and effectual execution of the laws relating to transportation, and the conviction of such as transgress them. But now, by the statute 19 Geo. III. cap. 74, all offenders liable to transportation may, in lieu thereof, at the discretion of the judges, be employed, if males (except in the case of petty larceny) in hard labour for the benefit of some public navigation; or, whether males or females, may, in all cases, be confined to hard labour in certain penitentiary houses, to be erected by virtue of the said act, for the several terms therein specified, but in no case exceeding seven years; with a power of subsequent mitigation, and even of reward, in case of their good behaviour: but if they escape and are retaken, for the first time an addition of three years is made to the term of their confinement; and a second escape is felony without benefit of clergy.

Transportation is said to have been first inflicted as a punishment by 39 Eliz. cap. 4. Blackst. Com. vol. iv.

TRANSPORTATION of Plants, is the removal of them from one country to another: with respect to which great caution is necessary. The plants sent from a hotter country to a colder should be transported in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter should be sent in the beginning of winter.

The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles, and holes bored in their bottoms to let out the moisture, filling them with earth, and planting the roots as close together as may be: the plants should be set in these boxes a fortnight or three weeks before they are to be put on board, and in good weather they

they should be set upon the deck, and in bad removed or covered with a tarpaulin.

If they are going from a hotter country to a colder one, they must have very little moisture; if, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

Very many plants, however, will live out of the earth a great while; as the sedums, euphorbiums, ficoides, and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored in the boxes, to keep them from heating and putrefying. In this manner they will come safe from a voyage of two or three, or even four or five months.

Several trees also will come safely in the same manner, taking them up at a season when they have done growing, and packing them up with moss. Of this sort are oranges, olives, capers, jasmines, and pomegranate-trees. These, and many others, are annually brought over thus from Italy; and though they are three or four months in the passage, seldom miscarry. And the best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. Miller. See SEED.

Those who are desirous of particular instructions with regard to the best means of collecting both seeds and plants in distant countries, and of preserving them during a voyage hither in a vegetating state, may consult Mr. Ellis's Directions for bringing over Seeds and Plants from the East Indies, and other distant Countries, in a State of Vegetation, &c. 4to. 1770.

TRANSPORTING, in *Sea Language*, the act of removing a ship from one place to another, by the help of anchors and ropes. See WARP.

TRANSPOSITION, in *Algebra*, the bringing any term of an equation over to the other side.

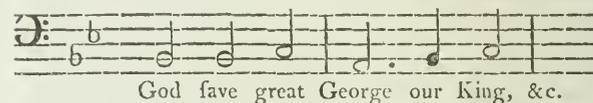

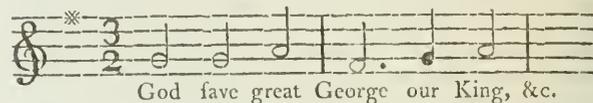

Thus, if $a + b = c$, and you may make $a = c - b$; b is said to be transposed. See REDUCTION of Equations.

TRANSPOSITION, in *Grammar*, a disturbing or dislocating of the words in a discourse; or a changing of their natural order of construction, to please the ear, by rendering the contexture more easy, smooth, and harmonious. A transposition, which renders the sense perplexed, is vicious. The construction of the ancient languages, being much more artful than that of the modern ones, allowed of much greater, and more frequent transpositions. The English, French, &c. scarcely ever allow of them but in oratory and poetry; in which cases, they serve to give a force and energy to the discourse, or the verse, and to prevent their languishing.

TRANSPOSITION, in *Music*. We will venture to say, from long experience, that no musician can transpose at sight, with certainty and firmness, but by a perfect knowledge of all the clefs necessary to change any one of the seven notes in music to any other we please. (See CLEFS.) This was Dr. Pepusch's method of teaching transposition, though not very clearly explained in his treatise; and Mr. Galliard's method, which he has made perfectly intelligible by a plate, in his translation of Tosi. Cerone, in 1614, seems to have been the inventor of this method. See CERONE.

The transposer, besides changing the notes higher or lower by imaginary clefs, without changing their original places on the staff, must likewise know what sharps and flats belong to every key. If, for instance, we wanted to transpose our national supplication of "God save great George

our King!" from G natural to E \flat , a major third lower, we have only to imagine a clef that will make the second line E, which is the soprano, or tenor clef, on the first line. If, again, a singer wished to have this favourite air a third higher than G, which is B \flat , the bass clef with two flats will render all the notes, which with the treble clef were in G, a minor third higher.

Now to render G on the fourth space in the bass E \flat , we have only to suppose the treble clef in the accompaniment instead of the bass. And to render the fourth space B \flat instead of G natural, we have only to imagine the bass clef on the third line with two flats, instead of the fourth with one sharp.

TRANS-RART, in *Geography*, a town of Algiers, near the coast of the Mediterranean, on a gulf called the Immisea; 30 miles S.W. of Oran.

TRANSTRAND, a town of Sweden, in Dalecarlia; 80 miles N.W. of Fahlun.

TRANSTRUM, in the *Naval Architecture of the Ancients*, a term used to express a sort of cross or transverse seats that were placed in the polycrote galleys of those times, and served for the places of several of the rows of men, who could move and work their oars under the seats of the other or lateral rowers of the next tier.

Meibomius, who has written expressly on the naval architecture of the ancients, has better understood the places and use of these transtra, than any other author of late times; by a proper arrangement of these seats, and the lateral ones above and below each, he has taken off greatly from the height allowed by Scaliger, and others, to the polycrote vessels.

TRANSUBSTANTIATION, TRANSUBSTANTIATIO, in the *Roman Theology*, the supposed conversion or change of the substance of the bread and wine, in the eucharist, into the body and blood of Jesus Christ.

Transubstantiation, taken in its general and literal sense, implies any change of one substance into another. Thus, the change of Moses's rod into a serpent; of the waters of the Nile into blood; of Lot's wife into a pillar of salt; were preternatural transubstantiations: and the change of the food we eat into the substance of our bodies, is a natural transubstantiation.

But the word, in its proper and technical sense, is restrained to the miraculous change which the Romish church holds is wrought in the sacrament, by the consecration of the priest.

One of the great articles of that church, rejected by the reformed, is that of transubstantiation; the latter maintaining the transubstantiation to be only figurative, and the former affirming it to be real.

The reformed interpret *est, is*, in the text *Hoc est corpus meum, This is my body*, by *significat*, q. d. *This signifies my body*:

body: but the council of Trent stand up strenuously for the literal sense of the verb. Thus, in can. 1. sess. 13. of that council, it is expressly decreed, that, in transubstantiation, the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine.

It is added, that by *truly*, we mean *properly*; and not only by signification, as if the eucharist were no more than a sign of the body and blood of Jesus Christ: that by *really*, we mean *in fact*, and not only in figure, as if the eucharist were only a figure and representation of the body and blood of the Saviour of the world; and that by *substantially*, we mean *in substance*, and not only in virtue and energy. Thus is *truly* opposed to a simple sign, *really* to a figure, and *substantially* to energy or virtue.

This doctrine was established in the fourth general Lateran council, under pope Innocent III., in 1215, who is said to have introduced and established the use of the term transubstantiation, which was hitherto absolutely unknown; though some say that Stephen, bishop of Autun, first used this term. Burnet on the Articles, p. 312.

It was principally owing to the authority of Lanfranc, the principal champion of this new doctrine against Berengarius, supported by Rome, that so strange a tenet was established in the eleventh century, both in England and France. At the beginning of this century it was unknown to the church of England, as is incontrovertibly proved by the epistles and canons of Ælfric, archbishop of Canterbury, and by the prayers and homilies used at that time.

It seems difficult, at first sight, to account for the zeal of the see of Rome in advancing and propagating a doctrine so full of absurdity as that of transubstantiation. What use, it may be said, could there be in understanding a figurative expression (with which manner of speaking the Scripture so much abounds) according to the letter, which makes it nonsense; when that nonsense does not appear to be productive either of power or profit to the church? The supremacy and infallibility of the bishops of Rome; the doctrine of purgatory, masses, and prayers for the dead; the worship of saints and images; the celibacy of the clergy; the merit of monastic vows; the necessity of confession to, and absolution by a priest, for the remission of sins; the power of the pope to grant indulgences, and apply to the benefit of other men the works of supererogation done by saints, and therefore belonging to the treasury of the church: all these opinions have a clear and evident tendency to raise and support the dominion and wealth of the Roman see and the clergy: whereas the multiplied contradictions and impossibilities contained in the notion of transubstantiation, seem to serve no purpose, but to expose the Christian faith to the ridicule and contempt of the Jews and Mahometans, or other unbelievers. Nevertheless, the solution of this difficulty may be found in the words of pope Paschal II. viz. "That it was a most execrable thing, that those hands, which had received such eminent power above what had been granted to the angels themselves, as, by their ministry to create God the creator of all, and offer up the same God, before the face of God the Father, for the redemption and salvation of the whole world, should descend to such ignominy, as to be put, in sign of subjection, in the hands of princes, &c."

The same words were also used by pope Urban II. at the council of Bari. And certainly nothing could so raise the idea of the priesthood, or produce such veneration for them in the minds of the people, as their being supposed to possess this more than angelical power. Lyttelton's Hist. of King Henry II., vol. i.

TRANSUBSTANTIATION, *Declaration against*. See DECLARATION.

TRANSVERSALIS COLLI, *transversaire grêle*, in *Anatomy*, a small narrow muscle, placed at the lower and lateral part of the neck, and upper part of the back, where it extends from the transverse processes of the five or six lower cervical vertebræ, to the corresponding processes of four or five dorsal vertebræ after the second. The splenius, levator scapulæ, sacrolumbalis, and longissimus dorsi, cover it behind, where it is inseparably connected to the two latter: it lies upon the trachelo-mastoideus, to which it is also intimately connected, the complexus, and multifidus spinæ. The front edge of the muscle is attached to the cervical transverse processes already mentioned: it passes over those of the two first dorsal vertebræ, and is then attached to the transverse processes of the four or five following ones. These attachments are effected by slender tendons, connected with those of the splenius, levator scapulæ, and multifidus spinæ. It will extend the neck on the back; or, if the muscle of one side acts separately, it will incline the neck to its own side.

TRANSVERSE, something that goes across another from corner to corner.

Thus bends and bars, in heraldry, are transverse pieces, or bearings: the diagonals of a parallelogram, or a square, are transverse lines.

Lines which make interfections with perpendiculars, are also called oblique or transverse lines.

TRANSVERSE *Axis*, or *Diameter*, called also the *first* or *principal axis*. See AXIS, DIAMETER, and LATUS-*Transversum*.

The transverse axis of an ellipsis is the longer axis, or that which transverses it lengthwise, in contradistinction from the conjugate one. See CONIC *Sections*, and ELLIPSE.

For the transverse axis of the hyperbola, see CONIC *Sections*, and HYPERBOLA.

TRANSVERSO-SPINALIS, in *Anatomy*, a name sometimes given to the multifidus spinæ. See MULTIFIDUS.

TRANSVERSUS ABDOMINIS, a broad muscle of the abdomen. See OBLIQUUS.

TRANSVERSUS *Nasi*, a synonyme of the constrictor narium. See NOSE.

TRANSVERSUS *Pedis*, *transversal des orteils*, a small muscle lying across the foot, immediately under the heads of the metatarsal bones, and extending from the four last of these bones to the first phalanx of the great toe. It is thin and fleshy; covered above by the metatarsal bones and interossei muscles, and covering below the flexor tendons, arteries and nerves of the toes. It arises from the heads of the four last metatarsal bones, and is inserted, together with the tendon of the adductor pollicis pedis, in the outside of the basis of the first phalanx of the great toe. It will approximate the great toe to the others; and by drawing the toes together, from side to side, will render the foot concave.

TRANSVERSUS *Perinei*, } two muscles of the pe-
TRANSVERSUS *Perinei Alter*, } rineum, of which the
former is connected to the end of the large intestine. See INTESTINE.

TRANSUM, in *Gunnery*, is a piece of wood which goes across the cheeks of a gun-carriage, or of a gun, to keep them fixed together: each transum in a carriage is strengthened by a bolt of iron. See CARRIAGE.

TRANSUMPTION, TRANSUMPTIO, in the *Schools*, a syllogism by concession or agreement, used where a question proposed is transferred to another, with this condition, that the proof of this latter shall be admitted for a proof of the former.

Thus

Thus Aristotle, in his book *De Cælo*, undertaking to shew, that all the stars are round, transfers the question to the moon, and proves her rotundity from her increasing and waning; supposing it a thing admitted by his opponents, that the stars are all alike.

TRANSYLVANIA, *Principality of*, in *Geography*, a country of Europe, bounded on the N. by Hungary, Poland, and Moldavia; on the E. by Moldavia; on the S. by Walachia and the bannat of Temeswar; and on the W. by Hungary. The form is nearly oval, about 400 miles in circumference. It is surrounded on all sides by lofty mountains, and is itself mountainous and woody; the mountains run from N. to S., and branch off likewise E. and W., and terminate at the centre, in hills covered with vineyards, and abundant in minerals. The air is generally warm, but more wholesome than that of Hungary; the soil is fertile, abounding in corn; flax of a very good quality, which is manufactured into linen; wine, cattle, and rich pastures: among the minerals are gold, silver, copper, iron, quicksilver, cinabar, antimony, sulphur, vitriol, rock-salt, salt-petre, ochre, &c. The principal quadrupeds are buffaloes, horses, wild asses, elks, bears, wild boars, linxes, chamois, martens, ermines, and beavers. The inhabitants are composed of different nations: Hungarians, Sikli or Scythian Huns, Saxons, Walachians, Armenians, Rascians, Bulgarians, and Greeks; to which may be added Jews and Cingars, who live in tents, and lead a vagabond life like gypsies. This country is by the Germans called *Siebenbergen*, and by the Hungarians *Erdely*. It was anciently a part of Dacia; and, conquered by Trajan, it became a Roman province. It afterwards fell into the hands of the Goths, Huns, and afterwards the Hungarians. In the year 1004, it was first made a province of Hungary, and continued under the government of a waiwode to the year 1526, when two rival princes contended for this principality; one of them was supported by the German emperor, and the other by the Turks; whereupon this country became the seat of war for many years. The princes of the house of Ragotski were at the head of the Protestant faction, and supported by the Turks, but being at length obliged to quit Transylvania by the Austrians, Ragotski fled for refuge into Turkey; and at the treaty of Carlowitz in 1699, this country was confirmed to the house of Austria by the Turks. The government of Transylvania is wholly different from that of Hungary; and, by the joint consent of prince and people, formed into an aristocratical government; and, since the year 1722, rendered hereditary to the princes and princesses of the house of Austria. Formerly the prince of Transylvania succeeded to the government by free election, but since the year 1722 by inheritance; and though his power is connected with that of the king of Hungary, and archduke of Austria, yet his government and privileges differ from both. The states of Transylvania, with respect to the number of its nations, are divided into Hungarians, Siculi, and Saxons; with respect to its different religions, into Catholics, Calvinists, and Lutherans; and formerly, also, into Unitarians: but, politically, after the example of Hungary, into prelates, nobility, gentry, and royal towns. The magnates consist of the great officers of state, the counts and barons. The gentry are Hungarians and Siculi, but the royal towns Saxons only. The nobility are generally very proud, and keep their peasantry in a state of slavery; four out of six days in the week the peasant is obliged to labour for his master, having only the remaining two days for himself. The principality of Transylvania is governed in the name of the prince and nobility, by the diet,

the office of state, the royal government, the exchequer, the assembly of Hungarian counts, the tribunals of justice, and the magistrates of the Siculi and Saxons. The diets meet by summons from the prince at Hermanstadt. The revenue arises from the contributions, customs, metals, minerals, rock-salt, royal demesnes, escheats, and confiscations; and are levied by the treasury. This province pays to the emperor in taxes of all kinds 1,500,000 florins annually, which is chiefly imposed upon the land, for the payment of the citizens is very trifling. Transylvania formerly could bring from 80,000 to 90,000 soldiers into the field; but at present the whole force of that principality consists of six regiments, under a commander-in-chief, for the defence of the country.

TRANTERY, in some *Customs*, denotes the money arising by amerciements of ale-sellers and victuallers for breaking the assize of bread and ale; particularly at Lufston, and other manors in Herefordshire.

TRAP, in *Geography*, a town of Maryland; 7 miles S.E. of Oxford.—Also, a town of Maryland; 7 miles S.W. of Salisbury.

TRAP, in *Geology*, a class or family of rocks, characterized by the tendency to assume a columnar shape, or to divide into steps forming natural terraces. The name is originally derived from the Swedish word *trappa*, a step. It was called by Wallerius *corneus trapezicus*.

Rocks of the trap family are very extensively spread over the globe, and no question in geology has excited greater attention than that respecting the mode of their formation. The near resemblance which many of these rocks bear to compact lava, the remarkable position in which they frequently occur, the regularity of their structure, and the changes which the rocks in their vicinity have evidently undergone, induce many geologists to ascribe to them an igneous origin; other geologists strenuously contend, that all trap-rocks have been originally formed by depositions from an aqueous fluid. Before detailing the facts in favour of these different hypotheses, it will be proper to describe the rocks which are comprised in the trap-formation. The earlier geologists have frequently applied the term trap indefinitely to a great variety of rocks, and the distinction made between trap and the rocks which the French mineralogists have denominated *cornéene*, is extremely vague.

The *roche de corne*, so frequently mentioned by Sauffure, according to Brongniart is a trap-rock in the Wernerian acceptance of the term. Werner, according to Mr. Jameson, restricts the term trap to rocks principally characterized by the presence of hornblende and black iron-clay; yet the same author informs us, in the following paragraph, that in the oldest or primitive trap, no iron-clay whatever occurs. Jameson's *Mineralogy*, vol. ii. p. 129.

The presence of hornblende and felspar, or augite and felspar, would have formed a more accurate and comprehensive definition of the constituents of trap-rocks, or of those rocks which are comprised by Werner in the trap-formation.

M. le Cordier, in an interesting memoir presented to the National Institute in 1815, asserts, that in the trap-rocks which are supposed to be of igneous origin, and in volcanic rocks, hornblende is extremely rare, but its place is supplied by augite, which has been mistaken for hornblende. The constituent parts of these two minerals are the same, and the proportions in which they combine do not greatly vary, so that considerable doubt has existed whether they should not be classed as the same species,

notwith-

TRAP.

notwithstanding the difference of their crystallization. Be this as it may, we consider it to be a question yet undecided, whether augite (*pyroxene* of Haüy) is confined to rocks of undoubted igneous origin, though Cordier, in the memoir before alluded to, has proved that this mineral is a constituent part of a considerable number of lavas, and of many rocks denominated trap; and we know that this opinion is further confirmed by the extensive observations of that eminent geologist Von Buch.

The classification of trap-rocks adopted by Werner having been extensively admitted, we shall endeavour to state it as concisely as is consistent with perspicuity. He divides trap-rocks into three formations: primitive trap, transition trap, and the newest flötz trap.

Primitive trap is almost always distinguished by a great predominance of hornblende, so that some of these rocks are entirely composed of this mineral, or nearly so. There are three principal species of primitive trap; common hornblende-rock, hornblende mixed with felspar, and hornblende mixed with mica.

Common hornblende-rock is principally composed of hornblende: it contains two subordinate kinds, granular hornblende-rock and hornblende-slate; the latter differs from the first in having a slaty structure. Hornblende-slate passes sometimes into gneiss, and sometimes into talcous slate. (See GNEISS, and TALCOUS SLATE.) These two kinds of hornblende-rock occur in gneiss and mica-slate, forming beds which are but few in number, and of inconsiderable magnitude; but in clay-slate they occur frequently, and in very thick beds.

Hornblende mixed with felspar. This species Werner divides into two subordinate kinds; greenstone and greenstone-slate. The term greenstone (*grunstein*, German) is used by Werner to denote a rock composed of crystals of felspar and hornblende, and nearly resembling sienite (see SIENITE); but in greenstone the hornblende generally predominates, and the felspar is commonly white, whereas in sienite it is red. When the greenstone includes large crystals of felspar, it is denominated porphyritic greenstone. When the granular basis is very fine, it is called greenstone porphyry. According to Mr. Jamefon, this is the black porphyry of the ancients. When the granular nature of the base is no longer visible to the naked eye, it has a blackish green colour, and includes crystals of compact felspar. It is the *porphyre verte*, or antique green porphyry of sculptors.

Greenstone-slate is composed of hornblende and compact felspar, and has a distinct slaty structure. The felspar is generally more abundant than the hornblende, and it sometimes contains scales of mica. It occurs in great beds and masses in clay-slate.

Hornblende mixed with mica is the third species of primitive trap: it is composed of an intimate intermixture of hornblende and felspar, and includes scales of mica. It occurs in beds in gneiss and mica-slate. Jamefon's Mineral. vol. iii.

Transition trap is divided into transition greenstone and transition amygdaloid; but it does not appear that these rocks have any very distinct character to distinguish them from the greenstone and amygdaloid of the other trap-formations. According to Mr. Jamefon, transition greenstone is a fine granular mixture of hornblende and felspar; but some of the primitive and flötz greenstones are also described by the same geologist as being finely granular. Transition amygdaloid is stated to have a base of wacke, (see WACKE,) and approaches more or less to the nature of greenstone, sometimes inclining to basalt, and sometimes to iron-clay.

The vesicles are filled with clay, or with chalcedony and agate: it alternates with transition lime-stone.

The newest flötz trap-rocks of Werner comprise greenstone, basalt, wacke, porphyry-slate or clink-stone porphyry, trap-tuff, greystone, amygdaloid, with compact felspar and clay-stone. He also includes pearl-stone, pitch-stone, obsidian, and pumice in this formation of trap. (See the various articles here enumerated.) It is these rocks, which Werner calls the newest flötz trap, that present the strongest indications of their igneous origin; and some of the substances here enumerated, such as obsidian and pumice, are now generally classed with volcanic products.

Some geologists are of opinion, that there is no foundation in nature for the division of trap-rocks into three distinct formations, introduced by Werner.

There are, however, certain peculiarities of position, which seem to indicate a difference in the mode of formation between the trap-rocks that occur imbedded in other rocks, and those which cover the secondary strata. To form a more distinct idea of this, we must refer to the general structure of the surface of the globe. The beds of rock which form the crust of the globe, are commonly arranged over each other in what is denominated a conformable position, as represented *Plate II. Geology, fig. 6.* where G is the foundation, or lowest rock, on which the different beds *a, b, c,* and *d* are laid, and may be supposed to cover the mountain with a general conformity to the shape of the lower rock. This is more distinctly seen in the same plate (*fig. 3.*), where the upper beds have the same elevations, depressions, and undulations as those of the lower. The other position in which rocks occur, is called unconformable. "If a thick stream of lava, as frequently happens, were to flow over a range of conformable rocks, filling up the cavities and inequalities of the surface, when it hardens by cooling, it would form a bed of *superincumbent unconformable rock.* Such instances are common in volcanic countries. Very extensive ranges of rocks occur in this position in various parts of the world, covering not only the primary, but the secondary rocks. These unconformable rocks, composed of different kinds of trap, porphyry, and sienite, frequently assume the columnar structure, and form vast ranges of natural pillars, as at Staffa and many of the Hebrides, on the northern coast of Ireland, and in Iceland, Sicily, and various volcanic countries. Now whatever theory we adopt respecting the formation of unconformable rocks in this position, we must admit that they are of more recent origin than the rocks which they cover; the lower rocks must have been hard and unyielding, when the upper were thrown upon them." Bakewell's Introduction to Geology.

The unconformable position of basaltic rocks, or rocks of the trap-formation, is represented *Plate IV. Geology, fig. 2.* *a, a, a,* being a series of regularly stratified rocks, covered by a mass of unconformable basalt, *b b.* The trap in this position is often divided into distinct beds, some of which are columnar, as represented at *c c,* and these columnar beds are frequently separated by beds of compact trap.

Masses of trap also occur, forming perpendicular walls (called *dykes* in the northern part of England): these intersect the strata and frequently change their position, as represented *Plate II. Geology, fig. 8.* where a series of strata *a, b, c, d, e, f, g,* which were once continuous, are broken by a dyke of basalt. The similar letters on each side of the dyke represent the same stratum, as *d d, e e,* broken by the intervention of the basalt. In such instances, the strata in the immediate vicinity of the basalt have undergone a considerable degree of change; and where the stratum *c c* is coal, it is frequently found converted into

coak, or charred for some distance on each side of the basalt. These walls or dykes of trap are sometimes twenty, thirty, or even a hundred yards or more in thickness, and sometimes range along through very extensive districts: indeed there is reason to believe that many mountains of trap which are arranged in one line along a country, have been originally dykes of enormous magnitude, through which valleys have been excavated by diluvial currents, by partial subsidence, and by other agents which have in former ages changed the surface of our present continents. See VEINS, *Mineral*.

Independently of theoretical opinions respecting the formation of trap-rocks, it is obvious that the masses of unconformable overlying trap, and also the trap or whin-stone in dykes, must be of posterior date to the rocks which they cover or intersect; whereas the hornblende-rock or primitive trap which is imbedded in gneiss, mica-slate, or clay-slate, must be coeval with the rocks in which it occurs; and the same is equally obvious with respect to trap-rocks alternating with secondary strata. Trap or basalt sometimes occurs in globular masses composed of concentric spheres, or of prisms of basalt in a radiated diverging form. The spheroidal basalt with concentric layers, frequently incloses in its centre a mass of basalt similar to that which envelops it; but sometimes the central mass is of a harder kind, or is a fragment of some other stone, as of shelly lime-stone. Many trap-rocks, in decomposing, present a spheroidal structure which was not before visible in the mass; and it is observed, that the balls of basalt which fall out or remain when the rock is decomposed, are harder than the main body of the rock. This is the case with the basalt at Rowley in Staffordshire, called Rowley Rag. See ROWLEY *Rag*.

The spheroidal structure is however not peculiar to basaltic rocks. Rocks of granite, in decomposing, sometimes present globular masses of harder granite imbedded in the mass.

In columnar trap we find the columns of all sizes, from a few inches to two hundred and fifty feet in length. The form of the prism or column is also various, and more or less regular, having generally three, four, or five sides: the latter or pentagonal form is the most common. The diameter of the larger columns is frequently four or five feet, or more, and sometimes is nearly equal to the height.

Rocks of the trap-formation are also frequently observed to form conical mountains, or to occur as detached masses on caps on the summits of other hills, and to occur at nearly the same level as represented *Plate IV. Geology, fig. 3. c, d, and e*. In such instances, it seems probable that the different caps have originally formed parts of one continuous bed, which has been broken either by the excavation of currents, by subsidence of the intermediate parts, or by the elevation of the hills from their primeval position.

The columnar structure and the overlying position so remarkable in trap-rocks, are also common to some kinds of porphyry, and to sienite, which are not included by geologists among trap-rocks, but to which they bear a near affinity. To take a just and enlarged view of this class of rocks, we must leave the minute subdivisions and classifications of cabinet philosophers, and contemplate the natural relations which these rocks have to each other, and the gradations which may be traced between mountain masses possessing great difference in their external appearance. Hornblende or augite forms an essential part of almost all trap-rocks, as well as rocks of undoubted volcanic origin. Now these minerals, though classed by mineralogists as two distinct species, are so nearly alike in their constituent parts, that we may consider them as identical, when they existed in

a fluid state in the matter of the rocks of which they form a part. Circumstances of minor import may easily be conceived to have changed the form of their crystals, as we know by experiment the slight causes which occasion varieties of form in the crystallization of the same constituent ingredients in our laboratories. The constituents of hornblende and of augite, are silica, alumina, lime, magnesia, iron, manganese, and a trace of potash: the proportions of each, which exist in the two minerals, do not vary more than the proportions which exist in substances classed by Haüy with hornblende, or between varieties of the same species in many other minerals.

We may regard then, in a geological view, the constituents of hornblende and augite as forming the same mineral, under whatever crystalline forms they may present themselves in rocks. It is this substance which forms the connecting link between granite, trap-rocks, and lava. Hornblende enters as a constituent part into many rocks of granite. According to Patrin, masses and veins of granite occur in hornblende-rocks, and masses and veins of hornblende in granite-rocks, in the Altaian mountains. Hornblende is found in some of the granites of the Higher Alps: it exists abundantly in most rocks of gneiss, which is only a laminated granite. When the hornblende in granite increases in quantity, so as to form a considerable part of the mass, the rock is denominated sienite. When the hornblende gives its colour to the rock, it forms greenstone. When the parts are more intimately mixed, it becomes a compact trap or basalt; and basalt and compact lava bear in many instances so near a resemblance, as not to be distinguished. According to the account of sir George Mackenzie, beds and even columns of basalt frequently occur in Iceland, the lower parts of which are a porous and vitreous lava or slag. The close resemblance between the compact lavas, and the columnar basalt in the vicinity of Etna, and other active volcanoes, is so great, that we believe it is extremely difficult, if not impossible, to distinguish them from each other by any well-defined characters. The currents of lava which have recently flowed, differ indeed from beds of basalt or trap by their porosity; but Cordier has well observed, in the memoir before alluded to, that it is only the superficial part of modern currents of lava that are exposed to our observation; and to judge of their real nature from the external scorix, would be like judging of the contents of a vat of wine, from the froth floating on its surface. The ancient currents of lava are some of them of immense size, and have frequently been excavated or broken, by which the internal parts are discovered, and these, as before remarked, bear a near resemblance to many of the regular rock-formations, and particularly to varieties of trap-rock.

Such being the leading characters in the composition, structure, and position of trap-rocks, we need not be surprised that the earlier geologists were disposed to class them all with volcanic products, and to assert that they had been formed by eruptions from ancient volcanoes, in a manner similar to the formation of modern currents of lava. This hypothesis, advanced before many phenomena attending volcanic eruptions were known, and when the effects of heat combined with pressure had not been investigated, was exposed to many weighty objections. Another theory, which ascribed the formation of trap-rocks to aqueous depositions, was warmly supported by many geologists on the continent, and particularly by M. Werner. He supposes, that after all the primitive and conformable rocks had been deposited, the primeval waters which covered the highest mountains sunk slowly to their present level.

TRAP.

From some unknown cause, a sudden rising of the water took place in a turbid and agitated state, and covered the whole globe: it then became calm, and during the period of its settling, deposited the different rocks of overlying trap, and again retired to its former level with considerable rapidity. The broken stratification, so characteristic of this formation, was caused partly by the rapid retreating of the water. The heaps of trees, the beds of clay, sand, and gravel, and their constant occurrence in the lower part of this formation, are evident proofs (says Mr. Jameſon of the rapid and tumultuous rising of the water. The ſubſequent calmneſs of the water is proved by the fineneſs of the mechanical and the increaſing fineneſs of the chemical ſolutions, as we approach the upper part of the formation. Jameſon's Mineralogy, vol. iii. p. 85.

According to this theory, the regular ranges of columns ſo frequent in trap-rocks, were produced by the ſhrinking in or drying of the maſs. As the inundation was general, the rocks of this family muſt be ſpread univerſally over the globe. Indeed the ſame geologiſt ſuppoſes there were two inundations, the firſt, which deposited the overlying porphyry and ſienite, the ſecond, which deposited the baſaltic or ſtætz trap-rocks. On this theory, Mr. Bakewell remarks in his Introduction to Geology, "it is ſcarcely poſſible for the human mind to invent a ſyſtem more repugnant to exiſting facts. Were baſaltic rocks, as Werner ſuppoſes, deposited from an aqueous fluid, that covered the whole globe after the formation of the ſecondary ſtrata, every part of the dry land and every valley muſt have been incruſted or filled with baſalt; it would be the prevailing rock of every diſtrict: on the contrary, overlying trap or baſalt exiſts only in detached maſſes, in particular ſituations, nor do fragments of baſalt occur in any quantity ſufficient to warrant the belief that it was ever formed univerſally over the globe."

Though the mode of aqueous formation, ſuggeſted by Werner, is utterly inadmiſſible, we do not think it improbable that many baſaltic rocks may have been formed in the humid way, by eruptions of mud of limited extent, like thoſe which iſſue at preſent from the volcanoes in South America. The opinion that all baſalt or trap-rocks have originally flowed in the form of lavas, we do not ſeem authorized, from exiſting facts, to maintain; and the great attitude given to this mode of formation, has induced other geologiſts to reject it altogether. But it has been well obſerved, that there is a wide difference between aſcertaining the agency by which a rock has been formed, and the manner in which that agent has been applied. Numerous obſervations, which have been recently made on trap-rocks in volcanic countries, have led to the opinion that many of theſe rocks have been ſoftened, and even fuſed, in their original poſition, without ever having flowed as currents of lava.

The principal objections againſt the agency of fire in the formation of theſe rocks are enumerated by Brochant. (Min. tom. ii.) Many of theſe objections, we think, can be ſatisfactorily answered.

1. "Baſalts are extremely rare among the products of burning volcanoes, and modern eruptions have not produced any."—This objection is founded on an aſſumption of facts, which are not admitted by other geologiſts. The obſervations of Daubuiſſon in Auvergne, of ſir George Mackenzie in Iceland and the Ferroe iſlands, and of Humboldt in South America, prove that trap-rocks are extenſively ſpread among volcanic products; though, in many inſtances, they appear to have been formed by the agency of ſubterranean heat acting on beds of ſchilt, which have been melted or ſoftened in their original poſition, and been ſubſequentially

elevated, without ever having flowed as lava. If modern eruptions have produced no baſalt, we may recollect that it is only the external parts or ſcoriæ that are expoſed to our view; and we have no opportunity of examining the currents of ſubmarine lavas, formed at great depths under the ocean, in circumſtances ſimilar to thoſe which may have attended the formation of baſalts. That many baſaltic rocks were formed under the ſea, is evident from their alternating with beds of lime-ſtone containing marine ſhells.

2. "Whatever origin may be attributed to the columnar or tabular ſtructure of baſalt, it is not peculiar to trap-rocks: there are gypſums, marles, and ſand-ſtones, which frequently preſent this ſtructure."—The columnar and globular ſtructure may be formed by the ſlow refrigeration of a melted maſs of baſalt, as was proved in the experiments of Mr. Gregory Watt. (See ROWLEY Rag.) The columnar ſtructure has been obſerved by colonel Imrie in a current of lava which had flowed from a volcano in Felicuda, one of the Lipari iſlands. This current could be traced from the mouth of the volcano to the ſea. That the columnar ſtructure may alſo exiſt in ſome rocks of aqueous origin, cannot invalidate the above facts. The particular forms which the columns of baſalt ſometimes preſent, which will be ſubſequentially noticed, appear to be the effects of partial fuſion.

3. "Baſalts often reſeſt immediately on coal, as at Meiſner, near Caſſel. Now, if this baſalt were volcanic, it muſt neceſſarily have produced the combuſtion of theſe beds of coal."—To this objection it will be ſufficient to reply, that numerous inſtances may be cited of baſaltic dykes and beds of baſalt having charred the coal in their vicinity, and reduced it to a ſtate of coke or cinder. (See VEINS, Mineral.) And from the experiments of Dr. Maccullock on powdered jet and wood-coal, incloſed in gun-barrels under preſſure, ſo as to confine a conſiderable part of the volatile products, it appears that they were converted into true mineral coal by a red heat; and had the conſiſtence, fracture, and every property of pit-coal. Where baſalt in contact with coal has reduced it to a coke, it appears highly probable that the volatile parts have been driven off by heat; and where the coal preſerves its true character, the volatile parts have been retained by compreſſion.

4. "The remains of animals and vegetables which are found in ſome trap-rocks, could not have reſiſted the action of volcanic heat without being deſtroyed. It is the ſame with many very fuſible minerals. Some ſuch fuſible minerals are alſo found in volcanic rocks; but theſe inſtances are rare, and cannot ſerve as a baſis for a general rule."—In the experiments of ſir James Hall on lime-ſtone expoſed to heat under compreſſion, it was found that chalk, which contained ſhells, might be melted and reduced to a cryſtalline ſtate by cooling, without deſtroying the organic ſtructure of the ſhells. Moſt of the organic remains in baſaltic rocks are in a ſofter amygdaloid, or in wacke, which may probably have been formed from eruptions of volcanic mud, like that called *moya*, from the South American volcanoes. The fuſible minerals found in baſalt and ſome volcanic products, there is every reaſon to believe, aſſumed a diſtinct cryſtalline form when the maſs was conſolidating.

5. "Cavities filled with water in ſecondary trap-mountains, oppoſe the ſuppoſition of their igneous origin."—That theſe cavities have been filled by infiltration is rendered almoſt certain, from the circumſtance that the water may be expelled by a gentle heat; and if the water can find a paſſage through the ſtone from the cavity to the ſurface, it may alſo find a paſſage from the ſurface to the centre of the maſs.

6. "There are not observed in trap-rocks either that black colour, or those indications of vitrification, that are apparent at least in certain portions of the products of burning volcanoes; real craters have never been observed. All those which have been cited were hollows, chasms filled with water, so common in some mountains."—This is an assumption of facts which recent observations disprove. The basalts in the Ferroe islands, and in Iceland, have, in some instances, the black appearance which is here denied: the columns and beds of basalt contain also in their lower, and sometimes in their upper parts, scoriae, and those indications of vitrification that are apparent in burning volcanoes; and the sides of the basaltic dykes are generally vitrified. That many of the hollows, supposed to have been craters, were hollows formed by depression, is probable; but what other appearance could the crater of an ancient volcano be expected to present, than a hollow or chasm which might be filled with water?

7. "Mandelstein (or porous amygdaloid) has certainly some resemblance to porous lava; but there are mandelsteins evidently not volcanic. Besides, the cavities in the mandelsteins of trap-mountains contain very different minerals, and such as could not have undergone the action of fire, without being changed."—The remarks made previously on very fusible minerals inclosed in basalts, and some lava, apply equally to this objection. It is also probable that soft and amygdaloidal basalts may have been formed from eruptions of mud, as before stated.

8. "Although from experiments made on basalts and lava, and from observations made on burning volcanoes, it is known that stony substances may, after perfect fusion, resume their stony character; but when this takes place in burning volcanoes, there are always found in the vicinity substances which are scorified or vitrified, and denote the action of fire."—It has before been remarked, that scoriae and vitrified substances occur in the basalts of Iceland and Ferroe: they accompany the basalts in Auvergne, and the vicinity of Etna. In almost all basaltic countries, some of the rocks present so striking a similarity to volcanic products, that the resemblance has often struck the most common observer. If other basaltic rocks do not present the same appearances, it may be owing to their having been formed by submarine eruptions, under circumstances very different from those which take place on land; and it is not contended that all basalts have originally flowed as lava.

9. "In various countries, beds of basalt are observed to alternate with sand-stone and stratified lime-stone."—It is observed in many parts of England and Scotland, and is probably general, that where beds of trap are interspersed between sand-stone or lime-stone, they are generally very irregular both with respect to thickness and extent, and have seldom the same uniform arrangement as the stratified rocks with which they alternate. That the lime-stone was formed under the sea, is proved by its containing marine shells; and there is no improbability in the supposition, that currents of submarine lava may have flowed at different periods over beds of shells or sand, and converted the one into lime-stone and the other into sand-stone.

10. "In many basaltic districts, basalt is only found on the summits of hills; and it is evidently perceptible, by the correspondence of the beds, that all these summits were parts of one and the same bed, which spread over all the district. This is not the form of volcanic deposits: they take a certain direction, and no similar instances of such vast volcanic deposits are known."—The frequent occurrence of detached caps of basalt forming the summits of hills, in an extensive district at nearly the same level, constitutes one

of the most remarkable peculiarities of the trap or basaltic formation, and deserves particular attention, as marking some of the latest revolutions that have changed the surface of the globe. To form a more distinct idea of the situation of these caps, we refer to *Plate IV. Geology, fig. 3*, where a mass of unconformable trap, *a*, lies upon the stratified rocks *b*, and may be seen on the summits of other stratified hills at *c, d*, and *e*. In some instances, as in the Isle of Skye, as described by Dr. Macculloch (*Geological Transactions, vol. iii.*), the mass at *a* appears to be connected with the lower rock *e*, and to form a part of it, as if it had broken through the strata, and been thrown over the surface in a state of fusion. The strata consist of grey lime-stone containing shells; but where the lime-stone is in the vicinity of the trap, it is converted into white crystalline statuary marble. A similar change is produced on chalk, or earthy lime-stone, when subjected to heat under pressure, as was proved in a series of experiments made by sir James Hall; and as we are unacquainted with any other cause which could produce this change, it appears probable that the lime-stone has been converted into marble by subterranean heat, and that the trap has flowed over the surface like lava, but under the pressure of the ocean; the existence of marine shells in the lime-stone proving that such must have been its original situation. The causes which have changed the relative level of the lime-stone, with respect to the sea, may have broken the continuity of the strata, and of the basalt which lies upon them. The basaltic mountains of Auvergne, in the departments of Puy-de-Dôme and Cantal, in France, have excited much attention from the existence of ancient volcanic craters in their vicinity. According to Daubuisson, the fundamental rock of that district is granite, covered in some places with a marley lime-stone. Nearly all the soil is covered with volcanic or igneous productions: they are of three kinds, and appear to have been formed at three distinct epochs. The most recent are currents of lava, which lead to craters still existing, though dormant. The second formation consists of masses or tables of basalt, separated by openings or vallies. The third consists of mountains composed of a kind of volcanic porphyry. The currents of lava are observed to have run from the bottom of a number of conical hills, from two hundred to four hundred yards in height. These hills, of which there are about one hundred, are formed of heaps of scoriae, fragments of lava, and rapillo or tufa. Their summit often presents a hollow in the form of a crater: they rest immediately upon granite. The lava at the bottom is of a basaltic nature; it is of a greyish-black colour, with a fine compact grain; it contains grains of augite, olivine, and felspar. The superficies is blistered and studded with asperities, which sometimes exceed a yard in height. The interior is more compact. The currents are spread in the adjacent plain; they have sometimes reached the bottom of certain vallies, and have followed their course for three or four leagues. In advancing progressively, they always descend to lower elevations; they follow the inequalities of the soil; and separate on meeting with any obstructing eminences in their passage. The history of these currents of lava, says M. Daubuisson, is complete, and there is nothing left for the imagination to supply. We behold the orifice from whence they issued, the course they pursued, and the country they occupy. As for the period when these lavas flowed, though anterior to the history of man, it is nevertheless recent, compared with those vast changes which the surface of the globe presents, and was posterior to the excavation of the vallies, since it flowed through them, and occupied their bottoms.

TRAP.

The igneous productions of the second kind are basalts, which in the form of beds, tabular masses, or peaks, cover the elevated parts of the ancient surface of the country, or occur on the summits of some mountains and isolated eminences. They are also observed on the scirting round the sides of Mont Dor and Cantal. They are, says M. Daubuisson, evidently only the remains and patches of different currents which have spread over the country: they present the same mineralogical characters as the basalts of Saxony, and other districts; they contain the same substances, and have the same tendency to form regular prisms or columns; they cover, without distinction, all kinds of rocks, and are never covered by them. An igneous origin cannot be denied to these basalts; the perfect resemblance between their paste and that of some of the currents of lava in their vicinity, which can be traced to existing craters, affords a strong presumption of this; but they present other infallible marks of their origin. In following step by step certain masses of basalt, which are near Mont Dor and Cantal, and supplying by imagination what has been taken away, where their continuity is broken, you arrive at the sides of these two enormous volcanic mountains, and we come to masses of scoria or of blistered rocks, where beyond doubt we are near the current: all the basalts which have been traced upwards made part of that current. A great number of these large basaltic platforms, which cover isolated mountains, display on their surface blisters, spongy scoria or drosses, like those which cover the best preserved lavas; nor can we refuse them a similar origin. Some of these platforms repose on volcanic ashes. It is true, some isolated eminences have summits of compact prismatic basalt of a black colour, and destitute of those unequivocal signs of the action of fire which are seen elsewhere; but these eminences of compact basalt most frequently stand by the side of those platforms with scoriated surfaces, before described: they once formed with them a continued whole, and have evidently been divided from them by the excavation of the ravines and vallies which now separate them. They cannot have had a different origin. The convulsive action of time and the elements must have destroyed the scoriated crust: only the compact nucleus remains, deprived of the marks of the action of fire, like the interior parts of most currents of lava, which are equally destitute of such marks. Thus, says M. Daubuisson, all the basalts of Auvergne present proofs either direct or indirect of an igneous origin; though the disintegration of the surface, and the derangement that the currents have suffered, prevent us from retracing them to the crater from whence they flowed, and from seeing the number, form, and extent of the different currents; but we are certain that their existence was anterior to the excavation of the vallies.

The porphyroidal trap is the third kind of igneous rock-formation in Auvergne. It forms eight or ten distinct mountains: the most considerable are Mont Dor, Cantal, and Puy-de-Dôme. The substance of these mountains, from the account of Daubuisson, appears to be a kind of felspar or clinstone porphyry: their passage, direct or indirect, into basalt, and, above all, the volcanic scoria imbedded in their mass, prove that they owe their existence to fire. These porphyries are the most ancient of the igneous productions of Auvergne; they are covered with basalt, and contain veins of that substance.

In the opinion of some geologists, these mountains and masses of porphyry have never flowed as lava, but have been fused in their native beds, and subsequently elevated. The homogeneity of their paste shews how complete the fusion has been. The crystals of felspar were, in all probability,

formed during the igneous fluidity of the mass. However different the currents of lava, the basalt, and the porphyritic trap may be, and however various the periods of their formation, they appear, says M. Daubuisson, to be united in a certain degree. Cantal, Mont Dor, Puy-de-Dôme, and the other porphyry mountains, are ranged in a direct line running nearly from north to south. Almost all the basalts of these regions, that can be, in some manner, retraced to their origin, seem to have taken their direction in the same line. It is also in this direction, and among the ancient products, that the greater part of the craters have been opened whose vestiges are still visible. When, at two leagues to the westward of Clermont, we see near sixty volcanic mountains ranged in a straight line, it can scarcely be believed to be the effect of chance. A cause has certainly existed, which has produced this effect. Perhaps, says Daubuisson, there was in this direction a vein of matter that contained the germ of volcanic fire, which burst forth and was renewed at different periods.

Perhaps this range of mountains may be regarded as an enormous basaltic dyke, which has broken through the crust of the globe along the line where they are now ranged, their continuity having been broken by partial subsidence, and by diluvial currents. Daubuisson's account of the trap-rocks or basalt of Auvergne is particularly interesting, as establishing the intimate connection between trap-rocks and those of undoubted igneous origin. It is further remarkable, as M. Daubuisson had previously published an account of the basalts of Saxony, in which he endeavoured to prove the aqueous formation of basaltic rocks.

The most remarkable trap-formation in Europe, and perhaps in the world, extends from the county of Antrim, in Ireland, through part of the Scotch Hebrides, and is probably the same which occurs in the Ferroc islands, and the island of Iceland. An account of the columnar basalt of this formation will be found under the articles *GIANT'S Causeway*, and *STAFFA*. The geological relations of the trap-rocks of Antrim with the regular strata in that country, have been recently traced by the Rev. J. Conybeare and Dr. Berger. The basalt of this district generally covers chalk, similar to the chalk on the eastern side of England, and like it resting upon beds of sand, and the grey stratified lime-stone called *lias*. In England we have no instance of basalt occurring above the chalk, or any of the strata over the *lias*, or in the *lias* itself, though it occurs in the coal-formation under the *lias*. A fine section of the beds of basalt with the chalk, sand-stone, *lias*, and coal-strata, may be seen for many miles along the coast, presenting numerous dykes and fractures of the strata, which have sometimes brought the basalt to the same level with the chalk, and in other situations with the coal-strata. The basalt in the interior, and in some parts of the coast, forms isolated caps on the summits of detached conical hills. The existence of these isolated caps has been attributed to diluvial currents, which have cut through the once continuous beds of basalt. Though such currents have doubtless existed in various situations, and have excavated vallies, another agent has obviously been employed in the formation of the vallies of Antrim. We have only to examine the coast to convince ourselves of this fact, where we may see the strata suddenly thrown down or elevated several hundred feet, by mineral veins or dykes filled with basalt. If we trace in imagination the same displacement into the interior, where it obviously extends, we shall see a sufficient cause for the existence of isolated caps or beds of basalt, separated from each other by vallies, or lower grounds, that have been formed by subsidence. Through these veins or dykes the basalt itself was probably

probably thrown up, and spread over the surface in a fluid state. Wherever these dykes pass through the chalk, they have converted it into crystalline lime-stone to a certain distance on each side, and produced various appearances, which tend further to prove that the matter of the basalt has been in a state of igneous fusion. See VEINS, *Mineral*.

That the basalt has been forced through the chalk and the other strata on which it now rests, is rendered almost certain, by the occurrence of broken strata of chalk enveloped in the basalt, and contorted in a manner which proves the violence of the disrapture, the upheaving of the basalt, and the lateral pressure to which the chalk-strata have been subjected. See Plate IV. *Geology*, fig. 4.

One remarkable feature in the arrangement of the basaltic columns in Antrim must not be overlooked. The great ranges of columns are nearly vertical, but the columns of basalt in the mineral dykes are arranged horizontally. This difference of position may admit of a probable solution, if we allow that the basalt, in both instances, had been in a state of igneous fusion. The beds of columnar basalt being thrown over the surface of the ground that formed the bed of the ocean, would begin to refrigerate at the upper and under side in a vertical direction. On the contrary, in mineral dykes intersecting rocks already formed, the basalt would suffer refrigeration most rapidly where it was in contact with them, which would be on the sides, and this refrigeration would gradually extend to the interior, in a horizontal direction: and to this difference in the mode of their consolidation, we may ascribe the horizontal or vertical position of the columns in the beds and dykes of basalt. For an account of the experiments of M. G. Watt and Sir James Hall on the fusion of basalt and lava, see ROWLEY *Rag*, and VOLCANO.

TRAP-Hole, in *Rural Economy*, a term applied to a round hole, which is cut out and prepared in the floors of the stowage-rooms, where hops are deposited after being dried, for the purpose and convenience of bagging them. It is formed exactly equal in size to the mouth or opening of the bag, around which a wooden frame is securely placed and fixed, to the edge of which, the border of the mouth of the bag is firmly attached all round. By this means the hops are readily forced into the bags in a close compact manner.

The term is also occasionally applied to other holes cut and formed in the floors of farm-buildings.

TRAPS, *Garden*, such as are contrived for the purpose of destroying mice and other vermin; which are often conveyed into such places with the straw, litter, and other matters that are made use of in them; and which are extremely hurtful and troublesome in the spring season, in destroying peas and beans, as well as lettuces, melons, and cucumbers in frames.

Traps for this purpose are contrived in a great many ways; but as field vermin are very shy, and will rarely enter traps which are close, the following simple cheap form has been advised by Mr. Forsyth, though it has nothing of novelty in it. These traps may be made by stringing garden-beans on a piece of fine pack-thread, in the manner of beads, and then driving two small stake-like pieces of wood into the ground at the breadth of a brick from each other, and setting up a brick, flat stone, or board with a weight on it, inclining to an angle of about forty-five degrees; tying the string, with the beans on it, round the brick or other substances and stakes, to support them in their inclining position, being careful to place all the beans on the under sides of the bricks or other matters. The mice in eating the beans, in such cases, will also destroy the pack-thread, and

by such means disengage the brick or other weighty body, which by falling on them readily destroys them.

Mice are always the best got rid of by some sort of simple open traps of this nature.

TRAPA, in *Botany*, a Linnæan name, whose idea is certainly taken from the warlike instrument called *Caltrop*, the *Tribulus* of the ancients, which consisted of four iron radiating spikes, so placed that one of them must always stand upwards, in order to wound the feet of passengers. Such is the figure of the singular fruit of this genus, hence named by Tournefort *Tribuloides*. *Calcitrapa*, an old botanical word of similar meaning to *Tribulus*, is compounded perhaps of *calco*, to tread, or kick, and *τρέψω*, to turn, because the Caltrops are continually kicked over if they fail of their intended mischief. Here we have the immediate origin of *Trapa*.—Linn. Gen. 62. Schreb. 84. Willd. Sp. Pl. v. 1. 681. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 267. Sm. Prodr. Fl. Græc. Sibth. v. 1. 104. Juss. 68. Lamarck Illustr. t. 75. Gært. t. 26. and t. 95. (*Tribuloides*; Tourn. t. 431.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Inundata*, Linn.? *Hydrocharidies*, Juss. or rather, as that author himself indicates, his *Onagra*.

Gen. Ch. *Cal.* Perianth superior, of four acute, equal, permanent leaves, firmly united to the sides of the germen. *Cor.* Petals four, obovate, larger than the calyx. *Stam.* Filaments four, the length of the calyx; anthers simple. *Pist.* Germen turbinate, crowned by the calyx, of two cells; style simple, as long as the calyx; stigma capitate, emarginate. *Peric.* none. *Seed.* Nut turbinate, more or less compressed, of one cell, armed with two or four horn-like protuberances, originating in the permanent calyx, thickened, either spinous or blunt. Kernel solitary.

Eff. Ch. Corolla of four petals. Calyx of four leaves. Nut armed with two or four opposite horns, originating in the leaves of the calyx.

1. *T. natans*. European Water-caltrops. Linn. Sp. Pl. 175. Suppl. 128. Willd. n. 1. Ait. n. 1. Prodr. Fl. Græc. n. 1. Gært. t. 26. (*T. aquaticus*; Camer. Epit. 715. Matth. Valgr. v. 2. 324. Ger. Em. 824.)—Nuts with four spinous ascending horns.—Native of ponds and muddy ditches in the south of Europe, flowering in summer. The plant is annual, and has several times been brought into England; but whether its seeds are not perfected here, or from any other cause, it has never yet been naturalized. The ponds at Versailles abound with this *Trapa*. The foliary fibrous root sends up a long, cylindrical, floating stem, varying in length according to the depth of the water, furnished with numerous, opposite, pectinated tufts of fibrous radicles, gradually diminishing to simple fibres, and at the top of the stem, which is thickened, these fibres are replaced by alternate stalked leaves, which are crowded at the summit into a large spreading star, floating on the surface of the pool, and often ten or twelve inches in diameter. Each leaf is rhomboid, succulent, an inch or more in breadth, veiny; strongly toothed in front; entire at the base; the veins rather hairy underneath. Footstalks three or four times as long as the leaves, smooth, swelling beyond the middle into an elliptical cellular body, rendering the plant more buoyant. Flowers small, white, on short, club-shaped, axillary, simple, partly hairy stalks, scarcely half an inch long. Nuts turbinate, about an inch in diameter, angular, smooth, with four, by accident only two or three, prominent ascending pointed horns, becoming lateral by the increase of the summit of the germen, two of them situated at the angles of the nut, two lower down at the sides. The kernel is eatable, somewhat like a chestnut. This plant is doubtless the *τριβολος ενδροςος* of Dioscorides, found by Dr. Sibthorp in countries bordering

on the north of Greece, though not in that country itself, nor the neighbouring islands. The wooden cut of Camerarius, executed, we believe, under Conrad Gesner's inspection, is one of the best representations of any known plant.—Linnaeus mistook the radicles for submerged foliage, like that of *Myriophyllum*.

2. *T. bicornis*. Chinese Water-caltrops. Linn. Suppl. 128. Willd. n. 2. Ait. n. 2. Gært. t. 95. Osbeck's Voyage, Engl. ed. v. 1. 305. (Bucephalon; Burm. in Plum. Ic. 56. t. 67. at the bottom. Linkoa, Ling-kamm, or Leng-ka, of the Chinese.)—Nuts compressed, with two opposite deflexed horns.—Native of ponds in China. Some of its nuts were procured by sir Joseph Banks, in bottles of water, from China. These being immersed in mud at the bottom of some tubs of water at Kew, as well as in Mr. Loddiges' stove at Hackney, vegetated, and produced plants hardly distinguishable, in any respect, from the foregoing, of which we obtained specimens, from the cisterns at Kew, in October 1790. These had the shell of the parent nut at their root, so that no deception could take place. This nut is very different from the former, being twice as large, much compressed, with two large, divaricated, recurved, opposite horns, more or less pointed, which could hardly be supposed to have originated from the calyx. We know nothing of the flowers of this species, nor are we persuaded of its existence at present in the English gardens. Mr. Aiton indeed marks it as a perennial greenhouse plant, but not as having flowered; and we presume, with deference to his well-known accuracy, that it perished as an annual, without flowering, we having never heard of it since the first season. One of our specimens has several stems from a single root, which may possibly be the case with *T. natans* occasionally. Gartner's figure is different from Burmann's, and from our Kew specimen, in the bluntness of its horns. We have a specimen like it, from China or the East Indies, and are not without a suspicion that it may belong to a third species, whose herbage is, as yet, unknown to botanists.

TRAPANI, in *Geography*, a sea-port town of Sicily, in the valley of Mazara, situated on a peninsula, with a good harbour, defended by a fort, which stands on a small island, called Colombara. This town was anciently called Drepanum, from the similitude its haven is thought to have borne to a sickle. It is ancient, and, according to Virgil, existed in the time of Æneas. According to Diodorus, it was fortified in the first Punic war by Hamilcar, the father of Hannibal. The Carthaginians were always desirous of possessing this city on account of its harbour. Here is a good pearl-fishery on the coast, and in the neighbourhood a considerable salt-work. The number of inhabitants is about 20,000; 43 miles W.S.W. of Palermo. N. lat. 38° 5'. E. long. 12° 30'.

TRAPESO, in *Commerce*, a weight in Malta, Sicily, and Naples. At Malta, gold and silver are weighed by the libra or pound of 12 ounces. The ounce is divided into 16 parts, or into 32 trapesi, and the trapeso into 18 grani. This pound weighs 4888 English grains: and thus 720 lbs. or ounces of Malta = 611 lbs. or ounces troy. At Naples, gold and silver are weighed by the libra of 12 ounces, the ounce being subdivided into 30 trapesi, and the trapeso into 20 acini. The pound of Naples weighs 4950 troy grains: hence 64 lbs. or ounces = 55 lbs. or ounces troy weight.

TRAPEZA, in *Ancient Geography*, a promontory of Asia Minor, in the Troade, at the entrance of the Hellespont, and 18 miles from the small town of Dardanium. Pliny.

TRAPEZIOIDES, } in *Anatomy*, bones of the carpus.
TRAPEZIUM, }

See EXTREMITIES.

TRAPEZIUM, in *Geometry*, a plane figure contained under four unequal right lines.

TRAPEZIUS, in *Anatomy*, (cucularis, dorso-fus-acromien,) a broad and flattened muscle, of triangular shape, describing with that of the opposite side the lozenge figure, whence its name is derived, situated on the posterior surface of the neck and back, and reaching from the head and vertebral column to the scapula and clavicle. Its line of origin is very long. It arises, by a thin aponeurosis, from the occipital tuberosity, and the external transverse ridge of the bone; from the ligamentum nuchæ in its whole length; from the spinous process of the last cervical vertebra; from the spines of all the dorsal vertebrae, and the intervening interspinal ligaments, by means of short aponeurotic fibres, except from the sixth cervical to the third dorsal vertebra inclusively, where these fibres are much longer, and form a broad semioval aponeurosis. At the lower part too, the origin of the trapezius presents an aponeurosis of some breadth. The muscular fibres pursue various directions: the superior, which are the thinnest, descend; the middle ones pass horizontally; and the inferior ones ascend: the two latter portions are much thicker than the upper. The middle fibres are the shortest, the upper and lower considerably longer. The fibres converge towards the shoulder, and form a flat aponeurosis, which, having passed over the smooth triangular space at the root of the spine of the scapula, is fixed to the superior margin of that process in its whole length, to the superior margin of the acromion, to the ligaments of the scapulo-clavicular joint, and to one third of the posterior edge of the clavicle. Numerous fleshy fibres are inserted, with aponeurotic ones, in the acromion and clavicle.

The posterior flat surface of the trapezius is every where subcutaneous; the cellular substance between it and the skin does not contain much fat, particularly about the neck. Its anterior surface covers the complexus, splenii, levator scapulae, ferratus superior posticus, supraspinatus, rhomboideus, the triangular surface at the root of the scapular spine, the infraspinatus, latissimus dorsi, and a small portion of the longissimus dorsi and sacrolumbalis. The upper and lower edges of the muscle are oblique: the former from the occiput to the clavicle, the latter from the last dorsal vertebra to the scapula.

The trapezius carries the shoulder backwards, at the same time making the scapula rotate, so as to turn its inferior angle forwards, and the superior backwards. In this way the shoulder is elevated, as in supporting a burden. If the levator scapula acts with it, the scapula is moved directly upwards: if the rhomboideus, directly backwards. When the shoulder is fixed, it will extend the head, and incline it, with the trunk, to one side.

TRAPEZOID, in *Geometry*, a plane irregular figure, having four sides, no two of which are parallel to each other.

TRAPEZOPOLIS, in *Ancient Geography*, a town of Asia Minor, in the interior of Caria. Ptolemy.

TRAPEZUNTINA LAURUS, a name used by some botanical authors for the *laurocerasus*, or common laurel.

TRAPEZUNTIUS, in *Biography*. See GEORGE of Trebizond.

TRAPEZUS, TREMISONDE, in *Ancient Geography*, a populous town of Greece, E. of Pontus, and on the coast of the Euxine sea. It was a colony of Sinope. In the

retreat

retreat of the 10,000 Greeks, they sojourned about a month near this town; and as they had a great number of cattle, they offered sacrifices to Jupiter the Saviour, to Hercules, and to other deities. They celebrated also the Gymnic games on the mountain where they encamped. The inhabitants of Trebifonde furnished the Greeks with two vessels, one of 50 and another of 30 oars. Trapezus was the boundary of the ancient kingdom of Pontus, and the commencement of the Colchide. — Also, a town of Arcadia, S. of the river Alpheus and near it, towards the W. and not far from Megalopolis. It was abandoned by its inhabitants, and sunk into ruin upon the establishment of Megalopolis. On the left of the Alpheus is a place named “Bathos,” where were triennially celebrated the mysteries of the great goddess. Here was also the fountain “Olympias,” which, as it was pretended, furnished water only once every two years. Here, it is said, the earth discharged flames, and the giants at this place had fought against the gods. See TREBISOND.

TRAPEZUS *Mons*, mountains of the Tauric Chersonesus, W.S.W. of mount Cimmerius. M. de Peyssonnel says that the Trapezus comprehended the mountains now called Jachelow, Bakchifarai, and Katchi.

TRAPEZUSA, a town of Asia, in the interior of the Cappadocian Pontus. Ptolemy.

TRAPOLIZZA, in *Geography*, a town of European Turkey, in the Morea; 30 miles N. of Mistras. N. lat. 37° 40'. E. long. 22° 26'.

TRAPP, JOSEPH, D.D. in *Biography*, a divine and poet, was born in 1679, probably at Cherrington, in Gloucestershire, where his father was rector, educated at Wadham college, Oxford, of which he was a fellow, and in 1702 commenced M.A. and took orders. As a specimen of his talents for poetry, he wrote a tragedy, entitled “Abramule, or Love and Empire,” which was acted in 1704. In 1708 he was chosen professor of poetry at Oxford, the duties of which office he performed by delivering lectures in elegant Latin; which lectures were published under the title of “Prælectiones Poeticæ,” and an English translation was printed by Bowyer in 1742. In 1711 Trapp was chaplain to the lord chancellor of Ireland, and published in the same year “A Character of the present Set of Whigs,” of which, as well as of the author, Swift, who sent it to the press, speaks contemptuously in his letters to Stella. He recommended him, however, to be chaplain to lord Bolingbroke, who gave him the rectory of Harlington in Middlesex. He was also appointed lecturer of St. Martin’s-in-the-Fields; and afterwards obtained the vicarage of the united parishes of Christ-church, Newgate-street, and St. Leonard’s, Foster-lane. At this time he was deemed a popular preacher. As a poet, he published a flat and profane translation of Virgil in blank verse, Latin versions of Anacreon, and Milton’s Paradise Lost. He also wrote several English poems, one of which was “On the Four Last Things.” In 1721 he married. His subsequent publications were “Sermons at Lady Moyer’s Lecture,” various other “Sermons,” and “A Defence of the Church of England against the Church of Rome.” In 1727 he was created D.D. at Oxford by diploma. He died at the parsonage-house in Christ-church, in 1747, with the character of an excellent scholar, an instructive preacher, and a worthy man. *Biog. Brit.*

TRAPPE, *Monks of La*, in *Ecclesiastical History*, monks of the Cistercian order, belonging to an abbey beautifully situated on a large valley in the province of Le Perche, on the confines of Normandy, in France. The abbey was

founded in 1140 by Rotrou, count of Perche, and dedicated under the name of the Blessed Virgin, in 1214, by Robert, archbishop of Rouen. This abbey was subjected to a very rigorous discipline by the abbé d’Rance, in 1664. *Encyclop.*

TRAPPINGS. Among the ancients, some will have the horse-trappings to have been placed on their breasts; others, on their forehead; and others, again, on their cheeks: that on the breast was a small kind of shield, finely polished.

TRAPRAIN LAW, in *Geography*, a mountain of Scotland, in the county of Haddington; 4 miles E. of Haddington.

TRAPS, *The*, a town of Pennsylvania; 26 miles N.W. of Philadelphia.

TRAPSALO, in *Zoology*, a name given by the Greeks in the Levant to a species or variety of Calamary, or *SEPIA Loligo* (which see), called by the Provençals *Arugi*. It resembles the common calamary, but differs from it by the extraordinary size of its eyes, by a less extent of fins, by its feet having a greater number of small bony points to their cartilaginous tubercles, by a less length of back-bone, by the sheath’s having a smaller quantity of black liquor, and by its becoming very large. The Greeks are of opinion, that their trapfalo is only the calamary changed by age. The arugi approaches the coast more frequently than the calamary; it often comes on the sand of the shore, and there deposits its eggs, whereas the calamary never goes on land. The flesh is better and less difficult of digestion; but their eggs have a slight purgative property, from which no bad effects are felt. It is considered as a presage of a tempest, when the calamaries dart out of the water. *Sonnini’s Greece*, p. 128.

TRAPTOWN, in *Geography*, a town of Maryland; 7 miles S.W. of Fredericktown.

TRAQUAIR, or TRE-QUAIR, a parish in the shire of Peebles, Scotland, on the southern bank of the Tweed, is watered by the river Quair, which has its rise and its whole course in the parish to which it communicated its name; Tre-quair signifying a dwelling on the Quair. The present parish is composed of the old parish of Traquair, with that half of the ancient parish of Kailzie, which lies on the south side of the Tweed, and to which it was annexed in the year 1674. Its greatest length from E. to W. is about nine miles; its greatest breadth, from the Tweed to the source of the Quair, is from four to five miles: the whole contains 17,290 acres, of which about 4000 are arable. The surface is rocky and mountainous. Minchmocr, one of the hills, is upwards of 2000 feet above the level of the sea; and Gumflegugh and some other heights are elevated above 200 feet more. The hills, in general, afford excellent pasture for sheep, of which there are above 10,000 in the parish. The soil in the low grounds is shallow and stony, but tolerably fertile; and the air salubrious. In the population return of the year 1811, the number of inhabitants was stated to be 621, occupying 102 houses. The church was rebuilt in the year 1785. A parochial school is established, with a salary of 300 merks and perquisites, a free house and garden. Traquair House, the residence of that branch of the Stewart family who derive the title of earl from this parish, is seated on the bank of the Tweed: and on the side of a hill, which overlooks the lawn, are the remains of “The Bush aboon Traquair,” celebrated in ancient melodies, and probably in former times a considerable thicket, but now reduced to five solitary thorn-trees. Part of the mansion is of very remote antiquity.

antiquity; and was built in the castellated form. There have been several other tower-houses in the parish, one of which is still almost entire at Cardrona. Several places, denominated *chesters*, exhibit evident marks of lines of circumvallation: they are mostly circular, and seem rather to have been intended to secure cattle against sudden incursions, than for regular encampments; though tradition dignifies them by the appellation of Roman camps: they are all constructed upon the summits of eminences not easily affailable. At the commencement of the Scoto-Saxon period, the Scottish kings possessed the forest of Traquair, with a castle on the isthmus, which is formed by the junction of the Quair with the Tweed. The first mention of it on record, is in the reign of David I., from whose time, till the death of Alexander III., the castle was occasionally the royal residence. Traquair was then a considerable village, which had arisen under the shelter of the castle, and appears to have been more opulent and populous than Peebles itself; but is now very much reduced.—Carlisle's Topographical Dictionary of Scotland. Beauties of Scotland, vol. ii. Chalmers' Caledonia, 4to. 1810.

TRAQUATUHA, a town of Brasil, on the river of the Amazons; 330 miles W. of Fort Rio Negro.

TRAQUENADE, in the *Manege*. See ENTREPAS.

TRARA, in *Geography*, a range of mountains in Algeria; 6 miles E. of Twunt.

TRASCALETA, a town of Spain, in the province of Galicia; 16 miles S.E. of Lugo.

TRASCINA, in *Ichthyology*, a name by which some authors have called the fish more usually known by the names of the *draco marinus*, and *araneus*.

TRASEN, in *Geography*, a river of Germany, which rises in the S. part of Austria, passes by Marcktl, Lilienfeld, Wilhelmsburg, St. Polten, &c. and runs into the Danube, 8 miles below Mauttern.

TRASIMENUS LACUS, or the *Lake of Trasimene*, in *Ancient Geography*, a lake of Italy, towards Etruria, S.E. of Cortona: famous for the battle called after its name, in which Hannibal, in the year of Rome 536, defeated the Romans under Flaminius; 15,000 Romans having been killed, 10,000 put to flight, and 1500 having died of their wounds.

TRASKIRCHEN, or DRASKIRCHEN, in *Geography*, a town of Austria; 3 miles E.N.E. of Baden.

TRASMAUR, a town of Austria, on the Trafen, with a citadel; it belonged to the archbishopric of Salzburg; 12 miles W. of Tulum.

TRAS-OS-MONTES, or TRA-LOS-MONTES, a province of Portugal, bounded on the N. and E. by Spain; on the S. by Beira, from which it is separated by the Duero; and on the W. by Entre Duero e Minho. It receives its name from its position, with respect to the province of Entre e Minho, lying on the other side of the mountain of Marao. In extent from N. to S. it is 70 miles, and from E. to W. about 50, being for the most part mountainous. It is wild, barren, and thinly inhabited, though blessed with fertile and delightful vallies, which produce rye, wheat, wine, and fruits: besides the Duero, it is watered by the small rivers of Tamega, Corgo, Tucla, and Sobor, which run all into the Duero. It contains two cidades or cities, and 57 villas or towns; according to De Lima's list, 549 parishes, in which, in the year 1732, were computed 135,804 souls.

TRASP, a citadel and lordship in the Engadine, on the borders of Tyrol, with a small garrison in it; 27 miles N. of Bormio.

VOL. XXXVI.

TRATOW, a town of the duchy of Holstein; 6 miles S. of Segeborg.

TRATTINNICKIA, in *Botany*, is so called by Willdenow, in honour of a Vienna botanist named Trattinnick. The name of Leopold Trattinnick occurs in Mr. Dryander's *Bibl. Bankf.* v. 3. 646, 648, and 654, as the author of some botanical treatises in German. Perfoon, it appears from Pursh 519, has a *Trattenickia*, which is *MARSHALLIA* of Pursh, after Schreber. (See that article.) We must presume Willdenow to be most correct in the above orthography.—Willd. Sp. Pl. v. 4. 975.—Class and order, *Polygamia Monoecia*, Willd.; rather *Pentandria Monogynia*. Nat. Ord. *Terebintaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, hairy, bell-shaped, with three teeth. *Cor.* of one petal, bell-shaped, longer than the calyx, with three slight teeth, somewhat hairy at its outside. *Stam.* Filaments five, awl-shaped, very short, inserted into the receptacle; anthers oblong, erect. *Pist.* Germen ovate, superior; style awl-shaped, the length of the stamens; stigma simple. *Fruct.* unknown.

Obs. There are some flowers male only, having merely a short style, without any germen. But we cannot for that reason admit the genus into *Polygamia*, there appearing to be no difference of structure in the other parts of the flowers.

Ess. Ch. Calyx bell-shaped, with three teeth. Corolla bell-shaped, with three teeth. Stamens inserted into the receptacle. Germen superior. Stigma simple.

1. *T. rhoifolia*. Sumach-leaved Trattinnickia. Willd. n. 1.—Found in the province of Para, in Brasil, by count Hoffmannsegg, who communicated a dried specimen to professor Willdenow.—A large and very handsome tree, whose ultimate branches are striated and smooth, as thick as the little finger. *Leaves* alternate, stalked, pinnate, two feet long, composed of seven pair of opposite leaflets, with an odd one, which are stalked, four or five inches in length, oblong, pointed, entire, rigid, rough on both sides, veiny; somewhat heart-shaped at the base. The common footstalk is semi-cylindrical and striated; partial ones half an inch long, corrugated. *Stipulas* lanceolate, an inch long, rough with hairs, deciduous. *Panicle* terminal, spreading, compound, five inches in length. *Flowers* white, sessile, in little round tufts. The panicle ends in a pointed bud, expanding into a branch after the flowering is over, so that the branches of the panicle subsequently become lateral. The habit of this plant most resembles *Canarium*, though the genus is unquestionably distinct. Willd.

TRATUZ, in *Geography*, a town of European Turkey, in Moldavia; 49 miles S. of Niemez.

TRAU, or TROGHIR, a town of Dalmatia, pleasantly situated on a piece of land, which was formerly a peninsula, but now separated from the continent by a canal cut through. It is divided into the New and Old; the latter of which has a double, the former only a single wall, and defended by three towers. The harbour, which is formed by a bay, has depth of water enough for the largest ships, which ride there sheltered by two capes. It abounds also in fish, particularly fine sardines. It was an ancient Roman colony of the emperor Claudius; and so early as the year 997, put itself under the protection of Venice; on which it has been continually dependent ever since the year 1420, though not without many changes and disastrous revolutions. Vines, olives, figs, and almonds are cultivated here, and some corn, which however is not the richest produce of these parts. The internal part of the territory of Trau, which

is about 100 miles in circuit, on the continent, produces very little wine, and scarcely any oil. The flocks that feed there, together with those on the island under the same jurisdiction, yield about 400,000 pounds of cheese, and wool in proportion. The number of inhabitants in this territory is about 20,000; 12 miles W. of Spalatro. N. lat. $43^{\circ} 30'$. E. long. $16^{\circ} 30'$.

TRAU *Vecchia*, a town of Dalmatia; 12 miles S.W. of Trau.

TRAVAIATO, a town of Italy, in the department of the Mela; 6 miles W.S.W. of Brescia.

TRAVAIL, (from the French verb, *travailler*,) labour, toil, fatigue; but it is more generally applied to the pains of labour, or child-birth. See LABOUR.

TRAVAIL, in the *Manege*. See TRAVICE.

TRAVAILLER, Fr., in *Music*, to labour, work. In English music, a fugue is said to be *well-worked*, when the subject is frequently and ingeniously brought in, with new accompaniments and modulation: and an inward part of a Polyphonic composition is said to be *well-worked*, if some particular design is carried on in a spirited manner, while the other parts are sustaining slow notes in pure and pleasing harmony. The Italians express much the same at present by the term *tirato*. A subject or theme well treated, is said to be *ben tirata*. The old Italian masters used to call any series of notes ascending or descending, regularly *tirata*, in the same sense as the French *tirade*; which see.

TRAVANCORE, in *Geography*, a city of Hindoostan, and capital of a country of the same name; 108 miles S.S.W. of Madura. N. lat. $8^{\circ} 22'$. E. long. $77^{\circ} 14'$.

TRAVANCORE, a country of Hindoostan, situated in the S. part of the coast of Malabar, and westward of the Carnatic; about 90 miles in extent from N. to S.; governed by a rajah. This country began to rise into importance about the year 1730, by the abilities of the king, or rajah. Around the capital and chief province, he suffered the woods to grow for a number of years, till they formed an impenetrable belt of great depth. This, cut into labyrinths, afforded easy egress to his people, and rendered all attacks from without impracticable. Immured within these natural fortifications, he encouraged the cultivation of the arts and sciences; he invited the approach of men of genius and knowledge; he cultivated the friendship of the Brahmins, and was himself admitted into their society, by the ceremony of passing (as Raynal says) through a golden cow, which became the property of the Brahmins, the cow being sacred in India, as formerly in Egypt; and by preparing his own military stores, casting iron, making gunpowder, &c. he rendered himself independent of foreign aid. The subjects of his remoter provinces, who, to avoid the ravages of war, had taken refuge within the woody circle, now returned with their families and effects to their former habitations. Even the approach to this difficult retreat was impeded by the famous lines of Travancore, which extended from the southern banks of the river Cranganore, close to the sea, to the foot of the Ghauts, strongly fortified in their whole extent. These proved the first check to the ambition of Tippoo Sultan. Tippoo, from the outside of the lines, was a spectator of the horrid carnage of his soldiers. The Nays pressed on him on all sides, and being repulsed with disgrace, and himself thrown from his horse in the retreat, he is said to have made an oath, that he never would wear his turban again, till he had taken the rajah's lines; and accordingly he prepared to attack them by regular approach. On April 12th, 1790, he completely executed his menaces, and laid Cranganore in ruins, carried desolation through the country, and put every opponent to flight.

TRAVAY BAY, a bay on the S.W. coast of Tiree, one of the Western islands of Scotland. N. lat. $56^{\circ} 31'$. W. long. $6^{\circ} 48'$.

TRAUCHBURG, or TRAUENBURG, a town and castle of Germany, in the circle of Swabia, which gives name to a small county situated to the S.W. of the territory of Kempten; 12 miles E. of Wangen.

TRAVE, a river of Germany, which rises from a lake in the duchy of Holstein, 2 miles W. of Arensboeck, passes by Oldeffohe, Lubeck, &c. and runs into the Baltic, about 10 miles N.E. of Lubeck. N. lat. 54° . E. long. $10^{\circ} 55'$.

TRAVE, in *Agriculture*, a term applied, in some districts, as Essex, to a large sort of stook of the wheat kind. In the work of traving, fourteen sheaves are set in a slanting position, head to head, across a furrow, and pressed together as close as may be; a single sheaf being then firmly placed in the furrow against each end of the trave. The traves are by this means made quite secure, solid, and compact, and may defy almost any force and violence of the wind. In some cases, instead of placing sheaves at the ends in this way, they are laid along the top or ridge of the trave; which, without doubt, at once better preserves the trave from the rain and wet, and gives a freer passage to the air between the sheaves, and sooner dries them, in case of their having been thoroughly soaked with rain; but then they are not nearly so strong to withstand powerful storms and blasts of wind as in the other mode of constructing them. See HARVESTING.

TRAVE, among *Farriers*, the same with *travice*.

TRAVELLER, in a *Ship*, a sort of thimble, whose diameter is much longer, in proportion to the breadth of its surface, than the common ones. It is furnished with a tail formed of a piece of rope, about three feet in length, one end of which encircles the ring to which it is spliced. These machines are principally intended to facilitate the hoisting or lowering of the top-gallant-yards at sea: for which purpose, two of them are fixed on each back-stay, whereon they slide upwards and downwards, like the ring of a curtain upon its rod; being thus attached to the extremities of the top-gallant-yard, they prevent it from swinging backwards and forwards, by the agitation of the ship, whilst the yard is hoisting or lowering at sea. Falconer.

TRAVELLER'S JOY, in *Botany*. See CLEMATIS.

TRAVEMUNDEN, in *Geography*, a sea-port of the duchy of Holstein, on the Baltic, at the mouth of the Trave, belonging to the city of Lubeck, which appoints a governor or commandant. The harbour is capable of containing 60 vessels, and deep enough for those of 200 tons. Men of war ride at anchor in the road. Travemunden is defended by a small fortress, mounting 40 guns, and a garri-son of 50 men; 8 miles N.E. of Lubeck. N. lat. 54° . E. long. $10^{\circ} 51'$.

TRAVENDAL, a town of Holstein, on the Trave; 2 miles S.W. of Segeborg.

TRAVERON, a town of France, in the department of the Meuse; 10 miles E. of Gondrecourt.

TRAVERS, JOHN, in *Biography*, a musician brought up in St. George's chapel at Windsor, and afterwards bound apprentice to Dr. Greene, about the year 1730, was elected organist of St. Paul's Covent-Garden; and in 1737, on the death of Jonathan Martin, was appointed one of the organists of the king's chapel. He afterwards attached himself to Dr. Pepusch, and confined his studies solely to the correct, dry, and fanciless style of that master. His compositions, however pure the harmony, can only be ranked with pieces of mechanism, which labour alone may produce, without the assistance of genius.

His passion for fugues, resembled that of an inveterate punster, who never hears a phrase or sentence uttered in conversation, without considering what quibble or pun it will furnish: so Travers seems never to have seen or heard any series of sounds, without trying to form them into a fugue, and meditating when and where the answer might be brought in.

TRAVERS, in *Geography*, a town of the county of Neufchâtel; 11 miles W. of Neufchâtel.

TRAVERSE, or TRANSVERSE, something that goes athwart another, *i. e.* that crosses and cuts it obliquely.

TRAVERSE is particularly used for a piece of wood or iron placed transversely, to strengthen and fortify another: such are those used in gates, windows, &c.

To plane a board against the grain, is also called, among joiners, &c. to traverse it.

TRAVERSE, in *Gunnery*, signifies to turn or point a piece of ordnance, which way one pleases, upon her platform.

The laying or removing of a piece of ordnance, or a great gun, in order to bring it to bear, or lie level with the mark, is also called *traversing the piece*. See GUNNERY.

TRAVERSE, in *Fortification*, denotes a trench with a little parapet, sometimes two, one on each side, to serve as a cover from the enemy that might come in flank. See GLACIS, and *Plate V. Fortification, fig. 6*, in which *v, v,* represent traverses, constructed at the extremities of the places of arms, which serve to enclose them: these traverses are three toises thick, and as long as the covert-way is broad; and a passage is cut in the glacis round them of about six or eight, in order to have a free communication with the rest of the covert-way. There are also traverses of the same dimensions before every salient angle of the bastion and out-works, and they in the same direction of the faces of those works produced; and the thickness lies at the same side as the parapets. The passages round these last traverses are from six to eight feet wide. The second covert-way has also traverses every where, in the same manner as the first.

Traverses are sometimes covered over-head with planks, and loaded with earth. Each traverse is furnished with a foot-bank, and a row of palisades planted on the foot-bank; and the passage round its end should be furnished with klinkets, or doors, to shut them up when necessary. They are very commodious for stopping an enemy's way, and to prevent being enfiladed: they likewise make a good defence, in a dry foss, in making the parapet on the side next the opposite flank.

TRAVERSE, in a *wet foss*, is a sort of gallery, made by throwing fascines, joists, fascines, stones, earth, and other things, into the foss, over-against the place where the miner is to be put to the foot, or the wall, in order to fill up the ditch, and make a passage over it.

TRAVERSE also denotes a wall of earth, or stone, raised across a work which is commanded, in order to cover the men.

TRAVERSE also signifies any intrenchment, or line fortified with fascines, barrels, or bags of earth, or gabions.

TRAVERSE, in *Navigation*, is the variation or alteration of a ship's course, occasioned by the shifting of the winds, currents, &c.; or a traverse is a compound course, in which several different courses and distances are known.

Traverse sailing is used when a ship, having set sail from one port towards another, whose course and distance from the port sailed from are given or known, is, by reason of contrary winds, or other accidents, forced to shift and sail on several courses, which are to be brought into one course, to learn, after so many turnings and windings, the true course

and distance made from the place sailed from, and the true point or place where the ship is; that so, the wind coming fair, it may be known how, afterwards, to shape a course for the place intended.

This may be performed geometrically two ways: the first by drawing new meridians, through the extremity of every course, parallel to the first meridian, or north and south line at first made, and setting off every course with a sweep of sixty, as if it were a question in plain sailing: you may also let fall perpendiculars to every new meridian, from the point that the ship sailed to upon that course; by which you have the course, distance, difference of latitude, and departure, to every course.

To illustrate this by an example: a ship, being bound for a port distant 120 miles N.E. $\frac{1}{2}$ E. sails S.S.E. 30 miles, then N.E. by N. 40, then E. by N. 25, then N.N.E. 44: it is required to find the course and distance made good, and also the course and distance to the port bound for?

Draw the line H K (*Plate VI. Navigation, fig. 1.*) at pleasure, for a meridian, or north and south line, and therein assume a point, as A, for the port sailed from; then, with 60 of the chords, and one foot in A, draw the arc L m, upon which set off two points (because the course is S.S.E.) from L to m, and draw the line A m, upon which set off the distance 30 from A to B; then is the ship at B: thus letting fall the perpendicular B K, A K $27^{\circ} 7'$ is the difference of latitude, and B K $11^{\circ} 5'$, the departure of the first course.

For the second course: with the distance K B draw the parallel B N, and thereby with the chord of 60, as before, set off the second course and distance, N.E. by N. 40, from B to C, and let fall the perpendicular C L; then is the ship at C, the difference of latitude upon the course is B L $33 : 3$, and departure C L $22 : 2$.

Proceed in the same manner for the third course: with the parallel C O, set off E. by N. 25, from C to D, and draw the line D P, from which set off the last course, N.N.E. 44, then is your ship at E.

Since, then, the ship came from A, and is now at E, the line A E, measured on the same equal parts upon which all the other distances were taken, will be found 91 miles; and the arc R Q, measured on the rhumbs, five points; *viz.* N.E. by E.; so that the ship is now 91 miles N.E. by E. from the port sailed from.

To find her course and distance to the port bound for, set off four half-points upon the arc R Q, from R to S, and from A through S draw the line A S F; upon which set off 120, the distance from the port sailed from, to the port bound for, from A to F; then is F the port bound for: now the port bound for being at F, and the ship being but at E, the line E F, measured on the same equal parts that the rest was taken from, will be found to be 31; and the arc T V, measured on the chords, is $35^{\circ} 12'$, or N.E. by N. somewhat easterly, &c. This method is useful where the courses tend generally one way, without intersecting one another; but if they often cross, it is best to have recourse to the second method, which is without new meridians.

In order to this, observe how many points are between the point next to be laid down, and the point opposite to the course laid down; for that is the point for laying down: then when the chord of 60, and one foot in the point the ship is last come to, describe an arc; upon which set off the points found by the above-said rule, and through that draw the line for the next course, &c. For an example:

Draw a north and south line, as in the former, as the line R M (*fig. 2.*), in which assume a point, as at A, for the

port failed from; then from A fet off the first course and distance, viz. N.N.W. 68, from A to B; and for the second course, with the chord of 60, and one foot in B, draw the arc T W, upon which to fet off the next course S.S.W. 70: observe the rule above delivered; viz. to take the number of points between the point next to fail on. The reason of which rule is this; if from A to B your course be N.N.W., then back from B to A must needs be S.S.E. the opposite point; and then if you were to fail S. by E. it must be one point to the southward of that S.S.E. line; if S. it is two points; and consequently the next course being S.S.W., you are to fet off four points, upon which fet off 70 miles, from B to C, and then is your ship at C: for the third course, if from B to C be S.S.W., then from C to B is N.N.E.; but the next course being E. $\frac{1}{2}$ N. the points between N.N.E. and E. $\frac{1}{2}$ N. are five points and a half; and therefore, with the chord of 60, and one foot in C, draw the arc X Y, upon which fet off five points and a half from X to Y; and through Y draw the line C D, upon which fet off 90 miles from C D: then is your ship at D.

After the same manner lay down all the rest, as D E, which is W.N.W. $\frac{1}{2}$ N. 70; then E F, S. 25; then F G, E. $\frac{1}{2}$ S. 45; then lastly G H, S. 30, which is the last course.

Thus your ship being at H, and the port failed from at A, the line A H, 28 miles, is the distance made good; and the angle at A is four points, viz. S.E.; but the port intended for being S.W. 55, fet it from A to K; and the ship being at H, the line H K, 62 miles, is the distance from the ship to the port bound for; and the course is found by measuring the angle at H $71^{\circ} 48'$; or W.S.W. more than a quarter westerly, &c.

To work a Traverse by the Tables of Difference of Latitude and Departure.—This is the principal use those tables are intended for; and the way of working a traverse by them is equal to the best for exactness, and superior in point of expedition.

Make a little table with six columns, the first for the course, the second for the distance, the third for the northing, the fourth for the southing, the fifth for the easting, the sixth for the westing. Then find the difference of the latitude and the departure to every course, and fet them in their proper columns; as, where the course is northerly, fet the difference of the latitude under northing, or in the north column; and where the course is southerly, fet the difference of latitude in the fourth column.

Again, where the course is easterly, fet the departure in the east column, and when westerly, fet it in the west column: then, adding up each column by itself, subtract the north and south columns, the less from the greater, the remainder is the northing or southing made good. Also subtract the east and west columns, the less from the greater, the remainder is the easting or westing made good; then you have the difference of latitude and departure given to find the course and distance.

In the first example above specified, the first course is S.S.E. 30 miles, or two points 30 miles; for which I find the difference of latitude 27 : 7. Now the course being between south and east, I place my difference of latitude in the fourth column, and my departure, 11 : 5, in the east column, leaving the north and west columns blank.

Then for the second course N.E. by N. or three points 40 miles, my difference of latitude, 33 : 3, is to be placed in the north column, and the departure, 22 : 2, in the east column; because the course is between the north and east.

Then the third course being E. by N. or seven points 25 miles, I place my difference of latitude, 4 : 9, in the north column; and departure, 24 : 5, in the east column.

And so for the fourth course N.N.E. or two points 44 miles, I place my difference of latitude, 40 : 6, in the north column; and my departure, 16 : 8, in the east column: then adding up each column, the sum of the northing column is 78 : 8, and the sum of the southing column is 27 : 7; which subtracted from the northing, 78 : 8, the remainder, 51 : 1, is the difference of latitude made good, which is northing, because the northing was the greater number.

Again, the sum of the easting column is 75 : 0, which, because there is no westing to subtract from it, is the easting made good. Thus you have the northing 51 : 1, and the easting 75 : 0 given, to find course and distance; and though you cannot find in the table the exact number of 51 : 1 and 75 : 0 together, yet find the nearest you can, which is 75 : 4, and 50 : 9, over which, at the top, you find 34 degrees for the course, which is N.E. by N. $0^{\circ} 15'$ easterly, and the distance is 91 miles.

To resolve a Traverse by the Scales on Gunter's Scale, improved by Mr. Robertson.—E. g. A ship in 40° N. lat. and $5^{\circ} 14'$ W. long. fails the S.E. by S. 68 min. then S.W. by W. 55 min. and then W.N.W. 75 min. What is her difference of latitude and departure in this general run?

The proportions are, for the

First Course.

As rad. : Diff. :: S. Co. cour. : Diff. lat. :: S. co. : Depart. S. 8 pts. : 68' :: S. 5 pts. : 57' S. :: S. 3 pts. : 38' E.

Second Course.

S. 8 pts. : 55' :: S. 3 pts. : 30.6 S. :: S. 5 pts. : 46' W.

Third Course.

S. 8 pts. : 75' :: S. 2 pts. : 28.8 N. :: S. 6 pts. : 69.5 W.

Traverse Table.

	Courses.	Dist.	Diff. Lat.		Departure.	
			N.	S.	E.	W.
1	S.E. by S.	68		57.0	38.0	
2	S.W. by W.	55		30.6		46.0
3	W.N.W.	75	28.8			69.5
			28.8	87.6 28.8		115.5 38.0
	General diff. Lat.			58.8		77.5

viz. departure made good in this day's run.

To work the above on the Sliding Gunter.—Set sine of 8 points on the fixed piece, by the help of the brass index, against 68 num. on the slide; then draw the said index to S. 5 points, you will find 57 num. on the slide for the difference of latitude; and (without any alteration) against S. 3 points, on the fixed piece, you will have 38 num. on the slide for the departure.

With the compasses, take the extent from 8 points on the sine rhumbs to 68 on the numbers; the said extent laid the same way from sine 5 points will reach to 57 on the num.

num. and the same extent laid the same way will reach to 38 on the num. as before: and in like manner may the rest, and all others of the like kind, be wrought with ease and dispatch. See Mountaine's Description of the Lines drawn on Gunter's Scale, as improved by Mr. J. Robertson, and executed by Messrs. Nairne and Blunt, p. 32, &c.

TRAVERSE-Board, in a *Ship*, a little round board hanging up in the steerage, and bored full of holes upon lines shewing the points of the compass upon it. By moving of a little peg from hole to hole, the steersman keeps an account how many glasses, that is half-hours, the ship steers upon any point.

This implement is particularly useful in light and variable winds. Thus, if the wind is northerly at the beginning of the watch, the ship, being close-hauled on the larboard-tack, will steer W.N.W. If, after the first half-hour, the wind changes to N. by W., the ship will fall off to W. by N. Both these courses are marked by the helmsman upon the traverse-board, by putting in one peg for every half-hour in which she steers the same course: as one peg into W.N.W. and two pegs into W. by N., if she fails an hour on the latter course; and so on. The lee-way and variation of the compass are afterwards allowed by the pilot, on summing up the whole.

TRAVERSE-Table, in *Navigation*, is the same with a table of difference of latitude and departure; being only the difference of latitude and departure ready calculated to every degree, point, half-point, and quarter-point of the quadrant; and for any distance under one hundred miles, though it may conveniently serve for greater distances, by taking their halves, thirds, fourths, &c. and doubling, tripling, quadrupling, &c. the difference of latitude and departure found to those parts of the distance.

This table is one of the most necessary things a navigator has occasion for; for by it he can readily reduce all his courses and distances, run in the space of twenty-four hours, into one course and distance; whence the latitude he is in, and his departure from the meridian, may be found.

See a table of this kind, in which the distances are continued to one hundred and twenty, for the sake of more easy subdivisions, and which is divided into two parts; the first containing the whole points and quarter-points in a quadrant, and the second part fitted to every degree and quarter of a degree in the quadrant; in Robertson's *Navigation*, at the close of book 7. See also a table of the same kind in Mackay's *Complete Navigator*.

TRAVERSE the Yard, on board a ship, is to brace it aft.

TRAVERSE, in *Law*, denotes the denial of some matter of fact, alleged to be done in a declaration, or pleadings; upon which the other side coming, and maintaining that it was done, issue is joined for the cause to proceed to trial.

The formal words of a traverse are in the law-French *sans ceo*; in Latin, *absque hoc*; in English, *without that*, &c.

An answer, says West, (speaking of bills in chancery,) is that which the defendant pleadeth or saith in bar to avoid the plaintiff's bill or action, either by confessing and avoiding, or by denying and traversing the material parts of it. A replication is the plaintiff's reply to the defendant's answer, which must affirm and pursue his bill, and confess and avoid, deny or traverse, the defendant's answer.

A plea is naught, which neither traverses nor confesseth the plaintiff's title, &c. Every matter of fact alleged by the plaintiff may be traversed by the defendant, but not matter of law, or what is part matter of law and part matter of fact; nor may a record be traversed, as this is not to be tried by a jury.

If a matter be expressly pleaded in the affirmative, which is expressly answered in the negative, no traverse is necessary, there being a sufficient issue joined: also where the defendant hath given a particular answer in his plea to all the material points contained in the declaration, he need not take a traverse: because when the thing is answered, there needs no farther denial.

TRAVERSE of an Indictment or Presentment is the contradicting or denying some chief point of it, and taking issue thereon. See **INDICTMENT**, and **PRESENTMENT**.

Thus, in a presentment against a person for a highway overflowed with water, for default of scouring a ditch, &c. he may either *traverse the matter*, by alleging that there is no highway, or that the ditch is sufficiently scoured; or he may *traverse the cause*, viz. by alleging that he hath not the land, or that he and they whose estate, &c. have not used to clean the ditch.

It is not customary, nor agreeable to the general course of proceedings, unless by consent of parties, to try persons indicted of smaller misdemeanors at the same court in which they have pleaded *not guilty*, or traversed the indictment. But they usually give security to the court, to appear at the next assizes or sessions, and then and there to try the traverse, giving notice to the prosecutor of the same.

TRAVERSE of an Office, is the proving that an inquisition made of lands or goods is defective, and untruly made. See **OFFICE**.

No person shall traverse an office, unless he can make to himself a good right and title: and if one be admitted to traverse an office, this admission of the party to the traverse supposes the title to be in him, or else he could have no cause to traverse.

TRAVERSE is sometimes used in *Heraldry*, for a partition of an escutcheon, which they blazon parti per pale, traverse, argent and gules.

TRAVERSE, in the *Manege*. A horse is said to traverse, when he cuts his tread cross-wise; throwing his croupe to one side, and his head to another.

TRAVERSE Tyles. See **TYLE**.

TRAVERSE Bay, Grand, in *Geography*, a bay on the east side of lake Michigan. N. lat. 44° 45'. W. long. 85°.

TRAVERSE Islands, a chain of islands at the east end of Noquet's bay, in lake Michigan: on one of the largest is a town of the Ottoway Indians.

TRAVERSE River, a river of Louisiana, which runs into the Missouri, N. lat. 38° 30'. W. long. 92° 5'.

TRAVERSIERE, FLUTE, commonly called the German-flute, being supposed of German invention. But it has its title of *flute traversiere* in France, from the different manner of holding it from that of *la flute à bec*, or common flute.

Its original compass was from the lowest D in the treble, to *a* in altissimo.

Such was the extent of the scale in 1752, when Quantz published his "Methode de la Flute," who was the late Frederic king of Prussia's master on that instrument, and the first who added keys to correct and clear the bad notes.

In the folio *Encyclopédie*, tom. vi. there is a scale of all the tones, semi-tones, and shakes possible on the instrument, with an additional half-note, C \times or D \flat , below the usual lowest note of its compass, and three notes above A in altissimo, the highest note of Quantz's scale. See *Music Plates*.

For the history of the flute traversiere, Quantz tells us that in the year 1620 it had no key to make D \times or E \flat , and was called the Swiss flute. It was the French who added the first key; but it was not known by whom or when

when. Quantz himself added a second key in the year 1726, and about 1732, a third. Two more keys have since been added by subsequent performers on the instrument; but it has been thought more for parade than use: as the management of five keys in rapid performance, would be as difficult as running divisions on an organ with all the five short keys split into quarter-tones. See TACET.

TRAVESTY, or TRAVESTI, a term which some late authors have introduced into poetry: it is originally French, being a participle of the word *travestir*, to disguise one's self, or to appear in masquerade. Hence travesty comes to be applied to the disfiguring of an author, or the translating him into a style and manner different from his own; and is generally applied to pieces of humour.

Travesty, or parody, may be divided into two classes:—that which is intended to ridicule absurdity, and that the purpose of which is to extract gaiety and laughter from compositions in their own nature grave and admirable. The Rehearsal by the duke of Buckingham is the best specimen of the former. At a period when false taste seems to have prevailed in an eminent degree, which would be most likely to happen when a man of splendid talents like Dryden condescends to sacrifice his better judgment for the specious allurements of a temporary popularity, an author of wit has the appearance of doing the public a service, who shall call them to sobriety and good sense by the force of ridicule. The second kind of travesty has still less that can be alleged in its favour. Its direct operation is to pollute our better feelings, and tarnish with a putrefying film of ridicule all the noblest and most exquisite effusions of the human mind. Here unfortunately ridicule most easily takes hold. We cannot laugh at nothing; the prattle of inanity bids defiance to the ludicrous. There must be something of what we have been accustomed to view with honour in the composition we are successively invited to contemplate again and again with bursts of laughter against the author. But that which is most easily turned into burlesque, and affords the most permanent hold of an attack of this sort, is the language and sentiments that had before excited in us the deepest and most sacred emotions. The very contrast between the solemn feelings with which these things had been formerly regarded, and the unexpected colour of absurdity which is given them now, makes the temptation to laughter the more violent and irresistible.

G. Battista Lalli has travestied Virgil, or turned him into Italian burlesque verse. Scarron has done the same in French; and Cotton and Philips in English verse.

Castalio is, by some, charged with having travestied the sacred text, by reason of the difference of air and style between his version and the original.

TRAVICE, in the *Manege*, is a small inclosure or oblong quadrangle placed before a farrier's shop, and consisting of four pillars or posts, kept close together by cross poles. This inclosure is designed for holding and keeping in a horse that is apt to be unruly or disorderly in the time of shoeing, or of any operation.

This, in some of the remoter parts of England, goes by the name of a *break*; and is called in French, *travail*.

TRAUMATICS, *Τραυματικά*, *Vulneraries*, or medicines good for the healing of wounds. See VULNERARY and AGGLUTINANT, HEALING, and CONSOLIDATION.

TRAUMATICUM, BALSAMUM. See BALSAMUM *Traumaticum*.

TRAUN, in *Geography*, a river of Austria, which rises in the Halfatter See, forms a considerable lake, called Traun See, and runs into the Danube, about three miles below Steyregg.—Also, a river of Bavaria, which rises

from two lakes, Forchenfee and Daubenfee, and enters the Alza, 4 miles N. of Chiemfee.

TRAVNIKOVA, a town of Russia, on the Lena; 6 miles S.S.E. of Orlenga.

TRAUNKIRCHEN, a town of Austria; 10 miles S.S.E. of Voglabruck.

TRAUNSTAIN, a town of Austria; 4 miles S.W. of Zwettl.

TRAUNSTEIN, a town of Bavaria, on the Traun, where are some considerable salt-works; 18 miles W. of Salzburg. N. lat. 47° 51'. E. long. 12° 35'.

TRAUSI, in *Ancient Geography*, a people of Thrace, in the environs of mount Hæmus, whose manners, described by Herodotus, resembled those of the other Thracians.

TRAUSTADT, or Wschowa, in *Geography*, a town of the duchy of Warlaw; 40 miles S.S.W. of Posen.

TRAUTENAU, a town of Bohemia, in the circle of Koniggratz; 21 miles N. of Koniggratz. N. lat. 50° 27'. E. long. 15° 48'.

TRAUTENFELS, a town of the duchy of Stiria; 7 miles E.N.E. of Groming.

TRAUTMANSDORF, a citadel in the county of Tyrol; 4 miles N.E. of Tyrol.

TRAUTMANSTORFF, a town of Austria; 6 miles W.N.W. of Brugg.

TRAVUS, in *Ancient Geography*, a river of Thrace, which discharges its waters into the lake of Bistonis.

TRAYAGUERA, in *Geography*, a town of Spain, in Valencia, surrounded by a wall flanked with towers. Here is a manufacture of fine earthenware; 80 miles N.E. of Valencia.

TRAYL-BASTON, or TRAIL-BASTON. Edward I. in his 32d year, sent out a new writ of inquisition, under this denomination, against the intruders on other men's lands, who, to oppress the right owner, would make over their lands to great men; against batterers hired to beat men, breakers of peace, ravishers, incendiaries, fighters, false assisors, and other malefactors: which inquisition was so strictly executed, and such fines taken, that it brought in much treasure to the king.

Hence, also, *justices of trayl-baston*, a denomination given to the justices appointed to execute this commission, either by reason of their severe and summary way of proceeding, or because a staff was delivered them as the badge of their office, and the offenders were dragged before this jurisdiction.

TRAYTOR, TRAITOR, *Traditor*, a betrayer of his king and country, or one guilty of high-treason. See TREASON.

TRAYTOROUS or TRAITEROUS *Position*, is particularly understood of a tenet, which some formerly held, of the legality of taking arms, by the king's authority, against his person, and those commissioned by him; which is condemned by statute 14 Car. II. c. 3.

TRAZA, in *Geography*, a town of Arabia, in the country of Yemen; 70 miles N. of Loheia.

TREACLE, in *Pharmacy*, &c. See THERIACA.

This word treacle is also popularly used for melasses; and in this sense it is that Dr. Shaw, in his "Essay on Distillery," has endeavoured to bring into use several sorts of treacles, which might be made at home, and would serve very conveniently for the distillation of spirits, or the making of potable liquors. These are the inspissated juices or decoctions of vegetables: such as the sweet juice of the birch, or sycamore, procured by tapping or piercing the trees in spring, and the common wort made from malt, or from other vegetable substances treated in the same manner. These liquors

liquors are severally to be boiled down in a copper till they begin to inspissate, and then to be poured into a balneum Mariæ, when the remainder of the evaporation may be finished without burning the inspissated juices: thus prepared, it may be at any time reduced to the state of wort, only by adding a sufficient quantity of warm water.

Treacle is employed for the more quickly fattening some sorts of domestic animals, such as sheep and neat cattle, when properly mixed and united with different sorts of dry materials, such as pollard, bruised grain, cut hay, and many other matters of the same nature, as they mostly soon become very fond of it, and it is well known to be of a very nutritious quality. Trials have been made with it in this view, with great success. See *STALL-Feeding*.

TREACLE-Mustard, or *Mithridate*, in *Botany*. See *THLASPI*.

The seed enters into the composition of the theriaca, and externally used, cleanses all sorts of ulcers, and is also a ptarmic, but not very common. It is reckoned an enemy to pregnant women, because it kills the fœtus. James. See *THLASPEOS Semen*.

TREACLE-Mustard, is also a name given to the clypeola.

TREACLE-Water, *Aqua Theriacalis*, a compound cordial, or spirituous water, distilled with a spirituous menstruum, from any cordial and sudorific drugs and herbs, with a mixture of some of the theriaca Andromachi, or Venice treacle; whence its name.

TREAD, in the *Manege*. See *PISTE*.

The tread of a horse is considered to be good, when firm, and without the animal resting upon one side of the foot more than upon the other, or setting down the toe or heel one before the other. Where the heels are first set down to the ground, it is often supposed to be a sign that the animal is unsound in its feet. And where the toes are first put to the ground, it is considered as shewing that the horse has been of the team or draught kind. Consequently, in a good going horse of the saddle sort, the whole foot should be set down equally, at the same instant of time, and neither turned out nor in, in any perceptible degree.

TREAD upon the *Coronet*, is a term applied to any injury which is done to it by the treading of the other horses or animals on it. See *CORONET*.

TREADHAVEN CREEK, in *Geography*, a branch of the river Choptank.

TREADING in *Wheat*, in *Agriculture*, the practice of making such land as is light, sandy, and friable, hard and firm by such means after the seed has been put into it, in order to secure its vegetation and growth in a more perfect manner. It has been suggested as useful on different kinds of soil, but it is evidently the most proper for those that are light and open, either from their particular nature and quality, or the sorts of crops by which they have been occupied, as those of the potatoe, turnip, or other similar kinds. In all such cases, it will be found of great utility and advantage in promoting the establishment of the roots of the plants, by forcing the wheat to strike more strongly into the soil, and by keeping the frosts from injuring and throwing them out while in the early state of their growth. But in stronger lands it may be injurious and hurtful in many instances, and mostly unnecessary.

The best mode of effecting it is probably by the use of sheep immediately after the land has been sown and harrowed, by turning them upon it in sufficient quantities, as they do it in a very effectual manner. Some have, however, recourse to other sorts of animals, as neat cattle and horses, and to rolling; but this last seldom answers well, as it is liable to increase the friability below in such soils. The

cattle and horses, when in sufficient number, often produce much benefit in this way; and in some places, where the land is of a soft abraded stony quality, teams of six or eight oxen are used in covering in the seed, in drawing a light pair of harrows, in this intention. Wherever treading is necessary in this view, it should constantly be performed in an effectual manner, with whatever sort of live-stock it is done, whether sheep, oxen, or horses. Sometimes treading is found beneficial for wheat, on such soils, so late as March, even more so than at the time of putting in the seed, as tending to destroy weeds, such as the corn-poppy, &c.

The practice of treading in the wheat is, of course, mostly to be adopted, in all these cases, as tending to secure and increase the quantity of the produce whenever such sorts of land are sown with that kind of crop. See *WHEAT*.

TREASON, TREACHERY, the act or crime of infidelity to one's lawful sovereign.

Treason is a general appellation made use of by the law, to denote not only offences against the king and government, but also that accumulation of guilt which arises whenever a superior reposes a confidence in a subject or inferior, between whom and himself there subsists a natural, civil, or even spiritual relation; and the inferior so abuses that confidence, and so forgets the obligation of duty, subjection, and allegiance, as to destroy the life of any such superior or lord. Whence

Treason, in our laws, is of two sorts, *high* and *petty*.

TREASON, *High*, or *Treason Paramount*, which is equivalent to the *crimen lese majestatis* of the Romans, (as Glanvil denominates it also in our English law,) is an offence committed against the security of the king or kingdom, whether by imagination, word, or deed.

In order to prevent the inconveniences which arose in England from a multitude of constructive treasons, the statute 25 Edw. III. c. 2. was made; which defines what offences only for the future should be held to be treason: and this statute comprehends all kinds of high-treason under seven distinct branches.

1. "When a man doth compass or imagine the death of our lord the king, of our lady his queen, or of their eldest son and heir." A queen pregnant is also within the words of the act, though it does not extend to the husband of such a queen. And the king here intended is the king in possession, without any respect to his title: consequently, a king who has resigned his crown, such resignation being admitted and ratified in parliament, is no longer the object of high-treason: and the same reason holds in case the king abdicates the government; or, by actions subversive of the constitution, virtually renounces the authority which he claims by that very constitution. As the compassing or imagination, expressed by this statute, is an act of the mind, it cannot possibly fall under any judicial cognizance, unless it be demonstrated by some open or *overt* act. The statute expressly requires, that the accused "be thereof upon sufficient proof attained of some open act by men of his own condition." Thus to provide weapons or ammunition for the purpose of killing the king, is held to be a palpable overt act of treason in imagining his death: to conspire to imprison the king by force, and move towards it by assembling company, is an overt act of compassing the king's death: and taking any measures to render treasonable purposes effectual, as assembling and consulting on the means to kill the king, is a sufficient overt act of high-treason. It now seems clearly to be agreed, that, by the common law and the statute of Edw. III., words spoken amount only to a high misdemeanor, and no treason. If the words be set

down in writing, it argues more deliberate intention; and it has been held, that writing is an overt act of treason; for *scribere est agere*. But even in this case, the bare words are not the treason, but the deliberate act of writing them. It was formerly held, that the publication of a treasonable writing was a sufficient overt act of treason at the common law; though of late even that has been questioned.

2. The second species of treason is, "if a man do violate the king's companion, or the king's eldest daughter unmarried, or the wife of the king's eldest son and heir." By the king's companion is meant his wife, and by violation is understood carnal knowledge, as well without force, as with it; and this is high-treason in both parties, if both be consenting.

3. The third species of treason is, "if a man do levy war against our lord the king in his realm." And this may be done by taking arms, not only to dethrone the king, but under pretence to reform religion, or the laws; or to remove evil counsellors, or their grievances, whether real or pretended; and by intimidation and violence to force the repeal of law.

4. "If a man be adherent to the king's enemies in his realm, giving to them aid and comfort in the realm, or elsewhere," he is also declared guilty of high-treason. This must likewise be proved by some overt act, as by giving them intelligence, by sending them provisions, by selling them arms, by treacherously surrendering a fortress, or the like.

5. "If a man counterfeit the king's great or privy-seal," this is also high-treason.

6. The sixth species of treason under this statute is, "if a man counterfeit the king's money; and if a man bring false money into the realm counterfeit to the money of England, knowing the money to be false, to merchandize and make payment withal." Counterfeiting the king's money is treason, whether the false money be uttered in payment, or not. Also if the king's own minters alter the standard or alloy established by law, it is treason. But gold and silver money only are held to be within this statute. With regard, likewise, to importing foreign counterfeit money, in order to utter it here; it is held that uttering it, without importing it, is not within the statute.

7. The last species of treason ascertained by this statute is, "if a man slay the chancellor, treasurer, or the king's justices of the one bench or the other, justices in eyre, or justices of assize, and all other justices assigned to hear and determine, being in their places doing their offices." This statute extends only to the actual killing of them, and not to a wounding, or bare attempt to kill them. The barons of the exchequer are not within the protection of this act; but the lord keeper or commissioners of the great seal now seem to be within it, by virtue of the statute 5 Eliz. c. 18. and 1 W. & M. c. 21.

The new treasons created since the statute 1 M. c. 1. and not comprehended under the description of statute 25 Edw. III. may be comprised under three heads. The first species relates to Papists; the second, to falsifying the coin (see *BRITISH COINS*) or other royal signatures; as falsely forging the sign manual, privy signet or privy seal, which shall be deemed high-treason. (1 M. st. ii. c. 6.) The third new species of high-treason, is such as was created for the security of the Protestant succession in the house of Hanover. For this purpose, after the Act of Settlement was made, it was enacted by statute 13 & 14 Will. III. c. 3. that the pretended prince of Wales, assuming the title of king James III., should be attainted of high-treason; and it was made high-treason for any of the king's subjects to hold cor-

respondence with him or any person employed by him, or to remit money for his use. And by 17 Geo. II. c. 39. it is enacted, that if any of the sons of the Pretender shall land or attempt to land in this kingdom, or be found in the kingdom or any of its dominions, he shall be adjudged attainted of high-treason; and corresponding with them or remitting money to their use, is made high-treason. By 1 Ann. stat. 2. c. 17. the offence of hindering the next in succession from succeeding to the crown is high-treason: and by 6 Ann. c. 7. if any person shall maliciously, advisedly, and directly, by writing or printing, maintain, that any other person hath any right to the crown of this realm, otherwise than according to the Act of Settlement, or that the kings of this realm, with the authority of parliament, are not able to make laws to bind the crown and its descent; such person shall be guilty of high-treason.

The punishment of high-treason in general is very solemn and terrible. 1. That the offender be drawn to the gallows, and not be carried or walk; though usually (by connivance, at length ripened by humanity into law) a sledge or hurdle is allowed, to preserve the offender from the extreme torment of being dragged on the ground or pavement. 2. That he be hanged by the neck, and then cut down alive. 3. That his entrails be taken out, and burned, while he is yet alive. 4. That his head be cut off. 5. That his body be divided into four parts. 6. That his head and quarters be at the king's disposal.

The king may, and often doth, discharge all the punishment, except beheading, especially where any of noble blood are attainted. For beheading being part of the judgment, that may be executed, though all the rest be omitted by the king's command. But where beheading is no part of the judgment, as in murder or other felonies, it hath been said that the king cannot change the judgment, although at the request of the party, from one species of death to another. See EXECUTION.

In the case of coining, the punishment is milder for male offenders; being only to be drawn, and hanged by the neck till dead. But in treasons of every kind, the punishment of women is the same, and different from that of men: for, as the decency due to the sex forbids the exposing and publicly mangling of their bodies, their sentence is to be drawn to the gallows, and there to be burnt alive.

The consequences of the judgment pronounced upon a traitor are *attainder*, *forfeiture*, and *corruption of blood*. See ATTAINDER, &c.

It is a maxim, that, *in majori proditione, omnes sunt principales*, there are no accessories in high-treason, all are accounted principals.

Also, that *voluntas non reputabitur pro facto, nisi in causa proditionis*, the will is never taken for the deed in any case, but in that of high-treason. See INDICTMENT.

TREASON, *Petty* or *Petit*, according to the stat. 25 Edw. III. c. 2. may happen three ways: by a servant killing his master, a wife her husband, or an ecclesiastical person (either secular or regular) his superior, to whom he owes faith and obedience. A servant, who kills his master whom he has left, upon a grudge conceived against him during his service, is guilty of petit treason: so if a wife be divorced *a mensa et thoro*, still the *vinculum matrimonii* subsists; and if she kill such divorced husband, she is a traitress: and if a clergyman is understood to owe canonical obedience to the bishop who ordained him, to him in whose diocese he is beneficed, and also to the metropolitan of such suffragan or diocesan bishop; and therefore to kill any of these is petit treason.

A person indicted of petit treason may be acquitted thereof, and found guilty of manslaughter or murder; and in such case,

it should seem that two witnesses are not necessary, as in the case of petit treason they are. See INDICTMENT.

The punishment of petit treason, in a man, is to be drawn and hanged; and in a woman, to be drawn and burnt: the idea of which latter punishment, says judge Blackstone, seems to have been handed down to us by the laws of the ancient Druids, which condemned a woman to be burnt for murdering her husband; and it is now the usual punishment for all sorts of treasons committed by those of the female sex. Persons guilty of petit treason, were first debarred the benefit of clergy by stat. 12 Hen. VIII. c. 7. which has been since extended to their aiders, abettors, and counsellors, by stat. 23 Hen. VIII. c. 1. 4., and 5 P. & M. c. 4.

This kind gives forfeiture of lands by escheat to the lord of the fee. See FORFEITURE and ESCHEAT.

TREASON, *Accumulative*. See ACCUMULATION. Blackst. Comm. vol. iv. &c.

TREASON, *Appeal of High*. It was anciently permitted, that any subject might appeal another subject of high-treason, either in the courts of common law, or in parliament, or (for treasons committed beyond the seas) in the court of the high constable and marshal. The cognizance of appeals in the latter still continues in force; and so late as 1631, there was a trial by battle awarded in the court of chivalry, on such an appeal of treason; but that in the first was *virtually* abolished by the first stat. 5 Edw. III. c. 9. and 25 Edw. III. c. 24. and in the second *expressly* by stat. 1 Hen. IV. c. 14. So that the only appeals now in force, for things done within the realm, are appeals of felony and mayhem. Blackst. Comm. vol. iv.

TREASON, *Constructive*, an offence raised, by forced and arbitrary construction, into the crime and punishment of treason, which never was suspected to be such: a multitude of these existed before the inconvenience was remedied by 25 Edw. III. c. 2. Constructive treasons were also numerous in the reign of Richard II. and afterwards between the reign of Henry IV. and queen Mary, and particularly in the bloody reign of Henry VIII., all which were abrogated by the stat. 1 Mary, c. 1. which once more reduced all treasons to the standard of the stat. 25 Edw. III.

TREASON, *Misprison of*. See MISPRISON.

TREASURE, THESAURUS, *θησαυρος*, a store, or stock of money, in reserve.

TREASURE-TROVE, q. d. *treasure found, thesaurus inventus*, in Law, is when money, gold, silver, plate, or bullion, is found in the ground, in any place, and none knows to whom it belongs.

This should naturally fall to the finder, to whom it formerly belonged, as was the rule of the civil law: but particular nations have made particular provisions for it. The Jews give it to the proprietor of the place where it was found: the Roman jurisprudence was various with regard to it; sometimes it was given to the master of the grounds, sometimes to the finder, and sometimes it was adjudged to the public treasury.

In England, and also in Germany, France, Spain, and Denmark, the general usage is, to have such treasure sequestered to the king, unless where the benefit of it is expressly granted or made over by the king to some other, as the lord of the manor: and that the prince shall be intitled to this hidden treasure, is now become, according to Grotius, *jus commune & gentium*. If, indeed, he that hid it be known, or afterwards found out, the owner, and not the king, is intitled to it. Also, if it be found in the sea, or upon the earth, it doth not belong to the king, but the finder, if no owner appears. So that it seems it is the hiding, not the abandoning of it, that gives the king a property.

VOL. XXXVI.

In some places in France it is divided into three parts, one for the king, one for the proprietor of the land, and one for the finder.

Briton says, it is every subject's part, as soon as he hath found any treasure in the earth, to make it known to the coroner of the county, &c.

The punishment for concealing treasure found in England, was formerly no less than death; but now it is only imprisonment and fine: but if any mine of metal be found in any ground, it always appertains to the lord of the soil, except it be a mine of gold or silver, which anciently always belonged to the king, in whose ground soever it were found; but, by an act of parliament, the king hath now only the pre-emption.

TREASURER, an officer to whom the treasure of the prince, or corporation, is committed to be kept, and duly disposed of, in payment of officers, and other expences. See TREASURY.

Of these there is a great variety. His majesty of Great Britain, in quality of elector of Brunswick, was formerly arch-treasurer of the Roman empire. In the states of Poland are two grand-treasurers; that of the kingdom of Poland, and that of the duchy of Lithuania.

In England, the principal officers under this denomination are, the lord high-treasurer, the treasurer of the household, treasurer of the navy, of the king's chamber, &c. Anciently, we had likewise a treasurer of the exchequer, treasurer of war, &c. In the Romish countries, the title of treasurer is also given, somewhat abusively, to an ecclesiastic, who has the keeping of the relics, and of the charters and archives of a church or monastery. This dignity succeeds, in some measure, to that of the ancient deacons, who had the like charge in the primitive church.

TREASURER of England, *Lord High*, is the principal officer of the crown; under whose charge and government is all the king's revenue kept in the exchequer.

He receives the office by delivery of a white staff to him from the king, and holds it during the king's pleasure: anciently he received it by delivery of the golden keys of the treasury.

He has the cheque of all the officers any way employed in collecting imposts, customs, tributes, or other revenues of the crown. He has the gift of all the customers, comptrollers, and searchers' places, in all the ports of London; and the nomination of the escheators in every county.

He alone (or others in commission with him) lets leases of all the crown-lands, gives warrants to certain persons of quality to have their wine custom-free, &c.

Killing the lord-treasurer in the execution of his office, is high-treason.

The office of lord-treasurer is now in commission.

The number of lords-commissioners is five.

TREASURER of England, *Under*. See UNDER-TREASURER.

TREASURER of the Household, is an officer who, in the absence of the lord-steward, has power, with the comptroller and other officers of the Green-cloth, and the steward of the Marshalsea, to hear and determine treasons, felonies, and other crimes committed within the king's palace. See HOUSEHOLD.

There is also a treasurer belonging to the establishment of her majesty's household, &c.

TREASURER of the Navy, is an officer who receives money out of the exchequer, by warrant from the lord high-treasurer, or the lords-commissioners executing that place; and pays all charges of the navy, by warrant from the principal officers of the navy. See NAVY.

TREASURER of the County, he that keeps the county stock.

There are two of them in each county, chosen by the major part of the justices of the peace, &c. at their general quarter-session; under previous security given for the money entrusted with them, and the faithful execution of the trusts reposed in them.

The justices may continue or remove these treasurers at pleasure, and allow each of them a salary of 20*l.* a year.

The county stock, of which this officer hath the keeping, is raised by rating every parish yearly; and is disposed of to charitable uses, for the relief of maimed soldiers and mariners, prisoners in the county-gaols, paying the salaries of governors of houses of correction, and relieving poor almshouses, &c. And the duty of these treasurers, with the manner of raising the stock, and how it shall be disposed of, is set forth particularly in the statutes of 43 Eliz. cap. 2. Jac. I. cap. 4. 11 & 12 W. III. cap. 18. 5 Ann. cap. 32. 6 Geo. I. cap. 23. See particularly 11 Geo. II. c. 20, and 12 Geo. II. cap. 29.

TREASURER, in *Cathedral Churches*, an officer whose business was to take charge of the vestments, plate, jewels, relics, and other treasures belonging to the said churches. At the time of the Reformation, the office was extinguished as needless in most cathedral churches; but it is still remaining in those of Salisbury, London, &c.

TREASURY, the place in which the revenues of a prince are received, preserved, and disbursed.

In England, the treasury is a part of the exchequer; by some called the *lower exchequer*.

The officers of his majesty's treasury, or the lower exchequer, are the lords-commissioners, one of whom is chancellor, two joint secretaries, private secretary to the first lord, two chamberlains, an auditor, four tellers, a clerk of the pells, ushers of the receipt, a tally-cutter, &c. See each officer under his proper article, CHANCELLOR, TELLER, TALLY, &c.

At Rome, under the emperors, there were two kinds of treasuries, the one called *ærarium*, wherein the monies destined to support the charges of the government were kept; the other *fiscus*, wherein were preserved those intended for the particular subsistence of the emperor and his court. In effect, the *ærarium* belonged to the people, and the *fiscus* to the prince. See *ÆRARIIUM* and *FISCUS*.

We have still a resemblance of this difference among us; but it is confounded in France, &c. where the king disposes absolutely of the public treasure, &c.

The Athenian treasury was sacred to Jupiter *Σωτηρ*, or the Saviour, and to Plutus the god of riches. Besides the public monies, there were always a thousand talents kept in it, which it was capital to touch, unless on the most pressing occasions. See *ΟΡΙΣΤΗΟΔΟΜΟΣ*.

The funds among the Athenians, which supplied their treasury, were four; viz. the *tele*, τέλη; the *phori*, φοροί; the *eiphora*, εισφοραί; and the *timemata*, τιμηματα.

The public treasury was divided into three parts, according to the use it was applied to: as, 1. The *χρηματα τῆς διοικήσεως*, or that expended in civil uses. 2. The *ερασιδικα χρηματα*, or money designed to defray the charges of war. 3. The *θυσιακα*, or money intended for pious uses, in which they included the expences at plays, public shows, and festivals, &c. Potter *Archæol. Græc.* tom. i. p. 82.

To each of these branches of the public revenue there was a treasurer appointed, as *ταμις τῆς διοικήσεως, των ερασιδικων, and θυσιακων*.

TREASURY, *Lords of the*. In lieu of one single director and administrator of his majesty's revenues, under the title

of lord high-treasurer, it is frequently thought proper to put that office in commission, *i. e.* to appoint several persons to discharge it, with equal authority, under the title of lords-commissioners of the treasury. See *Lord-high-TREASURER*.

TREASURY *Islands*, in *Geography*, a cluster of islands among Solomon's islands. S. lat. 6° 38' to 7° 30'. E. long. 155° 34' to 156°.

TREAT, in our old *Law-Books*, signifies as much as *taken out*, or *withdrawn*. Thus a juror was challenged, because he could not dispend 40*l.* and therefore was *treat* by the statute, or discharged.

TREATISE, *TRACTATUS*, a set discourse in writing, on any subject.

A treatise is supposed more express, formal, and methodical, than an essay; but less so than a system.

TREATY, Lat. *Fœdus*, a covenant between several nations; or the several articles or conditions stipulated and agreed upon between sovereign powers.

Sovereigns treat with each other by their proxies, who are invested with sufficient power, and who are commonly called plenipotentiaries. The rights of the proxy are expressed in the instructions that are given him; but every thing he promises within the terms of his commission, and the extent of his powers, bind his constituent. At present, in order to avoid all danger and difficulty, princes reserve to themselves the ratification of what has been concluded upon in their name by their ministers. A treaty is valid, if there be no fault in the manner in which it was concluded; and for this purpose nothing more can be required than a sufficient power in the contracting parties, and their mutual consent, sufficiently declared. If, however, a treaty has been honestly concluded by a sovereign without his perceiving any iniquity in it, and turns at length to the detriment of an ally, nothing can be more amiable, more laudable, more conformable to the reciprocal duties of nations, than to yield as much as possible, without being wanting to himself, without putting himself in danger, or without suffering a considerable loss. Since every treaty ought to be made with a sufficient power, a treaty pernicious to the state is null, and not at all obligatory; no conductor of the nation having the power to enter into engagements to do such things as are capable of destroying the state, for the safety of which the empire is entrusted to him. Moreover, a treaty made for an unjust and dishonest intention is absolutely null; nobody having a right to engage to do things contrary to the law of nature. Nations and their conductors ought to keep their promises and their treaties inviolable. This great truth, though too often neglected in practice, is generally acknowledged by all nations: the reproach of perfidy is esteemed by sovereigns a most atrocious injury; and he who does not observe a treaty is certainly perfidious, since he violates his faith. On the contrary, nothing adds so great a glory to a prince, and the nation he governs, as the reputation of an inviolable fidelity to his promise. To violate a treaty, is to violate the perfect right of him with whom we have contracted, and this is to do him an injury. No subsequent treaty can be made contrary to those that actually subsist. Nothing hinders a sovereign from entering into engagements of the same nature with two or more nations, if he is at the same time able to fulfil them with respect to all his allies. But in causes of competition or difference, the most ancient ally ought to be preferred; and, besides, the justice of the cause is another reason of preference between two allies; nor ought we to assist him whose cause is unjust, whether he be at war with one of our allies, or with another state.

Grotius (*De Jure Belli et Prin.* l. ii. c. 15. § 5.) divides treaties into two general classes: viz. 1. Those which turn

TREATY.

merely on things to which we were already bound by the law of nature; and 2. Those by which we engage something more. Of the first class are all the simple treaties of peace and friendship, when the engagements contracted in them add nothing to what men owe each other as brethren, and as members of the human society; as those that permit commerce, passage, &c. Treaties of the second class, in which sovereigns engage to do what they are not obliged to perform by the law of nature, are either equal or unequal. Equal treaties are those in which the contracting parties promise the same things, or things that are equivalent, or, in short, that are equitably proportioned, so that their condition is equal; such, *e. gr.* is a defensive alliance, in which they reciprocally stipulate for the same succours: such is an offensive alliance, in which it is agreed that each of the allies shall furnish the same number of vessels, the same number of troops, of cavalry and infantry, or an equivalent in vessels, in troops, in artillery, or in money. Such is also a league, in which the contingent of each of the allies is regulated in proportion to the interest he takes or may have in the design of the league. Equal treaties may be subdivided into as many kinds as the sovereigns have different transactions between them. Thus they treat of the conditions of commerce, of their mutual defence, of associations in war, of the passage they shall reciprocally grant to each other, or refuse to the enemies of their ally, &c.

Nations ought as much as possible to preserve equality in their treaties.

Equal treaties are distinguished from equal alliances. The former are those where equality is kept in promises; and the latter are those where equal treats with equal, forming no difference in the contracting parties, or, at least, admitting no superiority too plainly pointed out; but only some pre-eminence of honours and rank. Unequal treaties are those in which the allies do not promise the same things; and the alliance is unequal when it makes a difference in the dignity of the contracting parties. Those unequal treaties that are at the same time unequal alliances, are divided into two kinds; the first, where the inequality is found on the side of the most considerable power, and the second comprehending treaties where the inequality is on the side of the inferior power. Unequal alliances are subdivided into two kinds, such as degrade the sovereignty, and such as do not.

By another general division of treaties or alliances, they are distinguished into personal and real; the former are those that relate to the person of the contracting parties, and are restrained and in a manner attached to them. Real alliances relate only to the things of which they treat, without any dependence on the person of the contracting parties. The personal alliance expires with him who contracted it; but the real alliance is affixed to the body of the state, and subsists as long as the state, if the time of its duration is not limited. The alliance terminates as soon as the term of it is expired; but a treaty made for a time may be renewed by the common consent of the allies, and the renewal is manifested either expressly or tacitly.

Treaties between nations are sacred; and he who violates his treaties, violates at the same time the law of nations; for he despises the faith of treaties, that faith which the law of nations declares sacred, and he does all in his power to render it vain. But unhappy experience having too fully convinced mankind, that the faith of treaties is not always a sufficient warrant for their being observed, securities have been sought for against perfidy; and hence is derived the origin of a *guaranty*, and *hostage*, which see. The interpretation of treaties is subject to certain rules or maxims, of which writers on this subject have enumerated the following. It is not

allowable to interpret what has no need of interpretation: if he who can and ought to explain himself has not done it, it is to his own damage: neither of the contracting parties has a right to interpret the treaty at his pleasure: what a person has sufficiently declared, ought to be taken for true against him: the interpretation ought to be made according to certain rules previously understood and allowed. For these and other particulars, we refer to Vattel's Law of Nations, b. ii.

For the solemn manner in which the Romans used to conclude treaties, see Livy, lib. i. cap. 24. The ceremonies observed by the Greeks in making treaties may be seen in Potter, Archæol. Græc. lib. ii. cap. 6. tom. i. p. 252, seq.

In general, it appears that the ancients were very religious, grave and solemn in making treaties; which were always confirmed by sacrifices and mutual oaths, with horrid imprecations on the party that should break the terms of agreement.

There are treaties of war, of peace, of marriage, of confederacy, of neutrality, of capitulation, and of commerce and navigation.

Treaties relating to war are of several kinds. Some of these are connected with alliances, defensive and offensive. In judging of the morality of these several treaties or alliances, or of the lawfulness of them, according to the law of nations, the following is an incontestable principle: It is lawful and commendable to succour and assist, in any way, a nation making a just war; and this assistance is the duty of every nation, which can give it without being wanting to itself. But he who makes an unjust war is not to be assisted in any manner. Other treaties relating to war include those of neutrality. Sometimes necessity renders a treaty of this sort justifiable; at other times this kind of treaty is the best method of securing peace, and preventing altercation. Some treaties relate to the passage of troops through a neutral country; and others to the search of neutral ships, &c. When the powers at war have agreed to lay down their arms, the agreement or contract in which they stipulate the conditions of peace, with the manner in which it is to be restored and supported, is called the "treaty of peace." The effect of this treaty is to put an end to the war, and to abolish the subject of it. It leaves the contracting parties without any rights of committing hostility, either for the very subject which kindled the war, or for what has passed in the course of it: it is therefore no longer permitted to take up arms again for the same cause. Accordingly, in these treaties, the parties reciprocally oblige themselves to a perpetual peace, which is not to be understood as if the contracting parties promised never to make war on each other for any cause whatever. Peace relates to the war which it terminates; and as it forbids the revival of the same war by taking arms for the cause which at first kindled it, is in reality perpetual. As it is the end of peace to extinguish all subjects of discord, amnesty, or a perfect oblivion of what is past, should be the leading article of the treaty; and though the treaty should be silent on this head, it is necessarily understood. This treaty binds the contracting parties from the moment of its conclusion, as soon as it has passed through all its forms. From this time all hostilities cease, unless a day is specified when the peace shall take place; but this treaty becomes obligatory on subjects only from the time of its being notified to them. When no term is assigned for the accomplishment of the treaty, and the execution of the several articles, common sense dictates that every point should be executed as soon as possible. The faith of treaties equally excludes from the execution of them all neglect, all dilatoriness, and deliberate delays. A treaty of peace is a public treaty,

treaty, obligatory upon the whole nation; it is also a real treaty, obliging successors as well as the prince who signed it, since it obliges the state itself.

Treaties of commerce are the compacts or agreements by which different states secure to themselves and to one another something constant in their mutual trading intercourse; and they are usually followed by various tariffs, to adjust the duties of exportation and importation of merchandizes into the respective dominions of the contracting powers.

A nation having a full right to regulate itself in commercial affairs by what is useful or advantageous, it may make such commercial treaties as it shall think proper; and no other has a right to take offence, provided these treaties do not affect the perfect rights of another. Every such treaty is allowable among nations, and the execution of it ought not to be opposed; but that alone is in itself just and commendable, which, as far as is possible and reasonable in the particular case, is transacted with a tenderness for the general interest. Nations may accordingly, in their treaties, insert such clauses and conditions as they think proper; and they are at liberty to make them perpetual or temporary, or dependent on certain events. But when once a nation has entered into engagements by treaty, it is no longer at liberty to do, in favour of others, contrary to the tenor of the treaty, what it might otherwise have granted to them, agreeably to the duties of humanity, or the general obligation of reciprocal commerce; being to do for others no more than what is in its power. Having deprived itself of the liberty of disposing of a thing, that thing is no longer in its power. Therefore, when a nation has engaged to another that it will sell only to them certain goods or provisions, as, *e. gr.* corn; it can no longer carry them for sale to another market. The case is the same in a contract to purchase certain goods only of that nation. The natural liberty of trade is not hurt by treaties of this nature; for this liberty consists only in every nation being unmolested in the right of trading with those which consent to traffic with it; every one remaining free to close with or decline a particular commerce, as it shall judge most advantageous.

The celebrated treaties are those of Nimeguen, of Munster, of the Pyrenées, of Westphalia, of Ryfwick, of Utrecht, of Hanover, Vienna, &c.

The great treaty of peace, commerce, navigation, &c. between England and France, was signed at Utrecht, the 11th of April, 1713, and consists of 39 articles.

For other treaties, see the general titles.

It is the king's prerogative to make treaties, leagues, and alliances, with foreign princes and states; and yet, lest this plenitude of authority should be abused to the detriment of the public, the constitution has interposed a check, by the means of parliamentary impeachment, for the punishment of such ministers as, from criminal motives, advise or conclude any treaty, which shall afterwards be judged to derogate from the honour and interest of the nation.

TREATY, *Guarantee of a.* See GUARANTY.

TREBA, or TREBE *Auguste*, in *Ancient Geography*, a town of Italy, in the interior of Latium. Ptol.

TREBA, in *Geography*, a town of Saxony, in Thuringia; 2 miles S.W. of Salza.

TREBAU, or *Mabrisch Trebau*, a town of Moravia, in the circle of Olmutz; 10 miles W. of Muglitz.

TREBBIN, a town of the Middle Mark of Brandenburg; 20 miles S.S.W. of Berlin. N. lat. 52° 10'. E. long. 13° 6'.

TREBBIO ANTICO, a town of the Popedom, in the duchy of Urbino; 17 miles E.N.E. of Urbino.

TREBEJO, a town of Spain, in the province of Leon; 46 miles S. of Ciudad Rodrigo.

TREBELLIANICA, or TREBELLIAN *Fourth*, in the *Roman Jurisprudence*, a right belonging to an heir instituted by testament. If the testator, after appointing a full and general heir, spent and disposed of all his effects in legacies; or if he went *ultra dodrantem*, beyond three-fourths thereof; in that case, the heir was allowed to retrench and detain one fourth part of the legacies to his own use. This was called the *trebellianica*.

In like manner, if the testator charges his heir with a feoffment of trust, and to restore the inheritance to another; in that case, the heir might likewise retain a fourth of the whole succession, that the quality of heir might not be rendered wholly vain and fruitless.

TREBELLIIUS-POLLIO, in *Biography*, a Latin historian, flourished about the year 298 of the vulgar era. According to Vopiscus, he wrote the lives of the Roman emperors from the two Philips to Claudius; but we have extant only the latter part of the reign of the elder Valerian, that of his son, the lives of the two Gallieni, those of the thirty tyrants, and that of Claudius. He is reckoned one of the "*Historiæ Augustæ Scriptores*," and praised by Vopiscus for his exactness, which applies only to some dates, as in other points he is very incorrect. His style is somewhat superior to that of the other historians. Vossius.

TREBENDA, in *Ancient Geography*, a town of Asia Minor, in the interior of Lycia. Ptol.

TREBENTIZ, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 70 miles S.W. of Leitmeritz. N. lat. 50° 27'. E. long 14° 5'.

TREBENTSCHIKOV, a fortress of Russia, in the government of Caucasus, on the Ural; 64 miles N. of Guriev.

TREBERK, a town of Germany, in the duchy of Anhalt-Cothen; 4 miles N. of Cothen.

TREBES, a town of France, in the department of the Aude; 6 miles E. of Carcassone.

TREBIA, in *Ancient Geography*, a river which ran from south to north, commencing in Liguria, south of the valley inhabited by the Friniates, and passing into Gallia Cispadana, across the territory of the Anamani, watered the town of Placentia, and discharged itself into the Padus. The Trebia was famous for the victory obtained by Hannibal, near its mouth, over the presumptuous and imprudent Sempronius, in the year of Rome 435; on which occasion the Romans lost 26,000 men.

TREBIA, in *Geography*, a river of Italy, which runs into the Po, 2 miles W. of Piacenza.

TREBIGNO, a town of European Turkey, in Dalmatia; the see of a bishop; 60 miles S. of Mostar.

TREBINA, a town of Naples, in Basilicata; 5 miles S.S.W. of Turfi.

TREBISACCIA, a town of Naples, in the province of Calabria Citra, on the coast; 10 miles N.E. of Cassano.

TREBISOND, or TARABOSAN, a city of Asiatic Turkey, with a harbour, on the Black sea, in the country of the Colchians: founded by a Greek colony of Sinope, descended from the Milesians. It derives its historical fame more from the circumstance of its hospitable reception of the 10,000 Greeks after their celebrated retreat, than for having been the capital of that portion of the Lower empire. From the Romans it was taken by the Scythians, or Tartars, in the time of Valerian. The Greek emperors became afterwards masters of Trebisond, and erected it into a principality; Alexis Comnenes took possession of it in the year 1204. When the French and Venetians made themselves masters

matters of Constantinople, this principality, or, as it is sometimes called, empire, continued till the year 1462, when it was taken by Mahomet II., who carried David Comnenes and all his family prisoners to Constantinople, where they were mostly put to death. The town of Trebifond is built on the sea-side, at the foot of a little hill, pretty steep; its walls are almost square, high embattled, and, though they are not of the first ages, yet it is very probable they stand upon the foundations of the ancient inclosure, which got this town the name of "Trapezium," or "Trapezus." The present walls are built of the ruins of the ancient edifices, as appears by old pieces of marble set in several parts, and whose inscriptions are not legible, because they are too high. The town is large, and not well peopled; there are more woods and gardens in it than houses; and those houses that are there, though well built, are but one story high. The castle, which is pretty large, but very much neglected, is situated upon a flat rock, and its ditches are cut in the rock. The inscription that is on the gate of this castle, the arch whereof is a semi-circle, shews that the emperor Justinian repaired the edifices of the town. The port of Trebifond, called "Platana," is to the east of the town. The emperor Adrian caused it to be repaired, as we are informed by Arrian. This port is now proper for nothing but fauques. The mole which the Genoese are said to have built there is almost destroyed, and the Turks give themselves very little trouble about repairing such works; 170 miles N.N.E. of Sivas. N. lat. $41^{\circ} 1'$. E. long. $39^{\circ} 40'$.

TREBITSCH, or TREBITZ, a town of Moravia, in the circle of Iglau, on the Iglawa, with considerable manufactures of cloth, iron, glass, &c.; 20 miles S.E. of Iglau. N. lat. $49^{\circ} 14'$. E. long. $15^{\circ} 50'$.

TREBITZ, a town of Saxony; 3 miles N.N.W. of Schmiedeberg.

TREBIUS, in *Ichthyology*, a name given by Joannes Cuba, and some other writers, to the fish called *phycis* by Aristotle, *Alian*, and *Pliny*.

TREBLE, in *Music*, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

In the like sense we say, a treble violiu, treble hautboy, &c.

In vocal music, the treble is usually committed to boys and girls. Their part is the treble.

The treble is divided into first or highest treble, and second or base treble. The half treble is the same with the counter-tenor.

TREBLIZ, in *Geography*, a town of Bohemia, in the circle of Leitmeritz; 10 miles S.W. of Leitmeritz.

TREBNITZ, a town of Silesia, in the principality of Oels; 12 miles N. of Breslaw. N. lat. $51^{\circ} 18'$. E. long. $17^{\circ} 2'$.

TREBNIZ, a town of Bohemia, in the circle of Leitmeritz; 6 miles S.W. of Leitmeritz.

TREBOWE. See *TRIBAU*.

TREBSCHEN, a town of Brandenburg, in the New Mark; 6 miles S.E. of Zulichau.

TREBSEN, a town of Saxony, in the circle of Leipzig, on the Muldau; 26 miles W. of Meissen. N. lat. $51^{\circ} 16'$. E. long. $12^{\circ} 40'$.

TREBUCHET, TREBUCKET, or *Trebuchetum*, a tumbler, ducking, or cucking-stool. See *CUCKING-STOOL* and *SCOLDS*.

TREBUCHET, in *Artillery*, a machine for throwing stones, for which purpose a sling was sometimes fixed to it: it acted by means of a great weight fastened to the short arm

of a lever, which being let fall, raised the end of the long arm with a great velocity.

TREBULA MUTUSCA, in *Ancient Geography*, a town placed by Strabo and Pliny among the Sabines, the existence of which is testified by many inscriptions. Virgil recognizes it for its olives, which perhaps might have occasioned its being called "Oliveto."

TREBULA SUFFENATA, a town of Italy, in the Sabine territory. It is supposed to have been situated in the valley of Turano, probably at the place called Rocca Sinibalda.

TREBURG, in *Geography*, a town of Hesse-Darmstadt; 10 miles W. of Darmstadt.

TREBUXENA, a town of Spain, in the kingdom of Seville; 12 miles from Xeres de la Frontera.

TRECASE, a town of Naples, in the province of Otranto; 5 miles E.N.E. of Alessano.

TRECASSES, or TRICASHI, in *Ancient Geography*, a people of Celtic or Lyonesse Gaul, according to Pliny and Ptolemy; subject, in the time of Cæsar, to the city of Sens (civitas Senonum), which was very powerful.

TRECCATE, in *Geography*, a town of Italy, in the department of the Olona; 5 miles E. of Novara.

TRECCHINA, a town of Naples, in Basilicata; 36 miles S. of Potenza.

TRECENTA, a town of Italy, in the department of the Mincio; 25 miles E.S.E. of Mantua.—Also, a town of Italy, in the department of the Lower Po; 12 miles N.N.W. of Ferrara.

TRECHEDIPNA, *τρεχιδειπνα*, formed of *τρεχω*, I run, and *δειπνον*, a supper, in *Antiquity*, a kind of livery, or distinguishing habits worn by parasites; the wearing of which was a sufficient passport to the tables of their patrons whose livery it was.

TRECHINIA, or TRACHINIA, in *Ancient Geography*, a small country of Thessaly, occupying the whole mountainous part west of the Maliac gulf, between the river Sperchius to the north and mount Oeta to the south. Near it was Heraclea Trachinia.

TRECHIS. See *TRACHIS*.

TRECHON, one of the many names by which the chemical writers have called quicksilver.

TRECOTHIC, in *Geography*, a township of New Hampshire; 65 miles N.W. of Portsmouth.

TREDDLE, or TREADLE, *Chalaza*, in *Natural History*, a part of an egg. See *CHALAZA*.

TREDECILE. See *ASPECT*.

TREE, ARBOR, the first and largest of the vegetable kind, consisting of a single trunk, out of which spring forth branches and leaves.

Mr. Ray distinguishes the trees and shrubs of our native growth of England into, 1. Such as have their flower disjointed and remote from the fruit: which are,

1. The *nuciferous* trees, or such as bear nuts: as the walnut-tree, the hazle-nut-tree, the beech, the chestnut, and the common oak.

2. *Coniferous* trees, or such as bear a squamous or scaly fruit, of a conical figure, and a woody or hard substance, in which are many seeds, which, when they are ripe, the cone opens or gapes in all its several cells or partitions, and lets drop out: of this kind are the Scotch firs, male and female; the pine, which, in our gardens, is called the Scotch fir; the common alder-tree, and the birch-tree.

These trees are also called resiniferous, by reason that coniferous trees are generally covered with a bark that abounds in resin.

TREES.

3. *Bacciferous* trees, are such as bear berries, as the juniper and yew-tree.

4. *Lanigerous* trees, or such as bear a woolly, downy substance: as the black, white, and trembling poplar, and willows and osiers of all kinds.

5. Trees *which bear their seeds* (having an imperfect flower) in *leafy membranes and cases*: as the horn-beam, or hard-beam, called, in some places, the horn-beech.

II. Such as *have their fruits and flowers contiguous*; which are either with the flower placed on the top of the fruit, or adhering to the base or bottom of the fruit. Of the former kind, some are *pomiferous*, as apples and pears; and some *bacciferous*, as the forb, or service-tree, the white-thorn, or hawthorn, the wild rose, sweet-briar, currants, the great bilberry-bush, honey-suckle, ivy, &c.

The latter kinds are either such as *have their fruit moist and soft when ripe*: as, 1. *Pruniferous* ones, whose fruit is pretty large and soft, with a stone in the middle; as the black-thorn, or sloe-tree, the black and white bullace-tree, the common wild cherry, the black cherry, &c.

2. *Bacciferous* trees, as the strawberry-tree common in the west of Ireland, mistletoe, water-elder, the dwarf or spurge-laurel, the viburnum, or wayfaring-tree, the dog-berry-tree, the sea black-thorn, the berry-bearing elder, the privet, barberry, common elder, the holly, the buck-thorn, the berry-bearing heath, the bramble, and the spindle-tree or prickwood.

Or such as *have their fruit dry when ripe*: as the bladder-nut-tree, the box-tree, the common elm and ash, the maple, the gaule, or sweet willow, common heath-broom, dyer's-weed, furze or gorse, and the lime-tree.

TREES in *full Air*, or *Standards*, are such as naturally rise a great height, and are not topped. See STANDARDS, STANDARD-Trees, and TIMBER.

TREES, *Dwarf*, are such as are kept low, and never suffered to have above half a foot of stem. These are used to be kept vacant, or hollow in the middle, that the branches, spreading round about the sides, may form a kind of round bowl, or bush. See DWARF-Trees.

TREES, *Forest*. See FOREST-Trees and PLANTING.

TREES, *Wall*, are those whose branches are stretched out, and nailed against walls.

For dwarf and wall-trees, such are to be chosen out of the nursery for transplantation as are straight, and consist of a single stem, and a single graft, rather than two or three grafts in several branches: their thickness at bottom, when removed, should be two or three inches.

TREES, *Fruit*, are such as bear fruit. See FRUIT-Trees.

TREES, *Timber*, are those whose trunks are tall and straight, of which beams, masts, &c. are used to be made.

Trees that are nine inches girth about a yard from the ground, are commonly reckoned timber-trees, but none under this size. See TIMBER and PLANTING.

The growth of trees is a curious and interesting subject; but few experiments have been made in order satisfactorily to ascertain the annual accessions that are made to the bulk of trees at different periods of their age. Mr. Barker has furnished a table exhibiting the increase of three kinds of trees, *viz.* the oak, ash, and elm, in the Phil. Trans. for 1788. He states the result as follows:

"I find (says he) the growth of oak and ash to be nearly the same. I have some of both sorts planted at the same time, and in the same hedges, of which the oaks are the largest; but there is no certain rule as to that. The common growth of an oak or an ash is about an inch in girth in a year; some thriving ones will grow an inch and a half; the unthriving ones not so much. Great trees grow more

timber in a year than small ones; for if the annual growth be an inch, a coat of one-sixth of an inch is laid on all round, and the timber added to the body every year is its length multiplied into the thickness of the coat and into the girth, and therefore the thicker the tree is, the more timber is added."

We will present our readers with a table, shewing the growth of 17 kinds of trees for two years. The trees grew at Cavenham in Suffolk.

Names of Trees.	July 1785.	July 1786.	July 1787.
	Ft. In.	Ft. In.	Ft. In.
1. Oak - - -	0 10 $\frac{1}{2}$	0 11 $\frac{1}{2}$	1 0 $\frac{1}{2}$
2. Larch - - -	1 0 $\frac{1}{2}$	1 3	1 4
3. Scotch fir - - -	1 3 $\frac{1}{2}$	1 5 $\frac{1}{2}$	1 7 $\frac{3}{4}$
4. Spruce fir - - -	0 5 $\frac{1}{2}$	0 6 $\frac{1}{2}$	0 7 $\frac{1}{4}$
5. Spanish chestnut - - -	0 7 $\frac{1}{4}$	0 7 $\frac{1}{2}$	0 8
6. Elm - - -	2 7 $\frac{1}{2}$	2 9	2 11
7. Pinaster - - -	2 3 $\frac{1}{2}$	2 4 $\frac{1}{2}$	2 7 $\frac{1}{2}$
8. Larch - - -	1 5 $\frac{1}{4}$	1 6	1 7
9. Weymouth pine - - -	0 5	0 6	0 7 $\frac{1}{4}$
10. Acacia - - -	1 2 $\frac{3}{4}$	1 5 $\frac{3}{4}$	1 6 $\frac{1}{2}$
11. Beech - - -	0 6 $\frac{1}{4}$	0 6 $\frac{1}{2}$	0 7 $\frac{1}{4}$
12. Plane occidental - - -	0 6 $\frac{1}{2}$	0 7 $\frac{1}{4}$	0 8 $\frac{3}{4}$
13. Lombardy poplar - - -	1 8	2 0	2 3 $\frac{3}{4}$
14. Black poplar - - -	1 2 $\frac{1}{4}$	1 4 $\frac{1}{2}$	1 5 $\frac{3}{4}$
15. Willow - - -	2 9 $\frac{1}{2}$	3 2	3 3
16. Silver fir - - -	0 7 $\frac{3}{4}$	0 8 $\frac{3}{4}$	0 9 $\frac{1}{4}$
17. Lime - - -	1 8 $\frac{1}{2}$	1 10 $\frac{3}{4}$	2 0

Heat is so essential to the growth of trees, that we see them grow larger and smaller in a sort of gradation as the climates in which they stand are more or less hot. The hottest countries yield, in general, the largest and tallest trees, and those also in much greater beauty and variety than the colder do; and even those plants which are common to both, arrive at a much greater bulk in the southern than in the northern climates; nay, there are some regions so bleak and chill, that they raise no vegetables at all to any considerable height. Greenland, Iceland, and the like places, afford no trees at all; and what shrubs grow in them are always little and low.

In the warmer climates, where trees grow to a moderate size, any accidental diminution of the common heat is found very greatly to impede vegetation; and even in England, the cold summers we sometimes have, give us an evident proof of this; for though the corn and low plants have succeeded well enough, and gooseberries, currants, raspberries, or other low shrubs, have brought forth fruit in sufficient plenty, yet the production of taller trees has been found very much hurt; and walnuts, apples, and pears, have been very scarce among us.

Heat, whatever be the producing cause, acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal-fires in stoves, is found to supply the place of the sun.

Great numbers of the Indian trees, in their native soil, flower twice in a year, and some flower and bear ripe fruit all the year round; and it is observed of these last, that they are at once the most frequent and the most useful to the inhabitants; their fruits, which always hang on them in readiness, containing cool juices, which are good in fevers, and other of the common diseases of hot countries.

Plantations of useful trees might be made to very great advantage in many places in every country, and the country greatly

TREES.

greatly enriched by it, while the public would be also benefited by it, since it would raise a continual supply of timber used in ship-building, and on other public as well as private occasions.

We have in many places heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public to bring these to be truly valuable. Many, if not all of these heaths, would be found on trial capable of producing trees; and some of them are truly the remains of destroyed forests; and though the profit to be reaped from the planting of them would come late, yet the expence of doing it would be very trifling in comparison of that profit, and the means easy. See **TIMBER** and **PLANTATION**.

The authors who have given rules for planting, having employed themselves only about small spots of ground, the establishing of orchards or parks, are by no means to be supposed proper guides in attempts of this kind; and *Monf. de Buffon*, who had a great opinion of the knowledge of our *Evelyn* and *Miller*, who seem to speak of every thing from their own experience, found, when he set about large plantations, that their opinions and rules were erroneous; and was obliged to have recourse to experience only, which he varied a thousand ways; and though many of them proved unsuccessful, yet they all gave hints towards others, by which the attempt might afterwards be brought to succeed.

This sagacious enquirer into the operations of nature in the growth of vegetables, having set apart a considerable quantity of land for the trial, and procured a number of young trees, first divided the whole quantity into a number of small squares, and having made a plan of it, examined the nature, depth, and other circumstances of the soil in each, and minuted the whole down on a proper part of the plan; that himself, or whoever succeeded him, might judge from the different growths of a number of trees planted in the same state in these different soils, the different advantages and disadvantages of every circumstance in the depth and nature of the ground, in regard to the growth of useful trees. Different numbers of labourers were employed upon different spots of this ground, and the acorns for the young growth planted at different seasons: but the result in general was, that what should seem the best methods succeeded the worst; and those pieces where many labourers had been employed, and the acorns planted before winter, were much thinner of young oaks than those where the least labour had been bestowed upon the ground, and where the acorns had been planted in the spring: but those places which succeeded best from the sowing, were those which had the acorns planted in holes made by a pick-axe, without any preceding culture of the ground. And those where the acorns had only been laid upon the earth, under the grafs, afforded a great number of vigorous young trees, though the greater part had been carried away by birds and other devouring animals. Those spots of ground where the acorns were set at six inches depth were much worse furnished with young shoots, than those where they had been buried but at an inch deep; and in some places where they were buried at a foot deep not one shoot appeared, though in others, where they had been buried at nine inches, there were many.

Those acorns which had been steeped for eight or nine days in wine lees, and in the water of the common sewers, appeared out of the ground much earlier than those which were put in without this previous management.

But the most successful of all the trials, was that of planting in the spring such acorns as had been sown toge-

ther in another place, and had time to shoot there; of these scarcely any one failed, and the plantation was perfectly flourishing, though the growth of these young shoots was not so quick or vigorous as those of the acorns which had remained when first sown; which was probably owing to the injury the tender radicles received in transplanting.

Thus succeeded the experiments by sowing, while of those made by planting young trees, such as had been brought out of woods and places under covert, succeeded much worse than those which had grown in more exposed places.

The young trees of the several parts of the plantation kept on their growth in the manner they had begun to shoot, those of the more laboured parts continuing more weak, and lower than those of the less laboured.

Thus were a number of necessary experiments carefully tried, and the result of the whole was, that to make a plantation of oaks, on a soil of the common clayey or loamy kind, the most successful method is this: the acorns must be preserved during the winter in the earth in this manner: let there be made a bed of earth of six inches deep; on this place a layer of acorns, two inches deep; over these lay a bed of another half foot of earth, over that another layer of acorns, and so on successively, till as many are employed as there will be occasion for: the whole is then to be covered with a foot depth of earth to preserve all from the frost. In the beginning of March these beds are to be opened, and the acorns, which will by that time have shot out, and are then in reality so many young oaks, are to be planted out a foot distance each, and the success of a plantation of this kind need not be feared. This is a manner of planting that is done at a small expence, and even that might be in a great measure spared, were it not for the birds and other devouring animals; since, could the acorns be defended from these, they might be only laid on the surface of the ground under the grafs in autumn, and they would infallibly shew themselves in so many young oaks the succeeding spring.

It is easy to continue the carrying of the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the small stop the transplanting puts to their growth is in reality rather an advantage than an injury, since it only retards the young shoots for about three weeks, or less than that; and by that means secures them from the few cold mornings that may be expected about the time of their natural appearance. *Mem. Acad. Scienc. Paris, 1739.* See **TIMBER**.

An experiment to determine the comparative durability of different kinds of timber, when exposed to the weather, was made by a nobleman in Norfolk; of which an account is given by *fir Thomas Bevor*. This nobleman, in the year 1774, ordered three posts, forming two sides of a quadrangle, to be fixed in the earth on a rising ground in his park. Into these posts were mortised planks, an inch and a half thick, cut out of trees from 30 to 45 years' growth. These, after standing ten years, were examined, and found in the following state and condition:

The cedar was perfectly found; larch, the heart found, but the sap quite decayed; spruce fir, found; silver fir, in decay; Scotch fir, much decayed; pinaster, quite rotten; chesnut, perfectly found; abele, found; beech, found; walnut, in decay; sycamore, much decayed; birch, quite rotten. *Sir Thomas Bevor* justly remarks, that the trees ought to have been of the same age; and *Mr. Arthur Young* adds, they ought to have been cut out of the same plantation.

The

The immense quantity of timber consumed of late years in ship-building and other purposes, has diminished in a very great degree the quantity produced in this country. On this account, many gentlemen who wish well to their country, alarmed with the fear of a scarcity, have strongly recommended it to government to pay some attention to the cultivation and preservation of timber.

It appears, on the authority of Mr. Irving, inspector-general of imports and exports, that the shipping of England in 1760 amounted to 6107 in number, the tonnage being 433,922; and the shipping in Scotland amounted to 976 in number, the tonnage being 52,818. In 1788, the whole shipping of Britain and Ireland and their colonies amounted to 13,800, being 1,359,752 tons burden, and employing 107,925 men. The tonnage of the royal navy in the same year was 413,667. It also appears, from the report of the commissioners of the land revenue, that the quantity of oak-timber of English growth, delivered into the dock-yards from 1760 to 1788, was no less than 768,676 loads, and that the quantity used in the merchants' yards in the same time was 516,630 loads; in all 1,285,306 loads. The foreign oak used in the same period was only 137,766 loads. So that after deducting the quantity remaining in the dock-yards in 1760 and 1788, and the foreign oak, there will remain about 1,054,284 loads of English oak, consumed in 28 years, which is at an average 37,653 loads *per annum*, besides from 8300 to 10,000 loads expended annually by the East India Company within the same period.

A writer in the Bath Transactions, cited in the Encyclopædia Britannica, article *Tree*, says, that the aggregate of oaks felled in England and Wales for 30 years past, has amounted to 320,000 loads in a year; and as this statement seems to differ from that above given, under the authority of the commissioners of land revenue, we think it necessary to point out the reason of this difference. This we are enabled to do, by the liberal communication of the ingenious Samuel Purkis, esq. whose diligence of research and accuracy in making the necessary calculations, and fidelity in reporting the result of his inquiries, must be admitted by all who knew him without hesitation. He informs us, that the calculation was made by himself and a friend at the request of Mr. Pitt, then prime-minister, in order to ascertain whether there was a sufficient quantity of oak-timber in this country to supply the probable demand for many years.

The calculations were made from documents furnished by government, and upon principles which could not fail to afford an accurate result. This result was communicated by Mr. Purkis to Mr. South, a man of fortune and respectability in Hampshire, and was published by him in the Bath Transactions. The discrepancy above-mentioned is merely apparent, and not real. For the commissioners of the land revenue only stated the annual consumption in the royal navy, and by the East India Company; whereas Mr. Purkis's statement comprehended the annual consumption of the *whole kingdom*; nor had they the means which he possessed of making the latter estimate.

The building of a 70-gun ship, it is said, would take 40 acres of timber; and though this may seem to be an exaggerated estimate, it should be considered, that, according to the prevailing opinion of experienced surveyors, it will require a good soil and good management to produce 40 trees on an acre, which, in 100 years, may, at an average, be computed at two loads each. Reckoning, therefore, two loads at 8*l.* 16*s.*, one acre will be worth 350*l.* and consequently 40 acres will be only worth 14,200*l.* The building of a 70-gun ship is generally supposed to cost 70,000*l.*; and as ships do not last many years, the navy continually re-

quires new ships, so that the forests must be stripped in a century or two, unless young trees are planted to supply their place.

As the consumption of oak-timber is so considerable, methods should be devised and diligently practised for procuring a fresh supply.

Trees are liable to a variety of diseases and injuries, for the prevention or cure of which various means have been proposed.

The chevalier de Bienenberg of Prague, we are told, has discovered a method of effectually preserving trees in blossom from the fatal effects of those frosts which sometimes in the spring destroy the most promising hopes of a plentiful crop of fruit. His method is extremely simple. He surrounds the trunk of the tree in blossom with a wisp of straw or hemp. The end of this he sinks, by means of a stone tied to it, in a vessel of spring-water, at a little distance from the tree. One vessel will conveniently serve two trees; or the cord may be lengthened so as to surround several, before its end is plunged into the water. It is necessary that the vessel be placed in an open situation, and by no means shaded by the branches of the neighbouring trees, that the frost may produce all its effects on the water, by means of the cord communicating with it.—This precaution is particularly necessary for those trees, the flowers of which appear nearly at the same time as the leaves; which trees are peculiarly exposed to the ravages of the frost. The proofs of its efficacy, which he had an opportunity of observing in the spring of 1787, were remarkably striking. Seven apricot espaliers in his garden began to blossom in the month of March. Fearing that they would suffer from the late frosts, he surrounded them with cords as above directed. In effect, pretty sharp frosts took place six or eight nights: the apricot-trees in the neighbouring gardens were all frozen, and none of them produced any fruit, whilst each of the chevalier's produced fruit in abundance, which came to the greatest perfection. See FROST.

For Mr. Forsyth's remedy, we refer to the article *COMPOSITION for Trees*. See also *GRAFTING*.

Mr. Ray, and other authors, speak of several trees of prodigious bulk.

The jesuit d'Acoſta, in his History of the Indies, lib. iv. cap. 3, mentions a hollow tree at Tlacocharaya, three leagues from Guaxa, in New Spain, nine fathoms withinside near the ground, and sixteen withoutside. He adds, that it is under this tree the barbarians assembled to perform their religious ceremonies, dance round their idols, &c. Herrera mentions another, which sixteen men, joining hands, could not fathom. And F. Kircher, in his Latium, p. 50, affirms that he has seen a tree, near Gonzano, which would lodge a whole family of twenty-five persons in its cavity. The common people had a tradition, that this was planted by Augustus.

There are forests of very large chestnut-trees, growing out of the lava of mount *Ætna*, in Sicily. One of these, called the *Castagno di Cento Cavalli*, is much the most celebrated. It measures 204 feet round, and though said to be united below in one stem, it is a bush of five large trees growing together. The hollow of one of these chestnut-trees is said to contain a hundred sheep, and it is also related, that thirty people have been in it on horseback. Brydone's Letters, vol. i. p. 109, &c. See *ÆTNA*.

In the Indies there are very large forests formed from a single tree, whose branches bending to the ground, take root, and put forth new trees: the Indian fig-tree and paratuvier are of this kind.

M. Lonvillers mentions trees in Peru, one part of whose branches produce fruit one half the year, and the other part

TREES.

part the other half. In China there is a tree which bears tallow, of which that nation make their candles. See *SEBIFERA* and *TALLOW*.

Mr. Marham saw spruce and silver firs in the dock-yard at Venice above forty yards long, and one of thirty-nine yards was eighteen inches in diameter at the smallest end. It was said that they were brought from Switzerland. Some yews have been found in Britain sixty feet round. Palms in Jamaica attain the height of 200 feet, and some of the pines in Norfolk island are 280 feet high.

At Tortworth, in Gloucestershire, it is said by the writer of the report on agriculture for that district, that a chestnut-tree was measured in 1791, which was found to be forty-four feet and four inches in circumference.

The great Boddington oak, belonging to the manor-farm of the same name in the same district, before it was burnt down in 1790, either by accident or design, was not less remarkable. It grew in an old orchard-ground, and the following account was given of it by Marshall, in his work on planting, as it appeared in 1783. The stem was remarkably collected and snug at the root; the sides of its trunk more upright than those of large trees in general; its circumference at the ground somewhat more than eighteen yards, and at its smallest dimensions twelve. The greatest extent of arm, eight yards from the stem; and the greatest height of the branches, forty-five feet. The stem quite hollow, forming a capacious well-sized room, measuring on the floor, one way, more than sixteen feet in diameter. At that time it was perfectly alive and fruitful, with a large fine crop of acorns upon it. Part of the trunk, it is said, escaped the fire, and still remains.

In Needwood forest, the oak-tree called the Swilcar lawn oak contains, as Mr. Pitt supposes, in his account of the agriculture of Staffordshire, at least a thousand feet of timber. The Rev. Mr. Snow says, this oak, the father of the forest, girths at five feet high twenty-one feet; the lower stem is ten feet clear; the whole height about sixty-five; and the extent of the arms about forty-five feet. It is of great antiquity, but still fruitful in acorns.

In the first volume of the Agricultural Survey for the County of Essex, it is stated, that in Hatfield forest Sir John Barrington has a very beautiful oak, for which a timber dealer offered one hundred guineas. And that near it is the ruin of a most venerable tree of the same kind, which gave the name of Broad-Oak to Hatfield.

There is a Lombardy poplar in this district which is a very fine and beautiful tree, guessed to be above seventy feet high, and which at five feet from the ground measures seven feet three inches in circumference. It is one of the three original trees of this kind which were brought by Lord Rochfort from Italy, and planted at St. Olyth above forty years ago, and from which much the greater part of those which are now scattered through the kingdom originated.

Very near to it is the largest and most beautiful laurel of the Portugal kind that is almost any where to be seen; it is nearly of a semi-globular form; feathered all round to the lawn it grows in, and is fifty-two yards in circumference.

At a small distance from these prodigies of vegetation, it is said, another at least equally interesting, an arbutus, which would make no inconsiderable figure at Killarney. They are in the grounds of Mr. Nassau, in which the soil is a fine rich sound loam. See the Report.

There are now growing about Townley Hall, in Lancashire, besides many large fine oak timber-trees, an ash-tree, called the wain-lionc ath, which measures fourteen feet in circumference: a hazle-tree, which is three feet in girth: a yew-tree, which has six feet two inches of girth: and a

white-thorn, in New Copy field, which measures seven feet in circumference.

There are two or three very remarkable phenomena in the growth of trees, which have escaped the observation of the naturalists of all ages, except those of our own: these are the perpendicularity of their trunks or stems to the horizon, and the parallelism of their tufts to the spot of earth they grow on. See *PARALLELISM* and *PERPENDICULARITY*.

For the planting, transplanting, semination, pruning, felling, grafting, throwing, &c. of trees. See *PLANTATION*, *PLANTING*, &c.

On felling of trees, letters have sometimes been found in the midst of them. We have instances of this kind mentioned in the *Philos. Trans.* N^o 454, sect. 16. where the trunk of a beech being sawed, discovered several letters in the wood, about an inch and a half from the bark, and near the same distance from the centre of the trunk. It seems these letters had been formerly cut into the bark, and in process of time these might be covered.

In the same Transactions, we have an account of the horn of a deer found in the heart of an oak. Crucifixes have also been found in trees, and were of course shewn as miraculous to the ignorant. See p. 236. of the said Transactions in the Remarks.

Trees are often found buried in the earth. See *MORASS*, *FOSSIL WOOD*, and *BOG WOOD*.

For the punishment of stealing trees, see *LARCENY*.

By stat. 1 Geo. I. c. 48. maliciously to set on fire any underwood, wood, or coppice, is made single felony. By the Black-act, to cut down or destroy any trees planted in an avenue, or growing in a garden, orchard, or plantation for ornament, shelter, or profit, is felony without benefit of clergy; and the hundred shall be chargeable for the damages, unless the offender be convicted. By 6 Geo. III. cap. 36. and cap. 48. wilfully to spoil or destroy any timber or other trees, roots, shrubs, or plants, is, for the two first offences, liable to pecuniary penalties; and for the third, if in the day-time, and even for the first, if at night, the offender shall be guilty of felony, and liable to transportation for seven years.

TREES, Juices of. See *JUICE* and *SAP*.

TREES, Felling of. See *FELLING* and *TIMBER*.

TREES, Parallelism of Rows of. See *PARALLELISM*.

TREES, Fruit, Barking of, in *Rural Economy*, the injury of their having the bark eaten off by hares and rabbits in the winter season. It is particularly the case with young apple and pear trees, and occasionally with forest-trees and shrubs. Several different methods of preventing it, and of protecting the trees, have been proposed at different times; such as twisting straw-ropes round the trees; driving in small flat stakes all about them; and the use of strong-scented oils. But better and neater modes of effecting the business have lately been suggested in the Transactions of the Scotch Horticultural Society; as with hog's-lard, and as much whale-oil as will work it up into a thin paste or paint, with which the stems of the trees are to be gently rubbed upwards, at the time of the fall of the leaf. It may be done once in two years, and will, it is said, effectually prevent such animals from touching them.

Another and still neater method, is to take three pints of melted tallow to one pint of tar, mixing them well together over a gentle fire. Then, in the month of November, to take a small brush, and go over the rind or bark of the trees with the composition, in a milk-warm state, as thus

as it can be laid on with the brush. It is found that such a coating does not hinder the juices or sap from expanding in the smallest degree; and the efficacy of the plan is proved, in preventing the attacks of the animals, by applying the liquid composition to one tree and missing another, when it was found that the former was left, while the latter was attacked. Its efficacy has been shewn by the experience of five years. The trees that were gone over the first two years have not been touched since; and none of them have been injured by the hares.

It is a mode particularly well adapted for nurseries, where the ground is not well secured with a fence to protect the young fruit-trees and tender shrubs from hares.

The above is the proportion of the materials, whatever may be the extent of trees.

TREES, *Mossing of*, their becoming much affected and covered with the moss-plant or mossy substance. It is found to prevail in fruit-grounds of the apple kind, and in other situations, when they are in low, close, confined places, where the damp or moisture of the trees is not readily removed. It is thought to be an indication of weakness in the growth, or of a diseased state of the trees, and to require nice attention in preventing or eradicating it. The modes of removing it have usually been those of scraping, rubbing, and washing, but they are obviously calculated for trees only on a small scale. How far the use of powdery matters, such as lime, chalk, and others, which are capable of readily absorbing and taking up the wetness that may hang about the branches and other parts of the trees, by being well dusted over them, may be beneficial, is not known, but they would seem to promise success by the taking away the nourishment and support of the moss, when employed at proper seasons. And they are known to answer in destroying moss in some other cases, when laid about the stems of the plants, as in thorn-hedges, &c.

In the fruit-grounds of Gloucestershire it is recommended, the writer of the account of the agriculture of that district says, to wash with soap-suds, and rub off the moss with a brush, in wet weather when it is soft, and easily separable from the different parts of the trees. This work should be begun at an early period of the growth of the trees, when the branches are few and open, and be repeated every season; otherwise the labour would be too great to undertake on a large extent, when the trees are full-headed, and entangled with shoots. The fruit-farmer should not, however, be too easily discouraged, since it has been discovered, that the eggs of caterpillars are often lodged between the moss and the rind of the trees, and probably the insects issue forth from these depositaries in the spring, to the destruction of leaf and blossom.

In this district, the mossing of the trees is attributed to the plantations being made on grass-lands, which is the common practice in a great part of the county; as, it is said, that in the neighbouring counties, where the fruit-trees are planted in hop-grounds and arable fields, the trees, though not free, are less affected by it. This may, it is supposed, be owing to the frequent manuring and stirring of the mould near the roots, by which means the sun and rain have power to exert their influence, and by invigorating the fibres, promote a general kindness in the growth of the trees.

The mossing in all sorts of trees is injurious to their growth by depriving them of a portion of their nourishment, but more particularly hurtful to those of the fruit-tree kind, as preventing them from bearing full good crops of fruit by rendering them in a weak and unhealthy state.

TREES, *Espalier, Cast-iron Rails for*, a new mode of forming this sort of rails. It is noticed in a Paper in the first volume of the Memoirs of the Caledonian Horticultural Society, that the advantages attending rails of this kind in gardens, in respect to utility as well as ornament, are well known and acknowledged. The greater chance they afford to the fruit in setting and ripening, by the branches being laid in at regular and equal distances, the neatness of appearance which the trees exhibit, and the elegant vistas produced by the rail and trees when bordering the sides of well-kept walks, are all matters with which the admirers of horticulture have long been acquainted. It does not appear, however, whatever may have been the cause, that this, by no means uninteresting branch of the art, has hitherto in any considerable degree engaged the attention of the improver.

The rails for trees of this kind have, for the most part, been made of wood, though not without objections; the principal of which are, want of durability in the substance; the difficulty of keeping them in a perfectly rectilinear position; and the clumsiness of appearance which they constantly, in some degree, exhibit, when made of the dimensions necessary for the proper extension of the trees.

The most usual modes of constructing such rails are two: first, the having upright splits of dressed timber sunk into the ground, and mortised into a horizontal top-rail. This is greatly objectionable on account of the speedy decay, and from the splits always soon giving way where sunk into the ground, as well as from its being scarcely practicable to keep them straight. The second, or that which is the most generally practised, is to sink upright posts into stones, to mortise two cross-bars into them, and to nail upright slips to the bars. The great defect in this mode is, that by the bulk of the posts, rails, and splits, so great a strain is thrown upon the stones during high winds, that they cannot long resist it: and the consequence is, that the rail soon begins to twist, while the part sunk into the stones, in spite of every precaution, will at no great length of time decay, in consequence of moisture getting in between the wood and the stone.

In order to obviate these objections, the substitution of espalier rails formed of cast-iron instead of wood, has been proposed and tried with success by a gentleman in Dunbar-shire, Scotland.

Each portion of rail is formed of two rails inserted at the different ends into handsome upright columns or posts, having erect arrows or pieces fixed into them, somewhat in the manner of common iron paling, the whole sheet or portion resting upon three supports at the bottom, in the way directed below. The supporters on which it stands are thus contrived: the centre one is a piece of seasoned oak, driven firmly into the ground, and sunk a little below its surface. It receives the upright middle arrow-piece, which keeps up the centre of the bottom rail, and through which the different upright arrow-pieces to each side of it are put. It is supported below the rail by two pieces of the same metal in a triangular manner. Those at the ends are stones of two feet in length, having their tops hewn into an hemispherical shape, and perforated in the middle by a hole of four inches in depth, and two in diameter, which receives the bottom ends of the columns or posts. The upright arrow-pieces are each furnished with a ruff at the places where they meet the top and bottom rail.

The columns or posts have the length of six feet, their bottoms being sunk, as above, into the stones: the diameter of them at the bottom rail is an inch and a half, and at the top, one inch and one-eighth: the upright arrow-pieces are five feet in length, and their diameter half an inch: the bottom rails are three-eighths of an inch in thickness, and in breadth

breadth one inch and five-eighths; the top ones three-fourths by one-fourth of an inch. The columns, at the parts where the rails enter them, have a flank projecting at right angles to them, with a hole, through which, and through a hole in the end of the rail, a leaden rivet is put, for fastening the rail to the column or post. See TREILLAGE.

TREE, *Onion*, in *Gardening*, that sort of onion-plant which rises somewhat in the tree-like form, and which affords its produce or bulbs at the top of the stem or stalk. At what period this valuable and useful bulb-rooted plant was first introduced into this country, seems now to be quite uncertain; and it has never yet perhaps been grown or cultivated to any extent in any part, being mostly had in growth merely for the sake of curiosity. From a Paper inserted in the first volume of the *Memoirs of the Caledonian Horticultural Society*, it would appear, however, to be capable of being raised with advantage as a substitute, in part, for onions of the keeping kind, as might have been supposed from the severe nature of the climate from which it originally came.

In addition to the little which has been said of the nature of its culture for the purposes of ornament and variety under the head *Allium*, (which see,) the following observations on its culinary use may be given in this place.

It is stated, on the experience of some years, in the Paper alluded to above, that the root-bulbs, when two years old, put up each a stem from thirty inches to three feet in height, on which good-sized bulbs are formed at top: that from these, others push out of a second size; and that sometimes a third set is produced, which are still smaller; but that the first and second sizes are the only ones which are fit for planting. Towards the end of summer, the top-bulbs are in a proper state for gathering, and should be collected and carefully dried in a shady place, then put in a dry airy situation, until the season for planting them out. At this time the old stool-bulbs should be lifted, which have mostly one or two onions to each of them, which are of good quality, and keep well until late in the following spring season.

About the last week in the month of April is the most proper time for planting out the young top-bulbs for the purpose of a crop, as if sooner planted, they are apt to push that season, and neither produce good root-bulbs nor top-bulbs. The old roots should be planted out any time in the month of February, or the following one, as early planting has the power of making them produce good bulbs at top. The young bulbs of the first size should be separated and planted out in rows in any good garden ground, which is in an open situation, six inches by four: the second size in rows six inches by three, in shallow drills of very little depth, as the swelling and ripening of the roots are spoiled when they are deep.

The whole of these will, it is said, produce onions of a good size, which will keep, when well taken care of, until the middle of May. The old stool-bulbs, when not all wanted for planting, will likewise keep equally well; and after a sufficient stock of them has been provided, the rest may be used with the other principal sorts.

It is noticed that the old roots are the best for replanting for a crop of top-bulbs, as they are the most certain of running to stems.

The writer has never known these crops to be infested with vermin in any stage of their growth; the reason of which is, it is thought, their quick growth and coming to maturity before the season at which vermin commonly attack the usual spring-sown roots, as it has been found that the late or autumn-sown crops of the common kind, when

allowed to stand for an over-year produce, are seldom or ever affected in this way, even on light dry ground.

This sort of onion, besides its property of long keeping, is a strong well-flavoured kind, equal, if not superior, to most of the common sorts.

It is, however, perhaps the best calculated for private gardens, as requiring a good deal of attention, as in such, when once provided with a certain quantity of stool-bulbs, the proprietors would be rendered independent of the failure of the crops of common onions; and it is confidently asserted, that if the cultivation of it were generally well understood, it would be capable of being grown with both pleasure and profit in a great many cases.

TREE, *Celandine*. See BOCCONIA.

TREE, *Cork*. See CORK and OAK.

TREE, *Chaste*. See AGNUS CASTUS.

TREE of *Life*, *Arbor vite*, in *Botany*. See THUJA.

The occidental, which grows naturally in Canada and other northern countries, is used, according to professor Kalm, for many medicinal purposes. It is much extolled for rheumatic pains; with this intention the fresh leaves are pounded in a mortar, and mixed with hog's grease, or any other grease; this is boiled together, till it becomes a salve, which is spread on linen, and applied to the part where the pain is. This salve gives certain relief in a short time.

Against violent pains which move up and down in the thighs, and sometimes spread all over the body, they recommend four-fifths of the leaves of polypody (*polypodium fronde pinnata*, &c.) and one-fifth of the cones of the thuja, reduced separately to a coarse powder, and afterwards mixed. With this powder, and milk-warm water, they make a poultice, which they spread on linen, and wrap round the body; but they commonly lay a cloth between it and the body, otherwise it would burn and scorch the skin.

The decoction of thuja leaves is used as a remedy for the cough; and they use this at Saratoga for the intermitting fever.

TREE-Frog. See RANUNCULUS *Viridis*.

TREE, *Germander*. See TEUCRIUM.

TREE, *Mallow*. See LAVATERA.

TREE, *Mealy*, or *White-leaf*. See WAYFARING-Tree.

TREE-Moss, a species of *Lichen*; which see.

TREE, *Primrose*. See OENOTHERA.

TREE-Louse. See APHIS.

TREE, *Diana's*, in *Chemistry*. See ARBOR.

TREE, *Dormant*. See DORMANT.

TREE-Fold, in *Sheep-farming*, a term applied to that sort of sheep-fold which is formed or surrounded by trees in the growing state, and which is well suited for protecting them in certain exposed situations, as well as affording them other advantages. See SHEEP.

TREES, in a *Ship*, are of several sorts, as *cheese-trees*, *cross-trees*, *roof-trees*, *waste-trees*, *treffel-trees*. See CHESS-TREES, &c.

TREE Island, in *Geography*, a small island in the Indian sea, near the coast of Africa. N. lat. $17^{\circ} 10'$. — Also, a small island in the East Indian sea, near the E. coast of Sumatra. S. lat. $3^{\circ} 50'$. E. long. $105^{\circ} 51'$. — Also, a small island near the W. coast of Sumatra. S. lat. $1^{\circ} 58'$. E. long. $100^{\circ} 15'$. — Also, an island in the bay of Bengal, near the coast of Ava. N. lat. $18^{\circ} 12'$. E. long. $94^{\circ} 15'$.

TREE-A-TOP ISLAND, one of the Chusan islands, which undoubtedly deserved the appellation given to it, when it was first described by the Europeans above half a century ago, at which time they were permitted to trade to Chusan.

but the tree is gone, and this island, which is as bare as those surrounding it, is only known by its relative position in the chart. To the southward of this island, about three or four miles, there is excellent anchorage in five or six fathoms water, where ships are sheltered from every wind.

TREE-NAILS, or **TRENNELS**, in a *Ship*, are long cylindrical wooden pins, employed to connect the planks of a ship's side and bottom to the corresponding timbers, and to fasten the anchor-stock.

The tree-nails are justly esteemed superior to spike-nails or bolts, which are liable to rust and loosen, as well as to rot the timber: but it is necessary that the oak of which they are formed should be solid, close, and replete with gum, to prevent them from breaking and rotting in the ship's frame. They ought also to be well dried, so as to fill their holes when swelled with moisture. They have usually one inch in thickness to 100 feet in the vessel's length; so that the tree-nails of a ship that is 100 feet long, are one inch in diameter, and one inch and a half for a ship of 150 feet.

TREET, **TRITICUM**, in our *Statutes*, is used for fine wheat. See stat. 51 Hen. III. Hence *treet-bread*. See **BREAD**.

TRE-FALLOW, *To*, in *Husbandry*, is to plough land the third time before sowing.

TREFFEN, in *Geography*, a river of Carinthia, which runs into the Drave, 6 miles below Villach.

TREFFORT, a town of France, in the department of the Ain; 7 miles N.E. of Bourg-en-Bresse. N. lat. $46^{\circ} 16'$. E. long. $5^{\circ} 27'$.

TREFFURT, a town of Westphalia, in the territory of Eichsfeld; 10 miles W.S.W. of Muhlhausen.—Also, a town of Germany, in the principality of Hesse-Rhinfels, situated on a hill near the Werra; 36 miles E.S.E. of Cassel. N. lat. $51^{\circ} 8'$. E. long. $10^{\circ} 18'$.

TREFOIL, in *Architecture*, the usual mode of ornamenting an arch in the pointed style by the insertion of a *cusps* or point on each side of it. Other trefoils are inscribed within a circle, and resemble a head of clover-grass more perfectly.

TREFOIL, in *Botany*. See **TRIFOLIUM**.

Trefoil is a plant of the clover kind, which is not unfrequently sown or met with in grass-lands. It is always a valuable plant in such grounds as are kept under a permanent state of grass; and not much less useful, when sown and cultivated in those of the arable kind. See **CLOVER** and **MEDICAGO Lupulina**.

It succeeds well on soils of different descriptions, as on those of the dry, loamy, and the calcareous kinds and qualities. It was found to succeed perfectly on the stone-brash kinds, by Mr. Davis, in Oxfordshire; and it has been greatly advised for the chalky and some other dry forts, by Mr. Boys of Kent. It is constantly known to answer well in all the less moist loams. It is a plant, however, which has been objected to by some farmers, as being only a biennial; but as it sheds its seeds annually in great abundance, this is probably a matter of little consequence; and it is well known to seldom wear out of lands, in which it has been once well established. Its seed is readily procured, and with little expence or trouble.

The plant is of much less growth than that of common clover, being considerably slenderer in the stem or stalk part; yet notwithstanding this, it is not unfrequently sown with crops of the grain kinds, in the manner of that grass-feed. The proportion of seed, which is made use of in such cases, is usually about three pottles, or two gallons, when perfectly cleared of the husks; but when in the contrary state,

two bushels are mostly the quantity that is sufficient for the purpose. These quantities should, however, be constantly varied, according to the nature, circumstances, and conditions of the lands.

By some it is supposed to be a beneficial practice to sow it in these ways, especially where large stocks of animals are kept; as with the oats or wheats in the spring season, when they are to be followed with grain in the next; as, by this means, good feed is provided in the stubbles for the stock, in the latter part of the summer and in the autumnal months, while, at the same time, the land is left free for the purposes of tillage in the spring. When it is employed in the way of laying down land for pasture, as it is always of much importance to the farmer to have such land to produce a full crop the first year, this is proper; and as there are some grass-plants which require two or more years to establish themselves, and acquire their full growth, while others arrive at their extreme and perfect size and expansion the first year after being sown; some of the latter sort should constantly be had recourse to, among which this should never be neglected, as it is found, in most cases, to be highly valuable and useful in such circumstances. Hence, too, the advantage of mixing it with other sown grass-seeds is shewn in different instances. Some farmers consider the quantity of four pounds of trefoil-seed to the acre as too small a proportion; and think it an improvement to either double the quantity, or to add as much red clover-seed, which is probably the preferable method. In this quantity, it is supposed, they will not injure the other grass-seeds which may be sown at the same time, but furnish a copious vegetation, until the other may come to perfection; at which period, both the trefoil and clover have a natural tendency to disappear and be worn out of the land.

Trefoil is said to produce excellent pasturage for cattle-stock, but to be more particularly calculated for sheep, when either in mixture with clover or alone, as it is found not to be so liable to hurt them by swelling or *hoving* them as clover. It is of great importance in the feeding and support of sheep, in consequence of its being more early than clover, and its coming in well after the consumption of the rye and turnip crops, before the clovers become ready in the spring season.

The writer of the "Experienced Farmer" states, that this, by some, is supposed a bitter plant, and that sheep are not fond of it, but that he must own that nothing within the compass of his experience has led him to form such an opinion. It vegetates about a month earlier than white clover, and long before the rye-grass is exhausted. But it is thought improper for being sown alone, except for the express purpose of raising feed. There are no foils, it is thought, proper for trefoil but what are capable of producing rye-grass and white clover. Hay made from this plant alone, is a pretty hay, but seldom abundant in produce. It is conceived that more trefoil is capable of being raised on any sort of land, in any quantity, by sowing rye-grass among it, than without; as it has been observed that trefoil, like the vine and pea, wants support from some stronger material to which it may cling. For this reason it prospers well with red clover, round which its tendrils twine as woodbines in a thorn-hedge. It is believed, too, that the crop of clover will be very little less in quantity or weight from the trefoil growing in a state of mixture with it. The after-grass of trefoil is considered as not worth much, on which account some recommend it to be followed with wheat, but it can be declared on the grounds of constant experience, that land intended for wheat, cannot possibly

be too much smothered with crops of every sort of the close-growing shady kinds.

It has been stated by a late writer, that upon light and poor sandy soils, or lands on which clover does not succeed well, it is common husbandry to sow trefoil with a portion of white clover and rye-grass, with the intention of leaving it two years. In this case, six pounds of trefoil, four of white clover, and half a bushel of rye-grass seeds are the common quantities. These are with the intention of providing sheep-feed.

Where trefoil is left for hay, it does not afford a large produce, but a sort which is highly useful and advantageous as a sheep-fodder in the winter season, and less wasteful than most other kinds, when used in that way. At the same time, it is supposed to be less troublesome in the process of making into hay. However, it is asserted by Mr. Kent that it readily runs together, and becomes mouldy by wet.

The seed is to be collected from the second shoot, in the same manner as in common clover, the produce being in general from six to eight bushels of clear seed from the acre. In districts where it is grown for the seed, the crops are mown in the beginning of July; the heads or husks being often threshed off the straw in the field on a cloth, and then sold by the quarter to those who have mills and collect them, who grind the seed out of the husks, and then dispose of it to others, in different places, for the use of the farmers in those districts where it is rarely sowed. The acre mostly produces from about four or five to ten quarters in the husk, each of which affords about two bushels of clean seed when grown solely in this intention.

This plant has often the names of *black-grass*, *non-such*, *yellow clover*, and others, given it by writers on husbandry.

There are other different sorts or varieties of this plant occasionally cultivated by the farmer, such as the trefoil termed *bird's-foot*, which has been found useful when cultivated in meadows that are inclined to be moist, as growing to a great height, and affording an excellent hay. In some places too it is raised as pasturage for sheep. Also the trefoil called by the name of *hop*, which is often confounded with the real trefoil, as being nearly of the same duration, but which is more grateful to animals. The trefoils seem, on the whole, not to be so much discriminated by agricultural writers, as their importance as artificial grasses would appear to demand. Besides, much confusion is introduced in consequence of the diversity of their provincial titles. It has been remarked, that as some are annual, some biennial, and others perennial, where the two former sorts are sown where it is intended to have a permanent pasture, disappointment must of necessity be the consequence.

TREFOIL, *Bean*, a species of *Cytisus*; which see.

TREFOIL, *Stinking Bean*. See ANAGYRIS.

TREFOIL, *Bird's-foot*. See LOTUS.

The fruit of the lotus was, by the ancients, imagined to be endowed with the virtue of making strangers forget their native country.

TREFOIL, *Marsh*. See MENYANTHES.

TREFOIL, *Moon*. See MEDICAGO.

TREFOIL, *Shrubby*. See PTELEA.

The second species of this genus, or the ptelea with single leaves, was formerly shewn for the tea-tree in many of the European gardens, where it many years passed for it among those who knew no better.

TREFOIL, *Snail*. See MEDICAGO and LUCERNE.

TREFOIL of *Candia*, *Thorny*. See FAGONIA.

TREFOIL, *Base Tree*. See CYTISUS.

The ancient botanists seem to have been acquainted with two very different shrubs under the name *cytissus*; and there have been no small errors about the true meaning of several passages in Dioscorides and Theophrastus, on occasion of the mistaking one of these things for another. Dioscorides describes the *cytissus*, as being a shrub with leaves white and hoary, both on the upper and under side, and of no use, or value, to mankind: as to its wood, Pliny translates this account, and adds to it from Hyginus, that it was a very hardy and strong shrub, not being affected by heat or cold, snow or hail, or any other injuries of the weather, nor of its enemies, as Pliny expresses it (*hossium*). It is not very easy to conceive what enemies these should be; but the most probable conjecture, as to this odd passage, is, that Pliny had transcribed it in his usual careless way, and that what is called *hossium*, should be the word *nosstrum*.

The sense then is clear enough; the author had just before said that the wood was good for no use to mankind; and, therefore, when he was speaking of the trees standing a long time, and fearing the injuries of no weather, he might very well add, *nor of us*; for the wood being good for nothing, men would not be at the trouble of cutting it up. It is plain, however, that Theophrastus means quite a different shrub by this name *cytissus*; for, as Dioscorides says, that the wood of his was white throughout, and very light. Theophrastus observes, that it was black at the heart, and as heavy and solid as ebony; and, in many places, where he speaks of the hard and elegant woods used for inlaying, he mentions the *cytissus* wood, coupling it with the ebony, heart of oak, and other the hardest and most elegant woods known in his time.

Pliny mentions no other *cytissus* than that of Dioscorides, which was the common kind cultivated by the Greeks and Romans, as a food for cattle; he says it was raised by seed, and came to its perfection in three years, and that it was gathered in the spring just after the time of its flowering: he adds, that this was usually the office of children, or old women, unfit for other work, and was the cheapest of all the offices of husbandry. It is easy to conceive, that such a shrub as the *cytissus* of Theophrastus, with a wood as firm as the heart of oak, and hard as ebony, did not come to perfection in three years from the sowing; nor could any more be cut up by boys and old women, than eaten by cattle when taken up. There were, therefore, two kinds of *cytissus* among the ancients, the one sown and cultivated as food for cattle, the other a wild tree, or shrub, growing in woods, and being larger than the sown kind. Dioscorides and Pliny describe the first, and Theophrastus alone the latter, except that Pliny has now and then taken a sentence from Theophrastus, when he mentions the *cytissus* occasionally among other hard woods, and placed it to the account of his manured *cytissus*.

Ovid, indeed, where he mentions the *cytissus* as a wild wood shrub, certainly means this kind mentioned by Theophrastus:

“Nec tenuis *cytissus* curtave tinus abest.”

And Columella acknowledges both kinds. It may seem a natural objection, that culture could never make such a difference in this plant, as that it should be hard and black in the wood in its wild state, and soft and white in the cultivated kind. But we are not to suppose that the cultivated and wild *cytissus* were the same species of shrub, only altered by these two states. The ancients were not so accurate in their names as later botanical writers have been; and if a wood-shrub, in some respects, resembled their manured *cytissus*, they would call it by that name, though it

had

had not all the generical characters to make it the fame. Columella, de R. R. lib. ix. cap. 4.

TREFUMEL, in *Geography*, a town of France, in the department of the North Coasts; 6 miles S. of Dinan.

TREGARON, or TREV GARON, or *Caron*, a small market-town in the hundred of Pen-Arth, and county of Cardigan, South Wales; is situated in a valley watered by the river Berwyn, a contributory stream to the Teifi; 18 miles S. by E. from Aberystwith, and 170 miles W. from London. It was formerly a corporate town, but for some improper conduct at the election of a member to serve in parliament in the year 1742, the house of commons voted that the corporation had forfeited their charter. A weekly market is held on Tuesday, and an annual fair of three days' continuance in March. The church, which is a spacious structure of very rude masonry, consists of a nave and chancel: it stands on a rocky eminence, regularly circular, and forming an elevated centre to the town. In the church-yard are the remains of a Druidical circle, with the spaces filled up with stone-walling. The parish of Tregaron, which extends nine miles in length, and four miles in breadth, comprehends eight parcels or townships, and, according to the population return of the year 1811, contained 244 houses, and 1133 inhabitants. At a place called Castell Flemys, in this parish, is a very large intrenchment of a semi-circular form, well defended on three sides by a morass. On a hill called Penrhiwflur are three heaps of stones, called Carneddau, sepulchral monuments of Druidical origin; and a bank of raised earth runs in a straight line for several miles, in this parish as well as that of Gwnnws, and is said to lead into the sea, called "the furrow of Bannoy's oxen," the fame as were said to be employed in building the church of Llandewi Brefi. But it is probably the remains of an old British road. Thomas Jones, an eminent antiquary and poet, who lived at the end of the sixteenth century, was a native of Tregaron.—Malkin's Scenery, &c. of South Wales, 2 vols. 8vo. 1807. Carlisle's Topographical Dictionary of Wales. Beauties of England and Wales, vol. xviii. South Wales; by the Rev. T. Rees. Meyrick's History and Antiquities of the County of Cardigan, 4to. 1808.

TREGIANO, a town of Naples, in the province of Bari; 6 miles E.S.E. of Bittetto.

TREGONY, a market-town and borough in the western division of the hundred of Powder, and county of Cornwall, England; is situated on the river Fal, 8 miles E. from Truro, 40 miles S.W. from Launceston, and 250 miles S.W. by W. from London. This town was formerly a place of some consequence, but fell to decay when Truro began to flourish, and attract its trade and population. Tregony sent two members to parliament in the reign of Edward I.; and after a long dispute, recovered its ancient privilege in the year 1559: the right of election is vested in the housekeepers: the number of voters who polled in the year 1812 was 183, the exact number of houses returned under the population act of 1811; the number of inhabitants were therein stated to be 923. The town consists principally of one long street. It was anciently governed by a portreeve, or mayor; but in the year 1620, king James I. granted it a charter of incorporation. The market, which is on Saturday, is held by prescription: Henry de Pomeroy certified his right to it in the reign of Edward I. Henry III. granted a fair to the said Henry in the year 1266. Here are now five fairs. Both the fairs and market have for many years been in a declining state: till the middle of the last century, they were very considerable, and particularly noted for the sale of

woollen cloth, of which there was an extensive manufactory in the town. Tregony castle, of which there are now no remains, is said to have been built by Henry de Pomeroy at the time king Richard I. was in the Holy Land: it was standing, and was the seat of the Pomeroy's, in the reign of Edward VI. In the year 1696, Hugh Boscawen founded an hospital for decayed housekeepers, and endowed it with lands, now let at 30*l.* per annum, but capable of being soon raised to three times that value. On the north side of the town stood, what is called, Old Tregony, where was a church dedicated to St. James, the walls of which were standing till about the middle of the last century.

On the opposite bank of the Fal, is Trewarthenick, the seat of Francis Gregor, esq. The house is seated on an elevated piece of ground, abounding with fine groves, and commanding a variety of interesting prospects.

About two miles south-west of Tregony, is Ruan Lanihorne, a village seated on the banks of the Fal, of which the Rev. John Whitaker, the learned historian of Manchester, was nearly forty years the resident rector. He died Nov. 4, 1808, in the 73d year of his age, and lies buried within the rails of the communion-table.—Lyfons's Magna Britannia, vol. iii. Cornwall, 1814. Beauties of England and Wales, vol. ii. Cornwall; by J. Britton and E. W. Brayley, 1802.

TREGUIER, a sea-port town of France, in the department of the North Coasts, on a peninsula, near the English Channel; before the revolution the see of a bishop; 9 miles N.E. of Lannion. N. lat. 48° 47'. W. long. 3° 8'.—Also, a river of France, which runs into the English Channel, 6 miles N. of Treguier. N. lat. 48° 51'. W. long. 3° 8'.

TREIA, in *Ancient Geography*, a town of Italy, in Picenum, S.E. of Cingulum.

TREIA, in *Geography*, a town of the Popedom, in the marquisate of Ancona; 6 miles W. of Macerata.

TREIGNAC, a town of France, in the department of the Correze; 16 miles N. of Tulle.

TREIGNY, a town of France, in the department of the Yonne; 9 miles S.E. of St. Fargeau.

TREILLAGE, in *Gardening*, a sort of rail-work consisting of ranges of light posts and railings, for the purpose of training espalier trees to, and occasionally for wall-trees, where the walls do not admit of nailing the branches immediately against them; likewise for training wall-trees in forcing-frames, &c. They are made in different ways for use and ornament, as well as of different dimensions, from four or five to six or seven feet high.

For common espalier fruit-trees in the open ground they are absolutely necessary, and may either be formed of common stakes and rails nailed together, or of regular joinery work.

The cheapest and the easiest, and soonest made treillage for common espalier trees, is that formed with any kind of straight poles or stakes of under-wood, as cut in the coppices, being then cut into proper lengths, and driven into the ground in a range at distances of a foot each, all of an equal height, and then railed along the top with the same kind of poles, to preserve the whole straight and firm in a regular position. See *ESPALIER*.

And to render these still stronger, two or three horizontal ranges of rods may be nailed along the back part of the uprights, a foot or eighteen inches asunder.

The more elegant and ornamental treillages are formed with regularly squared posts and rails of hard timber, neatly planed and framed together; having for this purpose deal or oak posts, uniformly worked two or three inches square; but if the main posts are of oak, it will be of advantage

vantage in respect to strength and durability, fixing the main posts in the ground ten or twelve feet asunder, with smaller ones between, ranging the horizontal railings from post to post in three or more ranges; the first about a foot from the bottom, a second at top, and one or two along the middle space, and, if convenient, one between each of the intermediate spaces; then fixing thin slips of lath, or the like, upright to the horizontal railing as far as the branches of the trees extend, ten inches or a foot asunder; and painting the whole white in oil colour, to render it more ornamental and durable. In training the trees, their branches are tied both to the railing of the treillage and the upright laths, according as they extend in length on each side. In either of the above cases, for an espalier, five feet are generally of sufficient height, as, if much higher, the winds, having greater power, will loosen and displace them.

Where walls are built with large stones with the joints irregular and far asunder, and which do not afford opportunities, like brick-walls, for nailing properly in the regularity which is required, a neat treillage is sometimes uniformly crested all along close to the wall, to train and nail the branches to in a regular manner.

These may be made of coarse pieces of battens, railings, &c. or of such as are wrought in a neat manner, according to the convenience and taste of the person who has them.

In constructing treillages of this nature, some make them with clean straight rods or poles, and others with squared laths, which are an inch and a half in thickness; each of which sorts of materials answers the purpose very well. In performing the business, the workmen, as soon as they have provided themselves with a sufficient quantity of either of these kinds of articles, and a proper supply of hooked iron hold-fasts, first drive some of the hold-fasts into the joints of the walls in rows as much as possible at regular distances, which are left projecting about an inch or inch and half from it, in order to receive the rods or laths in both a horizontal and perpendicular direction, at nine or ten inches from each other, fixing in the first row of these hold-fasts towards the top or upper part of the walls, the second near to the bottom, and the third all along the middle space. When this has been accomplished, and the rods or laths are in readiness, the latter of which may, if thought necessary, be squared and planned to the place, they begin to proceed to the framing of the treillage, by first fixing the rods horizontally in three rows, in the three ranges of hooks as above, taking care that these horizontal rods be previously chopped off to nothing at each end, in order that they may be readily spliced to each other to extend them in length as far as it may be requisite. Having thus fixed up the first three rows of horizontal poles, some uprights or standard rods are fastened up in the front of the horizontal poles, at the distance of five or six feet, after which the remainder of the horizontal laths are ranged behind the standards, nine or ten inches asunder, fastening them with wire to the uprights, when they being all thus placed and fixed, the rest of the standards are fastened up in front at the same distance, the whole being made perfectly fast with wire twisted round the hooks, and the crossings or interfections of the rods of the treillage or frame-work. Where square laths are employed for this purpose, they are usually about an inch and half in the square, being planed quite even and smooth, and then framed together in a neat manner by proper mortises, and fixed up with strong hooks and nails.

Either of these kinds of treillages, when finished and fixed up, should be well painted over with white lead paint, in order to render them more lasting and handsome.

In frames and fives where wall-trees are intended for forcing, as they are planted both against the back wall, and

occasionally in a detached low range forward towards the middle or front space; treillages are indispensably necessary upon which to arrange the branches of the trees in a regular expansion, not to train them immediately close to the wall of the flues of that department, but detached several inches, and formed with light neat squared upright battens, and small horizontal rails, uniformly framed together, in a light open manner. See TREES, *Espalier*, *Cast-iron rails for*.

TREISENFELD, in *Geography*, a town of Germany, in the principality of Culmbach; 8 miles S.E. of Bayreuth.

TREISZ, a town of France, in the department of the Sarre, on the Moselle; 19 miles S.W. of Coblenz.

TREIZIEME, Fr. in *Music*, is the octave of the 6th, or the 6th of the octave; and is called in English the 13th, from its containing twelve diatonic degrees, that is to say, thirteen sounds.

TRELAWNY, in *Geography*, a town of Jamaica, and chief town of the Maroons; 60 miles N.W. of Kingston. N. lat. 18° 21'. W. long. 77° 42'.

TRELAZE, a town of France, in the department of the Mayne and Loire; 3 miles E.S.E. of Angers.

TRELLECH, a town of England, in the county of Monmouth; 5 miles S. of Monmouth.

TRELLIS, or TREILLIS, in *Gardening*, a term sometimes employed to signify the same as treillage, or a slighter and less strong sort of wooden frame-work of this nature, which is sometimes used in particular situations and circumstances. See TREILLAGE.

TRELON, in *Geography*, a town of France, in the department of the North; 9 miles S.E. of Avesnes.

TRELOOBING, in *Mining*, denotes a stirring and working the loobs or slimy earth of tin, &c. in a slime-pit, that the mud may be partly washed off with the water, and the ore settle at bottom.

TRELOU, in *Geography*, a town of France, in the department of the Aisne, on the Marne; 9 miles E. of Chateau Thierry.

TREMA, in *Botany*, from *τρῆμα*, *τρῆματις*; a hole, alluding to the perforations in the shell of the nut.—Lourei. Cochinch. 562.—Class and order, *Monoecia Pentandria*. Nat. Ord. *Urtica*, Juss.

Gen. Ch. Male, *Cal.* Perianth of five lanceolate spreading leaves. *Cor.* none. *Stam.* Filaments five, longer than the calyx; anthers roundish.

Female, on the same plant, above the male, *Cal.* as in the male, permanent. *Cor.* none. *Pist.* Germen superior, roundish, depressed; style none; stigmas two, short, villous. *Peric.* Drupa roundish, somewhat depressed, single-seeded. *Seed.* Nut minute, pierced with several holes.

Eff. Ch. Male, Calyx of five leaves. Corolla none. Female, Calyx of five leaves. Corolla none. Stigmas two. Drupa superior, roundish, with a perforated nut.

1. *T. cannabina*. Cày Rach chiéo of the Cochinchinese.—Native of the woods of Cochinchina. A tree of middling size, with a filamentous bark, and ascending branches. Leaves alternate, ovato-lanceolate with a long point, serrated, downy. Flowers on axillary branched stalks. Drupa yellow.—We know nothing of this plant but from the above description.

TREMANDREÆ, a new natural order of plants, pointed out by Mr. Brown in his truly excellent and instructive "Remarks on the Botany of Terra Australis," published at the end of captain Flinders's Voyage. This order is founded on the genus *TETRATHECA*, (see that article,) and another from the same country, named by Mr. Brown *Tremandra*, apparently from *τρῆμα*, a perforation, and *ἀνθρῆς*, a man, because of the pores of the anthers. The characters of the order are thus given.

Calyx

Calyx of four or five equal leaves, overlapping each other in the bud. *Petals* four or five, equal, involute, and unfolding the stamens, before expansion. *Stamens* eight or ten, below the germen, distinct; *anthers* attached by their base, of two or four cells, bursting by either a tube or pore at the summit. *Germen* (superior) of two cells, with from one to three pendulous seeds in each; *style* one; *stigmas* one or two. *Capsule* of two cells, and two valves, with partitions from their centres. *Seeds* albuminous, with a naked scar, and an appendage at the opposite extremity; *embryo* in the axis of the fleshy albumen, and half as long again; *radicle* directed towards the scar. The plants are humble shrubs, resembling *Erica*, with either scattered or whorled leaves, destitute of *stipulas*. Their *stalks* axillary, and single-flowered.

Mr. Brown prefers the name he has chosen for this order to one derived, as it ought in right of priority to be, from *Tetraheca*; because it better describes the structure of the stamens in both genera: the four distinct cells not existing in the ripe state of the anthers of *Tremandra*, nor even of all the species of *Tetraheca*. We are well aware of the truth of his assertion, that bilocular anthers in general have each cell divided by the inflexed valves, till they burst, being while young truly quadrilocular. We were however of opinion, in founding the genus *Tetraheca*, that the four cells being permanent, afforded an excellent name, as well as character. If this character does not exist in every species, it may be less important; but that it is not found in *Tremandra*, surely renders it the more descriptive of *Tetraheca*. Mr. Brown proceeds to remark, that the writer of this, like Labillardiere, has mistaken the fungous appendage to the apex of the seed for an umbilical *caruncula*, or appendage to the scar; hence one end of the seeds was taken for the other, and they were supposed erect, not pendulous; Labillardiere moreover was thus led to conceive that the radicle pointed towards the scar.

The *Tremandreae*, as Mr. Brown observes, are nearly related to *Polygaleae*, but he esteems them sufficiently distinct from the latter, not only in the regularity of the flower, and structure of the anthers, but in the æstivation, or manner of folding, of both *calyx* and *corolla*; in the appendage of the seed being at its apex; and, it may be added, in the tendency to produce an indefinite number of seeds in each cell. We would rather condense than dilate the number of natural orders, as well as genera, and with respect to the first reason of our learned friend, we would recall a remark of the sagacious Correa, that every natural order contains some regular and some irregular-flowered genera. The different æstivation is perhaps a necessary consequence of the last-mentioned difference. The other characters are surely of small account in this case.

"The greater number of *Tremandreae* are found in the principal parallel of New Holland. They extend also to the fourth end of Van Diemen's island, but none have been observed within the tropic."

TREMBLADE, in *Geography*, a town of France, in the department of the Lower Charente; 3 miles S. of Marenes.

TREMBLANT, in *Music*, the name of a very disagreeable stop in large church-organs on the continent. Its name describes its effect. In general, a steady tone in a voice or wind-instrument capable of sustaining a note, is the most essential requisite; but in the tremblant stop there is a perpetual quivering, such as we sometimes hear in the streets by the *vielle* and barrel-organ. See ORGAN.

TREMBLAY, LE, in *Geography*, a town of France, in the department of the Mayne and Loire; 18 miles N.E. of Angers.

TREMBLAY le Vicomte, Le, a town of France, in the department of the Eure and Loire; 7 miles S. of Dreux.

TREMBLEMENT, in *French Music*, is equal to *trillo* in Italian, and *cadence* in old French music: they all mean the same thing, which in English is a *shake*.

TREMBLEY, ABRAHAM, in *Biography*, an eminent naturalist, was born at Geneva in 1710, and having finished his own education in Holland, he undertook that of the children of M. Bentinck. He thence went to London, and had the charge of the young duke of Richmond. In the course of these employments he travelled into various parts, and directed his attention to various objects, particularly of natural history. His discovery with regard to the propagation of the fresh-water polypes (see POLYPE), engaged general attention, and he gave an account of it in his work printed at Leyden in 1744, and entitled "Memoire pour servir à l'Histoire Naturelle d'un Genre de Polypes d'eau douce a Bras en Forme de Cornes." His papers on other subjects of natural philosophy, as electricity, geology, &c. are printed in the Transactions of the Royal Society, of which he was a member. In 1757, upon his return to Geneva, he became a member of the Grand Council, and his conduct as a citizen contributed no less to his reputation, than his researches and discoveries as a philosopher. Having the superintendance of a granary, he made some useful observations on the insects that destroy corn, and the mode of counteracting the injury they occasion. To the young he was a pleasing instructor, adapting his mode of conveying useful knowledge to their years and capacities. With this view he published "Instructions d'un Père à ses Enfants sur la Nature et la Religion," 2 vols. 8vo. 1775; "Instructions d'un Père à ses Enfants sur la Religion Naturelle et Révélé;" 3 vols. 8vo. 1775; and "Instructions d'un Père à ses Enfants sur le Principe de la Religion, et du Bonheur," 8vo. 1782. This excellent person died at Geneva, highly esteemed and respected, in 1784. Haller.

TREMBLING POPLAR, in *Planting*, a name often applied to the aspen-tree. See POPLAR-Tree and POPULUS.

TREMBLING-ILL, a disease in sheep, which often produces great loss among lambs. It is an affection of the paralytic kind, which is sometimes lingering, but at others so speedy, that the animals are not unfrequently dead before it is suspected. Washing in cold water has been found useful. See THWARTER or Louping-ILL.

TREMBLOWA, in *Geography*, a town of Austrian Poland; 16 miles S. of Tarnopol.

TREMECEN, or TLEMSAN, a city of Algiers, and capital of the western division, which is governed by a bey or viceroy; situated on a rising ground, below some rocky precipices, from which issue a number of springs. In the west part of the city is a large square basin, of Moorish workmanship, 200 yards long, and about half as broad. Most of the walls of Tremeceen have been built or rather moulded in frames, a method of building used by the Africans and Spaniards. The mortar of which they consist, is made up of sand, lime, and gravel; which, by being at first well tempered and wrought together, has attained a strength and solidity not inferior to stone. About the year 1670, Hassan, then dey of Algiers, laid most of this city in ruins, as a punishment for the disaffection of the inhabitants; so that there is not remaining above one-sixth part of the old Tremeceen, which, when entire, might have been four miles in circuit. Among the eastern part of these ruins we meet with several shafts of pillars, and other fragments, of Roman antiquities; and in the walls of a mosque, made out of these old materials, we have a number of altars, dedicated to the Dii Manes; 50 miles S.W. of Oran. N. lat. 35° 1'. W. long. 0° 28'.

TREMELLA, in *Botany*, so called by Dillenius, from *tremo*, to tremble, or quake, because of its gelatinous, tender

TREMELLA.

and tremulous substance.—Dill. Musc. 41. Linn. Gen. 567. Schreb. 768. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc. Sibth. v. 2. 336. Hudf. 562. Juss. 6. Lamarck Illustr. t. 881. Perf. Fung. 622.—Class and order, *Cryptogamia Algæ*, Linn. *Crypt. Fungi*, Perfoon. Nat. Ord. *Algæ ambigua*, Sm. *Fungi*, Perf.

Eff. Ch. Fructification scarcely perceptible, in a membranous, gelatinous, expanded, undulated substance.

Nothing is more uncertain than the generic character, and even the natural order, of *Tremella*. The genus seems made up of various gelatinous productions, in which no traces of fructification have been detected. Having no shields, tubercles or warts, they could not be referred to *Lichen* or its allies; neither have they seeds imbedded throughout their substance, to make them *Ulvæ*; much less any aggregated seeds with or without a perceptible pericarp, as in *Fucus*. They moreover differ from both the latter genera, in not being *submersed Algæ*; for the aquatic species are, as Roth and Perfoon observe, much better excluded. The able cryptogamist last named refers *Tremella* to the order of *Fungi*; but without any attempt to shew that they produce powdery seeds from the surface of a *hymenium*, or superficial membrane; a most material character of such *FUNGI* (see that article) as have not a real pericarp with numerous enclosed seeds. Their habit indeed is essentially different. They are repeatedly revivifcent by means of moisture, thriving in a wet atmosphere only, though not living immersed in water. In these particulars they agree exactly with the *Lichenes*, not with genuine *Fungi*; which last, though they generally flourish in humidity, are scarcely revivifcent after having been once dried up.—The various species, of which Perfoon defines twenty-four, are generally parasitical, on the bark or branches of living trees, or on dead wood. We doubt the reality of several, which appear to us mere gummy exudations of the plants on which they are found. This will presently form a subject of enquiry. We propose to detail all the British species, real or supposed, along with any exotic ones that seem particularly worthy of notice.

We are not much satisfied with Perfoon's sections of this genus, nor do we think it adviseable to adopt them here, on account of the uncertainties above-mentioned. Our determination does not arise from any disrespect for that excellent author, one of the most methodical and accurate in this obscure and much neglected path.

T. mesenterica. Plaited Yellow Tremella. Retz. Prodr. 204. Perf. n. 1. Dickl. Crypt. fasc. 1. 14. Engl. Bot. t. 709. (*T. mesenteriformis*; Jacq. Misc. Austr. v. 1. 142. t. 13. *T. juniperina*; Hudf. n. 1. Nostoc luteum, mesenterii formâ; Vaill. Paris. t. 14. f. 4.)—Sessile, clustered, plaited, lobed, waved, orange-coloured.—Found in rainy weather in the autumn and spring, on dead branches of oak and other trees, or on decayed stumps of broom or furze; never on living wood or bark. This very striking and conspicuous species forms clusters of various dimensions, from one to four inches broad, of a rich orange hue, more or less deep; when young pale or whitish. The substance is soft and flexible, neither viscid, nor very tender. In dry weather, or after being gathered, it shrinks, becomes hard, and assumes a dirty brown colour; but revives in moisture. Little taste or smell is perceptible in any part, nor has any sign of fructification been discovered. Yet the plant appears to be annual, and consequently must be propagated by seed.

T. lutescens. Soft Yellowish Tremella. Perf. n. 2. Ic. et Descr. Fung. 33. t. 8. f. 9.—“Convolutè, extremely soft, deliquescent, pale yellow.”—Observed by Perfoon on

the branches of beech in autumn, but rarely. Half an inch broad, and of a softer substance than the foregoing. We are unacquainted with this species.

T. persistens. Perennial Purplish Tremella. Bulliard Fung. v. 1. 223. t. 304.—Horizontal, leafy, somewhat coriaceous, smooth, undulated, pale violet.—Found on the stems of the Savine, *Juniperus Sabina*, according to Bulliard, lasting for a number of successive years. When dried up it is hardly distinguishable from the black scales of the bark; but in very moist or rainy weather it appears in the form of horizontal leaves, half an inch or more in length, bluntly rounded and lobed, of a pale vinous purple. Bulliard.

T. ferruginea. Plaited Rusty Tremella. Engl. Bot. t. 1452.—Sessile, clustered, lobed, waved, of a rusty-brown; the surface finely pubescent.—Observed by the late Mr. Crowe, at Lakenham, near Norwich, growing on dead wood, in wet weather in winter, composing plaited convoluted tufts, three or four inches broad, pliable and tender, shrivelled and shapeless when dry, reviving imperfectly with moisture. The segments are rounded and waved, not lobed or notched; their colour a rich brown, white within; the surface finely downy, or rather covered with pale velvet-like granulations, interspersed with brown irregular specks, more like fructification than any thing else that has fallen under our notice in this genus, except perhaps what Bulliard describes in the following species.

T. verticalis. Upright Dark-purple Tremella. Bulliard Fung. v. 1. t. 272. (*T. mesenteriformis violacea*; Ibid. v. 1. 230. t. 499. f. 6, X, Y.)—Clustered, erect, lobed, sinuated and plaited, smooth.—Found on decayed stumps of trees in autumn. Of a vinous violet-colour when young; afterwards of a blackish red-brown. It always grows erect, from one to four inches high, gelatinous and elastic, crackling between the teeth. Laid when fresh on glass or white paper, it discharges from every point of its surface a very fine powder, supposed to be the seeds. This answers to the nature of *Fungi*, and high microscopic examinations are requisite to determine how these seeds are produced; whether in series of eight together, from cells of the upper surface, as in *PEZIZA*, see that article; or in a less regular manner, from pores of the *hymenium* investing the under surface. Bulliard has finally reduced the present species to a variety of his *mesenteriformis*; but it is surely very distinct in many essential points from our *mesenterica*, and we cannot but suspect him to have here confounded several things together. His original *verticalis* is said to be valuable for its colouring principle. When boiled in water for many hours, by which the form and colour of the plant are not altered, it yields a deep brown, likely to be useful in dyeing. For liming, Bulliard obtained by infusion of this Tremella in simple water, a fine reddish bistre-colour, very durable, and preferable to any that he could buy in the shops.

T. intumescens. Brown Tumid Tremella. Engl. Bot. t. 1870.—Sessile, clustered, twisted, tumid, brown, shining and gelatinous; when dry thin and membranous.—Gathered by Mr. W. Borrer, in January 1807, on a beech in St. Leonard's forest, Suffex. This consists of roundish soft pulpy masses, two or three inches broad, convoluted and inflated, like the intestines of some animal, of a darkish, dull, not red, brown; but with a shining viscid surface, obscurely dotted. When cut, brown vertical streaks are observable a little way into the substance, which may contain the seeds, though none have as yet been detected.

T. moriformis. Mulberry Tremella. Engl. Bot. t. 2446.—Sessile, clustered, twisted, black, opaque; internally fleshy, deep purple.—Found by Mr. C. E. Sowerby, on pales and rails in Surry, early in June. This grows sessile, on ex-

posed wrought wood, in roundish or oblong, tumid, sinuous masses, various in length from a quarter to an inch, not unlike mulberries, but coal-black; their inside only is of a rich deep purple, and the centre is attached by a strong root. The plant communicates a violet stain to whatever it touches in drying.

T. farcoides. Flethy Tremella. With. v. 4. 78. Engl. Bot. t. 2450. (*T. amethystea*; Bulliard Fung. v. 1. 229. t. 499. f. 5. With. v. 4. 82. *Helvella farcoides*; Dickf. Crypt. v. 1. 21. Bolt. Fung. v. 3. 101. t. 101. f. 2. Lichen farcoides; Jacq. Misc. v. 2. 378. t. 22. *Elvela purpurea*; Schæff. Fung. v. 4. 114. t. 323, 324.)—Sessile, gelatinous, reddish-purple; at first club-shaped; then rounded, lobed, plaited or curled; finally blackish.—Found on rotten wood, in damp shady situations, during the autumn. Perfoon has confounded with this *Tremella* his *Peziza farcoides*, the *tremelloidea* of Bulliard, t. 410. f. 1, which we believe to be a real *Peziza*. Our present *Tremella* is much more variable in figure, club-shaped at first, then turbinate, or funnel-shaped, variously rounded or lobed, in dense tufts. The colour is nearly uniform, a vinous purple, turning black in decay; the substance is internally gelatinous and semipellucid, with a toughish elastic skin. The plant has little taste or smell; nothing of the fungus nature.

T. vescaria. Bladder Tremella. (Bulliard Fung. v. 1. 224. t. 427. f. 3. Engl. Bot. t. 2451.)—Membranous, somewhat rigid, brownish-white, pouch-like, filled with viscid evanescent jelly.—Found by the late Mr. Jacob Rayer, near Maidstone, Kent. Bulliard speaks of it as very rare. It always grows on the ground, solitary or in tufts, attached by fibrous radicles. When young, the plant is a turgid, firm, but elastic, bag, full of viscid jelly, and nearly upright, from one to three inches high. The jelly in time escapes, by a rupture in the bag, which collapses, and looks like a fresh bladder, just emptied. From its original dirty white, it changes in decay to a reddish-brown; the inside being always brownish. Bulliard mentions a green variety.

T. flaccida. Pendulous Black Tremella. Engl. Bot. t. 2452.—Membranous, thin, flaccid and pendulous, very black; externally opaque and roughish; internally corrugated.—Found by Mr. Sowerby on the perpendicular trunk of a living oak in Peterham park. Several specimens, two or three inches long, grew one above another, pendulous, in a bell-shaped manner, so that the outer surface, naturally inferior, became uppermost, and when fresh resembled black crape in colour and roughness; the concave part being paler, smooth and shining, marked with coarse reticulated veins. This species, except its position, seems most akin to Bulliard's supposed variety of his *Peziza nigra*, v. 1. 238. t. 116, which we cannot conceive to belong to his t. 460. f. 1.

T. Auricula. Jew's-ear Tremella. Linn. Sp. Pl. 1625. Perf. n. 9. Bulliard Fung. t. 427. f. 2. Engl. Bot. t. 2447. (*Peziza Auricula*; Bulliard Fung. v. 1. 241. *Agaricum auriculæ formâ*; Mich. Gen. 124. t. 66. f. 1.)—Sessile, leathery, reddish-brown; rough beneath; rugged and plaited above, resembling an ear.—Not rare upon rotten elder-trees. Perfoon says he never found this species in any other situation. It forms large tufts of irregularly plaited and convoluted fleshy cups, of a semi-transparent reddish-brown; the inner or upper surface palest, smooth and shining; the outer darkest, opaque and roughish. The plaits branch from the middle, so as to convey an idea of the human ear; whether Jewish, Pagan, or Christian, depends on the complexion or cleanliness of the prototype. Bulliard asserts the seeds to be discharged from the upper surface entirely. If this

be correct, he is justified in transferring the plant to *Peziza*.

T. arborea. Witches'-butter Tremella. Hudf. 563. Engl. Bot. t. 2448. (*T. spiculosa*; Perf. n. 8. *T. glandulosa*; Bulliard Fung. v. 1. 220. t. 420. f. 1. *T. arborea nigricans*, minds pinguis et fugax; Dill. Musc. 54. t. 10. f. 15.)—Sessile, gelatinous, roundish, undulated, blackish, beset with mammillary white-headed processes on the upper side.—Common in autumn and winter on the decayed trunks of trees, and dead sticks, especially the Alder. The English name, according to Dillenius, arose from the plant being supposed efficacious against witchcraft, when thrown into the fire. It consists of roundish, unequal, lobed, indeterminate masses, most corrugated beneath, scarcely elevated on any stalk, of a brown pulpy substance, becoming darker by age, from two lines to half an inch thick; the upper side bearing short scattered black prominences, each with a little white head.

T. bolitiformis. Brown Rough-backed Tremella. Engl. Bot. t. 1819.—Nearly sessile, scattered, roundish, depressed, brown; smooth and shining above; rough and dotted beneath.—Found scattered over the dead branches of trees; in Suffex by Mr. W. Borrer, and in Norfolk by Mr. W. J. Hooker. Each plant is nearly sessile, irregularly orbicular, depressed, all over of a dull pale umber-brown; unequal, smooth and polished above; rough with prominent points beneath, whence the edges seem crenate. The diameter is from half an inch to an inch.

T. albida. Whitish Tremella. Hudf. 565. Engl. Bot. t. 2117. (*T. candida*; Perf. n. 7? *T. cerebrina*; Bulliard Fung. v. 1. 221. t. 386.)—Sessile, dilated, obtuse, whitish or somewhat brownish, pulpy, semi-pellucid.—Found on dead or rotten wood, in shady situations, bursting through cracks in the bark, and composing horizontal, rounded, convoluted masses, white and extremely tender, often very like the brain of an animal. Bulliard says, a plate of glass, on which the plant is laid, becomes covered with its powdery seeds. Such Mr. Sowerby found imbedded in the substance of the frond, forming round black masses. This should make it an *Ulva*. There are yellow, brown, or blackish varieties. The whole require further investigation.

T. Nostoc. Ground Tremella. Linn. Sp. Pl. 1625. Hudf. 564. Engl. Bot. t. 461. (*T. terrestris sinuosa*, pinguis et fugax; Dill. Musc. 52. t. 10. f. 14. *Ulva terrestris pinguis et fugax*; Dill. in Raii Syn. 64.)—Sessile, roundish, plaited, waved, of an olive-green.—This much controverted plant occurs after rainy weather in summer, on gravel walks, or in grassy pastures, growing slightly attached to the ground. It generally spreads two or three inches, being of a tender gelatinous substance, thin and smooth, variously dilated and tumid, of a dull olive-green. When young, it is said by Dillenius to be small and globular, or like little scales; but its growth is very rapid, and its existence short. We are not sure that it revives after being shrivelled and blackened by dry weather. The duration of the plant is therefore, in the strictest sense, annual, and yet we do not know any thing of the seeds. Roth, Perfoon, and others esteem it an *Ulva*, an opinion we cannot refute, if we are unable to confirm it. The most remarkable circumstances in the history of this vegetable, are its being mistaken by the vulgar for the remains of a Will-of-the-wisp, or fallen star; and by some philosophers for an animal production. The latter have been deceived by a similar substance, proved by Dr. Withering to be the remains of frozen frogs, or as some say, the skin and bones of those animals disgorged by herons. Whether these or the real plant were the object of examination

tion by Paracelsus, or any other chemist, as Geoffroy, cited by Dillenius, hints; from which those sapient philosophers hoped to extract an universal solvent, or medicine; we feel little courage or curiosity to enquire. The subject is as unprofitable as Geoffroy's own analyses of various plants, the only advantage of which is to prevent any similar mode of investigation in future.

T. granulata. Granulated Tremella. Hudf. 566. Engl. Bot. t. 324. (*T. palustris, vesiculis sphaericis fungiformibus*; Dill. Musc. 55. t. 10. f. 17. *Ulva granulata*; Linn. Sp. Pl. 1633; not Mant. 136.)—Green, globular, clustered, membranous, containing a fluid.—Frequent on the mud of ditches and ponds, partly dried up, in autumn, in various places round London. Innumerable crowded, somewhat stalked, globules, each about the size of mustard-seed, and attached by fibrous radicles, compose broad green patches, which crackle under the feet when trodden upon. Their watery contents, if not thus prematurely dislodged, are finally discharged spontaneously, by a hole at the top of each globule, after which the skin collapses into a cup-like form, with the same hole in the centre. This also must be an annual plant, and something like feeds appears under its pellicular coat. It might safely be removed, with *T. Nigella*, to *Ulva*. Both these species were noticed by Dr. Sibthorp in the isle of Zante.

We are now to speak of some reputed *Tremella* involved in more uncertainty than any of the foregoing, and which we have therefore reserved for the conclusion of our subject.

T. cruenta. Gory Tremella. Engl. Bot. t. 1800.—Minutely granulated, diffuse, indeterminate, shining, dark purple.—Common about the lower parts of walls and houses, in damp situations, during the wet wintry months. We have observed it in particular streets for many successive years; though in summer no traces of such a production are visible. Nobody can overlook this vegetable, which forms very broad, continuous, but indeterminate, patches, of a deep, rich, shining purple, as if blood, or red wine, had been poured over the stones or ground. Under a microscope, it proves to be a congeries of minute, pellucid, globular granulations, all nearly of equal size. No particular scent or flavour is perceptible, nor is there any other indication of affinity to the *Bifus Jolithus* of various authors, known by its violet scent. This plant retains its colour when dried.

T. Sabinae. Savine Tremella. Dickl. Crypt. fasc. 1. 14. (*Fungus gelatinus dentatus, Sabinæ adnascens, fulvi coloris*; Raii Syn. 16.)—Sessile, prominent, oblong, tooth-shaped, tawny, somewhat powdery.—This production springs from the live wood, under the bark, of the most vigorous branches of the Savine, which are always swelled in that part, though otherwise healthy. It is seen only in rainy, chiefly autumnal, weather; and consists of a number of oblong, tremulous, gelatinous bodies, of a pale brownish-orange, sometimes hollow, externally powdery, often lobed, various in length, from a line to about an inch, their size bearing a regular proportion to that of the branch whence they originate. In dry weather these bodies suddenly collapse and dry up. Similar excrescences are found on the Common Juniper, particularly its larger, or Swedish, variety, and are certainly what Linnæus meant by his *Tremella juniperina*, for which our first-described species, *T. mesenterica*, has more than once been taken. Bulliard has represented what is found on the Juniper, in his *Fungi*, t. 427, by the name of *T. ligularis*; from which the *T. digitata* of Villars, Dauph. v. 3. 1007. t. 56, appears not at all dissimilar; nor does his *T. juniperina*, described and figured in the same place, materially differ. Why the latter

is retained by Perfoon, n. 10, in his second section; and the *ligularis* of Bulliard, conjoined with other things in his fourth, n. 22, under Wulfen's name of *clavariaformis*, we are at a loss to imagine, their forms being so similar and so variable. It would be idle to detail all the imaginary species of various genera, by the name of *Tremella*, *Clavaria*, *Puccinia*, &c. which authors of the first authority have made out of the above-described, or similar, productions. We have tried in vain to understand them as such, and cannot but persist in our original opinion, that they are mere gummy exudations, caused by immoderate wet, accompanied by resinous particles, insoluble in water, which give them a powdery appearance. Objections have been brought against this hypothesis, but no facts that disprove it. We have seen in Italy a similar and indubitable exudation, in wet weather, from the stem of the vine.

TREMELLIUS, EMANUEL, in *Biography*, an excellent Hebrew scholar, was the son of a Jew at Ferrara, and born there about the year 1510. Having been converted to the Christian faith by cardinal Pole and M. Flaminio, he imbibed the principles of the Reformers, accompanied Peter Martyr, and resided for some time at Strasburg. From Strasburg he came to England in the reign of Edward VI., and on his death left this country, and employed himself in teaching Hebrew in the college of Hornbach in Germany. He was afterwards professor of Hebrew at Heidelberg, and at this place translated into Latin the Syriac version of the New Testament, and joined Francis Junius in a translation of the Old Testament from the Hebrew. From hence he removed to Metz, and finally to Sedan, prosecuting his employment of teaching Hebrew, and died at the latter place in 1580. All Tremellius's writings related to the Oriental languages; and of these were Hebrew, Chaldaic, and Syriac grammars, a Hebrew Catechism, Commentaries on the Prophecy of Hosea, and the above-mentioned translations. Of his version of the Bible, F. Simon says that it is not much esteemed by the Protestants; and that the writer's Judaism has given him a singularity of manner, which makes him often wander from the true sense of a passage, and moreover that his Latin style is affected and inaccurate. Simon, Hist. Crit. du Nouv. Test.

TREMENTINE, in *Geography*, a town of France, in the department of the Maine and Loire; 6 miles N.E. of Chollet.

TREMEZZO, a town of Italy, in the department of the Lario; 14 miles N. of Como.

TREMITI, three small islands in the Adriatic, near the coast of Naples; they are called Capraria, St. Domino, and Tremiti or St. Nicolo. N. lat. 42° 10'. E. long. 15° 34'.

TREMITUS, a town of the island of Cyprus, at one time the see of a bishop. It was destroyed by Richard I. king of England; 12 miles W.S.W. of Nicosia.

TREMLITZ, a town of Bohemia, in the circle of Bechin; 7 miles S. of Potschaken.

TREMOLANTE, in the *Glass Trade*, a name for the preparation of calcined brass, otherwise called *orpello*, used either for a sky-blue, or a sea-green.

TREMOLITE, in *Mineralogy*, a mineral which received its name from Tremola, a valley in the Alps, where it was discovered. This mineral is classed by Haüy with hornblende or amphibole, and called by him *amphibole gr. im-matite*. It is divided by some mineralogists into three subspecies; asbestos tremolite, common tremolite, and glassy tremolite. They have all a fibrous or radiated structure, with a vitreous or pearly lustre. The filaments feel harsh

and rough to the touch, and scratch glass when rubbed upon it under water. By this property it may always be distinguished from asbestos, to which it bears a considerable resemblance.

Asbestous tremolite (*amphibole blanc* and *soyeuse* of Häuy) is of various shades of white. It occurs massive in wedge-shaped or splintery concretions. The structure is fibrous and radiated: it is translucent on the edges, and somewhat brittle and sectile. The specific gravity is 2.683. It melts before the blowpipe into an opaque white mass. When rubbed or struck in the dark, it emits a pale reddish-coloured light: when thrown on hot coals, it gives out a greenish-coloured light.

Asbestous tremolite occurs most frequently in granular foliated lime-stone, or in dolomite. It is sometimes found in chlorite, and more rarely in trap-rocks. It occurs at Glenelg in Invernesshire, in Aberdeenshire, and Icolmkill, and in basalt at the castle-rock of Edinburgh. It is found also in various parts of Europe, and in granular lime-stone with augite on mount Vefuvius.

Common tremolite (*grammatite*, Häuy) occurs of various shades of white, and sometimes dark smoke-grey. It occurs massive and crystallized. The primitive form of the crystal, according to Häuy, is an oblique prism, with a rhomboidal base, the planes of which are inclined at an angle of 127° and 53° . The more common form of the crystals is a very acute rhomboidal prism, with the edges more or less truncated, and the lateral planes longitudinally streaked.

This mineral splits easily, not only in the direction of the planes of the crystal, but also in that of its diagonals. When one of the prisms is broken across, we may observe a line strongly marked in the direction of the principal diagonal; hence it may at first sight be considered as a twin crystal, but this is not the fact.

Common tremolite is translucent or semi-transparent; it scratches glass, is brittle, and is fusible, but with great difficulty, by the blowpipe. According to Brongniart, the crystals of tremolite are rarely found pure, but generally contain a portion of the accompanying rock in the interior. The constituent parts are stated as under:

	Chenevix.	Langier.
Silex	27.0	50
Magnesia	18.5	25
Lime	21.0	18
Alumine	6.0	0
Carbonic acid	25.0	5

It occurs in the same situations as asbestous tremolite, and also in metalliferous beds, and sometimes in serpentine and granite.

Glassy Tremolite.—Its colours are the same as those of common tremolite. It occurs massive, and in acicular crystals. The lustre is shining, but in a less degree than that of common tremolite. It is translucent and rather brittle. The constituent parts of this mineral vary in different specimens. According to Langier, the tremolite from St. Gothard varies as under:

Silex	28.4	to	41
Lime	30.0		15
Magnesia	18.0		15
Water and Carbonic acid	23.0		23

Though tremolite is arranged under a distinct species from hornblende and actinolite by professor Jameson, it is classed under the same family. In a general view he observes, that tremolite is characterized by its white colours,

actinolite by its light green colours, and hornblende by its dark green colours. The count de Bournon states, that the phosphorescence of tremolite is owing to an intermixture with dolomite, and when the latter mineral is separated from it by acids, the property is destroyed.

TREMÓN, in *Ancient Geography*, an island situated near that of Delos, subject to frequent earthquakes.

TREMONT, in *Geography*, a town of France, in the department of the Maine and Loire; 3 miles E.N.E. of Vihiers.

TREMOR, in *Medicine*. See PALSY.

TREMOR of the Heart. See PALPITATION.

TREMORÉL, in *Geography*, a town of France, in the department of the North Coasts; 8 miles S. of Broons.

TREMOUILLE, LA, a town of France, in the department of the Vienne; 6 miles E. of Montmorillon. N. lat. $46^{\circ} 28'$. E. long. $1^{\circ} 7'$.

TREMP, a town of Spain, in Catalonia, on the No-guera Palarefa; 20 miles N. of Balaguer.

TREMSBUTTEL, a town of the duchy of Holstein; 20 miles E. of Hamburg.

TREMULA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, upon the route from Ptoleofida to Tingis. Anton. Itin.—Also, a town of Hispania, belonging to the Bastitani.

TRENCH, in *Agriculture*, a narrow opening or furrow cut in land by the spade or plough, for the purpose of draining or watering, and some other uses. Also, a small opening made in digging and working land over in different cases, and in laying it up both in ploughing and gardening. See SPRING and SURFACE Drain, WATERING Land, RIDGES, and RIDGING-up.

The cutting should be very exact for the two first purposes, the different sorts of materials raised being laid to the different sides of the trenches, which, in the latter case, are now mostly made in the wedge form.

Many of the bogs in Ireland have been drained, and made good ground, by only digging trenches round them.

TRENCH Filled-Drain, that sort of surface-drain which is laid with some kind of material for affording a proper passage to the water in its lower part, the upper being covered in with loose earth. See SURFACE-Drain.

TRENCH-Planting, in *Agriculture* and *Gardening*, the practice of setting and putting out plants and other productive matters in trenches. It is a method which is had recourse to for many different sorts of crops in each of these departments of cultivation. In the former for potatoes and some others, and in the latter for a very great number of plants and roots, as is seen under their different heads.

It has lately too been practised for asparagus, and some other crops, with very great success. In planting this valuable vegetable in this way, it was done in the early spring, the ground being first dug to the depth of eighteen inches, and well incorporated with rotten dung quite to the surface; a trench four or five inches deep was then formed, in which the plants, at the time twelve inches in height, were planted at three inches apart, keeping the tops perfectly upright, and breaking or hurting the roots as little as possible, covering them in with the spade, and treading them gently with the foot; after which the work was finished by a good watering. The plants scarcely flagged at all, though no care had been taken to preserve the mould about their roots, and not one of them died, but they far surpassed in the course of the summer those in the seed-bed rows, and some of them were capable of being cut the following year, in consequence of their great progress. The soil had a large proportion of peat-earth in it.

Sea-kale has likewise been raised in trenches with great advantage. They were made the same depth as above, eight inches of loose soil being left in the bottom, with which, six inches depth of river-sand were then intimately blended. The trench was now a foot deep, and being filled with six inches more of very light sandy loam, and the whole well mixed together, was sown in a line along the middle; and as the plants grew they were earthed up. The plants became, in this mode, so stout in the second year, as to be made use of by being blanched by means of straw shaken loosely over them, removing it as it became wet and heavy.

There are probably many other plants, seeds, and roots, that have not yet been tried, which may be raised in this method of planting with great success and advantage.

TRENCH-Plough, in *Agriculture*, that sort of tool of this kind, which is contrived for the purpose of opening and working land to a much greater depth than the common kind, so as to allow tap-rooted plants to strike them deeper, and form them better. See **PLOUGH** and **TAP-Root**.

TRENCH-Ploughing, the practice of opening and loosening the soil of lands to a great depth by means of such ploughs, which is a method that is essentially necessary where the roots of crops are to shoot and strike down to great depths, as without it such roots are incapable of being grown in the best and most profitable manner. The work is sometimes performed at one operation, but in other cases the tool does it by going twice in the same track, rendering the earth loose, and capable of being penetrated to a still greater depth. This mode of preparing land is much too little had recourse to by farmers in many cases.

TRENCHES, in *Fortification*, are ditches which the besiegers cut, to approach more securely to the place attacked; whence they are also called *lines of approach*. See **PARALLELS**.

They say, *mount the trenches*, that is, go upon duty in them. *To relieve the trenches*, is to relieve such as have been upon duty there.

The enemy is said to have *cleared the trenches*, when they have driven away, or killed, the soldiers who guarded them.

TRENCH, *Tail of the*, is the place where it was begun: and the *head*, that to which it was carried.

Trenches are of several sorts, according to the nature of the soil: if the adjacent territory be rocky, the trench is only an elevation of bavons, gabions, wool-packs, or epaulements of earth, cast round about the place; but where the ground may be easily opened, the trench is dug in it, and bordered with a parapet on the side of the besieged.

The breadth of the trenches is from eight to ten feet, and the depth from six to seven: they are cut in *talus*, or a slope.

The trenches are to be carried on with winding-lines, in some manner parallel to the works of the fortress, so as not to be in view of the enemy, nor to expose their length to the enemy's shot: for then they will be in danger of being enfiladed, or scoured by the enemy's cannon: this carrying of the trenches obliquely, they call carrying them by *coudees*, or returns. See **PARALLELS**.

TRENCHES, *Opening of the*, is when the besiegers begin to work upon the line of approaches; which is usually done in the night; sometimes within musket-shot, and sometimes within half, or only whole cannon-shot of the place, if there be no rising ground about it, the garrison strong, and their cannon well served.

The workmen that open the trenches, are always supported by bodies of men against the sallies of the besieged; and sometimes those bodies lie between them and the place, as also on their right and left.

The pioneers sometimes work on their knees; and the men that are to support them, lie flat on their faces, in order to avoid the enemy's shot; and the pioneers are likewise usually covered with mantelets, or faucissons.

TRENCH-Guard. See **GUARD**.

TRENCH *the Ballast, To*, is a sea-phrase, signifying to divide the ballast into several trenches in a ship's hold.

TRENCHARD, JOHN, in *Biography*, a political writer, was the son of sir John Trenchard, secretary of state under king William, and born in 1669. Liberally educated, he was placed in one of the inns of court, with a view to the study of law. He was called to the bar, but as he preferred a political life, he abandoned the profession, and obtained the place of the commissioner of the forfeited estates in Ireland. Having acquired considerable wealth by marriage, by the death of an uncle, and by the decease of his father in 1695, he came into parliament for the borough of Taunton, and appeared as a patriotic member and writer. He was a zealous opponent of a standing army; and soon after the peace of Ryfwick in 1697, which rendered needles such a force, he published a pamphlet, entitled "An Argument shewing that a Standing Army is inconsistent with a free Government, and absolutely destructive to the Constitution of the English Monarchy." This was followed, in 1698, by "A short History of Standing Armies in England." These pamphlets are supposed to have occasioned the king's sending away his Dutch guards, and the army's being reduced to a very low establishment. In many subsequent years, Mr. Trenchard continued to write occasionally in favour of liberty; and having taken Thomas Gordon, a person of similar sentiments, into his house, they began in 1720 to publish periodically a series of papers, entitled "Cato's Letters," for the professed purpose of promoting civil and religious liberty. Trenchard died in 1723, at the age of fifty-four; and Gordon published his eulogy in the "Independent Whig." *Biog. Brit.*

TRENCHÉ, in *Heraldry*. See **TRANCHÉ**.

TRENCHÉ's Island, in *Geography*, an island near the coast of South Carolina; 25 miles in circumference. N. lat. 32° 13'. W. long. 80° 58'.

TRENCHING, in *Agriculture*, the operation and practice of working over land in trenches by the spade. It is had recourse to in bringing some kinds of waste lands into cultivation, in some cases and particular situations, as in the northern parts of the island, where labour is cheap; but in others it is mostly too expensive.

It, however, answers sometimes in cases where it could hardly have been expected, on account of its being so very complete, as scarcely to require any thing being done afterwards to the ground.

The term also signifies the laying up land in the ridge form, either by the spade or plough.

TRENCHMORE, the name of an old English dance; of which nothing certain is now known, but that it was a lively movement.

TRENCK, FREDERIC, *Baron von*, in *Biography*, an adventurer, was descended from a noble Prussian family, and born at Königsberg in 1726. Having been too much indulged in his youth, and losing his father when he was twelve years of age, he became ungovernable, and the sport of his own impetuous passions. In 1742, at the age of sixteen years, he entered into the Prussian guards, then quartered at Potsdam. In 1744, at the commencement of the second Silesian war, he attended the king as an aid-de-camp: but being suspected of a traitorous correspondence, he was arrested, and confined in the prison of Glatz, and failing in his first attempt to make his escape from prison, he at length succeeded

ceeded

ceeded by bribery, and got safe to Bohemia, and afterwards to Elbing, in Polish Prussia, in March 1747. After various adventures he arrived at Moscow, where he insinuated himself into the good graces of the lady of the grand-chancellor Bestuchef, the favourite of Elizabeth. From Moscow he made a circuitous tour to Vienna, with a view of recovering some contested property; and dissatisfied with the reception he found at the Austrian court, he determined to return again to Russia; but in passing through Dantzic, he was arrested at the request of the Prussian resident, and committed to prison at Magdeburg, where he remained ten years. Here he amused himself, during a tedious and rigorous imprisonment, in writing verses; which, long after his release in 1763, he published at Frankfort on the Mayne, in 1769. He published some other works at Aix-la-Chapelle, where he became editor of a gazette, and married a lady of respectable character and connections. Finding the occupation of a gazette-writer tiresome and not lucrative, he began business as a wine-merchant; but the wine-trade not answering his expectations, he disappeared about the year 1783. In 1792 he edited a journal at Hamburg and Altona, and from the latter place he removed to France, where he lost his life by the guillotine in the month of July 1794. The Memoirs of his own Life appeared at Berlin in 1787, in two parts, 8vo. Of the authenticity of the facts stated in these memoirs, great doubts have been entertained. His life, translated into French by himself, was published at Paris in 1789, 3 vols. 8vo. A new edition of his "Macedonian Hero" was printed in 1788, Frankfort and Leipzig, 8vo. Gen. Biog.

TRENCSIN, in *Geography*, a town and castle of Hungary, near the river Waag, situated on a rock, and defended by a very strong castle. Near it are some hot baths; 20 miles N.N.W. of Topoltzan.

TREND, that part of the flock of an anchor from which the size is taken.

TRENDING, in *Rural Economy*, the operation or practice of freeing wool from filth of different kinds. It is usually done by persons who are called trenders, and who are appointed and sworn for the purpose. In most sheep-districts, the best wool is always understood to have gone through this process, and then to be worth two or three shillings the tod more than other untrended wool. The fleeces in such cases are neatly rolled together, and bound with osier or with bands in some places. It is sometimes termed trendering. See SHEEP and WOOL.

TRENDLE, a term signifying the wheel of a barrow, or any thing which turns round in that manner when of the low wheel kind.

TRENNO, in *Geography*, a town of Italy, in the department of the Olona; 4 miles N.W. of Milan.

TRENSDORF, a town of Bavaria, in the bishopric of Bamberg; 4 miles S. of Bamberg.

TRENT, a city of the county of Tyrol; in Latin *Trentidum*, called by the Italians *Trento*, and by the Germans *Trentdt*; and situated upon the Adige or Etsch, in a very fruitful valley, surrounded with high hills. It was built by the Cenomani Gauls, who were dispossessed by the Romans. The Goths became masters of it when they came into Italy, and after them the Lombards. Afterwards it was possessed by the German emperors, until 1377, when Wenceslaus, son to Charles IV., gave it to the church of Rome. Afterwards its bishops, being made princes of the empire, became temporal as well as spiritual lords of the city. Some authors affirm that the name Tridentum is derived from Neptune's sceptre, or trident, to whom they say the city was once consecrated. This opinion took its rise

from an ancient marble being found there, on which was a Neptune holding his trident. Others derive the name from three rivers and torrents that fall into the Adige, a little above and below the city. Others say it owes its name to three high rocks in the neighbourhood, which appear like three teeth, *tres dentes*. The bishop was a prince of the empire, and temporal as well as spiritual lord of his diocese, which is of very considerable extent; but notwithstanding the sovereignty of the bishop, the city of Trent has its own distinct privileges, and magistrates to preserve them: these consist of two burgo-masters, who preside by turns, and twelve counsellors. Trent contains no streets exactly regular, and the houses are in general old. The palace is large, but in the antique style. Besides the cathedral, there are three parish-churches, a college, and some convents; 55 miles N. of Mantua. N. lat. 46°. E. long. 11° 5'.

TRENT, a princely bishopric of Germany, situated in the Tyrolse, in which this ancient bishopric was gradually increased by the liberality of the ancient Roman emperors. Though the bishop of Trent, after the stipulation ratified in the recess of the empire, at Augsburg, in the year 1548, held of the archducal house of Austria, as a land state, yet he enjoyed, as an immediate prince of the empire, both a seat and voice at the diets, in the college of princes of the empire, and likewise actually sent deputies to the diet of the empire. This prelacy was also a state of the circle of Austria. Among the indemnities agreed to at Ratibon, in 1802, the bishopric was given to the grand duke of Tuscany, as archduke of Austria. It was afterwards ceded to Bavaria.

TRENT, a town of the island of Rugen; 11 miles N.W. of Bergen.

TRENT, a river of England, which rises in the north-west part of Staffordshire, on the borders of Cheshire, about six miles south-west from Leek: taking a south-east direction, it crosses the county to the borders of Leicestershire and Derbyshire; it then takes a north-east direction, and crosses the county of Derby and Nottingham to Newark, from whence its direction becomes nearly due south, till after passing a small part in the north of Lincolnshire, it joins the Ouse, and the two streams form the Humber. Canals are made or making, to open a communication between this river and various parts of the kingdom, *viz.* from the mouth of the Idle, below Gainborough, to Redford and Chesterfield; to Lincoln, and from thence to Tatterfall, Horncastle, Seaford, Boston, and the sea; from near Nottingham, to Cromford and Winstar; from the mouth of the Derwent, one branch through the counties of Derby, Stafford, and Chester, to the Mersey, which is joined with another branch to Coventry and Braunston, where it meets with the canal from Brentford: other branches join the Thames at Lechlade, the Avon at Warwick, the Severn at Worcester, and many others. The Trent is of itself navigable from Burton in Staffordshire.

TRENT, a river of Canada, which runs from Rice lake to lake Ontario.—Also, a river of North Carolina, which runs into the Neuse, at Newbern.

TRENT, *Council of*, in *Ecclesiastical History*, denotes the council assembled by Paul III. in 1545, and continued by 25 sessions till the year 1563, under Julius III. and Pius IV., in order to correct, illustrate, and fix with perspicuity, the doctrine of the church, to restore the vigour of its discipline, and to reform the lives of its ministers. But it has been a matter of complaint by many, both in and out of the communion of the church of Rome, that this assembly, instead of reforming ancient abuses, rather gave rise to new enormities. It is alleged, that opinions of the scholastic doctors on intricate

intricate points, which had been left undecided, were by this council absurdly adopted as articles of faith, and imposed with violence upon the consciences of the people, under pain of excommunication: that there is an ambiguity in the decrees and declarations of this council, which renders the disputes and dissentions, that had rent the church, more intricate and perplexed, and which really multiplies and propagates, instead of lessening and suppressing them: that matters were decided in this assembly, according to the despotic will of the Roman pontiff, without regard to the dictates of truth, or the authority of Scripture: and that the few wise and pious regulations that were made in this council, were never supported by the authority of the church, but suffered to degenerate into a mere lifeless form or shadow of law, which was treated with indifference, and transgressed with impunity. It will not, therefore, appear surprising, that there are certain doctors in the Romish church, who, instead of submitting to the decisions of the council of Trent, as an ultimate rule of faith, maintain that these decisions are to be explained by the dictates of Scripture and the language of tradition: nor can we wonder that this council has not every where the same degree of credit and authority, even in those countries that profess the Roman Catholic religion. Some countries, indeed, such as Germany, Poland, and Italy, have adopted implicitly and absolutely the decrees of this council, without the least restriction. But in other places it has been received and acknowledged on certain conditions, which modify, not a little, its pretended authority. Among these latter we may reckon the Spanish dominions, which, during many years, disputed the authority of this council, and at length acknowledged it only so far as it could be adopted without any prejudice to the rights and prerogatives of the king of Spain. In other countries, such as France and Hungary, it has never been solemnly received or publicly acknowledged. Indeed in the former of these kingdoms, those decrees of Trent that relate to points of religious doctrine, tacitly and imperceptibly through the power of custom, acquired the force and authority of a rule of faith; but those which regard external discipline, spiritual power, and ecclesiastical government, have been constantly rejected, both in a public and private manner, as inconsistent with the authority and prerogatives of the throne, and prejudicial to the rights and liberties of the Gallican church.

Notwithstanding the preceding remarks, the decrees of the council of Trent, together with the creed of pope Pius IV., contain a summary of the principal heads of the Roman Catholic religion. See *POPERY*.

However, in these decrees and confession of faith, many things are expressed in a vague and ambiguous manner, with a view to the intestine divisions then prevalent in the church: and several tenets are omitted in both, which no Roman Catholic is allowed to deny, or even to question. But it must be acknowledged, that in these decrees, and in this confession, several doctrines and rules of worship particularly pertaining to the doctrine of purgatory, the invocation of saints, and the worship of images and relics, are inculcated in a much more rational and decent manner than that in which they appear in the daily service of the church, and in the public practice of its members: and it is to be observed, that in deducing a just notion of the doctrine of Rome from the decrees of the council of Trent, regard ought to be had, not so much to the terms made use of in these decrees, as to the real significations of these terms, which must be drawn from the customs, institutions, and observances, that are, every where, in use in the Romish church. *Mosh. Eccl. Hist. vol. iii. Eng. ed. 8vo.*

TRENT, Council of, congregation for interpreting the decrees of the, is a congregation, the plan of which was formed by Pius IV. and afterwards instituted and confirmed by Sixtus V. It was authorized to examine and decide, in the name of the pope, all matters of small moment relating to ecclesiastical discipline; while every debate of any consequence, and particularly all disquisitions concerning points of faith and doctrine, were left to the decision of the pontiff alone, as the great oracle of the church. Hence it was, that the approbation of Innocent XI. was refused to the artful and insidious work of Bossuet, bishop of Meaux, entitled "An Exposition of the Doctrine of the Catholic Church," until the author had suppressed entirely the first edition of that work; and made corrections and alterations in the second. See *POPERY*.

But though the court of Rome, and all those who favour the despotic pretensions of its pontiff, maintain, that he alone who governs the church as Christ's vicegerent, is entitled to explain and determine the sense of scripture and tradition in matters pertaining to salvation, and that a devout and unlimited obedience is due to his decisions; yet it has been impossible to persuade the wiser part of the Roman Catholic body to acknowledge this exclusive authority in their head. And accordingly, the greater part of the Gallican church, and a considerable number of learned men of the popish religion in other countries, think very differently from the court of Rome on this subject. They maintain, that all bishops and doctors have a right to consult the sacred fountains of scripture and tradition, and to draw from thence the rules of faith and manners for themselves and their flock; and that all difficult points and debates of consequence are to be referred to the cognizance and decision of general councils. *Mosh. Eccl. Hist. vol. iii. See INFALLIBLE.*

TRENTAL, TRIGINTAL, or TRICENNAL, a Romish office for the dead, consisting of thirty masses, rehearsed for thirty days successively after the party's death.

The trental is thus called from the Italian, *trenta, triginta, thirty*. It is mentioned anno primo Edw. VI.

TRENTON, in *Geography*, a town of New Jersey, in the county of Hunterdon, on the E. side of the Delaware. Here the legislature stately meet, the supreme court sit, and most of the public offices are kept. The court-house is a handsome building. There is a flourishing academy, and the number of inhabitants is about 3002; 24 miles N.N.E. of Philadelphia. N. lat. 40° 13'. W. long. 74° 48'.—Also, a post-town of the province of Maine, in the county of Hancock, containing 501 inhabitants; 31 miles N.E. of Penobscot.—Also, a town of North Carolina, on the river Trent; 20 miles S.S.W. of Newbern.—Also, a post-township of New York, in Oneida county, 12 miles N. of Utica; bounded northerly by Steuben and Remsen, easterly by West Canada creek or Herkemer county, S. by Deerfield, and W. by Floyd. The town is well watered by small streams, and by springs. The soil is good: the forest woods are elm, linden or bass-wood, butternut, beech, maple, &c. The inhabitants are principally of New England descent, though some are of the ancient Dutch from Holland; and their industry is well rewarded by the products of agriculture. There are some very remarkable falls in West Canada creek, on the eastern border of this town. This stream affords numerous scites for mills in Trenton. The population is 1548; the senatorial electors are 127. The largest compact settlement in this township contains from 70 to 80 buildings, and is distant 13 miles from Utica and 107 from Albany.

TREO, a town on the E. coast of the island of Paros.

TREOGAN, a town of France, in the department of the North Coasts; 9 miles W.S.W. of Rostrenen.

TREOGAT, a town of France, in the department of the Finisterre; 9 miles S.W. of Quimper.

TREPAN, in *Surgery*, a circular saw, by means of which the skull is perforated in the operation called trepanning. It bears a considerable resemblance to the well-known instrument named a wimple, and is worked in the same manner. A representation of it is given in *Plate VIII. fig. 6.* of the surgical plates. Formerly, the saw was sometimes made of a conical shape (see *fig. 5.*); but this construction rendered the action of the instrument difficult; and as the fear of a cylindrical saw penetrating too suddenly, so as to injure the brain, was found by experience to be an insufficient reason for the conical shape of the saw, the cylindrical trepan at length came into general use. In this country, the trepan is now superseded by the instrument called a *trepine*, which has a different kind of handle from that of the trepan, and is not worked in the same way. (See *TREPINE.*) On the continent, however, the trepan still has the preference. Mr. Rodman's trepan (*fig. 1.*) is objectionable, because with it you cannot increase and diminish the pressure on any particular point of the circular groove in the bone, as occasion requires. You must continue to saw every part of the circle. Hence, if the bone be sawn through in one place, and not in another, as generally happens before the operation is finished, the further action of Mr. Rodman's saw will inevitably do mischief to the dura mater, and is not well calculated for completing the division of the bone. See the following article.

TREPANNING, or TREPINING. From what has been said in some preceding articles of this work, (see particularly *HEAD, Injuries of, EXTRAVASATION, &c.*) the operation of trepanning or trepining, or that of sawing out a portion of the skull, is, in several affections of the brain from compression or irritation, the only means of preserving life, and of all other remedies the most urgent and effectual. It should be performed in good time, and the repetition made according to the exigency of the case. In the records of surgery, innumerable facts may be consulted, where the prudent and judicious employment of the trepan has effected wonderful cures, and been the only thing by which the patients' lives could possibly have been saved. The benefit which the operation brings about, is also sometimes so sudden and astonishing, that in no instance does the interposition of the surgical art display itself to greater advantage. The immediate restoration of sight by the depression or extraction of an opaque substance from the eye, is not more beautiful and striking, than the instantaneous communication of the intellectual faculties, and of the powers of speech, of feeling, &c. together with voluntary motion, to a person lying in an apparently lifeless state from an injury of the head. The utility of the trepan is occasionally manifested even in this degree. In the valuable essay of Mr. Abernethy on injuries of the head, a case may be seen, in which the patient, who had been in a condition almost bereft of animation, rose up and spoke the instant the extravasated blood was removed from the surface of the brain. And among the wounded at the battle of Waterloo, there was a soldier of the 44th regiment, whose case is of equal interest. He had been struck with a musket-ball on the right parietal bone, which was exposed, and had no appearance of being fractured. As, however, the symptoms of compression were urgent, and the patient was in nearly a lifeless state, the writer of the present article conceived it right to apply the trephine to the part on which the violence had acted. He had not sawn long before the external table came away in the hollow of

the trephine, leaving the inner table behind, which was not only splintered, but driven at one point more than half an inch into the membranes and substance of the brain. No sooner were the fragments taken out with a pair of forceps, than the man instantly sat up in his bed, looked round, and began to speak with the utmost rationality. It is a most extraordinary fact, that this patient got up and dressed himself the same day without leave from the medical officers, and never had a bad symptom afterwards. Immediately the operation was finished, the temporal arteries were opened, and some purgative medicines exhibited.

Let not the young surgeon, however, draw from these dazzling cases of success an immoderate solicitude to perform the operation; for it should never be undertaken but in the most pressing circumstances, and when the symptoms unequivocally shew, that a dangerous degree of pressure on the brain exists. We recollect an unfortunate example, in which an hospital surgeon of this metropolis ventured to saw out a portion of the frontal bone for a mere long-continued pain in the part: the patient was attacked with inflammation of the dura mater, and perished in three or four days. We may therefore conclude, that the operation is not itself exempt from danger; and it is certain that it ought never to be resorted to without deep consideration. "Gravis tamen fatis est operatio, ut nunquam, nisi indicationes sufficientes adfint, institui debet." Callisen Syst. Chir. Hodiern. tom. i. p. 658.

The trepan or trephine is never necessary in injuries of the head, except for the purpose of relieving the brain from pressure. Such pressure may be caused by a depressed portion of the cranium, or it may be produced by an extravasation of blood, or the lodgment of matter, betwixt the skull and the dura mater. The chief danger of concussion, when the accident is not directly or soon fatal from the disorganization and mischief done to the brain, depends upon the consequent inflammation of this organ, and therefore can be little likely to be benefited by the use of the trepan. If the operation becomes proper in such a case, it is when an abscess has formed under the cranium, and when the confined matter itself creates bad symptoms by its pressure on the brain. This state of things, however, cannot come on till after the inflammation of the brain and its membranes has prevailed a certain time, and it is always accompanied with a detachment of the pericranium and a puffy tumour of the scalp; or, if there be a wound of the latter part immediately over the abscess, the lips of the injury acquire suddenly an unfavourable appearance, and lose their vermilion colour. The patient has also had much preceding febrile disorder, pain and tension over the whole head, redness and turgescence of the eyes, and generally more or less delirium. When the matter is forming, there are usually some rigors, and as soon as it is formed, the patient falls into a comatose state, and paralytic symptoms shew themselves. Here the urgency for the prompt application of the trephine is very great, and the patient's chance of living is almost essentially connected with the immediate performance of the operation. This important case has been particularly dwelt upon in the writings of Mr. Pott.

In the articles *HEAD, Injuries of, EXTRAVASATION, &c.* we have laid down the most remarkable symptoms of concussion and compression of the brain, a subject which every surgeon should study with earnest attention, before he ever presumes to employ the trepan. For sometimes these accidents are extremely difficult to be discriminated; sometimes they exist together in the same individual, a complication which is peculiarly embarrassing; and in every instance where the symptoms are those of concussion, the oper-

TREPANNING.

operation, so far from being indicated, would be a step of all others the most likely to do harm, by increasing the irritation and inflammation of the brain and its membranes. A fall upon the back, or upon the head, occasions a direct concussion of the brain, and the shock, not being materially weakened by the intervention of any yielding elastic structure, is the more dangerous. When a person has fallen from a certain height, and pitched upon his head, his back, the buttocks, the knees, or even the soles of the feet; when he has been instantly deprived of his senses, and then by degrees recovered them and come to himself again; the fact of his having suffered concussion of the brain is clear and indisputable. Concussion has likewise taken place, though in a slighter degree, when the patient has been only stunned by the fall, and experienced a sensation of sparks. But a multitude of degrees separate this feeble concussion from that, in which the substance of the brain is instantaneously disorganized, so that the patient has not the possibility of recovery.

The symptoms of concussion of the brain are attended with coma, and the compression of this organ by an extravasation is also accompanied with lethargic heaviness. How, then, is the surgeon to ascertain, whether the comatose disorder arises from one or the other of these affections?

Here, in order to avoid repetitions, we beg leave to refer to the observations already made in the articles quoted above. But there is one criterion of such first-rate importance, that it may prevent innumerable fatal mistakes, and, indeed, without the continual recollection of it, no man ought to be rash enough to interfere with this dark and abstruse part of surgery. On this account we shall mention it here, notwithstanding we have already noticed it elsewhere. If the patient is knocked down and stunned directly by the blow, and remains in a state of insensibility, these primary symptoms are ascribable to the concussion. On the contrary, when the coma and loss of sense do not take place till an hour or two after the blow, they are to be imputed to an extravasation.

The shock given to the brain by concussion, must, like every other impulse communicated, continue to diminish until it ceases altogether. If, at the very time of the blow, the shock has not been forcible enough to produce alarming symptoms, such symptoms will not afterwards come on when their cause is weakened. Hence the reason may be discerned, why compression may be distinguished from concussion of the brain, when there has been an interval of sense between the receipt of the blow, and the occurrence of the bad symptoms. But the distinction of the symptoms into primary and consecutive, cannot be made when concussion and extravasation exist together.

Having made these few remarks on concussion and compression of the brain, remarks which seemed necessary before we entered into a description of the operation of the trepan, we shall next premise some observations relative to contusions and fractures of the skull, cases on which the most erroneous opinions have been entertained. It is true, that we have in another place (see *HEAD, Injuries of,*) considered the subject; but we think it better to recapitulate certain points here, because they have such immediate connection with the application of the trephine.

Contusions of the head not unfrequently occasion a small kind of tumour, which is soft in the centre, but hard and resisting at the circumference, especially when the violence has been considerable. Now the ease with which the centre or seat of the extravasated fluid admits of being depressed, while the circumference remains hard and elevated, is ex-

remely apt to give rise to the belief, that a fracture with depression has happened. The true nature of this accident was first clearly explained by the eminent M. J. L. Petit, and since his time the proper cautions, not to fall into a mistake concerning it, have been laid down by the generality of surgical writers.

Often nothing is more obscure than the diagnosis of fractures of the cranium: their existence indeed can only be made out with certainty, when they can be felt or seen. Thus a fracture of the skull, attended with a wound of the scalp, and exposure of the bone, shews itself in the form of a fissure more or less wide and extensive, and taking various directions. The accident may also be known by the touch, even when the soft parts continue entire, particularly if the fracture is accompanied with splinters, or the edges of the fissure are materially separated. When there are many splinters, entirely detached, a crepitus will likewise serve to explain the nature of the accident; but, unassisted by these symptoms, imparted to him by the sight, the hearing, or the touch, the practitioner cannot at once offer a decided opinion as to whether a fracture exists or not.

In order to procure more positive information, would it be right and judicious to make several incisions, and uncover the bone? But here the surgeon would be embarrassed in the very commencement of his proceedings; for how would he be able to judge where the knife should be applied? Why also should he resort to an useless and painful operation, which (to say the best of it) could only render the patient's cure more distant.

The symptoms indicating compression of the brain, can alone justify an examination of the fracture. These symptoms also must be urgent and alarming; for when they prevail in a slight degree, bleeding and evacuations promise more benefit than any operation on the skull, and consequently all examination of the part supposed to be broken must be unnecessary. The precept, too commonly given, to cut through the scalp for the purpose of bringing the fracture into view, will no longer be matter of surprise, when it is known that, with some surgeons, the operation of the trepan is a thing of course in all fractures of the cranium.

Even when the cranium has been denuded, so that the sight can convey the information respecting the solution of continuity in the bone, care must be taken not to be deceived by a future, or by the groove of a vessel. In cases of doubt, a modern surgical author advises us to scrape the outside of the bone; and he tells us, that if, after the removal of the external table, the fissure yet appear, and a thread of blood be seen at its outer part, no doubt exists of its being a real fissure. As, however, making this examination can answer no purpose, except with a view to determining the place where the trepan should be applied, we cannot recommend the plan, except where the symptoms are such as to render this information desirable. On the contrary, it appears to us, that all examinations of the bone, made seemingly from mere curiosity, and without any true surgical object, should be deprecated as rash and hurtful.

The danger of fractures of the skull does not depend upon the simple solution of continuity: it bears altogether a relation to the concussion and compression of the brain, with which the injury of the bone may be complicated. The pressure, which is caused by depressed splinters of bone, is less alarming, inasmuch as the cause of the compression is easy of removal. The pressure arising from extravasated fluid is far more serious, in consequence of the difficulty of ascertaining positively the existence and precise situation of such extravasation.

The seat of the extravasation is sometimes between the skull and the dura mater, which has been detached from the bone. More frequently it occurs either between the dura mater and tunica arachnoides, in the substance of the brain, or else in the ventricles. The quantity of extravasated fluid is generally less in those extravasations which are situated between the dura mater and the skull. The extravasations, which are formed in the substance of the brain itself, are not only more considerable, but also, as they mostly depend upon concussion, are more alarming, than effusions on the surface of the dura mater. It is indeed extremely difficult, if not impossible, to ascertain the situation of the extravasated fluid. In such cases, the trepan is likewise of no use; while concussion, when so violent as to produce internal extravasation, is invariably fatal. In extravasations between the dura mater and the skull, which are almost the only cases of the kind to which surgery can administer relief, when the effused fluid lies under a part of the skull accessible to the trepan, the extravasated fluid is almost always small in quantity. The danger, however, is not the less: ten or twelve drops of fluid are sometimes enough to produce a fatal compression. When the extravasation has happened in the substance of the brain, the compression is far more perilous; in short, it may be said to prove, with very few exceptions, certainly mortal. The danger is not so great, when the extravasation is situated between the skull and dura mater.

The lethargy, the degrees of which increase from mere drowsiness unto the most perfect coma, and the paralysis of the opposite side of the body to the seat of the extravasation, are the characteristic symptoms of this accident, in cases of injury of the head. Having explained elsewhere (see *HEAD, Injuries of, CONCUSSION, EXTRAVASATION, &c.*) some other symptoms, such as stertorous respiration, dilated pupils, &c. which usually indicate pressure on the brain, we need not here dwell upon them. The subsequent increase of the coma and paralytic affections, and the gradual augmentation of their intensity, serve to render these symptoms distinguishable from others, which are suddenly brought on by concussion. But there are instances, as every man of experience knows, in which the concussion ruptures the blood-vessels, and produces an extravasation of blood. In this circumstance, it is obvious that the symptoms of compression are blended with those of concussion. The symptoms, proceeding from the latter cause, always diminish in proportion to the time which has elapsed from the moment of the injury; while those of compression succeed, and, on the contrary, increase in intensity, in proportion as the quantity of extravasated fluid becomes more considerable. Notwithstanding these distinctions, however, it must be acknowledged that there are many cases, in which the surgeon is obliged to remain in doubt with regard to the particular cause of the symptoms. This indecision is the more embarrassing, because the operation of the trepan is necessary in cases of extravasation, but useless in those of concussion. Even when extravasation is known to exist, the practitioner requires more information; for he ought to know the precise situation of the effused fluid. It is true, indeed, that paralysis of one side of the body indicates the pressure to be upon the opposite hemisphere of the brain. But what surgeon would venture to follow the practice advised by Van Swieten, and apply to the suspected side of the head three crowns of the trepan? Possibly not one of them might fall on the situation of the extravasated fluid. When the skull is broken, the extravasation exists on the same side as the fracture. When it is the effect of concussion, or when the breach of continuity in the skull is what

is termed a counter-fissure, the effusion is generally on the side of the head most remote from the blow. If the pressure is caused by a detachment of the internal table of the skull, the nature of the case cannot be ascertained, before the operation of the trepan has been performed on the part of the skull upon which the violence has acted. When there are two extravasations; one depending upon a fracture, and situated immediately under it, between the dura mater and the skull; the other arising from concussion, and situated at some point directly opposite, either between the dura mater and tunica arachnoides, or within the substance of the brain itself; paralysis may occur on the same side as the fracture: and hence it may be inferred, that the palsy does not always take place on the side opposite to the extravasation. But an examination of the body quickly proves, that the case does not deviate from the common rule. The extravasation produced by concussion, being almost invariably more considerable than that caused by a fracture, accounts for the extension of the palsy to the same side of the body. Sometimes the side which is not paralyzed is affected with convulsions, the pulse is full and hard, and the respiration stertorous: in short, the symptoms are analogous to those caused by apoplexy.

The evacuating plan, recommended for the treatment of concussion, (see *CONCUSSION, and HEAD, Injuries of,*) is all that can be done, when every thing is uncertain relative to the situation of the extravasation. It is all that can be done in those frequent instances, where the effusion has taken place in the substance of the brain, so that it cannot possibly be voided. The trepan then is indicated only when there is an extravasation between the dura mater and the bone, the fracture being situated in a part of the skull accessible to instruments, and not at the base. We will not here dwell upon the doubtful example, where the fluid lies between the dura mater and the arachnoides. But are the cases, which we have just been describing, as frequent as they are supposed to be? Cannot the effused blood be generally discharged through the interspaces of the broken pieces of bone? Is the trepan usually necessary for the relief of injuries of the head, as Quenay, Pott, and the French Academy of Surgery maintained?—We think not. The operation is often useless, and sometimes dangerous. We believe that it should be limited to a small number of cases. The exact determination of the cases in which it is absolutely indispensable, is one of the greatest desiderata in modern surgery.

Richerand contends, that extravasations between the skull and the dura mater, so considerable as to produce compression of the brain, and render the trepan necessary, are much less common than many surgeons think. Even when they do occur, the dura mater is always detached to a certain extent; and, according to this writer, if the bone is much broken, the interspaces of the fragments are quite sufficient for the evacuation of the effused fluid. The following case is quoted in proof of this observation. A woman injured her head, by falling from a height of fifteen feet. The fracture reached the whole breadth of the skull, so that when the os frontis was taken hold of with one hand, and the os occipitis with the other, the two halves of the cranium admitted of being manifestly moved and separated. Blood issued from the fissure, the edges of which were kept apart by a small wedge of wood, in such a manner that the pulsations of the brain were visible. On the sixth day, as nothing was discharged from the fissure, the bit of wood was removed; and on the fifty-second, the wound had completely healed without any exfoliation. On the seventy-second, the patient was discharged from the Hôtel-Dieu, perfectly

TREPANNING.

perfectly cured. *Nofographic Chirurgicale*, tom. ii. p. 292. edit. 3.

Thus we see that the trepan is often unnecessary in injuries of the head, with fracture of the skull, notwithstanding the co-existence of an extravasation between the bone and the dura mater. This doctrine is very different from what is taught in the memoirs of M. Quesnay, in the first volume of those of the French Academy of Surgery. Default, in the last years of his practice, abandoned the operation of the trepan altogether. It has been remarked for many years, that in the Hôtel-Dieu this operation has had very little success; a circumstance which has excited a suspicion, that the foul air of the wards of that establishment may have had a share in bringing on the unfavourable event. We shall not here expatiate on the bad effect of the atmospheric air on the membranes of the brain; a thing of which B. Bell seems to have convinced M. Richerand.

When the skull is fractured by a blow or fall, and the case is a simple fissure, the trepan ought to be applied upon the solution of continuity, *if the symptoms indicate a dangerous degree of pressure on the brain*, and the edges of the fracture are not sufficiently separated to let the extravasated fluid escape.

When the detached portions of bone are depressed, so as to compress the brain, the operation is still requisite, if they cannot be elevated by other means. But Richerand maintains, that a positive indication for trepanning is not frequent, either because it is difficult to judge of the existence and situation of extravasations, or because extravasated fluids readily escape through the interspaces of the fragments, when there is a splintered fracture. Such facility is also increased, when one of the portions of broken bone is totally detached, so that it can be removed, leaving an aperture equivalent to what would be produced by the application of the trepan.

When the indications render it necessary, there is no point of the external surface of the cranium to which the trepan, or trephine, may not be applied. The region of the frontal spine and sinuses, however, and the situation of the spines and inequalities of the occiput, the lower part of the squamous portion of the temporal bone, and the track of the meningeal artery running under the anterior inferior angle of the parietal bone, are places to which the instrument ought never to be applied without urgent necessity. The surgeon may trepan upon the sutures, and over the sinuses of the dura mater, with perfect safety. A wound of the longitudinal sinus has not only been found to be free from danger, but actually beneficial, by the evacuation of blood that has followed. The experience of Pott, Callisen, &c. confirms this fact; and they have even purposely opened the vessel with a lancet. Callisen, *Syst. Chir. Hodiernæ*, tom. i. p. 659. edit. 1798.

The manner in which the two tables of the skull recede from each other at the frontal sinuses, would make the operation difficult. Besides, here the spine of the os frontis projects inward, so that the whole of the bone could not be sawn through, without the dura mater being lacerated. In an urgent case, however, the surgeon might trepan exactly on the frontal sinus, by removing the outer table of that cavity with a large trephine, and applying a small one to the inner table. Perhaps also, in these pressing examples, it would be proper to trepan on the centre of the os frontis, and use a chisel for breaking the inner spine of that part of the bone. In the same way, although a surgeon would always prefer avoiding the meningeal artery, he ought not, in urgent cases, to be afraid of it. The best modern surgeons well know that the hæmorrhage from that vessel is capable

of being easily suppressed, by the introduction of a small plug into its orifice.

The practitioner can never be too careful not to place the trepan on a loose part of the fractured bone, as it would be apt to be pressed inward, so as to do mischief to the brain.

When the cranium has been perforated with the trepan, and nothing is found between the skull and the dura mater, or underneath this membrane, in the situation where an extravasation may be suspected to exist, additional perforations are to be made elsewhere, if the symptoms should indicate such practice. The repetition of the trepan is particularly requisite in cases where the fissure runs across a future. The intimate adhesion of the dura mater to the future, explains why this membrane often continues undetached in that situation, while on each side it is separated from the bone, and blood effused upon it. There are then two distinct extravasations, and two perforations of the bone are absolutely necessary for the discharge of the blood.

Foreign surgeons invariably prefer, for the accomplishment of the operation, an instrument called the trepan, which much resembles a wimble, a tool extensively employed by coopers, and, like it, consists of a handle, to which is adapted a circular saw, or, as it is termed, the crown of the trepan. The diameter of the crowns varies from six to ten lines, and they are about one inch in height.

In England, the trepan (*Plate VIII. Surgery*) has gone into disuse, the trephine being generally preferred, though perhaps without great reason. The trephine differs from the trepan in having its crown fixed upon and worked with a common transverse handle, instead of being turned with a handle like that of a wimble. On the continent it is objected, that the trephine which the English surgeons make use of, requires a stronger hand and greater pressure than the trepan, so that at the moment of finishing the division of the bone, one runs a risk of forcing the instrument too deeply, and lacerating the brain and its membranes. We must confess, however, that we have never seen this accident occur, and the trephine is now made in so excellent a manner, that it will cut the bone fast enough without any occasion for immoderate pressure. If some badly made trephines cut with too much difficulty, the trepan may be accused of dividing the bone with too much celerity. A man of ordinary skill may use either instrument, and an awkward practitioner will be apt to do mischief let him employ which he will. See TREPHINE.

The first object in the performance of trepanning, is to expose the exact part of the bone on which it is intended to apply the instrument. In some cases, the scalp is so torn and injured, that a sufficient extent of the skull is already uncovered, and it is unnecessary to employ a scalpel. But in the majority of instances, the use of the knife must precede that of the saw. Incisions of a crucial form, or shaped like the letter T or V, are found to be the most eligible, because they allow their edges to be brought together again with ease, and they enable the surgeon to denude a larger surface of bone than could be managed with an incision of a different figure, but of equal size. The old surgeons ignorantly made circular wounds, and without consideration cut large portions of the scalp away before they applied the trepan. The consequence was, that the patient was sure of being permanently disfigured, and the edges of the perforation, remaining for a long while uncovered, frequently exfoliated.

The generality of surgical authors next advise us to be careful to scrape away the pericranium from the part to which the trepan, or trephine, is to be applied, so as to let the saw act with more facility. We have never found this

proceeding necessary, and conceive that, as more of the pericranium must always be removed than what is absolutely intended, it may sometimes be the cause of exfoliations. We advise it, therefore, to be rejected, as well as the old plan of scraping the periosteum off the bones which are to be sawn in amputations. The rugine, which is kept in most cases of trephining instruments for the purpose of scraping off the pericranium, would be no real loss if omitted.

Now, on first beginning to work either with the trephine or trepan, the practitioner would find that it would slip about and not steadily divide the bone, were it not for a particular contrivance. This is the centre-pin, which admits of being pushed down a little below the level of the teeth, and being very sharply pointed, immediately fixes itself in the mid-point of the circle of bone which is to be removed. As soon, however, as the teeth of the trephine have made a sufficient furrow, the centre-pin should be withdrawn, as it would otherwise wound the dura mater before the sawing of the bone were completed.

In making the incision through the scalp, when there is a fracture, the knife must be used with some degree of caution, lest it should depress the fragments of bone against the cerebrum, or be carried too deeply, so as to injure the dura mater. In certain instances, it will be advisable to make the requisite incision with a director and curved bistoury.

The trephine is worked by being rotated backward and forward; the trepan is turned round continually in one direction. In trepanning upon a simple fracture, or fissure, the crown of the instrument should be so placed as to include an equal portion of the bone on each side. But when there are portions of bone depressed and moveable, it is customary to apply the trepan upon an adjacent solid part of the cranium, which will serve after the operation as a fulcrum for the elevation or extraction of the depressed fragments. We must observe, however, that this method, if practised indiscriminately, will often lead to an unnecessary removal of bone; a circumstance which it is always desirous to avoid. Loose depressed pieces of bone should constantly be taken away with a pair of forceps, whenever it can be done; and then no trepanning will be needed. Also, when the fracture is shaped somewhat like the letter V, or when it is of an oblong form, the depressed piece of bone may frequently be entirely removed by sawing through the part which connects it with the rest of the cranium, and no circle of bone will stand in need of being sawn out. For the performance of such operation, Mr. Hey's saws (represented in the surgical plates) will be found exceedingly advantageous.

The surgeon should not press too heavily with the trephine, or trepan, when he is in the act of sawing the bone; but execute the business with as light a hand as possible. As soon as a sufficient groove is formed for the teeth of the crown, the centre-pin is to be taken out. The first part of the sawing may be done briskly. Afterwards, the operation is to proceed slowly and cautiously. With a bit of quill, the surgeon must examine the depth of the circular groove, in order to be sure that he has not sawn through at any particular point. When one side seems to be more cut than another, the saw must not be allowed to act upon it so much; and if there be any part of the circle which is completely sawn through, the instrument must not be applied to that point any longer. While the surgeon examines the depth of the groove with a piece of quill, an assistant takes care to clean the teeth of the saw with a small brush made for the purpose, by which means the action of the instrument will not be obstructed by the particles of bone.

When these become tinged with blood, the teeth of the saw are known to have reached the diploe; but the practitioner must remember, that the diploe is not a criterion which will be met with in every instance, as in some subjects it is so inconsiderable, that it does not give any tinge of blood to the bone-dust. It is of importance to be aware of this fact; for were a surgeon to saw boldly on in all cases until he sees marks of his having arrived at the diploe, he would frequently be apt to injure the dura mater and brain. When he knows that he is sawing the internal table, he is to proceed with great slowness and circumspection, making repeated examinations of the groove with the pointed quill. When the portion of bone to be taken out appears to be connected with the rest of the skull principally on one side of the groove, the trephine is to be inclined to that side. Immediately the circle is loose enough, it is to be taken out with a pair of forceps constructed for this object, or with the elevator. (See surgical plates.) But rather than run a hazard of sawing too deeply with the trephine, we would always recommend the surgeon to prefer breaking the few last fibres of bone which impede the circle from being taken out.

When there are any inequalities round the margin of the perforation, they must be carefully removed by means of the lenticular knife. (See plates.) In doing this part of the operation, care must be taken not to let the lenticular knife make improper pressure upon the dura mater, a thing which might have the worst consequences.

The circle of bone having been sawn out, the surgeon is to keep in mind the grand object of the operation; *viz.* that of relieving the brain from the pressure, which is the cause of the alarming symptoms. All depressed fragments of bone are to be raised, and, if quite detached, they ought to be entirely removed. All spiculæ of bone, penetrating the dura mater and substance of the brain, are to be extracted without delay. If there be blood or matter upon the surface of the dura mater, it now escapes, being expelled by the pulsatory movement of the cerebrum.

When the extravasation is under the dura mater, a puncture may be cautiously made through this membrane with the point of a bistoury, or lancet. There must be, however, a manifest elevation and tension of the dura mater, arising from the lodgment of a fluid below it, to justify the preceding practice. If blood should be found in the suspected situation, the puncture may be enlarged into a crucial incision.

According to surgical writers, if, after dividing the dura mater, the surface of the brain appears smooth and flabby, with a fluctuation, there is an abscess in its substance. They then sanction the method of carrying the point of the bistoury to the depth of an inch, if circumstances render so deep a puncture necessary. But, says Richerand, prudence forbids us to go further. Cutting the surface of the brain causes no pain, and it produces less danger than one could presume to expect; but experience and observation have proved, that the essential parts of this organ are situated near its base, and that its surface may be removed without danger or pain. *Nosogr. Chir. t. ii. p. 301. edit. 3.*

After the operation of trephining, the divided scalp is to be placed as nearly as possible in its natural situation, and lightly dressed with a simple pledget of any common unirritating ointment. In applying the dressings, the surgeon should invariably keep in view these objects; namely, to let whatever is put on the wound be as light as possible, not apt to make pressure on the brain, and of a nature which cannot excite irritation. All stimulants are to be strictly avoided; nor will any bandage be better than an ordinary

ordinary night-cap of sufficient size to be put on with facility. It may be secured with bits of tape, which are to be tied under the jaw.

The aperture in the skull usually becomes closed with soft granulations, which slowly acquire a hard consistence. These almost constantly grow from the edge of the perforation, and seldom from the surface of the dura mater. While the cicatrix is soft, it should be protected from external injury with a thin piece of horn or metal. Exfoliations from the margin of the perforation sometimes retard the healing of the wound; but now that the practice of dressing with drying spirituous applications has been exploded, and the removal of any part of the scalp is condemned by all the best surgeons, these unpleasant consequences are rendered much less frequent than in former days.

TREPANNING, in *Sheep*, the operation of extracting the bags or cysts that contain a watery fluid from the heads of these animals, which are the cause of disease. See **STURDY**.

TREPASSER'S BAY, or *Trepassi Bay*, in *Geography*, a bay on the south coast of Newfoundland. N. lat. $46^{\circ} 50'$. W. long. 53° .

TREPEIA, a town of Servia; 5 miles N.E. of Novibasar.

TREPHINE, in *Surgery*. The operation of trepanning is now frequently called the operation of trephining, from its being generally performed in this country with a trephine, which is a more modern instrument than the trepan. The trephine consists of a simple cylindrical saw, with a handle placed transversely, like that of a gimblet; and from the centre of the circle, which the teeth of the saw describe, a sharp little perforator projects, named the centre-pin. The upper part of the centre-pin is made to screw into a corresponding hole at the inside of the top of the saw, and is capable of being taken out or put in at the surgeon's option, by means of a little key for the purpose. Its use is to fix and steady the trephine, when the instrument first begins to work, that is, before the teeth of the saw have made a sufficient circular groove, in which they can securely move. But as soon as an adequate groove is formed, the centre-pin must always be taken out; because it is now unnecessary, and, if not removed, it would not only retard the progress of the operation, but inevitably penetrate the dura mater and brain, when the teeth of the saw had cut to a certain depth through the cranium. Some trephines contain centre-pins, which are contrived to slide up or down, and to admit of being fixed in either situation, by turning a little screw. This method seems to us both ingenious and convenient.

The cylindrical part of the trephine is often termed the *crown* of the instrument. The surgeon should always have at least two or three cylindrical saws of various sizes; for it is a commendable rule never to saw away any more of the cranium, or indeed of any other bone, than is absolutely requisite for the accomplishment of some assignable object. There is no occasion, however, for having more than one handle, which may be made to fit any of the saws.

The trepan is worked in the manner of a wimble, the instrument turning round and round upon its own axis; but the trephine only performs semicircular movements, which the surgeon imparts to it by the pronation and supination of his hand. As its teeth are arranged perpendicularly, they cut whether the instrument is turned from the left to the right, or from the right to the left.

Certainly cases do frequently present themselves, in which trephining is absolutely necessary; and yet there is no occasion for removing a complete circular portion of the cranium; the taking away of a piece of smaller size, and

different shape, would sometimes be much more advantageous. A very good instrument for effecting this purpose is a common trephine, terminating only in a semicircular saw, instead of a circular one. With this the surgeon can cut across the base of certain depressed portions of bone, and take them away, without any occasion for removing also a circle of the cranium.

The saws, however, which Mr. Hey has described, should constantly be kept in every case of trephining instruments. This practical writer remarks, that "the purposes for which any portion of the cranium is removed, are, to enable the surgeon to extract broken fragments of bone, to elevate what is depressed, and to afford a proper issue to blood or matter that is, or may be confined, &c."

"When a broken fragment of bone is driven beneath the found contiguous part of the cranium, it frequently happens that the extraction cannot be executed without removing some of the unbroken part under which the fragment is depressed. This might generally be effected with very little loss of sound bone, if a narrow portion of that which lies over the broken fragment could be removed. But such a portion cannot be removed by the trephine. This instrument can only saw out a circular piece. And as, in executing this, the central pin of the saw must be placed upon the uninjured bone, it is evident that a portion of the found bone, greater than half the area of the trephine, must be removed at every operation. When the broken and depressed fragment is large, a repeated application of the trephine is often necessary, and a great destruction of sound bone must be the consequence.

"When the injury consists merely of a fissure with depression, a small enlargement of the fissure would enable the surgeon to introduce the point of the elevator, so as to raise the depressed bone. But a small enlargement of the fissure cannot be made with the trephine. When it is necessary to apply the elevator to different parts of the depressed bone, a great deal of the found cranium must be removed, where a very narrow aperture would have been sufficient.

"The same reasoning will apply to the case of openings made for the purpose of giving a discharge to extravasated blood or matter.

"If a saw could be contrived, which might be worked with safety in a straight, or gently curvilinear direction, it would be a great acquisition to the practical surgeon. Such a saw I can now with confidence recommend, after a trial of twenty years, during which time I have rarely used the trephine in fractures of the skull. Its use has been adopted by my colleagues at the General Infirmary in Leeds; and will be adopted, I hope, by every surgeon who has once made trial of it." Mr. Hey next informs us, that the instrument was first shewn to him by Dr. Cockell of Pontefract; but that there is a saw, formed on the same principle, in Scultetus's *Armamentarium Chirurgicum*. The saws alluded to are very short ones, fixed at the end of a longish straight handle; their edges are made either straight, or semicircular. The latter construction qualifies the instrument for cutting in a curvilinear direction, which is often proper. The edge of the saw should always be made a little thicker than the rest of the blade, by which means it will work in the groove, which is cut, with more facility.

Saws made on the principle just described, are also of infinite use in cutting away diseased portions of other bones, besides the skull, exostoses, &c. In cases of necrosis, when a dead part of a bone is quite wedged in the substance of the surrounding new bony matter, Mr. Hey's saws may often be advantageously employed for cutting away the parts which mechanically prevent the detachment of the

dead piece. Hey's Practical Observations, and Cooper's Dictionary of Surgery.

TREPIDATION, in *Medicine*. See PALSY.

The first symptom of madness in dogs, is a trepidation of the limbs.

TREPIDATION, in the *Ancient Astronomy*, denotes what they called a libration of the eighth sphere; or a motion which the Ptolemaic system attributed to the firmament, to account for certain almost insensible changes and motions observed in the axis of the world; by means of which the latitudes of the fixed stars come to be gradually changed, and the ecliptic seems to approach reciprocally, first towards one pole, then towards the other.

This motion is also called the motion of the first libration.

TREPIGNER, in the *Manege*, the action of a horse who beats the dust with his fore-feet in maneging, without embracing the volt; and who makes his motions and times short, and near the ground, without being put upon his haunches. This is generally the fault of such horses as have not their shoulders supple, and at liberty, and withal have scarcely any motion with them. A horse may trepigner in going upon a straight line.

TREPONTE, in *Geography*, a town of Italy, in the Cadorn; 5 miles N. of Cadora.

TREPORT, LE, a sea-port town of France, in the department of the Lower Seine, situated on the English Channel, at the mouth of the Bresle. This place is the harbour for the town of Eu; from which it is distant about half a league. N. lat. $50^{\circ} 4'$. E. long. $1^{\circ} 26'$.

TREPTE le Grand, a town of France, in the department of the Isere; 21 miles E. of Lyons.

TREPTEOW, a town of Anterior Pomerania; 50 miles S. of Stralsund. N. lat. $53^{\circ} 39'$. E. long. $13^{\circ} 10'$.

TREPTEOW am Rega, or *New Treptow*, a town of Hinder Pomerania, on the river Rega, which is here made navigable; 16 miles N.E. of Cammin. N. lat. $54^{\circ} 2'$. E. long. $15^{\circ} 13'$.

TREPUZZI, a town of Naples, in the province of Otranto; 22 miles W.N.W. of Lecce.

TRERO, a river of the Popedom, in the Campagna di Roma, which runs into the Garigliano, near Isoletta.

TREBUS, in *Ancient Geography*, a country in the environs of Macedonia, in Pieria and Dardania. Pliny.—Also, a river of Italy, in Aufonia, which, according to Strabo, watered the town of Fabrateria, situated in Latium.

TRES HERMANOS, in *Geography*, three small islands in the bay of Honduras, near the coast. N. lat. $19^{\circ} 20'$. W. long. $88^{\circ} 50'$.

TRES Taberna, *Three Taverns*, in *Ancient Geography*, a place of Italy, near the Appian way. Zosimus says that it was the place where the emperor Severus was put to death by Maxentius. The Itin. of Anton. marks its situation in the Appian way, between Aricia and Appii Forum.

TRESA, a river of the northern part of Italy, which ran among the Lepontii, into the lake Verbanus.

TRESANTI, in *Geography*, a town of Naples, in Capitanata; 13 miles S. of Manfredonia.

TRESANTON, in *Ancient Geography*, a river of Albion, probably the river Test, which falls into Southampton bay.

TRESAYLE, in *Law*, the name of a writ (now obsolete) to be sued, on ouster, by abatement, on the death of the grandfather's grandfather.

TRESBES, in *Geography*, a town of France, in the department of the Aude, near the Aude river; 3 miles E. of Carcassonne. N. lat. $43^{\circ} 13'$. E. long. $2^{\circ} 32'$.

TRESCHEN, a town of Germany, in the principality of Culmbach; 4 miles S.S.E. of Culmbach.

TRESCO, or ST. NICHOLAS, one of the Scilly islands. N. lat. 50° . W. long. $6^{\circ} 45'$.

TRESHANISH ISLANDS, a range of four small islands among the Western islands of Scotland, between Mull and Coll. They lie in a line, nearly from north to south. They are small, but the soil is generally fertile. N. lat. $56^{\circ} 30'$. E. long. $6^{\circ} 25'$.

TRESNEL, a town of France, in the department of the Aube; 3 miles from Pont-sur-Seine.—Also, a town of France, in the department of the Sarthe; 7 miles W. of St. Calais.

TRESPASS, in *Law*, signifies any transgression of the law, under treason, felony, or misprison of either.

TRESPASS, however, is most commonly used either for that wrong or damage which is done to the king in his forest, or by one private man to another.

In this sense, it is of two sorts: *trespass general*, otherwise called *trespass vi et armis*, where force or violence is used; to which belong threats, assault, battery, mayhem, &c.: and *trespass special*, otherwise called *trespass upon the case*; which should be that done without force, or where the injury is only consequential. See ACTION on the case.

But the two species are sometimes confounded.

Trespass on lands denotes an outcry on another man's ground without lawful authority, and doing some damage, however inconsiderable, to his real property. Every such unwarrantable entry on another's soil, the law entitles a trespass by *breaking his close*. But in order to be able to maintain an action of trespass, a man must have property in the soil, and actual possession by entry; or at least it is requisite that the party have a lease and possession of the vesture and herbage of the land. But before entry and actual possession, one cannot maintain an action of trespass, though he hath the freehold in law. However, by 4 Geo. II. c. 28. and 11 Geo. II. c. 19. in case after the determination of any term of life, lives, or years, any person shall wilfully hold over the same, the lessor is entitled to recover by action of debt, either a rent of double the annual value of the premises, in case he himself hath demanded and given notice in writing to deliver the possession; or else double the usual rent, in case the notice of quitting proceeds from any tenant having power to determine his lease, and he afterwards neglects to carry it into due execution.

A man is answerable not only for his own trespass, but that of his cattle also. See DAMAGE *feasant*.

In some cases trespass is justifiable; or, rather, entry on another's land and house shall not in those cases be accounted trespass; as if a man comes there to demand or pay money, there payable; or to execute, in a legal manner, the process of the law. A man may also justify entering into an inn or public-house, without the leave of the owner: a landlord may justify entering to distrain for rent: a commoner to attend his cattle, commoning on another's land; and a reversioner to see if any waste be committed on the estate. It hath also been said, that by the common law and custom of England, the poor are allowed to enter and glean upon another's ground after the harvest, without being guilty of trespass; which humane provision seems borrowed from the Mosaic law, Lev. chap. xix. ver. 9. chap. xxiii. ver. 22. Deut. chap. xxiv. ver. 19. In like manner, the common law warrants the hunting of ravenous beasts of prey, as badgers and foxes, in another man's land. But in cases where a man makes an ill use of the authority with which the law entrusts him, he shall be accounted a trespasser *ab initio*; as if one comes into a tavern and will not go out in reasonable

reasonable time: so if a landlord distrained for rent, and wilfully killed the distress, this made him a trespasser *ab initio*: and so would any other irregularity have done, till the statute 11 Geo. II. c. 19. which enacts that no subsequent irregularity of the landlord shall make his first entry a trespass; but the party injured shall have a special action on the case for the real specific injury sustained, unless tender of amends hath been made. But still, if a reverent, who enters on pretence of seeing waste, breaks the house, or stays there all night; or if the commoner, who tends his cattle, cuts down a tree; in these and similar cases the law judges that he entered for this unlawful purpose; and therefore, as the act which demonstrates such his purpose is a trespass, he shall be deemed a trespasser *ab initio*. So also in the case of hunting the fox or the badger, a man cannot justify breaking the soil, and digging him out of his earth.

A man may justify an action of trespass, on account of the freehold and right of entry being in himself; and this defence brings the title of the estate in question.—And this is one of the ways devised, since the disuse of real actions, to try the property of estates: though not so usual as that by ejectment, which being a mixed action, gives damages for the ejection, and possession of the land: whereas in trespass, which is a personal suit, the right can be only ascertained, but no possession delivered; nothing being recovered but damages for the wrong committed.

In an action of trespass, the plaintiff always sues for damages, or the value of the hurt done him by the defendant.

In order to prevent trifling and vexatious actions of trespass, as well as other personal actions, it is (*inter alia*) enacted by statutes 43 Eliz. c. 6. and 21 Jac. I. c. 16. and 22 & 23 Car. II. c. 9. that where the jury who try an action of trespass give less damages than 40s. the plaintiff shall be allowed no more costs than damages; unless the judge shall certify under his hand, that the freehold or title of the land came chiefly in question, or that an actual battery, and not assault only, was proved. And by statute 4 & 5 W. & M. c. 23. and 8 & 9 W. III. c. 11. if the trespasses were committed in hunting or sporting by an inferior tradesman, or if it appear to be wilfully and maliciously committed, the plaintiff shall have full costs, though his damages, as assessed by the jury, amount to less than 40s. Blackst. Comm. vol. iii.

Trespass is also divided into *local* and *transitory*.

TRESPASS, *Local*, is that which is so annexed to the place certain, that if the defendant join issue upon a place, and traverse the place mentioned in the declaration, and aver it, it is enough to defeat the action.

TRESPASS, *Transitory*, is that which cannot be defeated by the defendant's traverse of the place, because the place is not material.

The action of trespass, *quare clausum fregit*, ought to be local.

TRESSEL or TRESTLE-Trees, in a *Ship*, two strong bars of oak-timber resting on the cheeks of lower-masts, or hounds of top-masts. To lower-masts they are secured by being scored and bolted horizontally on the opposite sides of the mast, fore and aft, and further supported by two ribs or brackets, as shoulders under them. Topmast trestle-trees are supported by the hounds only. See MAST-MAKING.

TRESSNESS, in *Geography*, a cape on the south coast of the island of Sanday. N. lat. 59° 5'. W. long. 2° 25'.

TRESSON, a town of France, in the department of the Sarthe; 15 miles S.E. of Le Mans.

TRESSURE, in *Heraldry*, a diminutive of an orle, usually supposed to be half the breadth of it.

It is usually borne flory and counter-flory; sometimes double, and sometimes triple.

TRESTIANA, in *Geography*, a town of European Turkey, in Moldavia; 24 miles S.E. of Jassy.

TRESTLE, TRESSEL, or *Trussel*, is explained, by Minshieu, to be a three-footed stool; or, more particularly, a wooden frame or stand to bear up tables, scaffolds, or the like.

TRESUND, in *Geography*, a small island in the gulf of Bothnia. N. lat. 69° 13'.

TRET, or TRETT, in *Commerce*, an allowance made for the waste, or the dust, that may be mixed with any commodity, which is always four pounds in every 104 pounds weight. See TARE.

This allowance, which is said to be for dust or sand, or for the waste or wear of the commodity, was formerly made on most foreign articles sold by the pound avoirdupois; but it is now nearly discontinued by merchants, or allowed in the price. It is wholly abolished at the East India warehouses in London; and neither trett nor draft is allowed at the Custom-house. The weight which trett is allowed is called the "futtle weight."

TRETA, in *Ancient Geography*, a town of the island of Cyprus, in the S.W. part of the island, very near Palæpaphos, to the S. Strabo places it between Boofura and the promontory from which those were precipitated who had touched the altar of Apollo.

TRETE, an island of the Red sea, upon the coast of Arabia. Ptolemy.

TRETS, in *Geography*, a town of France, in the department of the Mouths of the Rhone; 12 miles E.S.E. of Aix.

TRETUM, in *Ancient Geography*, a small town of the Argolide, nearly N. of Argos. In the mountains near this town was a cavern, which was the abode of a very fierce lion, which is said to have been slain by Hercules, and which formed among the poets one of his labours. It was called the lion of the forest of Nemæa, situated near the town, to the W. of it.

TRETUM, or *Tritum*, a promontory of Africa propria, on the coast of the gulf of Numidia.

TRETUR, in *Geography*, a small village of South Wales, in the county of Brecknock; 3 miles N.W. of Crickhowel.

TREVA, in *Ancient Geography*, a town in the northern part of Germany. Ptolemy.—Also, a town of Italy, in Flaminia, watered by the river Clytumnus.

TREVANNION'S ISLAND, in *Geography*, an island in the South Pacific ocean, and one of the cluster called Queen Charlotte's islands, discovered by captain Carteret in 1767, near the coast of Egmont island, or New Guernsey, in a bay called Trevannion's Lagoon. S. lat. 10° 43'. E. long. 163° 43'.

TREUCHTLINGEN, a town of Germany, in the margravate of Anspach, on the Altmuhl; 28 miles S.S.E. of Anspach.

TREUEN, or DREVEN, a town of Saxony, in the Vogtland; 9 miles E.N.E. of Plauen.

TREUENBRIETZEN, a town of the Middle Mark of Brandenburg. This town was surrounded with walls in the year 1296. It was at first simply called Brietzen, but for its fidelity to the margrave Louis the Roman, was honoured

noured with the epithet of Treuen, or faithful. In the year 1641, this town was laid waste by the Swedes; 20 miles S. of Brandenburg. N. lat. $52^{\circ} 8'$. E. long. $12^{\circ} 47'$.

TREVENEN'S ISLAND, or *Rooapōa*, a small island in the Pacific ocean, discovered by lieutenant Hergeft, in the *Dædalus* store-ship, in 1792. S. lat. $9^{\circ} 4'$. E. long. $220^{\circ} 21'$.

TREVERI, or TREVIRI, in *Ancient Geography*, a people who occupied an extensive territory of Germany, from the Meuse to the Rhine. Of Treveri Cæsar says, "hæc civitas Rhenum tangit;" and the bridge constructed over the Rhine secures the bank on which this city was situated. The present Treves answers to the ancient position of Treveri. See TREVES.

TREVES, in *Geography*, lately an archbishopric and electorate of Germany, bounded on the N. by the electorate of Cologne; on the E. by the estates of the elector palatine, and of the house of Nassau; on the S. by France; and on the W. by the duchy of Luxemburg: about eighty miles in length, but of very uncertain breadth. The country is in general mountainous and woody, containing, indeed, good pasturage for cattle, and in many places also fruitful arable land, but yet stands in need of the importation of corn: on the contrary, the growth of wine on the Mosel is very considerable, with plenty of game. There are likewise mineral springs, and mines of coal, calamy, iron, copper, lead, tin, silver, and gold. The electoral subjects are Roman Catholics, but in some other places which the elector of Treves is possessed of in common with other houses, there are likewise Protestants. The ancient Teveri, from whom the principal town here, and the country also, had its name, were, till the fourth century, subject to the Romans, and afterwards to the Franks. In the divisions which the sons and posterity of the emperor Louis I. had made, this country was added, in the year 855, to the kingdom of Lorraine, and in 870, fell to the share of Louis, the German king, ever since which time it has continued annexed to Germany. The church of Treves, however, is held to be the most ancient in Germany. An archbishop of Treves was elected by the chapter there, and swore to a capitulation proposed by them. The pope confirmed such election in the usual manner, empowering one of the new elected bishops, allotted for that purpose, to consecrate him. The archbishop of Treves was in rank the second spiritual elector. At the election of an emperor, he delivered the formula of the election-oath to the elector of Mentz, to be sworn to by him; and he had also the first voice. As elector, the archbishop of Treves enjoyed both feat and voice in the electoral council at the diets of the empire. The suffragans of the archbishop of Treves were the bishops of Metz, Toul, and Verdun. The chapter of Treves consisted of forty canons, among whom were fifteen capitulars, and twenty-four domicelli. The archbishopric had regular troops, and a land militia. The former of these consisted, in times of peace and ordinarily, only of the circle troops, which the elector of Treves was bound to maintain, and which amounted to between 1100 and 1200 men. The elector also kept up a life-guard of forty persons. By the treaty of Luneburg, the archbishopric and the electorate are no more: and that part of the territories which lay on the left bank of the Rhine is annexed to France, composing chiefly the department of the Sarre. The principal part of the electorate lying on the right side of the Rhine was, in 1802, given as an indemnity to the prince of Nassau-Weilburg.

TREVES, or *Triers*, a city of France, and capital of the

department of the Sarre: late capital of an electoral principality, and archbishopric of the circle of the Lower Rhine, lying between two mountains on the Moselle, over which it has a stone bridge. This town is very old. Long before the birth of Christ, Treves was a town of note of the Treviri. Afterwards the ancient Roman emperors had a residence here; and it is also the head town of the first Belgium, and so early as the days of Constantine the Great, was the capital of all Gaul. About the year 458, from the Romans it fell under the power of the Franks. Under the Austrian monarchs, a royal court had its seat here; in which, as well under the Frankish kings as for a long time after, resided pfalzgraves. The archiepiscopal court, or palace near the cathedral church, was rebuilt by the elector Francis George. The cathedral church of St. Peter here stands on a hill, being a large building. Exclusive of this church, there are likewise here three collegiate and five parish-churches, together with three colleges, and thirteen monasteries and nunneries, as also a house of the Teutonic order, and a mansion belonging to that of St. John. For the establishment of the university here, papal privileges were issued so early as the year 1454, but these were brought duly to bear only in 1472, in 1535 renewed, and in 1722 improved. This town, according to the common opinion, was formerly imperial, and had a particular matricular evaluation of its own: but by a sentence of the electors pitched upon for the decision of this matter, in conjunction with the imperial aulic counsellors, nominated by the emperor, it was declared to be subject to the superiority of the elector of Treves, which was also immediately after effectually exercised by him over it. In the beginning of August 1794, the French republicans entered the city, which had been hastily evacuated by the German troops. The magistrates met them in their robes at the gates with the keys, congratulated them on their success, and declared they were glad to receive them. The good conduct of this army deserves commendation; and an English writer, speaking of it, observes, "they had no sooner entered Treves than they established a municipality; they broke in upon no property whatever, and left the different corporations, and all civil and religious institutions, as they found them:" 68 miles S.S.W. of Cologne. N. lat. $49^{\circ} 48'$. E. long. $6^{\circ} 48'$.—Also, a town of France, in the department of the Gard; 12 miles E. of Le Vigan.

TREVI, a town of Italy, in the duchy of Spoleto, anciently called *Mutufca* and afterwards *Trebula*; 6 miles N. of Spoleto.—Also, a town of the Papedom, in the Campagna di Roma; anciently the see of a bishop, erected about the year 1000, but in the year 1260 united to Anagni; 32 miles E. of Rome.

TREVICO, a town of Naples, in Principato Ultra; the see of a bishop, suffragan of Benevento; 14 miles N. of Conza. N. lat. $41^{\circ} 6'$. E. long. $15^{\circ} 14'$.

TREVIERES, a town of France, in the department of the Calvados; 12 miles E. of Carentan.

TREVIPIO, or TREVISO, a city of Italy, capital of the Trevifan, situated at the conflux of the Sile and the Piavefella; the see of a bishop, suffragan of Udina. An university was founded here, and afterwards removed to Padua. The town is three miles in circumference, and contains 2500 houses and 22,000 inhabitants; whom the culture of silk, the silk and woollen manufactories, and particularly the annual fair in the month of October, supply with abundant means of subsistence. Besides the cathedral, the town contains 16 parochial churches, 11 monasteries, 10 nunneries, 4 hospitals, and a pawn-bank. The streets and public squares are in

general

general irregularly laid out, but well paved, and surrounded with piazzas. Totila, king of the Goths, was a native of this town; 15 miles N.N.W. of Venice. N. lat. $45^{\circ} 42'$. E. $12^{\circ} 9'$.

TREVIGLIO, a town of Italy, in the department of the Adda; 11 miles N.N.W. of Crema.

TREVIGNO, a town of Spain, in the province of Alava; 12 miles S.W. of Vittoria.

TREVISAN, or TREVIGIANO, a province of Italy, bounded on the north by the Bellunese, on the north-east by Friuli, on the south-east by the gulf of Venice, on the south-west by the Paduan, and on the west by the Vicentin; about twenty-four miles in length, and nearly as much in breadth. The whole country is exceedingly fertile, and appears like a continued garden. When annexed to the Lombards, it was erected into a marca or marquisate. However, many considerable parts were detached from this marca in the progress of time; and only that part of it situated between the Friuli and the Paduan remained in the possession of the city of Treviso, when the republic of Venice acquired the dominion both of the city and adjacent district, by the peace of 1338. In the year 1344, a solemn embassy, sent by the inhabitants of Treviso to Venice, confirmed this acquisition. The marca Trevisana was divided into four principal districts; viz. the territory of Treviso, of Belluna, of Feltri, and the territory of Ceneda. Of the territory of Treviso, a small portion is mountainous, but the rest is even and very fertile. It produces all sorts of grain, wine, and fruit, in great plenty. There is also a vast number of sheep, black cattle, hares, common fowls, turkeys, fieldfares, quails, partridges, snipes, and other game; fish of every description, as trout, lampreys, pike, eels, craw-fish, &c. Excellent cheese is made; and, next to corn, silk and wool are the most important natural productions. The woods are very considerable. The principal rivers are the Piave, the Sile, and the Musone. The number of inhabitants amounts to 280,000. It is now annexed to the new kingdom of Italy.

TREVISANI, FRANCESCO, in *Biography*, a native of Treviso, was initiated in the art by Zanchi at Venice, where, in contradistinction of Angiolo, his relative, he was called Roman. At Rome he formed himself on the best styles of the day, but an unbounded talent for mimicking every manner, from Correggio to Cignani, never suffered him to persist long in the imitation of one model. Rome is gorged with his pictures: they often possess elegance of choice, a finished pencil, and a general strength of tone. His S. Joseph, in the church of the Collegio Romano, is a distinguished performance. He died in 1746, aged 90. Fuseli's Pilkington.

TREVISANI, ANGIOLO, was born and resided at Venice. His inventive power is proved at the Carita and other churches of that capital, but his real merit lay in portrait. By persevering in that study, he acquired a style not sublime indeed, but natural, select, and adapted to the times. The diligence and dexterity of his tool greatly assisted him in the management of his chiaro-scuro. He was living in 1753.

TREVOIL, in *Geography*, a town of France, in the department of Mont Blanc; 10 miles N.W. of Chambéry.

TREVOSE HEAD, a cape of England, on the north-west coast of Cornwall; 5 miles S.W. from the mouth of the river Alan or Camel. N. lat. $50^{\circ} 33'$. W. long. $5^{\circ} 1'$.

TREVOUX, a town of France, and principal place of a district, in the department of the Ain, on the Saône. Before the revolution, the capital of the principality of Dombes, and residence of a governor, a parliament, &c. It is but small, having suffered much in the wars between the dukes of Bourbon and Savoy, particularly in the year 1431; 10 miles N. of Lyons. N. lat. $45^{\circ} 57'$. E. long. $4^{\circ} 51'$.

VOL. XXXVI.

TREW, CHRISTOPHER JAMES, in *Biography*, a physician and naturalist, was born at Lauffen, in Franconia, in 1695, and settled at Nuremberg, where he gained medical and literary reputation, so as to be made director of the academy "Naturæ Curiosorum." He also contributed much towards establishing a society under the title of "Commercium Litterarium Noricum ad Rei Medicæ et Scientiæ Naturalis Incrementum institutum," which published its memoirs. To these societies he communicated several papers, and he also published several splendid works in anatomy and botany. Amongst others, we may enumerate the following: "De Differentiis quibusdam inter Hominem natum et nascendum intercedentibus," 1736, 4to.; "Epistola ad Alb. Hallerum de Vasis Linguae salivalibus et sanguiferis," 1734, 4to.; "Tabulæ Osteologicæ Corporis Humani," fol. max. with coloured plates, 1767. In 1750 he commenced his publication of one of the most splendid of the imitations of Flora, under the title of "Plantæ selectæ, quarum Imagines pinxit G. Dionysius Ehret." To the incomparable designs of Ehret, Trew added descriptions and remarks; and the work appeared in decades, seven of which were completed. In the same year he began a similar publication of garden flowers, intitled "Amœnissimæ Florum Imagines," which was carried on to six decades. He also published an improved edition of Blackwell's Herbal, in English and German, with an addition of some plants. Being in possession of Gesner's wooden plates, he gave an impression of 216 figures of plants from them, intitled "Icones posthumæ Gesnerianæ," 1748. Trew died in 1769. Haller. Eloy.

TREWARDRETH BAY, in *Geography*, a bay in the English Channel, on the south coast of Cornwall; 3 miles W. of Fowey. N. lat. $50^{\circ} 18'$. W. long. $4^{\circ} 42'$.

TREWIA, in *Botany*, was so named by Linnaeus, at the end of his *Genera Plantarum*, in honour of Christopher James Trew, an opulent physician at Nuremberg, who has distinguished himself as the editor of some of Ehret's figures, in the most splendid style, with learned descriptions and explanations of his own, under the title of *Plantæ Selectæ*. Of a similar character are his *Florum Imagines*, in six decades. His improved edition of Mrs. Blackwell's Herbal, in German, with valuable additions, has proved acceptable to his countrymen; as have his numerous botanical and physiological essays, published chiefly in the *Commercium Litterarium* at Nuremberg, between the years 1730 and 1746, to the scientific world in general. He is charged by Ludwig, in a letter to Haller, with undertaking more than he could accomplish; nor does he stand in the highest rank of correct and philosophical botanists. He died in 1769, aged 74. (See Trew.)—Linn. Gen. 580. Schreb. 354. Willd. Sp. Pl. v. 4. 834. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 406. Juss. 442. Lamarck Illustr. t. 466. (Tetragallis; Gartn. t. 109. Rottlera; Willd. in the Goettingen Journ. of Nat. Hist. v. 1. 8. Mallotus; Loureir. Cochincl. v. 2. 635.)—Class and order, *Diœcia Polyandria*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of three ovate, reflexed, coloured, equal leaves. *Cor.* none. *Stam.* Filaments numerous, capillary, about the length of the calyx, inserted into the receptacle; anthers roundish, of two distinct lobes.

Female, *Cal.* Perianth inferior, of one leaf in three or four segments. *Cor.* none. *Pist.* Germen superior, roundish; style short; stigmas three, very long, feathery on the upper side. *Peric.* Capsule turbinate, somewhat globular, of three or four lobes and as many cells, with twice as many valves. *Seeds* solitary, pendulous, angular on one side, convex on the other.

Eff. Ch. Male, Calyx of three leaves. Corolla none. Female,

Female, Calyx of three leaves. Corolla none. Style one. Stigmas several, feathery. Capsule of three cells, and six valves. Seeds solitary.

Obf. We believe the several genera, cited above, are here very properly united; see MALLOWUS and TETRAGASTRIS. The natural number in every part of the female fructification is probably three, though varying to four in the original species. Linnæus was but ill acquainted with this genus, nor does it appear that he ever examined a specimen.

1. *T. nudiflora*. Smooth-leaved Trewia. Linn. Sp. Pl. 1661. Willd. n. 1. Ait. n. 1. (*Rottlera indica*; Willd. as above t. 3. Canfchi; Rheede Hort. Malab. v. 1. 76. t. 42.)—Leaves ovate, undivided, entire, smooth on both sides.—Native of the East Indies, in sandy ground. It has been introduced into the stoves at Kew, but has never yet flowered. This is a tall tree, whose trunk is two or three feet in diameter; its branches numerous, round, smooth, with a filamentous bark. Leaves alternate, on long smooth stalks, broadly ovate, taper-pointed, three or four inches long, with three principal nerves, and many smaller ones, connected by fine transverse parallel veins, and numerous minute reticulations. Male flowers numerous, in axillary aggregate clusters, three or four inches long, greenish-white; sometimes, according to Rheede, four-cleft. Calyx externally downy, about two lines long. Female flowers on a separate tree, likewise axillary, but rarely more than two together, on a long stalk. Their calyx is either very small, or soon deciduous. Germen not so large as a pepper-corn, hoary. Style about as long as the germen, thick, hoary. Stigmas three or four, spreading, an inch long, densely covered along their upper side with feathery glands. Capsule rather depressed, slightly lobed, smoothish, of three or four cells.

2. *T. tricuspida*. Three-pointed Trewia. Willd. n. 2. (*Mallotus cochinchinensis*; Loureir. Cochinch. 635.)—Leaves ovate, downy and toothed; generally three-pointed.—For the history of this species we refer the reader to MALLOWUS.

3. *T. pubescens*. Downy Trewia.—Leaves ovate, undivided, entire, downy on both sides. Female flowers somewhat capitate, with ovate pointed bractæas.—A female specimen of this was sent us by the late Dr. Roxburgh, as an unknown tree from Amboyna. The shape and reticulations of the leaves, with the general habit of the plant, are so like the first species, that we feel confident of their being of the same genus. The branches and footstalks however, and the under side of the leaves, are densely clothed with soft velvet-like pubescence; the upper side of the latter is less downy. Near the base of each footstalk is a pair of awl-shaped, very downy, deciduous stipulas. Female flowers on simple, axillary, solitary, downy stalks, rather longer than the footstalks, composing small roundish heads, accompanied by four or five somewhat alternate, ovate, pointed, slightly toothed, downy bractæas, an inch long. Each flower appears to have a short partial stalk, which is very hairy, and the germen is no less bristly; inasmuch that we can but imperfectly develop the structure of the flower. The stigmas however are large and conspicuous, exactly those of a *Trewia*; but there is some appearance of their being solitary. Possibly some may have fallen off. We are unacquainted with the male of this species.

4. *T. discolor*. White-leaved Trewia.—Leaves ovate, entire; densely downy and white beneath.—Communicated by Lamarck to the younger Linnæus, along with several other plants from the East Indies, but without any name, or indication of its native country. We presume it to be the male of a nondescript species of *Trewia*. The form and veins of the leaves strongly indicate this; but their under

side differs from that of the rest, in being covered with the finest depressed, mealy or scaly, snow-white pubescence; while the upper is very smooth to the touch, appearing minutely granulated under a magnifier only. The branches and all the stalks are finely hoary, and, in the dried specimen at least, have a rusty hue. Panicle terminal, composed of numerous, alternate, racemose, many-flowered branches. Unexpanded male flowers about the size of a mustard-seed, downy, on short partial stalks.—It is evident we can have no certainty at present of the genus of this plant, but there is the greatest probability of its being rightly placed here.

TREYA, in *Geography*, a town of Denmark, in the duchy of Sleswick; 9 miles W. of Sleswick.

TREYSA, a town of Westphalia, in the principality of Hesse. In the year 1646, this town was burned down by the Imperialists; 26 miles S. of Cassel. N. lat. 50° 54'. E. long. 9° 10'.

TRIA PRIMA, among *Chemists*, the three hypostatical principles, viz. salt, sulphur, and mercury; of which they hold all bodies to be primarily made, and into which they are all held resolvable by fire.

TRIAD, TRIAS, τριᾶς. See TERNARY, TRIAS, and TRINITY.

TRIADICA, in *Botany*, from τριᾶς, τριᾶδος, ternary, alluding to the prevalence of the number three in the fructification; which however is not very remarkable.—Loureir. Cochinch. 610.—Class and order, *Dioecia Diandria*. Nat. Ord. *Amentacea*, Linn. Juss.

Gen. Ch. Male, Cal. Catkin elongated, thread-shaped, naked, separated into many-flowered tubercles. Perianth minute, bell-shaped, three-cleft. Cor. none. Stam. Filaments two, flat, very short; anthers flattish, of two lobes, which burst laterally.

Female, on a separate plant, Cal. Catkin and Perianth as in the male. Cor. none. Pist. Germen superior, roundish; style short and thick; stigmas three, oblong, erect. Peric. Berry roundish, dry, three-lobed, three-celled. Seeds solitary, roundish.

Ess. Ch. Male, Calyx three-cleft. Corolla none. Stigmas three. Berry superior, of three cells. Seeds solitary.

1. *T. cochinchinensis*. Câi Soi tià, or Câi Cha dam, of the Cochinchinese.—Leaves ovate, obtuse.—Found in the woods of Cochinchina. A large tree, with spreading branches. Leaves alternate, ovate, entire, smooth, on long red footstalks. Flowers nearly terminal. Berries small, of a brownish green.

2. *T. sinensis*. Ū Khau mǒ of the Chinese.—Leaves roundish, pointed.—Wild about Canton in China. A large tree, with spreading branches. Leaves alternate, stalked, smooth, entire. Calyx, of the male as well as female flowers, four-cleft. Seeds tunicated. Of this last circumstance nothing is said in the generic character.—We are not acquainted with any plants answering to the above description. ANTIDESMA perhaps (see that article and STILAGO) comes the nearest, especially when we contemplate the *Stilago diandra* of Roxburgh. If allowance be made for some occasional abortion in the cells of the fruit, or if we ourselves have misconceived Loureiro's ambiguous description, "*bacca trilocularis, monosperma*," *Triadica* may be no other than *Antidesma*.

TRIÆNA, τριᾶων, a trident, alluding to the very peculiar three-pointed awn.—Kunth Nov. Gen. et Sp. Plant. v. 1. 178.—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. Cal. a glume of two unequal, lanceolate, keeled,

keeled, pointed, membranous valves, containing one floret; the outer valve full half the size of the inner, with a rough dorsal awn, about its own length, united to it half way up. *Cor.* of two unequal, lanceolate, keeled, pointed, membranous valves; the outermost largest, three-ribbed, awnless; innermost narrower, with two keels, and a rough dorsal awn, twice its own length, of three equal points, and a common stalk the length of the glume, slightly connected therewith at the base only. *Stam.* Filaments three, capillary, shorter than the glumes; anthers hanging out of the flower, linear, notched at each end. *Pist.* Germen superior, ovate; styles two, thread-shaped, short; stigmas oblong, feathery. *Peric.* none, except the unconnected corolla. *Seed* one, ovate.

Eff. Ch. Calyx single-flowered, of two valves, with a dorsal awn. Corolla of two valves, unconnected with the seed, and a dorsal awn of three points.

1. *T. racemosa.* Cluster-flowered Trident-grass. Kunth as above, 179. t. 61.—Gathered by Humboldt and Bonpland, in dry cultivated ground in Mexico, between Guanajuato and Villalpando, flowering in September. This is an annual, upright, branching grass, about eighteen inches high, with a round, smooth, slender, jointed stem. *Leaves* linear, narrow, sheathing, flat, striated, rough on both sides, and somewhat hairy on the inner: their sheaths striated, smooth. *Stipula* very short, fringed. *Clusters* terminal, solitary, simple, erect, from one and a half to four inches long. *Flowers* alternate, two-ranked, on short, slender stalks.—We have presumed to alter the original description, chiefly with respect to the three-pointed awn, which Mr. Kunth considers as an abortive floret. The analogy of TRIATHERA (see that article) will surely authorize this alteration.

TRIAL, in *Law*, the examination of any cause, civil or criminal, according to the laws of the realm, before a proper judge.

Of this there are divers kinds: both in civil and in criminal cases. In civil cases there are seven species of trial; *viz.* by *record*: by *inspection* or *examination*, when, for the greater expedition of a cause, in some point or issue being either the principal question, or arising collaterally out of it, but being evidently the object of sense, the judges of the court, upon the testimony of their own senses, shall decide the point in dispute; as in case of a suit to reverse a fine for non-age of the cognizor, or to set aside a statute or recognition entered into by an infant, the king's justices determine, by view of the age of the party; also if a defendant pleads in abatement of the suit that the plaintiff is dead, and a person, calling himself the plaintiff, appears, the judges shall determine by inspection whether he be the plaintiff or not; likewise in the case of an idiot; in the appeal of mayhem; and in determining circumstances relative to a day past by inspection of an almanac: by *certificate*, as for matters without the realm, and also within the realm: the customs of the city of London are tried by the certificate of the mayor and aldermen, certified by the mouth of their recorder: marriage, bastardy, excommunication and orders, and other such matters, are tried by the bishop's certificate: ability of a clerk presented, admission, institution and deprivation of a clerk, shall be tried by certificate from the ordinary or metropolitan; and the customs of courts by certificate from the proper officers, &c.: by *witnesses*: by *wager of battle*: by *wager of law*: and by *jury*. In criminal matters, there was formerly the trial by *ordeal* and by *corsned*: these two methods of trial were chiefly in use among our Saxon ancestors, and are now antiquated; the next, which still remains in force, though very rarely in use,

was introduced among us by the princes of the Norman line, and is the trial by *battle*, *duel*, or *single combat*: the fourth method of trial used in criminal cases is that by the peers of Great Britain, in the court of parliament, or the court of the lord high steward, when a peer is capitally indicted: but that which most commonly occurs is the trial by *jury*, or the country, secured to every Englishman, as the great bulwark of his liberties, by the Great Charter. Blackst. Comm. vol. iii. &c. vol. iv. &c.

Before trial, in a criminal case, it is usual to ask the criminal how he will be tried? which was anciently a very pertinent question, though not so now; in regard there were formerly several ways of trial; *viz.* by *battle*, *ordeal*, and *jury*.

When the criminal answered, By God and his country, it shewed he made choice to be tried by a *jury*. But there is now no other way of trial. This is also called trying *per pais*, or *per patriam*.

TRIAL, *New*, is a re-hearing of the cause before another jury, with as little prejudice to either party, as if it had never been heard before. The causes of granting a new trial are such as these: want of notice of trial; or any flagrant misbehaviour of the party prevailing towards the jury, which may have influenced their verdict; or any gross misbehaviour of the jury among themselves: also if it appears by the judge's report, certified to the court, that the jury have brought in a verdict without or contrary to evidence, so that he is reasonably dissatisfied therewith; or if they have given exorbitant damages; and if the judge himself has misdirected the jury, so that they found an unjustifiable verdict: for these, and other reasons of the like kind, it is the practice of the court to award a new, or second trial. But if two juries agree in the same or a similar verdict, a third trial is seldom awarded; for the law will not readily suppose, that the verdict of any one subsequent jury can countervail the oaths of two preceding ones. There are instances of new trials in the year-books of the reign of Edward III., Henry IV., and Henry VII., &c. Blackst. Comm. vol. iii. &c.

TRIAL, JEAN CLAUDE, in *Biography*, director of the royal academy of music at Paris, and master of the prince of Conti's band, was born in 1734, in the Contat, that country so agreeable and fertile in excellent artists. The fine arts are generally inhabitants of beautiful nature.

At twelve years old, Trial quitted Avignon, in order to acquire knowledge from different masters whom he intended to visit. His talents were so extraordinary for his age, that at fifteen he was appointed director of the concert and opera of Montpellier. The passion which he had for the arts drove him to Paris, where he no sooner arrived, than he was placed at the head of the orchestra at what was then called the Italian theatre, or comic opera. From this orchestra he passed to that of the prince of Conti, of which he was appointed director; and his conduct and manners were such in that office, that on his death the prince deigned to say that he had lost a friend.

The protection with which he was honoured, procured him the important place of director of the Academie Royale. Permit us here to define the office of director of the academy of music, or serious opera. The management of the opera is a painful and embarrassing administration. It is necessary for the director of this complicated machine to attend to all the springs, to dissipate all impediments to their action, flatter the taste and sometimes the caprice of the inconstant public, unite to a point of concord very rarely attainable, a crowd of various and often rival talents, excite emulation without awakening jealousy, distribute rewards with justice

justice and delicacy, censure and punish with address, limit the unbounded demands of some by flattery, check the independence of others by apparent concessions, and try to establish in the interior government of this republic as much harmony as reigns in the orchestra. It is manifest that nothing but the most subtle, artful, and pliant character can hope to accomplish such Herculean labours.

The time necessary for such a ministry, did not allow Trial leisure for pursuing composition with the ardour and application with which he began his career. During his regency at the opera he composed but little, and that was generally in partnership with others.

In 1770 he was found dead in his bed, without any previous illness or warning. He married, in 1769, Mademoiselle Victoire, well known for her wit and talents, with whom he lived in the utmost harmony. A good son, a good husband, a good brother, and good friend.

His funeral manifested how much he was beloved; every one who attended it was in tears: no funeral oration is equal to such tears; for they are never shed but for objects worthy of them. Flattery lies, but never weeps.

TRIAL Point, in *Geography*, a cape on the fourth-east coast of the island of Jura. N. lat. $55^{\circ} 54'$. W. long. $5^{\circ} 52'$.

TRIALETE, a town of the principality of Georgia, in the province of Carduel; 40 miles S.W. of Gori.

TRIAMBO, in *Hindoo Mythology*, a name of the Hindoo god Siva, who corresponds in many points with the primary deities of the Pantheon of Greece and Rome. The name of Triambo seems to connect him with Dionysus or Bacchus; for after the conquest of India, we are told by Diodorus that the Greek deity assumed the title of Thriambus. One of the names of Siva is Baghefa; resembling that of the conqueror of India sufficiently nearly for etymological hypothesis to found an argument on, especially when points of character and attributes also correspond. (Of these see under our articles KARTIKYA and SIVA.) The signification of the title Triambo is not evident. Siva has several names allusive to his triple attributes and energies. Trilokan and Trinetra, for instance, mean with three eyes; Trifuli, with the trident; Trikala, or omnipresent; that is, existing in all times, the past, the present, and the future. See those articles, and TRIMURTI.

TRIANA, in *Geography*, one of the fauxbourgs of the city of Seville.

TRIANDRIA, in *Botany*, the third class in the sexual, or artificial, system of Linnæus, derives its name from having three unconnected stamens, in the same flower with the pistil, or pistils. This class is chiefly composed of what are termed monocotyledonous plants, the number three, or its double quantity, six, prevailing as much in that tribe, as the number five does in the dicotyledonous families. See PENTANDRIA.

The orders of this third class are three. 1. *Monogynia*, opening with the dicotyledonous and ambiguous genus *Valeriana*, some of whose species have but one stamen, though most have three. The sword-leaved plants (see *ENSATÆ*) follow; and then the *Calamaria*, or grass-like genera of *Schoenus*, *Cyperus*, *Scirpus*, and their allies. 2. *Digynia* consists of the true grasses; see *GRAMINA*. Some of these, indeed many of them occasionally, have abortive or male flowers interspersed with the perfect ones, and are for that reason placed by Linnæus in his class *Polygamia*. This measure, as we have often had occasion to observe, is attended with much inconvenience in various cases, though in none more than the present. 3. *Trigynia*, a small order, is made up, for the most part, of very limited genera of the

pink tribe, *Caryophyllea*, a tribe which, by its close relationship to the *Atriplices* and *Amaranthi* of Jussieu, tends, as that great writer candidly observes, to invalidate the distinction between his apetalous and polypetalous classes. It at least causes too great a separation in his system between orders nearly akin.

TRIANDRIA is moreover the title of a few orders of the Linnæan system; as the first of the *Monadelphica*, consisting chiefly of sword-leaved genera; the third of *Gynandria*, which perhaps has scarcely any real existence; the third of *Monoecia*, containing *Carex* and *Sparganium*, with some tricoecous genera; and the third of *Dioccia*, formed of some rushy, and some anomalous plants.

TRIANGLE, in *Geometry*, a figure comprehended under three lines or sides, and which, of consequence, has three angles.

If the three lines or sides of the triangle be all right, it is said to be a *plane* or *rectilinear* triangle.

If all the three sides of the triangle be equal (as A B C, Plate XV. *Geometry*, fig. 5.) it is said to be *equilateral*.

If only two of the sides of the triangle be equal (as in D E F, Plate VIII. fig. 105.) it is called an *isosceles* or *equicrural* triangle.

If all the sides of the triangle be unequal to each other, (as in A C B, Plate XV. *Geometry*, fig. 6.) the triangle is said to be *scaleneus*.

If one of the angles, as K (fig. 7.) of a triangle K M L be a right angle, the triangle is said to be *rectangular*.

If one of the angles, as N (fig. 8.) be obtuse, the triangle is said to be *obtusangular*, or *amblygonous*.

If all the angles be acute, (as in A C B, Plate XV. *Geometry*, fig. 5.) the triangle is said to be *acutangular*, or *oxygonous*.

If the three lines of the triangle be all curves, the triangle is said to be *curvilinear*.

If some of the sides be right, and others curve, the triangle is said to be *mixtilinear*.

If the sides be all arcs of great circles of the sphere, the triangle is said to be *spherical*.

TRIANGLES, *Similar*. See *SIMILAR*.

TRIANGLE, *Characteristic*, of a *curve*. See *CURVE*.

TRIANGLE, *Base*, *Canon*, *Hypothense*, *Legs*, and *Resistance of a*. See the several articles.

TRIANGLES, *Construction of*. 1. Two sides, as A B and A C (Plate XV. *Geometry*, fig. 9.) being given in numbers, or otherwise, together with the quantity of the angle intercepted between them, A; to construct a triangle. Assume A B as a base; and in A make the given angle: on the other leg set off the other given line A C; lastly, draw B C: then will A B C be the triangle required.

Hence, two sides with the intercepted angle being determined, the whole triangle is determined. Wherefore, if in two triangles A C B and *a c b*; *a = A*; and *a b : a c :: A B : A C*, the triangles are determined in the same manner, and are therefore similar; consequently *c = C*, and *b = B*, *a b : b c :: A B : B C*, &c.

2. Three sides, A B, B C, and C A (Plate XV. *Geometry*, fig. 5.) being given, any two of which, as A C, A B, taken together, are greater than the third: to construct a triangle. Assume A B for a base; and from A, with the interval A C, describe an arc *y*; and from B, with the interval B C, describe another arc *x*: draw the right lines A C and B C. Thus is the triangle constructed.—Hence, as of any three given right lines, only one triangle can be constructed; by determining the three sides, the whole triangle is determined.

Wherefore,

TRIANGLE.

Wherefore, if in two triangles ACB and acb (*Plate XV. Geometry, fig. 9.*) $AC : AB :: ac : ab$; $AC : CB :: ac : bc$; the triangles are determined in the same manner, and consequently are similar, and therefore mutually equiangular.

3. A right line, as AB , and two adjacent angles A and B , which, taken together, are less than two right ones, being given; to describe the triangle ABC . On the given line AB , make the two given angles A and B : continue the sides AC and BC , till they meet in C . Then will ABC be the triangle required.

Hence, one side and two angles being given, the whole triangle is determined. Wherefore, if in two triangles $A = a$ and $B = b$, the triangles are determined after the same manner, and therefore are similar.

TRIANGLES, *Measurement of.* To find the area of a triangle, multiply the base AB (*fig. 10.*) by the altitude Cd ; half the product is the area of the triangle ABC .

Or thus; multiply half the base AB by the altitude Cd ; or the whole base by half the altitude; the product is the area of the triangle.

<i>E. gr.</i>	$AB = 342$	$AB = 342$	$\frac{1}{2} AB = 171$
	$Cd = 234$	$\frac{1}{2} Cd = 117$	$Cd = 234$
	1368	2394	684
	1026	342	513
	684	342	342
	2)80028	40014	40014 area

See QUADRATURE.

Or, the area of any triangle is had by adding all the three sides together, and taking half the sum; and from that half sum subtracting each side severally, and multiplying that half sum and the remainder continually into one another, and extracting the square root of the product.

Hence, 1. If between the base and half the altitude, or between the altitude and half the base, be found a mean proportional; it will be the side of a square equal to the triangle. 2. If the area of a triangle be divided by half the base, the quotient is the altitude.

TRIANGLES, *Properties of Plane.* 1. If in two triangles ABC and abc (*fig. 9.*) the angle $A = a$; and the sides $AB = ab$, and $AC = ac$; then will the side $BC = bc$, and the angles $C = c$, and $B = b$; and therefore the whole triangles will be equal and similar.

2. If one side of a triangle ABC (*fig. 11.*) be continued to D , the external angle DAB will be greater than either of the internal opposite ones B or C .

3. In every triangle, the greatest side is opposed to the greatest angle, and the least to the least.

4. In every triangle, any two sides taken together are greater than the third.

5. In two triangles, if the several sides of the one be respectively equal to the sides of the other, the angles will likewise be respectively equal; and consequently the whole triangles will be equal and similar.

6. If any side, as BC (*fig. 12.*) of a triangle ACB be continued to D , the external angle DOA will be equal to the two internal opposite ones y and z taken together.

7. In every triangle, as ABC , the three angles A , B , C , taken together, are equal to two right ones, or 180° .

Hence, 1. If the triangle be rectangular, as MKL (*fig. 7.*) the two oblique angles M and L , taken together, make a right angle, or 90° ; and therefore are half right,

if the triangle be isosceles. 2. If one angle of a triangle be oblique, the other two taken together are oblique likewise. 3. In an equilateral triangle, each angle is 60° . 4. If one angle of a triangle be subtracted from 180° , the remainder is the sum of the other two; and if the sum of two be subtracted from 180° , the remainder is the third. 5. If two angles of one triangle be equal to two of another, either together or separately, the third of the one must be likewise equal to the third of the other. 6. Since in an isosceles triangle DFE (*Plate VIII. fig. 105.*) the angles at the base y and u are equal; if the angle at the vertex be subtracted from 180° , and the remainder be divided by 2, the quotient is the quantity of each of the equal angles: in like manner, if the double of one of the angles at the base y be subtracted from 180° , the remainder is the quantity of the angle at the vertex. See ISOSCELES Triangle.

8. If in two triangles ABC and abc (*Plate XV. Geometry, fig. 9.*) $AB = ab$, $A = a$, and $B = b$; then will $AC = ac$, $BC = bc$, $C = c$, and the triangle ACB equal and similar to the triangle abc . Hence, if in two triangles ACB and acb , $A = a$, $B = b$, and $BC = bc$; then will $C = c$; consequently $AC = ac$, $AB = ab$; and the triangle $ACB = acb$.

9. If in a triangle DFE , the angles at the base y and u (*Plate VIII. Geometry, fig. 105.*) be equal, the triangle is isosceles; consequently, if the three angles be equal, it is equilateral.

10. If in a triangle ABC (*Plate XV. fig. 14.*) a right line DE be drawn parallel to the base AC , then will $BA : BC :: BD : BE :: AD : EC$; and $BA : AC :: BD : DE$; consequently the triangle BDE similar to BAC . And, *vice versa*, a right line, which divides two sides of a triangle proportionally, is parallel to the remaining side. Moreover, if another right line FG be also drawn parallel to the base AC , the intercepted parts, DF , EG , are in the same ratio with the whole sides AB , BC ; *i. e.* $DF : EG :: AB : BC$. And if any number of lines be drawn parallel to the base, cutting the sides of a triangle, every two corresponding segments will have the same ratio.

11. Every triangle may be inscribed in a circle.

12. The side of an equilateral hexagon, inscribed in a circle, is equal to the radius.

13. Triangles on the same base, and having the same height, that is, being between the same parallel lines, are always equal. See PARALLELOGRAM.

14. Every triangle, as CAD , (*Plate X. Geometry, fig. 14.*) is one-half of a parallelogram $ACDB$ on the same, or an equal base CD , and of the same altitude, or between the same parallels; or a triangle is equal to a parallelogram upon the same base, but half the altitude; or half the base, and the same altitude. See PARALLELOGRAM.

15. In every triangle, as well plane as spherical, the sides or sines of the sides are proportional to the sines of the opposite angles.

16. In every plane triangle, as the sum of two sides is to their difference, so is the tangent of half the sum of the opposite angles, to the tangent of half their difference. See TANGENT.

17. If a perpendicular be let fall upon the base of an oblique-angled triangle, the difference of the squares, or, the rectangle under the sum and difference, of the sides is equal to double the rectangle under the base, and the distance of the perpendicular from the middle of the base.

18. The double of the square of a line drawn from the vertex to the middle of the base of any triangle, together

with double of the square of the semi-base, is equal to the squares of both the sides taken together.

19. A whole triangle is to a triangle cut off by a right line, as the rectangle under the sides cut off is to the rectangle of the other two sides.

20. In a right-angled plane triangle A D E (*Plate X. Geometry, fig. 17.*) a line D B drawn from the right angle or the vertex, perpendicular to the hypotenuse, divides the triangle into two other right-angled triangles, A D B, D B E, which are similar to the first triangle, and also to one another.

Hence it follows: 1. That $EB : BD :: BD : BA$; and $AE : ED :: ED : EB$; and $AE : AD :: AD : AB$. (See PROPORTIONAL.) Whence, 2. As the angle in a semicircle is a right angle, it follows that, if from any point D in the periphery of a semicircle A D E, a perpendicular D B be let fall upon the diameter A E, and from the same point D, to the extremities of that diameter, two chords D A, D E, be drawn; the square of that perpendicular will be equal to a rectangle under the two segments of the diameter; and the square of each chord equal to a rectangle under the whole diameter and its adjacent segment: *i. e.* $BD^2 = EB \times BA$; $ED^2 = E B \times EA$; and $AD^2 = AB \times EA$.

21. In every right-angled triangle, the square of the hypotenuse is equal to the sum of the squares of the other two sides. See HYPOTHENUSE and SUBTENSE.

22. If any angle of a triangle be bisected, the bisecting line will divide the opposite side, in the same proportion as the legs of the angle are to one another.

23. If the vertical angle of any triangle be bisected, the difference of the rectangles, made by the sides and the segments of the base, is equal to the square of the line that bisects the angle. Thus, if a right line B E (*Plate XV. Geometry, fig. 15.*) bisect an angle A B C of a triangle, the square of the said line $BE = AB \times BC - AE \times EC$.

24. To divide a triangle into any given number of equal parts; divide the base C D (*fig. 16.*) into as many equal parts as the figure is to be divided into; and draw the lines A 1, A 2, &c.

25. If in similar triangles from any two equal angles to the opposite sides two right lines be drawn, making equal angles with the homologous sides; those right lines will have the same ratio as the sides on which they fall, and also divide those sides proportionally.

26. If in two triangles having one side common to both, from any point in that side, two lines respectively parallel to two contiguous sides be drawn, terminating in the two remaining sides, those lines will have the same ratio as the sides to which they are parallel. Hence, if these sides are equal, those lines will be also equal.

27. If through any point within a triangle three right lines be drawn, from the angular points to cut the opposite sides, the segments of any one side will be to each other, as the rectangles under the segments of the other sides taken alternately. Hence if the former segments be equal, the forementioned rectangles will be equal, and therefore the sides of the triangle cut proportionally, and a line connecting the points of division will be parallel to the base.

28. Triangles having one angle in the one equal to one angle in the other, are in the ratio of the rectangles contained under the sides, including the equal angles. Hence, if the rectangles be equal, or the sides reciprocally proportional, the triangles will be equal.

TRIANGLES, *Properties of Spherical.* See SPHERICAL Triangle.

TRIANGLES, *Solution of.* See TRIGONOMETRY.

TRIANGLE, an iron musical instrument with three sides, which serves as an accompaniment to other instruments in a military band, and in the streets: the performer supports it by a ring at the top with his left hand, and beats it with a small iron rod in his right hand. At the lowest angle iron rings are placed, which by their vibration augment the sound.

TRIANGLE Island, in *Geography*, an island of South America, in the mouth of the Orinoko, where the French settled a factory in the year 1765.—Also, one of the smaller Bahama islands, so called. N. lat. $20^{\circ} 51'$. W. long. $69^{\circ} 53'$.

TRIANGLES, a dangerous shoal in the East Indian sea, near the N. coast of the Pracei, or Prasil.

TRIANGLES, *Southern*; a reef of rocks and islets in the bay of Honduras. N. lat. $17^{\circ} 45'$. W. long. $88^{\circ} 40'$.

TRIANGULAR *Apple-Ladder*, in *Rural Economy*, a ladder of this sort for gathering apples from the trees with ease and without bruising them. It is about eighteen feet in height, and has two other branches, which are each of the same length, fastened by iron hoops or rings at its top-part. These parts all diverge from each other when the ladder is in use, and appear somewhat in the manner of the corner rafters of a triangular roof, forming a sort of triangle. At about four feet from the ground, each branch and the ladder part has a hook fixed to it, for the purpose of stretching out a triangular cloth by; in the middle of which is formed a circular funnel of the same material. The cloth has at each corner a leather strap, pierced with a number of holes, in order that an equal degree of tension may constantly be given, whether the ladder and its branches be much extended or not.

In collecting the apples, the gatherer, ascending the ladder, throws the fruit as he strips it from the boughs of the trees into the cloth, whence it rolls down the funnel part into the basket which is placed to receive it below.

So much injury and mischief are done to apple-trees at all periods of their growth, by setting ladders against the boughs of them, and the fruit is so greatly bruised and depreciated, as well as subjected to decay, by gathering it in the usual modes, that both practices should be discontinued, and better ones, such as the above, be had recourse to in such cases.

TRIANGULAR *Battalion*, in the *Military Art*. See BATTALION.

TRIANGULAR *Canon*. See CANON and SINE.

TRIANGULAR *Compasses*, are such as have three legs or feet, by which to take off any triangle at once: these are much used in the construction of maps, globes, &c. See COMPASSES of three legs.

TRIANGULAR *Fort*. See FORT.

TRIANGULAR *Leaf*, in *Botany*. See LEAF.

TRIANGULAR *Numbers*, are a kind of polygonal numbers; being the sums of arithmetic progressions, the difference of whose terms is 1.

Thus, Of arithmetical progress.	1	2	3	4	5	6
are formed triang. numb.	1	3	6	10	15	21

For the rationale and management of these numbers, see Malcolm's Arith. book v. ch. 2.

TRIANGULAR *Quadrant*, is a sector furnished with a loose piece, by which to make it an equilateral triangle.

The calendar is graduated on it, with the sun's place, declination, and other useful lines; and by the help of a string and a plumbet, and the divisions graduated on the loose piece, it may be made to serve for a quadrant.

TRIANGULAR *Winding-stairs*. See STAIR.

TRIAN-

TRIANGULARIS STERNI, in *Anatomy*, a muscle of the ribs. See **INTERCOSTALES**.

TRIANGULARIS Genæ, the depressor anguli oris, a muscle of the mouth. See **DEGLUTITION**.

TRIANGULARIS Piscis, in *Ichthyology*, the name of a sea-fish of a very remarkable figure, called in English the *coney-fish*, of which there are two species, the one having two horns, the other wanting that character.

The horned kind is usually six or seven fingers breadth long, and about three fingers broad: the tail ends in a longish fin; the mouth is small, having twelve strong serrated teeth in the upper jaw, and eight larger ones in the lower; the head rises gibbously from the mouth to the horns, and the back is humped in the middle; it has only one small fin near the tail; its eyes are large and placed near the horns; beside the fin near the tail, it has four others; the tail being one, and one more being situated on the back, and two on the belly; it has two horns like cocks' spurs, growing straight out of its forehead, and two others in a contrary direction, out of its belly near the tail; it has no scales, but has a hard skin, white on the belly, and brown every where else, and wonderfully marked with trigonal, tetragonal, pentagonal, and hexagonal figures.

The species which has no horns has a broader belly, a longer tail, and is marked all over its body only with hexangular figures, and innumerable small tubercles: its belly is yellowish, and the rest of its body of a greyish or brownish yellow; the mouth is narrow, and the teeth small, five in the lower and eleven in the upper jaw; the eyes are large and round; it is hollow, and has very little flesh.

Both the species, which belong to the genus ostracion in the Linnæan system, are caught among the rocks, on the shores of the island of Java, and are sometimes eaten by the inhabitants, being first skinned. Cluf. Exot. lib. ii. cap. 27. Willughby's Hist. Pisc. p. 150.

TRIANTHEMA, in *Botany*, so named by Sauvages, Meth. Folior. 127, from τρεῖς, *three*, and ἀνθος, *a flower*; because of the flowers being situated three together in the bosoms of the leaves.—Linn. Gen. 214. Schreb. 300. Willd. Sp. Pl. v. 2. 635. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 64. Juss. 314. Lamarck Illustr. t. 375. Gærtn. t. 128.—Clafs and order, *Decandria Digynia*. Nat. Ord. *Succulentæ*, Linn. *Portulacæ*, Juss.

Gen. Ch. Cal. Perianth half-inferior, of five oblong leaves, internally coloured, pointed below the summit, permanent. Cor. none, except the calyx, which partakes of the nature of both parts, be considered as such. Stam. Filaments about ten, (from five to twelve,) capillary, the length of the calyx; anthers roundish. Pisl. Germen almost entirely superior, oblong, abrupt; styles one or two, thread-shaped, the length of the germen, hispid on one side; stigmas simple. Peric. Capsule oblong, abrupt, bursting all round, of two, transversely interrupted cells. Seeds one or two in each cavity, nearly ovate.

Obf. The number of stamens, as well as of styles, differs in different species.

Ess. Ch. Calyx of five leaves, with dorsal points. Corolla none. Stamens five or ten. Germen abrupt. Capsule bursting all round.

1. *T. monogyua*. Purslane Trianthea. Linn. Mant. 69. Willd. n. 1. Ait. n. 1. "Decand. Pl. Grasses t. 109." (*T. Portulacastrum*; Linn. Sp. Pl. 325. *Portulaca curassavica procumbens*, *capparidis folio*, *flore muscosa*, *capsulâ bifurcatâ*; Herm. Parad. 213. t. 213. *Kali curassavicum procumbens*, *foliis subrotundis*; Pluk. Phyt. t. 95. f. 4.)—Stamens more than five. Style one. Leaves elliptic-oblong. Stem with a hairy line along the upper side.—Native

of the West Indies and South America. Sometimes raised, for curiosity's sake, in our stoves, where it flowers in summer. The root is annual. Stems a foot long, much branched, leafy, spreading on the ground in every direction, smooth, except a dense, slender, hairy line along their upper side. Leaves opposite, unequal, stalked, oval or roundish, obtuse with a small point, entire, smooth, red at the edge, from one to two inches long. Stipulas membranous, acute, half the length of the footstalk, to which they are united. Flowers axillary, sessile, about three together, pale and membranous, with a pair of bracteas to each. Stamens from six to ten. Germen with two distant horns. Style, according to Linnæus, solitary, rough at one side, with a simple stigma.

2. *T. crystallina*. Crystalline Trianthea. Sm. Spicil. 24. t. 26, unpublished. Vahl. Symb. v. 1. 32. Willd. n. 2. (*Papularia crystallina*; Forfk. Ægypt.-Arab. 69. *Gyrospermum depressum*; Linn. MSS.)—Stamens five. Style one. Leaves elliptic-lanceolate. Stem papillary all over.—Native of the East Indies and of Arabia. We received it from Madras, by the favour of Dr. Roxburgh. Linnæus cultivated it at Upsal, and has left in his herbarium specimens, with a coloured drawing, and a description. He made this plant a new genus by the name of *Gyrospermum*, judging it akin to *Herniaria*. It would have appeared in the third number of our *Spicilegium*, had that work been continued; but the page, though printed, was never published. The root is perennial. Stems herbaceous (not shrubby), depressed, a span long, reddish, branched, leafy, clothed with pellucid papillary granulations, which in the dried specimen become shaggy hairs. Leaves opposite, stalked, like *Polygonum aviculare* in size and figure, with united membranous stipulas, as in the foregoing. Flowers axillary, sessile, one, two or three together, small, whitish with a red germen. Bracteas of two opposite scales under each flower. Stamens five, very short. Style one, with a divided stigma. Ripe capsule of one cell, embraced by the base of the calyx. Seeds two, one above the other, black, orbicular, depressed, rough, with concentric furrows. This species surely approaches in many points to *Salsola*, so far at least as to indicate a great affinity between the two genera.

3. *T. pentandra*. Smooth Trianthea. Linn. Mant. 70. Willd. n. 3. (*Rocama*; Forfk. Ægypt.-Arab. 71. *Portulacæ affinis polygonoides*, *bliti folio et facie moderatpatentis*; Pluk. Phyt. t. 120. f. 3.)—Stamens five. Styles two. Leaves obovate. Stipulas pointless. Stem nearly smooth.—Native of Arabia. Annual, cultivated by Linnæus at Upsal, but unknown in our gardens. The size and habit of the plant answer to the first species, but the stem has no hairy line, nor more than a slight papillary roughness, on the young branches only. Leaves nearly uniform, obovate rather than elliptical, on long stalks, to which the membranous stipulas are entirely united, without any separate points. Flowers purplish. Styles recurved. Willdenow copies Reichard's error of *Rocama*, for *Rocama*.

4. *T. fruticosa*. Shrubby Trianthea. Vahl Symb. v. 1. 32. Willd. n. 4. (*Gymnocarpus decandrum*; Forfk. Ægypt.-Arab. 65. Ic. t. 10. Desfont. Atlant. v. 1. 203.)—Stamens ten; five alternate ones imperfect. Style one. Leaves cylindrical, pointed. Stem shrubby, round, smooth.—Native of the sandy deserts east of Cairo, as well as about Tunis. A rigid spreading shrub, about a foot high; its bark grey and weather-beaten. Leaves fleshy, glaucous, smooth, obscurely triangular, about half an inch long, in little tufts. Flowers three to five, in tufts at the ends of the branches, sessile, violet-coloured, a third of an inch broad,

broad, hairy at their base and at their points. *Seed* solitary, according to professor Desfontaines, to whom we are obliged for a specimen. Vahl suspects there may be two *seeds*.

5. *T. humifusa*. Prostrate Cape Trianthema. Thunb. Prodr. 80. Willd. n. 5.—"Style one. Leaves lanceolate. Stem shrubby, round."—Gathered by Thunberg at the Cape of Good Hope, as well as the next. We have seen no specimen of either.

6. *T. anceps*. Two-edged Trianthema. Thunb. Prodr. 80. Willd. n. 6.—"Style one. Leaves lanceolate. Stem shrubby, two-edged."—Native likewise of the Cape.

7. *T. decandra*. Trailing Indian Trianthema. Linn. Mant. 70. Willd. n. 7. Ait. n. 2. (*Zaleya decandra*; Burm. Ind. 110. t. 31. f. 3.)—Stamens about ten. Styles two. Leaves obovate. Stipules pointless. Stem nearly smooth.—Native of the East Indies. The herbage of this species bears a great affinity to *T. pentandra*, but the *foot-stalks* are rather shorter. Their *flowers* indeed are very different, those of the present being much larger, on longish stalks, with a fleshy, scarcely membranous, *calyx*.

TRIARATHIA, in *Ancient Geography*, a town of Asia, in the Lesser Armenia, upon the route from Sebaste to Cocufon, between Tonofa and Coduzabala. Anton. Itin.

TRIARI, in the *Roman Militia*, a kind of infantry, armed with a pike, shield, a helmet, and a cuirass: they were thus called, because they made the third line of battle.

The triarii were also called *postignani*, because ranged behind the principes who bore the standard in a legion.

Polybius distinguishes four kinds of forces in the Roman army: the first, called *pilati*, or *velites*, he says, were a raw soldiery, lightly armed. The *hastati*, or spear-men, were a degree older, and more experienced. The third, called *principes*, princes, were still older, and better soldiers than the second. The fourth were the oldest, the most experienced, and the bravest; these were always disposed in the third line, as a corps de reserve, to sustain the other two, and to restore the battle, when the others were broken or defeated. See LEGION.

Hence their name of triarii: and hence the proverb, *Ad triarios ventum est*, to shew that one is at the last and hardest struggle.

TRIAS HARMONICA, Lat.; *Triade Harmonique*, Fr.; *Harmonical Triad*, Engl.; in *Musick*. This term has two different senses. In *calculation*, it is the harmonical proportion; in *practice*, it is the perfect major chord resulting from the same proportion, and which is composed of the fundamental sound, its major or sharp 3d, and its 5th. It is called a *triad*, because composed of three sounds; and *harmonic*, because in harmonical proportion; and is the sense of all harmony.

TRIATHERA, in *Botany*, from τρεις, *three*, and ἀνω, *an awn*. Palisot de Beauvois *Agrostogr.* 39. t. 9. f. 4.—Class and order, *Triandria Digynia?* Nat. Ord. *Gramina*.

Ess. Ch. Calyx single-flowered, of two valves. Corolla of two valves; the outermost with three bristly teeth; inner with a triple dorsal awn.

1. *T. juncea* of Desvaux is given as the only species, without any account of its native country. By the figure it appears to be a slender grass, with linear *leaves*, and a simple, upright, unilateral *cluster*, rather above an inch long; the *flowers* not a quarter of an inch in length. Nothing is known of the *stamens*, *pistil*, or *seed*. The *awn*, consisting of three rough equal bristles, more than twice the length of the *floret*, and united by a short simple base, is considered by the above author as the rudiment of an abortive *floret*, which idea is adopted in a similar case by Kunth. (See TRILENA.) We do not doubt that such an *awn* may take

place of a *floret*, by one of those metamorphoses so common in grasses, whose awns are known to be among the least permanent of their distinctions; but it is offering too great violence to language to use one term for the other.

TRIAUCOURT, in *Geography*, a town of France, in the department of the Meuse; 7 miles S. of Clermont en Argonne.

TRIAZEVA, a town of Russia, in the government of Upha; 88 miles N.N.W. of Upha.

TRIAZNUCHA, a town of Russia, in the government of Upha, on the Ural; 140 miles E. of Orenburg.

TRIBALE, LA, a town of France, in the department of the Tarn; 6 miles W.N.W. of La Caune.

TRIBALLI, in *Ancient Geography*, a people of Lower Mæsia, upon the banks of the Danube, called also Ser-vians.

TRIBAU, or TREBOWE, in *Geography*, a town of Moravia, in the circle of Olmutz; 28 miles N.W. of Olmutz. N. lat. 49° 43'. E. long. 16° 29'.

TRIBE, TRIBUS, in *Antiquity*, a certain quantity or number of persons; when a division is made of a city or people into quarters or districts.

The city of Athens was divided into ten tribes: the Jewish nation into twelve; or, if we separate the family of Joseph, thirteen tribes, the descendants of the twelve sons of Jacob, *viz.* the tribes of Judah, of Reuben, Gad, Asher, Dan, Naphthali, Ephraim, Manasseh, Simeon, Levi, Issachar, Zebulun, and Benjamin; the posterity of Joseph being divided into two tribes, that of Manasseh, and that of Ephraim.

There were ten of these tribes that revolted, and followed Jeroboam. The other two, *viz.* those of Judah and Benjamin, adhered to the house of David, and to the worship of the true God, whilst the other tribes declared for idolatry. This schism, which lasted above 200 years, ended at last in the captivity of the ten tribes, which were carried away by Shalmaneser into Assyria and Media: nor does it appear from history, that they ever returned into their own country, at least all of them, though we find it asserted by some modern Jews and ancient fathers of the church.

Mention indeed is often made in the New Testament of the twelve tribes (see Matt. xix. 28. Luke, xxii. 30. Acts, xxvi. 7. James, i. 1.); and St. James directs his epistle to them; but from these passages we cannot conclude, that they were then gathered together; but we may infer, that they were still in being. Perhaps the whole body of the Jewish nation retained the name of the twelve tribes, according to the ancient division, as we find the disciples called the Twelve, after the death of Judas, and before the election of St. Matthias. (John, xx. 24.) Moreover, there were Jews in a sufficient number of the ten tribes mixed with that of Judah, or dispersed into several parts of the world, to afford occasion for speaking of the twelve tribes, as making but one body with the Jewish nation. Of their dispersion into various parts of the East, we have accounts that cannot be questioned. Whether or not we admit Sir W. Jones's opinion, that the *Afgans* (which see) were descended from them, Dr. Buchanan has recently confirmed the opinion, that the posterity of the Jews still remain in India. A heathen author, quoted by Josephus, (Antiq. l. ix. and l. xi.) affirms, that the Persians had carried several thousands of Jews into Babylon, from whence it is natural to conclude, that a considerable number returned home with the others, when they were set at liberty by Cyrus. See 2 Chron. xxxiv. 9. 1 Chron. ix. 3. Jer. l. 4. Luke, ii. 36.

The tribe of Judah did not continue more faithful to

God

God than Samaria, the metropolis of the kingdom of Israel, had done. On this account they were often delivered into the hands of their enemies, and at last all carried away captive by Nebuchadnezzar in the 19th year of his reign. See CAPTIVITY and JEWS.

The Roman people were at first only divided into three tribes; and from this number *three, tres*, it was that the word *tribe, tribus*, took its rise. Livy says (l. vi. c. 5.) that the appellation was derived a *tributo*. This division was accommodated by Romulus to the several nations he had united; the first consisted of the Albans, the second of the Sabines, and the third of a mixture of fugitives, who came to seek an asylum at Rome.

Servius Tullius, fearing this partition might occasion seditions, divided the inhabitants of Rome by cantons, not by nations: accordingly, he distributed the city into four quarters, or tribes: and by reason a great number of citizens had retired into the country about, of those he composed twenty-six other tribes; so that from this time the Roman people consisted of thirty tribes.

Writers are not agreed concerning the precise number. With the four city tribes, and the seventeen rustic tribes of Servius, as some have arranged and denominated them, the Roman people made up the number of thirty-five tribes. However this be, in after-times the number of tribes amounted to thirty-five; but they then ceased to be ranged according to the quarters of the city. The distribution depended on the censors, who formed their list at discretion, frequently confounding the country tribes with those of the city.

A man was never absolutely a Roman citizen, unless he had the *jus tribus*, i. e. till he were intitled to the honours of the magistrature, as also a right of voting in assemblies of the people; and this is what they called *jus quiritium*. Hence the inhabitants of the municipal cities were only imperfect citizens, as being of no tribe.

The freed-men were obliged to purchase this *right of tribe*, which did not otherwise belong to them, though they were citizens of Rome.

The names of the thirty-five tribes were, 1. The Palatina; 2. The Suburrana; 3. The Collina; 4. The Esquilina; 5. The Romilia; 6. The Æmilia; 7. The Crustumina; 8. The Cornelia; 9. The Fabia; 10. The Galeria; 11. The Lemonia; 12. The Mentian, or Menenia; 13. The Oriculana; 14. The Papiria; 15. The Pollia; 16. The Popilia; 17. The Pupinia; 18. The Sergia; 19. The Veientina; 20. The Voltina; 21. The Claudia; 22. The Stellatina; 23. The Tromentina; 24. The Arnenfis; 25. The Sabatina; 26. The Pomptina; 27. The Publilia; 28. The Mæcia; 29. The Sceptia; 30. The Oufentina; 31. The Falerina; 32. The Anienfis; 33. The Terentina; 34. The Velina; 35. The Quirina. In ancient authors and inscriptions, we meet with the names of others, viz. the Pinaria, Sappinia, Camilla, Cestia, Cluentia, &c.

TRIBES of Plants, in Gardening, the particular kinds or sorts of cultivated garden vegetables of these descriptions, which are arranged and brought together under peculiar heads or names, according to their similar resemblances or appearances; the sameness of their habits of growth; and the general affinities which they bear, in some way or other, to each other. By these means, and in these several ways, a great number of different tribes of these sorts of plants are formed and constituted. Thus the time or duration of the growth of some afford several of these classes or tribes, such as the following: viz. the

Annual Tribe: that which contains all sorts of annual

VOL. XXXVI.

plants, or those only of one year's growth or duration, being often simply, on that account, termed *annuals*.

Biennial Tribe: that which includes all kinds of plants which are of two years' duration or length of growth, and which are sometimes called simply *biennials*.

Perennial Tribe: that which comprehends all sorts of plants which are of perennial or many years' growth or duration, and which is applicable to trees as well as herbs, though somewhat more frequently and generally used to herbaceous perennial plants. These are occasionally called *perennials* merely. See ANNUAL, BIENNIAL, and PERENNIAL Plants.

The nature and form of the root have also some influence in the formation of these tribes, as is evident in the following:

Bulbous-rooted Tribe: that which comprises all kinds of plants which have thick or bulbous roots; such as those of the onion, turnip, lily, crocus, narcissus, and several other kinds.

Tuberous-rooted Tribe: that which contains all sorts of plants which have thick, knobby, fleshy roots, such as those of the anemone, potatoe, Jerusalem artichoke, and many other kinds.

Fibrous-rooted Tribe: that which comprehends all sorts of plants which have small string-like fibrous roots, such as that of endive, and many other kinds. See ROOT.

The ligneous or woody nature of plants likewise causes distinctions of this description, such as these:

Ligneous or Woody Tribe: that which includes all sorts of plants of the tree or shrub kind which have woody or solid durable stalks or stems, such as those of the oak, ash, beech, and other similar kinds, as well as such shrubs as the holly, alaternus, althæa, and many other sorts. See TREE and SHRUB.

Arboraceous Tribe: that which contains all sorts of plants of the tree kind, which rise with an upright main stem or stalk to a considerable height, as in the ash, beech, &c. See TREE.

Fruicose or Shrubby Tribe: that which takes in all sorts of plants of the shrubby kind, or which have any thing of shrub-like growth, and which rise only to a moderate height, having a divided, low, stemmy, and branching bushy appearance about the bottom and other parts, as in the althæa frutex, syringa, &c. See SHRUB.

The habits of different sorts of plants, in regard to the loss or the retention of their leaves during particular seasons of the year, are a further source of the distinction of them in these modes.

Deciduous Tribe: that which comprises all sorts of both trees, shrubs, and plants, which cast their leaves during the winter season, or before it commences; such as the ash-tree, the syringa shrub, and the fennel, golden-rod, and mint plants.

Sempervirent or Evergreen Tribe: that which comprehends all the various sorts of trees and shrubs, as well as other kinds of plants, which have the property of retaining their green leaves the whole of the year round, such as the holly, yew, box, laurel, and many others. See DECIDUOUS and EVERGREEN Trees.

Herbaceous Tribe: that which contains all the different sorts of the herbaceous or herb kind of plants, which most commonly rise furnished with leaves immediately from the roots, and with soft herbaceous stems or stalks, without any sort of woodiness; but which, for the most part, decay and die about the close of the same year in which they were produced, such as the pea, bean, lettuce, mustard, cresses, and numerous others. See HERBACEOUS Plants.

There are others which are arranged in this manner from their juicy or succulent properties, as the following tribes.

Succulent Tribe: this is that which includes all the sorts of plants which have fleshy, moist, juicy leaves, which are sometimes of considerable thickness, but in other cases not, such as the sedum or house-leak, the cactus or melon-thistle, creeping cereus, &c., the aloe, the agave, and several others. See **SUCCULENT**.

The manner of feeding, and the economical uses to which plants are put, are further causes of their arrangement and distinction in this way.

Leguminous Tribe: that in which all the different plants that it embraces have the sort of seed-vessel which is usually denominated a legume, or pod, as in all the pea, bean, kidney-bean, and other papilionaceous-flowered plants.

Oleraceous Tribe: that in which the various plants that it contains are of the esculent or eatable kind for the table, or for being preserved and made use of for other culinary or domestic intentions. See **LEGUMINOUS** and **ESCULENT Plants**.

The forms of the leaves and plants, the manners of their flowering, the shapes of their flowers, the methods of feeding or fruiting, and the particular natures, qualities, and properties of plants, all have a further tendency to the introduction of more tribes of these kinds.

Pinnated Tribe: that in which all the sorts of the trees and plants which it contains have pinnated leaves, or those which are in the shape of wings, as is the case in a great number of different kinds, as in the acacia, the fumach, and many others.

Ensataceous or Sword-leaved Tribe: that which comprises plants that have sword-shaped leaves, as is the case in many sorts, such as the iris or flowering rush, the gladiolus or sword-lily, &c.

Spathaceous Tribe: that which contains all such plants as protrude and produce their flowers out of a spathe or sheath, and which are many in number, such, for instance, as the narcissus, or daffodil and jonquil, the galanthus or snow-drop, and the amaryllis or lily-daffodil, Guernsey lily and the belladonna and jacobæa lily.

Liliaceous Tribe: that which comprehends all the sorts of plants which have papilionaceous or butterfly-shaped flowers, such as those of the pea, bean, and all the leguminous kinds of plants. See **PAPILIONACEOUS Flowers**.

Campanaceous Tribe: that which contains all the various kinds of plants which have campanulated or bell-shaped flowers, as those, for instance, of the campanula or bell-flower, the convolvulus or bind-weed, and bean-kind, and others of the same sort.

Rotaceous Tribe: that which includes all sorts of plants which have rotated or wheel-shaped flowers, such as those of the lysimachia or loose-strife, the anagallis or pimpernel, and some others.

Umbelliferous Tribe: that which contains all such plants as produce their flowers in somewhat the form of an umbel, as in those of the angelica, the anethum or fennel, the pastinaca or parsnip, and some others. See **UMBELLATED Plants**.

Verticillate Tribe: that which comprises those sorts of plants which have their flowers produced in something of the form of a verticillus or whorl, as in those of the thymus or common thyme, the hyssopus or hyssop, the melissa or balm, the origanum or marjoram, the mentha or mint, and several others. See **VERTICILLATED Plants**.

Aggregate Tribe: that which comprehends such plants as produce their flowers in an aggregate form, consisting of

numerous florets or small flowers, each having its own proper calyx or cup, but the whole of which are collected into one close aggregate, or head, as in those of the scabiosa or scabius, the statice, thrift, or sea-pink, the globularia or globular blue daisy, and some others. See **AGGREGATE**, in *Botany*.

Composite or Compound Tribe: that which comprises those sorts of plants which have compound flowers, consisting of a great number of florets contained in one common calyx, or cup, as in those of the sun-flower, the marigold, the aster or star-wort, and many others. See **COMPOUND** in *Botany*.

Amentaceous Tribe: that which contains those plants which produce their flowers in amentums or catkins, as in those of the populus or poplar-tree, the corylus or hazle, the fagus or beech, the betula or birch, and some others. See **AMENTACEOUS**.

Baccaceous Tribe: that which comprehends all those sorts of plants which bear and produce any kind of berry, as the ribes or gooseberry and currant, the raspberry, the yew, and many others.

Coniferous Tribe: that which contains all such sorts of trees and plants as bear that kind of fruit or seed which is denominated a cone, as the various sorts of firs, &c. See **CONE**, in *Botany*.

Fungous Tribe: that which takes in all vegetables of the mushroom and other similar kinds, as the common mushroom or agaricus, &c.

Graminous Tribe: that which comprehends all such sorts of plants as are of the grass or grain kinds, such as the different field grasses, and those of the wheat, rye, barley, oat, and other similar kinds.

Lurid Tribe: that which includes all the sorts of plants which have any thing of an ominous appearance or hurtful or noxious quality about them, as those of the atropaga or deadly nightshade, the datura, thorn-apple or stramonium, the nicotiana or tobacco-plant, the solanum or love-apple, &c. the capsicum or guinea-pepper, the digitalis or fox-glove, and several others.

Nuciferous Tribe: that which comprehends all the sorts of the nut-bearing kinds of plants, as the hazle-nut-tree, the walnut-tree, &c.

Pomaceous Tribe: that which comprehends all such sorts of plants as bear or produce a fruit of the apple kind, as that of the pyrus malus or apple kind, the pyrus communis or pear kind, the pyrus cydonia or quince kind, the amygdalus or almond kind, the prunus or plum kind, the mespilus or medlar kind, the punica or pomegranate kind, and some others.

This sort of classification or arrangement of the different plants which are cultivated in the garden or pleasure-ground for the sake of their culinary uses, or the ornament which is afforded by their flowers, is often of very great utility and convenience, as supplying the means of throwing together those sorts of plants which have many circumstances and practices in their general culture and growth which have much similarity to each other, by which the common gardener has a far greater facility of raising and managing them, as well as of securing their produce in fruit or other ways. He is thereby also better enabled to make use of those of the ornamental kinds in the borders, clumps, and other parts of the grounds in which they are to be set out and placed.

TRIBENSEE, in *Geography*, a town of Austria; 3 miles N. of Tulln.

TRIBERG, a town of the Brisgau; 15 miles N.E. of Friburg. N. lat. 48° 9'. E. long. 8° 17'.

TRIBERL,

TRIBERL, BOHMISCH, a town of Bohemia, in the circle of Chrudim; 4 miles E.N.E. of Leutmischl.

TRIBISA, a river of Saxony, which runs into the Elbe, near Meissen.

TRIBOCOI, TRIBOCI, or *Triboces*, in *Ancient Geography*, a people of Germany, on this side of the Rhine, situated, according to Strabo and Cæsar, between the Mediomatici and the Treviri. Cæsar says they formed part of the army of Ariovistus. Their capital was Argentoratum or Straburg.

TRIBOLI, in *Geography*, a town of Asiatic Turkey, in the government of Trebifond; 4 miles W.S.W. of Trebifond.

TRIBOMETER, formed from $\tau\rho\iota\beta\omega$, *I rub*, and $\mu\epsilon\acute{\iota}\rho\omega$, *I measure*, in *Mechanics*, a term applied by Muschenbroeck to an instrument invented by him for estimating the friction of metals. It consists of an axis formed of hard steel, passing through a cylindrical piece of wood: the ends of the axis, which are highly polished, are made to rest on the polished semicircular cheeks of various metals, and the degree of friction is estimated by means of a weight suspended by a fine silken string or ribband over the wooden cylinder. For a farther description and figure of this instrument, and the result of various experiments performed with it, see Muschenb. Int. ad Phil. Nat. vol. i. p. 151, &c.

TRIBONIANUS, or TRIBONIAN, in *Biography*, an eminent jurist, was a native of Side, in Pamphylia, and richly furnished with Greek and Roman literature, so that he composed works on a great variety of subjects. But as he principally devoted himself to the study of civil law, he excelled in this department, and rose to some of the highest posts in the empire. In the office of questor, to which he was advanced, his avarice led to such a degree of oppression, that in the sedition of Constantinople, A.D. 532, his removal was one of the demands of the people. His influence, however, was such, that he was soon restored, and he continued, on account of his talents and by means of his servile adulation, to enjoy the favour and confidence of his sovereign for twenty years. He was elevated to the dignities of consul and master of the offices, and was consulted on all important occasions. Of his concern in compiling the code of civil law, we have elsewhere given an account. (See CODE and CIVIL LAW.) He has been charged with enmity to the Christian faith, and he has been under the inconsistent imputations of Atheism and Paganism. Whether charges of this kind be true or false, he was notorious for his avarice and want of integrity; and from the contrast presented by his heart and his understanding, Gibbon has drawn a parallel between him and our great Bacon. His death is placed about the year 546. Anc. Un. Hist. Gibbon's Rom. Emp.

TRIBRACHYS, formed from $\tau\rho\iota$, *three*, and $\beta\rho\alpha\chi\upsilon$, *short*, in the *Ancient Prosody*, a foot of verse, consisting of three syllables, and those all short; as, *Mēlīūs*.

Some of the ancients call this foot *trochæus*.

TRIBSEES, in *Geography*, a town of Anterior Pomerania. This town is reckoned a pass to Mecklenburg; 22 miles S.W. of Stralsund. N. lat. 54° 5'. E. long. 12° 47'.

TRIBSTADT, or TRIPSTADT, a town of France, in the department of Mont Tonnerre, late in the duchy of Deux Ponts; 18 miles N.W. of Landau.

TRIBUCH. See TREBUCHET, CUCKING-STOOL, and SCOLDS.

TRIBULOIDES, in *Botany*, Tourn. t. 431. See TRAPA.

TRIBULUS, $\tau\rho\iota\beta\omega\lambda\omicron\varsigma$ of the ancient Greeks, $\tau\rho\iota\beta\omega\lambda\iota$

of the moderns, was so called from the likeness of its fruit to the instrument of war denominated in English a caltrop. (See TRAPA.) Whether the name arose from $\tau\rho\iota\beta\omega$, *to tear*, or *injure*; or as some think from $\tau\rho\iota\varsigma$, *three*, and $\beta\omega\lambda\upsilon$, *a cast*, or *a wound*, may admit of controversy. The caltrop has four, not exactly three, points; and the seed-veffel of our plant has a much greater number, though the appearance of the whole very much resembles the above war-like, or rather treacherous, instrument.—Linn. Gen. 213. Schreb. 289. Willd. Sp. Pl. v. 2. 566. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 41. Sm. Prodr. Fl. Græc. Sibth. v. 1. 273. Juss. 296. Tourn. t. 141. Lamarck Illustr. t. 346. Gært. t. 69.—Class and order, *Decandria Monogynia*. Nat. Ord. *Gruinales*, Linn. *Rutaceæ*, Juss. but not correctly.

Gen. Ch. *Cal*. Perianth inferior, of one leaf, in five deep acute segments, rather shorter than the petals. *Cor*. Petals five, oblong, obtuse, spreading. *Stam*. Filaments ten, small, awl-shaped; anthers incumbent, simple. *Pist*. Germen roundish, bristly, the length of the stamens; style short and thick; stigma capitate, with five rays. *Peric*. roundish, thorny, of either five or ten capsules, which are gibbous externally, and armed with three or four sharp thorns; angular on the inner edge and crowded together; their cells several, transverse. *Seeds* solitary in each cell, oblong.

Obf. *T. maximus*, Linnæus by mistake says *cistoides*, has ten rugose capsules, almost destitute of lateral spines.

Ess. Ch. Calyx in five deep segments. Petals five, spreading. Style conical. Capsules five or ten, gibbous, spinous, with several seeds.

1. *T. maximus*. Great Caltrop. Linn. Sp. Pl. 553. Willd. n. 1. Ait. n. 1. Jacq. Coll. v. 4. 110. Ic. Rar. t. 462. (T. n. 2; Browne Jam. 220. t. 21. f. 3. T. terrestris major, flore maximo odorato; Sloane Jam. v. 1. 209. t. 132. f. 1; the figure at least, and part of the description. T. terrestris, fructu turbinato, foliis lanuginosis; Plum. Ic. 252. t. 254. f. 1.)—Leaflets about four pair; the outer ones largest. Fruit turbinate, wrinkled, slightly spinous, with ten furrows. Style permanent.—Native of dry waste places, or rocky gravelly ground, in most parts of Jamaica. Sloane. The root is annual, rather deep. Stems several, about two feet long, spreading flat on the ground, branched, round, leafy, striated, rather hairy. Leaves opposite, abruptly pinnate, loosely hairy, an inch and a half long, of six pair of half-ovate, entire, acute leaflets; the first pair smallest, the third largest; on a flat stalk. Stipulas awl-shaped, pale, hairy. Flowers axillary, solitary, inodorous, on simple stalks shorter than the leaves, hairy, and swelling upward. Calyx permanent. Petals obovate, half an inch long, dirty white, ribbed with dull purple. Germen roundish, hairy, crowned with a conical permanent style, exceeding its own length; stigma obtuse, marked with five rays. Fruit hairy, composed of ten corrugated tumid capsules, knobbed rather than spinous, and beaked with the thick style. Linnæus certainly alludes to this species, in the observation under his characters of the genus, and not to *T. cistoides*, which has the proper thorny fruit of the rest. It seems to us, that Sloane's definition and description of the flower belong, on the other hand, to *cistoides*, and that hence Linnæus, nevertheless, took his specific name of *maximus*, which is nowise suitable to the plant before us.

2. *T. lanuginosus*. Woolly Caltrop. Linn. Sp. Pl. 553. Willd. n. 2. (T. terrestris zeylanicus, cauliculis villosis, fructu acuminato; Burm. Zeyl. 266. t. 106. f. 1.)—Leaflets from five to seven pair, silky, nearly equal.

Fruit with ten horizontal awl-shaped thorns. Style deciduous.—Native of Ceylon. The *stems* seem woody, and probably perennial. Whole plant, excepting that circumstance, much like *T. terrestris* hereafter described, but the *leaves* are more hairy, or silky. Each of the five combined wrinkled *capsules* is armed with a pair of sharp, tapering, prominent thorns, twice the length of the capsule; but the base is nearly, or quite, destitute of spines. The *flowers* seem to be yellow, the size of the last, with a short, thick, deciduous *style*.

3. *T. terrestris*. Small Caltrops. Linn. Sp. Pl. 554. Willd. n. 3. Ait. n. 2. Sm. Fl. Græc. Sibth. t. 372, unpublished. Camer. Epit. 714. Matth. Valgr. v. 2. 323. Ger. Em. 1246.

Leaflets six pair, rather hairy, nearly equal. Fruit with ten horizontal awl-shaped thorns, and as many deflexed smaller ones. Style deciduous.—Native of the fourth of Europe, by way sides, as well as in cultivated ground. Dr. Sibthorp observed this species every where in Greece, retaining its ancient name a little altered, *τριβέλι*. This is doubtless the *τριβέλος χιερταίος*, or Land Caltrop, of Dioscorides. The Turks call it *Demio Dikiçni*. We have an East Indian specimen from the late Dr. Roxburgh. The annual *root* produces many long, reddish, hairy, leafy, slightly branched, prostrate *stems*. *Leaflets* smaller, and more numerous, than in our first species; leaflets hairy than in the second; all nearly of equal size, the outer, or terminal, ones being, if any thing, rather the smallest. *Flowers* yellow, on shortish, simple, solitary, axillary stalks. *Style* thick, hardly so long as the germen, deciduous. *Stigma* of five prominent rays. *Capsules* tuberculated, each with four awl-shaped thorns, of which the larger are scarcely half so big as those of *T. lanuginosus*. Those at the base are still smaller, pointing directly downwards, and serve chiefly to distinguish the present species from the last. The herb has been reputed cooling and emollient, ever since the time of Dioscorides. He says the Thracians, who inhabited the banks of the Strymon, fed their horses with the green plant, and made bread for themselves of its seeds.

4. *T. cistoides*. Cistus-flowered Caltrops. Linn. Sp. Pl. 554. Willd. n. 4. Ait. n. 3. Jacq. Hort. Schoenbr. v. 1. 54. t. 103. (*T. terrestris* major corallavicus; Herm. Parad. 236. t. 236. *T. terrestris* americanus, argemones flore flavo; Pluk. Phyt. t. 67. f. 4.)—Leaflets about eight pair, silky beneath, nearly equal. Petals twice as long as the calyx.—Native of meadows in the West Indies. A stove-plant with us, flowering in June and July, but not in general culture. The *root* is perennial, thick and woody, though Hermann says annual. *Stems* many, herbaceous, diffuse, clothed with handsome *leaves*, whose upper leaflets are smallest. *Flowers* yellow, large and handsome, two inches wide, their stalks longer than the corresponding leaves. *Capsules*, according to Jacquin, each armed with four thorns of nearly equal size.

TRIBULUS *Marinus*, the *caltrop-shell*, in *Natural History*, the name of a peculiar species of the purpura. It is of a whitish colour, and has three rows of spines.

TRIBUNAL, *Judgment-Seat*, the seat of a judge.

The tribunal, in a court of justice, is properly the seat or bench on which the judge, and his associates, are placed, for the administration of justice, &c.

The word is Latin, and takes its origin from a seat raised from the ground, on which the tribune of the Roman people was placed to administer justice.

TRIBUNAL, among the *Ancients*, was also a place from whence the people were harangued.

Among the Romans, it was an eminence in a temple, or

a forum, as that called *pro rostris*, where the people were harangued in tribes.

The French architects likewise use the word *tribune* for a gallery or eminence in a church, or any other place, in which the music is placed for a symphony or concert. Tribune, or tribunal, is also used for a room or hall in which justice is administered; such, *e. g.* as the courts at Westminster.

TRIBUNE of the People, *Tribunus Plebis*, in *Antiquity*, a Roman magistrate, chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 260. The first design of the creation was to shelter the people from the cruelties of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number, at first, was but two; and the next year, under the consulate of A. Posthumus Aruncius and Cassius Viscellinus, there were three more added; and this number of five was afterwards increased by L. Trebonius to ten.

The appellation tribune was given them, because they were at first chosen out of the tribunes of the army. See the article following.

The tribunes were, as it were, the heads and guardians of the people. They called assemblies of the people when they pleased; and in those assemblies they frequently annulled the decrees of the senate. Nothing could be concluded without their consent, which they expressed by subscribing the letter T at the bottom of the decree. They had it also in their power to prevent the execution of any decree, without giving any reason for it, and merely by subscribing *Veto*. This interposition was called *intercessio*. They sometimes even called the consuls and dictator to account for their conduct before the people. The tribunes of the people, by virtue of their office, claimed and exercised a power of summoning the senate at any time, whenever the affairs of the people required it, though the consuls themselves were in the city. It has been taken for granted, on the authority of Valerius Maximus, that the tribunes of the people, on their first creation, were not admitted into the senate, but had seats placed for them before the door in the vestibule. But we may reasonably conclude, that a magistrate so ambitious and powerful, who could controul, by his single negative, whatever passed within doors, would not long be content to sit without. Dionys. Halic. x. 31. Middlet. of Rom. Senat. p. 129. Val. Max. lib. ii. cap. 27.

A. Gellius says that they were not made senators before the law of Atinius, who is supposed to be C. Atinius Labeo, tribune of the people, A.U. 623; but that cannot possibly be true, since it is evident from the authority of Dionysius, that near four centuries before, the tribunes, by the mere weight and great power of their office, had gained an actual admission into the senate, within two years after their first creation; in which we find them debating and enforcing, with great warmth, the demands of the commons, for a liberty of intermarriages with the nobles, and the choice of a plebeian consul. So that the intent of this Atinian law could not be, as it is commonly understood, that the tribunes should be senators in virtue of their office, for that they had been from the beginning; but that for the future they should always be chosen out of the body of the senate, or, which is the same thing, out of those who had already borne the office of quaestor. A. Gell. xiv. 8. Vide

Pighil.

Pighil. Annales, A. U. 623. Dionys. lib. x. 11. Dionys. xi. 57. Middleton of Rom. Sen. p. 45.

Sylla, the dictator, was the first who presumed to put a stop to the encroachments of the tribunes, A. U. 672; but under Cotta, the consul, they recovered part of their power, A. U. 679; and in 683, Pompey the Great re-established them in the possession of their ancient privileges. Their power subsisted till the time of Julius Cæsar. And in the year of Rome 731, the senate by a decree transferred the whole authority of tribunes of the people to Augustus and his successors, so that they had little more than the name and form of magistrates; whence the emperors were said to be *tribunitia potestate donati*. Accordingly, Augustus himself was tribune for thirty-seven years; Tiberius assumed the same quality; as likewise did his successor; signifying the year of their tribunate on their medals and coins; but their design in it was only to possess themselves of all the authority, that there might be nobody to oppose them.

In the time of the emperors Nerva and Trajan, the dignity of tribune of the people was a mere title, without office and honour; and thus it continued till the reign of Constantine the Great, after which there occurs no mention of this magistrate.

TRIBUNE of the Soldiers, *Tribunus Militum*, or *Militaris*, an officer in the Roman army, who commanded in chief over a body of forces, particularly a division of a legion; and was much the same with our colonel, or the French *meistre de camp*.

There is a distinction of the tribunes into *laticlavii* and *angusticlavii*: those born of noble families were allowed, after they were made tribunes of a legion, to take the *latus clavus*. The rest were only to wear the *angustus clavus*; whence Suetonius takes care to inform us, that his father was *tribunus laticlavius* of the thirteenth legion. Over these tribunes of legions and cohorts, there were other tribunes who commanded in the absence of the consuls, and who were invested with a consular authority. Budæus will have these to be much the same as the marshals of France, or, at least, as our lieutenants-general.

Romulus likewise established a tribune of the cavalry, *tribunus equitum*, who was the same with the *magister equitum* under the dictators, the first officer after the kings.

The tribunes of the soldiery were of an elder standing than those of the people; those latter being elected out of the former. Varro will have it they were called tribunes, because, at first, they were only three in number in each legion, when the legion consisted of three thousand men, taken out of the three tribes then on foot. In proportion as the legion was increased, the number of tribunes was likewise increased to the number of six.

At first, the nomination lay in the general of the army; but in the year of Rome 391, it was appointed, that the people should nominate one part, and the general another; the latter were called *Rufuli*, from Rutilius Rufus, who passed that law.

Those chosen by the people in the comitia, were called *comitiati*; they were indifferently either patricians or plebeians; and they had the same marks of honour as the consuls themselves. The *tribune of the pretorian cohorts* was the captain of the guards.

TRIBUNE was also an appellation given to various other officers; as the *tribuni ærarii*, *tribunes of the treasury*. *Tribune of the celeres*, or Roman light-horse, the officer who commanded them. *Tribuni fabricarum*, those who had the direction of the making of arms. *Tribuni marinorum*, *tribuni nolanorum*, and *tribuni voluptatum*, mentioned in the Theo-

dosian Code, as intendants of the public shows, and other diversions.

The title of *tribune*, *tribunus*, was also given to the chief of each tribe.

TRIBUNITIAN, TRIBUNITIUS, a term among antiquaries and medallists. The *tribunitian power* was the dignity, office, or authority of a tribune of the people.

This power was assumed by the emperors, and makes one of the chief titles they bear on their medals: the quality was first introduced by Augustus, to keep the sovereign authority over the other magistrates without either taking that of dictator or king. Indeed, it was offered to Julius Cæsar, but he despised it. Augustus is the first who used it, and his successors followed his example. They reckoned the years of their empire on their medals by those of their tribunitian power.

This power was sometimes given them for a certain number of years, and sometimes for ever. Sometimes the emperors would communicate the power to such as they associated, or as they intended to succeed them: and Tiberius held it fifteen years with Augustus. But this practice only obtained till the time of Valerian and Gallienus. After them we only find TR. P. II. in Claudius; TR. P. V. in Aurelian; and TR. P. in Probus. This, however, is only to be understood of medals; for in inscriptions we find it after that time.

Cardinal Noris and F. Pagi have disputed about this tribunitian power, in which it consisted. The first maintains, that it did not at all differ from that of the ordinary tribunes, which consisted in three things: 1. In the right of opposing all the acts and resolutions of the other magistrates. 2. In that it rendered their persons sacred and inviolable. 3. In a power of making edicts and laws.

F. Pagi asserts, that it made an addition to the power of the tribunes; that the privilege it conferred of making edicts, was more ample than that of the ordinary tribunes; besides, that it carried with it a power of convening the senate at pleasure.

M. Spanheim is of F. Pagi's opinion; he believes that the tribunitian power had much the advantage of the tribunes: 1. In that it was peculiar to the patricians, and did not reduce the person who held it to the degree of a plebeian. 2. In that it was not confined to the city of Rome alone, like the other; but that it extended throughout the empire, as well as the proconsular power, which was usually annexed to it. 3. That the dignity of the tribunes was inferior to that of the pretors; whereas the tribunitian power of the Cæsars conferred, according to Tacitus, a sovereign authority over all magistrates, and rendered such as it was communicated to, equal to the emperors, and even made them their colleagues in the empire; besides the power of opposing the enterprizes of all the other magistrates; and that it rendered their persons sacred, and gave them a right to assemble and dismiss the senate; which were privileges the tribunitian power had in common with the tribunes.

F. Hardouin thinks we should distinguish two tribunitian powers; the one civil, the other military; but the proof he brings of them is very weak. M. Spanheim says, his distinction is only founded on vain conjectures, none of which deserve notice.

The learned are greatly divided as to the month and day on which the tribunitian power commenced: Sigonius and Petavius will have it begin on the 1st of January: others, as Perizonius, on the fifth of the calends of July: M. Toynard, on the fourth of the ides of December: Onuphrius, cardinal Noris, F. Pagi, &c. on the day of the emperor's accession

accession to the empire; with this difference, that F. Pagi takes it to be on the fifth of the calends of the month in which the emperor was proclaimed; and that this day was, for this reason, held sacred among the Romans.

F. Hardouin thinks, that on medals the tribunitian power commences on the anniversary of the building of Rome, viz. the eleventh of the calends of May, excepting on the Greek medals, where it begins in September, in regard this month, which began the Greek year, was near the time when the tribunitian power was first conferred.

Of all these sentiments, the most probable is that of Onuphrius, &c. setting aside the restriction of F. Pagi. See M. Spanheim, Dissert. xii. tom. ii. p. 429.

TRIBUTA COMITIA. See COMITIA.

TRIBUTARY, TRIBUTARIUS, one who pays tribute to another, in order to live in peace with him, or to share in his protection.

The republic of Ragusa is tributary to the grand Turk; so also is the cham of Little Tartary, &c.

TRIBUTE, TRIBUTUM, a tax, or impost, which one prince or state is obliged to pay to another, as a token of dependence; or in virtue of a treaty, and as a purchase of peace.

The Romans made all the nations they subdued pay them tribute. Mahomet laid it down as a fundamental of his law, that all the world should pay him tribute.

In the states of the grand signor, Christian children are taken, by way of tribute, to make agemogians, janizaries, &c.

TRIBUTE is sometimes also used for a personal contribution, which princes levy on their subjects by way of capitation, or poll-money.

In this it differs from an impost, which is properly what is laid on merchandizes.

TRICADIBA, in *Ancient Geography*, an isle of India, upon the coast, on this side of the Ganges, in passing from the gulf of Canticolpe to the Colchic gulf, and to the S. of the isle of Heptanesia. Ptolemy.

TRICÆ, in *Botany*, so called from τριχῆς, τριχως, a hair, because they seem composed of a horse-hair rolled, or partly folded, into a little round black head, are the peculiar fructification of the genus of Lichens named GYROPHORA. See that article; as well as LICHENES, their eighth kind of receptacle.

TRICALA, in *Geography*, a town of European Turkey, in Macedonia, on the Strimon; 50 miles E.N.E. of Saloniki.—Also, a town of European Turkey, in Theffaly; 21 miles S.W. of Larissa.

TRICALORE, a town of Hindoostan, in the Carnatic; 38 miles W. of Pondicherry. N. lat. 11° 58'. E. long. 79° 21'.—Also, a town of Hindoostan, in the Carnatic; 17 miles S. of Tanjore.

TRICARICO, a town of Naples, in Basilicata, the see of a bishop, suffragan of Acerenza; 13 miles S.E. of Acerenza. N. lat. 40° 43'. E. long. 16° 8'.

TRICARIUM, in *Botany*, a genus of Loureiro's, the name of which alludes to the three nuts of the fruit, being derived from τριαις, three, and καρπος, a nut.—Loureir. Cochinch. 557.—Class and order, *Monocœcia Tetrandra*. Nat. Ord. *Rhamnii*, or possibly *Elæagni*, of Jussieu?

Gen. Ch. Male, *Cal.* Perianth of four ovate, slightly spreading, coloured leaves, converging at the points. *Cor.* Petals none. Nectary of four ovate depressed glands. *Stam.* Filaments four, shorter than the calyx; anthers roundish.

Female, interperfed with the male, *Cal.* Perianth inferior, minute, in four deep ovate divisions. *Cor.* none. *Pist.* Germen superior, roundish; style none; stigma laciniated.

Peric. Drupa roundish, fleshy, of three cells. *Seeds.* Nuts solitary in each cell, roundish, with three furrows.

Eff. Ch. Male, Calyx of four leaves. Petals none. Nectary of four glands.

Female, Calyx in four deep segments. Corolla none. Stigma laciniated. Drupa with three nuts.

1. *T. cochinchinense*.—Found in the woods of Cochinchina, where it is known by the name of *Cây Trám ung*. A tree of a middling stature, with ascending branches. Leaves alternate, small, ovate, entire, smooth. Flowers red, in long, simple, slender, aggregate, nearly terminal spikes or clusters. Drupa of a moderate size, yellow, smooth, eatable.—We cannot refer this plant to any described genus, nor are we certain whether it belongs to either of the above natural orders, or to the *Euphorbie*, or perhaps the *Terebin-taceæ*, of Jussieu. Difficulties attend each supposition.

TRICASSES, in *Ancient Geography*. See TRECASSES.

TRICASTINI, or TRICASTENI, a people of Gallia Narbonensis. Hannibal passed through this country in his way to the Alps. Mention is made of these people at the time of the march of the Gauls into Italy, under the conduct of Bellovescius; and Pliny as well as Ptolemy take notice of them, the former specifying Augusta as their capital. It is certain that they inhabited the left bank of the Rhone, in a small country called Tricastin.

TRICCA, a town of Greece, in Theffaly, in the Estiœotide territory. A modern place, named "Tricala," gives its just position, and answers to Strabo's account of the situation of this town. Venus was worshipped in this city, and the inhabitants offered to her sacrifices of swine.

TRICCIANA, a town of Pannonia, on the route from Sirmium to Carnuntum, between Pons Manfuetianus and Cimbrianæ. Anton. Itin.

TRICE, in *Geography*, one of the Nicobar islands. N. lat. 7° 30'. E. long. 94° 5'.

TRICENNAL. See TRENAL.

TRICEPS, in *Anatomy*, a name given to a large muscle of the arm, and to one of the thigh, from the circumstance of their arising by three distinct portions.

TRICEPS *adductor cruris*, (triceps femoris; sous-pubeus, sous-pubi-, and ischii femoriens; adductor longus, adductor brevis, and adductor magnus; long, short, and great heads of the triceps). This muscle is placed at the upper and inner part of the thigh, consisting of three flattened portions, distinct from each other, making up the large mass of muscle on the inside of the limb, and extending from the pelvis to the linea aspera of the thigh-bone.

The long head of the triceps, adductor longus or primus, the first in order of the three portions towards the front, is elongated and flattened, narrow above, and considerably wider below, and extends from the front of the pubes to the middle of the linea aspera. It arises by a narrow but strong tendon from the pubes, close to the symphysis; the muscle descends, passing at the same time obliquely outwards and backwards, and increasing greatly in breadth: it terminates below in a broad and flat aponeurosis, fixed to the middle of the linea aspera, in an extent of about three inches. Some fibres join the tendon of the adductor magnus, while others unite with the vastus externus. The fascia lata, the sartorius, and the crural artery, cover it in front: it covers behind the two other adductors. Its outer edge is parallel to the inner margin of the pectinalis, and connected to it by a cellular line: its inner margin is much longer, and covered, in nearly its whole extent, by the gracilis.

The short head, adductor brevis or secundus, is also of a flattened figure, placed at the upper and inner part of the thigh, and extending from the pubis to the upper part of the

linea aspera. It arises, principally by fleshy fibres, from the anterior surface of the body and ramus of the pubes; it passes obliquely downwards and outwards, with a little obliquity backwards, becoming broader and thinner, and having an attachment of about three inches to the linea aspera, from the little trochanter downwards. Here it is closely connected to the two other adductors, and to the pectinalis. The perforating arteries go through its fibres. The pectinalis and adductor longus cover it in front; the adductor magnus behind. The inner edge is partly covered by the gracilis, partly concealed between the first and third adductors: the outer corresponds to the obturator externus and the tendon of the psoas magnus.

The adductor magnus or tertius, or the great head, is a broad and thick mass, flattened, nearly triangular, placed at the inside of the thigh, where it reaches from the ischium to the whole length of the linea aspera, and to the tubercle of the internal condyle. It arises, by a strong aponeurosis and by fleshy fibres, from the external surface, and from the margin of the ramus and tuberosity of the ischium. From this point the muscular fibres spread out into a great breadth, and take very different directions; the superior going nearly transversely, the middle obliquely, and the inferior almost perpendicularly downwards. The general direction of the muscle is from above downwards, and from within outwards. Its attachment begins at the upper end of the linea aspera, just below that of the quadratus: it is fixed to the whole length of that line, being connected to the two preceding muscles. When the linea aspera bifurcates at its termination, the adductor magnus divides into two portions; an external or posterior, which ends in a point between the vastus internus and the short head of the biceps; and an internal or anterior, which is connected to the edge of the vastus, and descends with it to the internal condyle. These two portions have between them an interval, occupied by the femoral artery and vein: this interval is covered in front by an aponeurosis, extended from the adductor to the triceps, and passing over the femoral artery. There are other openings in the aponeurosis for the passage of the perforating arteries. The adductor magnus is fixed to the linea aspera by short aponeuroses; and to the tubercle of the internal condyle by a strong tendon, which is expanded above into a broad aponeurosis. The muscular fibres pass between the tendon and aponeuroses, which fix the muscle to the ischium, and those which are connected to the femur. The internal fibres are very long, and directed obliquely downwards and outwards: the middle ones are shorter, and directed more outwards, and the external or upper are the shortest, and nearly transverse.

The first and second adductors, the sartorius, and the crural artery, cover it in front: the semi-tendinosus, semi-membranosus, biceps, gluteus magnus, and sciatic nerve, cover it behind. The inner edge is covered by the gracilis, sartorius, and fascia: the outer edge is the insertion in the linea aspera. The upper margin, or the base of the triangle, is parallel and close to the under edge of the quadratus; the lower extremity, or apex, is the tendinous attachment to the condyle.

The triceps will move the thigh in the direction of adduction, or towards the opposite limb: it will carry one thigh across the other, as in fitting cross-kneed: it will press the thighs against any thing between them, as the sides of the horse in riding. The first and second heads will bend the hip: the third will extend it, when it has been previously bent. All three will rotate the thigh outwards. By drawing the thighs inwards, the triceps muscles keep them perpendicularly under the pelvis, so that they support it, and

through it the whole upper parts of the body. When we stand on one leg, the triceps will regulate the degree of inclination of the pelvis over the thigh, and prevent it from falling over on that side.

TRICEPS *extensor cubiti*, (triceps brachialis; anconeus longus, externus, and internus, Winslow; scapulo-humero-olecranium,) a large thick muscle, of an elongated figure, covering the back of the arm, and extending from the scapula and humerus to the olecranon. Its long head arises from the inferior edge of the scapula, just below the glenoid cavity, by a flat tendon, about three-quarters of an inch broad: the second or external head commences, in a pointed form, from the back of the humerus, a little below its head; and the third, internal, or shortest head, begins on the inner and posterior part of the humerus, an inch below the second. The two latter are separated from each other by an interval, in which the profunda humeri major artery runs, accompanied by the radial or muscular spiral nerve: this vessel and nerve continue their course, from the inner to the outer sides of the limb, between the muscle and the bone. Below the points mentioned already, as the origins of the second and third heads, these portions arise by fleshy fibres from the whole posterior surface of the humerus, except where the radial nerve and the profunda humeri pass, and from the inter-muscular aponeuroses fixed to the lateral ridges of the bone. The long or middle head continues distinct from the others for some distance, passes behind the shoulder-joint, between the teres major and minor muscles, and in front of the latissimus dorsi; it then soon joins the two others. It is first thin and flattened; then increases in size. The two other heads are pointed and thin above, and increase gradually: they all then join about the middle of the humerus, which is the thickest part of the muscle; for below it again decreases. From the aponeurosis of the middle head, and from the back of the humerus, the fibres are continued obliquely downwards and backwards into a broad and flat tendon, which covers the lower and posterior part of the muscle, becomes narrower and thicker as it descends, passes behind the elbow-joint, closely adhering to its synovial membrane, and is inserted into the upper and posterior rough extremity of the olecranon. Several fibres are detached from it to the fascia of the fore-arm, and particularly to that part of the fascia which covers the anconeus.

The posterior surface of this muscle is convex; covered above by the teres minor and deltoid, and in the rest of its extent, merely by the fascia and skin. The anterior surface is in contact above with the subscapularis, teres major, and latissimus dorsi; with the whole back of the humerus; and with the synovial membrane at the back of the elbow. The outer edge is fixed to the external ridge of the bone, and to the external intermuscular aponeurosis, the attachment being interrupted only at the passage of the radial nerve. The internal edge is fixed to the corresponding parts on the inside: the ulnar nerve lies on it. The upper extremity is divided into three portions, forming the three heads already described: the lower extremity is single.

The triceps extends the elbow-joint, by moving either the bones of the fore-arm on the arm, or *vice versa*. Its long head may carry the arm backwards.

TRICEPS, in *Mythology*, a surname given to Mercury, because he exercises his functions in heaven, on earth, and in the infernal regions, and is exhibited under three different forms, according to the three different places in which he is employed.

TRICERA, in *Botany*, from $\tau\rho\iota\varsigma$, three, and $\kappa\epsilon\rho\alpha$, a horn, because of the three horns, originating in the perma-

ment styles, which crown the seed-vessel. Dr. Swartz had originally called this genus *Crantzia*, but another having been so named by Schreber, he adopted the above, which is very expressive.—Swartz Ind. Occ. 331. t. 7. Schreb. Gen. 630. Willd. Sp. Pl. v. 4. 338. Mart. Mill. Dict. v. 4. (*Crantzia*; Swartz Prodr. 38.)—Class and order, *Monoclea Tetrandria*. Nat. Ord. *Tricocca*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, deeply divided into four lanceolate, acute, erect, coloured segments. *Cor.* none. *Stam.* Filaments four, fleshy, cylindrical, inclining to ovate, erect, longer than the calyx; anthers terminal, ovato-lanceolate, acute, erect, furrowed along one side, recurved after flowering.

Female, in the same tuft, or cluster, *Cal.* Perianth of five ovate, acute, erect, coloured, permanent leaves. *Cor.* none. *Pist.* Germen superior, somewhat triangular; styles three, short, somewhat conical, separable at length into two parts; stigmas linear, longer than the styles, spreading, recurved, channelled, permanent. *Peric.* Capsule turbinate, triangular, with three cells, three valves, and three recurved horns, each horn splitting, by the opening of the elastic capsule, into two parts. *Seeds* two in each cell, oblong, triangular, polished, each enveloped in a whitish membranous lax tunic.

Eff. Ch. Male, Calyx in four deep segments. Corolla none. Stamens fleshy.

Female, Calyx of five leaves, inferior. Corolla none. Styles three. Capsule with three cells, three elastic valves, and three horns. Seeds in pairs, with a membranous tunic.

1. *T. lævigata*. Smooth *Tricera*. Swartz Ind. Occ. 333. Willd. n. 1. (*Crantzia lævigata*; Sw. Prodr. 38. Vahl Symb. v. 2. 99.)—Leaves ovato-lanceolate, triple-ribbed; veinless beneath. Umbels axillary.—Native of bushy hills, in the western part of Jamaica, flowering in spring. Swartz. Vahl received it from Santa Cruz.—A branching shrub, two or three feet high; its branches long and spreading, smooth, leafy, obscurely quadrangular. Leaves stalked, opposite, two-ranked, an inch long, acute, convex, entire, very smooth, rather rigid. Footstalks short, round. Flowers whitish, in small, axillary, opposite, stalked umbels; the males from four to eight, with little white opposite bractees on their partial stalks; female solitary in the centre, rather larger, sessile, conspicuous for its long spreading stigmas. Capsule the size of a large pea, with three taper horns, exceeding its own length. Seeds black, and shining, in a loose white tunic. Dr. Swartz justly indicates the affinity of this plant to *Buxus*, from which it is principally distinguished by the want of a corolla, the form of the filaments and stigmas, and the tunic of its seeds.

2. *T. citrifolia*, Lemon-leaved *Tricera*. Willd. n. 3. —“Leaves ovate-oblong, pointed, triple-ribbed, veiny on both sides. Clusters axillary.”—Gathered by M. Bredermeyer in the Caraccas. A shrub fifteen feet high, resembling the Coffee-tree, branched, with a pale-grey bark, and hard yellow wood. Leaves rigid and shining, four inches long, and two broad, on short stalks. Clusters about an inch in length, of about ten white male flowers, on short, alternate partial stalks, with minute, acute bractees, and one solitary, sessile, terminal female flower. Filaments a little compressed, most tumid in the upper part. Fruit much as in the foregoing.

3. *T. cordifolia*. Heart-leaved *Tricera*. Willd. n. 3.—“Leaves elliptical, obtuse, veiny; somewhat heart-shaped at the base. Flowers in lateral tufts.”—Native of the West Indies.—A shrub, with round grey branches; the

young ones somewhat quadrangular, smooth. Leaves opposite, stalked, half an inch long, coriaceous, entire, finely veined on both sides, sometimes emarginate; shining above; paler beneath. Flowers small, on the last year's branches. *Willdenow.*

TRICEROS, a genus of Loureiro's, has precisely the same derivation as *TRICERA*. (See that article.) The latter being a clear and well-established genus, we cannot allow one whose history is obscure, and which may possibly be already known to systematic botanists, under some other denomination, to “exalt its horns” against its brother. As to priority of date, there is little to consider, they having been published within a year of each other, the author of each thinking his the original name. We shall, notwithstanding, here give the characters of the *Triceros*, for the information of those who may wish to inquire what it is.—Loureir. Cochinch. 184.—Class and order, *Pentandria Trigynia*. Nat. Ord.

Gen. Ch. *Cal.* Perianth inferior, of five acute, spreading, permanent leaves. *Cor.* Petals five, oblong, spreading, longer than the calyx. *Stam.* Filaments five, capillary, about the length of the petals; anthers ovate, of two cells. *Pist.* Germen superior, roundish, unequal; styles three, short, distant from each other at the base; stigmas simple. *Peric.* Berry coriaceous, round at the base, with three horns at the top, of three cells. Seeds roundish, pointed, two in each cell.

Eff. Ch. Calyx of five leaves. Petals five, oblong. Berry superior, of three cells. Seeds two in each cell.

Obf. Loureiro says “*bacca disperma*,” by which, according to his frequent mode of expression, he means there are two seeds in each of the three cells; at least, so we feel ourselves obliged here to understand him.

1. *T. cochinchinensis*. Cày áu rùng of the natives of Cochinchina, where this plant grows wild on the hills. It is a tree of a middling stature, with spreading branches. Leaves bipinnate, with two pair of ovate, pointed, serrated, rigid leaflets, besides a terminal one, in each subdivision. Flowers white, in loose, nearly terminal, clusters. Berries small, ufeless.

TRICETO, in *Geography*, a town of Naples, in Calabria Citra; 14 miles E.S.E. of Scalea.

TRICHECHUS, in *Zoology*, a genus of the order of Bruta, and class of Mammalia, in the Linnæan system: the characters of which are, that it has no fore-teeth in the full-grown animal, either above or below; that it has solitary tusks in the upper jaw; that the grinders on both sides are formed of a rugged bony substance; that the lips are geminated or doubled; and the hinder feet, at the extremity of the body, united into a fin.

This genus is altogether marine, comprehending few species. Gmelin, in his edition of the Linnæan System, enumerates the three following

Species and Varieties.

ROSMARUS, the *Rosmarus* of Johnston, the *Morse* of Buffon, the *Sea-horse* of Ray and Ellis, and the *Arctic Walrus* of Pennant and Cook's last voyage. It is characterized by its distant, exerted tusks. It inhabits the Northern seas, and chiefly within the arctic circle. It grows to a large size, having been found 18 feet long, and 12 feet in girth round the body. Its form is inelegant; having a small head, short neck, thick body, and short legs; the lips thick, and the upper one cleft into two large rounded lobes, the surface having numerous semi-transparent bristles of a yellowish tinge, and about the size of a straw in diameter, and three inches long, pointed at their extremities; the eyes

TRICHECHUS.

eyes small; round orifices instead of ears; the skin thick and wrinkled, and scattered over with short brownish hairs; with five toes on each foot, connected by webs; the hind-feet broader than the fore-feet, and the tail very short. In the upper jaw are two long tusks, sometimes two feet but generally about one foot in length, without cutting teeth, and with four roundish grinders. These animals are found about the northern parts of America, in the gulf of St. Lawrence between 47° and 48° lat., in Davis's straits, and within Hudson's bay in lat. 62°; in great numbers about Spitzbergen, also on the coast of Greenland and of Nova Zembla, and on the headlands extending towards the north pole. They are gregarious, produce their young, one at a time, early in the spring, and feed on sea-plants, shell-fish, &c.

Unprovoked the walrus is harmless, otherwise furious and vindictive. The female, when surprised on the ice, flings its young into the sea, plunges after it, and having carried it to a safe distance, returns with great rage to revenge the injury. They sometimes fasten their teeth in the boats, to sink them, or crawl under them, to overfet them, indicating, by gnashing their teeth and roaring frightfully, great tokens of rage. Their attachment to one another is very strong; for a wounded walrus plunges to the bottom, and rises again suddenly with a number of attendants to attack the boat whence they received insult. They are said to lie on the ice in herds of many hundreds, loudly roaring, and giving notice of ice in the night or in a fog, when it could not be seen: some of the herd are always on the watch, who, on the approach of danger, awake the rest. They are soon frightened by a flash in the musket-pan, and plunge into the deep; but the female will defend the young to the last, on the ice or in the water; nor will the young one quit the dam, though he be dead. In the gulf of St. Lawrence, this animal is called a sea-cow, and it is said to resemble a cow much more than a horse, which name may probably be a corruption of the Russian name Morfe. The teeth of the walrus are used for ivory: the animals are killed chiefly for the sake of the oil; and it is said that a very strong and elastic leather may be prepared from the skin.

DUGONG, the *Dugon* of Buffon, and the *Indian Walrus* of Pennant, with approximate, exerted tusks. This animal inhabits the seas about the Cape of Good Hope and the Philippine islands.

MANATUS, the *Manati* or *Sea-cow* of Ray, and *Lamantin* of Buffon; without tusks, or slightly hairy; and with a horizontal tail in place of hind-feet. Found in the larger rivers as well as seas of Guiana, and growing to the length of 16 or 18 feet; the skin being dark-brown, with scattered hairs upon it; the feet with five toes; the body nearly of the same thickness to the tail, when it suddenly narrows; the tail flat, of the shape of a spatula, thicker in the middle, and thinner towards the edges.

The *T. Clusii*, or Clusius's Manati, is supposed to be a variety: it grows to an enormous size in the South American rivers. As an article of food, it is said to be superior to any other animal of this genus, particularly the young. It is taken by means of harpoons. The Indians take great numbers, by making dams across the mouths of the shallow lakes formed by the floods. Dr. Shaw mentions a manati, called by the inhabitants of the country, on account of its gentle nature, "Matum," which, at the time of the arrival of the Spaniards, was kept by a prince of Hispaniola in a lake adjoining to his residence: it hated the Spaniards, but would offer itself to its Indian favourites, and carry over the lake tea at a time, singing and playing on its back. The *T. Hydrophilus*, or *Sea-ape Manati* of Pennant, is only

known from the description of Steller, who, near the coast of America, saw a singular animal which he named a sea-ape, and which Pennant supposes to belong to this genus. It was an animal that delighted in frolic, and sported like a monkey.

T. Australis, the variety α of *T. manatus*, according to Gmelin's Linnæus, but a distinct species in Shaw's Zoology; hairy, with four-toed unguiculated feet, or with a horizontal tail in place of hind-feet; the *round-tailed Manati* of Pennant; growing to the length of 14 or 15 feet, and found in the rivers of Africa, particularly in the Senegal. The specimen in the Leverian Museum was about six feet and a half long, and three feet eight inches in circumference in the thickest part of the body, and in the thinnest part near the tail about two feet two inches. The flesh of this animal is said to resemble veal; but it is chiefly killed by the Negroes for the sake of its blubber or fat.

T. Borealis, a variety of *T. Manatus* in Gmelin's edition of Linnæus, but a distinct species in Shaw's Zoology; hairless, with feet furnished neither with toes nor nails; or with a horizontal tail in place of hind-feet; the *whale-tailed Manati* of Pennant. It approaches nearly to the whale tribe; it never goes ashore, nor attempts to climb the rocks, like the walrus and the seal. It brings forth in the water, and, like the whale, suckles its young in that element. It inhabits the seas about Bering's and the other Aleutian islands, but never appears off Kamtschatka, unless blown thither by a tempest. It is the same species that inhabits near Rodriguez, or Diego Reys, an island east of the Mauritius, and probably extending to New Holland. These animals live perpetually in the water, but in calm weather frequent the mouths of rivers in great numbers, and approach in time of flood so near the land, that they will suffer themselves to be stroaked with the hand; but if hurt, swim out to the sea, presently returning again. They live in families, one near another; each consisting of a male, a female, a half-grown young one, and a very small one. The affection between the male and female is so great, that if the latter is attacked, the former will defend her to the utmost; and if she is killed, will follow her carcase to the shore, and for some days swim near the place where it was landed. They are very voracious, and when full of the fuci that grow in the sea, fall asleep on their backs. The back and sides are generally above water, and gulls are found perching on their backs, in order to pick up the insects which they find upon them. They are taken by harpoons fixed to a strong cord; but when struck, it requires the force of thirty men to draw them on shore. When a manati is struck, its companions swim to its assistance, and make many efforts to overturn the boat, or break the rope of the harpoon, and others will strike at the harpoon with their tails. They make a noise, by loud breathing, like the snorting of a horse. Their size is enormous, some being 28 feet long, and 8000 lbs. in weight. The circumference of the body near the shoulders is 12 feet, about the belly 20, near the tail 4 feet 8 inches, the head 31 inches, the neck near seven feet; and hence we may infer the deformity of the animal. Near the shoulders are two feet, or rather fins, two feet two inches long, without fingers or nails; beneath they are concave, and covered with hard bristles; the tail is thick, strong, and horizontal, terminating in a stiff black fin, and resembling the substance of whale-bone; the skin is thick, hard, and black, unequal on its surface, like the bark of oak, so hard as scarcely to be cut with an axe, and without hair; beneath the skin is a thick blubber, tasting like oil of almonds. The flesh is coarser than beef, and will not soon putrefy; that of the young ones has the taste of veal. The

skin is used for shoes, and for covering the sides of boats. The Russians call this animal "Moriska Korowa," or sea-cow, and "Kapustnik," or eater of herbs. Pennant's *Quadr.* vol. ii. Shaw's *Zoology*, vol. i. pt. 1.

TRICHERIÆ, in *Natural History*, the name of a genus of fossils, of the class of fibraria; the characters of which are, that they are not elastic, and are composed of straight and continuous filaments.

The word is derived from the Greek *τριχες*, capillaments or fibres. The bodies of this genus are divided into those which have narrower filaments; and there are six known species of it, all which burn very readily to a fine plaster, like the gypsums; and some of them are found in particular places in such great abundance, that it would be very advantageous to collect and burn them. Hill.

TRICHESTRUM, the name of a genus of fossils, of the class of the selenites, but differing extremely in figure and structure from the common kinds.

The word is derived from the Greek *τριχες*, hairs or filaments, and *αστρος*, a star, and expresses a set of bodies, composed of filaments arranged into the form of a star. The selenites of this genus are composed of filaments, scarcely any where visibly arranged into plates or scales, but disposed in form of a radiated star, made up of a number of disjunct striae.

Of this genus there is only one known species, which is of a pale brown, and is composed of extremely fine and slender filaments. It is formed like the lepastrum in the accidentally open cracks in the septaria, or ludus Helmontii, and is no other way different from the bodies of that genus, than as in all the selenites the plates they are composed of are made up of filaments nicely arranged: in this, as in some other of those bodies, the filaments have never arranged themselves into plates at all, but are disposed into the form of a star composed of single threads. This body very readily and regularly splits according to the arrangements of the fibres; and is in some pieces tolerably pellucid.

It is found only in one place, so far as is yet known, which is under the cliffs of Sheppey island, in Kent; where it is very plentiful, and makes a very elegant figure on the broken masses of septaria, which are in immense numbers strewn upon the shore. Hill.

TRICHIA, in *Botany*, first, we believe, received its name from Haller, though he admitted some things into this genus of *Fungi*, which other botanists have rejected, or referred to other places. The above name is formed from *τριχες*, *τριχος*, a hair, or bristle, in allusion to the internal mass of elastic fibres, gradually expanding after the head bursts.—Hall. *Hist.* v. 3. 114. Perf. *Syn. Fung.* 176. Lamarck *Illustr.* t. 890.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Ess. Ch. Head at length bursting irregularly, permanent. Internal fibres compact, attached to the base of the head, expanding elastically, and discharging the powdery seeds.

To shew the limits of this genus, as defined by the most eminent botanists in this department, we shall give a compendious view of Perfoon's eleven species.

SECT. 1. *Head turbinate, or pear-shaped.*

1. *T. Botrytis.* "Perf. *Disp. Meth.* 9. and 54." ("T. pyriformis; Hoffm. *Veg. Crypt.* v. 2. 1. t. 1. f. 1.")—Stalked, clustered, opaque, dark red; stalks longer than the heads, combined, somewhat racemose.—Found on decaying trunks of trees in autumn. Several specimens, cohering together, form a sort of tuft. Perfoon mentions a small and simple-stalked variety, with a solitary head, which he suspects may be *T. ferotina* of Schrader's

Journal, v. 2. 67. t. 3. f. 1, (not f. 2, as erroneously cited by the author, and by Perfoon; that being *Stilbum tomentosum*, p. 65.) The figure having been so widely mistaken, may account for the doubt expressed; but we are left in great uncertainty as to what Perfoon intended by his variety.

2. *T. rubiformis.* "Perf. *Disp. Meth.* 54. t. 4. f. 3. and t. 1. f. 3." (T. n. 2167; Hall. *Hist.* v. 3. 115. t. 48. f. 5.)—Stalked, clustered, of a shining blue; stalks combined, spreading at the base, shorter than the heads.—Not rare on the rotten bark of trees in autumn. There is a smaller variety, of a red or rusty aspect. Perfoon is remarkably incorrect in his citation of Haller, (n. 2162. t. 40. f. 2.)

3. *T. fallax.* Perf. *Obf. Mycol. fasc.* 1. 59. t. 3. f. 4, 5. ("Clathrus stipitatus, reticulo deciduo; Schmid. *IC.* t. 33. f. 1—18." *Sphærocarpus ficoides*; Bull. *Fung.* v. 1. 130. t. 417. f. 3; excluding the synonyms. *Mucor miniatus*; Jacq. *Austr.* t. 299.)—Simple, stalked; at first red; then of a dull grey. Base of the head, and top of the stalk, plaited.—Found in autumn, upon soft rotten wood. The head when young is bright red, and roundish; by age it becomes pear-shaped, on a stalk about its own length, and altogether of a dirty slate-colour, cracking and expanding at the top into a kind of cup. Jacquin's figure represents the young, Bulliard's the old, plant.

4. *T. clavata.* Perf. *Obf. Mycol. fasc.* 2. 34.—"Simple, yellow and shining. Stalk rugged, elongated, tapering downwards."—Found on the trunks of trees, either solitary, or composing dense tufts. It is among the larger species. The stalk is slender, of a reddish-yellow. We have seen no specimen nor figure.

5. *T. nigripes.* Perf. n. 5. (T. pyriformis; Perf. *Obf. Mycol. fasc.* 2. 33. Bull. *Fung.* v. 1. 129. t. 417. f. 2?)—Rather scattered. Head pear-shaped, yellowish, longer than the blackish stalk.—On the trunks of trees, but rare. The head is obovate and obtuse. Stalk half a line long, black, standing on a manifest membranous base common to many individuals. Perfoon remarks, that the stalk in Bulliard's plate is thicker than his, besides being of the same colour as the head. He mentions also a smaller more common variety, verging towards an olive hue, and more brittle than the above-described. The following, originally thought distinct, are now reduced by Perfoon to the species before us.

β. *T. cordata.* Perf. *Obf. Mycol. fasc.* 2. 33.—Nearly sessile, small, scattered, yellowish. Heads somewhat compressed, inversely heart-shaped. Stalk very short, blackish.—On trunks of trees.

γ. *T. cylindrica.* *Ibid.*—Rather scattered, ochre-coloured. Heads cylindrical or ovate, contracted in the middle. Stalk blackish, extremely short.—A pretty little fungus, occurring rarely on mosses, or the trunks of trees.

δ. *T. vulgaris.* *Ibid.* 32. (T. turbinata; Sowerb. *Fung.* t. 85?)—Scattered. Head roundish, somewhat turbinate. Stalk blackish, extremely short; sometimes entirely wanting.—Frequent after heavy rains in autumn, upon rotten beech-trees; appearing when young in the form of white granulations, turning afterwards of the colour of yellow ochre, and more opaque. The stalk in an early state is hardly discernible. Mr. Sowerby's synonym seems to us to belong to the following, as he himself supposed.

6. *T. ovata.* Perf. *Obf. Mycol. fasc.* 1. 61. fasc. 2. 35. (T. pyriformis; Villars *Dauph.* v. 3. 1060. T. n. 2168; Hall. *Hist.* v. 3. 116. t. 48. f. 7. *Clathrus turbinatus*; Hudf. 632. Bolt. *Fung.* 94. t. 94. f. 3.)—Crowded, sessile, obovate, opaque, of an ochrey tan-colour.—Frequent

in autumn, in woods, upon rotten wood, mosses, &c.—It forms dense tufts, each plant the size of garden poppy-feed, and bursting in an irregularly circular manner, near the top. This is one of our most frequent species.

7. *T. olivacea*. Perf. Obs. Mycol. fasc. 1. 62.—Scattered, sessile, roundish, or obovate, abrupt at the base, olive-coloured. Internal hairs compact, yellowish.—Found rarely on the stems of trees. Heads globular, or hemispherical, becoming by mutual pressure, when crowded, oblong, or somewhat cylindrical. Perfoon is doubtful whether this be a distinct species. We have seen no specimen.

SECT. 2. *Head round, or kidney-shaped.*

8. *T. nitens*. Perf. Obs. Mycol. fasc. 1. 62. (“*Lycoperdon favogineum*; Batsch Elench. Fung. 257. t. 173.”) —Crowded, sessile, globular, of a shining yellow or cinnamon-colour.—Found in autumn, about the decaying trunks of fir-trees, as well as on beeches. In the former case it is more opaque; in the latter more bright and shining. The head is occasionally a little turbinate.

9. *T. varia*. Perf. Obs. Mycol. fasc. 2. 32. (*Lycogala luteum, omnium minimum, reniforme*; Mich. Nov. Gen. 216. t. 95. f. 4.)—Rather crowded, yellowish, partly deflexed. Head kidney-shaped, roundish, or somewhat oblong.—Grows on rotten trees in autumn. Found by Micheli in the celebrated gardens of Boboli, behind the palace Pitti, at Florence. He represents it as forming globular masses, the size of a large pea, each plant smaller than poppy-feed. The lateral ones appear to be deflexed, or forced outward, by those in the middle.

SECT. 3. *Receptacle elongated, thread-shaped, creeping, simple, or interbranching like veins.*

10. *T. Serpula*. “Perf. Disp. Meth. 10.” (*Mucor Serpula*; Scop. Carn. 493. t. 65.)—Thread-shaped, unbranched, very long, somewhat zigzag, yellow.—On the trunks of trees in Carniola, near the roots. *Scopoli*. This is represented as a smooth yellowish thread, creeping like a *Serpula*, or Worm-shell, and resembling a small animal intestine. It bursts and discharges, from every part, tufts of fine hairs besprinkled with yellow powder. *Scopoli*. *T. spongoides*, Villars Daup. v. 3. 1061, is thought by Perfoon to be a variety of this. But the author’s description of “from three to five little oblong, cylindrical, worm-like bodies, whose yellowish internal woolly substance soon confounds them in one woolly mass,” indicates rather some of the former sections, or perhaps an *Arcyria*.

11. *T. reticulata*. “Perf. Ic. et Descr. Fung. fasc. 2. 46. t. 12. f. 1.” (*Lycoperdon lumbricale*; “Batsch Elench. Fung. 259. t. 30. f. 174.” Willd. Berol. 414.)—Thread-shaped, branched, reticulated, yellow.—Found in autumn on the trunks and mossy bark of trees, but very rarely. We have never heard of this or the preceding in Britain. The present species is described as spreading to the extent of an inch, consisting of a yellow net-work, bursting here and there, and protruding tufts of yellow hairs, enveloping a powder, or seeds, of the same colour.

It will readily be perceived that the species of this genus, however curious, can, as yet, be but imperfectly defined; nor are we certain how far the *Arcyria*, *Stemonitis*, *Cribraria*, &c. of Perfoon are entitled to rank as generically distinct.

TRICHIASIS, (derived from $\tau\rho\iota\chi\eta$, *the hair*,) in Surgery, sometimes also named *entropion*, denotes a faulty inclination of the eye-lashes inwards against the globe of the eye. According to Scarpa, the disease presents itself under two distinct forms: the first is, where the cilia are turned inwards, without the natural position and direction of the tarsus being at all changed; the second consists in a morbid inclination of

the tarsus, and consequently of the eye-lash towards the ball of the eye.

The first form of this disease is very rare, nor has it come under the observation of the experienced Scarpa more than once; and in this instance, only some of the hairs had changed their direction. The second species or form of trichiasis, or that which consists in a folding inwards of the tarsus and cilia at the same time, is that which is commonly met with in practice. This may be either complete, affecting the whole of the tarsus; or incomplete, occupying only a certain portion of the edge of the eye-lid, and most frequently near the external angle of the eye. Sometimes the disease is confined to one eye-lid; at other times it affects both; and occasionally the patient is afflicted with it in both eyes.

To these two species of trichiasis, some writers have added a third, which they call *distichiasis*, and which they suppose to be produced by a double and unusual row of hairs. But this third species, as Scarpa observes, is only imaginary, and the reason of such subdivision seems to have arisen from not recollecting what was long ago remarked by Winslow and Albinus, that although the roots of the cilia appear to be disposed in one line only, they nevertheless form two, three, and in the upper eye-lid even four rows of hairs, unequally situated, and as it were confused. Whenever, therefore, in consequence of disease, a certain number of hairs are separated from each other in a contrary direction and disorderly manner, the eye-lash will appear to be composed of a new and unusual row of them, while, in fact, there has been no change, either with respect to their number or natural implantation.

It is not an easy matter to determine precisely, says Scarpa, what are the causes which sometimes make a few of the hairs deviate from their natural direction, while the tarsus continues in its right position. They are commonly referred to cicatrices in consequence of previous ulceration, whereby the cilia fall off, and those which are growing are hindered from taking their proper direction. There must, however, be other causes sometimes concerned; for in the case seen by professor Scarpa, two or three hairs were turned inwards against the eye-ball, although there had been no preceding ulceration, nor cicatrices of any part of the tarsus. Indeed Scarpa is inclined to believe, that the small ulcers and scars which are sometimes formed upon the internal margin of the tarsus, are more likely to produce the second form of the disease, or the inversion of the edge of the eye-lid, and consequently of the cilia towards the globe of the eye. As these ulcers, when neglected, destroy the internal membrane of the eye-lids near the tarsus, it necessarily follows, that in proportion as they heal and diminish, they draw along with them and turn inwards the tarsus, and hairs inserted into it. And since these little ulcerations do not always occupy the whole extent of the internal margin of the eye-lid, but are sometimes confined to a few lines, in the middle or extremity, near the external angle of the eye-lid; so after the cicatrices are formed, the whole of the hairs are not invariably turned inwards, but only a certain number of them, which correspond to the extent of the ulcers previously situated along the internal edge of the tarsus. Indeed, in every case of imperfect trichiasis from a cicatrix of the inner margin of the eye-lid, the tarsus and cilia are every where in their natural situation, except opposite the part where the ulcers formerly existed. Also, if the eye-lid be everted, its internal membrane, near that part of the margin corresponding to the seat of the trichiasis, will be found pale, rigid, and hardened, the inversion of its cartilaginous border and of the cilia being plainly a consequence of the contraction of the cicatrized point.

Besides these causes, there are others which may produce the complaint. Chronic ophthalmies of long continuance sometimes have this injurious effect, in consequence of the skin of the eye-lid being kept for a long time in a state of distention and œdema, terminating in a relaxation of them. The cartilaginous margin of the eye-lid then loses the proper support of the integuments, inclines towards the eye-ball, and afterwards turns inwards, drawing the eye-lashes along with it in the same improper direction. Long-continued puriform discharges from the ciliary glands, likewise spoil the shape and consistence of the cartilage of the eye-lid, and therefore not unfrequently occasion trichiasis. Scarpa doubts, whether a spasmodic contraction of the orbicularis palpebrarum muscle can ever be a cause of the disease, notwithstanding what Mr. B. Bell has asserted upon the subject.

The annoyance which must necessarily result from the hairs perpetually pressing upon the cornea and white of the eye, may be easily imagined, even by those who have little acquaintance with surgery. The evil is rendered still greater, by the hairs which are turned inwards becoming much longer and thicker than those which retain their natural direction. And although the trichiasis be confined to one eye, both the eyes usually suffer from the effects of the disease. Indeed, generally the eye on the sound side cannot be moved without occasioning pain in that which is exposed to the irritation and friction of the inflected hairs. In almost all instances, both the eyes are very irritable, and incapable of bearing the light. As, in cases of incomplete trichiasis, the patient retains some little power of opening the eye-lids for the purpose of seeing, and that most frequently towards the internal angle of the eye, the head and neck are often inclined in an awkward manner, so that in children a distortion of the neck and shoulders is at last produced, which cannot be rectified without difficulty, even after the trichiasis is cured. Unfortunately, also, children are impatient of the uneasiness arising from the inflected hairs, and, therefore, are continually rubbing the eye-lids, which act very much increases all the ill effects of the complaint, such as the varicose chronic ophthalmia, opacity, and ulceration of the cornea.

The cure of the second species of trichiasis, or that which is commonly met with in practice, is accomplished by artificially everting the eye-lid, and fixing it permanently in its natural position, together with the eye-lashes, which so grievously irritate and press against the globe of the eye. According to professor Scarpa, this indication is perfectly fulfilled by the excision of a piece of the skin close to the edge of the eye-lid, of such a breadth and extent, that when the cicatrix is formed, the tarsus and margin of the eye-lid may be turned outwards, and sufficiently separated from the eye-ball, the cicatrix of the integuments affording a point of support fully adequate to keeping the parts in their natural position and direction. Scarpa believes that there are now very few modern surgeons, who, with a view to the radical cure of this disease, place any confidence either in plucking out the inverted eye-lashes, bending them outwards, and retaining them so by means of adhesive plaster, or in plucking them out and destroying their roots with caustic: much less in extirpating the edge of the eye-lid along with the hairs, or dividing the orbicularis muscle on the internal surface of the eye-lid, under an idea that the disease is sometimes produced by a spasmodic contraction of it.

The following is the mode of proceeding recommended by Scarpa: the patient being seated in a chair, if an adult, or, if a child, laid upon a table, with the head raised, and firmly held by an assistant, who must stand behind the patient, the surgeon is to push outward, with the end of a

probe, the hairs which irritate the eye. Then, with a pair of dissecting forceps, or the ends of his fore-finger and thumb, (which answer equally well, and, in many cases, much better than forceps,) the operator should lift up a fold of the skin of the affected eye-lid, taking great care that the piece which is taken hold of, corresponds exactly to the middle of the whole extent of the trichiasis; for, as we have already explained, sometimes the whole, sometimes a half, and, in other instances, only a third of the extent of the tarsus is inverted. The surgeon, with his left-hand, must raise the fold of the skin, more or less, according as the relaxation of the integuments, and the inversion of the tarsus, are more or less considerable. The reason of this is exceedingly evident, *viz.* that the greater the quantity of skin is which is raised, the greater is the quantity which will be cut away. Supposing the patient to be an adult, as soon as the fold of skin has been raised in a certain degree, the surgeon must request him to open his eye, and if, in this act, the tarsus and eye-lashes resume their natural place and direction, the portion of skin already raised will be sufficient for the purpose. We must trust to our own judgment with regard to children, as they seldom let us have recourse to the mode of discrimination just related. When the integuments are elevated by means of a pair of dissecting forceps, and care is taken to lay hold of the skin precisely at the middle point of the whole extent of the trichiasis, it necessarily follows, that the consequent section of the skin will form an oval, and that the greatest width of the wound will correspond exactly, or nearly so, to the middle of the eye-lid, and its narrowest parts to the angles, or commissures of the same. This contributes very materially to make the cicatrix correspond to the natural fold of the eye-lid, and hinder the origin of a disease of an opposite nature to the one about to be remedied, towards the angles of the eye, *viz.* an eversion of the commissures of the eye-lids. See ECTROPIUM.

Besides this caution relative to the situation and figure of the fold of the integuments to be cut off, the surgeon must be careful that the division of the skin be made very near the inverted tarsus. Were this circumstance neglected, the operator might have the mortification of finding, after the wound is healed, that although the eye-lid is shortened, on the whole, from the eye-brow to the place of the resection, yet it is not equally so at the space which is between the edge of the eye-lid and the cicatrix of the skin. Hence the tarsus would remain inverted as before, or not be sufficiently turned outward to keep the eye-lashes from rubbing against the eye. This inconvenience would oblige the patient to submit to a second operation, done lower down than the first.

Things being thus arranged, the surgeon, holding up the fold of skin by means of the forceps in his left-hand, is with a pair of probe-pointed, sharp curved scissors, to cut off the whole of the duplicature, being first sure that one of the blades of the instrument is applied close to the edge of the eye-lid. If both eye-lids should be affected, the same operation must immediately be done upon both of them, with such cautions, and in such proportion, as the extent of the disease, and the degree of inversion of each eye-lid may require.

Scarpa next dissuades us from employing any suture to unite the wound, and represents, that it will be sufficient to keep the eye-brow as much downward as possible, if the operation has been done on the upper eye-lid, or, if on the lower, to support it against the inferior arch of the orbit, by pressing it from below upwards, so as to keep the edges of the wound from becoming separated. Then the lips of the

TRICHIASIS.

the wound are to be put into exact contact, by means of strips of adhesive plaster, which should extend from the superior arch of the orbit to the zygoma, and the support of the wound in apposition will be still more securely effected by placing two compresses, one on the eye-brow, and another on the zygoma, together with a bandage.

On taking off the first dressings, the third day after the operation, the surgeon will find that the patient can open his eye with ease, and that the inverted tarsus and eye-lashes have resumed their natural position and direction. In the partial or incomplete trichiasis, or that which only occupies a half, or a third of the whole length of the tarsus, and in subjects who have had the skin of the eye-lids very loose, Scarpa has often had the pleasure of finding the wound perfectly united on removing the first dressing.

When, however, only a part of the incision has healed, while the rest seems disposed to heal by suppuration and granulation, the surgeon covers the wound with a small piece of lint, spread with the unguentum ceruise; and if the sore should become slabby, it must be touched, every now and then, with the *argentum nitratum*, until the cure is perfected, which commonly happens in the course of a fortnight.

Thus far, Scarpa's observations have related to the radical cure of the second, or most frequent kind of trichiasis.

With regard to the first form of this disease, or that in which the eye-lashes project against the eye-ball, without the natural position of the tarsus being at all altered (a case which is fortunately very rare), the accomplishment of a cure is very difficult, since, as we have already explained, neither the pulling out of the hairs, nor burning the situation of their roots, are means at all to be depended upon for producing a complete cure of the disorder; and since turning the tarsus out of its natural position would make the patient liable to an irremediable flowing of the tears over the cheek, attended with a chronic thickening of the lining of the eyelid. The treatment of this species of trichiasis is still imperfectly understood, and seems to claim more attention than appears hitherto to have been paid to it. In the instance of this form of the disease which Scarpa met with, only two or three of the eye-lashes inclined against the eye-ball. He found, on turning the eye-lid a little out, opposite to the situation of the faulty hairs, that he could not, indeed, completely put them in their natural position; but he saw that he could thus remove them so far from the cornea, that they would not rub against it, without altering the position of the eye-lids so much as to occasion a perpetual discharge of the tears over the cheek. And, as in the patient alluded to, the skin about the eye-lid was very tense, Scarpa deviated from the above rule, by making an incision with the back of a lancet, near the tarsus, three lines long, and he took away a small piece of skin of the same length; but very little more than one line broad. When the cut healed, the operation was found to answer as well as the nature of the case would allow, though the cure was not complete, nor would it have obviated all inconveniences in cases of greater extent.

The trichiasis being cured, something more always remains to be done, for the purpose of correcting the cause of the disease, as well as curing the disorder of the eye, occasioned by the previous friction and irritation of the inverted hairs. The usual indications are, to restore the tone of the vessels of the conjunctiva, to lessen the swollen Meibomian glands, and to remove any cloudiness of the cornea.

Two new methods of performing the operation, for the

cure of trichiasis, have been recently proposed by Dr. Crampton and Mr. Saunders.

The following is the account which Dr. Crampton gives of his plan, which he tried in one instance with complete success. "Let the eye-lid be well turned outwards by an assistant; let the operator then with a lancet divide the broad margin of the tarsus completely through, by two perpendicular incisions, one on each side of the inverted hair or hairs; let him then, by a transverse section of the conjunctiva of the eye-lid, unite the extremities of the perpendicular incisions. The portion of cartilage contained within the incisions, can then, if inverted, with ease be restored to its original situation, and retained there by small strips of adhesive plaster, or perhaps, what is better, by a *suspensorium palpebræ*, adapted to the length of the portion of the tarsus which it is intended to sustain, should one or two hairs be displaced without inversion of the tarsus." *Essay on the Entropion*, p. 55.

Mr. Saunders entertained a favourable opinion of Dr. Crampton's operation for the cure of the disease in its early stage; but he contended, such a vicious bending of the tarsus inward was often the consequence of repeated ophthalmia, attended with ulceration of the conjunctiva and inside of the eye-lid; and that every endeavour to rectify the wrong position of the tarsus, and restore its original direction, would be fruitless. Hence, he believed, that its excision was decidedly indicated; an operation which is said to be followed by no pain nor uneasiness, and which is sure in its effect. No particular shortening of the eye-lid ensues; the deformity is materially lessened; and unless the cornea be already too opaque, perfect vision is re-established.

Mr. Saunders directs a piece of thin horn, or a plate of silver, having a curvature corresponding to that of the eyelid, to be introduced under this part, with its concavity towards the eye-ball. On this instrument the eye-lid is to be stretched. An incision is to be made through the integuments and orbicularis palpebrarum, down to the tarsus, immediately behind the roots of the cilia. The cut should extend from the *punctum lachrymale* to the external angle. The exterior surface of the tarsus is then to be dissected, until the orbital margin is exposed, when the conjunctiva is to be cut through directly by the side of the tarsus, which must now be disengaged at each extremity. The *punctum lachrymale* must be left uninjured. The operation is described as being exceedingly simple, and if any embarrassment arises, it is from the hæmorrhage of the ciliary artery, the blood sometimes obscuring the *punctum lachrymale*, just when the operator is about to divide the tarsus by the side of it. No dressings are required, it being merely necessary to keep the eye covered for a few days. The skin will continue to be elevated, just as the perfect eye-lid was; and though less completely, yet enough to leave the pupil clear, when the eye is moderately directed upward. In all the cases in which Mr. Saunders operated, a fungus grew from the wound. He recommends the excrescence to be destroyed with caustic, or the knife.

Respecting this operation, we shall merely observe, that it is more severe than that advised by professor Scarpa, and must leave more disfigurement. Unless, therefore, the latter method prove ineffectual, we see no reason for abandoning it.

Inversion of the lower eye-lid is much less common than that of the upper one. The late Mr. Saunders never saw this disease arise from the same causes which induce it in the upper eye-lid, though he acknowledges the possibility of such a case. However, he met with several instances of the affection, in consequence of encysted tumours, which,

as they increased, carried the orbital edge of the tarsus outwards, and, in the same proportion, inclined the ciliary edge towards the globe of the eye.

An inversion of the inferior palpebra is sometimes produced by inflammation and swelling of that part of the conjunctiva which connects the eye-lid with the eye-ball. In cases of ophthalmia, this membrane often forms between the latter parts a distinct fold, which is situated just on the inside of the orbital edge of the tarsus, and pushes it outward; while the contraction of the orbicularis musculus turns the ciliary edge inwards, and inclines it between the swelling of the conjunctiva and the eye. In this particular case, Mr. Saunders assures us, that replacing the eye-lid in the early stage of the disease, and maintaining it so, until the ophthalmia has been lessened by proper means, will be found effectual. But when the conjunctiva is much thickened and indurated, Mr. Saunders recommends cutting such diseased part of it away, and the application of compresses to keep the orbital margin of the tarsus inward.

Albinus has recorded a species of trichiasis, which originated from the growth and inversion of one of the hairs upon the caruncula lachrymalis. The plan of relief consisted in plucking out the irritating hair; but, as Scarpa observes, it should have been mentioned whether the hair grew again, and in what direction. Scarpa on Diseases of the Eyes, ch. 4. Saunders on Diseases of the Eyes, chap. 3. Crampton on Entropion. S. Cooper's Practice of Surgery, p. 308. edit. 3.

TRICHIDES, in *Ichthyology*, a name used by the ancients for a fish of the harengiform kind, probably the pilchard, which they called also *sardinia* and *sardella*.

TRICHILIA, in *Botany*, a name apparently originating with Browne, and which De Theis has derived from τριχων, *three-fold*, no otherwise applicable to this fine genus, than as the capsule has three cells and three valves, very conspicuous in Sloane's figure of the original species, which probably the author had under his eye. Professor Martyn leaves this name unexplained.—Browne Jam. 278. Linn. Gen. 211. Schreb. 285. Willd. Sp. Pl. v. 2. 552. Mart. Mill. Dict. v. 4. Ait. Epit. 375. Swartz Ind. Occ. 730. Juss. 265. Poir. in Lamarck Dict. v. 8. 56. Gært. t. 95. (Portesia; Cavan. Diff. 369.)—Class and order, *Decandria Monogynia*. Nat. Ord. *Tribilata*, Linn. *Melia*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, short, with five small teeth. Cor. Petals five, lanceolate, spreading. Nectary cylindrical or conical, tubular, with ten teeth, shorter than the petals, formed, as it were, out of the ten combined filaments. Stam. Filaments none; anthers ten, erect, sessile on the margin of the nectary, and rising above it, deciduous. Pist. Germen superior, obovate, obscurely three-lobed; style short; stigma capitate, with three notches. Peric. Capsule roundish, slightly triangular, of three cells, and three valves at length reflexed, with partitions from the centre of each. Seeds solitary, pendulous, ovate, with a pulpy coat, or tunic.

Eff. Ch. Calyx with about five small teeth. Petals five. Nectary cylindrical, bearing the anthers on its teeth. Capsule of three cells, and three valves. Seeds solitary, with a pulpy coat.

Obs. The parts of the flower vary, or differ in different species, from five and ten to four and eight. The cells and valves of the capsule are, in some instances, but two, as in the *Portesia* of Cavanilles. The seeds have truly a more or less pulpy coat, though not a distinct tunic. It is remarkable that Cavanilles has not admitted *Trichilia* into his Dissertations on Monadelphous Plants, where this genus is as much

entitled to a place as any others of Jussieu's *Melia*. Probably he was not furnished with any materials to describe or delineate the species. The gardens certainly could not supply him.

1. *T. birta*. Green-flowered *Trichilia*. Linn. Sp. Pl. 550. Willd. n. 1. Swartz Obs. 171. (T. n. 1; Browne Jam. 278? *Pruno forte affinis arbor, folio alato, flore herbaceo pentapetalo racemoso*; Sloane Jam. v. 2. 128. t. 220. f. 1.)—Leaves pinnate, of about seven elliptical, pointed, smooth leaflets. Clusters dense, stamens combined.—Native of Jamaica, in the meadows about Kingston and other places, on a dry gravelly soil. Browne calls it a *shrub*; Sloane a *tree*, about twenty feet high, with a smooth greyish bark, and sending out at the height of seven feet, or more, several declining *branches*. The *leaves* are scattered, not numerous, pinnate with an odd one; the *leaflets* opposite, an inch and half long, uniform, smooth, entire, dark green, on short partial stalks. *Flowers* greenish-white with purple *anthers*, in axillary compound clusters. Browne says the *seeds* of all the species are enveloped in a scarlet waxy substance. Linnæus, and perhaps Browne, confounded this with the following. We do not find much reason for the specific name *birta*, which seems more applicable to the following.

2. *T. spondioides*. White-flowered *Trichilia*. Jacq. Amer. 128. Hort. Schoenbr. v. 1. 54. t. 102. Willd. n. 2. Swartz Ind. Occ. 730. (*Euonymus caudice non ramoso, folio alato, fructu rotundo tripyreno*; Sloane Jam. v. 2. 103. t. 210. f. 2, 3.)—Leaves pinnate, of about fifteen ovate-lanceolate, pointed leaflets; downy at the edges. Clusters rather lax. Stamens distinct.—Native of mountainous woods in Jamaica and Hispaniola, flowering in the spring. Swartz. In the stove at Schoenbrun, according to Jacquin, it blossomed in September and October.—The *stem* is fifteen or twenty feet high, slightly branched at the top. *Leaves* a foot long; their *leaflets* much more numerous than the former, ovate-lanceolate, not elliptical, more or less hairy, especially at the edges. *Clusters* several, less crowded than in the foregoing. *Flowers* yellowish or greenish-white. *Stamens* not united, though closely converging into a cylinder, or cone. *Capsule* roundish, downy, the size of a small cherry. We should conceive this rather to be Browne's plant, which he terms *subhirsuta*, but we have no specimen to determine the point.

3. *T. emetica*. Emetic Arabian *Trichilia*. Vahl Symb. v. 1. 31. Willd. n. 3. (Elcaja; Fork. Ægypt.-Arab. 127.)—"Leaves pinnate; leaflets elliptical, downy beneath, the outer ones largest."—Frequent on the mountains of Yemen. The Arabs call this tree *Roka*. The *flowers* resemble orange-blossoms. The *fruit*, mixed with perfumes, is used by the Arabian women for washing their hair. The ripe *seeds* are made into an ointment with oil of *Sesamum*, against the itch. Forkall found mention of the *fruit*, in an Arabic book, as an emetic, by the name of *Djouz elkai*, whence he took his barbarous generic name above quoted. He describes this species as a large *tree*, with alternate downy *branches*. *Leaves* alternate, pinnate with an odd one, of nine oval-oblong, stalked *leaflets*, the lower ones two inches in length, the upper or outer ones three; all smooth above, but, according to Vahl, downy beneath; their *common stalk*, about a span long, is also downy. *Stipulas* none. *Stalks* axillary, corymbosely panicled. *Flowers* twice the size of the last, greenish-yellow. *Stamens* united half way up. *Capsule* obovate, downy, an inch long, with two *seeds* in each cell. Forkall, Vahl.

4. *T. glabra*. Smooth Havannah *Trichilia*. Linn. Syft. Nat. ed. 12. v. 2. 294. Willd. n. 4. (T. havanensis; Jacq. Amer. 129. t. 175. f. 38.)—Leaves pinnate; leaflets obovate, obtuse, smooth; tapering at the base; the outer-

TRICHILIA.

most gradually largest.—Native of mountainous woods about the Havannah. A lofty, branched, spreading tree, exhaling a fetid, very disagreeable scent. *Leaves* from five to seven smooth and shining leaflets, nearly sessile; on a slightly winged stalk, about five inches long. *Clusters* axillary, very short. *Capsules* globose, greenish. *Jacquin*.

5. *T. pallida*. Pale Trichilia. Swartz Ind. Occ. 733. Willd. n. 5. (*Portefia ovata*; Cavan. Diff. 369. t. 215.)

—Leaves pinnate; leaflets smooth, membranous, elliptic-oblong. *Clusters* axillary, simple, somewhat aggregate. *Flowers* four-cleft, octandrous. *Capsules* of two valves only. —Native of bushy places, in the mountainous parts of Hispaniola, flowering in February and March. A tree, whose trunk is from twelve to fifteen feet high, branched, smooth, with nearly horizontal, smooth, round, subdivided branches. *Leaves* large and handsome, thin, reticulated with innumerable veins. *Leaflets* from two to five inches long, the outermost gradually largest, the partial stalk of the terminal one not longer than the rest. *Clusters* about an inch long, usually two or three together, somewhat downy, or silky. *Flowers* whitish. *Calyx* and *petals* downy. *Nectary*, or eight combined stamens, externally smooth, hairy within at the summit. *Capsule* roundish, of two cells and two valves, with two seeds in each cell, one above the other, invested with scarlet viscid pulp.

6. *T. moschata*. Musky Trichilia, or Musk-wood. Swartz Ind. Occ. 735. Willd. n. 6.—Leaves alternately pinnate; leaflets ovate, pointed, smooth. *Clusters* axillary, compound. *Flowers* four or five-cleft, monopetalous. *Nectary* undivided. *Capsule* with one seed.—Found in old woods of the northern part of Jamaica, flowering in May. The inhabitants know this tree by the name of *Musk-wood*, because every part, the bark, bruised leaves, flowers, and fruit, smell powerfully of musk. The pulp of the seed has a sweet taste. The trunk is twenty feet high, or more. *Leaflets* alternate, veiny; shining on the upper side; on very short partial stalks; their common stalk hoary. *Clusters* solitary, erect, of many small whitish flowers. *Calyx* downy. *Corolla* in four or five deep ovate segments, with a short tube. *Nectary* scarcely longer than the tube of the corolla, undivided, bearing rarely more than eight anthers, though the corolla is generally five-cleft. *Capsule* down, of three or four valves. *Seed* solitary, like a drupa with a brittle skin, and a juicy rich scarlet pulp, including a hard oblong kernel, separable into two parts.

7. *T. odorata*. Sweet-scented Trichilia. Andr. Repof. t. 637. Ait. Epit. 375.—Leaves oppositely pinnate; leaflets elliptic-lanceolate, pointed, smooth. *Clusters* axillary, compound, dense. *Petals* four. *Nectary* in ten double-pointed segments, with a slightly stalked anther between the points.—Native of the West Indies? It was sent by Dr. A. Anderson, from the botanic garden at St. Vincent's to Sir Abraham Hume, about the year 1801, and flowered in his stove at Wormleybury, in 1810. The plant has a musky scent, but appears otherwise different from the last. The leaflets are seven or nine; their common stalk smooth, except when very young. *Flowers* pale green, numerous, in short, dense, compound clusters. We find them, as described in Mr. Andrews's work, with four broad-ovate separate petals, though the nectary consists of ten flat segments, united half way up, deeply forked at the summit, and each bearing from the fork an ovate, inflexed, two-celled anther, on a very short slender stalk, or filament. Nothing is known of the fruit.

8. *T. spectabilis*. Handsome New-Zeeland Trichilia. Forst. Prodr. 33. Willd. n. 7.—“Leaves pinnate; leaflets obovate. *Clusters* axillary, compound.”—Gathered by

Forster in New Zealand. His specific character, all we know of the plant, is not sufficient to distinguish it from our fourth species, *T. glabra*, though the two species are probably widely different.

9. *T. alliacea*. Garlic Trichilia. Forst. Prodr. 33. Willd. n. 8.—“Leaves pinnate; leaflets lanceolate, acute. *Clusters* axillary, repeatedly compound.”—Native of the island of Namoka.

10. *T. glandulosa*. Glandular-veined Trichilia.—Leaves pinnate; leaflets five or seven, elliptic-lanceolate, bluntly pointed, with axillary hairs on their veins beneath. *Petals* four. *Nectary* undivided. *Stigma* depressed.—Native of New South Wales, near Port Jackson. A specimen from thence was communicated to us by Sir Joseph Banks, under the name of *T. octandra* of Solander, which not being published, we presume to change, as the octandrous species of this genus are numerous, though this only was then known to the great botanists who first discovered it. The leaves agree nearly with *T. heterophylla*, hereafter described, in size and shape, but are all pinnate, and remarkable for axillary glands, bearing tufts of hairs, along the mid-rib of each leaflet beneath, as in the Laurustinus, of which we perceive no indications in any other species, except perhaps the first. *Clusters* axillary, solitary, stalked, an inch or two in length, simple, of few flowers. *Calyx* four-cleft, minutely fringed. *Petals* four. *Nectary* undivided. *Anthers* eight, sessile. *Stigma* capitate, broad. *Capsule* triangular, depressed, with three deflexed lobes. *Seeds* in a red, pulpy, elastic tunic.

11. *T. heterophylla*. Various-leaved Trichilia. Willd. n. 9. (*Portefia mucronata*; Cavan. Diff. 370. t. 216.)—Leaves pinnate or ternate; leaflets elliptic-obovate, pointed. *Clusters* simple, axillary and terminal. *Petals* four. *Nectary* undivided. *Anthers* eight. *Stigma* club-shaped.—Gathered by Commerfon in Madagascar. *Leaves* smooth; of three or five stalked, mostly elliptical, taper-pointed leaflets, near two inches long. *Clusters* an inch long, solitary or in pairs. *Flowers* small, four-cleft. *Fruit* unknown.

12. *T. trifoliata*. Three-leaved West Indian Trichilia. Linn. Sp. Pl. 551. Willd. n. 10. Jacq. Amer. 129. t. 82. Vahl Symb. v. 1. 31. (*T. quæ Halefia* Loefflingii; Loeffl. It. 188.)—Leaves ternate; leaflets obovate, polished, obtuse; tapering at the base; the odd one much the largest.—Native of South America, and some of the West Indian islands, flowering in April and May. A tree fifteen feet high, exhaling from every part a disagreeable, though not powerful, odour. *Leaves* alternate, stalked; their two opposite leaflets an inch long, the odd one two inches; all very obtuse, tapering greatly at the base, without any partial stalks. *Clusters* axillary, very short, of about six small, whitish, five-cleft flowers. *Capsule* green, with brownish dots, globose, of three valves. *Seeds* with a scarlet skin. The negro women are said to procure abortion by a decoction of the roots. *Jacquin*.

13. *T. nervosa*. Three-leaved East Indian Trichilia. Vahl Symb. v. 1. 31. Willd. n. 11. (*Melia* Koctjape; Burm. Ind. 101, excluding Plukenet's synonym.)—Leaves ternate; leaflets ovate, acute; their ribs hairy beneath.—Native of Java. *Branches* downy at the extremity. *Leaves* stalked; leaflets on short stalks, entire, two inches long, and we presume all three about equal in size; common stalk downy, the length of the leaflets, shorter than the axillary upright flower-stalks. *Flowers* in short dense panicles, with a lanceolate bractea at the base of each. *Calyx* and *corolla* villous.

14. *T. spinosa*. Thorny Trichilia. Willd. n. 12. (“*Turraea virens*; Hellenius in Stockh. Transf. for 1788. 294. t. 10. f. 1.” We suspect an error in the page.)—“Leaves simple,

simple, ovate, emarginate. Branches spinous."—Native of the East Indies. Fruit a berry of three cells, with a seed in each; hence this plant seems intermediate between *Trichilia* and *Limonia*. Willdenow. We know nothing of it, but there appears little reason to place it here.

The genus *Trichilia* is sufficiently natural, notwithstanding the aberrations of structure in the *nectary*, or *stamens*, and of number in other parts of the *flower*. The species are by no means well determined, or correctly named. One alone has appeared in the European stores, nor are well-ascertained specimens frequent in collections. The presence or absence of axillary glands on the *leaves*, and the structure of the part bearing the *anthers*, whatever it may be called, seem to promise the best marks of specific distinction. The seeds in *T. glandulosa*, the only one whose fruit has fallen under our examination, are each inclosed in a rigid, elastic, permanent, bivalve *tunic*, whose outside is clothed with red pulp. Whether this be precisely the case in the rest, the descriptions of authors are not exact, nor consistent, enough to help us to determine.

TRICHINIUM, from *τριχων*, a hair, alluding to the shaggy aspect of its flowers.—Brown Prodr. Nov. Holl. v. 1. 414.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Amaranthaceae*, Juss. Brown.

Eff. Ch. Calyx in five deep linear segments. Stamens connected at their base, without teeth. Anthers of two cells. Stigma capitate. Capsule without valves, single-seeded, inclosed in the converging base of the calyx, whose segments are spreading and feathery.

The species of this genus are herbaceous, generally perennial, with alternate *leaves*. Flowers terminal, capitate or spiked, each accompanied by three membranous shining bractees. The hairs of the *calyx*, at first close, subsequently become extended, and give the segments a feathery aspect. *Trichinium* is truly, as its learned author observes, very closely related to *Ptilotus*; see that article. We should indeed feel no scruple in considering them one genus. Perhaps they ought strictly to be referred to the class *Monadelphica*, or at least they, and their Linnæan allies *Gomphrena*, *Achyranthes*, *Celosia*, &c. should be indicated at the head of that class, for the convenience of young botanists. Why the latter were not all placed there by the author of the sexual system, to the great relief of his fifth class, can only be attributed to his peculiar idea of the structure of their flowers. He calls a *nectarium*, what Mr. Brown esteems the united base of their filaments; but we believe an enlarged consideration of the whole tribe will justify the latter opinion.

1. *T. fusiforme*.—Leaves linear, very narrow, smooth as well as the branches. Stems numerous. Root spindle-shaped. Heads of flowers nearly ovate. Bractees acute, single-ribbed.—Gathered by Mr. Brown, in the tropical part of New Holland.

2. *T. gracile*.—Leaves linear, very narrow, smooth. Stem nearly simple. Head of flowers almost globular. Bractees obtuse, ribblefs. Filaments unequal.—Found in the same country.

3. *T. difans*.—Leaves linear, very narrow, smooth as well as the branches. Spike elongated, rather lax.—From the same country.

4. *T. spatulatum*.—Radical leaves obovato-spatulate, flat, smooth. Spike cylindrical.—Gathered by Mr. Brown in Van Diemen's island.

5. *T. macrocephalum*.—Stem-leaves lanceolate, wavy, smooth as well as the angular branches. Spike oblong, with a woolly stalk—Native of the south coast of New Holland.

6. *T. incurvum*.—Leaves lanceolate, hoary and downy as well as the round branches. Spikes nearly ovate, lateral as well as terminal.—Gathered by M. Baudin, on the west coast of New Holland.

We have seen no specimens of this genus, any more than of *Ptilotus* above-mentioned.

TRICHIRI, in *Geography*, a small island in the Grecian Archipelago; 5 miles E. of Specia.

TRICHISMOS, from *τριξ*, the hair, in *Surgery*, a capillary fissure, or fracture of the skull, so called from its being so fine as to resemble a hair put upon the bone.

TRICHIURUS, in *Ichthyology*, a genus of the order of Apodes; the characters of which are, that the head is extended, with lateral opercula or gill-covers; that the teeth are ensiform, and semi-fagittated at the apex or tips; that it has seven branchiostegous or gill-membrane rays; that the body is compressed and ensiform, and the tail subulated, without any fin: whence it is called *lepturus*, and in English *needle-tail*. There are two

Species.

LEPTURUS or *Argentus*; Silvery Trichurus. With the lower jaw longer than the upper; and equally distinguished by the singularity of its shape, and brilliancy of its colour; the body very compressed, tapering towards the extremity, and terminating in a fine point: the whole body, except the fins, of a bright silver-colour; the head narrow and the mouth wide; the lateral line of a gold-colour, commencing at the gills and continued to the tip of the tail; the dorsal fin moderately wide, transparent, and of a yellowish tinge, commencing almost immediately behind the head, and terminating near the end of the tail in a mere membrane, the other parts being strongly radiated; the pectoral fins small and of an oval shape; without any direct vent-fin, but having a series of very small naked spines or rays, about 110 in number, continued from the vent, which is situated about the middle of the body, to nearly the tip of the tail. Its general length is from two to three feet: it is said to be very voracious, swims with rapidity, and in the pursuit of its prey sometimes leaps into small vessels, which happen to be failing by it. It is a native of the rivers and larger lakes of South America, and is considered as an eatable fish: it is also found in some parts of India and in China.

INDICUS, or *Electricus*, or *Fuscus*; Brown Trichurus. With jaws of equal length; nearly equal in size to the preceding, but different in the conformation of the jaws, which are of equal length, and in the form of its teeth, which are very minute; the tail less slender and sharp, and the colour of the whole fish pale brown, variegated with spots of a deeper cast: a native of the Indian seas, and possessing a degree of electrical power.

TRICHOCARPUS, in *Botany*, from *τριξ*, *τριχος*, a hair, or bristle, and *καρπος*, fruit; alluding to the remarkable prominent rigid bristles, projecting from every part of the capsule.—Schreb. Gen. 366. Willd. Sp. Pl. v. 2. 1224. Mart. Mill. Dict. v. 4. (Ablania; Aubl. Guian. 585. Juss. 440. Lamarck Illustr. t. 479.)—Class and order, *Polyandria Dignia*. Nat. Ord. uncertain, Juss. Perhaps akin to his *Tiliaceae*.

Gen. Ch. Cal. Perianth inferior, of one leaf, in four or five deep, ovate, acute, spreading, permanent segments. Cor. none. Stam. Filaments numerous (sixty or seventy), capillary, longer than the calyx, inserted into the receptacle; anthers small, roundish. Pist. Germen simple, superior, ovate, villous; styles two, thread-shaped, erect, much longer than the stamens, divided at the summit; stigmas obtuse. Peric. Capsule elliptical, with four angles, one cell, and four valves,

valves, clothed all over with numerous rigid, projecting deciduous bristles. *Seeds* numerous, small, inserted into an ovate-oblong, central, unconnected receptacle, and enveloped in a viscid membrane.

Eff. Ch. Calyx in four or five deep segments. Corolla none. Styles two, divided. Capsule bristly, of one cell and four valves, with many seeds.

1. *T. laurifolia*. (*Ablania guianensis*; Aubl. t. 234.) Laurel-leaved Ablani, or Trichocarpus.—Found by Aublet, on the banks of rivers in Guiana, particularly about one which empties itself into the Sinemari river, thirty leagues above its mouth. This tree bears flowers and fruit in November, and is known to the Caribbee Indians by the name of *Goulougou-Ablani*. Its trunk is forty or fifty feet high, about two feet and a half thick, with a smooth reddish bark; the wood white, with some redness at the heart. Branches numerous and widely extended in all directions. Leaves alternate, stalked, elliptical, bluntly pointed, entire, rigid, smooth, undulated, with one rib and many transverse veins; their greatest length seven inches; breadth two and a half. Flowers small, in short, simple, axillary or terminal, spreading clusters. Stamens white, with yellow anthers. Capsule, when its bristles are fallen, about the size of a filbert. Its valves are likewise soon deciduous, leaving the seeds enveloped in a red viscid membrane. Nothing is recorded of the use or qualities of any part.

TRICHOCEPHALUS, in *Zoology*, a genus of the Infusoria order of Vermes; the characters of which are, that the body is elastic and contorted, the hinder part thick and elevated, the anterior capillary and of double length, sometimes terminating knotty. Of this genus there are six species, distributed into two classes: *viz.*

* *With simple Head.*

HOMINIS. Above subcrenated, beneath smooth, fore-part very subtly striated; two inches long.

EQUI. Two inches and a half long.

APRI. With tail on both sides furnished with crenated scales; equal to the human.

MURIS. With the head three-knotted: found in the intestine of the mouse, between the duodenum and rectum.

VULPIS. With an acute head; neck transversely striated, and unilateral vesicles. Found in the cœcum of the fox.

** *With uncinated or hooked Head.*

LACERTÆ. With tail on both sides scaly. Found in the intestines of the lizard.

TRICHODA, a genus of the Infusoria order of Vermes; the characters of which are, that the worm is inconspicuous with the naked eye, pellucid, and hairy on the other part. Gmelin's edition of Linnæus comprehends forty-seven species.

* *Without a Tail.*

PATELLA. Univalve; before and behind furnished with extended unequal bristles. Found in the marshes of Denmark.

INQUILINUS. Vaginated with a green small cylindrical bag, and retortile pedicel. Found in very pure sea-water.

ANAS. Elongated, with the apex of the neck elongated beneath. Found in pure waters.

LARUS. Dilated forward, with a gibbous back. Found in marshes in which the leaves of the poplar putrefy.

URSULA. Smooth, elongated, equal, on the fore-part hairy. Found in putrid infusions of hay and other vegetables.

SANNIO. Incurvated; above ciliated, below truncated. Found rarely in water furnishing duck-weed.

VOL. XXXVI.

LINTER. Ovate-oblong, somewhat prominent at both ends. Found by the Greenlanders in water, in which the lichen coriarius has been infused.

PUBES. Ovate-oblong, gibbous, on the fore-part depressed. Found in duck-weed water.

CYPRIS. Obovate, above sinuated towards the hinder part, on the fore-part hairy. Found in water covered with duck-weed.

CYCLIDIUM. Ovate, with gaping apex and hairy base. Found in water in which vegetables have been infused.

URINARIUM. Ovate, with a very short hairy beak. Found in an infusion of hay.

LEPUS. Ovate, with hairy apex and bristly base. Found in animal and vegetable infusions.

CALOPTIUM. Broadish, oblong, on the fore-part furnished with shining small cornicles. Found in vegetable infusions.

SILURUS. Oblong, hairy before and behind, with a ciliated back. Found in water abounding with conferva.

MYTILUS. Subclavated, at both ends wider, green and ciliated. Found in marsh-water.

URNULA. Pitcher-shaped; before hairy. Found rarely in water covered with duck-weed.

LYNCEUS. Subquadrate, with hooked beak and hairy mouth.

SEMILUNA. Semi-orbicular, on the fore-part below hairy. Found in duck-weed water.

ORBIS. Orbicular, emarginated and hairy on the fore-part.

CIMEX. Above convex, below smooth and hairy. Found in vegetable infusions.

CIARON. Cymbiform, on the front hairy. Found in sea-water.

TINEA. Clavated, on the fore-part hairy; behind thick. Found in hay infusion.

TRIGONA. Convex, before ciliated, and behind eroded.

ANGULUS. Angulated, hairy at the apex. Found in hay-water.

PULLASTER. Ovate, before sinuated; cristated in front and hairy at the base. Found in duck-weed water.

PULEX. Ovate, before incised; in the front and base hairy. Found as the last.

PELLIONELLA. Cylindric, before hairy, behind bristly: in vegetable infusions.

CAMELUS. Hairy on the fore-part, thickish in the middle; and on both sides emarginated. Found as the last.

ACARUS. Piriform, on the fore-part below hairy, behind pedated: in water covered with duck-weeds.

BOMBA. Mutable, on the fore-part furnished with scattered hairs: as the last.

GRANATA. Spherical, with opaque centre, and hairy periphery: as before.

COMETA. Spherical, before hairy, with an appendant globule. Found in very pure water.

GRANDINELLA. Spherical, pellucid, above hairy: as the last.

SOL. Globular, radiated: in water kept three weeks.

SYNCASTER. Subquadrate, with obtuse beak, and dilt with shining pedicels. Found in sea-water that has been kept.

RATTUS. Oblong carinated, the fore-part having very short hairs, the hind-part a long simple bristle: in stagnant waters.

CILIATA. Ventricose, behind pectinated with hairs. Found in muscle-water.

SULCATA. With ovate ventricose apex, acuminate, ventral furrow and on both sides hairy : as before.

** *With Tail.*

TRANSFUGA. Broadish, before hairy, behind bristly, sinuated on one side, micronated on the other. Found in sea-water for some time kept.

DELPHINUS. Oblong, before hairy, behind truncated with a reflex tail. Found in hay-water.

LUDIO. Cirrated, above hairy, with an extended tail. Found rarely in the grove-waters of Denmark.

MUSCULUS. Oval, on the fore-part hairy, the hinder part caudated. Found in hay-water.

PISCIS. Oblong, on the fore-part hairy, behind very finely attenuated into a tail : in duck-weed water.

CUNICULUS. Oblong, before hairy, behind somewhat sharpened : in pure water.

CLAVUS. Before rounded and hairy, behind with an acuminate tail. Found in marshes.

PUPA. Aculeated, hairy in front, with a bent tail. Found in duck-weed water.

CLAVA. Clavated, hairy in front, with a reflexile tail. Found rarely in the marshy waters of Denmark.

TRICHODERMA, in *Botany*, from $\tau\rho\iota\chi\eta$, $\tau\rho\iota\chi\eta\varsigma$, a hair, and $\delta\epsilon\rho\iota\mu\alpha$, a coat.—Perf. Syn. Fung. 230. (*Farinaria*; Sowerb. Fung. t. 360.)—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Naked. Powder copious, mealy, encompassed with a downy or shaggy coat.

1. *T. fuliginoides.* Perf. n. 1.—“Large, nearly globular, villous, whitish. Powder bright red, intermixed with clustered threads.”—Found in autumn, on the rotten trunks of Spruce Firs. An inch or two wide, soft, but not melting. The threads to which the seeds are attached spread radiating through the powdery mass, in little tufts, from a subjacent membrane. *Perfoon*.

2. *T. roseum.* Hoffm. Germ. v. 2. t. 10. f. 1. Perf. n. 2. (*Farinaria rosea*; Sowerb. Fung. t. 360. f. 3.)—Rose-coloured, encompassed with a fine, spreading, depressed, filamentous border. Frequent in spring on rotten branches, especially between the wood and bark of the Sallow and Aspen. Half an inch broad, roundish or oblong, with a cobweb-like circumference.

3. *T. aurantiacum.* (*Farinaria aurantiaca*; Sowerb. *ibid.* f. 2.)—Tawny, orbicular. Powdery particles somewhat ovate, partly scattered, with a slight filamentous border. On leaves, often forming, as it were, a little nest, with a few cottony filaments towards the edges. *Sowerby*.

4. *T. seminarium.* (*Farinaria seminarium*; Sowerb. *ibid.* f. 1.)—Powder black, in little compact globules, on a white, mealy, slightly fibrous, orbicular base.—Observed by the Rev. J. Holme, of Peter-house, Cambridge, on the leaves of a Willow. This consists of little white scattered orbicular spots of a white mealy substance, from a quarter to half an inch broad, lodging several minute deciduous masses of black powder, or seeds.

5. *T. viride.* Perf. n. 3. “*Disp. Meth. Fung. 12.*” (*Pyrenium lignorum* 2, *vulgare*; Tode Fung. Mecklenb. v. 1. 33. t. 3. f. 29.)—Roundish or unequal, very soft, with bright-green powder, and whitish fugacious filaments.—Found after autumnal rains, among fragments of fallen branches of trees, or of the stems of large herbaceous plants. Its substance is extremely soft, two or three lines in diameter. The white cobweb coat opens at the top, and exposes the minute condensed grains, or powder, of a most beautiful verdigris-green. *Perfoon, Tode*.

6. *T. aureum.* Perf. n. 4. Obf. Mycol. fasc. 1. 99.—“Widely expanded. Hairy coat whitish, very thin. Pow-

der dull yellow.”—This occurs rarely, in fives or hot-houses, on rotten wood, into which it is sunk. Almost three inches broad, being one of the largest of its genus, but scarcely two lines in thickness. The shaggy covering is thin and evanescent. *Perfoon*.

7. *T. nigrescens.* Perf. n. 5. “*Disp. Meth. Fung. 12.*” —“Rather spreading, flattish. Powder footy. Shaggy coat grey, very thin.”—Produced in the winter and early spring, on felled trunks of trees, especially of the maple kind. Half an inch broad, and one line thick, staining the fingers, and soon becoming black. *Perfoon*.

8. *T. dubium.* Perf. n. 6. (See Perf. Obf. Mycol. fasc. 1. 99.)—Linear, slightly downy; first whitish, then yellowish; of an uniform friable substance.—Frequent on decayed trees in autumn. About half an inch long, and one line broad. There is scarcely any distinct fibrous margin, though the whole fungus appears slightly downy. The inside is dense and cohering, not powdery, nor volatile; so that *Perfoon* expresses great doubts concerning the genus of this little production.

9. *T. pyrenium.* Perf. n. 7. (*Pyrenium lignorum* β , *aureum*; Tode Fung. Mecklenb. v. 1. 33.)—Oval, compressed, with a bright-yellow, downy, separating coat. Nucleus whitish, turning orange.—On the naked wood of decaying branches of beech, in May, but very rare. A line long, scattered. The internal substance rather soft and friable.

10. *T. leve.* Perf. n. 8. Obf. Mycol. fasc. 1. 12.—Whitish, spreading, smooth, turning buff-coloured. Powder yellow. This is found on the ground, as well as spreading over mosses, to the breadth of an inch and half or two inches, but is not among the common species. It is more permanent than some others.

11. *T. tuberculatum.* Perf. n. 9. Obf. Mycol. fasc. 1. 12. t. 2. f. 8.—Pure white, nearly orbicular; at first downy; afterwards tubercular. Powder grey.—Frequent after great rains, on the ground in shady woods. When young it is very white, of a cobweb texture, but soon becomes greyish. When full-grown the surface is beset with oblong tubercles. In a few days the whole changes to a grey powder.

TRICHODESMA, from $\tau\rho\iota\chi\eta$, $\tau\rho\iota\chi\eta\varsigma$, a hair, and $\delta\epsilon\sigma\mu\alpha$, a tie, alluding to the connexion of the anthers by their pubescence.—Brown Prodr. Nov. Holl. v. 1. 496. (*Borraginoides*; Boerh. Lugd.-Bat. v. 1. 188. fig. E—K. *Borago*; Gærtn. t. 67. *Cynoglossoides*; Inard in Mem. de l’Acad. des Sc. for 1718; German edition 194. t. 9. 10. “*Pollichia*; Medicus Phil. Bot. part 1. 32.”)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Asperifoliae*, Linn. *Borraginæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, permanent segments. *Cor.* of one petal, wheel-shaped; the length of the calyx; tube short, somewhat funnel-shaped; limb spreading, nearly flat, in five deep, equal, keeled, taper-pointed segments; throat naked. *Stam.* Filaments five, very short, inserted into the throat of the corolla; anthers oblong, prominent, converging, shorter than the limb, tipped with twisted bristly points, and bound together by their two rows of dorsal hairs. *Pist.* Germens four, superior; style central, thread-shaped, longer than the stamens; stigma simple, bluntish. *Seeds.* Nuts four, ovate, gibbous, half sunk in the cells of the four-winged central column near its summit.

Eff. Ch. Corolla wheel-shaped, with a naked throat. Anthers connected by dorsal hairs.

Mr. Brown has separated this genus, consisting of three known species, from the Linnæan *Borago*, for the very sufficient reason of the corolla having no valves or prominences

in its throat; to say nothing of the connexion of the *anthers*, or insertion of the *seeds*. The plants are herbaceous, clothed with pungent bristles; their *flowers* axillary, or racemose with *bracteas*. See BORAGO.

1. *T. indicum*. Indian Trichodesma. (Borago indica; Linn. Sp. Pl. 197. Willd. Sp. Pl. v. 1. 776. Ait. Hort. Kew. v. 1. 296. Borriginoides angustifolia, flore pallescente cæruleo; Boerh. as above 188, with a plate. Cynoglossoides folio caulem amplexante; Inard as above, t. 9.)—Flowers axillary. Segments of the calyx auricled at the base. Seeds without a border. Leaves clasping the stem.—Native of the East Indies. A tender annual, cultivated by Miller, and flowering throughout the summer and autumn. The *stem* is much branched, rather diffuse. *Leaves* sessile, oblong, bluntish, entire, rough with hairs and callous points; clasping the stem with their slightly heart-shaped base. *Flowers* axillary, solitary, stalked, drooping, white, pale blue, or reddish, with five rusty spots round the mouth. *Calyx* hairy, each segment acute, much elongated at the base. *Seeds* pale, nearly smooth.

2. *T. africanum*. African Trichodesma. Borago africana; Linn. Sp. Pl. 197. Willd. Sp. Pl. v. 1. 777. Ait. Hort. Kew. v. 1. 296. Cynoglossoides africana verucosa et hispida; Inard as above, t. 10.)—Clusters alternate, terminal. Calyx without auricles. Seeds bordered. Leaves ovate, stalked.—Native of the Cape of Good Hope. A tender annual, cultivated by Miller, flowering in July and August. The whole plant is very harsh and hispid. *Leaves* opposite. *Flowers* smaller than the last, but much more numerous, pale blue, yellowish about the mouth, with five purplish spots. *Antbers* with long convoluted points. *Seeds* bordered, fringed.

3. *T. zeylanicum*. Ceylon Trichodesma. Br. n. 1. (Borago zeylanica; Linn. Mant. 202. Willd. Sp. Pl. v. 1. 777. Ait. Hort. Kew. v. 1. 297. Jacq. Coll. v. 3. 169. Ic. Rar. t. 314. Burm. Ind. 41. t. 14. f. 2. Anchusa buglossoides, lithospermi femine; Pluk. Mant. 13. Phyt. t. 335. f. 4.)—Clusters terminal. Calyx without auricles. Seeds smooth, without a border. Leaves nearly sessile, tapering at the base.—Native of Ceylon, and other parts of the East Indies, as well as of New Holland, within the tropic. Dr. Roxburgh sent seeds to Sir Joseph Banks, in 1799. This, like the rest, is an annual plant, flowering in the stove about July and August. The herbage is, as Mr. Brown remarks, very variable in its quantity of bristles and soft hairs; the latter, in wild specimens, are sometimes very abundant, giving the long *flower-stalks*, and *calyx*, more especially, a hoary aspect. The *leaves* are oblong or obovate, mostly opposite. *Clusters* leafy. *Corolla* white and semi-transparent. *Seeds* ovate, grey, smooth and highly polished, like our Common Gromwell.

TRICHODIUM, received that name from Michaux, who constructed it out of *τριξ*, *τριχος*, a hair, and *ειδος*, form, or appearance, in allusion to the capillary stalks of the panicle.—Michaux Boreal.-Amer. v. 1. 41. Pursh 61.—Clas and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume single-flowered, of two linear-lanceolate, acute, awnless, nearly equal valves. *Cor.* Glume of one valve, shorter than the calyx, ovato-lanceolate, membranous, awnless, smooth, permanent. Nectary a deeply cloven scale. *Stam.* Filaments three, capillary, longer than the calyx; anthers oblong, cloven at each end. *Pist.* Germen roundish-obovate; styles two, distant, short; stigmas loosely feathery, with long roughish hairs. *Peric.* none. *Seed* one, roundish, pointed at each end, unconnected with the corolla.

Eff. Ch. Calyx of two nearly equal valves, single-flowered. Corolla of one valve, shorter than the calyx, awnless. Stigmas feathery, nearly sessile.

1. *T. laxiflorum*. Spreading Trichodium, or Brittle-grass. Michaux as above, 42. t. 8. Pursh n. 1. (Cornucopiæ hyemalis; Walt. Carolin. 73. Agrostis scabra; Willd. Sp. Pl. v. 1. 370, according to Pursh.)—Stems erect. Leaves upright, linear-fetaceous, with roughish sheaths. Calyx-valves lanceolate.—Common in all grassy situations, from Hudson's bay to Florida, flowering from May to August. *Michaux*, *Pursh*. Root perennial. *Leaves* narrow and short, nearly erect. *Panicle* short, with very fine capillary stalks, loosely spreading, each branch bearing but a few small *flowers* about the extremity.

2. *T. decumbens*. Decumbent Brittle-grass. Michaux as above. Pursh n. 2. Ait. Epit. 375. (Cornucopiæ perennans; Walt. Carolin. 74. Agrostis anomala; Willd. Sp. Pl. v. 1. 370. A. Cornucopiæ; Frazer Monogr. with a plate.)—Stems decumbent. Leaves spreading, linear-lanceolate, with smooth sheaths. Calyx-valves taper-pointed.—On moist hills, and in short grass-meadows, from Canada to Carolina, flowering from June to August. *Root* perennial. This and the foregoing are highly valuable grasses. *Pursh*. Larger than the first species, with longer and broader smooth *leaves*, which spread in every direction. *Stipula*, as Willdenow observes, larger, lanceolate, torn. *Panicle* large and loose. *Flowers* about the size of our *Agrostis alba*, being twice the size of the foregoing, and much more numerous.

This, known by the name of Frazer's New American Grass, was brought from Carolina by that indefatigable collector, in the year 1788. His friend Mr. Walter, in the *Flora Caroliniana*, extols this grass as one of the Creator's most precious gifts, which he himself was destined to make first known to mankind. Kalm had indeed, long ago, sent a specimen to Linnæus, but without any particular account of its use or distinctions, so that his specimen remained undistinguished from other species, which it much resembles. The solitary valve of the *corolla* led Mr. Walter to refer this plant to the genus *Cornucopiæ*, to which it has no other affinity. He was moreover flattered by this name, as concurring with his own idea of the value of his discovery. Nor do we doubt the accuracy of his statements, published in Mr. Frazer's Monograph above cited. Nevertheless, this grass has disappointed the hopes of European cultivators, and has now totally disappeared. "The places that knew it, know it no more." It is not even mentioned in Mr. Sinclair's elaborate and valuable experimental work, the *Hortus Gramineus Woburnensis*, nor by Mr. Dryander in the *Hortus Kewensis*, though Mr. Aiton has supplied the latter defect in his *Epitome*. So difficult is it to cultivate grasses, in general, away from their native situations, for any agricultural profit, that the disappointment we are obliged to record, is no impeachment of the accuracy of those who still reckon our *Trichodium* among the best grasses in America.

3. *T. elatum*. Tall Brittle-grass. Pursh n. 3. (Agrostis dispar; Michaux Boreal.-Amer. v. 1. 52. Cornucopiæ altissima; Walt. Carolin. 74.)—Stems erect. Leaves linear, rough, with smooth sheaths. Calyx-valves membranous, ovato-lanceolate, pointed.—In sandy deep swamps of New Jersey, Carolina, &c. Perennial, flowering in July and August. Near three feet high. *Panicle* close, coloured. *Pursh*. *Stem* hard. *Flowers* large. *Michaux*.

TRICHOGAMILA, a name of Dr. Patrick Browne's, which he has left, according to his usual custom, unexplained. It appears derived from *τριξ*, a hair, and *γamos*,

marriage, alluding to the pubescence enveloping both organs of impregnation.—Browne Jam. 218.—We have seen no specimen of this plant. It is said to grow close to the beach at Bull-bay, in Jamaica. The *stem* is shrubby, stiff, simple, three or four feet in height, and as many lines in diameter. *Leaves* round, smooth, alternate. *Flowers* small and whitish. *Outer calyx* (rather *bracteas*) two small deciduous leaves; *inner* cup-shaped, of one leaf, divided half way down into five ovate segments. *Corolla* of five oblong, abrupt, somewhat spreading petals, or of one petal divided to the base. *Filaments* ten, downy, erect, shorter than the corolla. *Anthers* roundish. *Germen* minute, in the bottom of the calyx. *Style* downy, the length of the stamens, with a bluntness *stigma*. *Drupa* the size and appearance of a gall-nut, but light and hollow, globose, woody, thin, with a thin coat, of one cell, inflated, rather uneven in its surface. *Nuts* two, oblong-ovate, two-lobed; one of them usually abortive; the other fixed to the bottom of the drupa, but not half occupying its cavity.

Jussieu, Gen. Pl. 260, suspects this to be the same genus with CHALCAS or MURRAYA (see those articles); and Linnæus has written *Chalcas* against Browne's description. We presume it is the same individual species, which, though of East Indian origin, had accidentally been conveyed to the shores of Jamaica. If this be correct, Browne mistook the *leaflets* for simple *leaves*, and perhaps did not meet with the *fruit* in its natural more juicy state.

TRICHOMA, in *Surgery*, the disease more commonly called *plica Polonica*.

TRICHOMANES, in *Botany*, an ancient Greek name for some small delicate kind of fern, supposed, from the description of Dioscorides, book 4. chap. 137, to be *Aplenium Trichomanes* of Linnæus, which very well answers to that description. The name, from *τριχ*, *τριχος*, a hair, (whatever may be the origin of the rest of the word, about which etymologists disagree,) alludes to the slender shining stalks, common to most of the fern tribe, which procured them the appellation of Capillary herbs, and the reputation of improving the growth of the human hair. Linnæus selected this name for a delicate, pellucid, capillary-stalked genus, to which it is very suitable; more especially if we take into consideration, as he probably did, the peculiar character of a prominent hair or bristle, originating from the receptacle of the seed-vessels.—Linn. Gen. 560. Schreb. 758. Willd. Sp. Pl. v. 5. 498. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 529. Sm. Mem. de l'Acad. de Turin, v. 5. 417. Tracts 255. Swartz Fil. 141. Ind. Occ. 1724. Brown Prodr. Nov. Holl. v. 1. 159. Sprengel Crypt. Engl. ed. 164. t. 5. f. 35. Juss. 16. Lamarck Illustr. t. 871.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

Gen. Ch. *Fruifications* inserted into the margin of the frond, terminal, distinct, tubular. *Involucrum* of one leaf, urn-shaped, of the texture of the frond, opening outward. *Capsules* of two valves, bound by an elastic ring, numerous, sessile on the lower part of a cylindrical common receptacle, or *column*, whose capillary naked point projects beyond the *involucrum*.

Ess. Ch. *Fruifications* placed at the edge of the frond. *Involucrum* urn-shaped, of one leaf, opening outwardly. Common receptacle prominent, bristle-shaped.

Obs. HYMENOPHYLLUM (see that article) was first separated by the writer of this, from *Trichomanes*, with which it had, on account of their similar membranous pellucid habits, been always confounded. The bivalve *involucrum*, enclosing the *common receptacle*, clearly distinguishes it

from the genus before us, whose *involucrum* has a spreading undivided border.

The second edition of *Species Plantarum* contains eleven, and the fourteenth edition of *Systema Vegetabilium* thirteen, species of *Trichomanes*, as Linnæus understood the genus. But though from these are deducted what are now referred to HYMENOPHYLLUM and DAVALLIA, Willdenow enumerates thirty-four species of genuine *Trichomanes*. These are distributed into four sections, according to the subdivision of their fronds. We shall select examples.

SECT. 1. *Fronde simple*. Twelve species in Willdenow.

T. reniforme. Kidney-shaped Bristle-fern. Forst. Prodr. 84. Willd. n. 1. Swartz Fil. 369. "Schkuhr Crypt. 130. t. 134." R. A. Hedw. Fil. fasc. 3.—Fronds kidney-shaped, undivided, on bordered stalks.—Gathered by Forster, as well as by Mr. A. Menzies, in New Zealand. An elegant very singular fern, with long, creeping, thread-shaped, perennial roots, attached by rigid downy fibres, and throwing up scattered erect fronds, various in size, each on a simple smooth stalk, from one to six inches high, bordered, or slightly winged, especially in the upper part. The leaf itself is vertical, kidney-shaped, from one and a half to three inches wide, of a dull olive-green, membranous, semi-pellucid, smooth, full of numerous, radiating, repeatedly forked veins; the margin entire, slightly wavy; in the larger or older specimens beset with a row of cup-shaped immersed *involucrum*s, each terminating a vein, and each protruding a thick rough *column*, twice its own length, bearing a number of pale shining annulated *capsules*.

T. membranaceum. Membranous Bristle-fern. Linn. Sp. Pl. 1560. Willd. n. 5. Swartz Ind. Occ. 1724. (*Darea americana lichenoides*; Petiv. Mus. n. 763. *Adiantum muscosum, lichenis petræ facie*; Plum. Fil. 83. t. 101. f. a. Amer. 34. t. 50. f. a; inaccurately copied in Pluk. Phyt. t. 285. f. 3; and again in Petiv. Fil. t. 13. f. 5.)—Fronds sessile, dilated upwards, obtuse, undivided, or torn; the margin beset with peltate scales.—Found on wet, often inundated, stones and rocks about the banks of rivers, in Hispaniola. This has the colour and membranous texture of the foregoing, but with a silky gloss. Its black, shaggy, creeping roots bear scattered fronds, destitute of stalks, sometimes roundish, but mostly wedge-shaped, from one to three inches high, variously split, dilated, and jagged, beset with innumerable crowded radiating veins, and much resembling the texture of a bat's wing. The margin, as well as the tip of each segment, bears brown peltate scales, whose use is unknown, but which, as Dr. Swartz remarks, might easily cause this fern to be taken for an *Adiantum*, were there not found on the same individual, though far more sparingly, the proper fructification of a *Trichomanes*, consisting of deeply immersed, slender, tubular *involucrum*s, dilated, orbicular, and roughish at the mouth, each with a prominent (not as Swartz says a concealed) *column*.

T. muscoides. Mossy Bristle-fern. Swartz Ind. Occ. 1726. Willd. n. 6. (*T. hymenoides*; R. A. Hedw. Fil. t. 3. f. 3. *Phyllitis scandens minima, musci facie, foliis membranaceis subrotundis*; Sloane Jam. v. 1. 74. t. 27. f. 1.)—Fronds roundish-oblong, irregularly sinuated, wavy, obtuse, on short hairy stalks. *Involucrum* prominent, cylindrical; bivalve at the mouth.—Found creeping over the trunks of trees, in low wet places, in Jamaica. The root is black, thick, and woolly, spreading to the extent of several inches. *Fronds* light green, lying over each other, scarcely more than half an inch wide, with strong, branching, but not parallel or crowded veins; the segments rounded and wavy. *Involucrum*s at length stripped as it were, and projecting entirely beyond the leaf on winged stalks; their

TRICHOMANES.

margin of two rounded valves, edged with brown. The *column* is certainly prominent. Our description differs from Dr. Swartz's in some material points, though taken from his own specimens.

T. reptans. Trailing Bristle-fern. Swartz Ind. Occ. 1727. Willd. n. 9. R. A. Hedw. Fil. t. 3. f. 4, bad. — Fronds obovate-oblong, nearly sessile, irregularly pinnatifid, with oblong obtuse segments; their base wedge-shaped. Involucrum immersed, its orbicular mouth not projecting beyond the leaf.—Native of old mossy trunks of trees, in the mountainous part of Jamaica. If we are right in our ideas of this species, it is browner and thinner than the last, with a larger *frond*, but shorter *stalk*; the veins much less thick and prominent. The *involucrum* moreover does not project, till stripped by age, nor is its margin divided. The *column* is certainly prominent. We do not boast, in this case, an original specimen from the author, and therefore may be mistaken.

T. sinuosum. Sinuated Bristle-fern. Willd. n. 10. Lamarck f. 1. (*T. crispum*; Linn. Sp. Pl. ed. 1. 1097. ed. 2. 1560, excluding the synonyms of Plumier and Petiver.)—Frond lanceolate, pinnatifid; tapering at the base; segments ovate, obtuse, somewhat angular, with zigzag veins, and mostly solitary fructifications. — Native of the West Indies; Willdenow says of Guadaloupe. A very elegant and distinct species, sometimes resembling the outline of an oak-leaf, but it is more usually of a linear-lanceolate figure, tapering at each end, four inches, more or less, in height, light olive, pellucid, finely reticulated, flat, rarely a little hairy, with elegant, zigzag, equally dispersed veins. *Involucrum* immersed at the blunt point of each segment, almost always solitary, its dilated orbicular border not projecting beyond the leaf. *Column* slender, prominent, full twice as long as the *involucrum*. This seems, by the Linnæan herbarium, to be what Linnæus intended for *T. crispum*; but it is evident from the specific character and name that he had full as much in his contemplation Plumier's t. 86, quoted for a synonym; and the latter being universally received as the true *crispum*, we shall so retain it. See the next section.

T. polypodioides. Polypody Bristle-fern. Linn. Sp. Pl. ed. 1. 1098. ed. 2. 1561. Swartz Fil. 145. Willd. n. 11. — "Frond lanceolate, pinnatifid, wavy. Flowers solitary, terminal."—Native of India.—"*Frond* the length and breadth of the finger, pinnatifid almost to the mid-rib; lobes lanceolate, bluntly serrated, acute at the summit, each of them furnished with a solitary flower at the point. The *frond* moreover is pellucid, with alternate veins."—Such is Linnæus's description of this species, which no person has ever discovered, and which can only be determined from his works or herbarium. In the latter nothing presents itself under this name; but the specimen marked *crispum*, mentioned under our preceding species, so precisely answers to this description of *polypodioides*, that we cannot but believe it is the very plant, and that Linnæus has here fallen into a most complicated mistake. As we are, nevertheless, unable to prove this, we would still retain the excellent name of *sinuosum*, to which those who think as we do may refer *polypodioides* as a synonym, with or without a mark of doubt.

T. elegans. Elegant Bristle-fern. Rudge Guian. 24. t. 35. Willd. n. 12.—Barren fronds lanceolate, deeply pinnatifid; fertile ones linear, pinnate, on longer stalks.—Native of watery mossy places in Guiana. *Fronds* tufted; the *barren* ones leafy, pellucid, of numerous, deep, parallel, linear, bluntish, somewhat jagged segments, that are near an inch long; their common *stalk* round, about two

inches in length, nearly smooth; *fertile* ones fewer, their *stalks* erect, five or six inches long, the *frond* itself four or five, and only half an inch wide, scarcely at all leafy, but composed of two dense rows of numerous, crowded, stalked, cylindrical, two-edged *involucral cups*, each with a small orbicular border, and protruding a long, curved, rough, slightly club-shaped *column*, thrice the length of the *involucrum* itself.

Seçt. 2. *Frond pinnate*. Three species; Willd.

T. crispum. Crisped Bristle-fern. Linn. Sp. Pl. 1560? Swartz Ind. Occ. 1731. Willd. n. 14. R. A. Hedw. Fil. t. 4. f. 2. (*Trichomanes* n. 1; Linn. Hort. Cliff. 476. *Polypodium crispum caliciferum*; Plum. Fil. 67. t. 86; copied in Petiv. Fil. t. 11. f. 8.)—Frond pinnate; leaflets oblong, obtuse, wavy, crisped, hairy, many-flowered at the extremity; the upper ones confluent.—Native of various parts of the West Indies. The tufted hairy *root* bears many lanceolate stalked *fronds*, about a foot high, of a light pellucid olive-green, very thin and membranous; their numerous leaflets about an inch long, elegantly crisped and plaited, copiously veined, clothed with scattered tawny hairs. The blunt extremity of each leaflet, except some of the inferior ones, bears from four to six large, immersed, rather crowded, tubular *involucrums*, with orbicular entire slightly dilated mouths. From each proceeds a long slender, almost capillary, roughish *column*, whose point when entire is blunt, or rather capitate.

T. floribundum. Many-flowered Bristle-fern. Willd. n. 15. (*T. pinnatum*; Swartz Fil. 142. R. A. Hedw. Fil. t. 4. f. 1. *T. rhizophylla*; Cavan. Leccion. 279. Swartz Fil. 142.)—Frond pinnate; leaflets lanceolate, serrated; the upper ones decurrent, confluent. Fructification marginal, fringe-like, prominent.—Native of several parts of the West Indies. Twice the size of the last. The *leaflets* are usually near two inches long, above half an inch broad, alternate, bluntish, nearly smooth, beset with innumerable close transverse veins, connected by fine reticulations; their margin undulated and finely serrated: those of the barren fronds crowded; of the fertile ones remote, most of their serratures tipped with a little, brown, cup-shaped, entirely prominent and naked *involucrum*, with a capitate *column* about its own length. Cavanilles speaks of this as the handsomest species he had seen. His description leaves no doubt as to the identity of his plant, though we have not seen an instance of any sprouting roots from the tip of the frond, which probably led Dr. Swartz, without seeing specimens, to adopt it as distinct.

Seçt. 3. *Frond doubly pinnatifid*. Six species; Willd.

T. crinitum. Hairy Bristle-fern. Swartz Ind. Occ. 1730. Willd. n. 19. R. A. Hedw. Fil. t. 1.—Frond pinnate; leaflets obtuse, pinnatifid, decurrent, confluent; hairy at the margin and veins; segments often cloven. Stalk hairy.—Found on the trunks of trees, on the lofty mountains of Jamaica. *Frond* about three inches in length, pale, pellucid; its tawny-haired *stalk* scarcely so long. *Involucrums* here and there imbedded at the ends of the segments of each *leaflet*, with a dilated, fringed, orbicular margin. *Column* long, roughish, capitate with a taper point. The segments of the *leaflets* are lanceolate, bluntish, not so generally divided in our specimens as in Hedwig's figure.

T. pyxidiferum. Covered Bristle-fern. Linn. Sp. Pl. 1561. Swartz Ind. Occ. 1739? Willd. n. 21. (*Filicula pyxidifera*; Plum. Fil. 74. t. 50. f. E; copied in Petiv. Fil. t. 13. f. 13.)—Frond pinnate; leaflets oblong, obtuse, decurrent, pinnatifid, with linear, obtuse, decurrent, entire, mostly three-cleft segments. Stalks all winged. *Involucrum* closed by a lid bearing the *column*.—Found by Plumier

TRICHOMANES.

mier on mossy trees in Hispaniola. He is our only certain authority for this species, the description of Swartz not answering exactly to his account, and the figure in R. A. Hedwig, t. 3. f. 2, indicating something very different. The true *T. pyxidiferum* is so named because the *involverum* is formed like a box with a convex lid, through which latter the long prominent *column* is continued. We have seen indications of no such character in any other species. The *root* is creeping and hairy. *Fronde* stalked, three or four inches high, smooth, very thin, their *common* as well as *partial stalks* winged throughout, and of the same linear form as the segments of the *leaflets*, which are notched at the end. *Involverums* one or two about the lower part of each principal *leaflet* cup-shaped, quite closed by the above-mentioned lid.

T. europæum. European Bristle-fern. (*T. pyxidiferum*; Hudf. 461. Bolt. Fil. 56. t. 30. Hymenophyllum tunbrigense δ ; Fl. Brit. 1142. H. alatum; Engl. Bot. t. 1417. Filix humilis repens, foliis pellucidis et splendens, caule alato; Dill. in Raii Syn. 127. t. 3. f. 3, 4.)—Fronde bipinnate; leaflets oblong, decurrent, pinnatifid, with linear, obtuse, decurrent, entire segments. Stalks all winged. *Involverum* open, with a slightly spreading border. Few plants of any country have caused more enquiry, or more diversity of opinion, than this fern, originally discovered by Dr. Richardson "at Belbank, scarce half a mile from Bingley, Yorkshire, at the head of a remarkable spring." From thence Mr. R. Teesdale and Mr. Dickson have brought us young plants, like Dillenius's f. 4, but could find none like his f. 3. The botanists of Ireland have been more fortunate. Mr. J. T. Mackay met with perfect specimens in fructification, on rocks about the cascade, at the bottom of Turk mountain, Killarney. Some of these, more perfect than what is figured in Engl. Bot., lead us to concur with Mr. Brown's opinion, expressed in his *Prodromus*, in removing this plant from *Hymenophyllum*, to the present genus. It was indeed considered by Linnæus as not distinct from *T. pyxidiferum*, nor is this opinion so wide of the truth as has been supposed. By a comparison with Plumier's figure of the latter, this will be found to differ chiefly in being more compound, with a smaller, more slender, two-edged *involverum*, in which we can discover nothing like a lid. Its margin is narrow, but rather spreading. The *capsules* are few and large, bright yellow, with a broad ring. *Column* long and prominent. Some appearances in this and other species lead us to believe the *column*, laden with *capsules*, is generally protruded out of its *involverum* after the *capsules* are ripe, and it may therefore, in a very early state, be found entirely inclosed therein. This being the only European *Trichomanes*, we hope our specific name may be allowed, that of *alatum* being preoccupied; see Willd. n. 17.

T. venosum. Veiny Bristle-fern. Brown Prodr. n. 1.—"Fronde pinnate; leaflets linear, veiny, wavy, somewhat crenate; the lower ones lobed or pinnatifid at the base, and bearing a solitary *involverum* at their inner margin."—Gathered by Mr. Brown, in the island of Van Diemen, and near Port Jackson, New South Wales. This should seem akin to the two last, but we have seen no specimens.

Sect. 4. *Fronde* triply pinnatifid, or pinnate. Thirteen species; Willd.

T. trichoides. Capillary Bristle-fern. Swartz Ind. Occ. 1741. Willd. n. 23. (*T. tenellum*; R. A. Hedwig. Fil. t. 3. f. 1.)—Fronde triply pinnate; leaflets linear, almost capillary, divided, emarginate. *Involverums* stalked, lateral, solitary, near the base of the principal branches.—In moist, shady, grassy places, in the cooler parts of Jamaica and Hispaniola. This is a peculiarly delicate and slender

fern, from two to four inches high, whose ramifications are so exceedingly narrow as to appear capillary, though the ultimate divisions are truly leafy, consisting of a wiry midrib, bordered with a continued, even, entire, scarcely discernible, leafy margin at each side, slightly dilated upward, and blunt at the end. The *fructification* is lateral and solitary, much as in the three preceding; each *involverum* stalked, tubular, two-edged, with a broad, orbicular, wavy margin. The *column* is very long and capillary.

T. rigidum. Rigid Bristle-fern. Swartz Ind. Occ. 1738. Willd. n. 29. R. A. Hedwig Fil. t. 2.—Fronde triply pinnate; leaflets pinnatifid, with linear, entire, taper-pointed segments. Common stalks two-edged, rigid. *Involverums* stalked, lateral, solitary, near the base of the secondary branches. Found about the roots of trees, on the lofty mountains of Jamaica. The creeping *root* sends up numerous rigid upright *fronds*, twelve or eighteen inches in height, of which at least one half consists of a brown, shining, round, firm *stalk*. The *leafy* part is finely and elegantly divided, dark green, peculiarly elastic, and when dry rigid and inflexed. *Involverum* urn-shaped, with a membranous spreading border. *Column* thick, not much protruding.

T. radicans. Winged Climbing Bristle-fern. Swartz Ind. Occ. 1736. Willd. n. 30. (*T. scandens*; R. A. Hedwig Fil. t. 6, excluding the synonyms.)—Fronde doubly pinnate; leaflets pinnatifid, with linear, cloven, obtuse segments. Common and partial stalks smooth, all winged. Stem climbing, creeping. Found on the mountains of Jamaica, creeping up the trunks of trees to a great extent, the downy rusty-coloured main *stem*, or *root* as it might be called, being firmly attached to the bark of the tree, throwing out little radicles as it goes. *Fronde* scattered, from nine to twelve inches long, on winged *stalks* measuring from one to three inches, ovate-lanceolate, twice or thrice pinnate, dark green, smooth, the stalks of all their subdivisions bordered with an entire uninterrupted wing; branches, leaflets and segments alternate. *Involverum* cylindrical or somewhat ovate, slightly winged with a portion of the segment which it terminates; the mouth spreading. *Column* long and slender. A very different species from the following, for which it has been mistaken by several botanists, to some of whom, though not quoted by Hedwig, we can trace his error.

T. scandens. Great Climbing Bristle-fern. Linn. Sp. Pl. 1562. Willd. n. 31. Swartz Ind. Occ. 1737. (*Adiantum scandens ramosissimum, laciniis retusis dissectum*; Plum. Fil. 76. t. 93; copied in Petiv. Fil. t. 12. f. 5.)—Fronde triply pinnate; leaflets oblong, pinnatifid, with linear obtuse segments. Common stalks round; partial winged, hairy. Stem climbing, creeping. Native of mountainous forests in Hispaniola, where it was gathered by Plumier, and since by Dr. Swartz. A much larger plant than the foregoing, creeping over the trunks of old trees. Each *frond*, two feet high, has a round, not bordered, main *stalk*, the partial ones only being winged. All the *leaflets* and their stalks are clothed with long loose hairs, of a shining or golden brown, such as are often likewise observable on the main stalk. The colour of the whole fern is more olive than the last, and its reticulations much coarser. *Involverum* much the same, nor do we find the *column*, when perfect, shorter in one than the other. Sloane's v. 1. t. 58. may be intended for *T. scandens*, but it is not sufficiently exact to afford any information.

T. tamarisciforme. Tamarisk Bristle-fern. Jacq. Coll. v. 3. 285. t. 21. f. 2. Willd. n. 34.—Fronde doubly pinnate; leaflets lanceolate, pinnatifid, with linear, very narrow, smooth

smooth segments. Common stalk round, bristly; partial winged, smooth. Involucrum stalked.—Native of the isle of Bourbon. Our specimen was communicated by M. Thouin to the younger Linnæus, who took it for *T. scandens*; but there is no appearance of any common trailing stem. The frond is almost two feet high. Stalk pale and smooth where naked, but in the leafy part of the frond blackish and hispid. Divisions of the leaflets peculiarly fine, regular and delicate, bluntish, sometimes emarginate, olive-green, without any hairs. Involucrum short and roundish, on a stalk more or less winged; its mouth spreading. Column long.

TRICHOMANES, in Gardening, comprehends plants of the herbaceous fern kinds,—the maiden-hair ferns; among which, the species which are cultivated for garden use and variety, are the canary maiden-hair fern (*T. canariense*); and the Tunbridge maiden-hair (*T. tunbridgensis*).

These are both perennial plants, which have something curious and interesting in their frondose growth and habit, and are therefore proper to be cultivated for the ornament and variety which they afford.

Method of Culture.—Both these plants may be increased by slipping their branches, or dividing their roots, and planting them in pots of light earth in the first fort, and the latter kind either in the same way, or in a dry border of light mould, the former to be removed in the winter season to the protection of the greenhouse, but the latter to remain where planted, or some put into pots, to be placed out in particular situations, as occasion may require.

They both form a singular variety when put in assemblage with other different plants of the exotic greenhouse forts, and other kinds in the borders and various compartments.

TRICHONEMA, in Botany, from $\tau\rho\iota\chi\omicron\varsigma$, $\tau\rho\iota\chi\omicron\varsigma$, a hair, and $\nu\mu\alpha$, a filament, or stamen, alluding to the hairiness of that particular part of the flower.—Ker in Sims and Kon. Ann. of Bot. v. 1. 222. Curt. Mag. 575. Ait. Hort. Kew. v. 1. 82. (Romulea; Maratti Plant. 13. t. 1.)—Class and order, *Triandria Monogynia*. Nat. Ord. *Enfata*, Linn. *Irides*, Juss.

Gen. Ch. Cal. Sheath inferior, more than half the length of the corolla, of two lanceolate, entire, permanent valves. Cor. of one petal, superior; tube very short, funnel-shaped; limb regular, divided to its very base into six nearly equal, somewhat spreading, concave segments. Stam. Filaments three, inserted into the mouth of the tube, erect, much shorter than the corolla, downy; anthers rather large, converging, oblong, cloven at the base. Pist. Germen roundish; style thread-shaped, erect, longer than the stamens; stigmas three, deeply divided, equal, spreading, very slender, rather abrupt. Peric. Capsule roundish, membranous, tumid, of three cells and three valves. Seeds several, globose.

Ess. Ch. Sheath of two valves. Corolla with a very short tube, and equal regular limb. Filaments downy. Stigmas three, deeply divided, very slender. Capsule roundish. Seeds globose.

Obs. The shortness of the tube, divided stigmas, and pubescent stamens, distinguish this genus from *IXIA*. (See that article.) The last character is but slightly perceptible, and the others may perhaps hardly be thought sufficient to separate plants so precisely alike in habit. We shall nevertheless enumerate the species as given by Mr. Ker, late Gawler.

1. *T. Bulbocodium*. Channel-leaved Trichonema. Ker n. 1. Ait. n. 1. (*Ixia Bulbocodium*; Linn. Sp. Pl. 51. Willd. Sp. Pl. v. 1. 196. Jacq. Coll. v. 3. 265. Ic. Rar. t. 271. Curt. Mag. t. 265. Redout. Liliac. t. 88.

Sm. Fl. Græc. Sibth. t. 36. Compend. Fl. Brit. ed. 2. 6. Engl. Bot. t. 2549. Dickf. H. Sicc. fasc. 18. n. 1? Silyrinchium Theophrasti; Column. Ecphr. 328. t. 327. Crocus vernus; Ger. Em. 153. f. 1, 2.)—Leaves linear, channelled, recurved, longer than the flower-stalk.—Native of grassy hillocks, and sandy ground near the sea, in the south of Europe, from Jersey and Guernsey to the Archipelago, in which last country it is very abundant, flowering in March and April. We have no where seen this pretty plant more beautiful, with its numerous varieties, than on the hillocks around the celebrated fountain of Egeria, near Rome. There all the different appearances of the flower, with respect to size and colour, which the above figures represent, and indeed many more, may be collected at once; nor can they fail to convince an observing botanist that they are no more distinct species, than our red or blue garden anemonies. The bulb is ovate, the size of a filbert, with many entire smooth coats. Leaves radical, recurved and widely spreading, narrow, smooth, rusty. Stalks one or two, combined at the base, single-flowered, more or less curved, round, smooth, much shorter than the leaves, though considerably elongated after flowering. Sheath somewhat coloured. Corolla from one to two inches long, purplish, pale rose-coloured with a yellow base, or almost white in the border, always variously streaked; the backs of the three outer segments greenish; all the segments elliptical, but various in breadth. Capsule membranous, corrugated, purplish. We cannot separate Mr. Ker's *roseum*, for which he cites *Curt. Mag.* t. 265, however different that figure may, at first sight, appear.

2. *T. cruciatum*. Square-leaved Trichonema. Ker n. 3. Curt. Mag. t. 575. Ait. n. 2. (*Ixia cruciata*; Willd. Sp. Pl. v. 1. 197. Jacq. Ic. Rar. t. 290. Bulbocodium pedunculis nudis unifloris, foliis subulatis linearibus longifimis; Mill. Ic. 160. t. 240; not 260, as in Hort. Kew. an almost unique error of the kind in the accurate Mr. Dryander, caused by the awkward roman numerals.)—Leaves linear, four-sided, with as many deep channels.—Native of the Cape of Good Hope. The leaves are more erect than in the former, various in breadth, but always known by their four-sided figure, displayed in a transverse section. The stalk is solitary, short and simple. Corolla variable in size, pale crimson or purplish, streaked, externally green; its segments acute and recurved.

3. *T. chloroleucum*. Green and white Trichonema. (*T. chloroleucum*; Ker n. 4. *Ixia chloroleuca*; Jacq. Coll. v. 4. 180. Jacq. Ic. Rar. t. 272, not 270. Willd. Sp. Pl. v. 1. 196.)—Leaves linear, revolute. Leaves of the sheath equal, coloured.—Native of the Cape of Good Hope. The leaves are usually two, unequal, one of them decumbent; their margins revolute, whence they become almost acetaceous. Stalk solitary, single-flowered, erect, much shorter than the leaves. Sheath light purple, membranous. Corolla near two inches long, erect, white, striated, the three outer segments light green at the back. *Jacquin*.

4. *T. speciosum*. Crimson Trichonema. Ker n. 5. (*Ixia Bulbocodium*, var. *flore speciosissimo*; Andr. Repof. t. 170.)—Leaves linear, channelled, the length of the stem, which bears a solitary leaf near the top.—Native of the Cape of Good Hope, from whence Mr. G. Hibbert received its bulbs in 1800. These flowered in his garden at Clapham the following March. Thus appears most akin to the first species in its leaves, except their being more erect, and scarcely exceeding the length of the stem. The latter, though simple, bears one leaf near the top, according to Mr. Andrews, who is our only authority. We are aware that the European *T. Bulbocodium*, when it has two flowers,

bears also a leaf at the junction of their stalks. The *flower* of the present plant is uncommonly handsome, near two inches long, of a rich crimson; violet at the base; its three outer segments yellowish at the base, with crimson veins. The *sheath* is narrow, green and leafy, less membranous, or coloured, than in most of the rest.

5. *T. pudicum*. This is merely mentioned by Mr. Ker, as the *Ixia pudica* of Dr. Solander in Sir Joseph Banks's herbarium, without any indication of its character or distinctions.

The able writers from whom we adopt this genus, indicate several European as well as African species, that remain hitherto undefined. Of the latter we have not sufficient materials to judge; but the probability of there being some such cannot be doubted. What we have seen of the European specimens would, however, render us much on our guard against those of exotic origin.

TRICHONIUM, in *Ancient Geography*, a town of Greece, in Etolia.

TRICHOPHORUM, in *Botany*, from $\tau\rho\iota\chi\omicron\varsigma$, a bristle, and $\phi\epsilon\rho\omega$, to bear, because of the bristles encompassing the seed, in allusion to *Eriophorum*, (see that article,) out of which the present genus is extracted.—“Perfoon Ench. v. 1. 69.” Pursh 57.—Class and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperoideæ*, Juss.

Gen. Ch. *Cal.* Spike, or Catkin, imbricated every way, with ovate, flattish, pointed, keeled, loose scales, distinguishing the flowers. *Cor.* none. *Stam.* Filaments three, capillary; anthers erect, oblong. *Pist.* Germen superior, roundish, very small; style thread-shaped, the length of the scale, deciduous; stigmas three, elongated, reflexed. *Peric.* none. *Seed* solitary, beaked, ovate, triangular, with from six to nine capillary, wavy, brown bristles at the base, six times its own length. *Receptacle* cylindrical, cellular, and toothed.

Ess. Ch. Glumes chaffy, imbricated every way. Corolla none. Style deciduous. Seed triangular, beaked, furrounded at the base with from six to nine hairs, scarcely longer than the spike.

Obs. The difference between this genus and *Eriophorum* consists in the comparatively small number of hairs furrounding the base of the seed, and their much shorter proportion, to say nothing of their brown hue. All these circumstances certainly give the *Trichophorum* a different, and far less brilliant, aspect. It is in fact more akin to various species of *Scirpus*, whose seeds are accompanied by short, flat, rough bristles.

1. *T. cyperinum*. Many-headed Hair-rush. Pursh n. 1. (*Eriophorum cyperinum*; Linn. Sp. Pl. 77. Willd. Sp. Pl. v. 1. 313. Ait. H. Kew. v. 1. 134. *Scirpus Eriophorum*; Michaux Boreal.-Amer. v. 1. 33. *Cyperus millicæus ex provinciâ Marianâ, paniculâ villosâ aureâ*; Pluk. Mant. 62. t. 419. f. 3.)—Stem leafy. Panicle doubly compound.—In ditches and near ponds, from Canada to Carolina, flowering in July and August, perennial, very tall. Pursh. The tufted partial *flower-stalks*, angular and rough, resemble little compound umbels, with many scaly bristles at the base. Heads numerous, each the size of a large pea, their brown scales partly concealed by the fine prominent tawny hairs. Seeds white.

2. *T. alpinum*. Alpine Hair-rush. Pursh n. 2. (*Eriophorum hudsonianum*; Michaux Boreal.-Amer. v. 1. 34.)—Stem naked. Spike solitary.—In bogs on the mountains of Pennsylvania, Vermont, &c. flowering in August. Perennial. Stem triangular, as in the first species, but quite naked. Leaves radical, few, setaceous, channelled. *Mi-*

chaux, Pursh. We have Newfoundland specimens from Mr. Frazer, which answer to these characters. If so, the spike consists of scarcely more than three or four flowers, and the bristles of the seed are about the length of the shining tawny scales.

TRICHOPUS, from $\tau\rho\iota\chi\omicron\varsigma$, a hair, and $\pi\omicron\upsilon\varsigma$, a foot, expressive of the long taper stalk of the capsule.—Gærtner. v. 1. 44. t. 14.—Class and order unknown.

Ess. Ch. Capsule inferior, membranous, with three wings, and three cells, not burfing. Seeds two in each cell, triangular, deeply notched.

1. *T. zeylanicus*. Bempul of the Cingalese, described by Gærtner from the collection at Leyden. Capsule ovate, very thin, without valves, each angle extended into a wavy membranous border; each side marked with a longitudinal furrow; partitions from the centre of each valve, very thin; the base running down into a triangular stalk, gradually tapering to a fine capillary extremity. Seeds rusty-coloured, tumid, variously and deeply notched or lobed. Skin simple. Albumen conformable to the seed, with a longitudinal furrow, hard, cartilaginous, pale. Embryo very minute, in the lowest part of the albumen, monocotyledonous.

Gærtner observes some affinity between this plant and the *Commelina* tribe, but the inferior capsule appeared to him to denote a very distinct genus, of which he could discover no traces in any author.

We do not perceive why the great length of the stalk was admitted by Gærtner into the generic character, as the capsule being inferior, renders it a mere flower-stalk. No following botanist has thrown any light on this genus.

TRICHOPUS, in *Ichthyology*, a new genus of fishes, described by Cope from the MSS. and drawings of Comerson; the characters of which are, that the body is compressed, and that the ventral fins have an extremely long filament. Cope has unnecessarily divided these fishes into two distinct genera, calling one “*Osphronemus*,” and the other “*Trichopodus*.” These fishes are natives of the Indian seas and rivers, and are distinguished, one species excepted, by the remarkable length of one ray of the ventral fins, which extends the whole length of the body, or even beyond it.

Species.

GORAMY; Rufescent *Trichopus*. With a silvery cast on the sides, and the second ray of the ventral fins extremely long; *Osphronemus Goramy* of Cope. Native of the fresh waters of China, where it is greatly esteemed as an article of food, and known by the name of “*Goramy*.” It is a prolific species, and easily introduced into new situations; having been imported into Java, and many other of the eastern islands.

ARABICUS; Greenish *Trichopus*. With violet and blue stripes, and second ray of the ventral fins extremely long; the *Osphroneme Gal* of Cope, the *Labrus Gallus* of Linn. Syst. Nat. Gmel., and the *Scarus Gallus* of Forsk. Arab. See *LABRUS Gallus*.

SATYRUS. With sinking forehead, projecting chin, and extremely long, single-rayed ventral fins; *Trichopode Mentonier* of Cope. This fish is known in some countries by the name of “*Goramy*,” or “*Gouramy*.”

PALLASII; Brown *Trichopus*. With pale undulations; a black spot on each side of the body and tail; and long single-rayed ventral fins. Described by Dr. Pallas as a species of *Labrus*, and by Kolreuter, in the Petersburg Transactions, as a *Sparus*. See *LABRUS Trichopterus*.

MONODACTYLUS; Silvery *Trichopus*. With brownish back; and short, single-rayed, rigid ventral fins; *Monodactyle*

daizyle falciforme of Cepede, and described by him under the genus *Monodactylus*. Shaw's Zoology, vol. iv. pt. 2.

TRICHOSANTHES, in *Botany*, elegantly so called by Linnæus, from *τριχος*, a hair, and *ανθος*, a flower, in allusion to the fine capillary segments which border the corolla. The same idea may be expressed in English by Hair-blossom.—Linn. Gen. 505. Schreb. 661. Willd. Sp. Pl. v. 4. 598. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 340. Juss. 396. Lamarck Illustr. t. 794.—Class and order, *Monoclea Syngenesia*, Linn. *Monoclea Polyadelphia* rather, as suggested in Sm. *Introd. to Bot.* ed. 3. 363. Nat. Ord. *Cucurbitaceæ*, Linn. Juss.

Gen. Ch. Male. *Cal.* Perianth of one leaf, club-shaped, very long, smooth, with five small reflexed teeth at the mouth. *Cor.* of one petal, united with the calyx, flat, spreading, deeply divided into five ovato-lanceolate segments, fringed with very long, branched, capillary, ipreading subdivisions. *Stam.* Filaments three, very short, crowning the rim of the calyx; anthers five, combined into a cylindrical upright body, marked all over with a line curved up and down in all directions, bearing the pollen.

Female, on the same plant, *Cal.* Perianth as in the male, superior, deciduous. *Cor.* as in the male. *Pist.* Germen inferior, oblong, slender; style thread-shaped, the length of the calyx; stigmas three, oblong, awl-shaped, splitting. *Peric.* Berry oblong, coated, of three widely separated cells. *Seeds* numerous, compressed, obtuse, unicated.

Eff. Ch. Male. Calyx with five teeth. Corolla in five deep segments, with a branched fringe. Filaments three.

Female, Calyx with five teeth. Corolla in five deep segments, with a branched fringe. Style three-cleft. Berry oblong.

1. *T. anguina*. Snake Hair-blossom, or Snake Gourd. Linn. Sp. Pl. 1432. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 722. (*Anguina sinensis*, flore albo elegantissimo, &c.; Mich. Gen. 12. t. 9. Mill. Ic. t. 32. *Cucurbita sinensis*, fructu longo anguino, &c.; Till. Pis. 49. t. 22.)—Fruit cylindrical, elongated, incurved. Leaves heart-shaped, lobed, wavy, with little pointed teeth.—Native of China and Cochinchina, according to Micheli and Loureiro. A tender annual in our stoves, whose seeds are often imported from the East Indies. The herbage is trailing, luxuriant, and much branched, like the rest of its tribe, with *tendrils*, and broadish melon-like *leaves*, whose under surface is finely downy. *Flowers* in loose long-stalked *clusters*, conspicuous for their snowy whiteness, and capillary or cobweb-like border, by which, in the warm stillness of a stove, they seem suspended in the air, though the least breath might destroy them. The *fruit*, three or four feet long, and an inch or two in diameter, of a dark shining green, often marked with white, more or less coiled or undulated, lies on the ground, partly shaded by the *leaves*, and has the appearance, at first sight, of a large snake. Hence Micheli took his generic name, which is most commodiously, as a specific one, made into an adjective.

2. *T. scabra*. Rough Hair-blossom. Loureir. Cochinch. 589. Willd. n. 2. (*T. angulata*; Lamarck Dict. v. 1. 190? Willd.)—Fruit roundish, many-lobed. Leaves roundish-heart-shaped, rough, very rugged. Stalks single-flowered.—Native of woods in Cochinchina, where it is called *Dua nhà thoi*. Stem shrubby, many-furrowed, climbing by means of cloven *tendrils*. *Leaves* alternate, stalked. *Flowers* solitary, on simple axillary stalks, white, with a short fringe. *Fruit* small, red, roundish, with twelve lobes, and five cells. *Seeds* numerous, flat, oblong. This de-

scription of Loureiro does not, as to the *fruit*, answer well to the character of the genus; but that part is known to be the least uniform or constant of any, in this tribe, even in the same species.

3. *T. fetidissima*. Fetid Hair-blossom. Jacq. Coll. v. 2. 341. Ic. Rar. t. 624.—Fruit ovate, pointed, furrowed. Leaves oblong-heart-shaped, viscid, nearly entire. Corolla fringed with simple teeth.—Native of the coast of Guinea. Jacquin says it proved a greenhouse plant with him, flowering in summer in the open air. The *root* is perennial, tap-shaped. Whole *plant* viscid and fetid like putrid flesh, or the *Stapelia hirsuta*, which odour adheres to the hands of any person who touches it. *Stems* one or more, annual, herbaceous, branched, leafy, rising by *tendrils* to the height of eight feet. *Leaves* drooping, hairy, stalked, from one and a half to three inches long; paler beneath. *Flowers* small, yellow; their border beset with bristly teeth. *Fruit* tawny, measuring with its beak about an inch and a half. Nothing can less answer to the idea of the original species than the present, nor ought they to rank in the same genus.

4. *T. nervifolia*. Rib-leaved Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 4. (*Tota-piri*; Rheede Hort. Malab. v. 8. 33. t. 17. Raii Hist. v. 3. 337, not 377.)—"Fruit ovate, acute. Leaves oblong-heart-shaped, three-ribbed, toothed."—Found about Cranganore, on the coast of Malabar, flowering in the rainy season. *Stems* slender. *Leaves* paler beneath. *Flowers* white, with a long entangled fringe. *Fruit* like a cucumber. A sneezing medicine is made of the leaves, with garlic, supposed useful in the epilepsy. The juice of these *leaves*, mixed with some kind of oil, is used to anoint the temples of maniacs; to whom also a fumigation, made by a woollen thread dipped into the juice of the leaves and bruised fruit, and then burnt, is thought in India to be beneficial.

5. *T. caudata*. Beaked Hair-blossom. Willd. n. 5. (*T. cuspidata*; Lamarck Dict. v. 1. 190. Scheru-padavalam; Rheede Hort. Malab. v. 8. 31. t. 16. Raii Hist. v. 3. 337.)—Fruit turbinate-ovate, with an elongated point. Leaves oblong, heart-shaped, three-ribbed, toothed.—Native of the East Indies. Nearly related to the following, but smaller in every part, and the *fruit* is turbinate, crowned with the tube of the *calyx*.

6. *T. cucumerina*. Cucumber Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 6. Ait. n. 2. (*Padavalam*; Rheede Hort. Malab. v. 8. 30. t. 15. Raii Hist. v. 3. 337.)—Fruit ovate, acute. Leaves roundish-heart-shaped, deeply lobed, angular, wavy.—Native of sandy ground among trees, on the Malabar coast, flowering in June and July. Every part is fetid. *Root* widely ipreading, fibrous, annual. *Stems* herbaceous, angular, hairy, not very harsh. *Leaves* soft and downy, divided down to the stalk. *Flowers* white, small, with a long entangled fringe. *Fruit* yellowish; the *seeds* lodged in red pulp. Prepared with sugar, this *fruit* is thought to help digestion, and cure pains of the stomach and bowels, killing worms, promoting expectoration, &c. The juice of the *root* is purgative and emetic, useful in intermittent fevers.

7. *T. amara*. Bitter Hair-blossom. Linn. Sp. Pl. 1432. Willd. n. 7. (*Colocynthis flore albo simbratio, fructu oblongo*; Plum. Amer. 86. t. 100. Raii Hist. v. 3. 332.)—Fruit oblong-obovate, obtuse. Leaves heart-shaped, sinuated, rough; dotted beneath.—Gathered by Plumier, in the woods of Hispaniola, flowering in December, and bearing ripe fruit in April. The *leaves* are remarkably small, hardly an inch and a half in breadth or length, roughish,

with minute points. *Flowers* white, as large as in *T. anguina*, but with a simple, much shorter fringe. *Fruit* four or five inches long, and an inch and a half in diameter, contracted at the base; its rind thin, smooth, greenish, variegated; the pulp white and very bitter, with brown seeds.

8. *T. tricuspida*. Three-pointed Hair-blossom. Loureir. Cochin. 589. Willd. n. 8.—“Fruit ovate, acute. Leaves heart-shaped, three-pointed, many-ribbed, smooth.—Native of Cochinchina. *Stem* shrubby, climbing, with three-cleft tendrils. *Leaves* finely toothed, with thick, nearly orbicular, crenate stipulas. *Flowers* fringed, white, in axillary spikes, with large toothed bractees. *Fruit* small, yellow, of two cells, with two seeds. Loureiro.

9. *T. pilosa*. Villous Hair-blossom. Loureir. Cochin. 588. Willd. n. 9.—Fruit ovate, acute. Leaves heart-shaped, toothed, hairy; the lower ones palmate; upper three-lobed. Found wild in Cochinchina. *Stem* rather shrubby, climbing to a great extent, by means of divided tendrils, hairy as well as the leaves. *Spikes* lateral, long, with lanceolate serrated bractees. *Flowers* white, with a long fringe. *Fruit* scarlet, of one cell. *Seeds* rhomboid, compressed, lobed, brown.

10. *T. tuberosa*. Tuberos Hair-blossom. Willd. n. 10. Ait. n. 3. (*T. corniculata*; Lamarck Dict. v. 1. 191. Anguria fructu parvo, florum segmentis ramosis; Plum. Ic. 14. t. 24.)—Fruit elliptic-oblong. Leaves in three deep lobes; the lateral ones cloven; all entire.—Native of the West Indies. M. Thouin sent it in 1810 to Kew, where it blossoms in the stove about June and July. The root is a huge, globular, perennial, tuberculated, fleshy mass, near a foot in diameter. *Stems* annual, climbing by simple tendrils. Segments of the leaves lanceolate, divaricated, two or three inches long. *Flowers* somewhat umbellate. *Corolla* with a longish rather sparing fringe at the end of each segment, if we may rely on Burman's copy of Plumier's figure. Willdenow has taken rather an unwarrantable liberty in changing Lamarck's printed names, of this and our fifth species; though in the present instance certainly for the better, the resemblance of horns, in the flower, being probably a deception.

11. *T. laciniosa*. Jagged Hair-blossom. Willd. n. 11.—“Fruit ovate, acute. Leaves heart-shaped, palmate, with five or seven lobes, toothed, smooth.”—Native of the East Indies. Sent by Klein to Willdenow, who describes it with a smooth, slender, angular, climbing stem. *Leaves* two or three inches long, remotely toothed. *Male flowers* about six together, in axillary corymbose clusters; with ovate toothed petals: female ones solitary, on axillary stalks; their petals fringed.

TRICHOSTEMA, so called by Gronovius, from $\tau\rho\iota\chi\omicron\varsigma$, hair, and $\sigma\tau\eta\mu\alpha$, the stamen of a flower, alluding to the peculiarly long capillary filaments of the original species.—Linn. Gen. 300. Schreb. 397. Willd. Sp. Pl. v. 3. 170. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 425. Pursh 414. Juss. 116. Lamarck Illustr. t. 515.—Class and order, *Didymia Gymnospermia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped; the upper lip twice the largest, in three equal acute segments; lower in two deep acute segments. *Cor.* of one petal, ringent; tube very short; upper lip compressed, falcate; lower in three deep segments, the middle one oblong, very small. *Stam.* Filaments four, capillary, remarkably long, incurved, two rather shorter than the rest; anthers simple. *Pist.* Germen four-cleft; style capillary,

the length and shape of the filaments; stigma cloven. *Peric.* none, except the enlarged, inflated, closed calyx, so reflexed that its upper lip becomes the lower. *Seeds* four, roundish.

Ess. Ch. Upper lip of the corolla falcate. Stamens very long. Calyx two-lipped.

Obs. It is necessary to note, that the above characters, as far as respects the stamens, agree with the specific definition of one of the two Linnæan species only. Linnæus has left a manuscript remark, that “Adanson refers this genus to *TEUCRIUM*”; see that article. He certainly does so, in his *Familles des Plantes*, v. 2. 188, like Dillenius; but in contradiction to his own just character of the latter, confining in the want of an upper lip.

1. *T. dichotomum*. Marjoram-leaved Annual Trichostema. Linn. Sp. Pl. 834. Willd. n. 1. Ait. n. 1. Pursh n. 1. (*Trichostema*; Linn. Hort. Cliff. 493. *T. staminibus longissimis exsertis*; Gron. Virg. ed. 2. 90.)—Stamens very long, prominent. Leaves rhomboid-lanceolate. Flowering branches twice forked.—In fields and on sunny hills, from Pennsylvania to Carolina. Annual, flowering in July and August. *Flowers* large, fine blue. The whole plant has an agreeable resinous scent. *Pursh.* Root fibrous. *Stem* a span high, erect, round, downy, with opposite crossing branches. *Leaves* opposite, lanceolate, obtuse, entire, rough, the lower ones accompanied by axillary tufts of small leaves, or rudiments of branches. *Flowering branches* from the bosoms of the upper leaves, taller than the stem, crossing each other, and bearing a leaf similar to those just described. Each branch ends in a panicle form, with forked divisions, the proper flower-stalks single-flowered. *Stamens* setaceous, very long. *Calyx* reflexed after flowering. Linn. Hort. Cliff.

Pursh adopts from Walter, *Fl. Carol.* 164, a variety with linear leaves, called by that writer *T. lineare*.

2. *T. brachiatum*. Sessile-leaved Trichostema. Linn. Sp. Pl. 834. Willd. n. 2. Ait. n. 2. Pursh n. 2. (*Teucrium virginicum, organi folio*; Dill. Elth. 380. t. 285.)—Stamens short, within the flower. Leaves ovate-lanceolate. Flowering branches opposite, panicle.—Native of Virginia, according to Dillenius. Mr. Pursh never saw this species but in the Banksian herbarium, nor have we examined an authentic specimen. The habit of the plant seems much like the last, but the leaves are more sessile. Dillenius's representation of the parts of the flower, though, doubtless, accurate, but ill agrees with the Linnæan generic description, nor are those parts far unlike those of a *Teucrium*. The stamens are strongly incurved, or involute, and therefore do not project out of the flower. We suspect this may not be a distinct species from the foregoing. Both require elucidation from American botanists.

3. *T. spirale*. Spiral Trichostema. Loureir. Cochin. 371. (*Cây râu mèd* of the Cochinchinese.)—“Stamens very long and spiral. Leaves ovate, acute.”—Native of Cochinchina. *Stem* herbaceous, erect, square, four feet high, with opposite crossing branches. *Leaves* opposite, entire, downy. *Flowers* pale violet, in long terminal spikes. *Corolla* ringent, its upper lip falcate. *Stamens* very long, rolled up spirally, and retained within the corolla. Loureiro. This last character answers exactly to Dillenius's plate of *T. brachiatum*, to which Loureiro thought his plant nearly akin. Not having, probably, access to that plate, he did not discover how well it agreed, even where he thought the difference greatest.

TRICHOSTOMUM, from $\tau\rho\iota\chi\omicron\varsigma$, τριχος, a hair, and $\sigma\tau\eta\mu\alpha$, the mouth, because the fringe of this moss is remarkable

TRICHOSTOMUM.

remarkable for the length and slenderness of its hairs. Fringe-mosses.—Hedw. Fund. v. 2. 90. t. 8. f. 43, 44, but indifferent. Sp. Musc. 107. Schreb. Gen. 760. Sm. Fl. Brit. 1235. Engl. Bot. t. 1152. Swartz Musc. Succ. 29. Turn. Musc. Hib. 33. (Didymodon; Hedw. Crypt. v. 3. 8. Sp. Musc. 104. Schreb. 760. Swartz Musc. Succ. 27. Swartzia; Hedw. Crypt. v. 2. 72. Cynontodium; Hedw. Sp. Musc. 57. Bryi species varix; Linn. Hudf.)—Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Capsule oblong. Fringe of thirty-two capillary straightish teeth, approximated or united in pairs.

Trichostomum of Hedwig has, or ought to have, all the teeth of its fringe minutely connected together, at the very base, in pairs. The genera which the writer of this article first presumed to reduce to the present, as above indicated, have distinct teeth, though those teeth nevertheless approach each other in a similar manner. These genera differ among themselves in having separated or united flowers. None can be more naturally akin than they all are, and they have been disunited by obscure and difficult, as well as unnatural marks. Of this so good a judge as Mr. Turner could not but be aware, and we are happy in having his concurrence. What is said under the article DICRANUM of the general habit of that genus, is in a great measure applicable to this; except a remarkable difference in the aspect and texture of their fringes. This part in *Trichostomum*, instead of being broad, stout, transversely furrowed, red, with pale points, is long, slender, and of even thickness and colour. The small and unbranched species of the two genera most resemble each other. The great branched hoary *Trichostoma*, comprehended under *Bryum hypnoides* of Linnæus, Hudson, &c. are least allied to *Dicranum*. We are not aware of any *apophysis*, or glandular base, to the capsule, in the genus before us.

The species are commodiously disposed in two sections, distinguished by the separation or combination of their teeth. Eighteen are natives of Britain, which is about the number that Hedwig reckons up all together. We shall describe the most remarkable.

SECT. 1. *Teeth of the fringe all distinct at the base*. Five British species.

T. trifarium. Three-ranked Fringe-mosses. Fl. Brit. n. 1. Engl. Bot. t. 1707. (Cynontodium trifarium; Hedw. Sp. Musc. 57. Swartzia trifaria; Hedw. Crypt. v. 2. 76. t. 28. Bryum trifarium; Dickf. Crypt. fasc. 3. 8.)—Leaves lanceolate or awl-shaped, in three rows, keeled, entire. Capsule ovate. Stem branched.—Native of barren hilly ground. Dr. Abbot discovered it at Clapham Springs, near Bedford. None but a discerning botanist would distinguish this little moss from many others, far more common. The tufts are perennial, scarcely half an inch high, of a dull rusty green. *Leaves* with a strong, often reddish, mid-rib, but no bristly point; the lower ones broadest. *Flowers* terminal, each consisting of a few jointed *stamens*, and still fewer brown *pisils*, of which latter one only comes to perfection. *Fruit-stalk* hardly an inch high, rather wavy, bulbous at the base, its lower half red. *Capsule* erect, small, of a shining brown. *Lid* conical, slightly curved, scarcely so long as the capsule. *Fringe* paler in our specimens than in Hedwig's plate, but drawn rather too long in *Engl. Bot.*

T. capillaceum. Capillary Fringe-mosses. Fl. Brit. n. 2. Engl. Bot. t. 1152. (Swartzia capillacea; Hedw. Crypt. v. 2. 72. t. 26. Bryum capillaceum; Dickf. Crypt. fasc. 1. 4. t. 1. f. 6. Fl. Dan. t. 1000. f. 1. B. æstivum; Hudf. 485, excluding the synonym of Dillenius. B. n. 1806;

Hall. Hist. v. 3. 44. t. 45. f. 1.)—Leaves capillary, in two rows; sheathing and dilated at the base. Capsule elliptic-cylindrical. Lid conical. Stems very densely tufted.—Not uncommon in bogs on the mountains of Scotland, Wales, and the north of England, as well as Switzerland and Sweden, bearing capsules in April or May. Though figured by Haller, this moss was little understood by British botanists, when the writer of the present article gathered it on the Pentland hills, near Edinburgh, in May 1782, and communicated it to Mr. Dickson, to whom it was new. The *stems* are several inches high, very slender, rusty, crowded into dense and wide perennial tufts, soaked in water, and conspicuous for the delicate bright green of the fine capillary *leaves* which clothe their summer shoots. The numerous *fruit-stalks*, an inch and half or two inches long, red and shining, at length zigzag, are of an equally slender and delicate habit. *Capsule* erect, small, nearly cylindrical, thin, smooth, pale shining brown, darker or tawny at the edge, as is the small conical *lid*. *Veil* very slender. *Fringe* brownish, deciduous.

T. papillosum. Papillary Fringe-mosses. Fl. Brit. n. 5. Engl. Bot. t. 2533. (Bryum papillosum; Dickf. Crypt. fasc. 4. 12. t. 11. f. 5.)—Leaves awl-shaped, keeled. Capsule elliptical, nearly erect, gibbous on the lower side at the base. Lid conical. Stem branched.—Found by Mr. Dickson alone, on turfy bogs, in the Highlands of Scotland. The *stems* are branched and level-topped about half an inch high. *Leaves* dark-green, slender, imbricated every way, entire. *Fruit-stalks* an inch or inch and half high, terminal, erect, red, with a cylindrical sheath at the base. *Capsule* red-brown, smooth, with a prominence, like a short spur, at the base, which renders this species very remarkable and distinct, but does not seem to be of the nature of an *apophysis*. The *lid* is conical, short. *Teeth* of the fringe certainly thirty-two.

SECT. 2. *Teeth of the fringe connected in pairs at the base*. Thirteen British species.

T. lanuginosum. Toothed Hoary Fringe-mosses. Hedw. Sp. Musc. 109. Crypt. v. 3. 3. t. 2. Fl. Brit. n. 8. Engl. Bot. t. 1348. (T. ferratum; Ehrh. Crypt. n. 94. Bryum hypnoides α; Linn. Sp. Pl. 1584. Fl. Dan. t. 476. B. hypnoides polycephalon, lanuginosum, montanum; Dill. Musc. 372. t. 47. f. 32.)—Leaves lanceolate, with a pellucid toothed point. Capsule ovate. Stem procumbent, branched in a pinnate manner.—This, a genuine specimen of the habit of a *Trichostomum*, is a very common moss in dry mountainous woods, and on exposed rocks, stones, walls or heaths, bearing capsules, though rarely, in autumn. The copiously branched, arching, elastic, leafy *stems* compose large light soft tufts, on which many a tired hunter or botanist has reposed. The *leaves* are of a dull yellowish-green, rendered hoary, when dry, by their flat white inflexed points, which are curiously bordered with short, broad, abrupt teeth, in a manner unlike every other species, and not ill resembling the cogs of a wheel. *Fruit-stalks* from the small branches, lateral, solitary, half an inch long, tawny, twisted when dry. *Capsule* erect, brown, smooth, thick and short, with an awl-shaped lid, and a pale reddish *fringe*. The *veil* is conical, brown-pointed, splitting up in many different parts, not all at one side.

T. ericoides. Heath-like Hoary Fringe-mosses. Schrad. Spicil. 62. Fl. Brit. n. 9. Engl. Bot. t. 1991. Turn. Musc. Hib. 38. (T. elongatum; Ehrh. Crypt. 233. Bryum ericoides; Dickf. Crypt. fasc. 4. 14. B. hypnoides γ; Linn. Sp. Pl. 1585. B. hypnoides, ericæ facie, capsulis barbatis, alpinum; Dill. Musc. 371. t. 47. f. 31.)—Leaves ovato-lanceolate, recurved, keeled and deeply chan-

TRICHOSTOMUM.

nelled, with a pellucid finely ferrated point. Capsule ovate. Stem erect, with very short branches.—One of the most handsome, as well as most rare, of its genus. Dr. Richardson originally sent it to Dillenius from the highest part of Snowdon. Two of our best British cryptogamists, Messrs. Borrer and Hooker, found it in fructification, in 1808, on the sandy shores of the Tay near Dunkeld. The stems are perennial, two or three inches high, erect, in loose tufts, leafy, subdivided, and furnished moreover with abundance of short spreading branches, which give the plant that resemblance to *Erica vulgaris*, expressed in the name. Leaves deep green, or tawny, spreading and recurved, revolute, entire, keeled with a deep channel resembling a mid-rib, and tipped with a fine ferrated hair-like point, most visible when dry. Fruit-stalks terminating the last year's shoots, about an inch and a half long, red, finally dark purple, twisted. Capsule erect, smooth, brown. Lid red, awl-shaped, straight, nearly of the same length. Fringe purple, almost as long, straight and slender. Veil fringed with jagged teeth, not splitting.

T. canescens, Common Hoary Fringe-mofs. Hedw. Sp. Musc. 111. Crypt. v. 3. 5. t. 3. Fl. Brit. n. 10. Engl. Bot. t. 2534. (*Bryum hypnoides* z; Hudf. 480. *B. hypnoides* hirsutie canescens, vulgare; Dill. Musc. 368. t. 47. f. 27?)—Leaves ovate-lanceolate, with a central channel, but no nerve, and a pellucid rough point. Capsule ovate. Stem erect, with upright branches.—Very common every where, on open, dry, sandy heaths, or moors, both in mountainous and maritime situations, bearing capsules about February or March, but not frequently. The branches are more level-topped and ascending than in the last-described, and the leaves of a yellower green, becoming very hoary when dry, in consequence of their white points, rough in every direction. The want of a mid-rib in this species, though there is a furrow appearing like one, has been pointed out as a means of distinguishing it from the rest, especially from *T. ericoides*. But the same character is found, as we have already described, in that species; while some of Dillenius's specimens of the present, very carefully examined, prove to have an actual rib. These are possibly accidental fragments of another species. The present certainly has no mid-rib, and has its capsule, fringe, and lid accord exactly with *ericoides*. The latter may be, as Hedwig thought, but a variety of this more common and less elegant kind. Whether there be any permanent difference in the roughness of the points of their leaves, which affords a clear distinction in *T. lanuginosum*, can only be determined by a more minute examination than our materials will admit.

T. fasciculare. Beardless Hoary Fringe-mofs. Schrad. Spicil. 61. Fl. Brit. n. 11. Engl. Bot. t. 2005. (*B. hypnoides* β; Linn. Sp. Pl. 1585. *B. hypnoides*, hirsutie virefcens, fasciculare alpinum; Dill. Musc. 370. t. 47. f. 28.)—Leaves lanceolate, pointed, revolute, keeled. Capsule ovate-oblong. Stem branched, diffuse.—An inhabitant of dry rocky mountains in the North, bearing plenty of capsules in the spring, whose empty blackened remains continue long. This species approaches several mountain kinds of *Dicranum* in habit, but is a genuine *Trichostomum*. The hoariness of the old plants arises partly from a whitish hue assumed by the leaves in decay, and partly from their slightly pellucid edges; but not from any pellucid or hair-like point, the want of which renders *T. fasciculare* very distinct from the three foregoing. Its fringe too is much shorter, and the leaves have a mid-rib.

T. glaucescens. Glauous Fringe-mofs. Hedw. Crypt. v. 3. 103. t. 37, B. Fl. Brit. n. 14. Engl. Bot. t. 2381. (*Bryum glaucescens*; Dickf. Crypt. fasc. 4. 10.)—Leaves

linear-lanceolate, acute, rather glaucous. Capsule ovate, slightly furrowed. Stem erect, somewhat branched.—Native of Sweden and Scotland, in which last country Mr. Dickson discovered this pretty and uncommon species, growing in shady rather mountainous situations. We have not heard of it from any other person. The stems compose perennial leafy tufts, scarcely half an inch high. Leaves erect, pointless, rather incurved when dry, of a light-green, slightly glaucous, entire, keeled, with a mid-rib; the upper ones most elongated and tapering. Capsules peculiarly light-coloured and shining, with a purple fringe, and a conical oblique lid, reddish at the base, half the length of the capsule. The internal cavity of the latter does not reach to the bottom, which, as the thin outer coat of the capsule dries, causes a contraction there, like an *apophysis*, but of a very different nature. The same appearance is observable in some species of *Bryum* with club-shaped fruit.

T. lineare. Linear-leaved Fringe-mofs. Fl. Brit. n. 17. Engl. Bot. t. 1598. (*Bryum lineare*; Dickf. Crypt. fasc. 3. 6. t. 8. f. 2.)—Leaves linear-lanceolate, imbricated, acute. Capsule elliptical. Lid conical, oblique. Stem erect.—Native of Scotland, Wales, and Northumberland, in wet places, on a calcareous or sandy soil, bearing capsules in the spring. Stems tufted, branched, perennial, an inch or more in height, clothed with dark-green leaves, which vary from an almost linear to an ovate form, and turn either yellowish or blackish, from constant immersion in water, or from its dripping upon them. Fruit-stalks red, an inch long. Capsule ovate, smooth, with a taper lid of its own length. The aspect of this mofs, especially when growing in a wet shady place, is much like *Dicranum pellucidum*, and it has caused some mistakes by that means. Still more perhaps does it resemble a *TORTULA*, (see that article,) but the short straight delicate fringe truly indicates a *Trichostomum*. The teeth, standing in pairs, are connected by one common base, according to Mr. Sowerby.

T. fontinalioides. River Fringe-mofs. Hedw. Crypt. v. 3. 36. t. 14. Fl. Brit. n. 19. (*Fontinalis minor*; Hudf. 468. Dickf. Dr. Pl. 17. Engl. Bot. t. 557. *F. triangularis minor* carinata, e cymis capsulifera; Dill. Musc. 257. t. 33. f. 2. Hypnum n. 1796; Hall. Hist. v. 3. 41, excluding the synonyms of Dillenius and Linnaeus.)

β. *Fontinalis alpina*; Dickf. Crypt. fasc. 2. 2. t. 4. f. 1. (*Hypnum nigricans*; Villars Dauph. v. 3. 905, B.)—Leaves lanceolate. Capsules ovate, nearly sessile at the ends of the lateral shoots. Stem floating, very much branched.—Native of rivers, in various parts of England, as the Thames at Lambeth, the Isis at Oxford, and the Ouse at Oakley, Bedfordshire. The mountain variety β inhabits the stony beds of the more rapid streams of Scotland, Wales, and the north of England. Both are firmly attached to walls or stones under water, their numerous tufted, branched leafy stems, four or five inches long, floating with the stream. The leaves are of a very dark dull olive-green, narrower and almost black in the variety β, loosely imbricated, lanceolate, entire, acute, keeled, with a strong rib; all undulated and twisted when dry. Capsules terminating the lateral branches, solitary, erect, ovate, brown, smooth. Lid half as long, conical, rather curved. Fringe long, tawny or red, its teeth variously connected and pierced at the base, slightly convoluted when dry, soon falling off. The habit of this mofs is so little like the rest of its genus, that we cannot but wish the character of its fringe were more decidedly sufficient to establish a new one. The specific name moreover, though expressive, is barbarously constructed.

The reader will observe that *T. cirratum*, Fl. Brit. n. 6, is omitted in the Compendium, ed. 2, proving merely a large variety of *Dicranum polyphyllum*, Fl. Brit. 1225. Engl. Bot. t. 1217.

Some species referred to *Trichostomum* by Hedwig, on account of the approximation of their teeth, we consider as *Grimmia*, because they have only sixteen teeth, not thirty-two. An instance occurs in *G. homomalla*, Fl. Brit. 1194. Engl. Bot. t. 1900, so like *heteromalla*, which immediately precedes it in these works, that they can hardly be distinguished but by the above minute character. We acknowledge indeed that the dwarf species of *Trichostomum*, in general, have almost entirely the habit of *Grimmia*. But the difference between the numbers sixteen and thirty-two, in their teeth, appears, by the analogy of other genera, a most certain and natural generic distinction. See GRIMMIA.

TRICHOURI, in *Natural History*, a term used by some authors to express such flies as have one or more hairs growing out at their tails: these are called also *seticauda*.

TRICHRUS, the name of a stone described by the ancients, and said to yield three colours: in their common way of preparing bodies of this kind for medicinal use (which was by rubbing them down on a porphyry, or other hard stone with water), this first coloured the water black, then red, and lastly white. It seems to have been a kind of hæmatites, or blood-stone.

TRICKANDORE, in *Geography*, a town of Hindoostan, in the province of Tinevelly; 30 miles E.S.E. of Palamcotta.

TRICKUT, one of the Nicobar islands. N. lat. 8° 3'. E. long. 94° 10'.

TRICLARIA, in *Mythology*, an epithet given to Diana, in Achaia; and Pausanias tells us (In Corint.) that Menalippus and Cometho gratified their lust in the temple of Diana Triclaria. This profanation, as it is said, was followed with a general barrenness, inasmuch that the earth produced no fruit, and with an epidemical distemper, which swept away numbers of people. The Achæians, having consulted the oracle of Apollo, were answered by the priests, that the impiety of Menalippus and Cometho was the cause of all their calamities, and that the only way to appease the goddess was to sacrifice to her every year a boy and a young virgin.

TRICLINIUM, in *Antiquity*, the name given by the Romans to the room in which they eat; and also to the beds upon which they reclined at meat, so called, because it was contrived to accommodate three persons.

TRICOCCÆ, in *Botany*, one of the natural orders among the *Fragmenta* of Linnæus, where it ranks as the thirty-eighth, between the COLUMNIFERÆ and SILIQUOSÆ, (see those articles,) though without having scarcely any affinity of characters or qualities with either. The name is derived from *τρις*, three, and *κοκκος*, a grain, or seed, and alludes to the form of the seed-vessel, apparently composed of three combined lobes, each of which comprehends a single-seeded cell. (See DICOCcus.) We are not however to understand that every such seed-vessel belongs to this order. *Thea* is one exception among several; while, on the other hand, some genera which do belong to it may have only two lobes to their fruit; witness *Mercurialis*; while *Plukenetia* has four, and *Hura* a much greater number. The valves are generally powerfully elastic, serving by that means to scatter the seeds widely, as soon as they are fully ripe.

The plants composing this natural order have alternate, mostly simple, leaves, often furnished with glands. Their secreted fluids are milky, and extremely acrid, their milk being a natural emulsion, of a most virulent resin, or gum-

resin, mixed with a watery liquid. The calyx and corolla have, as Linnæus observes, always something unusual in their conformation, especially about the nectary. The style is generally peculiar, being three-cleft, sometimes very deeply, and each branch again divided. Many of the genera have separated, either monoecious or dioecious, flowers. The stems are either shrubby, sometimes very fleshy; or herbaceous, with annual or perennial roots.

Euphorbia is selected by Linnæus to exemplify the order of *Tricocca*. No genus can be more natural or distinct, however different the habit, or herbage, of some of the numerous species from each other. According to the generally received idea of this genus, its flowers are simple or united, each having a calyx of one concave or inflated leaf, whose four or five marginal teeth bear as many abrupt, coloured, nectariferous glands. These latter, in some instances, as *E. corollata*, assume perfectly the appearance of petals. Yet Linnæus was always much puzzled and surprised at the petals thus originating from the teeth of the calyx, of which he could scarcely find another example. Other peculiarities in this remarkable genus could not escape so accurate an observer, as the long stalk which elevates the germen out of the flower, and turns it to one side; and the progressive nature of the stamens, as well as their anthers, which come forth in succession. The herbage too is remarkably various, arboreous and succulent, or herbaceous; spinous or unarmed; the leaves opposite, or alternate, or deficient. Two species having an irregular calyx, gibbous underneath, were separated into a distinct genus by Dillenius, under the faulty name of *Tithymaloïdes*, but they are too naturally akin to the rest to justify such a measure.

Although the above is the generally received idea of *Euphorbia*, Jussieu, Gen. Pl. 386, has hinted that the flower is perhaps a compound one, consisting of a central female floret, with many monandrous male ones, distinguished by chaffy scales, all in one common involucre. Mr. Brown, in his very instructive Remarks on the Botany of Terra Australis, published at the end of captain Flinders's Voyage, has confirmed this opinion, by an additional observation. He conceives what all authors have taken for a joint in each filament, to be in fact the separation of the filament from its footstalk; or in other words the base, or receptacle, of the flower, or floret, which is entirely destitute of a proper perianth and corolla; the female floret likewise having its footstalk, on whose dilated, sometimes obscurely lobed, summit, the sessile germen is placed. In support of this doctrine, it is suggested that the real filament is, as in other plants, produced subsequent to the formation of its anther, and of the stalk below the joint; their surfaces moreover, in some species, being different in nature. But the most conclusive certainty is given to Mr. Brown's theory, by the discovery of a new genus, hitherto unpublished, having an involucre nearly similar to *Euphorbia*, inclosing several fasciculi of monandrous male flowers, around a solitary female; while in this there is an obvious perianth, regularly divided into lobes, at the joint of each supposed filament, as well as at that by which the germen is connected with its stalk.

The above idea of *Euphorbia*, as a monoecious genus, brings it nearer to the rest of this natural order, which have almost universally separated, either monoecious or dioecious, flowers. At least such is the case with the genera properly belonging to it, and which constitute Jussieu's order of *Euphorbia*, or *Euphorbiaceæ*.

TRICOLLORI, in *Ancient Geography*, a people of Gallia Narbonensis, whose capital was Alarante; who occupied the territory of Siteron.

TRICOLONI, or TRICOLONS, a town of Arcadia, N.E.

N.E. of Megalopolis. Here was a temple of Neptune, near it a sacred wood, and at a small distance a temple of Diana, surnamed Calista.

TRICOMIA, a town of Asia, in Phrygia Major.

TRICOR, a name by which some of the chemical writers have called gold.

TRICORD, an ancient musical instrument with three strings. The first lyre of Mercury is supposed by many to have had but three strings. Most of the writers on music among the ancients, have supposed that the three sounds of this primitive lyre, were E, F, G.

Julius Pollux called the *pandora*, or *pandura*, the instrument with three strings.

The emperor Heliogabalus, says Lampridius, sung, danced, recited, or declaimed to the sound of the flute, founded the trumpet, played on the *pandura* and the organ.

Here is work for ingenious conjectures: what was meant by reciting to the flute? What music could an instrument without a neck produce with only three strings? And what kind of instrument was the organ upon which Heliogabalus played, before organs were supposed to have been invented?

TRICORII, in *Ancient Geography*, a people of Gallia Narbonensis, mentioned by Lucan in his *Pharsalia*, and also by Livy and Polybius, in their account of the march of Hannibal. Livy says that Hannibal, having passed the Rhone, took his route on the left, through the country of the Tricastini, and touching on the territory of the Vocontii, entered into that of the Tricorii. Ascending along the Rhone, he arrived on the fourth day of his march at the junction of a river with the Rhone, on the confines of the Allobroges, who inhabited the territory between these rivers. This river is called Scoras by Polybius, and Arar (the Saone) by Livy. Some critics, however, are of opinion that this name is erroneous, and that it was Isere.

TRICORNIS, in *Anatomy*, an epithet applied to the lateral ventricle of the brain. See BRAIN.

TRICORYNE, in *Botany*, from *τρεις*, *three*, and *κορυνη*, *a club*, expressive of the three club-shaped seed-vessels.—Brown Prodr. Nov. Holl. v. 1. 278.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronarie*, Linn. *Afphodeli*, Juss.

Ess. Ch. Corolla in six deep, spreading, equal segments, deciduous. Filaments with tufts of hairs. Anthers vertical, cloven at the base. Germen deeply three-lobed, connected at the base with the thread-shaped style. Stigma simple. Capsules three, club-shaped, not bursting. Seeds solitary.

This genus ranges naturally between *Anthericum* and Mr. Brown's *Casia*. The species are herbaceous, with fibrous, mostly perennial, roots. Leaves grassy, narrow. Branches, if any, accompanied by an interior *stipula* (or *bractea*). Flowers umbellate, erect, yellow, their partial stalks having a joint at the summit. Corolla twisted as it fades, and soon falling. Seed-vessels resembling coated nuts, one of them sometimes abortive, but rarely more than one.

1. *T. simplex*.—Stem undivided. Leaves flat, roughish at the edges. Umbel solitary, of from ten to sixteen flowers. Partial stalks thrice as long as the involucre.—Observed by Mr. Brown at Port Jackson, New South Wales.

2. *T. elatior*.—Stem round, smooth, leafy; branches smooth, paniced, angular and striated. Leaves flat. Umbels of from five to seven flowers. Native of the same country.

3. *T. scabra*.—Stem round, hispid, leafy. Branches paniced, angular and striated, rough. Leaves flat, mi-

nutely toothed. Umbels of from five to seven flowers.—Native of the tropical part of New Holland.

4. *T. tenella*.—Stem slender, round, forked, smooth, leafless, scaly. Umbels of two or three flowers.—Found by Mr. Brown on the south coast of New Holland.

5. *T. anceps*.—Stem much branched, leafless, scaly, angular, smooth. Branches two-edged. Umbels of few flowers.—Gathered by Sir Joseph Banks, in the tropical part of New Holland, and seen only in his herbarium by Mr. Brown.

TRICOT, in *Geography*, a town of France, in the department of the Oise; 13 miles N.W. of Compeigne.

TRICRANA, in *Ancient Geography*, an island situated on the coast and to the S.E. of the peninsula of the Argolide, having to the S. the island Aristera, to the N.W. that of Hydreia, and to the N. the promontory of Acra. Pausanias mentions this island.

TRICRATUS, in *Botany*, so named by the late M. l'Heritier, from *τρεις*, *three*, and *κρως*, *power*, or *distinction*; perhaps in allusion to the three-fold affinity or resemblance of the plant, indicated by Jussieu, who remarks that it has the habit of *Valeriana*, the flowers of *Primula*, and nearly the character of *Mirabilis*. We still do not perceive any reason for Jussieu's original name, *Abronia*, (from *αβρος*, *pretty and delicate*,) being superseded by the above.—L'Herit. Monogr. with a plate. Willd. Sp. Pl. v. 1. 807. (*Abronia*; Juss. Gen. 448. Lamarck Illustr. 468. t. 105.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Aggregate*, Linn. *Nyctagines*, Juss.

Gen. Ch. Cal. Perianth none. Cor. of one petal, inferior; tube funnel-shaped, inflated at the base, then suddenly contracted; limb shorter than the tube, flat, equal, in five deep, inversely heart-shaped segments. Nectary cup-shaped, of one leaf, encompassing the germen, and united with the inflated base of the tube. Stam. Filaments five, thread-shaped, unequal, shorter than the tube, to which they are united in their lower part, and inserted into the nectary; anthers oblong, within the tube. Pist. Germen superior, roundish, embraced underneath by the nectary; style one, thread-shaped; stigma undivided. Peric. none. Seed. Nut elliptic-oblong, pointed at each end, five-angled, invested with the hardened base of the corolla, of one cell.

Ess. Ch. Corolla funnel-shaped, with an inflated permanent base; its limb in five deep, cloven segments. Nectary cup-shaped, embracing the germen, bearing the stamens. Calyx none. Nut with five angles and one kernel.

1. *T. admirabilis*. L'Herit. as above. Willd. n. 1. (*Abronia umbellata*; Lamarck Illustr. 469. t. 105.)—Native of the sea-coast of California, where its seeds were collected by M. Colignon, a gardener who was sent out with La Peyrouse. These produced flowering plants in the Paris garden in 1788. The herbage is delicate, with several branches spreading on the ground; whether perennial or annual is not mentioned. Leaves simple, opposite, ovate, entire, on long stalks. Flowers in axillary, long-stalked heads, with an ovate *bractea* under each flower. Tube green. Limb of an elegant rose-colour. This little plant is perhaps the only fruit of La Peyrouse's unfortunate expedition.

TRICRENA, or TRICRINA, in *Ancient Geography*, the name of three fountains, a place of Peloponnesus, in Arcadia, E. of Pheneos.

TRICUSPID, in *Anatomy*, three-pointed, one of the valves of the heart, placed at the right auriculo-ventricular aperture. See HEART.

TRIDACNÆ, in *Natural History*, a genus of bivalve shells.

TRIDACTYLIA, in *Ornithology*, a genus of birds, separated by Dr. Shaw from *Picus*, on account of the number of toes; this having but three, whereas the genuine Pice are all furnished with four. Its generic characters are; beak many-sided, straight, wedge-shaped at the tip; nostrils covered with setaceous recumbent feathers; and feet with only three toes, placed two before and one behind. The species are the following.

HIRSUTA. Downy, varied with black and white. See *PICUS Tridactylus*.

UNDULATA. Waved, varied with black and white, beneath white. The southern three-toed woodpecker of Latham. First described by Brisson, and by him said to inhabit Cayenne.

TRIDAX, in *Botany*, from *τρις*, three, and *δανω*, to bite, or wound, because of the three deep divisions of its marginal florets. Such is the explanation of De Theis, and it seems consonant with the meaning of Linnæus; yet the latter in his *Philosophia Botanica* enumerates this word, which he considers as synonymous with *τριδοξ*, lettuce, among the old Greek names incapable of explanation. Possibly he had forgotten his original idea, between the writing of his *Hortus Cliffortianus* and the *Philosophia*; especially as he had not since seen the plant. Pliny speaks of *Ostrea tridacna*, a kind of oysters, so called because one of them was large enough for three bites, or mouthfuls.—Linn. Gen. 435. Schreb. 568. Willd. Sp. Pl. v. 2214. Mart. Mill. Dict. v. 4. Juss. 190. Gært. v. 2. 451, no figure.—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifolia*, Linn. *Corymbifera*, Juss.

Gen. Ch. Common Calyx cylindrical, imbricated, with ovate-oblong, sharpish, upright scales. Cor. compound, radiant. Florets of the disk all perfect, tubular, funnel-shaped, erect, five-toothed; those of the radius female, ligulate, in three deep segments of equal length, the middle one narrowest. Stam. in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. Pist. in the perfect florets, Germen oblong; style bristle-shaped, the length of the stamens; stigma obtuse; in the female ones, Germen oblong; style thread-shaped, the length of the corolla; stigma obtuse. Peric. none, except the permanent calyx. Seeds, in both kinds of florets, solitary, oblong. Down simple, rather longer than the calyx. Recept. flat, clothed with lanceolate chaffy scales, shorter than the seeds.

Eff. Ch. Receptacle chaffy. Down of many simple hairs. Calyx imbricated, cylindrical. Florets of the radius in three deep segments.

1. *T. procumbens*. Procumbent Tridax. Linn. Sp. Pl. 1268. Willd. n. 1. Mill. Dict. ed. 8. (Tridax; Linn. Hort. Cliff. 418. After americanus procumbens, foliis laciniatis et hirsutis; Houstoun's MSS.)—Gathered at Vera Cruz by Dr. Houstoun, who sent seeds to Miller. The latter cultivated this plant, in his bark-stove at Chelsea, but it flowered sparingly, and seldom perfected seed. He sent a dried specimen to Clifford, which Linnæus described, but there is none preserved in the Linnæan collection, nor has any figure of the *Tridax* ever appeared. It seems to be herbaceous and perennial, propagating itself by the trailing stems, which throw out roots, and are hairy, clothed with opposite, nearly sessile, rough, hairy, ovate leaves, an inch and half long, acute at each end, sharply serrated, their lowest and largest serratures, which are about the middle of the leaf, making a sort of angle at each side. Flower-stalks long, naked, simple, at first terminal, but afterwards becoming lateral. Flowers solitary, erect, palish copper-

coloured, or whitish; Linnæus erroneously supposed the radius to be yellow.

TRIDE, in the *Manege*, signifies short and swift; thus a *tride pace*, is a going of short and quick motions, though united and easy. A *tride career* is a very fast gallop, with the times or motion short and nimble; and so of other motions. Some apply the word only to the motion of the haunches.

TRIDENT, TRIDENS, an attribute of Neptune; being a kind of sceptre, which the painters and poets put into the hands of that god. It is in form of a spear, or fork with three prongs, whence the word.

The poets tell us, that Neptune makes the earth open whenever he strikes it with his trident.

Mythologists give several reasons for assigning to Neptune the trident. Some say that it was designed to denote by its three points, the quality of the three sorts of waters that are upon the earth; those of the sea, which are salt; those of the fountains, that are sweet; and those of the ponds, that partake of both these qualities. Others say, that it alludes to Neptune's threefold power over the sea, which he troubles, assuages, and preserves. But without hunting after mysteries, it is sufficient to allow, that the trident was a kind of sceptre used by ancient kings.

TRIDENT, among *Mathematicians*, is used for a kind of parabola, by which Descartes constructed equations of six dimensions.

TRIDESMIS, in *Botany*, so called by Loureiro, from *τρις*, three, and *δραμις*, a little tuft or bundle, descriptive of the styles.—Loureir. Cochinch. 576.—Class and order, *Monocæcia Polyandria*. Nat. Ord. *Tricocæa*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, Cal. Perianth of five lanceolate, hairy, spreading leaves. Cor. Petals five, lanceolate, downy, nearly equal to the calyx, inserted into the receptacle. Stam. Filaments about twenty, shorter than the corolla; anthers oblong, erect.

Female, at the base of the same spike, Cal. Perianth inferior, of the structure of the male. Cor. none. Pist. Germen superior, roundish; styles from fifteen to twenty, thread-shaped, longer than the stamens, collected into three bundles; stigmas thickish. Peric. Capsule roundish, bristly, of three cells and three valves. Seeds solitary, angular at the inner side, gibbous externally.

Eff. Ch. Male, Calyx of five leaves. Petals five. Stamens about twenty.

Female, Calyx of five leaves. Corolla none. Styles numerous, in three bundles. Capsule of three cells, with solitary seeds.

1. *T. hispida*. Bristly Tridesmis. *Ki quât yông* of the Chinese. Loureir. n. 1.—“Leaves hispid on both sides, Spike short.”—Found in bushy places about Canton, in China. An unbranched upright shrub, about ten inches high, with a perfectly simple, very long, vertical, twisted, thick-barked root. Leaves scattered, ovate, rather acute, slightly serrated. Flowers in a short, simple, terminal spike. A decoction of the root is thought by the Chinese to strengthen the tendons and bones.

2. *T. tomentosa*. Downy Tridesmis. *Ca sí mà* of the Chinese. Loureir. n. 2.—“Leaves downy beneath. Spike elongated.”—Found wild about Canton. Stem shrubby, erect, four feet high, with numerous ascending branches. Leaves alternate, lanceolate, somewhat serrated. Flowers in long, simple, terminal spikes. Stamens but ten. Styles six, long, in three pairs. Capsule hairy.

We cannot precisely reduce these plants to any known genus,

genus, and yet it is very probable they may be already described among the numerous species of *Croton*, which Jussieu justly calls *genus recognoscendum*, as requiring perhaps to be divided, or better defined.

TRIE, in *Geography*, a town of France, in the department of the Upper Pyrenees; 13 miles E.N.E. of Tarbe.

TRIE le Château, a town of France, in the department of the Oise; 3 miles W.N.W. of Chaumont.

TRIEBEL, a town of Lower Lusatia, in the circle of Guben; 12 miles W. of Sorau. N. lat. $57^{\circ} 36'$. E. long. $14^{\circ} 51'$.—Also, a town of Saxony, in the Vogtland; 3 miles S.S.W. of Oelsnitz.

TRIEBSCHBACH, a river of Saxony, which runs into the Elbe, near Meissen.

TRIEDROSTYLA, derived from τρις, *thrice*, εδεα, *a side*, and στυλος, *a column*, in *Natural History*, the name of a genus of spars.

The bodies of this genus are spars, in form of trigonal columns, adhering by one end to some solid body, and terminated at the other by a trigonal pyramid. Of this genus there are four known species. Hill.

TRIEL, in *Geography*, a town of France, in the department of the Seine and Oise; 6 miles N. of St. Germain.

TRIELEN, a small island in the English Channel, near the coast of France. N. lat. $48^{\circ} 22'$. W. long. $4^{\circ} 50'$.

TRIERMERUS, the *three-day fly*, in *Natural History*, a fly somewhat like the butterfly; it has four large yellowish wings, and a long body, with a head furnished with long antennæ, large eyes, and a spiral trunk. It is found among the nettles and mallows.

TRIMIMERIS, τριμιμερις, *semiteritaria*, a kind of cæsuræ in Latin verse, in which, after the first foot of the verse, there remains an odd syllable, which helps to make up the next foot.

As in, *Ille latus niveum molli fultus hyacintho*.

TRIENACH, in *Geography*, a bay of the county of Donegal, Ireland, on the west coast. N. lat. $54^{\circ} 53'$. W. long. $8^{\circ} 17'$.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

Thus we say, a triennial government: most regular monasteries have triennial superiors; that is, they elect new ones at the end of each three years.

In 1695, an act was made for triennial parliaments, *i. e.* for parliaments which should be dissolved, and the members be elected anew, every three years. Till that time, the king had it in his power to prorogue and continue his parliaments as long as he pleased. This opened a door to corruption, which the triennial bill was intended to prevent.

The triennial act has, from some other views, been since repealed; for the great struggles usual at elections, the great ferment it usually put the nation into, the great expences upon that occasion, with other considerations, determined the legislature, in 1717, to change triennial parliaments for septennial ones. See *Dissolution of PARLIAMENT*.

TRIENS, in *Antiquity*, a copper money, of the value of one-third of an *as*, which on one side bore a Janus's head, and on the other a water-rat.

This was the piece of money used to be put in the mouths of the deceased, to pay Charon his fare for their passage into another world.

TRIENS, or *Triental*, was also used for a drinking cup; and that which was ordinarily used. It contained four cyathi.

TRIENTALIS, in *Botany*, from *triens*, the third part of

any thing, usually of a foot measure. A name borrowed by Linnæus from John Bauhin, who calls this pretty little plant *Herbatrientalis*, alluding to its humble stature.—Linn. Gen. 183. Schreb. 244. Willd. Sp. Pl. v. 2. 282. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 406. Ait. Hort. Kew. v. 2. 333. Pursh 254. Juss. 96. Lamarek Illustr. t. 275. Gærtn. t. 50.—Class and order, *Heptandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Lyfimachia*, Juss.

Gen. Ch. reformed. *Cal.* Perianth inferior, of about seven linear-lanceolate, pointed, spreading, permanent leaves. *Cor.* of one petal, star-shaped, flat, in seven deep, ovato-lanceolate segments, alternate with the calyx, very slightly connected. *Stam.* Filaments seven, capillary, inserted into the base of each segment, spreading, the length of the calyx; anthers simple, recurved. *Pist.* Germen superior, globose; style thread-shaped, equal in length to the stamens; stigma capitate. *Peric.* Capsule ovate, of one cell, and as many ovate, rigid, cartilaginous, thick-edged valves as there are calyx-leaves, and opposite to them, highly polished internally. *Seeds* several, nearly orbicular, convex externally, angular within, blackish, dotted, each enveloped in a snow-white, finely reticulated, combined, membranous tunic. *Recept.* central, globose, very large, with a cavity for each seed.

Ess. Ch. Calyx of seven leaves. Corolla in seven deep equal segments, flat. Capsule of one cell, and many valves. Seeds in a reticulated tunic.

Obf. Linnæus remarks that seven is the most usual number in the parts of fructification, though sometimes liable to vary. He adds, that the fruit is a dry berry, not bursting with valves like a capsule. So Gærtner likewise represents this fruit; and as botanists have rarely seen it, they have, like ourselves, adopted the opinions and descriptions of these great writers. Yet nothing is more certain, if we may believe our eyes, than that the fruit of *Trientalis* from Scotland, is, as above described, a capsule with rigid spreading valves, probably soon breaking off from the base, and leaving a brittle, dry, globular mass of seeds, sticking around their receptacle, and enveloped in a most elegant white network, originally perhaps pulpy, which has been taken for the membranous coat of a dry berry. At first we were inclined to suspect the valves of the capsule might be a permanent hardened corolla, but their being opposite to the calyx soon decided that point. It is high time for us to correct this, too long neglected, error.

1. *T. europæa*. European Chickweed Winter-green. Linn. Sp. Pl. 488. Fl. Lapp. ed. 2. 109. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 15. Fl. Dan. t. 84. (*Herba trientalis*; Bauh. Hist. v. 3. 536. *Pyrola alpinæ flore major*; Bauh. Prodr. 100; copied in Morison, sect. 12. t. 10. f. 6.)—Leaves elliptical.—Native of turfey heaths, or of woods on the sides of hills, in Scotland and the northern countries of Europe, as well as some parts of the north of England, flowering in May and June. The perennial root is slightly tuberous, with many long whitish fibres. *Stem* solitary, simple, erect, four or five inches high, almost naked, except at the top, where it is crowned with a tuft of nearly sessile, bright green, smooth, entire leaves, delicately veined, an inch and half or two inches long; tapering at the base; more or less blunt at the extremity. Among them are several axillary, capillary stalks, about the same length, each bearing a very pretty and delicate white flower, with yellowish, or pale pink, anthers and stigma. Linnæus was particularly fond of this plant, and has celebrated its "fascinating beauty" in his elegant and eloquent *Flora Laponica*.

2. *T. americana*. American Chickweed Winter-green. Pursh

Pursh n. 2. (T. europæa; Michaux Boreal.-Amer. v. 1. 220.)—Leaves lanceolate, tapering at each end.—In cedar swamps, and other places, among bog-moss, on high mountains, from Canada to Virginia, perennial, flowering in July and August, and differing considerably from the European species. *Pursh*. We have this from Newfoundland, as well as from the garden of the late right honourable Charles Greville, at Paddington. The leaves are narrower, more lanceolate, and tapering at each end, but we can discover no difference in the flowers, nor any other part besides. Both kinds blossom at the same time in our gardens.

TRIERARCHI, τριηραρχοι, among the Athenians, commissioners chosen annually out of the richest citizens, who are obliged to provide all sorts of necessaries for the fleet, and to build ships at their own charge. See Potter, Archæol. Græc. lib. i. c. 15. tom. i. p. 86.

TRIERES, or TRIERIS, in *Ancient Geography*, a town of Syria, burnt by Antiochus.

TRIERON, a promontory of Africa Propria, at the extremity of the Lesser Syrtis. Ptolemy.

TRIERS, in *Law*. See TRIORS.

TRIERTY, in *Geography*, a small lake of the county of Donegal, Ireland, near the borders of the county of Fermanagh.

TRIESING, a river of Austria, which runs into the Danube, 3 miles N.W. of Fischamund.

TRIESTE, a sea-port town of the duchy of Carniola, situated in the Adriatic, at the north-east part of what is called the Gulf of Trieste. The houses here stand on the ascent of a mountain, extending themselves quite to the sea, and on the top of the mountain is a castle. The harbour consists of the inner and outer. The empress-queen, Maria Theresa, caused it to be considerably improved and fortified, and also declared it a free port, imparting to it all the requisite immunities and privileges, whence all sorts of wares, both by water and land, in and out of the time of fairs, may be imported here, free from any duties and taxes; but from this immunity, iron, steel, copper, quicksilver, salt, gunpowder, mirrors, and crystal, are excepted. By these means many ships and vessels are induced to arrive there, which at this place unlade their goods, and take others on board, which are conveyed from hence by land-carriage out of the hereditary lands belonging to the house of Austria, and also out of Germany. A wall, fortified with a bastion, serves as well for the defence of the harbour against any hostile attempt, as for screening it against the wind, and also for the security of the shipping. On the north-west side of the town, where formerly were salt-pits, a beautiful suburb has been erected, and thereby the bad air, which formerly arose from these salt-pits, meliorated: but still at the time of flood, which often rises here four or five feet in height, a stench is perceived, the sea at this place having a boggy ground. The water also of a fresh spring has been conducted by pipes from the distance of two Italian miles to the town. These and other improvements and good regulations, have in view the increase of the trade of the place. Trieste is likewise the see of a bishop, who is suffragan to the archbishop of Goritz, and bears the title of the count of Trieste. In its cathedral too are twelve canons. The sovereign captain, who governs the town and its territories, resides in the castle. Lotharius, king of Italy, made a donation of this town and circumjacent country, together with the right of mintage, to John, at that time bishop of the place; but bishop John II. disposed of the jurisdiction over it to the community of Trieste for 500 marks. Afterwards it was incorporated with the duchy of Carniola, but again dismembered. In 1795, this place was taken by the French. The number of fixed in-

VOL. XXXVI.

habitants is estimated at 30,000, without including sea-faring people and strangers; 74 miles S.S.W. of Vienna. N. lat. 45° 53'. E. long. 13° 55'.

TRIESTE. See TRISTE.

TRIESTY, mountains in the north-western part of the county of Mayo, Ireland, near the Mullet, and immediately north of Tullaghan bay.

TRIETERIA, in *Antiquity*, feasts which the Bœotians and Thracians held every three years in honour of Bacchus, and in remembrance of his expedition into India, which lasted three years.

TRIETERIS, τριητηρις, in the *Ancient Chronology*, a cycle of three years.

Thales, it is said, observing that the lunar revolution never exceeded thirty days, appointed twelve months of thirty days each; so that the year consisted of three hundred and sixty days: and in order to reduce these months to an agreement with the revolution of the sun, he intercalated thirty days at the end of every two years, whence that space of time was called a *period of three*, because the intercalation was not made till after the expiration of full two years, though really it was only a period of two years; as we are informed by Censorinus, De Die Natali, cap. 18.

TRIEWALD, MARTIN, in *Biography*, an eminent mathematician and engineer, was born at Stockholm in 1691, and being intended for trade, he travelled to England for information and improvement on subjects that concerned his commercial pursuits. Disappointed in prospects of this kind, he changed his object; and was fortunately engaged by the proprietor of some coal-mines near Newcastle to superintend the machinery of his works. This situation corresponded to his genius and inclination; and he was thus led to pay particular attention to mechanics, both in theory and practice. In 1726 he returned, after an absence of ten years, to his native country, where he constructed a steam-engine, and read lectures in philosophy, illustrated by a course of experiments, similar to those of Desaguliers, which he had attended in London. He thus attracted the notice of the king and of the States, who conferred upon him a pension, with the title of director of machinery. He also proposed some improvements in the manufacture of iron and steel. Thus diligently and actively employed for the benefit of his country, he received a commission as captain of engineers and inspector of fortifications; and he invented various machines connected with those offices, models of which are preserved in the Academy of Sciences at Stockholm and also in the Academy of Lund. Diving was also an object of his attention, and on this subject he wrote a treatise, entitled "Konst at lefwa under Watnet, or the Art of living under Water;" Stockholm, 1741, 4to. (See DIVING-BELL.) For this invention he received honorary rewards both from his own sovereign and the king of France. In 1729 he was elected a member of the Society of Upsal; and the same honour was conferred upon him by the Royal Society of London and other learned bodies. Triewald died suddenly in 1747. He communicated various papers to the Academy of Sciences at Stockholm, which appear in its Memoirs for the years 1739, 1740, and 1747. Beckman's Hist. of Inventions. Desaguliers' Philos. Gen. Biog.

TRIEXAHEDRIA, formed of τρις, *thrice*, ις, *fix*, and ἰδεα, *a side*, in *Natural History*, the name of a genus of spars.

The bodies of this genus are perfect and pellucid crystalliform spars consisting of thrice six planes, being composed of an hexangular column, terminated at each end by an hexangular pyramid: of this genus there are three known species. Hill.

TRIFALTIGKERT, in *Geography*, a town of Prussia, in Natangen; 16 miles S.S.E. of Königsberg.

TRIFAX, among the *Romans*, a javelin three cubits long, which was thrown by the catapulta.

TRIFELS, in *Geography*, a citadel of France, in the department of Mont Tonnerre. Here Richard I., king of England, was kept, when he appeared before the diet of Worms; 1 mile S.E. of Anweiler.

TRIFOLIASTRUM, in *Botany*, Bastard Trefoil, a name given by Micheli, *Nov. Gen. Pl.* 26. t. 25, to such species of *Trifolium* as have their legume projecting beyond the calyx, which he, on that account, separates from thence. Neither the character, nor the name, has met with the sanction of following writers. See TRIFOLIUM.

TRIFOLIUM, τριφυλλον of the Greeks, Trefse of the French, from which last is more immediately derived our Trefoil; names all expressive of the same idea, of the three leaves, or leaflets, growing on one stalk, which is so characteristic of this popular and well-known genus. — *Linn. Gen.* 387. *Schreb.* 509. *Willd. Sp. Pl.* v. 3. 1352. *Enum.* 791. *Mart. Mill. Dict.* v. 4. *Sm. Fl. Brit.* 781. *Prodr. Fl. Græc. Sibth.* v. 2. 93. *Ait. Hort. Kew.* v. 4. 378. *Pursh* 477. *Juss.* 355. *Tourn.* t. 228. *Lamarck Illustr.* t. 613. *Poiret in Lam. Dict.* v. 3. 1. *Gärtn.* t. 153. (*Melilotus*; *Tourn.* t. 229. *Willd. Enum.* 739. *Juss.* 356. *Lamarck Illustr.* t. 613. *Trifoliastrum*; *Mich.* *Gen.* 26. t. 25. *Lupinaster*; *Buxb. in Comm. Petropol.* v. 2. 345. t. 20. *Lupulinum*; *Rivin. Tetrap. Irr.* t. 10. *Lagopus*; *ibid.* t. 15—17. *Triphylloides*; *Ponted. Anthol.* 240.)—Class and order, *Diadelphia Decandria*. *Nat. Ord. Papilionaceæ*, *Linn. Leguminosæ*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, five-toothed, permanent. *Cor.* papilionaceous, with long claws, mostly permanent, withering; standard reflexed; wings shorter than the standard; keel of one petal, shorter than the wings. *Stam.* Filaments two, distinct, one simple, one in nine segments; anthers simple, roundish. *Pist.* Germen oblong-ovate; style awl-shaped, ascending; stigma simple, smooth. *Peric.* Legume short, of one valve, and one cell, not bursting, scarcely exceeding the calyx in length, deciduous. *Seeds* one to four, roundish.

Ess. Ch. Calyx tubular, five-cleft. Keel simple, shorter than the wings and standard. Stigma smooth. Legume not bursting, deciduous, scarcely longer than the calyx. *Seeds* very few.

All botanists have perceived the difficulty of defining the technical characters of this genus, and yet none can be, in itself, more natural. Linnæus reckoned it the most difficult in the whole vegetable kingdom to discriminate by any essential mark. He comprehends under *Trifolium*, as may be seen above, various other genera of good systematic writers, differing among themselves as follows. *Melilotus* of Tournefort and Jussieu, has a legume longer than the calyx, with loosely spiked flowers; *Trifoliastrum* of Micheli, a legume longer than the calyx, with capitate flowers: *Lupinaster* of Buxbaum, a legume with several seeds, and five leaflets in each leaf: *Lupulinum* of Rivinus, a permanent corolla, whose standard is inflexed and flattish, ribbed or plaited: *Lagopus* of the same author, a shaggy calyx, equal in length to the corolla: and finally *Triphylloides* of Pontedera, has a monopetalous corolla, the standard wings and keel being all united into one tube; which is likewise the case with a great many more species than this author, or Linnæus, has indicated.

Linnæus admitted the inflorescence as a part of his natural, and even his essential, character of this genus, defining it "a little umbel or head." He was always very unwilling

to adopt this measure, and we presume to think he has, in no case, resorted to it with advantage. In the present it is neither correct nor discriminative, scarcely any species being really umbellate, and though many are capitate, as many are spiked, while several are racemose. We have therefore followed the example of Jussieu, who in this instance wisely lays aside the inflorescence; attempting a more full and explicit character from the parts of fructification themselves. In natural affinity the present genus comes nearest to TRIGONELLA, which will presently follow in alphabetical order. Some of the *Meliloti* especially, closely accord therewith, both in characters, habit, and qualities, particularly in an appropriate scent, allied to that of new hay and bitter almonds, most powerful, and very permanent, in the dried herbage. Some compare it to the smell of a pig-stye. The Blue Melilot, and Common Fenugreek, possess this odour in the greatest perfection.

Trifolium is a very extensive genus. Linnæus has forty-six species in the fourteenth edition of his *Systema Vegetabilium*; Willdenow has seventy-two in his *Sp. Pl.*—Eighteen are natives of Britain. Fifty-six are enumerated by Mr. Aiton in his *Hortus Kewensis*. We have three to add from the *Prodr. Fl. Græc.*, two or three American ones of Mr. Pursh, and a few from other sources. It is necessary to take a view of the whole, partly for their more correct botanical distinction, though in general they are better defined than the species of most, equally extensive and natural, genera. A correct knowledge of these plants is supremely important to the agriculturist; because the qualities of some, very near in external appearance, differ widely in utility; and because there are many, hitherto little observed, which promise to be as valuable as any of the rest. Some of these are known and cultivated in other countries, and others may be well worthy of trial. Unless they are first accurately distinguished, nothing respecting them can either be perfectly understood, or clearly communicated.

The species are distributed into five very natural sections, and are all herbaceous. Some in each section are annual, others perennial. The stems are branched. Leaves alternate, more or less stalked, of three, mostly obovate, and equal, toothed or entire, rarely linear, leaflets, with a pair of membranous ribbed stipulas united to the base of the foot-stalk. Inflorescence terminal or lateral, generally stalked, either tufted, capitate, spiked or racemose. Flowers red, purplish, white or yellow; sometimes, though rarely, fragrant.

SECT. I. MELILOTI. Legumes projecting beyond the calyx; with several seeds. Flowers racemose.

1. *T. caruleum*. Blue Melilot Trefoil. *Linn. Sp. Pl.* 1077. *Willd. n. 1.* *Ait. n. 1.* *Bieberst. Taur.* v. 2. 207. (*T. odoratum*; *Ger. Em.* 1195. *Melilotus carulea*; *Rivin. Tetrap. Irr.* t. 9. *Lotus sylvestris*; *Camer. Epit.* 894; not 724, as in *Willd.* and *Ait.* after *Linn.*; the latter being *T. arvense*.) A good coloured figure is wanting.)—Clusters roundish-ovate, long-stalked. Legumes half-naked, beaked, with slight longitudinal ribs, and two seeds. Stem erect. Stipulas entire.—Native of Bohemia, Tauria, Germany, &c. in dry barren ground, flowering in summer. Cultivated in our gardens, for curiosity, ever since the time of Turner, Gerarde, &c. The root is annual, fibrous. Stem two or three feet high, smooth, angular, leafy, scarcely branched. Leaflets pale, elliptical, toothed, an inch long, smooth; the odd one stalked. Flowers pale blue, in numerous, solitary, long-stalked, axillary heads, all the way up the stem. The whole plant, either fresh or dried, has a sweet liquorice-like scent, lasting

TRIFOLIUM.

a great number of years, and perfuming every thing near it.

2. *T. indicum*. Indian Melilot Trefoil. Linn. Sp. Pl. 1077. Willd. n. 2. Ait. n. 2. (*Melilotus lutea* Indiarum orientalis erecta, folliculis rotundis parvis, spicis florum ex foliorum alis multiplicatis; Pluk. Phyt. t. 45. f. 4.)—Clusters cylindrical. Legumes naked, strongly reticulated, single-seeded, obtuse. Stem erect. Stipulas nearly entire.—Native of the East Indies. Cultivated at Oxford before 1680. Annual, flowering in summer. Smaller and more slender than the foregoing, with long slender clusters of small, yellow, drooping flowers. The leaflets also are smaller and narrower. Legumes not much bigger than mustard-seed, turgid, pale, roundish-elliptical, strongly corrugated, with a sort of elevated net-work, and tipped with the capillary style, not properly beaked. Such is the Linnæan plant, which does not agree with Willdenow's definition. We cannot answer for the varieties enumerated in *Sp. Pl.* Some are said to have white flowers. The yellow fades greatly in what we have examined, before the corolla falls. Willdenow has in his *Enumeratio*, 789, distinguished the β , which is Plukenet's-t. 45. f. 5, as a species, by the name of *Melilotus rugulosa*.

3. *T. messanense*. Sicilian Melilot Trefoil. Linn. Mant. 275. Suppl. 339. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 741, unpublished. Desfont. Atlant. v. 2. 192. (*T. fructu racemoso*; Bocc. Mus. 163. t. 124. *Melilotus messanensis procumbens, folliculis rugosis sublongis, spicis florum brevioribus*; Raii Hist. 952. Tourn. Infl. 407. *M. minima recta lutea, siliquis crassis curtis in capitulum congestis, femine fœnugræci*; Morif. v. 2. 162. sect. 2. t. 15. f. g. t. 16. f. 9, very good.)—Clusters shorter than the leaves. Legumes naked, ovate, pointed, with crowded, concentric, interbranching ribs, single-seeded. Stems decumbent.—Gathered by Ray, in a moist situation, on the tongue of land separating the port of Messina from the straits of Sicily. Signor Arrostiti, who sent us specimens in 1811, informs us this species is not now found about Messina, but in the fields of Girgenti. Professor Desfontaines met with it in fields in Barbary; and Dr. Sibthorp in cultivated ground every where throughout Greece. It there bears the name of $\tau\rho\iota\phi\lambda\lambda\iota$, which belongs indeed to most of this genus, in modern Greek. Dr. Sibthorp judged it to be the $\lambda\omega\lambda\omicron\varsigma \eta\mu\epsilon\rho\varsigma$; of Dioscorides, a point equally difficult to disprove or establish. This species is little known in our gardens, though cultivated in Morison's time, whose figure cannot be mistaken. The root is said to be annual, though furnished with many little fleshy granulations, to enable it to resist occasional drought, such as occur in *Vicia lathyroides*, and some other annual vetches. Stems several, a foot long, diffuse or procumbent, the central one only being erect, all stout, smooth, leafy, scarcely branched. Clusters axillary, oblong, hardly longer than the common footstalks, each on a short stalk, and composed of ten or twelve yellow flowers, twice or thrice as large as the last. The leaves are not very different. Legume one-third of an inch long, peculiarly distinguished by its ovate, oblique, pointed, somewhat compressed, figure, and especially the numerous concentric elevated lines, like coiled horse-hair, more or less interbranching in the middle, which occupy its sides. The luxuriance of the herbage, and the nature of its root, indicate this plant as worthy of agricultural experiment, though its procumbent mode of growth may be an objection to the mower. It is certainly very different from Mr. Sinclair's *T. macrorhizum*, Hort. Gram. Woburn. 290, of which we propose to speak under *T. officinale*.

4. *T. mauritanicum*. Barbary Melilot Trefoil. Willd. n. 4.

Ait. n. 4. Sm. Fl. Græc. Sibth. t. 742, unpublished. (*Melilotus fulcata*; Desfont. Atlant. v. 2. 193.)—Clusters longer than the leaves. Legumes naked, nearly orbicular, obtuse, pointless, with concentric elevated ribs, single-seeded. Stems diffuse.—Native of cultivated fields in Barbary and Sicily; very abundant about Messina, according to signor Arrostiti. There can be no doubt as to the synonymy of Desfontaines. We have not seen the work of Schousboe, cited by Willdenow. This is an annual species, with numerous branching diffuse stems, but more slender in every part than the last. Leaflets elliptic-lanceolate, obtuse. Flowers yellow, small, very numerous, in long, slender, linear, longish-stalked clusters, much exceeding the leaves. Legume hardly so big as in *T. indicum*, formed as it were of a convoluted line or hair, somewhat in the manner of the last, but the whole legume is not a quarter so large, nor has it any elongation or point. These two species have, nevertheless, been confounded by botanists, for want of a good figure of the present, which deficiency the *Flora Græca* will supply.

5. *T. macrorhizum*. Long-rooted Melilot Trefoil. Willd. n. 5. "Waldst. et Kitaib. Hung. v. 1. 24. t. 26." Ait. n. 5.—"Legumes racemose, naked, rugose, single-seeded. Stems and branches ascending. Leaflets linear."—Native of moist salt-marshes in Hungary. "Root perennial. Seeds toothed above their scar." We have no knowledge of this plant. See *T. officinale*.

6. *T. polonicum*. Polish Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 6. Ait. n. 6.—Clusters lax, on very long stalks. Legumes naked, two-seeded, lanceolate, pointed, transversely corrugated. Stem erect. Leaflets pointed, nearly entire.—Native of Poland. Sent to Kew garden in 1788, by M. Thouin. A very distinct annual species, of a slender habit. Stem quite round. Leaflets obovato-lanceolate, acutely pointed, rather silky, and somewhat glaucous, almost perfectly entire; the odd one hardly an inch long. Flowers yellow, distant, small, on long and slender partial stalks; their common ones at least thrice the length of the leaves. Legume rather compressed, pendulous, a quarter of an inch long, beaked, and tipped with the style, not hairy.

7. *T. spicatum*. Spiked Melilot Trefoil. Sm. Prodr. Fl. Græc. Sibth. n. 1783. Fl. Græc. t. 743, unpublished.—Legumes naked, single-seeded, spiked, erect, corrugated, acute. Stipulas awl-shaped, entire. Stem erect.—Gathered by Dr. Sibthorp, in the isle of Cyprus. Root annual. Stem twelve or eighteen inches high, branched and bushy. Leaflets obovate, toothed, half an inch long. Spikes stalked, about as long as the leaves, consisting of yellow, deflexed flowers; when in fruit becoming twice as long, more lax, and somewhat racemose, the legumes being slightly stalked, erect, roundish-obovate, with a short broad point, tipped with the capillary white style; their sides marked with concentric elevated corrugations. Seed globose.

8. *T. dentatum*. Toothed Melilot Trefoil. "Waldst. et Kitaib. Hung. v. 1. 41. t. 42." Willd. n. 7. Ait. n. 7.—"Legumes racemose, naked, two-seeded, somewhat rugose, rather acute. Stipulas toothed at the base. Stem erect."—Native of moist meadows in Upper Hungary. Perennial. Abundantly different from the *officinale*, the leaflets being sharply and doubly toothed; the stipulas also toothed, and deeply divided at their base. Willdenow.

9. *T. officinale*. Common Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 8. Fl. Brit. n. 1. Engl. Bot. t. 1340. Mart. Rust. t. 72. Fl. Dan. t. 934. Sincl. Hort. Gram. Woburn. 293. (*Saxifraga lutea*; Fuchs. Hist. 749.)—Legumes racemose, naked, two-seeded, somewhat corrugated, ovate, acute, rather compressed. Stipulas awl-shaped. Stem erect.—Native of bushy places, hedges, banks, or cultivated

TRIFOLIUM.

tivated fields, on clay or marle, throughout Europe, flowering in June and July. Not rare in England. Dr. Sibthorp met with it in moist low situations, throughout Greece and the Archipelago, and confirmed the old opinion, of its being the *μυλλωβος* of Dioscorides. From this old Grecian's venerable authority the plant has long been esteemed medicinal, but is now out of use; nor is it cultivated, with us at least, for any agricultural purpose. The seeds, even in a very small quantity, poison the flavour of flour. *Martin, Sinclair.* The root is annual. Stem branched, two or three feet, or more, in height, angular and furrowed. *Leaflets* dark green, smooth, obovate, ferrated. *Flowers* full yellow, veiny, in long dense clusters. *Keel* and *wings* equal, and nearly as long as the *standard*. *Legume* hairy, transversely wrinkled, but not very strongly. *Stigma* capitate.

Mr. Sinclair's specimen named *T. macrorhizum*, in his elaborate and very valuable agricultural work, the *Hortus Gramineus Woburnensis*, 291, does not exhibit any marks of specific difference from the *officinale*, of which however it appears to be an important variety, differing in its biennial root, larger leaflets and flowers. The seeds are two in each legume, never, as is sometimes the case with the *officinale*, more than two. It produces a great crop of fodder, or hay, at the time of flowering, but little afterwards. If kept from flowering, the root will last four or five years. Such is Mr. Sinclair's account, who nevertheless now candidly assents to our opinion of its being a variety. We have no means of ascertaining whether this may be Willdenow's *macrorhizum*, our n. 5, but it does not answer to his character. We can vouch for its being widely different from *mesfansense*, n. 3. Can it be Willdenow's *officinale* γ?

10. *T. germanicum*. White German Melilot Trefoil. (*T. officinale* β; Willd. n. 8. Sm. Prodr. Fl. Græc. Sibth. v. 2. 94. Melilotus; Rivin. Tetrap. Irr. t. 6? *M. germanica*; Ger. Em. 1205. *M. vulgaris*; Willd. Enum. 790. *M. officinarum germanicæ*, flore albo; Tourn. Inf. 407. *Lotus sylvestris*, flore albo; Tabern. Kreuterb. 893.)—Legumes racemose, naked, single-seeded, corrugated, obovate, acute. *Stipulas* fetaceous. Stem erect.—Native of cultivated fields in Germany. Dr. Sibthorp observed it near Thessalonica. Root biennial. Stem taller than the last. *Flowers* white. *Wings* longer than the *keel*, though shorter than the *standard*. The figure of Rivinus answers better to this description than to our common *T. officinale*, and was probably taken from what is the most usual German plant. We have never compared specimens, but must observe, that the *stipulas* are sometimes perfectly fetaceous in our *officinale*.—Gerarde seems to have been well acquainted with the *germanicum*, as was also his editor Johnson.

11. *T. Kochianum*. Scentless Melilot Trefoil. (*Melilotus Kochiana*; Willd. Enum. 790.)—"Legumes racemose, naked, two-seeded, nearly even, ovate, acute, compressed. *Stipulas* toothed. Stem ascending."—Native of Germany. Biennial. Without scent. *Corolla* yellow; its wings the length of the *keel*, but shorter than the *standard*. *Willd.*

12. *T. Petitpierreanum*. White Single-seeded Melilot Trefoil. (*Melilotus Petitpierreana*; Willd. Enum. 790.)—"Legumes racemose, naked, single-seeded, corrugated, obovate. *Stipulas* fetaceous. Stem ascending."—Native of Germany. Biennial. *Corolla* white; its wings longer than the *keel*, and equal to the *standard*. *Willd.* The author whom we quote acknowledges his obligations to the accurate Dr. Hayne for distinguishing the three last species from *T. officinale*.

13. *T. italicum*. Italian Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 9. Ait. n. 9. (*Melilotus italica*;

Camer. Hort. 99. t. 29, excellent. Willd. Enum. 790. *M. filiculis pendentibus, curtis, lutea, &c.*; Morif. sect. 2. t. 16. f. 4.)—Legumes racemose, naked, two-seeded, elliptical, obtuse, strongly corrugated and crisped. Stem erect. *Leaflets* roundish-obovate, nearly entire.—Native of Italy, Barbary, and Greece. Dr. Sibthorp gathered it on the dry parts of the famous mount Hymettus, near Athens. This species has long been cultivated in curious gardens, both in England and on the continent. Gerarde describes it under his *Melilotus*, n. 2, but the figure does not agree. The root is annual. Stem stout, angular, leafy, about two feet high, overtopped, as the fruit advances, by the numerous, elongated, upright, cylindrical clusters, of pendulous, roundish-elliptical legumes, each as big as a small pea, conspicuous for their strong, prominent, zigzag, and plaited wrinkles, by which the present species is clearly distinguished. Its leaflets moreover are of a much broader and rounder figure than any of the foregoing, rather wavy than ferrated. *Stipulas* ovate, taper-pointed, toothed. *Flowers* yellow. Dr. Sibthorp conjectured, with great probability, that this might be the kind of Melilot, mentioned by Dioscorides as growing in the south of Italy, about Nola, of a yellowish colour, and weaker scent.

14. *T. hamosum*. Hooked Melilot Trefoil. Bieberst. Taur. v. 2. 207. (*Fœnugræcum meliloti facie minus*; Buxb. Cent. 2. 39. t. 44. f. 1?)—"Legumes racemose, naked, compressed, single-seeded, ribbed, hairy, with a hooked point. *Stipulas* awl-shaped, undivided. Stems ascending."—Gathered by the chevalier de Steven, in Georgia, and the southern part of Tartary. "The root is annual, simple. Stems several, from three to nine inches long, rarely more, slightly branched. Clusters axillary, stalked, short and somewhat capitate. Flowers yellow, the size and shape of *T. officinale*. Calyx hoary. Legume ovate, deflexed, hoary; smooth at the base; terminating in a long inflexed point. Seed kidney-shaped, of a dirty yellow. Leaflets wedge-shaped, sharply toothed. Stipulas small." We have seen no specimen.

15. *T. creticum*. Cretan Melilot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 10. Ait. n. 10. (*T. peltatum creticum*; Bauh. Pin. 329. Prodr. 142, with a figure. Morif. sect. 2. t. 14. f. 3.)—Legumes racemose, naked, two-seeded, membranous, compressed, bordered, nearly orbicular. Stem ascending.—Native of Crete, Greece, and Barbary. Root annual. Stem branched, twelve or eighteen inches high. Leaflets broad, thick and fleshy, like those of *T. italicum*, bordered with shallow teeth, inodorous. Flowers pale yellow. Legumes very remarkable for their broad, elliptical, nearly orbicular, flattish figure, half an inch in diameter, in loose clusters, two or three inches long. They are represented much too turgid in the above engravings, especially in Morison's.

16. *T. ornithopodioides*. Bird's-foot Trefoil. Linn. Sp. Pl. 1078. Willd. n. 11. Fl. Brit. n. 2. Engl. Bot. t. 1047. Curt. Lond. fasc. 2. t. 53. Fl. Dan. t. 368. (*Fœnugræcum humile repens, ornithopodii siliquis brevibus erectis*; Raii Syn. 331. t. 14. f. 1.)—Legumes about three on a stalk, naked, eight-seeded, twice the length of the calyx. Stems procumbent.—Native of England, France, and Denmark, on barren gravelly heaths, among short grass, flowering in June and July. The fibrous annual root is furnished with fleshy tubercles, such as are mentioned under n. 3. Stems mostly simple, depressed, two or three inches long, clothed with little leaves, resembling many of the third section, the stalks of the leaflets being all equal; and neither they, nor the slender pale-purple flowers, two or three on each short axillary stalk, having any affinity to the

TRIFOLIUM.

Melilots, with which the present species is associated entirely on account of its many-seeded, transversely furrowed, prominent, bivalve *legumes*, which moreover are umbellate, not racemose. This species therefore connects the Melilots by its *fruit*, with the true Trefoils by its habit, stipulas, inflorescence, &c. We should gladly have retained the genus *Melilotus*, adopted of late, from preceding writers, by Willdenow in his *Enumeratio Plant. Hort. Berol.* had we found his generic characters faithful. These are the deciduous *corolla*, and the bursting *legume*, longer than the *calyx*. But the legume of most of the *Meliloti* does not burst, any more than that of a genuine *Trifolium*. Their general habit indeed, and their peculiar odour, agree far better with TRIGONELLA, (see that article,) than with *Trifolium*.

SECT. 2. LOTOIDEA. *Legumes covered by the calyx; with several seeds.*

17. *T. Lupinaster*. Bastard-lupine Trefoil. Linn. Sp. Pl. 1079. Willd. n. 12. Ait. n. 12. Mart. Ruß. t. 16. Curt. Mag. t. 879. (*T. leguminibus polyspermis, foliis pluribus; Gmel. Sib. v. 4. 19. t. 6. f. 1.*)—Flowers in short unilateral tufts. Leaflets five, without a naked common stalk. Legume with many seeds.—Native of Siberia. Observed also near Constantinople by the abbé Sestini and Dr. Sibthorp. It sometimes appears in our gardens, from exotic seeds; but though hardy as to cold, does not endure long. The root is naturally perennial, tap-shaped. Stems erect, simple or branched, a foot, more or less, in height. Leaflets lanceolate, about an inch and half long, smooth, elegantly veined and finely toothed, usually five, rarely six or seven, each on a minute partial stalk, crowning the ribbed common one, which is bordered all the way up, on each side, with a long and broad membranous *stipula*. Flowers crimson, occasionally white, numerous, handsome, in terminal heads; their partial stalks directed one way, hairy, each with a little cup-like membranous *bractea* at the base.

18. *T. reflexum*. Reflexed American Trefoil. Linn. Sp. Pl. 1079. Willd. n. 13. Ait. n. 13. Pursh n. 1. (*T. capitulis fructiferis reflexis, &c.; Gron. Virg. ed. 2. 110.*)—Heads reflexed when in fruit. Legumes three-seeded. Stem procumbent. Leaves downy.—On dry hills and among rocks, in Pennsylvania, Kentucky, and on the mountains of Carolina, flowering in June and July, perennial. Flowers of a fine purplish-red. Pursh. Mr. John Hunnemann is recorded as having sent this Trefoil to Kew in 1794. We have never met with a specimen. The leaflets are described as obovate, slightly ferrated, soft and downy, variegated with white. Flowers large and handsome, in terminal and axillary heads. Seeds two or three in each legume.

19. *T. angulatum*. Angular Trefoil. Waldst. et Kitaib. Hung. v. 1. 26. t. 27. Willd. n. 14. Ait. n. 14.—Heads reflexed when in fruit. Flowers with partial stalks. Legumes four-seeded. Stem decumbent, zigzag, angular and furrowed.—Native of Hungary, on a saline soil. Annual. Sent to Kew by Mr. Hunnemann, in 1803, where it flowers from June to August, in the open ground. Stems branched, smooth. Leaflets obovate, sharply toothed, emarginate, pointed. Heads, or rather dense umbels, stalked, composed of stalked, red, reflexed flowers. Calyx smooth, with nearly equal awl-shaped teeth. Willd.

20. *T. striatum*. Upright Small Trefoil. Linn. Sp. Pl. 1079. Willd. n. 15. Ait. n. 15. "Waldst. et Kitaib. Hung. v. 1. 36. t. 37." (*Trifolium pratense annuum erectum minimum, foliis longis angustis pulchre venatis ac tenuissimè ferratis, floribus albis, in capitulum sphericum*

congestis, siliquis minimis dispermis; Mich. Gen. 29. t. 25. f. 7.)

β. *T. lævigatum*; Desfont. Atlant. v. 2. 195. t. 208. Willd. n. 16.

Heads nearly globose. Legumes two-seeded. Stem erect. Leaflets lanceolate, finely ferrated. Stipulas rhomboid, toothed at one side.—Native of Italy, Spain, France, Hungary and Barbary. Micheli gathered it in various grassy or heathy places about Florence, flowering in May. The root is annual. Leaflets somewhat like those of *T. Lupinaster*, n. 17, in shape, but the lower leaves have a long common footstalk. The stipulas are remarkable for their square figure. Heads of flowers small, dense, on long, solitary, axillary stalks. Corolla white. Legume half-ovate, with a recurved beak. We agree with Willdenow, though we have not compared specimens, that the plant of Desfontaines is very near that of Micheli. Indeed we cannot find marks to define it as even a variety. Linnæus adopted his *T. striatum* from the last-named author, in writing the second edition of *Sp. Pl.*, but before that work was printed, he obtained a specimen of what he thought the same, and this is elaborately described there, though the cross annexed to the specific character, as in the original manuscript before us, indicates his not having seen the plant. What he there described is *T. parviflorum* of Ehrhart, Willdenow's n. 56, our n. 66. We must presume that this description, according so very ill with what professor Desfontaines found in Barbary, prevented his recognizing the Linnæan plant.

21. *T. cæspitosum*. Tufted White Trefoil. Willd. n. 17. Reynier Mem. pour servir à l'Hist. Phys. et Nat. de la Suisse, v. 1. 162, with a plate, under the French name of *Trefle gazonant*. (*T. Thalii; Villars Dauph. v. 3. 478. t. 41.*)—Heads roundish. Flowers slightly stalked, erect. Legumes mostly four-seeded. Leaflets obovate, minutely toothed. Stems decumbent, tufted, shorter than the flower-stalks. Native of the mountains of Switzerland and Dauphiny, in barren, waste, or trodden places. This most resembles our Common White Trefoil, or Dutch Clover, hereafter described, but the short, depressed, entangled stems, though composing a dense turf, do not creep. The root is woody and perennial. Stalks of the flowers, and even of the leaves, longer than the stems; the former terminal, solitary, erect, from two to five inches in length, bearing a globular, but slightly racemose, head of white flowers, purplish at the base, less depressed than in *T. repens*, but we find no perceptible difference as to the comparative inequality of their calyx-teeth. Legume small, elliptical, compressed, strongly ridged at each margin, beaked with the permanent style and capitate stigma, enveloped in the dry, brown, ribbed corolla, and containing three or four small seeds. No valuable properties with respect to agriculture have been discovered in this plant, nor has it been hitherto raised in England.

22. *T. hybridum*. Mule White Trefoil, or Tall Dutch Clover. Linn. Sp. Pl. 1079. Fl. Suec. 258. Willd. n. 18. Ait. n. 16? (*T. flore albo; Rivin. Petrap. Irr. t. 11. f. 2. T. n. 368; Hall. Hist. v. 1. 160. Trifolium pratense corymbiferum, erectum, annuum et præatum, caule crassiore fistuloso, &c.; Mich. Gen. 28. t. 25. f. 2, but not f. 6. Melilotus qui Trifolium orientale altissimum, caule fistuloso, flore albo; Cor. Inst. R. Herb. 27; Vaill. Paris. t. 22. f. 5.*)—Heads globose. Flowers stalked. Legumes two-seeded. Leaflets elliptical. Stem erect, zigzag, hollow, many-flowered.—Native of Tuscany, in places where water has stagnated in winter. Micheli. Of Sweden, in open situations on a clay soil. Linnæus. In meadows of the Morea. Sibth. Root annual, according to Micheli, to whom

TRIFOLIUM.

whom also we are indebted for the character of the *legume* having but two *seeds*, which we have never had an opportunity of examining. *Stem* upright, twelve or eighteen inches high, hollow, striated, smooth, leafy, with three or four upright branches, under each of which the main stem divaricates at an obtuse angle. *Leaves* on very long stalks, with a pair of large, ovate, somewhat deltoid, pale, membranous, veiny, long, and taper-pointed *stipulas*: *leaflets* all equally nearly sessile, an inch long, broadly elliptical, rather ovate than obovate, emarginate, finely serrated; the lower ones partly entire. *Flowers* white, on hairy partial stalks, composing numerous dense globular heads, hardly an inch in diameter, whose common stalks are but of a moderate length, stout and angular. Such is the genuine *T. hybridum* of Linnæus, whose synonyms above quoted cannot be disputed, though others have been confounded herewith. This is one of the species well worthy of agricultural experiment, though hitherto unnoticed in England. Its crop must be very considerable.

Linnæus calls the *stem* "ascending;" yet the specimen in his herbarium is perfectly erect, though zig-zag in the upper part. Ehrhart, in his *Phytophyllacium*, n. 26, gives, under the name of *T. hybridum*, Upsal specimens whose *stem* is decumbent, or partly ascending, hollow, but not zig-zag. The *leaflets* are narrower, as well as much more sharply and copiously serrated, than in the Linnæan specimen, and the *flower-stalks* are longer. This appears to be the *Trifolium lupinum corymbiferum annuum album majus, folio longiore obtuso, siliquâ incurvâ latâ compressâ ac dispermâ*; Mich. Gen. 28. t. 28. f. 5. The form of the *leaflets* perhaps is variable, as those of neither this, nor of the true *hybridum* above described, do really answer well to Micheli's figures. This decumbent or ascending plant, doubtless known to Linnæus, must have been comprehended in his idea of *T. hybridum*, of which it is probably a variety. Ehrhart has named it, according to a mode of his own, *Bubroma*, indicating its value as food for oxen. The tubular *stem* clearly distinguishes these two plants, whether species or varieties, from all to which they are near akin, especially from the following, and *T. repens*.

23. *T. Vaillantii*. Trailing White Clover, or Trefoil. Poiret in Lamarek Dict. v. 8. 4. Prodr. Fl. Græc. n. 1789. (T. n. 758; Hall. Enum. Rar. 41. *Trifolium annuum corymbiferum album et procumbens, folio cordato, subtus atro-virente splendente, siliquâ tetraspermâ, infernè falcatim discriminatâ*; Mich. Gen. 27. t. 25. f. 6. *Melilotus parisiensis humifusus, foliis ferratis glabris*; Vaill. Parif. t. 22. f. 1.)—Heads globose. Flowers stalked. Legumes four-seeded. Leaflets elliptic-obovate, finely serrated. Stems branched, decumbent, solid, many-flowered.—Found in meadows and pastures about Florence very abundantly. *Micheli*. About Paris. *Vaillant*. In the meadows of Switzerland. *Haller, Lachenal*. In the Morea. *Sibth*. Some dried specimens of this do not, at first sight, look much unlike the Linnæan one of *T. hybridum*, though smaller, and the general size of every part is much less. The *leaflets* vary greatly, and are sometimes wedge-shaped. The decisive character of the *stem* being not tubular, but filled with spongy pith, and always decumbent, though not creeping, will ever clearly distinguish this from every variety of the last, to which we may add Micheli's mark of the four *seeds*, doubtless correct; but some of them are liable to prove abortive, so that only one ripe *seed* can sometimes be found. The present species promises far less advantage to the cultivator than the *hybridum* or the *repens*, and therefore ought carefully to be distinguished from both.

24. *T. repens*. Common White Trefoil, or Dutch Clover. Linn. Sp. Pl. 1080. Fl. Succ. 259. Willd. n. 19. Fl. Brit. n. 3, excluding the syn. of Vaillant. Prodr. Fl. Græc. n. 1790. Engl. Bot. t. 1769. Pursh n. 2. Curt. Lond. fasc. 3. t. 46. Mart. Ruft. t. 34. Fl. Dan. t. 990. Riv. Tetrap. Irr. t. 13. f. 2. (*T. pratense*; Ger. Em. 1185, the figure only. *Trifolium pratense corymbiferum majus repens*, n. 1—9; Mich. Gen. 26. t. 25. f. 1, 3 and 4.)—Heads nearly globose. Flowers stalked. Legumes four-seeded. Leaflets inversely heart-shaped, or roundish. Stems creeping, solid, many-flowered.—Very common in meadows and pastures throughout Europe, from Sweden to Greece, and all the islands of the Archipelago, flowering from May to September, and varying excessively with regard to luxuriance, as well as in the pale and whitish, or dark and purplish, marks of its *leaves*. Mr. Pursh says it is found in fields, pastures, and cleared lands on the mountains of North America, making its appearance wherever lands are cleared of timber, in the most remote parts of the country; from 60 to 100 miles distant from any place where it grew naturally. So it springs up in recently cleared ground in England, being one of the most universal plants of the temperate zone. It forms an excellent bottom for pastures, and is particularly valuable for fodder in the dry autumnal months. Mr. Sinclair thinks it less eligible in the spring, except mixed with grasses, being apt to cause in sheep the disease termed red-water, especially if the weather be cold and moist. The *roots* are fibrous and perennial. *Stems* many, quite prostrate, branched near their origin, creeping to a great extent, with radicles from most of the joints; they are round, smooth, full of pith. *Leaves* very variable in size, and somewhat in shape, sharply toothed, on long stalks. *Stipulas* tubular. *Flower-stalks* much longer than the *leaves*, axillary, solitary, mostly erect, angular, solid. *Heads* rather depressed. *Flowers* white; brown in decay. *Legume* oblong, smooth, with three or four *seeds*. In oster-holts, and such rich moist places, the *stem* is more upright and luxuriant; but being solid, cannot be confounded with *T. hybridum*, a species never yet discovered in England, any more than *T. Vaillantii*. Linnæus blames Micheli for making a great number of imaginary species out of this common *T. repens*, but he himself, in some degree, has erred, on the other hand, in confounding two or three very distinct species together. How far we are correct in citing Micheli as above, and whether some other things, distinguished by him, do not likewise come under the *repens*, could be determined only by a most careful scrutiny of his own specimens, and perhaps the cultivation of the plants themselves.

25. *T. ambiguum*. Doubtful Pale Trefoil or Clover. Bieberst. Taur. v. 2. 208; excluding the syn. of Haller, n. 368, not 138. (See *T. hybridum*, n. 22.)—"Heads with stalked flowers. Legumes with one or two seeds. Calyx-teeth nearly equal. Standard lanceolate. Leaflets ovate, bluntish, finely serrated. Stem creeping."—Frequent in the meadows of Tauria and Caucasus, as well as about the Don and the Wolga, flowering in summer. Larger and more robust than the *hybridum* and *repens*, equally creeping and forming tufts. Flowering *stems* a span, rarely a foot, in length. *Stipulas* lanceolate, withering. *Leaflets* the size of *T. alpestre*, but broader and blunter, yet not emarginate, striated in like manner with very prominent ribs, ending in extremely sharp and crowded marginal teeth. *Heads* dense, twice the size of the two species just mentioned, as are also the *flowers*, which are bent downwards as they fade. *Calyx* striated, with awl-shaped divaricated teeth,

TRIFOLIUM.

teeth. *Corolla* pale, reddish in decay, like those species. *Petals* distinct. *Standard* much longer and narrower than in those. *Legume* short, often single-seeded. *Marschall a Bieberstein*. The creeping *stem* surely distinguishes this species from *hybridum*; it is much to be wished the learned author had told us whether it be hollow or not. The form of the *leaflets* and *standard*, and the small number of *seeds*, appear sufficiently unlike *repens*.

26. *T. comosum*. Tufted Trefoil. Linn. Sp. Pl. 1080. Willd. n. 20. Ait. n. 18. (*T. carolinianum*; Michaux Boreal.-Amer. v. 2. 58? Pursh n. 3? Poiret in Lamarck n. 2? Lagopus americanus, floribus majoribus comosis; Petiv. Mus. 26. n. 254.)—"Heads globose. Flowers stalked, imbricated. *Standard* deflexed, permanent. *Legumes* four-seeded."—Native of America. *Linnaeus*. The *carolinianum* of authors, here quoted with doubt, is described as diminutive and erect; its *leaflets* inversely heart-shaped, roundish, smooth, fringed and finely crenate; *stipulas* cloven; *heads* reflexed, of few flowers; *corolla* hardly projecting beyond the *calyx*; *seeds* about three. This is found in sandy fields near Charlestown, South Carolina, flowering from June to August, and is perennial. *Flowers* small, white. *Pursh*. How far the opinion of Poiret, adopted by Pursh, that the above two plants constitute one species, is correct, we are utterly unable to determine, having seen neither; but Petiver's definition of the *flowers* is altogether at variance with that of Michaux and Pursh.

27. *T. alpinum*. Dwarf Alpine Trefoil. Linn. Sp. Pl. 1080. Willd. n. 21. Ait. n. 19. Dickf. Dr. Pl. 38. (*T. n. 369*; Hall. Hist. v. 1. 161. *T. alpinum*, flore magno, radice dulci; Bauh. Prodr. 143, no figure. *T. alpinum rheticum*, afragaloides; Bauh. Hist. v. 2. 376. *T. angustifolium alpinum*; Ger. Em. 1207. *Trifoglio angustifoglio alpino*; Pon. Bald. 194.)—Heads hemispherical, somewhat racemose and whorled. Flower-stalks radical, naked. *Legumes* two-seeded, pendulous. *Leaflets* linear-lanceolate.—Abundant in the alpine pastures of Switzerland, Italy, the Pyrenées, and the south of France, flowering in August. The most unscientific visitant of those beautiful scenes could hardly overlook this plant, whose large bright crimson *flowers*, each above an inch long, seem to spring almost immediately from dense tufts of no less elegant *leaves*. If this species, procured for the English gardens above forty years ago by Dr. Pitcairn and Dr. Fothergill, be still preserved, a coloured figure of it would be highly acceptable to the public. The *root* is perennial, thick and woody, running very deep into the ground, and said to have the sweetness of liquorice. *Stems* very short, or scarcely any. *Herbage* smooth. *Stipulas* long, lanceolate, membranous, finely striated. *Common flower-stalks* simple, often not taller than the leaves. No other species can be confounded with this.

28. *T. involucreatum*. Striped-flowered Trefoil. Willd. n. 49. Donn. Cant. ed. 5. 183.—Heads roundish, dense, each with an orbicular, ribbed, many-toothed, spinous involucrem. *Stem* erect, branched. *Leaflets* lanceolate. *Stipulas* many-toothed. *Legumes* two-seeded.—Native of the west coast of North America, from whence its seeds were brought by Mr. Menzies, and raised in the Cambridge garden in 1791. We obtained specimens there August 3d, 1796. Yet this species does not occur either in Hort. Kew., or in Pursh, nor did we discover it in Willdenow, till we had hit on the same name, he having greatly misplaced it, in the next section, after *T. angustifolium*. The *root* is annual. *Stem* twelve or eighteen inches high, branched, leafy, hollow, round, smooth like the rest of the plant. *Stipulas* membranous, with many unequal bristly teeth. *Leaflets*

elliptic-lanceolate, toothed, an inch or an inch and half long. *Heads* of flowers above an inch broad, on long, stout, striated, axillary stalks, and each subtended by a very remarkable membranous orbicular *involucrem*, whose strong, close, radiating ribs, end in unequal spinous teeth. *Flowers* sessile. *Calyx* ribbed and spinous, membranous, pale with green teeth. *Corolla* variegated with purple and white. *Legume* ovate, abrupt, compressed, with two entirely distinct valves, and two *seeds*. The whole plant sometimes becomes very diminutive from starvation.

sect. 3. LAGOPODA. *Calyx* more or less villous.
29. *T. subterraneum*. Subterraneous Trefoil. Linn. Sp. Pl. 1080. Willd. n. 22. Fl. Brit. n. 4. Engl. Bot. t. 1048. Curt. Lond. fasc. 2. t. 54. Rivin. Tetrap. Irr. t. 13. f. 1. (*T. pumilum supinum*, flosculis longis albis; Raii Syn. 327. t. 13. f. 2.)—Heads of about four flowers. *Calyx*-teeth linear, hairy. *Involucrem* central, reflexed, rigid, star-like, embracing the fruit.—Native of Italy, the Levant, France, and England, on dry gravelly heaths, among short grass, flowering in May, and very common in Hyde park, Greenwich park, &c. *Root* annual, knobbed. *Stems* depressed, spreading, almost concealed by the numerous, broad, pale purple-veined *stipulas*. *Leaflets* inversely heart-shaped, dark green, hairy. *Flower-stalks* at first erect, each bearing three or four *flowers*, conspicuous for their long white *corolla*. After flowering, these stalks bury the *legumes*, which are thin and single-seeded, in the ground, and fix them there, by shooting out several spreading firm and thick fibres, constituting an *involucrem* of the *fruit*, though apparently like roots. The herbage of this species is trifling, and though it conduces to the spring verdure of many an otherwise barren tract, has nothing to encourage cultivation.

30. *T. globosum*. Globular Cotton-headed Trefoil. Linn. Sp. Pl. 1081. Willd. n. 23. Ait. n. 21. Sm. Fl. Græc. Sibth. t. 744, unpubl. (*T. orientale*, capite lanuginoso; Tourn. Cor. 27.)—Heads globose, many-flowered. *Calyx* very hairy all over, with linear teeth. Upper flowers numerous abortive, densely villous. *Stems* decumbent.—Native of Arabia and Syria, as well as of Cyprus and Asia Minor. A rare annual species, which *Linnaeus* cultivated from *Hasselquist's* seeds, and which may have been in our gardens a century ago, though not at present to be met with. It preserves some analogy with the last, though very unlike in appearance, having many pink *flowers*, in upright *heads*, and the *stems* are far less depressed. The *leaflets* have each a white transverse stripe, but not constantly. The analogy alluded to consists in the *flowers*, which perfect seed, being overwhelmed and borne down by a number of abortive ones above them. These seem to grow out as the others fade, in the form of empty *calyces* with innumerable, woolly, entangled teeth. No figure of the present species has yet appeared, but Mr. Bauer has prepared a very admirable drawing for the *Flora Græca*.

31. *T. hispidum*. Brittly-headed Trefoil. Desfont. Atlant. v. 2. 200. t. 209. f. 1. Willd. n. 24. (*T. hirtum*; Allion. Auctuar. 20.)—Heads terminal, solitary, globose. *Calyx* very hairy, with taper teeth. *Involucrem* of several roundish-ovate pointed leaves. *Stem* erect.—Gathered by *Desfontaines* in fields in Barbary, near Mafcar; by *Allioni* in Monteferrato. *Root* annual, long and tapering. *Stem* erect, a span high, more or less branched in a corymbose manner, striated, leafy, shaggy with soft hairs, as are likewise the *leaves* and their *stalks*. *Leaflets* obovate, finely toothed, obtuse, not emarginate. *Heads* many-flowered, sessile, subtended by three or four close, membranaceous, ribbed, hairy *bractææ*, all pointed, and a
solitary

TRIFOLIUM.

solitary leaf like those lower down. *Corolla* rose-coloured, longer than the calyx-teeth, which however gradually extend beyond it as the flower fades. We much doubt whether this be a distinct species from the following. The *bracteas* are very similar, except being pointed, and the position of the *stems*, as well as the form of the *leaflets*, are known to be uncertain marks.

32. *T. Cherleri*. Hairy Pink Trefoil. Linn. Sp. Pl. 1081. Willd. n. 25. Ait. n. 22. Sm. Fl. Græc. Sibth. t. 745, unpubl. (*T. glomerulis perforatæ, Cherleri*; Bauh. Hist. v. 2. 377. *Lagopus minor, supinus, molli et compresso capite, flore albo*; Barrel. Ic. t. 859.)—Heads terminal, solitary, globose. Calyx very hairy, with taper teeth. Involucrum of three roundish-ovate pointless leaves. Stems procumbent.—Native of France, Spain, and Barbary, in barren dry places. Dr. Sibthorp gathered it on the shores of Greece and the Archipelago. The seeds are sometimes introduced into our gardens from abroad. This is a little annual species, usually with several procumbent *stems*, three or four inches long; in a starved state having a solitary more erect one. *Leaflets* inversely heart-shaped, with a dark-purple mark. *Flowers* numerous, in dense heads. *Corolla* twice as long as the *calyx*, pale blush-coloured, with a long crimson *standard*; but the calyx-teeth subsequently rise above it. The *involucral* leaves are like the last, except in being blunt, and are also accompanied by a leaf.—*T. pictum*, Willd. n. 26. Bieberst. Taur. v. 2. 210, appears not to differ from *T. Cherleri*, and is doubtless Dr. Sibthorp's plant gathered on the shores of Greece and the Bosphorus. Nothing can be more uncertain than the spots on the *leaves*, which gave occasion to the name; and the proportion of the *corolla* to the *calyx* depends on the period of examination. Barrelier faithfully represents it longer than the *calyx* in *Cherleri*, when the flower is in perfection.

33. *T. sphaerocephalum*. Round-headed White Trefoil. Desfont. Atlant. v. 2. 201. t. 209. f. 2. Willd. n. 27.—Heads terminal, solitary, globose. Calyx very hairy, with taper teeth, twice the length of the corolla. Involucrum of three rounded leaves. Stems procumbent.—Native of fields in Barbary, near Mafcar. *Desfontaines*. Very like the last, except its little white *corolla*, shorter than the *calyx*. The citation of Barrelier, copied by Willdenow from Desfontaines, is the very same which, in the preceding page, he had transcribed from Linnæus, though less exactly given by the latter. The proportion of the *corolla* does not answer to this, but to *T. Cherleri*, which may very probably have occasionally, as Barrelier says it has, a white *flower*. We should hardly scruple to reduce these three last described, with *pictum*, to one species.

34. *T. saxatile*. Thyme-headed Trefoil. Allion. Pedem. v. 1. 305. t. 59. f. 3. Willd. n. 28. (*T. thymiflorum*; Villars Dauph. v. 3. 487. *T. parvum rectum, flore glomerato cum unguiculis*; Bauh. Hist. v. 2. 378. *Trefle des glaciers*; Reyn. Mem. pour servir à l'Hist. Phys. et Nat. de la Suisse; v. 1. 166.)—Heads terminal, mostly in pairs, hemispherical, leafy. Calyx densely hairy, with taper teeth, as long as the corolla. Upper stipulas bracteaceous, ovate, acute. *Leaflets* wedge-shaped, emarginate.—Native of the sandy beds of torrents, among the alps of Dauphiny and Piedmont, or the glaciers of Switzerland. Our specimens from M. Reynier's herbarium were gathered at the glaciers of mount Sylvio, which terminates the valley of St. Nicholas in the Vallais, by the celebrated herbalist M. Thomas. The *root* is described as biennial. *Stems* several, a finger's length, simple, leafy, rather silky than hairy, crowned with one or two small, densely silky *heads*,

of little white *flowers*; the central ones, according to Villars, imperfect or abortive. *Leaflets* small, silky, scarcely toothed, deeply emarginate. *Stipulas* purplish, ribbed, acute, for the most part lanceolate, but those of the two opposite leaves, close under the heads of flowers, are broad and ovate, serving as *bracteas*.

35. *T. capense*. Bracteated Cape Trefoil. Willd. n. 29. (*T. diffusum*; Thunb. Prodr. 136.)—"Heads globose, woolly, bracteated. Stem herbaceous, decumbent. *Leaflets* obovate, obtuse, hairy."—Native of the Cape of Good Hope. Thunberg.

36. *T. lanatum*. Naked-flowered Cape Trefoil. Thunb. Prodr. 136. Willd. n. 30.—"Heads globose, woolly, without bracteas. Stem herbaceous, decumbent. *Leaflets* obovate, obtuse, hairy."—From the same country.

37. *T. hirsutum*. Hairy Cape Trefoil. Thunb. Prodr. 136. Willd. n. 31.—"Heads globose, hairy. Stems herbaceous, diffuse. *Leaflets* oblong, hairy."—Found also at the Cape, by Thunberg. It is impossible to form a correct idea of these three last species, from the above characters, which suit equally well a number already known, to which the author appears never to have adverted. We merely register these plants here for future inquiry.

38. *T. lappaceum*. Bur Trefoil. Linn. Sp. Pl. 1082. Willd. n. 32. Ait. n. 24. Sm. Fl. Græc. Sibth. t. 746, unpubl. (*T. capitulo glomerato rigido*; Bauh. Hist. v. 2. 378.)—Heads globose, somewhat elliptical. *Calyx*-teeth awl-shaped, fringed; at length divaricated. Stems much branched, spreading. *Leaflets* obovate, toothed.—Native of fields in the south of France, and the isle of Cyprus. Introduced at Kew, in 1787, by the late Mr. Bell. An annual plant, with a dense tuft of branching, leafy, quadrangular, variously spreading *stems*, a foot high. *Stipulas* lanceolate, ribbed, hairy. *Heads* many-flowered, terminal, stalked, or nearly sessile. *Calyx* strongly ribbed and mostly smooth, with long fringed teeth, finally much shrunk, rigid, and widely spreading. *Corolla* twice as long as the *calyx*-teeth, monopetalous, which we believe to be the case with most of this round-headed tribe; its tube, or united claws, white, wings pale; *standard* pink, the length of the tube. *Legume* minute, ovate, single-seeded.

39. *T. diffusum*. Diffuse Hungarian Trefoil. Ehrh. Beitr. v. 7. 165. Pl. Select. n. 39. Willd. n. 33. Ait. n. 25. Waldst. et Kitaib. Hung. v. 1. 49. t. 50. Bieberst. Taur. v. 2. 210.—Heads roundish-ovate, very hairy. *Calyx*-teeth unequal, bristle-shaped, almost as long as the corolla. Stem diffuse, hairy. *Leaflets* oval, fringed, nearly entire.—Native of sandy ground in Hungary and Siberia. *Root* biennial. *Heads* stalked, terminal, as big as *T. pratensis*, accompanied by two *leaves*. *Corolla* monopetalous, its segments almost of equal length, purplish. *Legume* not quite covered by the *calyx*, one or two-seeded. Ehrhart, Bieberstein. The *stem* is twelve or eighteen inches long, the *leaflets* full an inch.

40. *T. rotundifolium*. Round-leaved Lilac Trefoil. Sm. Prodr. Fl. Græc. Sibth. n. 1795. Fl. Græc. t. 747, unpubl.—Heads globose, terminal, solitary, with lanceolate bracteas. Calyx very hairy, longer than its teeth. Stems simple, diffuse. *Leaflets* nearly orbicular, toothed, hairy.—Gathered by Dr. Sibthorp in the Morea. A very pretty and distinct annual species, which seems never to have been noticed before. The *stems* are scarcely a span long, clothed, like the rest of the herbage, with copious hoary hairs. *Leaflets* remarkably round, not half an inch in diameter, strongly and unequally toothed. *Calyx* tubular, very slightly inflated, with short, lanceolate, upright teeth. *Corolla* twice the length of the calyx, elegantly variegated with

TRIFOLIUM.

with pale purple and white, its *petals* distinct. *Germen* hairy.

41. *T. Lagopus*. Oblong Hairy Trefoil. Willd. n. 34.—“Spikes oblong, villous, terminal, solitary. Calyx-teeth bristle-shaped, as long as the monopetalous corolla. Stems simple, diffuse. Leaflets obovate, toothed.”—Native of Spain. *Pourret*. Root annual, slender. Stems several, four inches long, villous. Leaflets small, villous, obtuse, not emarginate. *Stipulas* ovate, large, ribbed, finely toothed. Spikes eight lines long, subtended by a leaf. *Willdenow*.

42. *T. stipulaceum*. Stipulaceous Cape Trefoil. Thunb. Prodr. 136. Willd. n. 35.—“Heads villous, ovate, terminal. Stem herbaceous, decumbent at the base. Leaflets jagged, villous.”—Found at the Cape of Good Hope, by Thunberg, whose specific character is all we know of this species. The word “herbaceous” is truly superfluous in any specific character of a *Trifolium*!

43. *T. microcephalum*. Little-headed Trefoil. Pursh n. 4.—“Ascending, downy. Leaflets obovate, emarginate, finely toothed. Stipulas ovate, pointed. Heads minute, stalked, of a few sessile flowers. Involucrum ovate, awned. Calyx awned, as long as the corolla.”—Found by governor Lewis, on the banks of Clarck’s river, flowering in July. Perennial. Flowers exceeding small, pale purple. *Pursh*. Some specimens from the north-west coast of America answer nearly to these characters, except being quite smooth; and we are persuaded they are only a diminutive state of *T. involucreatum*, n. 28.

44. *T. rubens*. Red Long-spiked Trefoil, or Clover. Linn. Sp. Pl. 1081. Willd. n. 36. Ait. n. 26. Jacq. Austr. t. 385. Mart. Rust. t. 9. (*Lagopus major*, *spicâ longiore*; Ger. Em. 1192.)—Spikes long and cylindrical. Calyx-teeth hairy; the lowermost about the length of the monopetalous corolla. Stipulas sword-shaped, longer than the footstalk. Leaflets lanceolate, sharply serrated. Stem erect.—Native of Italy, the south of France, Germany, and Switzerland, especially in the warmer meadows of the latter, where, according to Haller, this handsome species is very common. It flowers in summer, and found a place in our English gardens in Gerarde’s days. Root perennial. Stem one or two feet high, erect, firm, full of solid pith, smooth like the very elegant, finely serrated, and veined, leaflets, which are two inches long. Their common stalk is united almost entirely to the long, entire, even, sharp-pointed stipulas, which reach far beyond it. Flowers crimson, in dense, cylindrical, thick, blunt spikes, two or three inches long, beset with the prominent bristly calyx-teeth, of which the lowermost is much the most conspicuous. This Trefoil, though not hitherto brought into cultivation, seems, as professor Martyn observes, of a good quality, and sufficiently productive.

45. *T. pratense*. Common Purple Trefoil, or Clover. Linn. Sp. Pl. 1082. Willd. n. 37. Fl. Brit. n. 6. Engl. Bot. t. 1770. Mart. Rust. t. 3, and t. 36. Fl. Dan. t. 989. Afzel. Tr. of Linn. Soc. v. 1. 240. Matth. Valgr. v. 2. 189. (*T. pratense purpureum*; Fuchf. Hist. 817. *Trifolium*; Rivin. Tetr. Irr. t. 11. f. 1.)—Spikes ovate, dense. Stems ascending. Corolla monopetalous, unequal. Four of the calyx-teeth equal. Stipulas awned.—Common in grassy meadows and pastures throughout Europe, flowering from May to September. In its native situations, particularly on dry calcareous or gravelly hills, this valuable plant is truly perennial, though, like Saintfoin, less permanent in cultivated manured land. For its agricultural properties, and management, see CLOVER. Great difficulties have long attended the botanical discrimination of this and some other species, which we

shall presently describe; but they are for ever set at rest, by the most minute and laborious details of Mr. Afzelius, in the first volume of the Linnæan Society’s Transactions. Nor is this question merely curious or speculative; for the qualities of the plants, in an economical view, are as widely different as can well be. The root of *T. pratense* is tapering and branched, but not creeping. Stems about a foot high, more or less, slightly branched, leafy, solid, downy in the upper part. Leaflets elliptical, more or less acute, entire, smoothish, with a pale lunate spot. Upper leaves, near the flowers, mostly opposite. Stipulas rather broad, ovate, pale, purple-ribbed, with taper points. Spikes terminal, solitary, sessile, of numerous light-purple flowers, with a sweet, but faint scent, their petals united at the base, and combined with the filaments. Calyx hairy, ten-ribbed, its lowest tooth longer than the rest, but much shorter than the corolla. The figures in Fl. Dan. and Martyn represent the cultivated plant; that of Engl. Bot. the wild one. What Dillenius represents, in his edition of Ray’s Synopsis, t. 13. f. 1, seems merely a starved plant. There is said to be a procumbent, very hairy, kind, found on the loftiest mountains of Switzerland and Dauphiny, which is also but a variety.

46. *T. medium*. Zigzag Trefoil, or Bastard Clover. Linn. Faun. Suec. ed. 2. 558. Hudf. ed. 1. 284. Afzel. Tr. of Linn. Soc. v. 1. 237. Willd. n. 38. Fl. Brit. n. 7. Engl. Bot. t. 190. Mart. Rust. t. 2. (*T. flexuosum*; Jacq. Austr. t. 386. *T. alpestre*; Fl. Dan. t. 662. Hudf. ed. 2. 326, but not of Linnæus.)—Spikes lax. Stems zigzag, branched. Corolla monopetalous, nearly equal. Two upper calyx-teeth shortest. Stipulas linear, taper-pointed. Native of most parts of Europe, particularly in elevated calcareous pastures, or on a gravelly soil over clay, flowering in July. Differs from the last in its zigzag, more branched, stem, whose pith is so very thin and pellucid, that the centre seems hollow. The longer and linear stipulas, and more lax spikes, as well as the fringed elliptical leaflets, somewhat glaucous beneath, further mark this species, which ought to be carefully distinguished, as being destitute of any value to the farmer. The root is perennial.

47. *T. alpestre*. Oval-spiked Narrow-leaved Trefoil, or Clover. Linn. Sp. Pl. 1082. Willd. n. 39. Ait. n. 29. Jacq. Austr. t. 433. Mart. Rust. t. 1. Afzel. Tr. of Linn. Soc. v. 1. 234. (*T. folio longiore*, flore purpureo; Rivin. Tetr. Irr. t. 12. f. 1.)—Spike globose, mostly solitary. Calyx-teeth hairy; the lowermost as long as the monopetalous corolla. Stipulas bristle-pointed. Leaflets lanceolate, nearly entire. Stem simple, erect.—Native of mountain forests, in Siberia, Germany, Thrace, and Switzerland. The late Mr. Davall, who never met with this species, except in one little spot, in a forest near Orbe, was persuaded it was unknown to Haller, his n. 376, though taken for this, being probably our *medium*. Among fifteen or sixteen plants, Mr. Davall saw but one with two heads of flowers. The root is perennial. Stem straight, angular, downy, a foot high. Leaves most like *T. rubens*, as beautifully striated with veins, but far less visibly toothed. Stipulas hairy, linear, united to the footstalk about half its length only; their points almost thread-shaped, very long, hairy, shorter than the lower footstalks, longer than the upper. Flowers crimson, in a round head, overtopped by the upper leaves. Of no use for cultivation, affording few leaves, and never branching.

48. *T. bracteatum*. Morocco Clover. Willd. Enum. 792.—“Spikes conical, somewhat ovate, dense, solitary, sessile. Corolla monopetalous. Calyx-teeth nearly equal.

TRIFOLIUM.

Stipulas awned. Stem branched. Leaflets ovate, obtuse, slightly and minutely toothed."—Found by Mr. Schousboe in Morocco. Root annual, or biennial. *Willd.* We know nothing more of this species.

49. *T. pennsylvanicum*. Pennsylvanian Buffalo Clover. *Willd. Enum.* 793. *Pursh n.* 6.—“Spikes ovato-cylindrical, solitary, dense. Lowest tooth of the calyx shorter than the monopetalous corolla. Stipulas awned. Stem much branched, zigzag. Leaflets ovate-elliptical, obtuse, entire.”—In woods and fields, from Pennsylvania to Virginia, flowering from June to September, and known by the name of Buffalo Clover. It resembles *T. medium* very much. The flowers are of a fine red. *Pursh.*

50. *T. pannonicum*. Hungarian Trefoil, or Clover. *Jacq. Obf. fasc.* 2. 21. t. 42. *Linn. Mant.* 276. *Willd. n.* 40. *Ehrh. Pl. Select.* n. 9. *Allion. Pedem.* v. 1. 304. t. 42. f. 2. (*T. orientale majus villosissimum, floribus flavescens*; *Tourn. Cor.* 27.)—Spikes dense, elliptic-oblong, solitary. Calyx hairy; its lowest tooth longest. Corolla monopetalous; standard very long and linear-lanceolate. Stipulas with awl-shaped points. Leaflets hairy, nearly entire, minutely pointed. Stem erect.—Native of meadows in Lower Hungary, Armenia, and about the Bithynian Olympus. Cultivated by professor Williams, at Oxford, in 1799. One of the most striking species, on account of its very large and dense oblong spikes of innumerable cream-coloured flowers, whose corolla is about an inch and a quarter long. The root is perennial. Stem a foot and a half or two feet high, sometimes a little branched. Leaflets an inch and a half or two inches long, elliptic-lanceolate, either quite entire, or bluntly toothed towards the end, which is tipped with a little spinous point. Stipulas oblong, ribbed, united to the lower half of each footstalk; their points nearly twice as long, awl-shaped, hairy. Calyx furrowed, its upper part, and long teeth, clothed with long and dense silky hairs. The prominent rounded angle of each wing of the corolla retains, in the dried specimens, a remarkable whiteness, something of which may be seen in *T. ochroleucum*.

Professor Willdenow, in a note to his *Enumeratio*, 793, has separated Tournefort's plant by the name of *armenium*, distinguishing it chiefly by the leaflets being linear-lanceolate, and emarginate; for the slight differences in the proportion of the lower calyx-tooth and tube of the corolla, as well as the casual branching of the stem, are of no moment. Our Bithynian specimens have certainly narrower leaflets than one sent from Piedmont; but those in the Linnæan herbarium, as well as the plates of Jacquin and Allioni, are intermediate between the two. We have not examined an authentic specimen of Tournefort, but there is no reason, from Willdenow's definition, to suppose his a different species.

51. *T. elongatum*. Long-beaked Trefoil. *Willd. n.* 41.—“Spikes lax, elliptical, solitary. Lower calyx-tooth the length of the wings of the monopetalous corolla. Standard very long. Stipulas lanceolate. Leaflets lanceolate, villous. Stem ascending, branched.”—Native of Galatia. Perennial. The whole plant is villous. Stem half a foot high, branched from the base, round, striated. Leaflets toothed at the extremity. Stipulas oblong, with a lanceolate point. Calyx tubular, villous; with setaceous teeth, four of which are nearly equal. Standard lanceolate, twice as long as the wings or keel. Differs from *T. alpestre* in having small leaves, a longer standard, a branched ascending stem, and in being a hairy plant. *Willdenow.*

52. *T. canescens*. Hoary Oriental Trefoil. *Willd. n.* 42. *Ait. n.* 31. *Sims in Curt. Mag.* t. 1168. (*T. trichocephalum*; *Bieberst. Taur.* v. 2. 212. *T. orientale canescens*,

capitulo oblongo, fordidè albo; *Tourn. Cor.* 27.)—Spikes ovate, lax, solitary. Calyx-teeth hairy, lanceolate, all nearly equal. Corolla monopetalous. Stipulas taper-pointed. Leaflets elliptical, villous. Stem simple, ascending.—Native of Cappadocia, and of the alpine heights of Caucasus, towards Armenia. Mr. Loddiges of Hackney received it from the neighbourhood of mount Caucasus. A hardy perennial, flowering in May. Root cylindrical, rather woody, branching at the top into several leafy tufts. Stems several, a span high, or not so much, covered with close silky hairs, slightly leafy. Leaflets hardly an inch long, more or less acute, very nearly entire; most striated with fine elevated ribs near the edge. Stipulas pale, membranous, gradually tapering into a hairy point. Spike thick, two inches long. Calyx hairy; its lower tooth very little the longest. Corolla cream-coloured. We conceive there can be no doubt of the correctness of the above synonyms, though we have not compared specimens.

53. *T. ochroleucum*. Sulphur-coloured Trefoil. *Linn. Syst. Nat. ed.* 12. v. 3. 233. *Willd. n.* 47. *Ait. n.* 36. *Fl. Brit. n.* 5. *Engl. Bot. t.* 1224. *Jacq. Auftr. t.* 40. *Curt. Lond. fasc.* 6. t. 49. *Mart. Rust. t.* 35. *Afzel. Tr. of Linn. Soc. v.* 1. 229. (*T. squarrosum*; *Linn. Sp. Pl.* 1082. *Willd. n.* 44. *Ait. n.* 33.)—Spikes elliptical, hairy. Lowest calyx-tooth very long, linear, finally reflexed and rigid. Stem erect, downy. Lowest leaflets inversely heart-shaped.—Found in dry, bushy, gravelly or calcareous pastures, in England, Switzerland, Austria, and the south of Europe, as far as Constantinople, flowering in June or July. Root branching, perennial. Habit of the plant between *pratense*, *medium*, &c. with which it agrees in size, and *pannonicum*, which it resembles in colour of the flowers. The white point of the wings, when dry, is conspicuous in both. The stems are twelve or eighteen inches high, solid, but little branched, and of a stiff, slender, bare aspect. Leaves distant, on longish stalks; the uppermost opposite; leaflets linear-oblong, or somewhat elliptical, those of the lower leaves short, rounded, or orbiculate; all hairy, and almost perfectly entire. Stipulas linear, tubular, close, with simple ribs, and a very taper point. Head terminal, stalked, erect. Calyx furrowed, hairy, with bristle-shaped teeth, the lower one thrice the length of the rest, and, after flowering, still more elongated, wiry, and reflexed, giving the head a teasel-like aspect. Corolla monopetalous, yellowish cream-coloured, with a long erect standard. Legume membranous, with one seed, in the swelling tube of the calyx.

We remove this species nearer to its allies than where Willdenow has placed it. In an advanced state, it was described by Linnæus as distinct, by the name of *squarrosum*, but the original specimen from Sauvages's herbarium has enabled us to correct this mistake. The synonym of Morison, sect. 2. t. 13. f. 1, evidently belongs to *T. angustifolium*, n. 57, though possibly his “other species, with a round leaf,” may be *ochroleucum*; but this is of little importance. What *T. squarrosum* of Bieberst. *Taur.* v. 2. 214, with a purplish flower, may be, we cannot determine. It is requisite to correct an error in *Fl. Brit.* where Fuchsia is cited improperly, his plant being *T. montanum*, hereafter described.

54. *T. pallidum*. Pale Hungarian Trefoil. *Willd. n.* 46. *Ait. n.* 35. “*Waldst. et Kitaib. Hung. v.* 1. 35. t. 36.”—“Spikes solitary, roundish. Stipulas membranous; the upper ones opposite. Leaflets roundish. Corolla monopetalous. Border of the calyx bearded internally; its teeth nearly equal.”—Native of meadows in Upper Hungary. Annual or biennial. Differs from *T. pratense* in having
footstalks

TRIFOLIUM.

footstalks even to its uppermost opposite *leaves*, and also an emarginate *standard*; from *ochroleucum* in the *stipulas* being ovato-lanceolate, with a long point, and the *calyx-teeth* nearly equal; from both it is distinguished by the annual or biennial *root*, roundish *leaflets*, white *flowers*, and whole aspect. *Willdenow.*

55. *T. maritimum.* Teasel-headed Trefoil. Hudf. ed. 1. 284. Fl. Brit. n. 8. Engl. Bot. t. 220. Willd. n. 43. (*T. stellatum*; Hudf. ed. 2. 326. *T. stellatum glabrum*; Ger. Em. 1208. Pluk. Phyt. t. 113. f. 4. *T. spicatum minus, flore minore dilute purpureo*; Morif. sect. 2. t. 14.)—Spikes terminal, nearly globose. Calyx-teeth lanceolate, leafy; finally spreading. *Stipulas* lanceolate. Leaflets obovate.—Native of muddy marshes, especially near the sea, in various parts of the English coast, from Norfolk to Somersetshire, nor does this *Trifolium* seem to be known in any other part of the world. The plant is annual, flowering in June and July. *Stems* numerous, near a foot high, spreading or decumbent, branched, very leafy, round, striated, a little hairy. *Leaflets* from half an inch to an inch long, of a narrow obovate form, nearly entire, dark green, hairy. *Footstalks* mostly longer than the leaflets, and usually much longer than the lanceolate, taper-pointed *stipulas*. Uppermost *leaves* opposite. *Spikes* dense, more or less stalked, about half an inch in length and breadth. *Calyx* chiefly hairy at the top of its tube; teeth, after flowering, enlarged, leafy, deep green, three-ribbed, permanent; the lower one rather longest. *Corolla* pale purple. *Legume* turbinate, with one seed.

56. *T. incarnatum.* Crimson Trefoil. Linn. Sp. Pl. 1083. Willd. n. 45. Ait. n. 34. Curt. Mag. t. 328. Sm. Fl. Græc. Sibth. t. 748, unpublished. (*Lagopus maximus*; Clus. Hist. v. 2. 246. Ger. Em. 1192. *L. latifolius*; Rivin. Tetr. Irr. t. 17.)—Spikes cylindrical, obtuse, leafless, hairy. Leaflets inversely heart-shaped, rounded, crenate, hairy. Calyx-teeth awl-shaped, nearly equal.—Native of Italy, France, Switzerland, &c. Gathered by Dr. Sibthorp on the celebrated mount Athos. This is a hardy, annual, and considerably ornamental, plant, long known in our gardens, flowering in July, but not in such general cultivation as it deserves. The broad roundish *leaflets*; obtuse, wavy, red-veined *stipulas*; and especially the long dense *flower-spikes*, of a peculiarly rich and beautiful crimson or carmine colour, readily distinguish this species. As the *seeds* ripen, the spreading, rigid, pointed *calyx-teeth* render the *spikes* very prickly. The *stem* is erect, softly hairy, eighteen or twenty-four inches high.

57. *T. angustifolium.* Narrow-leaved Trefoil. Linn. Sp. Pl. 1083. Willd. n. 48. Ait. n. 37. Sm. Fl. Græc. Sibth. t. 749, unpublished. (*T. alopecurum angustifolium elatius*; Barrel. Ic. t. 698. *Lagopus hispanicus*; Rivin. Tetr. Irr. t. 16. *L. angustifolius hispanicus*; Clus. Hist. v. 2. 247. Ger. Em. 1193.)—Spikes cylindrical, hairy. Leaflets linear, pungent. Calyx-teeth bristle-shaped; the lowermost rather longest.—Native of the south of France, Spain, Italy, Germany; Carniola, Caucasus, Greece, and the Archipelago, flowering early in summer. In the latter countries it goes by various modern Greek names, synonymous with Cat's-tail. This Trefoil has often been raised in our gardens, being a hardy annual, distinguished from the last by its long, very narrow, grassy *leaflets*, and the pale pink, or lilac, hue of its *corolla*.

58. *T. arvense.* Hare's-foot Trefoil. Linn. Sp. Pl. 1083. Willd. n. 50. Fl. Brit. n. 9. Engl. Bot. t. 944. Curt. Lond. fasc. 6. t. 50. Pursh n. 7. Fl. Dan. t. 724. (*Lagopus*; Fuchf. Hist. 494. Camer. Epit. 724. Rivin. Tetr. Irr. t. 15. *Lagopodium, Pes leporis*; Ger. Em.

1193.)—*β.* *Lagopus perpusillus lupinus perelegans maritimus*; Dill. in Raii Syn. 330. t. 14. f. 2.—Spikes very hairy, nearly cylindrical. Calyx-teeth bristle-shaped, longer than the corolla. Leaflets narrow-obovate.—Native of dry sandy fields, throughout Europe and the Levant, as well as in North America, from Canada to Virginia, flowering in July and August. *Root* annual. *Herb* very various as to luxuriance, erect or decumbent. *Stems* much branched, rather zigzag, round, hairy. *Leaflets* from half an inch to an inch long. *Stipulas* ovato-lanceolate, acute, ribbed, often red. *Spikes* from half an inch to an inch and a half long, but always about half an inch thick, very soft and downy, the slender, prominent, equal *calyx-teeth* being densely fringed, with fine, silky, reddish hairs, and projecting far beyond the little white *corolla*. *Legume* very small. An entirely useless weed, not eaten readily by any animals that we are acquainted with.

59. *T. stellatum.* Starry-headed Trefoil. Linn. Sp. Pl. 1083. Willd. n. 51. Ait. n. 39. Compend. Fl. Brit. ed. 2. 110. Engl. Bot. t. 1545. Sm. Fl. Græc. Sibth. t. 750, unpublished. Ger. Em. 1028. (*T. stellatum purpureum monspessulanum*; Bauh. Hist. v. 2. 376. f. 2. Morif. sect. 2. t. 13. f. 9. *Lagopus minor erectus, capite globoso stellato, floribus purpureis*; Barrel. Ic. t. 860.)—Spikes terminal, hairy, ovate. Calyx-teeth spreading, leafy, equal, taper-pointed. Leaflets inversely heart-shaped, toothed. *Stipulas* elliptical. *Stems* spreading.—Found in sandy fields throughout the south of Europe, and every part of the Levant, flowering in June and July. Tradescant cultivated this pretty plant, and Gerard has left us a good description, but no figure. Hudson latterly mistook his own *maritimum*, n. 55, for the *stellatum*; but the latter was discovered by Mr. W. Borrer in Sussex, in 1804, growing plentifully between Shoreham harbour and the sea. The *herb* is annual, varying much as to luxuriance, always considerably hairy, spreading or diffuse. *Leaflets* small and abrupt. *Flowers* white, or blush-coloured, monopetalous, the *standard* erect, rising much above the very hairy *calyx*, whose enlarged, red or tawny, teeth spread in a starry manner after flowering, when their crimson bases are elegantly contrasted with a dense tuft of white cottony hairs, which close the mouth, and conceal the little membranous single-seeded *legume*.

60. *T. leucanthum.* White-blossomed Tartarian Trefoil. Bieberst. Taur. v. 2. 214.—“Spikes villous, nearly globose, stalked. Calyx spreading, with nearly equal teeth, shorter than the corolla. *Stipulas* awl-shaped. Leaflets obovate-oblong, slightly serrated at the extremity.”—Native of dry hills, in the southern parts of Tartary, flowering in May and June. Pallas mistook it for *T. stellatum*, to which it is described, in the above work, as being very near; but the *stems* are only about a finger's length, *stipulas* lanceolate-awl-shaped, entire, (which is the most material distinction,) *leaflets* more oblong, at least the upper ones, *flowers* smaller, the villous hairs of the *calyx* (we presume in its mouth) reddish, not white.

61. *T. clypeatum.* Buckler-shaped Trefoil. Linn. Sp. Pl. 1084. Willd. n. 52. Ait. n. 40. Allion. Pedem. v. 1. 306. Sm. Fl. Græc. Sibth. t. 751. (*T. clypeatum argenteum*; Alpin. Exot. 307. t. 306.)—Spikes terminal, ovate. Calyx-teeth ovate, leafy, very unequal, finally spreading; the lower one very large. *Stipulas* ovate. Leaflets roundish-obovate.—Native of Crete, Cyprus and Piedmont; also of Greece and Asia Minor. Cultivated in Chelsea garden, early in the last century, and at Cambridge by the late Mr. Donn. A hardy annual, flowering in summer. The general habit and size of the plant are not unlike

TRIFOLIUM.

T. pratense, but the leaflets are shorter and rounder, sometimes marked at each side with a small marginal purple streak, not a central spot. Flowers either light rose-coloured, or white. Calyx very remarkable, especially as the fruit advances, for its broad, ovate, pointed, hairy, many-ribbed teeth, or segments, forming a sort of five-angled shield, green and leafy, its mouth closed by an oblong valve, under which is the small, membranous legume, with a gibbous seed. The great inequality of its calyx-teeth distinguishes this plant from the *stellatum* and *maritimum*; its broad stipulas approach the former, but are totally unlike the latter. Indeed these three species, though more naturally allied, by the peculiarities of their calyx, to each other than to any of the foregoing besides, are very unlike in habit. Many of the following accord with them in the leafy nature of their calyx, but differ in having lateral heads, to say nothing of their much smaller dimensions.

62. *T. albidum*. Whitish Starry Trefoil. Retz. Obs. fasc. 4. 30. Willd. n. 53. Ait. n. 41.—“Spikes stalked, nearly globular. Calyx spreading; its lower tooth linear-awl-shaped. Stipulas linear-awl-shaped. Leaflets oblong. Stems diffuse.”—The native country of this species is unknown. Professor Retzius raised the plant from seeds sent him under a wrong name. Mr. Aiton mentions it as introduced at Kew about 1796. It proves a hardy annual, flowering in July and August. The stems are branched, round, slightly downy; branches knotty at the base. Leaves opposite; leaflets of the lower ones ovate, of the upper lanceolate, with a short recurved terminal bristle, the margin and keel fringed. Stipulas streaked with green and white. Heads on long straight stalks, without floral leaves; nearly globular when in flower, ovate in fruit. Calyx cylindrical, downy, with close-pressed awl-shaped teeth; the lowermost three-ribbed, about the length of the corolla, which is yellowish-white and monopetalous; the dorsal ones, which are rather shorter than the two next, are clasped so close to the corolla, that their points are hidden under the lateral teeth. As the fruit advances, the calyx-teeth become dilated and spreading, as in *T. stellatum*. Retzius. We have seen no specimen.

63. *T. scabrum*. Rough Trefoil. Linn. Sp. Pl. 1084. Willd. n. 54. Fl. Brit. n. 10. Engl. Bot. t. 903. Curt. Lond. fasc. 6. t. 48. (*T. flosculus albis*, in glomerulis oblongis, asperis, caulibus proximè adnatis; Vaill. Paris. t. 33. f. 1. *T. minus*, capite subrotundo parvo albo et eclinato; Barrel. Ic. t. 870.)—Heads ovate, sessile, axillary. Calyx-teeth unequal, lanceolate, rigid; at length recurved.—Native of England, France, Italy, Switzerland, Germany, the Morea, and about Constantinople, generally in dry chalky ground, or on sand over a stratum of chalk, flowering early in summer; chiefly occurring with us in Norfolk and Kent, but not commonly in either. This is a small, depressed, rigid, annual species, of no account in agriculture. Stems four to six inches long, zigzag, angular, hairy. Leaflets small, obovate or orbiculate, hairy, toothed and strongly veined. Stipulas broad-lanceolate, membranous. Heads lateral and terminal, always axillary, half an inch long. Calyx-teeth green and leafy, though narrow, rigid, hairy, finally recurved and spinous. Corolla white or flesh-coloured. Legume membranous, enclosed in the hardened furrowed calyx.

64. *T. echinatum*. Little Hedge-hog Trefoil. Bieberst. Taur. v. 2. 216.—“Heads ovate, terminal and axillary, stalked, leaflets. Calyx-teeth awl-shaped, unequal, hairy, shorter than the corolla. Stem declining, branched. Leaflets obovate-oblong, entire.”—Native of mount Caucasus. Annual. Habit of *T. lappaceum*, n. 38. Stem rather hairy,

with subdivided branches. Stipulas awl-shaped, hairy. Leaflets entire, slightly hairy. Flower-stalks much longer than the heads. Calyx striated, downy all over; tube very short; teeth extremely narrow, finely pointed, clothed with spreading hairs; the lowermost longest; all widely expanded when the fruit ripens, as in *T. lappaceum*. Corolla monopetalous, pale, twice the length of the calyx, with a long lanceolate standard. We have seen no specimen. This species appears indeed to be very near *lappaceum*, though ranged after *scabrum* by the learned author who is our only guide.

65. *T. glomeratum*. Round-headed Smooth Trefoil. Linn. Sp. Pl. 1084. Willd. n. 55. Fl. Brit. n. 11. Engl. Bot. t. 1063. Curt. Lond. fasc. 4. t. 51. (*T. cum glomerulis ad caulum nodos rotundis*; Pluk. Phyt. t. 113. f. 5. *T. arvense fupinum verticillatum*; Barrel. Ic. t. 882.) Heads hemispherical, sessile, lateral, smooth. Calyx-teeth equal, heart-shaped, reflexed, veiny.—Native of Spain, and of gravelly meadows and pastures in various parts of England, but not universally. Annual, flowering about Midsummer. Root furnished with fleshy knobs. Whole plants destitute of pubescence. Stems slender, various in length, quite prostrate, scarcely branched. Leaflets neatly toothed and striated, often marked across with a white or yellowish stripe. Stipulas ovate, membranous. Flowers rose-coloured, very pretty, with little green leafy calyx-teeth. Seed minute.

66. *T. parviflorum*. Small-flowered Trailing Trefoil. Ehrh. Beitr. v. 7. 165. Pl. Select. n. 29. Willd. n. 56. Bieberst. Taur. v. 2. 218?—Heads globose, axillary, stalked, nearly smooth. Calyx-teeth awl-shaped, rather unequal, spreading, recurved, longer than the corolla. Stem procumbent. Leaflets obovate, toothed.—Native of Hungary and Siberia. Willdenow. Linnæus knew this plant, but confounded it with his *striatum*; see n. 20. It is most akin to *glomeratum*, in size, habit, smoothness, mode of growth, and peculiar characters; but differs essentially in the length and form of its calyx-teeth, as well as the stalked heads, and remarkably membranous pellucid stipulas, with green awl-shaped teeth. The corolla seems to be rose-coloured. A few hairs are sometimes seen on the calyx, which is very strongly ribbed.

67. *T. striatum*. Soft Knotted Trefoil. Linn. Sp. Pl. 1085. Willd. n. 57. Fl. Brit. n. 12. Engl. Bot. t. 1843. (*T. parvum hirsutum, floribus parvis dilutè purpureis, in glomerulis mollioribus et oblongis, femine magno*; Raii Syn. 329. t. 13. f. 3. Vaill. Paris. t. 33. f. 2.)—Heads ovate, sessile, lateral and terminal. Calyx elliptical, hairy, furrowed, with bristle-shaped, rather unequal, teeth. Leaves downy.—Native of dry, rather barren, sandy pastures, in Germany, Hungary, France, Spain, and England, flowering in June. Root annual, with small fleshy knobs. Whole herb downy, and very soft to the touch, by which it is known from all the species which it otherwise resembles. Stems procumbent, from three to six inches long, branched, round, often zigzag. Leaflets obovate, finely toothed. Stipulas ovate, broad, pointed, somewhat membranous between the ribs. Heads mostly terminal. Calyx-teeth green, fringed, lengthened out after flowering. Corolla pale rose-coloured, about as long as the calyx. Germen with rudiments of two seeds; legume with only one, which is thrice as large as that of *glomeratum*, n. 65.

68. *T. gemellum*. Twin-headed Trefoil. Willd. n. 58.—“Heads oblong, terminal, in pairs. Calyx hairy: its teeth bristle-shaped, unequal, longer than the corolla. Leaflets wedge-shaped, emarginate, finely toothed at the extremity. Stems simple.”—Native of Spain, from whence specimens were sent by the abbé Pourret, to professor Willdenow, under the above name. Root annual. Stems a finger’s

TRIFOLIUM.

finger's length, or more, diffuse, villous. *Leaflets* villous, hoary, lanceolate-wedge-shaped, striated with veins. *Stipulas* lanceolate-pointed, membranous, ribbed. One of the *heads* stalked, the other sessile. *Willd.*

69. *T. phleoides*. Cat's-tail Trefoil. Willd. n. 59.—“Heads oblong. Calyx hairy; its teeth lanceolate-awl-shaped, unequal, rigid, spreading. Leaflets oblong, emarginate, nearly entire; the floral ones linear.”—Sent from Spain by Pourret. Annual. *Stems* nearly simple, about six inches long. *Leaflets* tapering at the base, clothed, like the stem, with close-pressed hairs: those of the floral *leaves* very narrow and entire. *Stipulas* lanceolate. *Spikes* nearly sessile, not unlike those of a *Pbleum*. Lowest tooth of the *calyx* longest. *Willd.*

70. *T. alexandrinum*. Egyptian Trefoil. Linn. Sp. Pl. 1085. Amoen. Acad. v. 4. 286. Willd. n. 60. Ait. n. 45. Forst. Ægypt.-Arab. 139.—Heads ovate, on axillary stalks, longer than the leaves. Calyx hairy; teeth awl-shaped, unequal. Stem erect. Floral leaves opposite. Leaflets elliptic-lanceolate, with shallow teeth.—Native of Egypt. The root is annual. Stem a foot or more in height, naked in the lower half, round, striated, smooth. Leaflets uniform, an inch or inch and half long, somewhat downy, about the length of the common stalks. Stipulas oblong, veiny, with green leafy awl-shaped points, of their own length. The lowest leaves only are opposite, one of them embracing the flower-stalk, the other the main stem, which rises some inches above it, bearing many alternate leaves, and perhaps more flowers. Heads solitary, near an inch long. Corolla monopetalous, white; standard linear, obtuse, longer than the wings, which are marked by a small prominent callosity at their base. Stigma downy towards the standard.

Forsskall says, this is the Trefoil universally cultivated in Egypt, being the best, and indeed the principal fodder for cattle in that country. It is sown only at the recess of the Nile; and where the fields are too high to be inundated by that river, they are watered by means of hydraulic engines, the seeds being committed to the earth while it is wet. The produce is three separate crops, the plants growing each time about half an ell in height, and there are three months between each harvest. After the last they die. The first crop is the best. When the Trefoil is wanted for seed, it is sown along with the wheat. Both are gathered at once, by the hand, not reaped or mown, and are threshed out together, the Trefoil seed being afterwards separated by a sieve. Our British agriculturists do not appear to know any thing of this species of Clover, which being so important in its own country, might be worth trying, at least, in this. We beg leave to recommend it to their notice. The plant was introduced at Kew, in 1798, by Mr. Hunnemann, and we trust its progeny has been continued. For the occupiers of low oozy lands in the fens it promises most benefit, provided the Egyptian mode of culture be the most eligible.

71. *T. suffocatum*. Suffocated Trefoil. Linn. Mant. 276. Willd. n. 61. Fl. Brit. n. 13. Engl. Bot. t. 1049. Tr. of Linn. Soc. v. 2. 357. Jacq. Hort. Vind. v. 1. 24. t. 60.—Heads sessile, lateral, roundish, nearly smooth. Calyx-teeth lanceolate, acute, recurved, longer than the corolla.—Found in the loose blowing sand of the sea-coasts of Sicily and England, flowering in June and July. Mr. Wigg first discovered and ascertained it near Yarmouth. Others have met with the plant, along the coast, from that place to Landguard fort. This little annual species is more truly subterraneous than our n. 29, the stems and flowers being often buried entirely in dry sand, the leaves only

peeping above the surface, so that the species might well remain in obscurity. In smoothness and general habit it comes so near to *glomeratum*, n. 65, that we have sometimes doubted its being more than a variety, caused by peculiarity of situation. But the calyx-teeth are lanceolate, by no means heart-shaped, and extend considerably beyond the corolla, which is closed so as to protect the organs of impregnation, which perform their functions under the dry sand. To provide against accident, each legume has two seeds, both which are often perfected. The petals, naturally rose-coloured, are rendered whitish by the exclusion of light. The stipulas are broad. Leaflets wedge-shaped, finely toothed, smooth.

72. *T. uniflorum*. Dwarf White Trefoil. Linn. Sp. Pl. 1085. Amoen. Acad. v. 4. 285. Willd. n. 62. Sm. Fl. Græc. Sibth. t. 752, unpubl. (T. verum repens, flore albo exiguo; Buxb. Cent. 3. 18. t. 31. f. 2. Melilotus cretica humillima humifusa, flore albo magno; Tourn. Cor. 28. Spica trifolia; Alpin. Exot. 169. t. 168.)—Stems much shorter than the footstalks, depressed. Stalks single-flowered, aggregate, shorter than the points of the stipulas. Tube of the calyx longer than its awl-shaped teeth.—Native of Syria, Arabia, and the neighbourhood of Constantinople. Dr. Sibthorp observed it on the loftiest mountains of Crete, as well as in Lemnos, Greece, and Asia Minor. The root is perennial. Stems several, most like those of *T. caespitosum*, n. 21, in their depressed position, but still shorter, closely invested with sheathing membranous stipulas, whose long, green, awl-shaped points extend beyond the axillary flower-stalks. The latter, a quarter or half an inch long, grow usually three together, from one common base, attended by very minute bractæas, each of them bearing a large white flower, full an inch long, whose calyx is tubular, ten-ribbed, nearly smooth, with rather unequal hairy teeth, half the length of the tube, having curved points. Standard broadish, erect, emarginate, longer than the wings or keel. Footstalks twice as long as the flowers, measuring full two inches, slightly hairy. Leaflets broadly obovate, smoothish, strongly ribbed, with fine, sharp, partly hooked, marginal teeth. It is very probable this species may have several seeds in each legume, and may belong to the second section. This point we want materials to determine.

SECT. 4. VESICARIA. Calyx inflated, swelling after flowering.

73. *T. spumosum*. Bladdery Trefoil. Linn. Sp. Pl. 1085. Willd. n. 63. Ait. n. 47. Sm. Fl. Græc. Sibth. t. 753, unpubl. (T. caule nudo, glomerulis glabris, &c.; Bauh. Hist. v. 2. 379, bad.)—Heads ovate. Calyx of the fruit ovate, tumid, smooth, with bristle-shaped recurved teeth. Bractæas membranous, lanceolate. Stem and branches erect.—Native of Languedoc, Italy, and Cyprus, in cultivated fields. Root annual. Stems numerous, spreading, a span high, leafy, branched, smooth like the whole plant, which has the general aspect of our common purple Clover, though totally different when examined. Footstalks from two to four inches long. Leaflets obovate, striated, toothed, marked with white. Stipulas pale, membranous, ovate, taper-pointed, entire. Heads solitary, terminal, ovate or roundish. Corolla long and slender, crimson, with a white tube; standard ovato-lanceolate, erect, entire. Calyx tubular, membranous, flesh-coloured, very smooth, with five nearly equal, green, slender, spreading teeth, one-third the length of the tube. As the fruit advances, the tube becomes inflated, obliquely elliptical, with many red ribs, connected by fine reticulations; the teeth rather unequal, and recurved; the corolla remaining dry and hardened in the mouth of the calyx, and investing the legume, which

TRIFOLIUM.

which is four-seeded, furnished with a long prominent beak. Each flower has a narrow lanceolate *bractea*; besides the five broader ones under the head. The latter are said to be wanting in *T. turgidum*, Bieberst. Taur. v. 2. 216, which is perhaps a variety, with paler flowers.

74. *T. recurvum*. Recurve-branched Trefoil. Willd. Enum. 795. "Waldst. et Kitaib. Hung. v. 2. 179. t. 165."—"Heads ovate in flower, oblong in seed. Calyx of the fruit inflated, naked. Stems erect. Branches recurved. Leaflets with bristly ferratures."—Native of Hungary. Biennial. Willd.

75. *T. resupinatum*. Reversed, or Salamanca, Trefoil. Linn. Sp. Pl. 1086. Willd. n. 64. Ait. n. 48. (*T. folliculatum*, five vesicarium, minus, purpureum; Bauh. Hist. 379. *T. pratense folliculatum*, flore inverso; Barre. Ic. v. 1. 73. n. 824. t. 872.)—Heads roundish. Flowers reversed. Calyx of the fruit inflated, oblong, membranous, reticulated, downy, with two terminal spinous teeth. Stems prostrate.—Native of Germany, Flanders, Italy, all Greece, and the Archipelago, flowering in the spring. A smooth annual plant, much agreeing in habit with our English *glomeratum*, but larger, and the lateral heads of little crimson flowers are supported by longish stalks. Each flower is turned on its back. The heads in seed are twice as large, being then near an inch broad. Calyx of the fruit much enlarged, split lengthwise, pale green, beautifully reticulated with strong veins, terminating in two teeth only, and besprinkled with short tawny hairs. Legumes two-seeded. Leaflets obovate, ribbed, ferrated. Stipulas short, abrupt, with lanceolate teeth. We presume *T. bicornis*, Forst. Egypt.-Arab. 139, can hardly be different from the present species.

76. *T. tomentosum*. Woolly Ball Trefoil. Linn. Sp. Pl. 1086. Willd. n. 65. Ait. n. 49. (*T. fragiferum*; Rivin. Tetrap. Irr. t. 10. f. 2. *T. fragiferum tomentosum*; Magn. Monsp. 265. t. 264. *T. glomerulis tomentosus per caulium longitudinem*; Bauh. Hist. v. 2. 379.)—Heads globose. Calyx of the fruit inflated, globose, membranous, reticulated, densely woolly, with two minute terminal teeth. Stems prostrate.—Native of the south of France, as well as of Spain, Portugal, Barbary, Greece, and the Levant. Cultivated by Parkinson, before 1640. Ait. Root perennial. Stems numerous, from two to six inches long, branched, prostrate, but not creeping. Leaflets obovate, smooth, obtuse, neatly ribbed, bordered with minutely spinous teeth. Stipulas ovato-lanceolate, pointed. Heads lateral, stalked, shorter than the leaves and footstalks, hemispherical while in flower, in which state the tube of the calyx is very smooth, with three teeth, on the under side; gibbous and woolly on the upper, with two teeth. As the fruit ripens, each head becomes an aggregate ball, half an inch in diameter, of globular, crowded, densely woolly calyces, exquisitely reticulated with pink veins. Nothing can be more distinct from the last, yet their specific characters are not easy to define in a striking manner. Linnæus justly remarks, that this species comes nearer to *resupinatum*, with which its corolla agrees, than to *fragiferum*, which it so much resembles in fruit. Some copies of Rivinus want the figure above cited, which was added to the plate after its first publication.

77. *T. fragiferum*. Strawberry-headed Trefoil. Linn. Sp. Pl. 1086. Willd. n. 66. Fl. Brit. n. 14. Engl. Bot. t. 1050. Curt. Lond. fasc. 2. t. 55. Fl. Dan. t. 1042. Ger. Em. 1208. (*T. fragiferum, folio oblongo*; Vaill. Paris. t. 22. f. 2.)—Heads roundish, on stalks much longer than the leaves. Calyx of the fruit inflated, globose, membranous, reticulated, nearly smooth, with two awl-

shaped, terminal, curved teeth. Stems creeping.—Native of low moist pastures or heaths, especially by rivers, in a black boggy soil, throughout Europe, from Sweden to Greece, and in Asia Minor, flowering in summer. Root perennial. Herbage so like *T. repens* as to be easily confounded therewith, except that the heads of flowers are smaller, and most generally pink; though oftener white in Sweden. Stipulas lanceolate, large, acute, white and membranous, with green veins. The heads, when perfecting fruit, strikingly resemble a hautbois strawberry, in size and colour, being larger than those of the last species, nearly smooth, and more richly coloured with red and green. The two spinous points of the calyx are also far more considerable. Legume with two seeds. This Trefoil is eaten by cattle, but its crop is late, and of trifling amount.

78. *T. physodes*. Bladder-headed Trefoil. Bieberst. Taur. v. 2. 217.—"Heads roundish. Calyx of the fruit inflated, membranous, downy, with five nearly equal bristle-shaped teeth, as long as the tube. Flower-stalks as long as the leaves. Stems procumbent, very smooth."—Native of Georgia. Chev. de Steven. Resembles the last, but is a distinct species. Stems scarcely taking root, long and slender, very smooth, not clothed with scattered spreading hairs as in *T. fragiferum*, any more than the footstalks and flower-stalks. Stipulas narrower, with a longer point. Leaflets larger, and of a brighter green. Flower-stalks shorter. Flowers with partial stalks a line in length, which render the head less dense. Calyx-teeth all nearly equal, resembling the two terminal teeth of the last. Corolla redder; with a longer and narrower standard. Such is the description of the author quoted. The calyx-teeth appear to us to afford the most decided specific distinction. *T. tumens* of the same writer is probably, as he suspects, only a more slender variety of his *physodes*, with longer stalks, smaller heads, and fewer flowers; but especially smaller calyx-teeth.

SECT. 5. LUPULINA. Standards of the flowers inflexed.

79. *T. montanum*. White Mountain Trefoil. Linn. Sp. Pl. 1087. Willd. n. 67. Ait. n. 51. Bieberst. Taur. v. 2. 218. (*T. folio longiore, flore albo*; Rivin. Tetrap. Irr. t. 12. f. 2. *T. pratense album*; Fuchs. Hist. 818. Ic. 472. *T. majus primum*; Clus. Hist. v. 2. 245. *T. majus flore albo*; Ger. Em. 1185.)—Spikes roundish. Standard awl-shaped, withering. Stem erect. Leaflets elliptical, with bristly teeth.—Native of dry mountainous pastures, in Germany, Switzerland, Savoy, and Crete, flowering in August. Dr. Pitcairn is said to have imported it in 1786. The root is woody and perennial. Stems about a foot high, silky as well as the footstalks. Lower leaflets broadest and obtuse; upper more lanceolate and very acute; all smooth above, light green, neatly ribbed. Heads stalked, at first hemispherical, but from the drooping of the lowermost flowers, as they fade, soon becoming elliptical, and near an inch long. Corolla white. Tube of the calyx pale, hairy about the top only; teeth about as long, awl-shaped, erect, rather unequal, remaining unchanged. The standard, like the other petals, does indeed remain in a dried hardened state, but scarcely more than in *T. hybridum, repens, &c.* to which the present species is so nearly related in every other respect, and so little like the rest of this section, that we could wish to remove it from hence, were not Linnæus and every other author against us.

80. *T. speciosum*. Purple and Yellow Trefoil. Zant Hay. Willd. n. 68. Ait. n. 52. Sm. Fl. Græc. Sibth. t. 754, unpubl. (*T. creticum elegantissimum, magno flore*; Tourn. Cor. 27.)—Spikes hemispherical. Standard kidney-shaped, toothed as well as the wings. Stems zigzag, decumbent.

TRIFOLIUM.

decumbent.—Found wild on the mountains of Crete, and in the isles of Cyprus and Zant. Mr. Hawkins observed this beautiful Trefoil as the only plant made into hay in the latter country. It might perhaps be tried with advantage in the dry open parts of the south of England. The root is annual, if we may judge by appearances. *Herbage* rather glaucous, nearly smooth. *Stems* spreading in every direction, much branched, purplish, about a foot high, but by culture they would certainly become more luxuriant. *Leaflets* obovate, toothed, emarginate. *Stipulas* lanceolate. *Heads* numerous, above an inch broad, on axillary stalks, longer than the leaves. *Calyx* smooth or hairy, its tube very short, and two upper teeth not longer; three lower (Willdenow erroneously says the upper) thrice as long, though shorter than the claws of the *petals*. *Standard* of a dull but elegant lilac hue, strongly ribbed, sharply toothed, withering and permanent, turning brown as it fades. *Wings* and *keel* yellow, shorter, the latter very small. The *flowers* are not reversed. Willdenow was misled by a dried specimen.

81. *T. agrarium*. Golden Trefoil. Linn. Sp. Pl. 1087. Willd. n. 69. Sm. Prodr. Fl. Græc. Sibth. n. 1814. Dickf. Dr. Pl. n. 80. Ehrh. Herb. n. 29. Fl. Dan. t. 558. (*T. aureum*; Pollich Palat. v. 2. 344. *T. montanum lupulinum*; Bauh. Prodr. 140. *Lotus montanus aureus*, amplo lupuli capite, annuus; Barrel. Ic. t. 1024, excellent.)—Heads oval, nearly globular. Standard elliptical, deflexed, entire. *Calyx*-teeth linear-awl-shaped, elongated, unequal, smooth. *Leaflets* all equally sessile. Stem erect.—Native of Sweden, Germany, Switzerland, Savoy, Greece, Crete, and Asia Minor, but not of England; generally in woods and coppices, in hilly or alpine situations, flowering in July and August. Root annual. *Stems* from four to twelve or fifteen inches high, scarcely branched. *Leaflets* obovate-oblong, more or less toothed, ribbed, shorter than their common stalk. *Stipulas* ovato-lanceolate. *Heads* one, two, or three, full as big as the last, about the top of the stem, on longish, stout, angular, hairy stalks. *Corolla* of a bright golden yellow, large, shining, turning brown by age or drying only; *standard* furrowed, inflexed. Tube of the *calyx* short, bell-shaped, smooth as well as the teeth, which are all more or less elongated, though the two uppermost are shortest. *Legume* small, elliptical, single-seeded. See the next species.

82. *T. spadicum*. Bay-coloured Trefoil. Linn. Sp. Pl. 1087. Willd. n. 70. Ait. n. 53. Curt. Mag. t. 557. Ehrh. Herb. n. 19.—Heads oval, nearly cylindrical. Standard elliptical, deflexed, entire. Three lower calyx-teeth awl-shaped, hairy; two upper obsolete, or very short. *Leaflets* all equally sessile. Stem erect.—Native of Sweden, in mountainous meadows at Gottfund, near Upsal, and other places, but rarely. Linnæus. Whether it be found also in Germany, we are not certain; but whatever has been taken for this species in other parts of Europe, we have ascertained to be the foregoing, to which all its synonyms, except the above, belong; even, probably, *Lupulinum montanum, capitulis spadicis*; Rupp. Jen. 248. ed. 2. 256. The excellent figure in Curtis is therefore a great acquisition. Indeed the synonyms of *agrarium*, cited by Linnæus, are wrong. *T. agrarium* of Dodonæus, Pempt. 576, is actually *Medicago lupulina*! Yet hence the specific name, a very inapplicable one, was taken. *T. spadicum*, sent to Kew by M. Thouin in 1778, is a hardy annual, flowering in July and August. It differs very decidedly from the last, in being a smaller more slender plant, though equally upright. The *heads* in particular are but half the size of that species, or if sometimes nearly as long, they are much more slender and cylindrical. The *flowers*,

though at first yellow, soon change to a peculiarly rich dark snuff-colour, and are essentially distinguished by the very small upper teeth of their *calyx*, as well as the long bristly hairs which clothe the lower ones.

83. *T. procumbens*. Hop Trefoil. Linn. Sp. Pl. 1088. Fl. Suec. ed. 2. 261. Willd. n. 71. Fl. Brit. n. 15. 792. and 1403. Compend. 111. Engl. Bot. t. 945. Pursh n. 9. Fl. Dan. t. 796. (*T. agrarium*; Hudf. 328. Curt. Lond. fasc. 3. t. 45. Mart. Ruft. t. 121. *T. lupulinum*; Rivin. Tetrap. Irr. t. 10. f. 1. *T. pratense luteum, capitulo Lupuli, vel agrarium*; Raii Syn. 330. Melilotus, qui *Trifolium pratense luteum, capitulo Lupuli, vel agrarium*; Vaill. Paris. t. 22. f. 3.)—Heads oval, many-flowered. Standard furrowed. *Stems* procumbent. *Leaflets* obovate. Common footstalk elongated in the lower part.—Native of dry gravelly pastures and fields throughout Europe, from Sweden to Greece and Asia Minor, as also in North America, flowering in June and July. This is one of three common annual procumbent species, with yellow flowers, all of which have been confounded, in some respect or other, by Linnæus and his disciples, and for the right understanding of which we acknowledge ourselves obliged to the Rev. Dr. Beeke, now dean of Bristol; see Engl. Bot. v. 18. Before the publication of Fl. Brit. v. 1 and 2, the present plant was taken, by all British botanists, for the Linnæan *agrarium*, n. 81. From that it differs in being much smaller, with procumbent branching stems, which are only occasionally supported by neighbouring plants, or a little ascending at the end. From the two following it differs in having oval, many-flowered heads, which assume in fading a hop-like aspect; but they have never the shining bronzed hue of the real *agrarium*, though the *standard*, like that, is furrowed. The *leaflets* are obovate, emarginate, toothed, smooth, slightly glaucous; their common footstalk much longer below the side leaflets than beyond them, the odd leaflet being sometimes nearly sessile. *Stipulas* half-ovate, acute, ribbed, entire, often fringed, *branches* and *flower-stalks* more or less hairy, especially upward. *Heads* at most half an inch long. *Calyx*-teeth unequal, but variable. *Corolla* lemon-coloured, changing to a light, tawny brown; the *standard* rounded, strongly furrowed. *Legume* small, elliptical, pointed, with one seed. Professor Martyn recommends this species to the notice of the agriculturist. Cattle are fond of it, but the crop will probably not be so abundant as the Nonfuch, or *Medicago lupulina*.

84. *T. minus*. Lesser Yellow Trefoil. Relh. Cant. 290. Fl. Brit. 1403. Compend. 111. Engl. Bot. t. 1256. Ait. n. 55. (*T. filiforme* β; Fl. Brit. 793. *T. filiforme*; Ehrh. Herb. n. 49. *T. procumbens*; Hudf. 328. Curt. Lond. fasc. 5. t. 53. *T. lupulinum alterum minus*; Raii Syn. 330. t. 14. f. 3. *T. luteum minimum*; Ger. Em. 1186.)—Heads hemispherical. Flower-stalks straight and rigid. Standard nearly smooth. *Stems* prostrate. Common footstalk very short below the leaflets.—Very frequent in dry gravelly pastures, of England, Germany, and Switzerland, flowering in June and July. Root small, annual, often furnished with little fleshy knobs. *Stems* but little branched, from six to twenty-four inches long; most succulent and brittle in the larger variety, Engl. Bot. f. 1, which Dr. Beeke recommends as likely to prove a most valuable plant, for cultivation in upland pastures, being highly acceptable to cows and sheep. The central leaflet is elevated on a much more considerable partial stalk than in the foregoing or the following species; while the common footstalk, though variable, is in general remarkably short. *Leaflets* obovate and emarginate, or orbiculate, serrated. *Flowers* from twelve to fifteen only, pale yellow, making a little hemispherical head, and all finally deflexed. *Standard* scarcely wrinkled or furrowed. *Legume* obovate,

obovate, obtuse. *Seeds* rarely more than one in each legume. *Calyx-teeth* very unequal, taper, hairy. Linnæus confounded this with the preceding, as appears by his herbarium. Others have thought it not distinct from the following; but we trust both those mistakes are now sufficiently cleared up.

85. *T. filiforme*. Slender Yellow Trefoil. Linn. Sp. Pl. 1088. Fl. Suec. ed. 2. 261. Willd. n. 72. Fl. Brit. 1404. Engl. Bot. t. 1257. (*T. lupulinum minimum*; Dill. in Raii Syn. 331. t. 14. f. 4.)—Heads lax, of few flowers. Flower-stalks capillary, wavy. Standard smooth. Stems prostrate. Leaflets all nearly sessile.—Native of rather moist gravelly pastures, among short grass, in Scania, as well as in England, flowering in June and July. Annual, like the last, but usually more prostrate, and much smaller, discoverable chiefly by its little yellow heads of *flowers*, entangled by their capillary stalks, among the radical leaves of short grass, on grass-plats, where the soil, though gravelly or sandy, is somewhat moist, and prone to bear moss. The stems are about a finger's length, numerous, slender, and branched. *Leaflets* narrow, nearly or quite sessile, on a short common stalk. *Flowers* from three to eight, drooping, each on a very slender, though elongated, partial stalk, and all leaning toward one side. *Calyx* quite smooth; its teeth less remarkably disproportioned than in *T. minus*. *Legume* obovate, sometimes two-seeded, scarcely covered by the withered pale-brown *corolla*, whose standard is not at all furrowed.—Sometimes the size of this species exceeds that of the smaller variety of the last; but if the above characters be attended to, no confusion can arise.

For *T. biflorum*, Linn. Sp. Pl. 1088, and *T. guianense*, Aubl. Guian. t. 309, see STYLOSANTHES, n. 4 and 5.

Linnæus, at the end of this genus, classes the various species according to their inflorescence, whether racemose, umbellate, fasciculate, capitate, or spiked; which serves to shew the impropriety of any generic character derived from thence.

TRIFORIUM, the gallery which usually goes round a church of the pointed style, over the side-aisles, so called by Gervadius and other ancient writers.

TRIFORMIS, in *Mythology*, an epithet given to *Diana*; which see.

TRIGA, in *Antiquity*, a kind of car, or chariot, with three horses.

The triga, in reality, was only drawn by two horses; so that it was properly a biga; but it had, besides, a third horse tied to the others, like a led horse, for change. Statius calls the third horse, *equus funalis*; Hesychius, *παραπονος*; and Dionysius Halicarnassensis, *συναγαιος*.

We do not find the triga on any ancient monument; but it was a long time in use among the Romans, at their *ludi Circenses*. The Greeks, who first introduced it, soon abandoned it.

TRIGAL, in *Geography*, a town of Prussia, in Natangen; 9 miles S. of Lick.

TRIGAMY, a third marriage; or the state of a person who hath been married three times.

In the ancient church, trigamy was only allowed to such as had no children by their former marriages.

If, having children by one or both the former, they married again, after forty years of age, they were excluded from communion for five years. If they were only forty years old, the penance was but four years. See BIGAMY.

TRIGAULT, NICHOLAS, in *Biography*, a Jesuit missionary, was born at Douay in 1577, and having entered into the Society of Jesus, was sent, in 1610, on a mission to the East Indies. After a year's residence in China, he came to Europe for a recruit of missionaries, and returned with forty-

four associates. At length his life and labours terminated at Nanking in 1628. Of his works, which were numerous, we shall only mention his treatise entitled "De Christiana Expeditione apud Sinas ex Matthei Ricci Commentariis," 1615, 4to. This work, composed from the memoirs of Ricci, contains a description of the manners, laws, and customs of the empire of China, with an account of the acts of the Jesuits in that country. "A Chinese Dictionary," 3 vols. printed in China. Moreri.

TRIGEMINI NERVI, in *Anatomy*, the nerves of the fifth pair of the head. See NERVE.

TRIGINTAL. See TRENTAL.

TRIGLA, or GURNARD, in *Ichthyology*, a genus of fish of the order of the Thoracici; the characters of which are, that the head is large, mailed, and marked by rough lines; the eyes large and round at the vertex; the mouth large; the palate and mandibles armed with sharpened teeth; and the nostrils double; the aperture of the branchiæ or gills large; the gill-cover spiny, and the gill-membrane seven-rayed; the body covered with scales, wedge-formed; the back straight, with a longitudinal furrow on both sides spinous; the lateral line near the back, straight; the abdomen thick, the ventral and pectoral fins large, and, in some species, near the pectoral fins are finger-shaped processes.

Species.

CATAPHRACTA; Red Gurnard. With double fingers; forked elongated snout, and octagonal mailed body: its length is about twelve inches: the longitudinal rows or divisions of the body are marked by as many serrated or aculeated lines; beneath the throat is a pair of ramified cirri; the pectoral fins and tail are pale-brown; the other fins pale-yellow, and nearly transparent; rays of the first dorsal fin running out beyond the membrane. A native of the Mediterranean.

LYRA; Red Gurnard. Silvery beneath, with triple fingers, and bifid denticulated snout. This is the Piper of the British Zoology. Its length is from one to two feet or more; its lateral line formed of small scales; its scales are small, pectoral fins large, slightly tinged with dull blue; tail of like colour; the other fins yellowish, with red rays. Native of the European seas, and considered as an excellent fish for the table.

GURNARDUS; Grey Gurnard. With triple fingers, and lateral line mailed with rounded whitish scales: length the same as that of the former: colour above deep grey, with blackish and red spots, beneath silvery; scales small, lateral line strongly marked with a series of larger, rounded, whitish scales, with a dusky central spot. Native of the European seas, and not uncommon about our own coasts, feeding on worms, insects, &c.

CUCULUS; Red Cuckow Gurnard. Silvery beneath, with triple fingers, and first dorsal fin marked by a black spot: an elegant species, about a foot in length, of a more slender shape than the last; colour on the upper parts a beautiful red, more or less distinctly marked by whitish transverse bars; scales extremely small; lateral line composed of pointed white scales edged with black, and a similar row on each side of the back; fins transparent; the first dorsal marked on the edge by a black spot, the second tinged near its edge with yellow. Native of the European seas, and esteemed as a food.

LUCERNA. With triple fingers, sub-bifid snout, and lateral line bifid at the tail. Native of the Northern seas, and conjectured to be a variety of *T. hirundo*.

HIRUNDO; Grey-brown Gurnard. Silvery beneath, with triple fingers, and very large olivaceous pectoral fins spotted with

with blue: the Sapphiric gurnard of the British Zoology; and stock-fish of Willughby. Of the same size with the grey gurnard; scales middle-sized, lateral line rough, pectoral fins very large, of a violaceous olive, sometimes richly edged and spotted with blue. Native of the European seas, occasionally springing out of the water to some distance by means of its large pectoral fins.

LINEATA; Red Gurnard. Marked above by dusky-sanguine spots, with the body crossed on each side by numerous perpendicular lines: the streaked gurnard of the British Zoology. Size and habit of *T. cuculus*; colour bright-red, abdomen silvery; on each side of the back, close to the base of the dorsal fins, a row of broad, serrated, short processes of a yellow colour; lateral line formed by a row of similar ones; scales small, sides above and below the lateral line marked into very numerous, narrow perpendicular divisions; pectoral fins large, rounded, of a dusky-brown, spotted with black; rest of the fins yellowish, with a tinge of red, especially the tail, which is slightly lunated. Native of the Mediterranean sea.

ASIATICA; Silvery Gurnard. With quadruple fingers; body smooth, snout smooth and prominent; anterior gill-covers serrated; pectoral fins falcated. Native of the Indian seas.

EVOLANS; Springing Gurnard. With triple fingers, and three serrated spines between the dorsal fins; allied to the *T. volitans*, but furnished with three separate pectoral processes; the pectoral fins very large, but less than those of the next species; the pectoral fins blackish. Native of the American seas.

VOLTANS; Red Gurnard. With aculeated scales, very large pectoral fins spotted with blue, and sextuple fingers connected by a membrane; the *Milvus* of Salvan, Aldrovandus, Willughby, &c. This is highly singular and beautiful species; length about twelve inches; colour crimson above, pale or whitish beneath; head blunt, armed on each side with two very strong large spines, pointing backwards; the whole body covered with very strong carinated and sharp-pointed scales, hardly separable; first dorsal fin pale violet, crossed with deeper lines, and at its origin two separate rays longer than the rest; second dorsal fin pale, with the rays barred by brown; pectoral fins very large, transparent, of an olive-green, richly varied with numerous bright-blue spots, six pectoral processes, not separate, but united, and appearing like a small fin on each side of the thorax; tail pale violet, with the rays crossed by dusky spots, and strengthened on each side of the base by two obliquely transverse bony ribs or bars. Native of the Mediterranean, Atlantic, and Indian seas, where it swims in shoals, and is often seen flying out of the water to a considerable distance.

JAPONICA, or **ALATA**; the Japanese Gurnard. With eleven fingers on each side, palmated by a membrane. About four inches in length; head angular; lower jaw and hinder margin of the gill-covers furnished with two strong spines. Native of the Japanese sea.

ADRIATICA. With the body verticillated by scales, with aculeated lateral line; pectoral fins black beneath, and triple fingers; supposed to be a variety of *T. lineata*, and differing from it by being varied with bands of black spots, and having the spots of the pectoral fins disposed into two transverse bands, the edges being marked beneath by a row of blue spots. Observed in the Adriatic sea.

MINUTA. With triple fingers, and bicarinated back. A small species: head hard and rough, emarginated and denticulated in front, and furnished with two spines above the eyes; posterior gill-covers spiny; pectoral and ventral

fins very sharp-pointed; tail rounded. Native of the Indian seas.

CAROLINA; Whitish Gurnard. Speckled with red, with triple fingers, and brown pectoral fins transversely banded with black; length about ten inches; dorsal fins pale orange spotted with brown; the first fin marked by a black spot; tail slightly rounded at the end, and crossed by three or four rows of brown spots. Native of the American seas.

CAVILLONE; Red Gurnard. With a single spine above each eye, and six on each side of the back of the head. Length about three inches; body covered with small, denticulated, rough scales; colour red; pectoral fins white above, and dark-green or olive beneath. Native of the Mediterranean, and known on the French coasts by the appellation of Cavillone.

PUNCTATA; Rose-red Gurnard. With blood-red specks, and broad obtuse head, spined on the hind-part. Length about eight inches; head broad, obtuse, and furnished behind with strong spines; scales middle-sized; pectoral fins very large, rounded, and of a dusky-blue colour, speckled with red, and inclining to yellow towards their tips; rest of the fins and tail yellow speckled with red. Native of the American seas.

PINI; Red Gurnard. With triple fingers, and body marked on each side by numerous transverse convex lines. Similar in habit to that of *T. piper*, but in other respects much allied to *T. lineata*: colour red, with yellowish abdomen; scales small; dorsal and lateral line aculeated, from which pass perpendicular convex lines terminating rather obtusely above and below, and bearing some resemblance to pine-leaves; fins and tail yellowish; ventral fins red, with an obscure blueish cast. Native region unknown.

CHABRONTERA. With the body mailed beneath, and red fins. Allied to the *T. cataphracta*, but differing by not having the body marked into an octagonal form; the under parts only being furnished with bony divisions: above the snout are several spines pointing backwards: and above and below the tail are also placed three spines: all the fins, except the tail, are of a bright red. Native of the Mediterranean. Shaw's Zoology, vol. iv. pt. 2.

TRIOLA, in *Mythology*, the name of a divinity among the Germans with three heads, which was undoubtedly Diana Trivia, or Hecate.

TRIGLAND, JAMES, in *Biography*, a learned theologian, was born at Haerlem in 1652, and educated at the universities of Harderwyk and Leyden, where he diligently studied the Oriental languages. He became a candidate for the ministry in 1676, and having exercised it for some time at different places, he at length settled at Leyden, where, in 1686, he was made professor of theology, to which was afterwards added the office of explaining Hebrew antiquities. He was twice nominated rector of the university by William prince of Orange, by whom he was greatly esteemed. He died in 1705. His erudition was profound, and his works, on literary and theological subjects, various. Moreri.

TRIGLOCHIN, in *Botany*, very well named by Linnæus, from *τρις*, three, and *γλοχιν*, the point of a dart, or arrow, alluding to the three sharp lower ends of the capsule-valves, which, when started from their original situation, give to the fruit the appearance of a triple-barbed dart; whence also its English name of Arrow-head, or Arrow-grass.—Linn. Gen. 179. Schreb. 239. Willd. Sp. Pl. v. 2. 264. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 378. Ait. Hort. Kew. v. 2. 325. Brown Prodr. Nov. Holl. v. 1. 343. Pursh 247. Just. 47. Lamarek Illustr. t. 270. Gærtn. t. 84. (Junceago; Tournef. t. 142. Michx. Gen.

Gen. t. 31.)—Class and order, *Hexandria Trigynia*. Nat. Ord. *Tripetaloidea*, Linn. *Junci*, Juss. *Alismaceae*, Brown.

Gen. Ch. *Cal.* Perianth inferior, of three roundish, obtuse, concave, deciduous leaves. *Cor.* Petals three, ovate, concave, obtuse, similar to the calyx. *Stam.* Filaments six, very short; anthers at the back of the filaments, shorter than the corolla. *Pist.* Germen superior, large; styles none; stigmas three or six, reflexed, feathery. *Peric.* Capsule ovate-oblong, obtuse, with as many cells as there are stigmas, bursting at the base, with acute valves. *Seeds* solitary, oblong, erect.

Obf. Gærtner and Brown, perhaps more justly, consider the fruit as an assemblage of three or six single-seeded capsules, without valves. Analogy confirms this opinion.

Eff. Ch. Calyx of three leaves. Petals three, like the calyx. Styles none. Capsule superior, of three or six cells, separating at the base. Seeds solitary.

1. *T. palustre*. Marsh Arrow-grafs. Linn. Sp. Pl. 482. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 366. Fl. Dan. t. 490. Leers 92. t. 12. f. 5. Pursh n. 2? (*Gramen aquaticum spicatum*; Ger. Em. 13.)—Capsules of three cells, nearly linear; tapering at the base. Stigmas erect.—Native of boggy inundated places, in various parts of Europe, particularly towards the North. Common in England, flowering in July. The root is fibrous, perennial. Leaves radical, two-ranked, erect, sheathing, linear, channelled, smooth, six inches high. Flower-stalk radical, simple, round, or partly angular, taller than the leaves, terminating in a long, linear, simple, slender cluster, of small green flowers. These are succeeded by upright prismatic capsules, slightly elliptical, half an inch long, separating at the base into three sharp points.

2. *T. bulbosum*. Bulbous Arrow-grafs. Linn. Mant. 226. Willd. n. 2. Jacq. Ic. Rar. t. 454.—Capsules of three cells, linear-lanceolate, tapering upwards. Stigmas spreading. Root bulbous.—Native of the Cape of Good Hope. Smaller than the foregoing, with shorter leaves, and ovate bulbous roots, concealed by the numerous fibrous remains of old leaves. Germen with three spreading points, each crowned by a little starry stigma. Capsule rounded at the base.

3. *T. mexicanum*. Mexican Arrow-grafs. Kunth Nov. Gen. and Sp. v. 1. 244.—Capsules of six cells. Spike very long. Leaves cylindrical. Root tuberous.—Native of moist exposed situations in New Spain, flowering in January. Root perennial, oblong, horizontal, the thickness of a swan's quill, very densely clothed with the rudiments (rather probably the remains) of leaves. All the leaves are radical, linear, narrow, bluntish, smooth, two or three inches long, sheathing at the base. Stalk erect, round, smooth, six or eight inches high, including its cluster, which measures half as much. Stamens six. Stigmas red. Two or three of the cells, or capsules, are generally abortive. Kunth.

4. *T. procerum*. Tall Arrow-grafs. Brown n. 1.—“Capsules of six cells. Stigmas linear, recurved. Spike very long. Leaves linear, rather cylindrical at the base.”—Found by Mr. Brown, near Port Jackson, as well as in the tropical part of New Holland.

5. *T. maritimum*. Sea Arrow-grafs. Linn. Sp. Pl. 483. Willd. n. 3. Fl. Brit. n. 2. Engl. Bot. t. 255. Pursh n. 1. Fl. Dan. t. 306. (*Gramen marinum spicatum*; Lob. Ic. 16. *G. spicatum alterum*; Ger. Em. 20.)—Capsules elliptical, of six cells, rounded at the base. Leaves semicylindrical. Root tuberous.—Native of salt-marshes, in England and other parts of Europe, as well as North America, flowering throughout the summer. Much

flourer in habit than our other British species, n. 1, from which also it is readily known by its short rounded capsules, and their six cells. Cattle are said to eat this plant with avidity.

6. *T. triandrum*. Triandrous American Arrow-grafs. Michaux Boreal.-Amer. v. 1. 208. Pursh n. 3.—“Stamens three. Capsules roundish, triangular. Leaves almost fetaceous, nearly as tall as the stalk and its spine.”—Native of overflowed marshes, near Charlestown, Carolina. Michaux.

7. *T. dubium*. Doubtful Arrow-grafs. Brown n. 2.—“Capsules of three, oblong-cylindrical, distinct cells; one or two of them here and there abortive. Spike elongated.”—Gathered in the tropical part of New Holland by Mr. Brown.

8. *T. decipiens*. Deceitful Arrow-grafs. Brown n. 3.—“Capsules roundish, of three cells, with three dorsal keels; pointless at the summit: three alternate ones abortive, without stigmas. Leaves femicylindrical. Stipula intrafoliaceous, undivided.”—Found in New South Wales, Van Diemen's island, and the south part of New Holland by Mr. Brown. The abortive cells look like partitions.

9. *T. mucronatum*. Pointed-fruited Arrow-grafs. Brown n. 4.—“Capsules somewhat turbinate; the points of their three perfect cells divaricated; three abortive ones like partitions. Leaves nearly cylindrical. Spike of few flowers.”—Gathered by Mr. Brown, without flowers, on the southern coast of New Holland.

TRIGLOCHINE, in *Anatomy*, a synonym of the tricuspidal valve. See TRICUSPID.

TRIGLYPHS, formed from *τριγλωφοι*, *q. d.* three engravings, from *γλυψω*, *sculpo*, in *Architecture*, a sort of ornaments repeated at equal intervals in the Doric frieze. Each triglyph consists of two entire gutters, or channels, cut to a right angle, called *glyphes*, and separated by three interstices, called by Vitruvius *femora*, from each other, as well as from two other half-channels which are at the sides.

The ordinary proportion of triglyphs, is to be a module broad, and one and a half high. But this proportion, M. le Clerc observes, sometimes occasions ill-proportioned intercolumnations in the porticoes; for which reason he chooses to accommodate the proportion of his triglyphs to that of the intercolumnation.

The intervals between the triglyphs are called *metopes*.—Under the channels, or glyphes, are placed guttæ, or drops.

The triglyphs make the most distinguishing character of the Doric order. Some imagine them originally intended for the conveyance of the guttæ that are underneath them; others fancy they bear some resemblance to a lyre, and thence conjecture the ornament to have been originally invented for some temple sacred to Apollo. See DORIC.

TRIGLYPH, *Capital of a*. See CAPITAL.

TRIGLYPTON, in *Ancient Geography*, a town of Italy, on the other side of the Ganges, in the country called Randa-marcotta.

TRIGNO, in *Geography*, a river of Naples, which runs into the Adriatic, 12 miles N.W. of Termoli.

TRIGOLO, a town of Italy, in the department of the Upper Po; 5 miles S.E. of Crema.

TRIGON, TRIGONUS, formed from *τριγωνος*, *triangle*, in *Geometry*, a triangle.

TRIGON, in *Astrology*. See TRIPPLICITY.

TRIGON, in *Astronomy*, denotes an aspect of two planets, wherein they are 120 degrees distant from each other: this is called also *trine*.

The trigons of Mars and Saturn are by astrologers held malific aspects.

TRIGON, *Trigonum*, was also a musical instrument, used among the ancients.

The trigon was a kind of triangular lyre, or harp, and was invented by Ibycus.

It was used at feasts, and played on by women, who struck it either with a quill, or beat it with small rods of different lengths and weights, to occasion a diversity in the sounds. See TRIGONUM.

TRIGON or *Triangle of Signs*, is the name of an instrument used for drawing the arcs of the signs upon dials: it may be made of brass or any other solid matter, and of any size at pleasure. This instrument is constructed after the following manner: first draw the line *ab* (*Plate XXI. Astronomy, fig. 5.*) representing the axis of the world, and *ac* perpendicular to it, representing the radius of the equinoctial; and about the point *a* describe the circular arc *dce* at pleasure. Then reckon $23\frac{1}{2}^{\circ}$ both ways from the point *c* upon the said arc for the sun's greatest declination, and draw the two lines *ad, ae*, for the summer and winter tropics: likewise draw the line *de*, which will be bisected by the radius of the equinoctial in *o*; about which point, as a centre, draw a circle, whose circumference passes through the points *d* and *e* of the tropics, and divide the circumference into 12 equal parts, beginning from *d*: through each point of division equally distant from *d* and *e*, draw occult lines parallel to the radius of the equinoctial circle: these lines will intersect the arc *dc* in the points, through which and the centre *a*, lines being drawn, will represent the beginnings of the signs of the zodiac at 30° distance from each other. But to divide the signs into every 10th or 5th degree, the circumference must be divided into thirty-six or seventy-two equal parts. The characters of the signs are annexed as in the figure; and when the trigon is divided into every 10th or 5th degree, the letter of the month is placed to the first 10° of each sign agreeing with it. However, this instrument may more readily be made by means of a table of the sun's declination; for having drawn the two lines *ab* and *ac* at right angles, lay the centre of a protractor on the point *a*, with its limb towards the point *c*; and keeping it fixed, count $23\frac{1}{2}^{\circ}$ on both sides of the radius *ac* for the tropics of \varnothing and ♋ , $20^{\circ} 12'$ for the beginnings of the signs \varnothing , ♈ , ♉ , and ♊ , and $11^{\circ} 30'$ for ♈ , ♉ , ♊ , and ♋ . And thus the spaces for each sign may be graduated in every 10th and 5th degree by means of a table. The equinoctial points of φ and \approx are placed at the end of the radius of the equinoctial *ac*.

TRIGON of *Diurnal and Nocturnal Arcs*. These are drawn upon sun-dials by curve-lines, like the arcs of the signs, and by means of them the shadow of the style shews how many hours the sun is above the horizon, in any given day, &c.

The trigon of signs is the same for all latitudes, the sun's declination being the same for the whole earth; but the diurnal arcs are different for every particular latitude, and as many of these arcs are drawn upon a dial, as there are hours of difference between the longest and shortest days of the year. For the construction of this sort of trigon, draw the right line *RZ* (*fig. 6.*) for the radius of the hour-line of 12, or of the equinoctial: and about the point *R*, with any opening of the compasses at pleasure, describe the circular arc *T'SV*, and lay off both ways on it from the point *S* two arcs, *SV, ST*, each equal to the complement of the latitude. Then draw the right line *T'XV*, and about the point *X*, as a centre, describe the circumference of a circle *TZVY*, which divide into forty-eight equal parts by dotted

lines, drawn parallel to the radius of the equinoctial *RZ*: then these lines will intersect the diameter *T'XV* in points, through which and the point *R* you may draw the radii of the hours. The angles which all the radii make at the point *R* may be found trigonometrically by the following proportion: as radius is to the co-tangent of the latitude, so is the tangent of the difference between the semidiurnal arc at the time of the equinox, and the arc proposed to the tangent of the sun's required declination.

The trigon of signs may be annexed to a rule or index *A* (*fig. 7.*) in order to draw the arcs of the signs upon great dials. The diurnal arcs may be drawn likewise upon this trigon, but the arcs of the signs and diurnal arcs too must not be drawn upon one and the same dial, for avoiding confusion. In the centre of the index there is a small hole, through which is put a pin, that the instrument may turn about the centre of a dial. The trigon slides along the index, and may be fixed in any part of it by means of the screw *B*. The arcs of the signs with their characters are round about the circumference, and there is a fine thread fixed in the centre, in order to extend over the radii quite to the hour-lines of a dial.—For a farther account of these instruments and their use, see Bion's *Constr. and Use of Math. Instr.* by Stone, p. 231, &c.

TRIGONAL LEAF, among *Botanists*. See LEAF.

TRIGONAL Numbers. See TRIANGULAR Numbers.

TRIGONELLA, in *Botany*, the diminutive of *trigona*, three-sided, alluding to its little triangular flower.—Linn. Gen. 388. Schreb. 510. Willd. Sp. Pl. v. 3. 1398. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc. Sibth. v. 2. 107. Ait. Hort. Kew. v. 4. 397. Juss. 356. Lamarck Illustr. t. 611. Gærtn. t. 152. (*Fænium græcum*; Tourn. t. 230.)—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-shaped, divided half way down into five little, awl-shaped, nearly equal, teeth. *Cor.* papilionaceous, apparently tripetalous; standard nearly ovate, obtuse, reflexed and spreading; wings two, ovate-oblong, reflexed and spreading outwards, in such a manner that, with the standard, they almost constitute a regular tripetalous corolla; keel very short, obtuse, occupying the centre of the flower. *Stam.* Filaments in two distinct sets, one simple, one in nine segments, short, ascending; anthers simple, roundish. *Pist.* Germen ovate-oblong, compressed; style simple, ascending; stigma simple. *Peric.* Legume linear-oblong, somewhat curved, compressed, much longer than the calyx, of one cell, and two valves. *Seeds* numerous, roundish.

Ess. Ch. Standard and wings nearly equal, spreading, in the form of a tripetalous corolla. Stigma smooth. Legume of one cell, with many seeds, compressed, longer than the calyx.

Obs. Linnæus remarks that the figure of the corolla alone stamps this as a distinct genus. We could wish that character were more evident. The closest affinity exists between some *Trigonella*, which we shall indicate, and the *Meliloti*, constituting the first section of TRIFOLIUM. See that article.

The species of this genus, seventeen in Willdenow, are herbaceous, for the most part annual, strong-scented plants, with three leaflets on a stalk, and indeed the general habit of *Trifolium*. Their flowers are tufted rather than properly capitate, usually yellow. *T. Fænium græcum* has blueish flowers, which are quite sessile, or truly capitate, their corolla that of a *Trifolium*, and their beaked legume splitting chiefly along its upper margin. This species certainly does not well accord with the rest.

TRIGONELLA.

1. *T. ruthenica*. Small, or Russian, Fenugreek. Linn. Sp. Pl. 1093. Willd. n. 1. Ait. n. 1; excluding the synonym of Gmelin, which Linnæus subsequently discovered to belong to *Medicago falcata*. (Lotus n. 156; Amm. Ruth. 119, and Melilotus n. 159; *ibid.* 120.)—Legumes stalked, crowded, drooping, linear-lanceolate, straight. Leaflets lanceolate-obovate, abrupt, with three terminal teeth.—Common throughout Siberia. A hardy perennial, flowering in June and July, sent by the Siberian botanist Amman, to Miller, before the year 1741. *Herb* nearly smooth. *Stems* numerous, spreading or decumbent, much branched, round, leafy. *Leaves* alternate, stalked, of three narrow, delicate leaflets, tapering and entire towards the base, toothed about the extremity; the odd one largest, an inch long, on an elongated partial stalk. *Stipulas* small, awl-shaped. *Flowers* yellow within, purplish externally, in short, axillary, capitate clusters. *Standard* broad, almost orbicular. *Calyx* hairy, bell-shaped, with five lanceolate, rather unequal, teeth. *Legume* half an inch long, compressed, with four or five kidney-shaped seeds. We know of no figure of this species.

2. *T. platycarpus*. Round-leaved Fenugreek. Linn. Sp. Pl. 1093. Willd. n. 2. Ait. n. 2. (T. n. 34; Gmel. Sib. v. 4. 25. t. 9. Melilotus n. 158; Amm. Ruth. 119. "Comm. Petrop. v. 8. 209. t. 12. Comm. Goett. v. 1. 213. t. 13.")—Legumes stalked, crowded, pendulous, half-oval, compressed. *Stem* diffuse. Leaflets roundish-obovate, sharply ferrated.—Native of Siberia. Sent to England by Dr. Amman, with the foregoing. A hardy biennial, flowering from June to September. *Stem* angular. *Leaflets* often an inch long, and nearly as broad, smooth. *Stipulas* half arrow-shaped, toothed. *Flowers* like the last, but larger, sweet-scented, yellow streaked with brown. *Calyx* hairy. *Legume* above an inch long, somewhat veiny, many-seeded.

3. *T. hybrida*. Mule Fenugreek. Pourret in Act. Tolos. v. 3. 331.—Legumes stalked, rather crowded, pendulous, half-oval, compressed, reticulated with prominent veins. *Stem* diffuse. Leaflets roundish-obovate, nearly entire.—Native of the south of France. A specimen from the author cited shews this to be nearly related to the last; but the *legume*, though full-grown, is but one-third of an inch long, most elegantly marked with elevated reticulations. The *leaves* too are smaller, and scarcely toothed or wavy.

4. *T. striata*. Striated, or Abyssinian, Fenugreek. Linn. Suppl. 340. Willd. n. 3.—Legumes umbellate, linear, compressed, incurved, reticulated; their common stalk longer than the leaves. Leaflets wedge-shaped, toothed.—Native of Abyssinia, according to the herbarium of Linnæus, who cultivated the plant at Upsal. *Root* annual. *Stems* square, diffuse. *Leaflets* half an inch long, ribbed, sharply toothed, as well as the *stipulas*. *Flowers* light yellow, about six in each long-stalked head, or umbel. *Legumes* an inch long, narrow, slightly hairy, with six or seven seeds.

5. *T. polycerata*. Many-horned, or Spanish, Fenugreek. Linn. Sp. Pl. 1093. Willd. n. 4. Ait. n. 3. (Fœnum græcum sylvestre; Ger. Em. 1196. Lob. Ic. v. 2. 45.)—Legumes nearly sessile, crowded, erect, nearly straight, longer than the leaves; the common stalk pointless.—Native of Spain, Italy, and the south of France. Cultivated here in the middle of the seventeenth century. Annual. *Stem* branched from the bottom, diffuse, twelve or eighteen inches long. *Leaflets* obovate, toothed. *Flowers* yellow, three or four together in little, axillary, almost sessile, heads. *Calyx* hairy, as well as the young leaves. *Legumes* three or four,

an inch and half long, narrow, clothed with close hairs, and beautifully reticulated.

6. *T. hamosa*. Hooked Egyptian Fenugreek. Linn. Sp. Pl. 1094. Willd. n. 5. Ait. n. 4. Sm. Fl. Græc. Sibth. t. 764, unpubl. (Melilotus ægyptius, Alehimelech vocatus; Alpin. Ægypt. 122. t. 124. Bauh. Hist. v. 2. 357.)—Legumes racemose, stalked, declining, recurved, nearly cylindrical, even, hairy; their common stalk spinous, longer than the leaf.—Native of Egypt, from whence the Linnæan specimen was brought by Hasselquist. Dr. Sibthorp met with it in Cyprus. A small, diffuse, annual, hairy herb, whose leaflets are wedge-shaped, strongly toothed, on a long common stalk. *Flowers* deep yellow, fragrant, in stalked clusters, half an inch long. *Legumes* an inch long, curved into a semicircle, quite destitute of reticulations, both futures peculiarly dilated, pale and even; the sides green and very hairy. The seeds are said to be used by the Egyptians, in fomentations, for all kinds of pains.

7. *T. torta*. Twisted Egyptian Fenugreek.—Legumes umbellate, cylindrical, twisted, reticulated; their common stalk much shorter than the leaves. Leaflets inversely heart-shaped, toothed, obscurely ribbed.—Native of Egypt, from whence Dr. Delisle favoured us with wild specimens, under the name of *hamosa*, but they do not agree with the Linnæan specimen, nor with the specific character, any more than with the figure in *alpinus*, as far as any thing can be determined therefrom. The plant of Dr. Delisle is as smooth as possible in every part. Its stems round, branched, firm, hardly a span high. *Leaves* on long footstalks, rather fleshy; leaflets all of equal size and shape, one-third of an inch long; the odd one on a stalk nearly its own length. *Flowers* yellow, drooping, five or six in each axillary umbel, whose stalk is not half the length of the adjoining common footstalk, and, after flowering, becomes very stout, round, and firm. *Legumes* drooping, rather more than half an inch long, rigid, pale, slightly twisted spirally, quite destitute of hairiness, but marked with peculiar oblong reticulations of elevated veins.

8. *T. flexuosa*. Zigzag Egyptian Fenugreek. Delisle Ægypt. MSS.—Legumes in nearly sessile umbels, compressed, reticulated, zigzag. Leaflets inversely heart-shaped, toothed, obscurely ribbed.—Native of Egypt. A figure of this plant was destined, under the above name, for the great work on Egypt, but we have not heard that it has proceeded so far. This species very closely accords with the last in habit, and precisely in foliage, but the umbels are nearly sessile, flowers smaller, calyx-teeth longer and more pointed. The legumes are essentially different, not only in their compressed figure, but in being strongly folded, or plaited, as it were, into a zigzag position. If expanded, they might possibly equal the length of the last. Both appear to be annual, and perhaps grow prostrate.

9. *T. hirsuta*. Hairy Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 6.—"Legumes racemose, reflexed. Leaflets oblong, obtuse, villous."—Gathered by Thunberg, at the Cape of Good Hope.

10. *T. villosa*. Villous Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 7.—"Legumes racemose, villous. Leaflets obovate, smooth."—From the same country.

11. *T. armata*. Thorny-branched Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 8.—"Legumes lateral, hairy. Leaflets ovate, smooth. Branches becoming spinous."—Native also of the Cape.—We have no further information concerning the three last species.

12. *T. spinosa*. Thorny-stalked Fenugreek. Linn. Sp. Pl. 1094. Willd. n. 9. Ait. n. 5. (Fœnum græcum

TRIGONELLA.

cum sylvestre polyceraton majus creticum; Breyn. Cent. t. 33. f. 1.)—Legumes linear, declining, compressed, falcate, transversely veiny, two or three on each very short, axillary, spinous-tipped stalk.—Native of Crete. A hardy annual, cultivated in England above one hundred years ago, flowering in July and August. The *stem* divides at the base into several rather slender, smooth, simple, diffuse *branches*, a span long. *Leaflets* obovate, toothed, emarginate, equal, tapering at the base. *Flowers* small. *Legumes* naked, an inch and a half long, narrow, with transverse, interbranching, but scarcely reticulated, veins.—Their length exceeds that of the *leaves* and *footstalks*.

13. *T. corniculata*. Horse-shoe Fenugreek. Linn. Sp. Pl. 1094. Willd. n. 10. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 761, unpubl. (Melilotus italica; Fuchf. Hist. 528. M. major; Trag. Hist. 592. M. coronata; Ger. Em. 1205.)—Legumes numerous, crowded, declining, compressed, falcate, transversely veiny, on a spinous-tipped axillary stalk, longer than the leaves.—Native of the south of Europe. A hardy annual, cultivated by Gerarde, flowering in June and July. The *stems* are numerous, a foot high, nearly erect, zigzag, leafy, and many-flowered, smooth, or a little hairy. *Stipulas* nearly entire. *Leaflets* obovate, toothed. *Flower-stalks* spreading, stout, each bearing a dense, umbellate tuft, of about ten yellow, highly fragrant *flowers*, like a little *Coronilla*. *Corolla* thrice the length of the *calyx*. *Legume* only an inch long, though twice as broad as the last, which it imitates in the style of its veins. *Seeds* kidney-shaped, rough. The modern Greeks know this *Trigonella* by the name of *νιόζου*. Dr. Sibthorp observed it in Rhodes, the Morea, and other places in the Levant.

14. *T. elatior*. Tall Fenugreek. Sm. Prodr. Fl. Græc. Sibth. n. 1830. Fl. Græc. t. 762. (Melilotus syriaca odora; Lob. Ic. v. 2. 42. f. 2. Trifolium italicum, five Melilotus italica, corniculis incurvis; Bauh. Hist. v. 2. 372. f. 2. Lotus sylvestris, ex codice cesareo; ibid. 373.)—Legumes racemose, pendulous, linear, slightly curved; their stalk longer than the leaves, pointless. Stem erect. *Stipulas* lanceolate, toothed.—Found by Dr. Sibthorp in Asia Minor, and the isle of Cyprus. Annual. The *stem* is twice or thrice as tall as the last, and less zigzag. *Leaflets* three- or four times as large, often an inch long, obovate, but varying in breadth, sharply toothed, except about the base. *Stipulas* copiously and deeply toothed, or jagged. *Flowers* and *legumes* in clusters about an inch in length; their *common stalks* of a longer proportion than the foregoing, destitute of a spinous point. *Legumes* compressed, nearly or quite straight, and, as far as we can judge of them in a half-ripe state, not marked with elevated veins. *Seeds* six or seven. A specimen of this is attached, in the Linnean herbarium, to the *corniculata*, from which it is very distinct, and, except its *legume* and *seeds*, more nearly allied to the Melilots, (see *TRIFOLIUM*, sect. 1.) than to the other *Trigonella*. Dr. Sibthorp very justly suspected the *λως αγριος* of Dioscorides to be *T. corniculata*, or near it; nor can we doubt this *T. elatior* being the very plant. If the famous old manuscript at Vienna be admitted as authority, it confirms our opinion. The figure in John Bauhin, copied from thence, though rudely and unscientifically drawn, is sufficiently indicative of this species. From what occurs, here and there, in the old botanical writers, this *Trigonella*, neglected by modern systematics, appears to be not of rare occurrence in the south of Europe, and may possibly be met with in botanic gardens. It is well worth the notice of the farmer, for experiment at least, on account of its luxuriant growth, and the qualities of many

plants to which it is related; as they may possibly be found in great perfection in this species.

15. *T. spicata*. Spiked Fenugreek. Sm. Prodr. Fl. Græc. Sibth. n. 1831. Fl. Græc. t. 763, unpublished.—Legumes spiked, pendulous, short, hairy, on a spinous-tipped axillary stalk, longer than the leaves. *Stipulas* awl-shaped, entire.—Gathered by Dr. Sibthorp in the isle of Seriphus. This is an annual species, with many *stems*, about a foot high, which partakes of the same ambiguity, respecting the Melilots, as the foregoing. At least the shortness of the *legume*, and consequent small number of *seeds*, answers best to *Trifolium*. But we want certain information on this point, having not seen any ripe fruit. The habit of the plant, especially the spinous *flower-stalk*, belongs to *Trigonella*. The *leaflets* are half an inch in length, obovate-oblong, narrow, smooth, serrated. *Flowers* yellow, in crowded *clusters* resembling *spikes*, half an inch long, becoming afterwards twice that length, beset with the numerous reflexed beaks of the crowded pendulous *legumes*. The lowest tooth of the *calyx* is very short; the four others long and awl-shaped.

16. *T. parviflora*. Small-flowered Fenugreek.—Legumes in capitate clusters, ascending, linear-lanceolate, compressed, slightly curved, with about two seeds; their stalk as long as the leaves, pointed. Stem ascending. *Stipulas* ovate, pointed, toothed.—Found by M. Du Cros, in a meadow near the mill of Coinfins, in Switzerland. The *stems* are a span high, decumbent at the base. Size and aspect of the plant like *T. monspeliaca*, hereafter described, but some of its characters accord more with *elatior*, to which it has otherwise little resemblance. The *stalks*, *calyx*, *legumes*, and young *leaves*, are more or less silky. *Leaflets* broadly obovate, the lower ones rather quadrangular, none more than half an inch long, most of them less; all toothed, ribbed, of a light green. *Flowers* very small, yellow, on *partial stalks* as long as themselves, collected into hemispherical silky heads. *Calyx-teeth* lanceolate, as long as the *corolla*, somewhat unequal. *Legume* half an inch long, curved upwards, veinless, contracted at each end, containing only one or two *seeds*. This species seems to have escaped the notice of all authors that have fallen in our way. It was sent for *corniculata*, but the *legumes* are totally different, and the *flowers* not a quarter so large, neither is the *stem* zigzag.

17. *T. monspeliaca*. Trailing Fenugreek. Linn. Sp. Pl. 1095. Willd. n. 11. Ait. n. 7. “Waldst. et Kitaib. Hung. v. 2. 152. t. 142.” Sm. Fl. Græc. Sibth. t. 765, unpublished. (Fœnugræcum polyceraton; Rivin. Tetr. Irr. t. 82. F. minus monspeliacum; Breyn. Cent. t. 33. f. 2. Securidacæ genus triphyllon; Bauh. Hist. v. 2. 373.)—Legumes spreading, crowded, curved, compressed, hairy, obliquely veined, shorter than the leaves, on a very short pointed stalk. Stems prostrate.—Native of the south of France, Hungary, Switzerland, Greece, Cyprus, and Asia Minor. A hardy annual with us, sometimes cultivated for curiosity, flowering in June and July. *Stems* quite flat on the ground, hardly a span long, a little hairy, like the rest of the plant. *Leaflets* sharply toothed; their *common footstalks* an inch long. *Flowers* deep yellow, twice the size of the last. *Calyx* hairy, with rather unequal teeth, scarcely half so long as the *corolla*. *Legumes* declining, not an inch in length, prettily marked with oblique transverse ribs, and clothed with scattered close hairs. *Seeds* several, rough.

18. *T. glabra*. Smooth Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 12.—“Legumes umbellate, reflexed, smooth. Leaflets ovate, smooth, toothed.”—Found by Thunberg, at the Cape of Good Hope. We have not seen

seen this plant. If the *leaflets* be really ovate, not obovate, it is a very remarkable species indeed.

19. *T. tomentosa*. Downy Cape Fenugreek. Thunb. Prodr. 137. Willd. n. 13.—“Legumes stalked, three together. Leaflets and branches downy.”—From the same country.

20. *T. laciniata*. Jagged Fenugreek. Linn. Sp. Pl. 1095. Willd. n. 14. (*Melilotus ægyptia annua*, foliis elegantè incis; Lippi MSS.)—Legumes stalked, somewhat umbellate, elliptical, reticulated. Leaflets wedge-shaped, toothed. Stipulas lacinated. The Linnæan specimen of this rare species was sent by Burmann, with the above synonym, by which we learn that it was gathered in Egypt by Lippi, who did not live to publish his discoveries. (See LIPPIA.) This is a slender, delicate, smooth, apparently decumbent, plant, resembling *Medicago laciniata*. The stems are about six inches long, unbranched, angular. Leaflets a quarter of an inch long, abrupt, ribbed, very deeply and sharply toothed at the end. Stipulas palmate, acute. Flower-stalks axillary, shorter than the footstalks, tipped with a small point. Flowers from three to six, yellow. Calyx pale, slightly hairy, with awl-shaped teeth of its own length. Legume twice the length of the calyx, minutely reticulated, rather hairy, acute at each end.

21. *T. pinnatifida*. Pinnatifid Fenugreek. Cavan. Ic. v. 1. 26. t. 38. Willd. n. 15. Ait. n. 8.—Legumes nearly sessile, axillary, linear, compressed, two or three together. Leaflets pinnatifid. Stipulas toothed.—Native of the borders of fields about Madrid, flowering in May. Its seeds were brought from thence to Kew, by the late marchioness of Bute. This little annual species is closely related to the last, being of the same size, with several quadrangular stems. But the leaflets are more oblong, and deeply pinnatifid, not merely cut about the extremity. Flowers from three to five in the bosom of each leaf, on very short stalks, pale yellow. Calyx like the last. The legumes, as Cavanilles observes, are totally different, an inch or more in length, very narrow, slightly curved, with many seeds. Only two or three legumes seem to be perfected, though the flowers are described as rather more numerous.

22. *T. Fœnum-græcum*. Common Fenugreek. Linn. Sp. Pl. 1095. Willd. n. 16. Ait. n. 9. Woodv. Med. Bot. t. 158. Sm. Fl. Græc. Sibth. t. 766, unpublished. (Fœnum græcum; Camer. Epit. 199. Ger. Em. 1196. f. 1. Fœnugræcum; Rivin. Tetr. Irr. t. 81. Fœnogræcum; Fuch. Hist. 798. Matth. Valgr. v. 1. 374.)—Legumes axillary, sessile, oblong, compressed, hairy, with an oblique, awl-shaped beak. Stems spreading. Stipulas ovate, entire.—Native of the south of Europe. Dr. Sibthorp found it plentifully on the shores of Asia Minor, as well as in Rhodes and Cyprus; more sparingly on mount Hymettus near Athens. It has long been cultivated for the sake of its seeds, which from the days of Dioscorides have been thought cooling and detergent. Their scent is very powerful, resembling Melilot; which renders them disagreeable in fomentations and cataplasms, the only uses for which they have been retained in the apothecaries' shops. They are now nearly exploded. (See FENUGREEK.) The herbage is used in some European countries for fodder. The root is annual. Stems various in luxuriance and direction, from one to two feet long, reddish, stout, leafy and hairy. Leaflets inversely heart-shaped, various in size from a quarter of an inch to an inch, mostly smooth, of a deep, rather glaucous, green, more or less toothed. Footstalks hairy, rather longer than the leaflets. Flowers two or three, axillary, sessile, yellow, white, or pale blue; standard an inch long, emarginate, erect; wings and keel much shorter, by

no means answering to the generic character. Calyx hairy, with awl-shaped, nearly equal, teeth. Legume, in a wild state, about an inch long, veiny, a quarter of an inch broad, tapering into an oblique beak, longer than itself, but very various in that respect: in the cultivated plant, the length of the legume, containing above a dozen seeds, greatly exceeds that of the beak. Dr. F. Buchanan, in his Journey through the Myfore, v. 1. 374. relates, that this herb, known by the name of *Mentea*, when cultivated in gardens is always used green. When sown for the seed, as grain, the ground is plowed twice at the same season, and divided into plots like a kitchen-garden. The seed is sown, covered by hand, and according to the nature of the soil, and watered once in ten or fifteen days. “The ripe seed,” says this author, “falls very high, and is reckoned the most delicate kind of pulse. The young leaves are used as greens, and the unripe legumes put into Curries.” We find these seeds are one ingredient in the receipts for Curry powder, communicated from India. *T. gladiata*, Bieberst. Taur. v. 2. 222, must be presumed a variety of the species before us.

23. *T. indica*. Indian Fenugreek. Linn. Sp. Pl. 1095. Willd. n. 17. Ait. n. 100. (*Lotus maderaspatanus*, villosus, ornithopodii siliqua singulari; Pluk. Phyt. t. 200. f. 7, faulty, as representing the legumes terminal.)—Legumes linear, nearly sessile, mostly solitary, slightly curved, much longer than the leaves. Leaflets entire. Stem diffuse.—Native of the East Indies, from whence its seeds were sent by Dr. Roxburgh to Kew, in 1793. An annual stove plant, flowering in July and August. The whole herb is minutely hairy, or silky. Stems a foot long, round, branched. Leaflets obovate, narrow, three-quarters of an inch long, all equally nearly sessile, on a stalk of their own length. Flowers small, yellow or reddish, drooping, on very short stalks, usually two together, from the bosoms of the leaves. Calyx-teeth lanceolate, leafy. Legumes an inch and a quarter or an inch and a half long, compressed, narrow, pale, hairy, with many seeds. We should have supposed the seeds of this species to have made an ingredient in the Curry powders of India; but we find nothing of this kind recorded, nor is the plant mentioned in the admirable work of Dr. Buchanan, cited under the last species.

TRIGONELLA *Fossilis*, in *Natural History*, the name of a fossil shell, of the cockle kind, but approaching to a triangular figure, having a broad bottom to which it descends, almost in straight lines: on each side from the head or cardo, these are usually found small, but there are some met with of four or five inches round; they are found at different depths, in stone quarries, bedded in the matter of the strata; and that often in the hardest stone. In some instances, the shells are found remaining in their native state; but most frequently the shell itself is perished and gone, and there is a stony or sparry matter deposited in its place. Hill.

TRIGONIA, in *Botany*, so named from τρις, three, and γωνια, an angle, alluding to its triangular fruit.—Aubl. Guian. 387. Schreb. Gen. 493. Willd. Sp. Pl. v. 3. 921. Mart. Mill. Dict. v. 4. Vahl Eclog. fasc. 2. 53. Schrad. Tour. v. 1. 355. Juss. 253. Lamarck Illustr. t. 347.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Lomentaceæ*, Linn.? *Malpighiis affine*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate; limb in five segments, the two upper ones most deeply divided, erect, spreading. Cor. papilionaceous, of five petals; standard erect, pitted at the base, flat, with a claw; wings longer and narrower, reflexed; keel of two converging petals. Nectary two scales at the base of the germen. Stam. Filaments ten, united into one common sheath,

sheath, separate above, some of them often abortive, and the common sheath finally splits into two; anthers oblong. *Pist.* Germen superior, ovate, small; style short, ascending; stigma capitate, flat, with a membranous border. *Peric.* Capsule oblong, acute, with three angles and three intermediate channels, of one cell and three valves, which are boat-shaped, double, the outer coat coriaceous, inner membranous, lined with wool. *Seeds* numerous, roundish, enveloped in long wool, and connected with a triple thread-shaped receptacle.

Ess. Ch. Calyx in five deep segments. Corolla papilionaceous; standard pitted at the base. Nectary two scales at the base of the germen. Some filaments imperfect. Capsule leguminous, triangular, with three cells and three valves. *Seeds* woolly.

1. *T. villosa*. Villous Trigonion. Aubl. 388. t. 149. Willd. n. 1.—Leaves obovate, downy and hoary beneath.—Native of Guiana, growing chiefly by way sides, in cultivated grounds, or in the borders of groves and thickets, bearing flowers and fruit at various seasons. The stem is shrubby, with twining branches, supporting themselves upon neighbouring trees, round, downy and leafy. *Leaves* opposite, stalked, entire, three inches long and one and a half broad, veiny. *Stipulas* ovate, in pairs, deciduous. *Clusters* compound, terminal. *Flowers* aggregate, small, yellow, with a red keel. *Fruit* three inches, or more, in length, clothed with reddish down, splitting from the base.

2. *T. levis*. Smooth Trigonion. Aubl. 390. t. 150. Willd. n. 2.—Leaves elliptical, smooth and shining on both sides.—Found on the banks of a rivulet, near the base of the hill of Courou, in Guiana. The branches of this species are smooth, but twine round any thing in their way, like the preceding. *Leaves* only one and a half or two inches long, oval, entire, on shortish stalks. *Clusters* several at the ends of the branches, accompanied by some leaves. *Flowers* opposite, accompanied by small bractæas, white, with yellow anthers. *Fruit* about an inch long, greenish, rather rough to the touch. *Seeds* enveloped in soft white wool. Nothing is mentioned of any useful properties in either of these plants.

TRIGONIS, so called by Jacquin, because each of its petals forms an inverted isosceles triangle. See CUPANIA.

TRIGONOMETER, ARMILLARY. See ARMILLARY Trigonometer.

TRIGONOMETRY, from *τριγωνος*, triangle, and *μετρον*, measure, signifies literally the measure of triangles; but it is used here to denote that science which relates to the determination of the sides and angles of triangles, from certain parts which are given. When it is applied to the solution of plane triangles, it is called *plane* trigonometry; and its application to spherical triangles, is called *spherical* trigonometry.

Trigonometry, from its numerous and important uses, may be considered as one of the most interesting branches of the pure mathematics: practical and physical astronomy, navigation, surveying, geodesia, mechanics, in short nearly every branch of the pure and mixed mathematics, with the exception of geometry and arithmetic, are either wholly or in part connected with the principles of trigonometry; and we accordingly find that the improvements in this department have kept pace with, or rather perhaps have preceded, those which modern authors have introduced into all the other branches of the exact sciences: in fact, the trigonometry of the Greeks, and that of the moderns, which immediately followed the invention of logarithms, and, lastly, the analytical form given to it by Euler, Lagrange, &c. exhibit the same science under three very distinct characters,

of which it will be proper to give a slight sketch as an introduction to the present article.

It is very uncertain at what time trigonometry first began to be cultivated as a science, no records having yet been discovered which enable us to trace it to a higher age than to that of Hipparchus, who flourished about 150 years before Christ, and who, as we are informed by Theon, wrote a work, in twelve books, on the chords of circular arcs, which, from the nature of the title, must have been a treatise on trigonometry: but the earliest work extant on this subject is the Spherics of Theodosius, in which the several propositions are demonstrated after the manner of Euclid; and the next in order to this, is a work by Menelaus, who flourished about the middle of the first century of the Christian era, and who is said to have written nine books on this subject; but of which, only three have been transmitted down to our times. The six that are lost consisted principally of tables and the nature of their construction, which if we possessed them would, in all probability, be rather matters of curiosity than of real utility. The earliest tables of trigonometry, of any importance, that we possess of the ancients, are those given by Ptolemy in his Almagest, in which he adopts the sexagesimal division of the radius, and of the arc whose chord is equal to radius, and then estimates all the other arcs by 60ths of that arc, and all the other chords by 60ths of that chord. From the time of Ptolemy, viz. from about the beginning of the second century, nothing of importance, except what we owe to Theon, was added to the science of trigonometry, till about the close of the eighth century after Christ, when the ancient method of computing by chords was changed for that of sines, an alteration first introduced by the Arabians, to whom we are also indebted for several axioms and theorems which are at present considered as the foundation of modern trigonometry; but they still continued the sexagesimal division; and in this state it remained till Purbach, about the middle of the 15th century, constructed a table of sines to the division of the radius into 600,000 equal parts, and computed them for every ten minutes of the quadrant; and afterwards Regiomontanus, the disciple and friend of Purbach, carried the computation to every minute, dividing the radius into 1,000,000. He also enriched this science with many new theorems and precepts, which, except for the use of logarithms, render the trigonometry of this author little inferior to that of our times.

Soon after the period here mentioned, several other mathematicians also contributed to the advancement of this science, either by some useful alterations in the form of the tables, or by other improvements; amongst whom we may mention, as the most distinguished, Werner, Copernicus, Rheindold and Maurolycus: but the most complete work which had yet appeared, was published by Vieta in 1579; and some other tracts on the same subject and due to the same author were published by Schooten in 1646.

The first part of the work to which we have above alluded, was entitled "Canon Mathematicus seu ad Triangula, cum Appendicibus," in which there is given a table of sines, tangents, and secants for every minute of the quadrant to radius 100,000, with their differences; and towards the end of the quadrant, the tangents and secants are extended to eight or nine places of figures. They are also arranged after the manner of our modern tables, increasing from the left-hand side to 45°, and then returning backwards from the right-hand to 90°; so that each number and its complement stand upon the same line.

The second part, entitled "Universalium inspectionum ad canonem mathematicum," contains, besides a regular account

count of the construction of the tables, a compendious treatise on plane and spherical trigonometry, with their application to a variety of curious subjects in geometry and mensuration, and other branches of mathematics; as also a number of particulars relating to the quadrature of the circle, the duplication of the cube, and similar problems, which are all treated of in a manner worthy of the genius of their author. The tract published by Schooten likewise contains many curious theorems due to Vieta, particularly those relating to what the author calls angular sections; *viz.* to the multiples and submultiples of arcs; and general formulæ for the chords and consequently for the sines of the sums and differences of arcs; and of such as are in arithmetical progression, which have since been so extensively and usefully applied, both in this science and in some of the higher branches of analysis. See *Arithmetic of SINES*.

The next writer on this subject, deserving of particular notice, was Rheticus, who formed the design of computing the trigonometrical canon for every ten seconds of the quadrant to fifteen places of figures; and although he did not execute the whole of this laborious enterprize, he nevertheless accomplished that part of it which related to the sines and cosines, all of which he calculated according to his original plan; besides those of every single second for the first and last degrees of the quadrant; but was deterred from publishing the table on account of the expence attending the impression. The work, however, was afterwards completed and published by his disciple and friend Otho, under the title of "Opus Palatinum de Triangulis" (folio 1596); but it was found to contain many errors, which were afterwards corrected by Pitiscus, and the whole published under the new title of "Thesaurus Mathematicus, &c." folio 1613. The Trigonometry of the same author, which was published in 1599, is also a very complete work, and was long considered, both with respect to its tables and its numerous practical applications, as the most commodious and useful treatise on the subject then extant.

We might here enumerate many other writers of this period, who distinguished themselves either by their computation of new tables, or by their inventions of theorems; but the discovery of the use of logarithms, which happened about this time, produced a complete revolution in the method of treating this subject, and which therefore renders it unnecessary for us to enter into any minute explanation of the particular inventions and improvements of the authors to whom we have above alluded.

Amongst the earliest promoters of trigonometry, after the invention of logarithms, was Napier himself, to whom we are not only indebted for that admirable discovery, but also for the new and excellent analogies which he introduced into trigonometry, and which still bear his name, as likewise for the well-known rules called the *five circular parts*. (See PARTS.) Our limits, however, will not allow of tracing the history of this science, through all its successive improvements, from the time of Napier to the present day; we shall therefore content ourselves with referring to the article LOGARITHM for an account of many of the most useful and valuable tables of the logarithmic kind, and shall merely mention Briggs as an author who contributed much to the advancement of this science, both by the assistance that he afforded to the practical calculator in many intricate and abstruse computations, and by the numerous improvements of a higher kind, with which his works abound. Other writers afterwards, either by the construction of tables, or by the simplification of the rules and processes hitherto adopted, reduced the practice of trigonometrical operations to their simplest possible state, at least while it retained that geome-

trical form, which in the earlier stages of this science it naturally assumed. But about the middle or rather towards the close of the last century, trigonometry was again subjected to another complete revolution, by changing the geometrical form for the analytical one; and it is probable that to this change we are indebted for many of the most brilliant discoveries that of late years have enriched the two great branches of astronomical science. The foundation of this method, however, may be traced to a much higher date than that to which we have above alluded; *viz.* to the time of Vieta, whose theorems for the differences and sums, as also for the multiples and submultiples of the chords of arcs, which, although left without demonstration, and in the latter case probably formed by induction from the law of the terms and their co-efficients, have nevertheless been the germ of most of the numerous and elegant formulæ which have since enlarged and enriched this branch of the mathematics.

The exponential formulæ also for the sines and cosines of arcs, first given by De Moivre, greatly contributed to the progress of the analytical branch of this subject, by abridging its operations, and shortening the labour of investigation. See *Arithmetic of SINES*.

Having given this brief sketch of the history of trigonometry, it now remains for us to explain and illustrate its principles, and the various methods of applying it and of performing the requisite computation. With this view we shall commence with the definitions of all the terms which most frequently occur in this doctrine, in order to save the references which it would otherwise become necessary to make to the different articles in the body of the work.

In plane trigonometry, the circle is supposed to be divided into 360 equal parts, called degrees; every degree into 60 equal parts, called minutes; and every minute into 60 equal parts, called seconds; and so on into thirds, fourths, &c.; and the measure or quantity of an angle is estimated by the number of degrees, minutes, and seconds, contained in the arc by which it is bounded; the degrees being marked or denoted by a small °, the minutes by one dash, as ', the seconds by two dashes ", &c.; thus, 70 degrees 16 minutes 17 seconds, is written $70^{\circ} 16' 17''$.

It may be observed, however, that the division of the circle is perfectly arbitrary, and that any other number might have been employed instead of 360; and the subdivisions might also have proceeded upon any other scale as well as the sexagesimal: and accordingly, the modern French mathematicians have adopted a different division; *viz.* they suppose the entire circle to be divided into 400 degrees, or each quadrant into 100 degrees; the next subdivision is the 10th of a degree, the next 100th, and so on; and hence the measure of an angle is expressed by them in the same manner as any other integral and decimal quantity, which notation is undoubtedly far superior to that in common use.

The *complement of an arc or angle*, is what it wants of 90° , or of a quadrant; and the *supplement of an angle*, is what it wants of 180° , or of a semicircle: thus, if an angle measures 50° , its complement is 40° , and its supplement 130° . As to the several lines made use of in this science, they will be readily understood by a reference to *Plate II. Trigonometry, fig. 14.* aided by the following definitions; *viz.*

The *sine or right sine* of an arc, is a line drawn from one extremity of an arc perpendicular to the diameter which passes through the other extremity: thus, B F is the sine of the arc A B, or of the supplemental arc B D E.

The *versed sine* of an arc, is that part of the diameter which is intercepted between the arc and its sine: thus, A F is the versed sine of the arc A B, and D F the versed sine of the arc E D B.

TRIGONOMETRY.

The *tangent* of an arc, is a line touching the circle in one extremity of that arc, and continued thence to meet a line drawn from the centre through the other extremity of it, which last line is called the *secant* of the same arc: thus, A H is the tangent, and C H the secant of the arc A B; also E I is the tangent, and C I the secant of the supplemental arc B D E; and this latter tangent and secant are equal to the former, but are accounted negative, as being drawn in an opposite or contrary direction to the former.

The *cosine*, *cotangent*, and *cosecant*, of an arc, are the sine, tangent, and secant of the complement of that arc; the letters *co.* being only a contraction of the word complement. Thus, the arcs A B, B D, being the complement of each other, the sine, tangent, and secant of the one of these, is respectively the cosine, cotangent, and cosecant of the other: thus,

B F, the sin. of A B, is the cof. of B D.
 B K, the sin. of B D, is the cof. of A B.
 A H, the tan. of A B, is the cotan. of B D.
 D L, the tan. of B D, is the cotan. of A B.
 C H, the sec. of A B, is the cosec. of B D.
 C L, the sec. of B D, is the cosec. of A B.
 F A, the vers. of A B, is the coverf. of B D.
 D K, the vers. of B D, is the coverf. of A B.

The above are the principal definitions relating to plane trigonometry, as far as regards the solution of plane triangles, which is that part of the subject to which we must more particularly confine our remarks in this article: what concerns the mutations or changes in the quantities above defined in passing successively round the circumference, and their particular values at certain points, have been already explained under the article *Arithmetic of SINES*, to which the reader is referred. In every triangle there are six parts; *viz.* three sides and three angles, any three of which being given (except the three angles), the other three may be found; and that either by geometrical construction, arithmetical or logarithmic computation, or by instrumental operation: that is, either by constructing the figure with the compasses and a scale of chords, or other instrument for measuring angles; or by means of tables of natural or logarithmic sines, tangents, &c. in which the computation depends upon the proportionality of the sides of similar triangles; and lastly, by means of a Gunter or other scale constructed for this particular purpose, by which the results are obtained by the proper application of a pair of compasses to certain lines on the scale: in the present article, however, we shall only attempt an illustration of the second method.

There are only three distinct cases in trigonometry; *viz.*

1. When a side and its opposite angle are two of the given parts.
 2. When two sides and the included angle are given.
 3. When the three sides are given.
- Case 1.*—When a side and its opposite angle are two of the given parts.

As any one side :
 Is to any other side ::
 So is the sine of the angle opposite to the former :
 To the sine of the angle opposite to the latter.

This analogy supposes two sides and one angle to be given: if two angles and one side be given, the order of the terms becomes,

As the sine of any angle :
 Is to the sine of any other angle ::
 So is the side opposite to the former :
 To the side opposite to the latter.

VOL. XXXVI.

For let A B C (*fig. 15.*) represent any triangle; take A c, B c, equal to each other, and let them represent the tabular radius; then c a, c b, will also be the tabular sines of the angles A and B. Now by similar triangles,

$$\begin{aligned} AC : A c &:: CD : c a \\ BC : B c &:: CD : c b. \end{aligned}$$

Consequently, since $A c = B c$, and the third terms being equal, we have

$$\begin{aligned} AC : BC &:: c b : c a, \text{ or} \\ AC : BC &:: \sin. B : \sin. A; \end{aligned}$$

which is the same as the theorem in words.

Hence in the triangle A B C (*fig. 16.*), let A B, B C, and the angle A be given; then it will be

$$BC : BA :: \sin. A : \sin. C,$$

$$\text{or } \sin. C = \frac{BA \times \sin. A}{BC},$$

$$\text{or } \log. \sin. C = \log. BA + \log. \sin. A - \log. BC.$$

Again, if the angles A and B were given, and the side B C; then,

$$\sin. A : \sin. B :: BC : AC,$$

$$\text{or } AC = \frac{\sin. B \times BC}{\sin. A},$$

$$\text{or } \log. AC = \log. \sin. B + \log. BC - \log. \sin. A.$$

It should be observed here, that the angle found by the first of these analogies is ambiguous, or uncertain, *viz.* whether it be acute or obtuse, unless its magnitude be such as to prevent the ambiguity; for when this is not the case, there will be two different triangles, which have the same three parts, but the other three different in each; and there is nothing in the abstract solution to determine which of the two is the required one: but in any practical case, there will be always found some circumstance or other to decide the question. This will be understood from *fig. 17.* where there are two triangles A B C, A B C'; in each of which the sides A B, B C, or B C', and the angle A, are the same; and, therefore, the angle C, determined by the analogy, may be either B C A or B C' A, which are the supplements of each other, and which two angles, we have shewn in the definitions, have always the same sine. The tabular sine, however, is always that belonging to the acute angle; and, therefore, when the obtuse angle is required, the acute angle must be subtracted from 180° , which will be the obtuse angle. But if the angle be a right angle, or greater than a right angle, the acute angle found by the table must be the required angle; and, therefore, in this case, there is no ambiguity.

Let us propose, as an example, a triangle A B C, in which the side A B = 345, B C = 232, and angle A = $37^\circ 20'$.

First, to find the angle at C.

As the side B C = 232	2.3654880
Is to side A B = 345	2.5378191
So is sine < A = $37^\circ 20'$	9.7827958
To sin. < C = $64^\circ 24'$	9.9551269

That is, by adding together the logarithms of the second and third terms, and subtracting the first, we obtain the logarithmic value of the sine of < C, which is found in the table to answer to the angle $64^\circ 24'$. But we have seen that

TRIGONOMETRY.

an angle and its supplement have the same sine; therefore, the sine we have found may either answer to the angle $64^{\circ} 24'$, or to its supplement $115^{\circ} 36'$. This question, therefore, involves that ambiguity to which we have above alluded; and we must proceed to find the third side under each of the values of the angle C, and the two corresponding values of the angle B.

Since the sum of the three angles of a triangle = 180° ,

$$\begin{aligned} < A &= 37^{\circ} 20' \\ < C &= 64 \quad 24 \\ \hline 180^{\circ} &- (101 \quad 44) = 78^{\circ} 16' = < B. \end{aligned}$$

Again,

$$\begin{aligned} < A &= 37^{\circ} 20' \\ < C &= 115 \quad 36 \\ \hline 180^{\circ} &- (152 \quad 56) = 27^{\circ} 4' = < B. \end{aligned}$$

Hence, from the first values of the angles C and B, we have,

$$\begin{array}{l} \text{As sin. } < A = 37^{\circ} 20' \quad 9.7827958 \\ \text{Is to sin. } < B = 78^{\circ} 16' \quad 9.9908291 \\ \text{So is BC} = 232 \quad \underline{2.3654880} \end{array}$$

$$\text{To AC} = 374.56 \quad \underline{2.5735213}$$

Again, assuming the second values of the angles B and C, we have,

$$\begin{array}{l} \text{As sin. } < A = 37^{\circ} 20' \quad 9.7827958 \\ \text{Is to sin. } < B = 27^{\circ} 4' \quad 9.6580371 \\ \text{So is BC} = 232 \quad \underline{2.3654880} \end{array}$$

$$\text{To AC} = 174.07 \quad \underline{2.2407293}$$

The side and angles sought are, therefore, $AC = 374.56$, or 174.07 ; and the angle $B = 78^{\circ} 16'$, or $27^{\circ} 4'$; and angle $C = 64^{\circ} 24'$, or $115^{\circ} 36'$; either of which results equally answer all the conditions of the original data. But it is obvious, that if the given angle A had been a right angle, or greater than a right angle, this ambiguity could not have had place; because, in that case, the other two angles are necessarily acute.

Case 2.—When two sides and their included angle are the three given parts.

As the sum of the sides :
Is to the difference of the sides ::
So is the tangent of half the sum of the required angles :
To the tangent of their half difference.

Then to half the sum add half the difference for the greater angle, and subtract it for the less. The three angles of the triangle being thus known, the required side may be found by *Case 1*.

Note.—The half sum of the angles is found by subtracting the given angle from 180° , and taking half the remainder; or, instead of the tangent of the half sum, the cotangent of half the given angle may be used, being the same thing.

Let ABC (*fig. 18.*) be any triangle; produce AB , making $BE = BC$; also take $BD = BC$; join DC and CE , and draw DF perpendicular to DC . Now since DB , BC , and BE , are all equal to each other, a semicircle described from the centre B , and with the radius DB , would pass through D , C , and E ; consequently DCE is a right angle, or CE is perpendicular to DC , and is there-

fore parallel to DF ; and hence DF and EC are respectively the tangents to the angles DCF , and CDE of the same radius DC . But CDE or $CDB =$ half the sum of the angles BAC and BCA ; for since $DB = BC$, the angle BDC is obviously = to half the external angle CBE , which is equal to the sum of the angles at A and C ; therefore, $CDB =$ to half that sum, and $DCF =$ half the difference of the same angles ACB and CAB ; for $ACB = BCD + DCA$, and consequently $BAC = BDC$, or $BCD - DCA$; therefore $DCA =$ half their difference. Whence $CE =$ tangent of half the sum, and DF the tangent of half the difference of the angles A and C ; and it is evident from the construction that $AE =$ the sum of the sides, and $AD =$ the difference of the same; consequently, since DF and CE are parallel, we have

$$AE : AD :: CE : DF;$$

that is,

As the sum of the sides $AB + BC$:
Is to the difference of the sides $AB - BC$::
So is the tangent of half the sum of the angles A and C :
To the tangent of half their difference.

Let us take as an example a triangle (*fig. 19.*), in which the following dimensions are given, *viz.*

$$AB = 75, AC = 58, A = 108^{\circ} 24';$$

$$\begin{array}{l} \text{then will } AB = 75 \quad AB = 75 \quad A + B + C = 180^{\circ} 0' \\ AC = 58 \quad AC = 58 \quad A = 108 \quad 24 \end{array}$$

$$\text{Sum } 133 \text{ differ. } 17 \quad BC = 71 \quad 36$$

$$\frac{1}{2}(B + C) = 35 \quad 48$$

$$\text{Log. of } AB + AC, \quad 2.1238516$$

$$\text{Log. of } AB - AC, \quad 1.2304489$$

$$\text{Log. of tan. } \frac{1}{2}(B + C), \quad 9.8580694$$

$$\text{Sum of log.} \quad 11.0885183$$

$$\text{Log. of tan. } \frac{1}{2}(C - B) \quad 8.9646667$$

The nearest corresponding number to which is $5^{\circ} 16'$.

$$\frac{1}{2}(B + C) = 35^{\circ} 48' \quad \frac{1}{2}(B + C) = 35^{\circ} 48'$$

$$\frac{1}{2}(C - B) = 5^{\circ} 16' \quad \frac{1}{2}(C - B) = 5^{\circ} 16'$$

$$C = 41^{\circ} 4' \quad B = 30^{\circ} 32'$$

If the other side CB were required, having found the angles, it may be easily determined by the first case.

Case 3.—When the three sides of a triangle are given, to find the three angles.

Assume any side of the triangle as a base (*fig. 20.*), and let fall a perpendicular upon it from the opposite angle; then say,

As the base :
Is to the sum of the other two sides ::
So is the difference of the same sides :
To the difference of the segments of the base.

To the base or sum of the segments add the half difference for the greater segment, and subtract it for the less.

The segments being thus found, the angles may be determined by the first case. The demonstration is here very obvious; for, by the 47th proposition of the first book of Euclid,

$$AD^2 + DC^2 = AC^2$$

$$BD^2 + DC^2 = BC^2;$$

therefore,

TRIGONOMETRY.

therefore, $AD^2 - BD^2 = AC^2 - BC^2$;

consequently,

$$AD + DB : AC + BC :: AC - BC : AD - DB;$$

which is the same as the theorem in words.

As an example, let a triangle be proposed (*fig. 21.*), in which the three sides are as follow, *viz.*

$$\begin{aligned} AB &= 36, AC = 45, BC = 40 \\ AC &= 45, AC = 45 \\ AB &= 36, AB = 36 \end{aligned}$$

$$\begin{aligned} AC + AB &= 81 & FC &= 9 \\ \text{Log. of } BC & & &= 1.6020600 \\ \text{Log. of } AC + AB & & &= 1.9084850 \\ \text{Log. of } FC & & &= 0.9542425 \end{aligned}$$

$$\text{Sum of log.} = 2.8627275$$

Log. of CG = 1.2606675 The nearest corresponding number to which, in the tables, is 18.22

$$\begin{aligned} BC &= 40.00 & EG &= 10.89 \\ CG &= 18.22 & CG &= 18.22 \end{aligned}$$

$$BG = 21.78 \quad CE = 29.11$$

$$\begin{aligned} BE &= 10.89 \\ \text{Log. of } AB & & &= 1.5563025 \\ \text{Log. of whole sine} & & &= 10.0000000 \\ \text{Log. of } EB & & &= 1.0370279 \end{aligned}$$

Log. of fin. of EAB = 9.4807254 The corresponding number to which, in the tables, is $17^\circ 36'$; consequently, the angle ABE $72^\circ 24'$.

$$\begin{aligned} \text{Log. of } AC & & &= 1.6532125 \\ \text{Log. of the whole sine} & & &= 10.0000000 \\ \text{Log. of } CE & & &= 1.4640422 \end{aligned}$$

Log. of fin. of EAC = 9.8108297 To which the nearest correspondent number, in the tables, is $40^\circ 18'$; therefore ACE $49^\circ 42'$, and CAB $57^\circ 54'$.

The three preceding cases include all the possible varieties that can arise in the solution of plane triangles; but, under certain relations of the data, more simple operations may frequently be employed. Some of these solutions we shall investigate analytically at the conclusion of this article, and it will therefore be sufficient to point out in this place a few particulars relative to the solution of right-angled plane triangles.

In any right-angled triangle, any of the unknown parts may be found by the following proportions.

As radius :
Is to either leg of the triangle :
So is the tangent of the adjacent angle :
To the opposite leg ; and ::
So is the secant of the same angle :
To the hypotenuse.

For AB (*fig. 22.*) being supposed the given leg, let AD represent the tabular radius, describe the arc DE, and draw DF perpendicular to AD; so shall DF represent the tabular tangent, and AF the tabular secant of the angle A; and because of the parallels, as AD : AB :: DF : BC :: AF : AC, which is the same as the theorem in words.

$$\text{Whence } BC = \frac{AB \times DF}{AD} = \frac{AB \times \tan. A}{\text{rad.}}$$

$$AC = \frac{AB \times AF}{AD} = \frac{AB \times \sec. A}{\text{rad.}}$$

When the hypotenuse is given, each of the legs will represent, or have the ratio of, the sines of their opposite angles, the hypotenuse itself being assumed for the radius.

In this case, therefore, it will be

As radius :
Is to the hypotenuse ::
So is the sine of either acute angle :
To the opposite side.

That is, AE : AC :: AG : BC;

$$\text{or } \begin{cases} \text{rad.} : AC :: \sin. A : \frac{AC \times \sin. A}{\text{rad.}} = BC \\ \text{rad.} : AC :: \sin. B : \frac{AC \times \sin. B}{\text{rad.}} = AB \end{cases}$$

Note.—The radius is equal to the sine of 90° , or to the tangent of 45° .

The preceding theorems have been deduced from the geometrical properties of triangles and of their several parts; and they exhibit the simplest and most direct mode of solution that can be obtained generally for each case; but there are certain other forms of solution which are much more readily applied under particular relations of the data, which it will be proper now to consider, and in which we shall adopt the analytical mode of investigation instead of the geometrical one hitherto pursued.

Let ABC (*Plate III. fig. 1.*) be any plane triangle; C the vertical angle; CD a perpendicular let fall upon the base AB; and let *a, b, c*, denote the sides respectively that are opposite to the angles A, B, C.

Then because AC = *b*, AD is the cosine of A to that radius; consequently, when radius = 1, AD = *b* cof. A. In like manner, BD = *a* cof. B; therefore AD + BD = AB = *a* cof. B + *b* cof. A. If one of the angles, as A, were obtuse, the result would still be the same; because, while on the one hand cof. A would be negative, AD, lying on the contrary side of A to what it does in the figure referred to, it must be deducted from BD to leave AB; and a negative quantity subtracted, is equivalent to a positive quantity added: and by letting fall perpendiculars from the angles A and B upon the opposite sides, or upon their continuations, precisely analogous results will be obtained; and hence we derive immediately the following fundamental equations.

$$\left. \begin{aligned} a &= b \text{ cof. } C + c \text{ cof. } B \\ b &= a \text{ cof. } C + c \text{ cof. } A \\ c &= a \text{ cof. } B + b \text{ cof. } A \end{aligned} \right\} (1.)$$

Again, it is obvious, that in the same manner as we found AD = *b* cof. A, and DB = *a* cof. B, we might also obtain DC = *b* sin. A, and DC = *a* sin. B; therefore *a* sin.

$$B = b \text{ sin. } A; \text{ whence also } \frac{a}{b} = \frac{\sin. A}{\sin. B}; \text{ and in like}$$

$$\text{manner we have } \frac{a}{c} = \frac{\sin. A}{\sin. C} \text{ and } \frac{b}{c} = \frac{\sin. B}{\sin. C}. \text{ Or chang-}$$

ing the denominators, the relations of all the six quantities may be thus expressed:

$$\left. \frac{\sin. A}{a} = \frac{\sin. B}{b} = \frac{\sin. C}{c} \right\} (11.)$$

TRIGONOMETRY.

These formulæ shew immediately the truth of our first theorem, *viz.* "the sides of plane triangles have the same ratio as the sines of their opposite angles."

Again, since $a : b :: \sin. A : \sin. B$, we have $a + b : a - b :: \sin. A + \sin. B : \sin. A - \sin. B$; that is,

$$\frac{a + b}{a - b} = \frac{\sin. A + \sin. B}{\sin. A - \sin. B}.$$

But $\frac{\sin. A + \sin. B}{\sin. A - \sin. B} = \frac{\tan. \frac{1}{2} (A + B)}{\tan. \frac{1}{2} (A - B)}$.

See *Arithmetic of SINES*; consequently

$$\frac{a + b}{a - b} = \frac{\tan. \frac{1}{2} (A + B)}{\tan. \frac{1}{2} (A - B)}$$

Or $a + b : a - b :: \tan. \frac{1}{2} (A + B) : \tan. \frac{1}{2} (A - B)$;

that is, "the sum of the sides is to the difference of the sides, as the tangent of half the sum of the opposite angles is to the tangent of half the difference," which is our second theorem: and other forms of solution are readily obtained from the two fundamental equations (I.) and (II.) *viz.*

$$\begin{aligned} a &= b \cos. C + c \cos. B \\ b &= a \cos. C + c \cos. A \\ c &= a \cos. B + b \cos. A \end{aligned}$$

For multiplying the first of these equations by a , the second by b , and the third by c , and each of the equations thus obtained being taken from the sum of the other two, there will arise

$$\left. \begin{aligned} b^2 + c^2 - a^2 &= 2bc \cos. A \\ a^2 + c^2 - b^2 &= 2ac \cos. B \\ a^2 + b^2 - c^2 &= 2ab \cos. C \end{aligned} \right\} \quad \text{(III.)}$$

$$\cos. \frac{1}{2} A = \sqrt{\frac{\frac{1}{2} \{a + b + c\} \left\{ \frac{1}{2} (a + b + c) - a \right\}}{bc}} \quad \text{(VII.)}$$

which is purely logarithmic: the $\cos. \frac{1}{2} B$, and $\cos. \frac{1}{2} C$, being precisely analogous to the above, are omitted.

And in a similar manner, we find

$$\sin. \frac{1}{2} A = \sqrt{\frac{\left\{ \frac{1}{2} (a + b + c) - c \right\} \left\{ \frac{1}{2} (a + b + c) - b \right\}}{bc}} \quad \text{(VIII.)}$$

And again, by division,

$$\tan. \frac{1}{2} A = \sqrt{\frac{\left\{ \frac{1}{2} (a + b + c) - b \right\} \left\{ \frac{1}{2} (a + b + c) - c \right\}}{\left\{ \frac{1}{2} (a + b + c) - a \right\} \left\{ \frac{1}{2} (a + b + c) \right\}}} \quad \text{(IX.)}$$

Of these several rules for the determination of the sides and angles of plane triangles, we have before observed, that the formulæ (IV.) and (V.) are best adapted to small integral values of the sides; and to real fractional values of the cosine, in other cases, one or other of the three latter will best apply. When the angle sought is very small, it is usually better to employ N° (VIII.) than N° (VII.) The method indicated in N° (IX.) is commodious, and very correct, except when A is either very small or near 180° .

In some cases, where great accuracy is required, the operator may wish to obviate the uncertainties that would arise from the use of some of these formulæ; for which purpose Dr. Maskelyne has given, in the Introduction to Taylor's Logarithms, the following rules in reference to the sines and tangents of very small arcs.

1. *To find the Sine.*—To the log. of the arc reduced into seconds, with the decimal annexed, add the constant quantity

Hence, when two sides and the contained angle are given, we have

$$\left. \begin{aligned} a &= \sqrt{b^2 + c^2 - 2bc \cos. A} \\ b &= \sqrt{a^2 + c^2 - 2ac \cos. B} \\ c &= \sqrt{a^2 + b^2 - 2ab \cos. C} \end{aligned} \right\} \quad \text{(IV.)}$$

And when the three sides are given,

$$\left. \begin{aligned} \cos. A &= \frac{b^2 + c^2 - a^2}{2bc} \\ \cos. B &= \frac{a^2 + c^2 - b^2}{2ac} \\ \cos. C &= \frac{a^2 + b^2 - c^2}{2ab} \end{aligned} \right\} \quad \text{(V.)}$$

These formulæ are very convenient for computation, the former when the cosine of the given angle has any real fractional value, and the latter, when the three sides are completely integral, and small numbers: in other cases, they will be found more convenient under the following form, *viz.*

$$\left. \begin{aligned} \cos. A &= \frac{(b + c - a)(b + c - a)}{2bc} - 1 \\ \cos. B &= \frac{(a + c - b)(a + c - b)}{2ac} - 1 \\ \cos. C &= \frac{(a + b - c)(a + b - c)}{2ab} - 1 \end{aligned} \right\} \quad \text{(VI.)}$$

Or we may substitute for $\cos. A$ its equal $2 \cos.^2 \frac{1}{2} A - 1$, (see *SINE*), and we have,

4.6855749, and from the sum subtract one-third of the arithmetical complement of the log. cosine, and the remainder will be the log. sine of the given arc.

2. *To find the Arc from the Sine.*—To the given log. sine of a small arc, add 5.3144251, and one-third of the arithmetical complement of log. cosine; subtract 10 from the index of the sum, the remainder will be the logarithm of the number of seconds and decimals in the given arc.

3. *To find the Tangent.*—To the log. arc and the constant quantity 4.6855749, add two-thirds of the arithmetical complement of the log. cosine, and the sum is the log. tangent of the given arc.

4. *To find the Arc from the Tangent.*—To the log. tangent add 5.3144251, and from the sum subtract two-thirds of the arithmetical complement of log. cosine; take 10 from the index, and there will remain the logarithm of the number of seconds and decimals in the given arc.

TRIGONOMETRY.

TRIGONOMETRY, *Spherical*, relates to the resolution and calculation of the sides and angles of spherical triangles, which are formed by the intersection of three great circles of the sphere, and which, like plane triangles, consist of six parts, *viz.* three sides and three angles. See SPHERICAL Triangle.

In plane trigonometry, any three of the six parts of a triangle being given, except the three angles, the other parts may be found; but in spherical trigonometry this exception has not place, for any three of the six parts being given, the rest may thence be determined, the sides being measured or estimated by degrees, minutes, &c. the same as the angles.

Spherical trigonometry is divided into right-angled and oblique-angled, or the resolution of right and oblique-angled spherical triangles. When a spherical triangle has a right angle, it is called a right-angled spherical triangle; and when one of its sides is a quadrant, or 90° , it is called a quadrantal triangle.

The solution of all the cases of spherical trigonometry, although much more numerous than those in plane trigonometry, depends upon only three fundamental equations.

Theorem 1.—In any spherical triangle, the sines of the sides have the same ratio as the sines of their opposite angles.

Let O (*fig. 2.*) be the centre of the sphere, and having joined OA, OC, OB, draw AD perpendicular to the plane OBC; also make DE perpendicular to OB, and DF to OC; and join AE, AF.

Then, because AD is perpendicular to the plane OBC, each of the planes ADE, AFD, which pass through AD, will also be perpendicular to that plane; and since ED is perpendicular to OB, and the plane ADE to the plane OBC, the line AE, which lies in the plane ADE, and is drawn from the same point E, is also perpendicular to OB. Again, in like manner, because FD is perpendicular to OC, and the plane AFD to the plane OBC, the line FA, which lies in the plane AFD, and is drawn from the same point F, is perpendicular to OC; and, therefore, the angles AED and AFD, which measure the inclination of the planes AOB, AOC, will measure the angles CBA, BCA, of the spherical triangle ABC. Also AF, being perpendicular to OC, is the sine of the angle AOF, or of the arc AC; and AE, which is perpendicular to OB, is the sine of the angle AOB, or of the arc AB. But ADE, AFD, being right-angled plane triangles, right-angled at D, we shall have $AD = AE \sin. AED$, and $AD = AF \sin. AFD$. Whence, by equality, $AE \sin. AED = AF \sin. AFD$; consequently

$$AE : \sin. AFD :: AF : \sin. AED, \text{ or}$$

$$\sin. AB : \sin. \text{opp.} < C :: \sin. AC : \sin. \text{opp.} < B;$$

that is, the sines of the sides have the same ratio as the sines of their opposite angles.

Hence, if A, B, C, be supposed to denote the three angles of any spherical triangle, and a, b, c, corresponding opposite sides, we may from the above deduce the following fundamental equation, *viz.*

$$\frac{\sin. A}{\sin. a} = \frac{\sin. B}{\sin. b} = \frac{\sin. C}{\sin. c} \quad (I.)$$

Theorem 2.—In any spherical triangle,

As the rectangle of the sines of any two sides :

Is to the radius ::

So is the rectangle of radius and the cosine of the other side, minus the rectangle of the cosines of the same two sides :

To the cosine of the angle included by those sides.

For, having joined OA, OB, OC, (*fig. 3.*) draw FD in the plane OBC, and DE in the plane OAB, each perpendicular to their common section OB, and join EF. Then, because the angle EDF is the measure of the inclination of the planes OBC, OAB, it is also the measure of the spherical angle ABC or B. And because

$$\text{cof. EDF} = \frac{DE^2 + DF^2 - EF^2}{2DE \times DF}, \text{ and}$$

$$\text{cof. EOF} = \frac{OE^2 + OF^2 - EF^2}{2OE \times OF}, \text{ or}$$

$$EF^2 = OE^2 + OF^2 - 2OE \times OF \times \text{cof. EOF.}$$

See Form (V.) Plane Trigonometry.

And by substituting this in the first equation, cof. EDF

$$= \frac{DE^2 + DF^2 - OE^2 - OF^2 + 2OE \times OF \text{cof. EOF}}{2DE \times DF}.$$

But $OE^2 - ED^2$, and $OF^2 - DF^2$, are each equal to OD^2 ; whence cof. EDF , or its equal,

$$\text{cof. B} = \frac{OE \times OF \text{cof. EOF} - OD^2}{DE \times DF}, \text{ or}$$

$$\text{cof. B} = \frac{OE \times OF \text{cof. AC} - OD^2}{DE \times DF}.$$

Or, since $\frac{OE}{DE} = \frac{1}{\sin. DOB} = \frac{1}{\sin. AB}$, and $\frac{OF}{DF} = \frac{1}{\sin. DOF}$, &c. if these values be substituted in the former equation, we shall have

$$\text{cof. B} = \frac{\text{cof. AC} - \text{cof. AB} \cdot \text{cof. BC}}{\sin. AB \cdot \sin. BC},$$

which necessarily involves the conditions given in the enunciation of the theorem.

Here again, assuming A, B, C, to denote the angles, and a, b, c, the corresponding opposite sides, we deduce the following set of equations, *viz.*

$$\left. \begin{aligned} \text{cof. } a &= \text{cof. } b \text{cof. } c + \sin. b \sin. c \text{cof. } A \\ \text{cof. } b &= \text{cof. } a \text{cof. } c + \sin. a \sin. c \text{cof. } B \\ \text{cof. } c &= \text{cof. } a \text{cof. } b + \sin. a \sin. b \text{cof. } C \end{aligned} \right\} (II.)$$

These equations will apply equally to the supplemental triangle; thus putting for the sides a, b, c, $180^\circ - A'$, $180^\circ - B'$, $180^\circ - C'$; and for the angles A, B, C, $180^\circ - a'$, $180^\circ - b'$, $180^\circ - c'$, we shall have

$$- \text{cof. } A' = \text{cof. } B' \text{cof. } C' - \sin. B' \sin. C' \text{cof. } a'.$$

And here, again, we have three symmetrical equations applying to any spherical triangles, *viz.*

$$\left. \begin{aligned} \text{cof. } A &= \text{cof. } a \sin. B \sin. C - \text{cof. } B \text{cof. } C \\ \text{cof. } B &= \text{cof. } b \sin. A \sin. C - \text{cof. } A \text{cof. } C \\ \text{cof. } C &= \text{cof. } c \sin. A \sin. B - \text{cof. } A \text{cof. } B \end{aligned} \right\} (III.)$$

Another important relation may also thence be readily deduced; for, substituting for the $\text{cof. } b$ in the third of the equations N^o II.) its value in the second; substituting also for $\text{cof. } a$, its value $1 - \sin. a$, and then striking out the common factor $\sin. a$, we shall have

$$\text{cof. } c \sin. a = \sin. c \text{cof. } a \text{cof. } B + \sin. b \text{cof. } C.$$

But equation N^o (I.) gives $\sin. b = \frac{\sin. B \sin. c}{\sin. C}$; and

hence,

TRIGONOMETRY.

hence, by substitution,

$$\text{cof. } c \text{ fin. } a = \text{fin. } c \text{ cof. } a \text{ cof. } B + \frac{\text{fin. } B \text{ cof. } C \text{ fin. } c}{\text{fin. } C}$$

Dividing by $\text{fin. } c$, we have

$$\frac{\text{cof. } c}{\text{fin. } c} \text{ fin. } a = \text{cof. } a \text{ cof. } B + \frac{\text{fin. } B \text{ cof. } C}{\text{fin. } C}$$

But $\frac{\text{cof. } c}{\text{fin. } c} = \text{cot. } c$. See *Arithmetic of SINES*.

Therefore, $\text{cot. } c \text{ fin. } a = \text{cof. } a \text{ cof. } B + \text{fin. } B \text{ cot. } C$.

Thus, again, we get three symmetrical equations;

$$\left. \begin{aligned} \text{cot. } a \text{ fin. } b &= \text{cof. } b \text{ cof. } C + \text{fin. } C \text{ cot. } A \\ \text{cot. } b \text{ fin. } c &= \text{cof. } c \text{ cof. } A + \text{fin. } A \text{ cot. } B \\ \text{cot. } c \text{ fin. } a &= \text{cof. } a \text{ cof. } B + \text{fin. } B \text{ cot. } C \end{aligned} \right\} \text{(IV.)}$$

The classes of equations Nos. (I.) (II.) (III.) and (IV.) comprehend the whole of spherical trigonometry; or, in fact, N^o (II.), from which all the others can be derived, may be regarded as comprehending the whole. They require, however, some modifications to adapt them to logarithmic computations, which we shall now endeavour to illustrate.

I. *Solution of right-angled spherical Triangles.*—Let us suppose the angle A to be the right angle, then since $\text{fin. } A = 1$, N^o (I.) gives

$$\frac{1}{\text{fin. } a} = \frac{\text{fin. } B}{\text{fin. } b} = \frac{\text{fin. } C}{\text{fin. } c}; \text{ consequently}$$

$$\left. \begin{aligned} \text{fin. } B &= \frac{\text{fin. } b}{\text{fin. } a} \text{ fin. } C = \frac{\text{fin. } c}{\text{fin. } a} \\ \text{fin. } b &= \text{fin. } B \text{ fin. } a; \text{ or } \text{fin. } c = \text{fin. } c \text{ fin. } a \end{aligned} \right\} \text{(V.)}$$

Also, since $\text{cof. } 90^\circ = 0$, we have from N^o (II.)

$$\text{cof. } a = \text{cof. } b \text{ cof. } c. \quad \text{(VI.)}$$

For the same reason, Equation 1. N^o (III.) gives

$$\text{cof. } a \cdot \text{fin. } B \text{ fin. } C = \text{cof. } B \text{ cof. } C. \quad \text{(VII.)}$$

And upon the same hypothesis, $\text{cot. } A$ becomes $= 0$; so that Equation 1. N^o (IV.) becomes

$$\left. \begin{aligned} \text{cot. } a \text{ fin. } b &= \text{cof. } b \text{ cof. } C, \text{ or} \\ \text{cot. } a &= \frac{\text{cof. } b}{\text{fin. } b} \text{ cof. } C, \text{ or} \\ \text{cot. } a &= \text{cot. } b \text{ cof. } C \end{aligned} \right\} \text{(VIII.)}$$

The Equations 2. and 3. of N^o (III.) give also upon the same hypothesis, that is, angle $A = 90^\circ$,

$$\left. \begin{aligned} \text{cof. } B &= \text{fin. } C \text{ cof. } b \\ \text{cof. } C &= \text{fin. } B \text{ cof. } c \end{aligned} \right\} \text{(IX.)}$$

And, lastly, from N^o (IV.)

$$\left. \begin{aligned} \text{cot. } B &= \text{cot. } b \text{ fin. } c \\ \text{cot. } C &= \text{cot. } c \text{ fin. } b \end{aligned} \right\} \text{(X.)}$$

From these equations, by a few obvious transformations, the six usual cases of spherical right-angled triangles may be solved as follow.

Case 1.—Given the hypotenuse a , and an angle B , to find the other parts.

Here, $\text{fin. } b = \text{fin. } a \text{ fin. } B$;

or, $\text{fin. side req.} = \text{fin. opp. ang.} \times \text{fin. hyp.}$

Again, $\text{tan. } c = \text{tan. } a \text{ cof. } B$;

or, $\text{tan. side req.} = \text{tan. hyp.} \times \text{cof. includ. ang.}$

Lastly, $\text{cot. } C = \text{cof. } a \text{ tan. } B$;

or, $\text{cot. ang. req.} = \text{cof. hyp.} \times \text{tan. giv. ang.}$

In this case there can be nothing ambiguous, for in applying the first form, it is known that the angle and the

opposite side are always of the same affection; and in the two latter, the rules for the change of sines in the different quadrants (see *Arithmetic of SINES*), will determine to which the result belongs.

Case 2.—Given the hypotenuse a , and one of the sides, to find the other parts:

$$\text{fin. } B = \frac{\text{fin. } b}{\text{fin. } a}, \text{ or } \text{fin. ang. req.} = \frac{\text{fin. giv. side}}{\text{fin. hyp.}}$$

$$\text{cof. } c = \frac{\text{cof. } a}{\text{cof. } b}, \text{ or } \text{cof. side req.} = \frac{\text{cof. hyp.}}{\text{cof. giv. side}}$$

$$\text{cof. } C = \text{tan. } b \text{ cot. } a, \text{ or } \text{cof. ang. req.} = \text{tan. giv. side} \text{ and } \text{cot. hyp.}$$

Case 3.—Given two sides, including the right angle, namely b and c , to find the other parts.

Here, $\text{cof. } a = \text{cof. } b \text{ cof. } c$;

or, $\text{cof. hyp.} = \text{rect. of cof. given sides.}$

$$\text{Again, } \text{tan. } B = \frac{\text{tan. } b}{\text{tan. } c}, \text{ and } \text{tan. } C = \frac{\text{tan. } c}{\text{tan. } b};$$

$$\text{or, } \text{tan. ang. req.} = \frac{\text{tan. opp. side}}{\text{tan. adj. side}}$$

Case 4.—Given a side c , and its opposite angle B , to find the other parts.

$$\text{Here, } \text{fin. } a = \frac{\text{fin. } b}{\text{fin. } B}, \text{ or } \text{fin. hyp.} = \frac{\text{fin. giv. side}}{\text{fin. opp. side}}$$

Again, $\text{fin. } c = \text{tan. } b \text{ cot. } b$;

or, $\text{fin. side req.} = \text{tang. giv. side} \times \text{cot. opp. ang.}$

$$\text{Lastly, } \text{fin. } C = \frac{\text{cof. } B}{\text{cof. } b}, \text{ or } \text{fin. req. ang.} = \frac{\text{cof. giv. ang.}}{\text{cof. giv. side}}$$

Case 5.—Given a side c , and its adjacent angle B , to find the other parts.

Here, $\text{tang. } b = \text{tang. } B \text{ fin. } c$;

or, $\text{tan. side req.} = \text{tang. opp. ang.} \times \text{fin. giv. side.}$

$$\text{Again, } \text{tan. } a = \frac{\text{tan. } c}{\text{cof. } B}, \text{ or } \text{tan. hyp.} = \frac{\text{tan. giv. side}}{\text{cof. giv. ang.}};$$

or, $\text{cot. } a = \text{cof. } B \text{ cot. } c$; that is,

$$\text{cot. hyp.} = \text{cof. giv. ang.} \times \text{cot. giv. side.}$$

Lastly, $\text{cof. } C = \text{cof. } c \text{ fin. } B$;

or, $\text{cof. ang. req.} = \text{cof. opp. side} \times \text{fin. giv. ang.}$

Case 6.—Given the two oblique angles B and C , to find the rest.

Here, $\text{cof. } a = \text{cot. } B \cdot \text{cot. } C$;

or, $\text{cof. hyp.} = \text{cot. of one side} \times \text{cot. of the other};$

$$\left. \begin{aligned} \text{cof. } b &= \frac{\text{cof. } B}{\text{fin. } C} \\ \text{cof. } c &= \frac{\text{cof. } C}{\text{fin. } B} \end{aligned} \right\} \text{ or, } \text{cof. req. side} = \left\{ \begin{aligned} &\text{cof. opp. ang.} \\ &\text{fin. adj. ang.} \end{aligned} \right.$$

It may be proper to observe, that the rule of the signs, given under the article *Arithmetic of SINES*, will serve in all these cases to determine the kind or affection of the unknown parts.

In working by logarithms it must be observed, that when the resulting logarithm is the logarithm of a quotient, 10 must be added to the index; and when it is the logarithm of a product, 10 must be subtracted from the index.

TRIGONOMETRY.

11. *Resolution of oblique-angled spherical Triangles.*—This may be effected by means of four general cases, comprehending two or more problems.

Case 1.—Given three of these four things, viz. two sides b, c , and their opposite angles B and C , to find the fourth.

This case comprehends two problems, in one of which the unknown quantity is an angle, in the other a side; which are both resolved by means of equation N^o (I.) from which we have

$$\sin. C = \frac{\sin. c \sin. B}{\sin. b}; \sin. c = \frac{\sin. C \sin. b}{\sin. B}.$$

Case 2.—Of the four following things; viz. a, b, c , and an angle, any three being given, to find the fourth.

This case comprises three problems.

1. When the three sides are given, to find an angle.

Here, from equation N^o (II.) we have

$$\text{cof. } A = \frac{\text{cof. } a - \text{cof. } b \text{ cof. } c}{\sin. b \sin. c}$$

$$\text{cof. } B = \frac{\text{cof. } b - \text{cof. } a \text{ cof. } c}{\sin. a \sin. c}$$

$$\text{cof. } C = \frac{\text{cof. } c - \text{cof. } a \text{ cof. } b}{\sin. a \sin. b}$$

In this form, however, the equations are not adapted to logarithmic computation. We must therefore refer

$$\left. \begin{aligned} \tan. \frac{1}{2} A &= \sqrt{\frac{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (a + c - b)}{\sin. \frac{1}{2} (a + b + c) \sin. \frac{1}{2} (b + c - a)}} \\ \tan. \frac{1}{2} B &= \sqrt{\frac{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (b + c - a)}{\sin. \frac{1}{2} (a + b + c) \sin. \frac{1}{2} (a + c - b)}} \\ \tan. \frac{1}{2} C &= \sqrt{\frac{\sin. \frac{1}{2} (a + c - b) \sin. \frac{1}{2} (b + c - a)}{\sin. \frac{1}{2} (a + b + c) \sin. \frac{1}{2} (a + b - c)}} \end{aligned} \right\} \quad (\text{XI.})$$

The expressions for the sines of the half angles might be obtained with equal facility. As they are symmetrical, we shall put down but one; viz.

$$\sin. \frac{1}{2} A = \sqrt{\frac{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (a + c - b)}{\sin. b \sin. c}}$$

And expressions for the cosines and cotangents of the half angles may be readily found from the above by the forms $\text{cof.} = \frac{\sin.}{\tan.}$, $\text{cot.} = \frac{\text{cof.}}{\sin.}$.

When two sides, as b and c , become equal, the expression for $\sin. \frac{1}{2} A$, becomes $\sin. \frac{1}{2} A = \frac{\sin. \frac{1}{2} a}{\sin. b}$.

If $a = b = c = 90^\circ$, then $\sin. \frac{1}{2} A = \frac{\frac{1}{2} \sqrt{2}}{1} = \frac{1}{2} \sqrt{2} = \sin. 45^\circ$; and $A = B = C = 90^\circ$.

Leaving other corollaries to be deduced by the reader, let us proceed to the next problem in this case.

2. To find the side c opposite to the given angle C : that is, given two sides and the included angle, to find the third side.

Find from the data a dependent angle φ such, that

$$\tan. \varphi = \text{cof. } C \tan. b. \quad (\text{XII.})$$

Substitute for $\text{cof. } C$, in the third equation N^o (II.) its value in this, and it will become

$$\begin{aligned} \text{cof. } c &= \text{cof. } a \text{ cof. } b + \sin. a \text{ cof. } b \tan. \varphi \\ &= \text{cof. } b \left(\frac{\text{cof. } a \text{ cof. } \varphi + \sin. a \sin. \varphi}{\text{cof. } c} \right) \text{ or} \end{aligned}$$

to the formulæ given under the article SINE, where we have

$$1 + \text{cof. } A = 2 \text{ cof.}^2 \frac{1}{2} A, \text{ and } 1 - \text{cof. } A = 2 \sin.^2 \frac{1}{2} A.$$

Hence,

$$2 \text{ cof.}^2 \frac{1}{2} A = \frac{\sin. b \sin. c}{\sin. b \sin. c} + \frac{\text{cof. } a - \text{cof. } b \text{ cof. } c}{\sin. b \sin. c} = \frac{\text{cof. } a - \text{cof. } (b + c)}{\sin. b \sin. c}.$$

$$\text{Hence, also, } 2 \sin.^2 \frac{1}{2} A = \frac{\text{cof. } (b - c) - \text{cof. } a}{\sin. b \sin. c}.$$

The latter of these, divided by the former, gives

$$\tan.^2 \frac{1}{2} A = \frac{\text{cof. } (b - c) - \text{cof. } a}{\text{cof. } a - \text{cof. } (b + c)};$$

which is equivalent to

$$\tan.^2 \frac{1}{2} A = \frac{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (a + c - b)}{\sin. \frac{1}{2} (a + b + c) \sin. \frac{1}{2} (b + c - a)}.$$

See SINES.

Hence we have, for the tangents of the half angles, these three symmetrical equations; viz.

$$\text{cof. } c = \frac{\text{cof. } b \text{ cof. } (a - \varphi)}{\text{cof. } \varphi}. \quad (\text{XIII.})$$

Note.—The equation N^o (XII.) obviously reduces to

$$\frac{1}{\tan. \varphi} \text{cof. } C = \frac{1}{\tan. b}, \text{ or } \text{cot. } \varphi \text{ cof. } C = \text{cot. } b; \text{ which}$$

is analogous to N^o (VIII.) So that b is the hypothenuse, and φ one leg of a right-angled triangle. The above transformation, therefore, is equivalent to the division of the proposed triangle into two, by an arc from the vertical angle A falling perpendicularly upon the opposite side a .

3. To find the side a , not opposite to the given angle; b, c , and C being given

Here find φ , as before, by N^o (XII.) then from N^o (XIII.) we have

$$\text{cof. } (a - \varphi) = \frac{\text{cof. } c \text{ cof. } \varphi}{\text{cof. } b}. \quad (\text{XIV.})$$

Hence a is known by adding φ .

Case 3.—Of the four following parts; viz. two sides, a and c , and two angles, B and C , one opposite, the other adjacent; three being given, to find a fourth.

This case presents four problems.

1. Given a, c, B , to find C .

Determine an arc φ' by this condition,

$$\text{cot. } c = \text{cot. } \varphi' \text{ cof. } B, \text{ or } \frac{\text{cot. } c}{\text{cof. } B} = \text{cot. } \varphi'. \quad (\text{XV.})$$

Substitute

TRIGONOMETRY.

Substitute this value of $\cot. c$ for it in Equation 3. N° (IV.) and it will become

$$\sin. a \cot. \phi' \operatorname{cof.} B = \operatorname{cof.} a \operatorname{cof.} B + \sin. B \cot. C.$$

$$\text{Whence } \cot. C = \frac{(\cot. \phi' \sin. a - \operatorname{cof.} a) \operatorname{cof.} B}{\sin. B} =$$

$$(\cot. \phi' \sin. a - \operatorname{cof.} a) \cot. B; \text{ or}$$

$$\cot. C = \frac{\cot. B \sin. (a - \phi')}{\sin. \phi'}. \quad (\text{XVI.})$$

It may be observed, that equation N° (XV.) is analogous to N° (VIII.); which shews, that the operation here performed, is equivalent to letting fall a perpendicular arc from the angle A to the base a ; the subsidiary arc ϕ' being the segment adjacent to the given angle B .

2. Given B, C, c , to find a .

Here ϕ' must be found by N° (XV.) and then from N° (XVI.) we have

$$\sin. (a - \phi') = \frac{\cot. C \sin. \phi'}{\cot. B}. \quad (\text{XVII.})$$

Whence a becomes known.

3. Given B, C, a , to find c .

Find a dependent angle ϕ'' , by making

$$\cot. C = \operatorname{cof.} a \tan. \phi'', \text{ or } \frac{\cot. C}{\operatorname{cof.} a} = \tan. \phi''. \quad (\text{XVIII.})$$

$$\left. \begin{aligned} \cot. \frac{1}{2} a &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (A + B - C) \operatorname{cof.} \frac{1}{2} (A - B + C)}{-\operatorname{cof.} \frac{1}{2} (B + C + A) \operatorname{cof.} \frac{1}{2} (B + C - A)}} \\ \cot. \frac{1}{2} b &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (B + C - A) \operatorname{cof.} \frac{1}{2} (A + B - C)}{-\operatorname{cof.} \frac{1}{2} (B + C + A) \operatorname{cof.} \frac{1}{2} (A + C - B)}} \\ \cot. \frac{1}{2} c &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (A + C - B) \operatorname{cof.} \frac{1}{2} (B + C - A)}{-\operatorname{cof.} \frac{1}{2} (B + C + A) \operatorname{cof.} \frac{1}{2} (A + B - C)}} \end{aligned} \right\} \quad (\text{XXI.})$$

The following are the expressions for the sines of the half angles; *viz.*

$$\left. \begin{aligned} \sin. \frac{1}{2} a &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (A + B + C) \operatorname{cof.} \frac{1}{2} (B + C - A)}{-\sin. B \sin. C}} \\ \sin. \frac{1}{2} b &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (A + B + C) \operatorname{cof.} \frac{1}{2} (A + C - B)}{-\sin. A \sin. C}} \\ \sin. \frac{1}{2} c &= \sqrt{\frac{\operatorname{cof.} \frac{1}{2} (A + B + C) \operatorname{cof.} \frac{1}{2} (A + B - C)}{-\sin. A \sin. B}} \end{aligned} \right\} \quad (\text{XXII.})$$

It may here be observed, that notwithstanding the denominators are negative in the above expressions, the whole fraction under the radical are always positive.

2. Given A, B, c , to find C .

Here, by applying in like manner the equations N° (XII.) and N° (XIII.) to the supplemental triangle, we shall have

$$\cot. \phi = \operatorname{cof.} c \tan. B; \quad (\text{XXIII.})$$

from which the subsidiary angle ϕ may be determined, and thence

$$\cot. C = \frac{\operatorname{cof.} B \sin. (A - \phi)}{\sin. \phi}. \quad (\text{XXIV.})$$

3. Given B, C , and c , to find A .

Find ϕ from N° (XXIII.) then from N° (XXIV.) there results

$$(\sin. A - \phi) = \frac{\cot. C \sin. \phi}{\operatorname{cof.} B}. \quad (\text{XXV.})$$

from which A becomes known.

Of the Analogies of Napier.—In the introduction to the

Substitute the value of $\cot. C$ for it in equation N° (IV.) and it will reduce to

$$\cot. c = \frac{\cot. a \operatorname{cof.} (B - \phi'')}{\operatorname{cof.} \phi''}. \quad (\text{XIX.})$$

4. Given a, c, C , to find B .

Determine ϕ'' from N° (XVIII.); then

$$\operatorname{cof.} (B - \phi'') = \frac{\cot. c \operatorname{cof.} \phi''}{\operatorname{cof.} a}. \quad (\text{XX.})$$

from which B becomes known.

Case 4.—Of these four parts; *viz.* the three angles and a side, (suppose c), any three being given, to find the fourth.

This case comprises three problems.

1. Given three angles to find a side.

Suppose Equation 1. N° (XI.) to be applied to the solution of the supplemental triangle, by changing a, b, c , and C , into a', b', c' , and C' . Then to bring it back to the triangle proposed, let there be substituted for a', b', c' , and C' , the corresponding values $180^\circ - A, 180^\circ - B, 180^\circ - C$, and $180^\circ - c$; those equations will then be transformed into the following, which are applicable to the present problem.

present article we had occasion to mention the analogies of Napier, which it may not be amiss to illustrate before we proceed any farther in our investigations. These analogies are four simple and elegant formulæ, which we owe to the celebrated inventor of logarithms, of which two serve to determine any two angles of a spherical triangle by means of two opposite sides and their included angle; while the other two serve to find any two sides by means of their opposite angle and the contained side. They, therefore, together with equation N° (I.), will serve for the solution of all the cases of oblique-angled spherical triangles. The investigation of these analogies may be given as follow.

If from Equation 1. N° (II.) $\cot. c$ be exterminated, there will result, after a little reduction,

$$\cot. A \sin. c = \operatorname{cof.} a \sin. b - \operatorname{cof.} C \sin. a \operatorname{cof.} b;$$

and, by a simple permutation of letters,

$$\cot. B \sin. c = \operatorname{cof.} b \sin. a - \operatorname{cof.} C \sin. b \operatorname{cof.} a.$$

Adding these equations together, and reducing them, we have

$$\sin. c (\cot. A + \cot. B) = (1 - \operatorname{cof.} C) \sin. (a + b).$$

Now

TRIGONOMETRY.

Now from N^o (I.) we have

$$\frac{\sin. a}{\sin. A} = \frac{\sin. b}{\sin. B} = \frac{\sin. c}{\sin. C}$$

Clearing these equations of their denominators, and respectively adding and subtracting them, there results

$$\sin. c (\sin. A + \sin. B) = \sin. C (\sin. a + \sin. b)$$

$$\sin. c (\sin. A - \sin. B) = \sin. C (\sin. a - \sin. b)$$

Dividing each of these two equations by the preceding, there will be obtained,

$$\frac{\sin. A + \sin. B}{\cos. A + \cos. B} = \frac{\sin. C}{1 - \cos. C} \times \frac{\sin. a + \sin. b}{\sin. (a + b)}$$

$$\frac{\sin. A - \sin. B}{\cos. A + \cos. B} = \frac{\sin. C}{1 - \cos. C} \times \frac{\sin. a - \sin. b}{\sin. (a + b)}$$

Consequently, from the relation established under *Arithmetic of SINES*,

$$\tan. \frac{1}{2} (A + B) = \cot. \frac{1}{2} C \cdot \frac{\cos. \frac{1}{2} (a - b)}{\cos. \frac{1}{2} (a + b)}$$

$$\tan. \frac{1}{2} (A - B) = \cot. \frac{1}{2} C \cdot \frac{\sin. \frac{1}{2} (a - b)}{\sin. \frac{1}{2} (a + b)}$$

And these equations, expressed as analogies, are,

$$\cos. \frac{1}{2} (a + b) : \cos. \frac{1}{2} (a - b) :: \cot. \frac{1}{2} C : \tan. \frac{1}{2} (A + B)$$

$$\sin. \frac{1}{2} (a + b) : \sin. \frac{1}{2} (a - b) :: \cot. \frac{1}{2} C : \tan. \frac{1}{2} (A - B)$$

$$1. \frac{\sin. A}{\sin. a} = \frac{\sin. B}{\sin. b} = \frac{\sin. C}{\sin. c}$$

$$2. \tan. \frac{1}{2} A = \sqrt{\frac{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (a + c - b)}{\sin. \frac{1}{2} (b + c - a) \sin. \frac{1}{2} (a + c + b)}}$$

$$3. \tan. \frac{1}{2} B = \sqrt{\frac{\sin. \frac{1}{2} (b + c - a) \sin. \frac{1}{2} (a + b - c)}{\sin. \frac{1}{2} (a + c - b) \sin. \frac{1}{2} (a + b + c)}}$$

$$4. \tan. \frac{1}{2} C = \sqrt{\frac{\sin. \frac{1}{2} (a + c - b) \sin. \frac{1}{2} (b + c - a)}{\sin. \frac{1}{2} (a + b - c) \sin. \frac{1}{2} (a + b + c)}}$$

$$5. \tan. \frac{1}{2} a = \sqrt{\frac{-\cos. \frac{1}{2} (B + C - A) \cos. \frac{1}{2} (A + B + C)}{\cos. \frac{1}{2} (A + B - C) \cos. \frac{1}{2} (A + C - B)}}$$

$$6. \tan. \frac{1}{2} b = \sqrt{\frac{-\cos. \frac{1}{2} (A + C - B) \cos. \frac{1}{2} (A + B + C)}{\cos. \frac{1}{2} (B + C - A) \cos. \frac{1}{2} (A + B - C)}}$$

$$7. \tan. \frac{1}{2} c = \sqrt{\frac{-\cos. \frac{1}{2} (A + B - C) \cos. \frac{1}{2} (A + B + C)}{\cos. \frac{1}{2} (A + C - B) \cos. \frac{1}{2} (B + C - A)}}$$

$$8. \tan. \frac{b - a}{2} = \tan. \frac{1}{2} c \frac{\sin. \frac{1}{2} (B - A)}{\sin. \frac{1}{2} (B + A)}$$

$$9. \tan. \frac{b + a}{2} = \tan. \frac{1}{2} c \frac{\cos. \frac{1}{2} (B - A)}{\cos. \frac{1}{2} (B + A)}$$

$$10. \tan. \frac{c - b}{2} = \tan. \frac{1}{2} a \frac{\sin. \frac{1}{2} (C - B)}{\sin. \frac{1}{2} (C + B)}$$

$$11. \tan. \frac{c + b}{2} = \tan. \frac{1}{2} a \frac{\cos. \frac{1}{2} (C - B)}{\cos. \frac{1}{2} (C + B)}$$

$$12. \tan. \frac{a - c}{2} = \tan. \frac{1}{2} b \frac{\sin. \frac{1}{2} (A - C)}{\sin. \frac{1}{2} (A + C)}$$

$$13. \tan. \frac{a + c}{2} = \tan. \frac{1}{2} b \frac{\cos. \frac{1}{2} (A - C)}{\cos. \frac{1}{2} (A + C)}$$

$$14. \tan. \frac{B - A}{2} = \cot. \frac{1}{2} C \frac{\sin. \frac{1}{2} (b - a)}{\sin. \frac{1}{2} (b + a)}$$

These analogies being applied to the supplemental triangle, by putting $180^\circ - A$, $180^\circ - B$, &c. for a , b , &c. we have

$$\cos. \frac{1}{2} (A + B) : \cos. \frac{1}{2} (A - B) :: \tan. \frac{1}{2} c : \tan. \frac{1}{2} (a + b)$$

$$\cos. \frac{1}{2} (A + B) : \cos. \frac{1}{2} (A - B) :: \tan. \frac{1}{2} c : \tan. \frac{1}{2} (a - b)$$

From a due consideration of these four analogies, it results,

1. That $\frac{1}{2} (A - B) < 90^\circ$, or that the difference of two angles of a spherical triangle is less than 180° .

2. That $\frac{1}{2} (a + b)$ and $\frac{1}{2} (A + B)$ are always of the same affection.

3. That the difference of two sides is always less than 180° .

4. That $(a - b)$ and $(A - B)$ have always the same sign; whence it follows, that the greatest angle is opposite to the greatest side, and reciprocally.

To these it may be added,

5. That the least angle is opposite to the least side, and the mean angle to the mean side.

One or other of these observations will serve to remove the ambiguity in the doubtful cases where a , b , and B , or A , B , and b , are given.

We may now collect the most commodious of these theorems, and present in one place all that will be usually required in the solution of oblique-angled spherical triangles.

TRIGONOMETRY.

15. $\text{Tan. } \frac{B + A}{2} = \text{cot. } \frac{1}{2} C \frac{\text{cof. } \frac{1}{2} (b - a)}{\text{cof. } \frac{1}{2} (b + a)}$
16. $\text{Tan. } \frac{C - B}{2} = \text{cot. } \frac{1}{2} A \frac{\text{fin. } \frac{1}{2} (c - b)}{\text{fin. } \frac{1}{2} (c + b)}$
17. $\text{Tan. } \frac{C + B}{2} = \text{cot. } \frac{1}{2} A \frac{\text{cof. } \frac{1}{2} (c - b)}{\text{cof. } \frac{1}{2} (c + b)}$
18. $\text{Tan. } \frac{A - C}{2} = \text{cot. } \frac{1}{2} B \frac{\text{fin. } \frac{1}{2} (a - c)}{\text{fin. } \frac{1}{2} (a + c)}$
19. $\text{Tan. } \frac{A + C}{2} = \text{cot. } \frac{1}{2} B \frac{\text{cof. } \frac{1}{2} (a - c)}{\text{cof. } \frac{1}{2} (a + c)}$
20. $\text{Tan. } \frac{1}{2} c = \text{tan. } \frac{1}{2} (b - a) \frac{\text{fin. } \frac{1}{2} (B + A)}{\text{fin. } \frac{1}{2} (B - A)}$
21. $\text{Tan. } \frac{1}{2} c = \text{tan. } \frac{1}{2} (b + a) \frac{\text{cof. } \frac{1}{2} (B + A)}{\text{cof. } \frac{1}{2} (B - A)}$
22. $\text{Tan. } \frac{1}{2} a = \text{tan. } \frac{1}{2} (c - b) \frac{\text{fin. } \frac{1}{2} (C + B)}{\text{fin. } \frac{1}{2} (C - B)}$
23. $\text{Tan. } \frac{1}{2} a = \text{tan. } \frac{1}{2} (c + b) \frac{\text{cof. } \frac{1}{2} (C + B)}{\text{cof. } \frac{1}{2} (C - B)}$
24. $\text{Tan. } \frac{1}{2} b = \text{tan. } \frac{1}{2} (a - c) \frac{\text{fin. } \frac{1}{2} (A + C)}{\text{fin. } \frac{1}{2} (A - C)}$
25. $\text{Tan. } \frac{1}{2} b = \text{tan. } \frac{1}{2} (a + c) \frac{\text{cof. } \frac{1}{2} (A + C)}{\text{cof. } \frac{1}{2} (A - C)}$
26. $\text{Cot. } \frac{1}{2} C = \text{tan. } \frac{1}{2} (B - A) \frac{\text{fin. } \frac{1}{2} (b + a)}{\text{fin. } \frac{1}{2} (b - a)}$
27. $\text{Cot. } \frac{1}{2} C = \text{tan. } \frac{1}{2} (B + A) \frac{\text{cof. } \frac{1}{2} (b + a)}{\text{cof. } \frac{1}{2} (b - a)}$
28. $\text{Cot. } \frac{1}{2} A = \text{tan. } \frac{1}{2} (C - B) \frac{\text{fin. } \frac{1}{2} (c + b)}{\text{fin. } \frac{1}{2} (c - b)}$
29. $\text{Cot. } \frac{1}{2} A = \text{tan. } \frac{1}{2} (C + B) \frac{\text{cof. } \frac{1}{2} (c + b)}{\text{cof. } \frac{1}{2} (c - b)}$
30. $\text{Cot. } \frac{1}{2} B = \text{tan. } \frac{1}{2} (A - C) \frac{\text{fin. } \frac{1}{2} (a + c)}{\text{fin. } \frac{1}{2} (a - c)}$
31. $\text{Cot. } \frac{1}{2} B = \text{tan. } \frac{1}{2} (A + C) \frac{\text{cof. } \frac{1}{2} (a + c)}{\text{cof. } \frac{1}{2} (a - c)}$

We are indebted for many of the above transformations to Gregory's Trigonometry; others have been derived from Bonnycastle's treatise on the same subject.

We shall now conclude this article, by illustrating the solution of spherical triangles by means of Napier's *five circular parts*. See PART and CIRCULAR PART.

Solution of right-angled spherical Triangles, by Napier's circular Parts.—If either one or both the sides, including the right angle, come into the question, for it among the data, write its complement to a quadrant. Since then by the general rule delivered under the article CIRCULAR PARTS, and rendered logarithmic, the whole sine, with the sine complement of the middle part, must be equal to the sines of the disjunct parts, and the cotangents of the conjunct parts; from the sum of those data subtract the third datum; the remainder will be some sine or tangent, the side or angle corresponding to which, in the table of sines, &c. is the side or angle sought.

This universal rule being of great service in trigonometry, we shall apply it to the various cases thereof, and illustrate it with examples; which examples, in the case of disjunct or separate parts, will at the same time illustrate the common

method; but in the case of contiguous parts they admit of other solutions.

1. Given the hypotenuse BC, 60°, and the angle C, 23° 30'; to find the opposite leg AB (*fig. 4.*) Since AB is the middle part, C and BC are disjunct (see PART); the product of the whole sine, into the cofine of the complement AB, *i. e.* the sine itself of AB, is equal to the product of the sines of C and BC.

Therefore from the log. sine of C 9.6006997
+ sine of BC 9.9375306

Sum 19.5382303
Subtract whole sine 10.0000000

Remains sine of AB 9.5382303 The nearest corresponding number to which, in the tables, is 20° 12'.

2. Given the hypotenuse BC, 60°, and the leg AB, 20° 12'; to find the opposite angle C. It is evident from the preceding problem, that from the sum of the whole sine, and the sine of the leg AB, the sine of the hypotenuse BC is to be subtracted, the remainder is the sine of the angle C. The example therefore of the former case is easily converted into an example of this.

3. Given the leg AB, 20° 12', and the opposite angle C, 23° 30'; to find the hypotenuse BC. It is evident from the first case, that from the sum of the whole sine, and the sine of AB, is to be subtracted the sine of the angle C, and the remainder is the sine of the hypotenuse BC.

4. Given the hypotenuse BC, 60°, and one leg AB, 20° 12'; to find the other leg. Since BC is a mean part, and AB and AC are disjunct parts, the product of the whole sine, into the cofine of the hypotenuse BC, is equal to the product of the sines of the complements, *i. e.* the cofines of the legs AB and AC.

Therefore from the whole sine 10.0000000
Cofine of BC 9.6989700

Sum 19.6989700
Subtract cofine of AB 9.9724310

Remains cofine of AC 9.7265390 The corresponding number to which, in the tables, is 32° 11'; therefore AC = 57° 49'.

5. Given the legs AC, 57° 49', and AB, 20° 12'; to find the hypotenuse BC. It is evident from the preceding case, that the whole sine is to be subtracted from the sum of the cofines of the legs AB and AC; the remainder is the cofine of the hypotenuse BC. The example, therefore, of the preceding case is easily applied to this.

6. Given the leg AC, 57° 49', and the adjacent angle C, 23° 30'; to find the opposite angle B. Since B is a middle part, and A and C are disjunct parts; the product of the whole sine, by the cofine of B, is equal to the product of the sine of C, and the sine of the complement, *i. e.* the cofine of AC.

Therefore from the sine of C 9.6006997
Cofine AC 9.7265310

Sum 19.3272307
Subtract whole sine 10.0000000

Remains cofine of B 9.3272307 The nearest number corresponding to which, in the tables, is 12° 15'; therefore B = 77° 45'.

7. Given the leg AC, 57° 49', and the opposite angle B, 77° 45'; to find the adjacent angle C. It is evident from the preceding case, that the cofine of AC is to be subtracted

TRIGONOMETRY.

subtracted from the sum of the whole sine, and the cosine of B, the remainder, is the sine of C. The former example, therefore, is easily accommodated to the present case.

8. Given the oblique angles B, $77^{\circ} 45'$, and C, $23^{\circ} 30'$; to find the leg adjacent to the other, A C. From problem the sixth, it is evident that the sine of C is to be subtracted from the sum of the whole sine, and the cosine of B; and that the remainder is the cosine of A C. The example of the sixth problem may be easily applied to this.

9. Given the leg A C, $57^{\circ} 49'$, and the adjacent angle C, $23^{\circ} 30'$; to find the opposite leg A B. Since A C is a mean part, and C and A B conjunct parts, the product of the whole sine, by the sine of A C, is equal to the product of the cotangent of C, and the tangent of A B.

Therefore from the whole sine 10.0000000
Sine of A C 9.9275490

Sum 19.9275490

Subtract cotangent of C 10.3616981

Remains tangent of A B 9.5658519 To which the nearest corresponding number, in the tables, is $20^{\circ} 12'$.

10. Given the leg A B, $20^{\circ} 12'$, and the opposite angle C, $23^{\circ} 30'$; to find the adjacent leg A C. From the sum of the cotangent of C, and the tangent of A B, subtract the whole sine; the remainder is the sine of A C.

11. Given the legs A B, $20^{\circ} 12'$, and A C, $57^{\circ} 49'$; to find the angle C, opposite to one of them. From the sum of the whole sine, and sine of A C, subtract the tangent of B A; the remainder is the cotangent of C.

12. Given the hypotenuse B C, 60° , and the oblique angle C, $23^{\circ} 30'$; to find the adjacent leg A C. Since C is a middle part, and B C and A C conjoint parts; the product of the whole sine into the cosine of C, will be equal to the product of the cotangents of A C and B C.

Therefore from the whole sine 10.0000000
Cosine of C 9.9623978

Sum 19.9623978

Subtract cotangent of B C 9.7614394

Remains tangent of A C 10.2009584 The nearest number corresponding to which, in the tables, is $57^{\circ} 49'$.

13. Given the leg A C, $57^{\circ} 49'$, and the adjacent angle C, $23^{\circ} 30'$; to find the hypotenuse B C.

From the sum of the whole sine, and the cosine of C, subtract the tangent of A C; the remainder is the cotangent of B C.

14. Given the hypotenuse B C, 608, and the leg A C, $57^{\circ} 49'$; to find the adjacent angle C.

From the sum of the cotangent of B C, and tangent of A C, subtract the whole sine; and the remainder is the cosine of C.

15. Given the hypotenuse B C, 60° , and one angle C, $23^{\circ} 30'$; to find the other, B.

Since B C is the middle part, and B and C disjunct parts, the product of the whole sine, into the cosine of B C, will be equal to the product of the cotangents of B and C; and

Therefore from the whole sine 10.0000000
Cosine of B C 9.6989700

Sum 19.6989700

Subtract cotangent of C 10.3616981

Remains cotangent of B 9.3372719 The nearest corresponding number to which, in the tables, is $12^{\circ} 16'$; therefore B = $77^{\circ} 44'$.

16. Given the oblique angles B, $77^{\circ} 44'$, and C, $23^{\circ} 30'$; to find the hypotenuse B C. From the sum of the cotangents of C and B, subtract the whole sine; the remainder is the cosine of B C.

Solution of oblique-angled Spherical Triangles.—1. In an oblique-angled spherical triangle A B C, (fig. 5.) two sides, A B and B C, being given, together with an angle, A, opposite to one of them, to find the other, C: the rule is,

As the sine of the side B C is to the sine of the opposite angle A; so is the sine of the side B A to the sine of the opposite angle C.

Suppose, for example, B C, $39^{\circ} 29'$; A, $43^{\circ} 20'$; B A, $66^{\circ} 45'$; then will

Sine of B C 9.8033572
Sine of A 9.8364771
Sine of B A 9.9632168

19.7996939

Sine of C 9.9963367 The nearest corresponding number to which, in the tables, is $82^{\circ} 34'$.

2. Given two angles C, $82^{\circ} 34'$, and A, $43^{\circ} 20'$, together with the side A B, $66^{\circ} 45'$, opposite to one of them, C; to find the side B C opposite to the other of them, A; say, as the sine of the angle C is to the sine of the opposite side A B; so is the sine of the angle A to the sine of the opposite side B C. The former example may suffice for the present case.

3. Given two sides A B, $66^{\circ} 45'$, and B C, $39^{\circ} 29'$, together with an angle opposite to one of them A, $43^{\circ} 20'$; to find the angle included by them, B. Suppose the angle C to be acute, since the other, A, is also acute, the perpendicular B E falls within the triangle. In the right-angled triangle A B E, therefore, from the given angle A, and side A B, find the angle A B E. Since B E is assumed as a lateral part in the triangle A E B, the angle E B C is a middle part, and the side B C must be a conjoint part: the cosine of the angle E B C will be found by subtracting the cotangent of A B from the sum of the cosine of the angle A B E, and the cotangent of B C. If then the angles A B E and E B C be added together, or in case the perpendicular fall without the triangle, be subtracted from each other, you will have the angle required B.

E. gr. Whole sine 10.0000000
Cosine of A B 9.5963154

Sum - - 19.5963154

Cotangent of A - - 10.0252805

Cotangent of A B E 9.5710349 The nearest number corresponding to which, in the tables, is $20^{\circ} 26'$. A B E, therefore, is $69^{\circ} 34'$.

Cosine of A B E 9.5429713
Cotangent of B C 10.0841539

Sum - - - 19.6271242

Cotangent of A B - - 9.6330985

Cosine of E B C - 9.9940257 The nearest number corresponding to which, in the tables, is $9^{\circ} 29'$; therefore A B C = $79^{\circ} 3'$.

4. Given two angles A, $43^{\circ} 20'$, and B, $79^{\circ} 3'$, together with the adjacent side A B, $66^{\circ} 45'$; to find the side B C opposite to one of them.

From one of the given angles B, let fall a perpendicular E B to the unknown side of A C; and in the right-angled triangle A B E, from the given angle A, and hypotenuse A B, find the angle A B E; which, subtracted from the

M m 2 angle

TRIGONOMETRY.

angle $A B C$, leaves the angle $E B C$. But if the perpendicular shall fall without the triangle, the angle $A B C$ should have been subtracted from $A B E$. Since as the perpendicular $B E$ is taken for one of the lateral parts, the middle part in the triangle $A B E$ is the angle B , and the conjoint part $A B$; in the triangle $E B C$ the middle part is the angle B , and the conjoint part $B C$; the cotangent of the side $B C$ is found by subtracting the cosine of $E B A$ from the sum of the cotangent of $A B$, and the cosine of $E B C$. The example of the preceding case is easily applied to this.

5. Given two sides $A B$, $66^{\circ} 45'$, and $B C$, $39^{\circ} 29'$, with the angle A opposite to one of them, $43^{\circ} 20'$; to find the third side $A C$.

Letting fall, as before, the perpendicular $B E$; in the right-angled triangle $A B E$, from the given angle and hypotenuse $A B$, find the side $A E$. Since assuming $B E$ for a lateral part in the triangle $A E B$, $A B$ is the middle part, and $A E$ is the separate part; and in the triangle $B E C$, $B C$ is the mean part, and $E C$ a disjunct part; the cosine of $E C$ is found by subtracting the cosine of $A B$ from the sum of the cosines of $A E$ and $C B$. If then the segments $A E$ and $E C$ be added together, or in case the perpendicular fall without the triangle, be subtracted from each other, the side $A C$ will be had.

6. Given two sides $A C$, $65^{\circ} 31'$, and $A B$, $66^{\circ} 45'$, together with the included angle A , $43^{\circ} 20'$; to find the third side $B C$ opposite thereto.

Letting fall the perpendicular $B E$, find, in the right-angled triangle, the segment $A E$; which, subtracted from $A C$, leaves $E C$. If the perpendicular fall without the triangle, $A C$ is to be subtracted from $A E$. Since by assuming the perpendicular $B E$ for a lateral part in the triangle $A E B$, $A B$ becomes a middle part, and $A E$ a separate part; in the triangle $E B C$, $C B$ is the middle part, $E C$ a separate part: the cosine of $B C$ is found by subtracting the cosine of $A E$ from the sum of the cosines of $A B$ and $E C$.

7. Given two angles A , $43^{\circ} 20'$, and B , $79^{\circ} 3'$, together with the side $C B$, $39^{\circ} 29'$, opposite to one of them; to find the side $A B$ adjacent to both.

Letting fall the perpendicular $C D$ from the unknown angle C , to the opposite side $A B$; and that falling within the triangle; from the given angle B , and the hypotenuse $B C$, seek in the right-angled triangle $B C D$ for the segment $B D$. Since assuming the perpendicular $C D$ for a lateral part in the triangle $C D B$, $D B$ is the mean part, and the angle B a conjoint part; and in the triangle $C D A$, $A D$ is the middle part, and the angle A a conjoint part: the sine of the segment $A D$ is found by subtracting the cotangent of the angle B from the sum of the sine of $D B$, and the cotangent of the angle A . If then the segments $A D$ and $D B$ be added, or in case the perpendicular fall without the triangle, be subtracted from each other, the result will be the side $A B$ required.

8. Given two sides $A B$, $66^{\circ} 45'$, and $B C$, $39^{\circ} 29'$, with the included angle $79^{\circ} 3'$; to find the angle A opposite to one of them.

Letting fall the perpendicular $C D$, find the segment $B D$, as in the preceding problem. This, subtracted from $A B$, leaves $A D$. If the perpendicular fall without the triangle, $A B$ is to be added to $D B$. And since by assuming the perpendicular $C D$ for a lateral part in the triangle $C D B$, $B D$ is the middle part, and the angle B a conjoint part; and in the triangle $C D A$, $A D$ is the middle part, and the angle A a conjoint part, the cotangent of the angle A is formed by subtracting the sine of $D B$ from the sum of the cotangent of the angle B , and of the sine of $A D$.

9. Given two angles A , $43^{\circ} 20'$, and B , $79^{\circ} 3'$, together with the adjacent side $A B$, $66^{\circ} 45'$; to find the angle C opposite to the same.

From one of the given angles B , letting fall the perpendicular $B E$ to the opposite side $A C$; in the right-angled triangle $A B E$, from the given angle A , and hypotenuse $A B$, we find the angle $A B E$; which, subtracted from $A B C$, leaves the angle $E B C$. In case the perpendicular fall without the triangle, $A B C$ is to be subtracted from $A B E$. Since by assuming $B E$ for a lateral part in the triangle $C E B$, the angle C is a middle part, and the angle $C B E$ a disjunct part; and in the triangle $A B E$, the angle A is the middle part, and the angle $A B E$ the disjunct part: the cosine of the angle C is found by subtracting the sine of the angle $A B E$, from the sum of the cosine of the angle A , and the sine of $E B C$.

10. Given two angles A , $43^{\circ} 20'$, and C , $82^{\circ} 34'$, together with the side $B A$, $66^{\circ} 45'$, opposite to one of them; to find the other angle.

From the angle B sought, let fall a perpendicular $B E$; and in the right-angled triangle $A E B$, from the given angle A , and hypotenuse $B A$, find the angle $A B E$. Since assuming the perpendicular $E B$ for a lateral part in the triangle $E C B$, the angle C is the middle part, and the angle $C B E$ a disjunct part; and in the triangle $A B E$, the angle A is the middle part, and the angle $A B E$ is a disjunct part: the sine of the angle $E B C$ is found by subtracting the cosine of A from the sum of the cosine of C , and of the sine of $A B E$. If then $A B E$ and $E B C$ be added, or in case the perpendicular fall without the triangle, be subtracted from each other, the result will be the angle required $A B C$.

11. Given the three sides, to find an angle opposite to one of them. 1. If one side $A C$ (*Plate II. fig. 8.*) be a quadrant, and the leg $A B$ be less than a quadrant, find the angle A . Continue $A B$ to F , till $A F$ become equal to a quadrant; and from the pole A draw the arc $C F$, to cut the arc $B F$ at right angles in F . Since in the right-angled triangle $C B F$, we have given the hypotenuse $B C$, and the side $F B$, or its complement $A B$ to a quadrant; we shall find the perpendicular $C F$, which being the measure of the angle $C A B$, that angle is found of course.

2. If one side $A C$ be a quadrant, and the other $A B$ greater than a quadrant, seek again the angle A : from $A B$ subtract the quadrant $A D$, and from the pole A describe the arc $C D$, cutting the arc $A B$ at right angles in D . Since in the right-angled triangle $C D B$, the hypotenuse $B C$, and side $D B$, or excess of the side $A B$ beyond a quadrant, is given, the perpendicular $C D$ will be found as before, which is the measure of the angle A required.

3. If the triangle be isosceles, and $A C = C F$; and the angle $A C F$ be required; bisect $A F$ in D , and through D and C draw the arc $D C$. Since $D C$ is perpendicular to $A F$, the angles A and F , and $A C D$ and $D C F$, are equal; from the hypotenuse $A C$, and leg $A D$, given in the right-angled triangle $A C D$, we find the angle $A C D$; the double of which is the angle required $A C F$: and from the same data may the angle A or F be found.

4. If the triangle be scalenous, and the angle A (*Plate III. fig. 5.*) be required; from C let fall the perpendicular $C D$, and seek the half-difference of the segments $A D$ and $D B$, by saying, as the tangent of half the base $A B$ is to the tangent of half the sum of the legs $A C$ and $C B$; so is the tangent of their half-difference to the tangent of the half-difference of the segments $A D$ and $D B$: add then the half-difference of the segments to the half-base, to find the greater segment; and subtract the same from the same for the less.

Thus having in the right-angled triangle *CAD*, the hypothenuse *AC*, and the side *AD*, the angle *A* is found thence. After the same manner is *B* found in the other *CDB*, from *CB* and *DB* given.

12. Given the three angles *A*, *B*, and *C*, to find any of the sides. Since in lieu of the given triangle, another may be assumed, whose sides are equal to the given angles, and the angles to the given sides: this problem is resolved after the same manner as the preceding one.

TRIGONUM, or *Triangular Harp*, an ancient musical instrument. (See *Plate of ancient Instruments*.) One of this kind was taken from an ancient painting in the museum of the king of Naples, in which it is placed on the shoulder of a little dancing Cupid, who supports the instrument with his left hand, and plays upon it with his right. The trigonum is mentioned by Athenæus, lib. iv. and by Julius Pollux, lib. iv. cap. 9. According to Athenæus, Sophocles calls it a Phrygian instrument; and one of his Deipnosophists tells us, that a certain musician of the name of Alexander Alexandrinus was so admirable a performer upon it, and had given such proofs of his abilities at Rome, that he made the inhabitants *μυσομαγευειν*, *musically mad*. It may not be unworthy of remark, that this little instrument resembles the Theban harp, in the circumstance of wanting one side to complete the triangle. The performer too, being a native of Alexandria, as his name implies, makes it probable it was an Egyptian instrument upon which he gained his reputation at Rome.

TRIGUERA, in *Botany*, was so called by the late abbé Cavanilles, in honour of his friend Don Candido Maria de Trigueros, who gathered this plant, then supposed entirely nondescript, in Andalusia. Another genus was originally thus designated, now *Lagunæa lobata* of Willdenow, Sp. Pl. v. 3. 733. The present seems to be a good genus, though the plant on which it is founded proves to be the rare and little-known *Verbascum Osbeckii* of Linnæus, as the writer of the present article first discovered.—Cavan. Diff. 2. after page 106. Schreb. Gen. 114. Willd. Sp. Pl. v. 1. 839. Mart. Mill. Dict. v. 4.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Lurida*, Linn. *Solanæa*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, divided half way down, into five unequal acute segments. *Cor.* of one petal, bell-shaped; tube very short; limb inflated, plaited, five-cleft, longer than the calyx; the two upper segments reflexed. Nectary a short, membranous, five-toothed cup, surrounding the germen. *Stam.* Filaments five, very short, inserted into the teeth of the nectary at the outside; anthers arrow-shaped, converging. *Pist.* Germen superior, roundish, with two furrows; style thread-shaped, straight, rather longer than the stamens; stigma obtuse. *Peric.* Berry dry, nearly globular, of four cells. *Seeds* two in each cell, roundish, compressed, rough, one over the other.

Ess. Ch. Corolla bell-shaped, irregular. Nectary with five teeth, surrounding the germen, and bearing the stamens. Berry dry, of four cells, with two seeds in each.

Obs. Cavanilles observed one or two of the cells to be occasionally abortive.

1. *T. ambrosiaca*. Musky Triguera. Cavan. Diff. 2. A. Willd. n. 1. (*Verbascum Osbeckii*; Linn. Sp. Pl. 255. Willd. Sp. Pl. v. 1. 1006; excluding, from both, the reference to Tournefort, and the last-named place of growth. Obs. It. 52.)—Leaves decurrent, obovate, serrated. Calyx villous.—Native of Spain, towards the coast, and of Saké in Barbary, flowering in the spring. *Root* annual. *Stems* simple, erect or decumbent, angular, leafy, span high. *Leaves* alternate, two inches long, somewhat

hairy, coarsely ferrated, tapering at the base, and somewhat decurrent; the upper ones smaller. *Flower-stalks* axillary, in pairs, single-flowered, drooping. *Calyx* covered with woolly hairs. *Corolla* deep violet, an inch wide; nearly black in the throat. *Seeds* blackish, hard. The whole plant, called in Spanish *Almizquera*, and *Moradilla*, has a pleasant musky scent. It is spoken of as possessing the emollient narcotic virtues of Deadly Nightshade, and Hemlock, being, like those plants, useful in cancers of the breast; so far at least as to allay the pain.

2. *T. inodora*. Scentless Triguera. Cavan. as above. Willd. n. 2.—Leaves sessile, ovato-lanceolate, entire. Calyx smooth.—Found in Andalusia with the foregoing, and vulgarly named *Moradilla blanquezina*. Differs from the first in the smoothness of every part. The *flowers* are handsome, drooping. *Throat* very pale violet, or yellowish-white, with five stripes; limb pale violet, or purple, with entire pointless lobes.

TRIGUEROS, in *Geography*, a town of Spain, in the province of Seville; 8 miles N.N.E. of Moguer.

TRIGYNIA, in *Botany, from *τριη*, *three*, and *γυνη*, *a female*, the name of an order in many classes of the Linnæan artificial system, distinguished by the flowers having three styles, pistils, or sessile stigmas. Of the latter, *Viburnum* and *Sambucus*, in the fifth class, are instances. The order in question occurs in the 1st, 2d, 3d, 5th, 6th, 8th, 9th, 10th, 11th, 12th, and 13th classes; in the 4th and 7th it is wanting. Indeed in the 13th class, this order is but uncertain, *Delphinium* and *Aconitum*, on which Linnæus founded it, being variable in the number of pistils. In the 12th class, *Icosandria*, it forms such unnatural and troublesome distinctions, as to be much better abolished. See **PENTAGYNIA**.*

TRIHILATÆ, so denominated from *tres*, *tria*, three, and *hilum*, the scar of a seed, because some of the principal genera are remarkable for the broad scars of their three seeds; the 23d natural order among the *fragmenta* of Linnæus, standing between his *Caryophyllei* and *Corydales*, to the latter of which only it has any, even the slightest, affinity.

This is in itself but a heterogeneous assemblage, embracing several of Jussieu's orders, particularly the *Sapindi*, *Acra* and *Malpighiæ*, as also his *Meliæ*. It consists of three sections. In the first are *Melia*, *Trichilia*, *Guarea* and *Turraea*; to which Linnæus was afterwards inclined to add *Cedrela* and *Swietenia*. The second section consists of *Malpighia*, *Banisteria*, *Hirca*, *Triopteris*, *Acer* and *Æsculus*: and the third, of *Staphylea*, *Sapindus*, *Paullinia*, *Cardiospermum* and *Tropæolum*, to which Linnæus afterwards added *Hippocratea*, more certainly belonging to the second section.

Cavanilles, in his *Dissertations on Monadelphous Plants*, has added many new genera to the *Trihilatæ*; but he is extolled beyond measure by Giseke in his edition of the *Prælectiones* of Linnæus; where an account is given, not only of these genera, but of various others, considered by Cavanilles as monadelphous, though contrary to the general opinion. See **MONADELPHIA**.

TRIHING, **THRIHING**, or *Trithing*, from the Saxon, *drihinge*, an extent containing three or four hundreds, or the third part of a shire, or province. See **TRITHING**.

Mr. Thoresby thinks the word ought to be written *thrithing*. See Thoresb. Ducatus Leodens. p. 85.

These trithings still subsist in the county of York, where by an easy corruption they are denominated *ridings*.

The word is also used for a court held within that circuit, which was the same with what we now call a *court-leet*, which is above a court-baron, and inferior to the county-court.

TRIKALA, in *Mythology*, is a name of the Hindoo deity Siva. One of his names is Kala, or Time, and the epithet Tri prefixed denotes his omniscience and omnipresence as to all times, past, present, and to come; a mystical triad or union of time. The honourable designation of Trikala is sometimes given to, or assumed by, individuals of supposed profundity of knowledge, especially if of an inspired or prophetic description. The consort of Siva in this form or character is Trikali, or Trikala-devi-kumari, meaning the divine triple-maid, or triform divine maiden Kali. See TRISAKTI.

TRIKALA-DEVI. See the preceding article.

TRILATERAL, a term applied to all three-sided figures. See TRIANGLE.

TRILEUCUM PROMONTORIUM, or *Lapacia Cory*, in *Ancient Geography*, a promontory on the northern coast of Spain, N. of the country of the Callaici. According to Ptolemy, it lay between Flaviium Brigantium and the mouth of the river Metarus or Mearus.

TRILIX, in *Botany*, a Latin word, used for a tissue of three threads, woven or twisted together; but how it applies to this plant, we are not informed. Mutis, its discoverer, called the genus *Jacquinia*. De Theis understands the above name as merely equivalent to triple, and alluding to the three calyx-leaves, and three petals, which perhaps is right.—Linn. Mant. 153. Schreb. 347. Willd. Sp. Pl. v. 2. 1129. Mart. Mill. Dict v. 4. Juss. 435.—Class and order, *Polyandria Monogynia*. Nat. Ord. uncertain.

Gen. Ch. *Cal.* Perianth inferior, of three ovate, acute, spreading, flat, permanent leaves. *Cor.* Petals three, lanceolate, acute, smaller than the calyx. *Stam.* Filaments numerous, capillary, the length of the corolla; anthers roundish, minute, two-lobed. *Pist.* Germen superior, five-angled; style cylindrical; stigma simple. *Peric.* Berry obscurely five-angled, of five cells, covered by the calyx. *Seeds* numerous, roundish, minute.

Eff. Ch. Petals three. Calyx of three leaves. Berry of five cells, with many seeds.

1. *T. lutea*. Linn. Mant. 247. Willd. n. 1.—Gathered at Carthage, in South America, by Mutis, from whose description alone, contrary to his usual practice, Linnæus adopted this genus into his system. This, the only species, is a shrub two fathoms in height, with very numerous, round, roughish branches. *Leaves* alternate, stalked, somewhat peltate, ovate, rather heart-shaped, pointed, serrated, veiny, downy. *Footstalks* round, smooth. *Flowers* yellow, not from the corolla, but the anthers, generally terminal, racemose, their partial stalks simple, round, downy.

TRILL, in *Music*, a plain shake upon a single note, formed by a beating in the throat on the vowel *o*, or by the shaking of the palate on the throat in one sound upon a note: this grace is usually made in closes or cadences, and when on a long note exclamation or passion is expressed, the trill is made in the latter part of such note; but most commonly on binding notes and such as precede the closing note. See TRILLO.

TRILL-Hooks, those used to hold the sides of a cart up to the horse.

TRILLETTO, in the *Italian Music*, a little short shake or quaver; it differs from trillo only in point of continuance, being its diminutive.

TRILLION, in *Arithmetic*, the number of a billion of billions.

After billions, we reckon by trillions, which makes a class of numeration, and is divided, like the other classes, into three places: thus we say, *trillions, tens of trillions, hundreds of trillions, &c.*

TRILLIUM, in *Botany*, a Linnæan name, left unexplained by its author, evidently alludes, like *Trilix*, to the triple number, not only of the calyx-leaves and petals, but of the stigmas, cells of the fruit, and even of the leaves, which prevails throughout this genus.—Linn. Gen. 180. Schreb. 240. Willd. Sp. Pl. v. 2. 271. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 328. Pursh 244. Juss. 42. Lamarek Illustr. t. 267.—Class and order, *Hexandria Trigynia*. Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three spreading, ovate, permanent leaves. *Cor.* Petals three, nearly ovate, rather larger than the calyx. *Stam.* Filaments six, awl-shaped, erect, shorter than the calyx; anthers terminal, oblong, the length of the filaments. *Pist.* Germen roundish, superior; styles three, thread-shaped, recurved; stigmas simple. *Peric.* Berry roundish, of three cells. *Seeds* several, roundish.

Eff. Ch. Calyx of three leaves. Petals three. Berry of three cells.

This genus is entirely confined, as far as botanists have hitherto observed, to North America. Linnæus has described three species, nor has Willdenow any more, in his Sp. Pl. Pursh has given by far the best account of the genus, greatly increasing the number of species. We shall therefore follow him in the greater part of their arrangement. All are perennial, herbaceous, smooth, with a simple, erect, round stem, bearing three simple entire leaves at the top, and a solitary flower, sessile or stalked, in the centre between them. Five of these plants are mentioned by Mr. Aiton, as cultivated in England, all hardy, flowering in April or May. In natural affinity, *Trillium* comes very near to PARIS. See that article.

1. *T. sessile*. Dark sessile *Trillium*. Linn. Sp. Pl. 484. Willd. n. 3. Pursh n. 1. Ait. n. 5. Curt. Mag. t. 40. Redout. Liliac. t. 133. (Paris foliis ternis, flore sessili erecto; Gron. Virg. ed. 1. 44. Solanum triphyllum, flore tripetalato atro-purpureo, in foliorum sinu absque pediculo, sessili; Pluk. Phyt. t. 111. f. 6. S. triphyllum, &c.; Cateb. Carol. v. 1. t. 50.)—Flower sessile, erect. Petals lanceolate, erect, twice the length of the calyx. Leaves sessile, broadly elliptical, acute.—On the sides of fertile hills, in shady rocky ground, from Pennsylvania to Carolina, flowering in April and May. *Flower* dark chocolate-brown. *Berry* purple. I have seen a specimen with yellow flowers, brought from the Cherokee nation, which probably may be a distinct species. *Pursh*. Our plant has a thick, tuberous, horizontal root, with many simple fibres. *Stem* three or four inches high. *Leaves* spreading, rather deflexed, two inches long, spotted with light and dark-green, somewhat like *Erythronium Dens-canis*. *Calyx-leaves* an inch long, spreading, lanceolate, green with a purple tinge. *Petals* deep purple, nearly twice as long, converging, tapering at the base.

2. *T. petiolatum*. Plantain-leaved *Trillium*. Pursh n. 2.—“Flower sessile, erect. Petals linear-lanceolate, upright, rather longer than the calyx. Leaves elliptic-lanceolate, acute, on very long footstalks.”—About the waters of the Koozkoozky. *Gov. Lewis*. Flowering in June. This singular species, whose flowers resemble those of the foregoing, has leaves very much like *Plantago major*. *Pursh*.

3. *T. pitium*. Purple-veined *Trillium*. Pursh n. 3. (*T. erythrocarpum*; Michaux Boreal.-Amer. v. 1. 216. “*T. undulatum*; Willd. Hort. Berol. v. 1. 55.”)—“Flower-stalk nearly upright. Petals elliptic-lanceolate, acute, recurved, nearly twice as long as the linear-lanceolate calyx. Leaves ovate, pointed; rounded at the base; abruptly stalked.”

TRILLIUM.

stalked."—In sphagnous bogs, on the high mountains of Pennsylvania, Carolina, and Canada, flowering in May and June. *Flowers* white, with purple veins at the bottom. *Berry* scarlet. *Pursh*. We received from the late Rev. Dr. Muhlenberg, in 1799, a specimen answering precisely to this description, but not at all to Willdenow's name of *undulatum*. The *leaves* are an inch and half long, taper-pointed, on short stalks. *Flower-stalk* half that length. *Petals* an inch long, white, with slender parallel veins, which are of a fine purple at the base, even in the dried specimen. *Anthers* purple. *Germen* and *style* yellowish-white.

4. *T. ovatum*. Ovate Trillium. Pursh n. 4.—"Flower-stalk erect. Petals oblong, acute, spreading, rather longer than the linear calyx. Leaves ovate, tapering to a point, quite sessile."—On the rapids of Columbia river. *Gov. Lewis*. Flowering in April. *Flowers* pale purple. *Pursh*.

5. *T. pumilum*. Blunt-leaved Trillium. Pursh n. 5. (*T. pusillum*; Michaux Boreal.-Amer. v. 1. 215.)—Flower-stalk erect. Petals scarcely longer than the calyx. Leaves oval-oblong, obtuse, sessile.—Native of the pine-woods of Lower Carolina, flowering in May. *Petals* pale flesh-coloured. *Michaux*. Specimens in the Linnæan herbarium, which answer well to this description, were most unaccountably confounded by Linnæus with his *sessile*. They are inscribed "*Trillium, sive Tradescantia affinis, flore odorato unico tripetalo, radice tuberosâ.*"—Clayton. The *stem* is slender, five or six inches high. *Leaves* an inch and a quarter, or an inch and a half, broad, of a rather narrow elliptical shape. *Flower* on a very short stalk; in one specimen nearly sessile. *Calyx-leaves* exactly like the foliage, but only a quarter the size. *Petals* with fine, copious, interbranching veins, becoming purplish as they advance in age.

6. *T. cernuum*. Drooping Trillium. Linn. Sp. Pl. 484. Willd. n. 1. Ait. n. 1. Pursh n. 6. Sm. Spicil. 3. t. 4. Curt. Mag. t. 954. (*Solanum triphyllum, flore hexapetalo carneo*; Catesb. Carol. v. 1. 45. t. 45, on the authority of the author's herbarium, though his figure gives no idea of the plant.)—Flower-stalk recurved. Petals lanceolate, the size and shape of the calyx-leaves, reflexed. Leaves rhomboid, abruptly pointed, on very short stalks.—In shady rocky situations, from Pennsylvania to Carolina, particularly on the banks of Schuylkill, near Philadelphia, flowering in May. *Petals* white. *Berries* purple. This may be called the largest of the genus, as I have often seen it near two feet high, with *leaves* measuring nine inches in diameter. *Pursh*. Our garden specimens are but one-third as large. The *flower* is perfectly reflexed. *Petals* white, with green ribs. *Anthers* and *styles* purple. *Germen* pale yellow, ovate, with six wings.

7. *T. erectum*. Upright-stalked Trillium. Linn. Sp. Pl. 484. Willd. n. 2. Ait. n. 2. Pursh n. 7, a. Curt. Mag. t. 470. (*T. rhomboideum*; Michaux Boreal.-Amer. v. 1. 215. Redout. Liliac. t. 134. *Solanum triphyllum canadense*; Cornut. Canad. 166. t. 167.)—Flower-stalk erect. Flower inclining. Petals elliptical, pointed, spreading, the length of the calyx. Leaves rhomboid, pointed, sessile.—On the mountains, in boggy soil, from Pennsylvania to Carolina, flowering in May. *Pursh*. The *leaves* are three or four inches long, and three broad at the obtuse lateral angles. *Flower-stalk* nearly three inches long, erect, except a little curve at the top, from the drooping of the *flower*, which is fetid, and larger than any of the foregoing species. *Calyx-leaves* an inch and quarter long, ovate, pointed, spreading, green. *Petals* the same length, but broader and

more elliptical, dark purplish-brown. *Germen* and *filaments* purple. *Berry*, according to Pursh, almost black. This is certainly *T. erectum* of Linnæus, though the specimen in his herbarium has no resemblance to it, having half a dozen *flower-stalks*, and not being an original specimen, nor of any authority. The specific name is not one of the best, there being several species equally erect, but *rhomboideum* is liable to the same objection. Had we found a better in any work of character, we might have been induced to swerve from our general rule of not changing established Linnæan names. We do not profess to be bound to keep any others, unless they are good.

8. *T. pendulum*. White Small-flowered Trillium.—"Willd. Hort. Berolin. t. 35." Ait. n. 3. Pursh n. 9? (*T. erectum* β ; Curt. Mag. t. 1027. Pursh n. 7.)—Flower-stalk erect. Flower inclining. Petals ovate, pointed, spreading, longer than the calyx. Leaves rhomboid, pointed, sessile.—Native of the mountains of Pennsylvania and Carolina. We received a specimen from Dr. Muhlenberg in 1805, the same year in which Mr. Masson sent plants to Kew. It flowers in April and May, and though nearly allied to the last, must surely be a distinct species. Every part is much smaller; the *leaves* more rhomboid; *flower* less strongly fetid than the *erectum*, with white *petals*, a reddish *germen*, and yellow *anthers* and *styles*. Mr. Pursh seems to have inserted this species twice; see his n. 7. and 9. We have not had an opportunity of consulting the *Hortus Berolinensis*, but we rely on Mr. Dryander in Hort. Kew.

9. *T. grandiflorum*. Large-flowered Trillium. Salis. Parad. t. 1. Pursh n. 10. Ait. n. 4. (*T. erythrocarpum*; Curt. Mag. t. 855, excluding Michaux's synonym. *T. rhomboideum* γ ; Michaux Boreal.-Amer. v. 1. 216.)—Flower and its stalk drooping. Petals ovate; their claws converging into a tube; limb spreading thrice as broad as the calyx, and much longer. Leaves ovate, somewhat rhomboid, pointed.—On the mountains and rocky banks of rivers, in Virginia and Carolina, flowering in May. We received a specimen in 1797 from the honourable Mrs. Barrington's garden at Mongewell, the root having been sent perhaps a year or two before from North America. Mr. Masson is said to have sent the same to Kew in 1799. This is a large and handsome species. The *petals* are snow-white, veiny, two inches long; their bases convoluted into a sort of tube. *Anthers* yellow. *Calyx-leaves* ovato-lanceolate, an inch and half long, green.

10. *T. obovatum*. Obovate Trillium. Pursh n. 8.—"Flower-stalk erect. Petals obovate, bluntish, flat, spreading, scarcely longer or broader than the calyx. Leaves ovate, rhomboid, pointed, perfectly sessile."—Found in Canada, near Montreal. *Flowers* dark rose-coloured, probably white when first opening. *Pursh*. This author mentions some specimens in the herbarium of A. B. Lambert, esq. agreeing in every respect herewith, which are the *T. camtschaticum* of Pallas. This perhaps is what Dr. Sims speaks of, under a similar name, in Curt. Mag. t. 855. We have not examined either.

TRILLIUM, in *Gardening*, furnishes plants of the low, tuberous-rooted, showery, perennial kind, among which the species mostly cultivated are, the drooping trillium (*T. cernuum*); the upright trillium (*T. erectum*); and the sessile-flowered trillium (*T. sessile*).

Method of Culture—These plants may be increased by seeds, which should be sown on a shady border as soon as they become ripe in the autumn; when they appear in the spring, the plants should be kept clean from weeds, and in the

the autumn following be planted out where they are to remain and flower.

They succeed best in light soils, where the situation is rather shaded.

They all afford variety in such places.

TRILLO, in *Geography*, a village of Spain, situated on a small river near its union with the Tagus, and once famous for its curious water-mills, for sawing of timber brought down by the stream, but no longer existing. It is now celebrated for its medicinal waters, efficacious in cutaneous complaints, both externally and internally applied. The baths are up the river, on the opposite side of the Tagus, about the distance of a mile. They are divided into "Los quatro Banos," called the king's bath, divided into four separate baths, all equally commodious and handsome, with their proper appurtenances. The countess's bath, so named after the lady of the count de Cifuentes, who is lord of the place, is close to the river, but judiciously built and remarkably solid, to resist every impulse of the stream. According to the analysis of Dr. Ortega, these waters participate of five substances, two volatile, and three fixed; viz. a phlogistic vapour, extremely anodyne, penetrating, and friendly to the nervous system; of a moderate quantity of gas, calcareous earth, common salt, selenitic salt; and that to sixteen ounces of water, one may calculate twenty-five grains and a half of fixed principle. Dr. Ortega observes, that the lightness of this water may enter into competition with that of distilled water, the purest we know of: therefore its effects may be more easily accounted for: that the heat of the water does not equal that of the blood, in a person in good health, and comes near to that tepid degree prescribed by the physicians in artificial baths.

TRILLO, Ital. a shake, in *Musick*. Tosi has devoted his third chapter (in Galliard's Translation, p. 41.) to the importance, use, and acquisition of a shake. He advises the vocal student, with the assistance of the master, to strive at attaining one that is "equal, distinctly marked, easy, and moderately quick, which are its most beautiful qualifications." The student will find the shake on the semitone or half-note much easier to acquire than that on the whole tone; which it will be necessary to practise first, and most frequently ever, as it includes the other. Tosi describes seven different kinds of shake, but none are worth the study but those on the tone and half-tone, which must at first be practised slow, and its rapidity increased by minute degrees.

The *beat*, or *trillo mordente*, differs little from the shake; in fact it is the shake reversed, ending upon the upper of two notes, instead of the lower. This grace was much used by singers in the former part of the last century, particularly in recitatives, and after the appoggiatura from the note below. Mingotti was the last great singer whom we remember to have frequently used the *trillo mordente*, or *beat*. Mancini, however, gave a chapter to it in 1774. But he was of the Bernacchi school, which would now be called *antica*.

TRILOBOUS LEAF, among *Botanists*. See LEAF.

TRILOCLAR CAPSULE. See CAPSULE.

TRILOKAN, in *Mythology*, a name of the Hindoo deity Siva. The name means with three eyes, that god being in some of his forms, and often in pictures and statues, so represented. Siva corresponds in many points with the many-named and multiform Jupiter of the Greeks. We are informed by Pausanias, that Triopthalmos was an epithet of Zeus, and that a statue of him with three eyes was found so early as the Trojan war. From these circumstances, combined with many others, Sir W. Jones was led

to conclude that the identity of Jove and Siva, falls little short of being demonstrated. See SIVA

TRILOPUS, in *Botany*, a name given by Mitchell to the Linnæan genus HAMAMELIS. See that article.

TRIM, in *Carpentry*, is to fit one piece into another.

TRIM of a Ship, is her best posture, proportion of ballast, arrangement of her sails, and position of her masts for sailing.

Thus, the trim of the hold denotes the most convenient arrangement of the various materials contained in it, with relation to the ship's motion or stability at sea.

Trim, when applied to the sails, denotes the general arrangement which is best calculated to accelerate the ship's course, according to the direction of the wind.

Trim, when expressed of the masts, denotes their position with regard to the ship and to each other, so that they should not be too far forward or aft, nor too near nor too far apart: and, according to the situation or quality which communicates a greater velocity to the vessel, they should either be upright, or inclining aft or forward.

Hence, to find the best way of making a ship sail swiftly, is to find her trim.

TRIM a Boat, To, is to set the passengers so as to keep the boat even on both sides. See BOAT.

TRIM the Sails, To. See TACK.

TRIMMED, Sharp, in *Sea Language*, denotes the situation of a ship's sails in a scant wind.

TRIM, in *Geography*, the shire-town of the county of Meath, Ireland, situated on the river Bayne. Though the shire-town, it is a place of no importance, but it was formerly walled and defended by a strong castle, and it has some ruins of religious foundations. Before the Union, it was represented in parliament. It is 22½ miles N.W. by W. from Dublin.

TRIMACRUS, or TRIMACER, in the *Ancient Profody*, a foot in verse, consisting of three long syllables.

TRIMALORE, in *Geography*, a town of Hindoostan, in the Carnatic; 15 miles N. of Tanjore.

TRIMANETORE, a town of Hindoostan, in the Carnatic; 15 miles E. of Warriore.

TRIMAPORE, a town of Hindoostan, in Marawar; 9 miles N. of Trumian.

TRIMARKISIA, in the *Manege and War*, a body of horse among the ancient Gauls, so called because each soldier had three horses attending him, so that when one was either killed in battle, or overcome by fatigue, he might immediately mount another. The Tartars of the Krim retain the practice; for they never undertake an excursion, without allowing three horses to one rider; and many ancient nations, beside the Gauls, observed the same method.

TRIMBERG, or TRIMPERG, in *Geography*, a town of the duchy of Wurzburg; 20 miles E. of Schweinfurt.

TRIMBUCK, a town of Hindoostan, in Baglana; 18 miles W.N.W. of Naffuck.

TRIMELES, in the *Ancient Greek Music*, a nome or air for flutes.

TRIMELWADY, in *Geography*, a town of Hindoostan, in the Carnatic; 15 miles N.N.W. of Tanjore.

TRIMERES, in the *Ancient Greek Music*, a nome which was executed in three different modes successively: the Phrygian, the Dorian, and the Lydian. Some ascribe the invention of this compound nome to Saccadas the Argian, and others to Clonas of Thegea.

TRIMILCHI, a name by which the English Saxons called the month of May; because they always milked their cattle three times a day in that month.

TRIMITHUS, in *Ancient Geography*, a town in the eastern part of Cyprus, at some distance from the coasts, N. of Eucolla, and E. of the promontory Pedalium.

TRIMMANIUM, or TRIAMAMMION, a town of Lower Mœsia, on the Danube; marked in Anton. Itin. on the route from Viminacium to Nicomedia, between Scaidana and Exantaprittis.

TRIMMERS, in *Architecture*, pieces of timber framed at right angles to the joints, against the ways for chimneys, and well-holes for stairs.

TRIMODIA, among the Romans, a bag like an inverted cone, in which fowls carried their feed. It was suspended from their neck, and was so called from its containing three bushels.

TRIMONEER, a corruption of *timoneer*.

TRIMONTIUM, or TRIMANTIUM, in *Ancient Geography*, a town of Albion, belonging to the Selgovæ, according to Ptolemy; probably situated where Annan now stands.—Also, one of the names of Philippopolis in Thrace. Ptol.

TRIMPEN, in *Geography*, a town of Prussia, in Bartenland; 12 miles S. of Insterburg.

TRIMURTI, in the theological disquisitions of the Hindoos, is a word of mystical and varied import. Its most obvious meaning in the Sanscrit tongue is *three forms*; but as some sects of Eastern theologians profess to recognize the unity of the deity, the term is used singularly, and is equivalent to *triform*. In the Trimurti, the Hindoos fancy a union or reunion of the three great powers or attributes of the godhead, personified in Brahma, Vishnu, and Siva; or creation, preservation, and destruction. Many other triune conjunctions are found typified by this mysterious assemblage, of which some notice is taken under our articles O'M, SIVA, and TRISULA.

The Trimurti, or divine triad, is represented to the senses under the form of three heads joined. The well-known monstrous sculpture in the Elephanta cavern temple is of this subject. Of this triune bust, Niebuhr, Maurice, and others have given representations. (See ELEPHANTA and MAHAKALA.) One very like it was dug out of the ruins of an ancient temple on the island of Bombay, by the author of the Hindoo Pantheon, and an engraving is given of it in plate 81. of that work. A second Trimurti was found at the same time, but instead of being merely three heads, they are furnished with a body. This unusual form is also engraved for the work just mentioned; and the granite originals of both plates are deposited by the author in the museum at the East India House. The *miniature* bust of the gigantic sculpture in the Elephanta cave is so large as to weigh several tons. The Hindoos have other modes of representing the Trimurti; three heads and bodies on one leg, and other similar whimsicalities, not unlike the crude delineations of the early Trinitarians of the West.

The Hindoos are very prone to combinations of three in one, and fancy they see something very mysterious in such typifications. As well as that just noticed of the powers or attributes of the deity, they combine three letters in a monogram, and have such a reverence for it, that the sound which its articulation would convey is never uttered, or uttered most reverentially. These characters are equivalent to our A, U, M, and the sound would be like O'M.

The sun is a Trimurti, his properties of *creative* heat, *preserving* light, and *destructive* energy in an igneous form, comprehending the grand attributes of the deity, personified in Brahma, Vishnu, and Siva.

The Hindoos have a female Trimurti, composed of course of the consorts or Saktis, or energies of the great

powers. These are *Saraswati*, *Lakshmi*, and *Parvati*; which see.

Comparing the Hindoo triad with three of the gods of Greece, Cronus, Jupiter, and Mars, are those nearest in character and attributes to the Eastern polytheistic trinity. But the Greeks, largely as they seem to have borrowed from the mythology of the Hindoos, do not appear to have popularly adopted their male Trimurti. The female triad may be recognizable in the Paræ of the West, as noticed under SAKTI. The three goddesses give each a name to a sacred river, and a supposed junction of these waters is a fruitful subject to the Hindoo enthusiast or poet. See TRIVENI and SARASWATI.

Several other articles beginning with the Sanscrit word *tri*, contain something illustrative of the propensity of the Hindoos to triune combinations.

TRINACIA, or TRINACRIA, in *Ancient Geography*, a rich and powerful town of Sicily, and considered as the chief town of the island. Some writers have called it Tiracia.

TRINCA, in *Geography*, a town of South America, in the province of Tucuman; 66 miles N. of St. Miguel de Tucuman.

TRINCATTY, one of the Nicobar islands. N. lat. 8° 6'. E. long. 94° 5'.

TRINCAVELLI, VETTOR, in *Biography*, an eminent physician, was born at Venice about 1491. He studied at Bologna and Padua; and having graduated at the latter university, he settled at Venice, where he became professor of philosophy, and acquired distinction in the practice of medicine. In 1551 he was promoted to the chair of medical professor at Padua, with a very considerable stipend. He died at Venice in 1563, and was honoured with a public funeral. He was a good Greek scholar, and was the first professor at Padua who commented on the works of Hippocrates in the originals. He also translated many of Galen's treatises; and edited in the original Greek the works of Themistius, of Johannes Grammaticus, the Manual of Epictetus with Arrian's Commentary, Arrian's Alexander's Expedition, Stobæus, Hesiod, and other Greek writers. A collection of his works has been printed in 2 vols. fol. Haller. Gen. Biog.

TRINCIATELLA, in *Botany*, Ambros. Phyt. 543. Camer. Hort. Med. 173. See THIRINCIA.

TRINCOLI, in *Geography*, a town of the island of Ceylon, near the E. coast; 84 miles E.S.E. of Candy. N. lat. 7° 10'. E. long. 82° 6'.

TRINCOMALEE, or TRINCOMALEY, a town and harbour of Ceylon, lying in N. lat. 8° 30'. E. long. 81° 24'. The town runs in a N.E. direction along one branch of the bay. The country around it is mountainous and woody; the soil uncultivated and barren; and the whole appearance wild. The woods, which are very thick, contain abundance of wild beasts of various descriptions; particularly wild hogs, buffaloes, and elephants. The latter often come down to the lakes in the neighbourhood of the fort to drink and bathe; and have been frequently shot within a mile of the town. Trincomalee, from its situation and construction, is naturally strong. It occupies more ground than Colombo, but contains a much smaller number of houses, and those inferior in size and appearance to any that are met with in several towns on the S.W. coast. The circumference of Trincomalee, within the walls, is about three miles; within this space is also included a hill, or rising point, immediately over the sea, and covered with a great quantity of thick jungle, in which wild deer and other game find shelter. This rising ground is very little inhabited,

most of the houses being close to the landing place, which lies in the lowest part. Even the lower parts of the fort were much incumbered with wood till within these few years. The fort is strong, and commands the principal bays, and particularly the entrance into the grand harbour, or inner bay, which affords in all seasons and in every variety of weather a secure shelter to ships of all descriptions, being land-locked on all sides, and sufficiently deep and capacious to receive the largest vessel, or any number of vessels. The whole navy of England might find accommodation in this harbour. Its situation is such, that in either monsoon, ships can arrive at or depart from it, and make their passage good from or to any part of the eastern world, and whole fleets may remain within it, at every season of the year, in perfect security. This harbour is overlooked by fort Ostenburg, a strong fort standing on a cliff, which projects into the sea; it was originally built by the Portuguese out of the ruins of some celebrated pagodas which once stood here. This fort cannot be attacked by sea, unless the fort of Trincomalee be first taken, and the entrance of the harbour forced. In the bay the shores are so bold, and the water so deep close up to them, that it is almost possible to step from the rocks into the vessels that moor alongside of them. At the extremity of the rock, on which the fort stands, a strong battery is erected, where the flag-staff of the fort is placed.

This harbour, from its nature and situation, is that which stamps Ceylon one of our most valuable acquisitions in the East Indies. As soon as the violent monsoons commence, every vessel which is caught by them in any other part of the bay of Bengal is obliged immediately to put to sea, to prevent inevitable destruction. At these seasons Trincomalee and Bombay alone, of all the ports on the different coasts of the peninsula of India, are capable of affording a safe retreat. The incalculable advantages to be derived from such a harbour are increased by its proximity and easy access to our settlements in the bay of Bengal. A vessel from Madras may arrive here in two days, and can at any time enter the harbour. These circumstances point out Trincomalee as an object of particular attention to our government, and of far more consequence to retain than the whole of the rest of the island. It will, however, require great encouragement and many improvements to render the town populous or anywise equal to Colombo. For the country around is not by any means so fertile as to tempt settlers to reside there; nor are the natural productions calculated to attract commerce. The climate has also been looked upon as the hottest and most unhealthy of the whole island. But the woods and marshes which rendered the climate insalubrious have been already in great measure cleared and drained, and the beneficial effects of these improvements were soon experienced. It is to be hoped that remedies may in the same manner be applied to the other defects under which Trincomalee at present labours: its trade is nothing, as there are no valuable natural productions to nourish it; but, from its situation, it is capable of becoming the richest emporium of the East. The want of commerce, and the uncultivated state of the surrounding country, are defects which flow mutually from each other; and the removal of one would soon, in a great measure, do away the other.

The Malivagonga (which see) falls into the magnificent bay of Trincomalee. (Percival's Ceylon.) This harbour, says Barrow (Travels in Southern Africa, vol. ii.), is to a maritime province a jewel of inestimable value; it holds the bay of Bengal at its mercy, and affords every facility of overawing and controuling the navigation of the straits of Sunda and Malacca. Our Asiatic possessions, commerce

and marine, would consequently lie open to the depredations of the masters of Ceylon. Trincomalee was taken by the British troops in 1795; 70 miles N.E. of Candy.

TRINDELEN, a rock in the Scaggerac, at about equal distances between the coast of North Jutland and the coast of Norway; 7 miles N.N.E. from the island of Lessoe. N. lat. $67^{\circ} 27'$. E. long. $11^{\circ} 1'$.

TRINE, DIMENSION, or *threefold dimension*, includes length, breadth, and thickness.

The trine dimension is peculiar to bodies or solids.

TRINE, in *Astronomy*, is the aspect or situation of one star with regard to another, when they are distant 120 degrees.

It is also called *trigon*, and is usually signified by the character Δ .

TRINE, in *Rural Economy*, a term applied to the quantities of some sorts of articles, as the felines and spokes of wheels, which of the former is thirteen, and of the latter twenty-five.

TRINETRA, in *Mythology*, a name of the Hindoo god Siva. It means with three eyes, similar to *Trilokan*; which see.

TRING, in *Geography*, a small market-town in the hundred of Dacorum, and county of Hertford, England; is situated within a short distance of the Icknield way, 30 miles W. by N. from the county-town, and 31 N.W. by W. from London. The manor was granted by William the Conqueror to Robert, earl of Ewe, but it soon afterwards reverted to the crown; and in the year 1148 was given by king Stephen, with all its appurtenances, to the abbey of Feversham, which he had then founded. His grant was confirmed to the monks by succeeding sovereigns; and Edward II. gave them a charter for a weekly market, and two annual fairs to be held at Tring. After the dissolution, Henry VIII. granted the manor to the archbishop of Canterbury: it is now the property of sir Drummond Smith, bart. The parish church of Tring is a spacious, well-proportioned edifice, and consists of a nave, side aisles, and chancel, with a massive tower at the west end: the walls are supported by strong buttresses, and the whole is embattled. The nave is separated from the aisles by six pointed arches, rising from high clustered columns. The roof is of timber frame-work, with strong beams going across: the supporters on each side are terminated by carved figures. Most of the windows have obtuse pointed arches, and are divided into three compartments by mullions. In the interior are various monuments. Tring contains four meeting-houses for Dissenters of different denominations. A Sunday school for about eighty boys and girls has been established by subscription. The market-house is a mean edifice on wooden pillars, having a pillory and a cage beneath. The market is held on Fridays; principally for the sale of corn, meat, and straw-plat: the manufacture of the latter constitutes the employment of most of the females in this part of the country. Five fairs are now held annually. The population of Tring, as ascertained under the act of the year 1811, was 1847, occupying 352 houses.

Tring park, the seat of sir Drummond Smith, bart. consists of between three and four hundred acres, ranging on the S.E. side of the town. The mansion is large and convenient, and the principal apartments are spacious and neatly fitted up. The hall is ornamented with Corinthian pillars. On the floor above the hall, and running across the house, is a gallery or ball-room, with a circular dome in the centre. This house was erected about the time of Charles II. by Henry Guy, esq.

At a short distance N.E. from Tring, is Tring Grove, the

the residence of — Broadwood, esq. — Beauties of England and Wales, vol. vii. Hertfordshire, by E. W. Brayley.

TRINGA, SAND-PIPER, in *Ornithology*, the name of a distinct genus of birds, of the order of the Grallæ; the distinguishing characters of which are, that the beak is roundish, and of the length of the head; the nostrils linear; and that the feet have each four toes, the outmost being generally connected at bottom by a small membrane. The species are numerous, and as follow.

PUGNAX. With red bill and legs; three lateral tail-feathers unspotted, and face granulated with fleshy papillæ. See **RUFFE**.

VANELLUS. With red legs, dependent crest, and black breast. This is the lapwing or bastard plover of Ray, Willughby, Pennant, &c. See **LAPWING**.

GAMBETTA. With red bill and feet; body variegated with yellow and cinereous; beneath white. This is the totanus ruber of Brisson, the totanus alter of Willughby and Ray, and gambet of Pennant and Latham.

INTERPRES. With red legs; black body, varied with white and ferruginous; and white breast and abdomen. This is the arenaria of Brisson, the Hebridal sand-piper of Pennant, the turnstone or sea-dotterel of Ray, Willughby, Latham, &c. See **TURNSTONE**.

The *Morinella*, or tringa with red feet, blackish tail-feathers, white at the base, grey body, and black breast; or arenaria cinerea of Brisson, is a variety.

STRIATA. With base of bill and legs red; tail-feathers white with bands of brown, and many white tail-feathers. This is the totanus striatus of Brisson, and striated sand-piper of Pennant, &c. The totanus nævius of Brisson is a variety.

BONONIENSIS. With ochraceous legs; long head and neck; body above black, and beneath white; throat and breast marked with ferruginous spots. The greater lapwing of Latham.

MACULARIS. With base of bill and legs incarnated; body spotted; eye-brows and double band of the wings white. This is the turdus aquaticus of Brisson, the spotted tringa of Edwards, and the spotted sand-piper of Pennant.

LOBATA. With subulate bill, bent at the apex; pinnated legs, and white undulated breast: the grey coot-footed tringa of Edwards, and grey phalarope of Pennant and Latham. Of this there is a variety, white beneath, black above, with yellowish longitudinal streaks; the band of the wings white; and legs lobated.

HYPERBOREA. With subulate bill, bent at the apex; pinnated legs; cinereous breast, and sides of the neck ferruginous: the cock coot-footed tringa of Edwards, the small cloven-footed gull of Willughby, and red phalarope of Pennant and Latham.

ERYTHROPUS. With red legs, front, rump and tail red and white; the body above and wings cinereous-brown; the abdomen ferruginous: the red-legged sand-piper of Latham.

ALPINA. Testaceous-brown, with blackish breast; tail-feathers cinereous, whitish; legs brownish.

HELVETICA. With black bill and legs; beneath black; white vent; tail-feathers white with black bands: the Swiss sand-piper of Pennant.

OCROPHUS. With the apex of the bill pointed; legs greenish; back brown and green; abdomen and outermost tail-feathers white: the cinclus tertius of Aldr., Ray, and Will., the ocrophus medius of Gesner, and green sand-piper of Pennant and Latham. Of this there is a variety, viz. *Littorea*, with smooth bill, cinereous legs, and brown

tail-feathers: the shore sand-piper of Pennant; and also another variety, with the back and wings cinereous, with obsolete whitish spots.

HYPOLEUCOS. With smooth bill; livid legs; body cinereous with black streaks; beneath white: the common sand-piper of Ray, Willughby, and Pennant.

CANUTUS. With smooth bill; cinereous legs; first tail-feathers ferrated; and the outer white unspotted. This is the knot of Pennant, &c. See **KNOT**.

ARENARIA. With black bill and legs; grey body; under and whole face white; collars grey.

FASCIATA. With bill, vertex, hind part of the head, spot near the eyes, and abdomen, black; front and rounded tail white; back cinereous; seven first tail-feathers white.

CINCLUS. With bill and legs black; collars white; tail and rump grey and brown. This is the least snipe of Ray and Sloane, the wagtail of Brown, the fanderling of Albinus, and the purre of Pennant. The cinclus with brown legs is a variety.

CALIDRIS. With bill and legs blackish; body beneath olivaceous; and rump variegated: the dusky sand-piper of Latham.

PUSILLA. With brown bill and legs; body beneath reddish; outer tail-feathers with a white shaft, and variegated rump: the little sand-piper of Pennant; found in St. Domingo, north of Europe, and rarely in England.

GLAREOLA. With smooth bill; greenish legs; body punctated brown and white; breast whitish: the wood sand-piper of Pennant and Latham; found in Sweden.

RUFICOLLIS. With black legs; head above and neck striated with ferruginous and black; and ferruginous throat: the red-necked purre of Latham.

SQUATAROLA. With black bill; greenish legs; grey body, beneath whitish: the grey plover of Ray, &c. and grey sand-piper of Pennant and Latham. Of this there is a variety, with black bill and legs; body brown, variegated with white; tail-feathers white with brown bands.

ISLANDICA. With brown bill and legs; body beneath ferruginous; secondary tail-feather with a white margin: the red sand-piper of Pennant.

CINEREA. Cinereous; beneath white; legs obscurely green; head with black spots; neck obscurely variegated: the ash-coloured sand-piper of Pennant and Latham.

ATRA. With black head and neck; back and wings brownish, mixed with black; breast and abdomen cinereous; rump cinereous, undulated with white and black.

NOVEBORACENSIS. Obscure, beneath white; breast spotted with brown; tail cinereous: New York sand-piper of Pennant and Latham.

VIRGATA. Obscure, beneath white; with yellowish legs; head and neck obscurely striated lengthwise with white: streaked sand-piper of Latham.

BOREALIS. With brown bill and legs; body above cinereous, beneath white; tail and tail-feathers obscure.

NOVÆ-FERRÆ. Above black, beneath ash-white; bill, spurious wings, tail-feathers, and tail, black; with cinereous legs: Newfoundland sand-piper of Latham.

VARIEGATA. Above varied with brown, black, and red; front and throat pale; neck and breast streaked with whitish and black longitudinally; abdomen white; bill and legs obscure: variegated sand-piper of Latham.

GLACIALIS. With pinnated yellowish legs; apex of black bill dilated; cheeks and throat testaceous; body above obscure, beneath white: plain phalarope of Pennant.

FUSCA. With bill, vertex, and legs pinnated and black; body above brownish and cinereous, beneath white; throat

cinereous, tinged with red: the coot-footed tringa of Edwards, and brown phalarope of Pennant and Latham.

CANCELLATUS. With upper feathers brown, white at the margin; lower white lined transversely obscurely; pinnated legs obscure.

EUCOPTERA. Black, beneath red, with cinereous bill, green legs, and yellow vent: the white-winged sand-piper of Latham.

MARITIMA. Above varied with grey and white; beneath white, with yellow legs; middle of the back violet; throat and tail obscure: the fulviger sand-piper of Latham.

UNDATA. Obscure, undulated with yellow and white; the rump, the tip of the secondary tail-feathers, and wing-coverts, white; tail cinereous, white at the apex: the waved sand-piper of Pennant and Latham.

UNIFORMIS. Wholly dilutely cinereous, with a short black bill: uniform sand-piper of Pennant and Latham.

AUSTRALIS. Above cinereous, spotted brown; beneath reddish; abdomen and rump whitish; tail and tail-feathers obscure; bill and legs black: southern sand-piper of Latham.

NÆVIA. With obscure bill; legs greenish; body above cinereous, spotted with red and black; beneath reddish and white, spotted with obscure or bay: the freckled sand-piper of Pennant and Latham.

GRISEA. With black bill and legs; body above grey, beneath white; primary tail-feathers brown; tail grey and white at the margin; a band obscurely grey parallel to the margin: the grided sand-piper of Latham.

KEPTUSCHCA. With cinereous body; black vertex; abdomen blackish, terminating reddish.

TRINGAN, in *Geography.* See **TRANGANO.**

TRINGENSTEIN, a town of Germany, in the principality of Nassau Dillenburg; 6 miles E. of Dillenburg.

TRINGLE, in *Architecture,* a name common to several little square members, or ornaments; as reglets, listels, and platbands.

The word is French, where it signifies the fame.

TRINGLE is more particularly used for a little member fixed exactly over every triglyph, under the platband of the architrave; from whence hang down the guttæ, or pendant drops.

TRINIDAD, in *Geography,* a town of South America, in New Granada; 20 miles N.W. of Santa Fè.

TRINIDAD, an island near the coast of South America, about thirty leagues long, and from two to ten broad. This island was discovered by Columbus in his third voyage, who landed here in 1498, and was named by him after the Holy Trinity; because, says Herrera, having been in great danger in a violent storm, he made a vow to give that name to the first land he should find: soon after which a sailor, in the main-top, saw three points of land, by which the name was in every respect suitable to his vow. The original inhabitants were a colony of *Arrowauks*; which see. The climate is said by some to be unwholesome; the island being very often covered with thick fogs. The abbé Raynal says that it is excellent, being free from hurricanes. Heavy rains fall from the middle of May to the end of October. It is subject to slight earthquakes, and in the interior are four groups of mountains. The quality of its soil is variously reported; however, sir Walter Raleigh, who was there some time in the year 1593, and examined the island, gives an account, that the northern part of it is high land; but that its soil is good, proper for planting of sugar-canes, tobacco, &c. The southern coast is well adapted to the culture of coffee; and on the west is a large harbour, secure

in all seasons. Here are several sorts of animals, plenty of wild hogs, fish, fowl, and fruit. It also produces maize, cassava, and other roots, and in general all that is commonly found in America. The Spaniards owned to sir Walter, that they found gold in the rivers of this island, but nothing in comparison of what the main land produces. The natives called this island "Cairi;" but they themselves had different names, according to the different parts of the island where they dwelt. In 1797, it was taken by the British troops; and by the peace of Amiens, the island was ceded to Great Britain. The island of Tobago is separated from Trinidad by a channel called "Trinidad Channel." This island, situated at the eastern extremity of Terra Firma, from which it is only four leagues distant, is the natural magazine and resort where the contraband traders of Cumana, Barcelona, Margareta, and Guiana, make their purchases. The position of the island is singularly favourable to this commerce. The Spanish coasts, extensive, solitary, defenceless, and to leeward, offer both to the English and Spaniards the greatest facility for prosecuting it. The gulf of Paria, which washes the western part of Trinidad, receives the waters of the river Guarapiche, which penetrates the province of Cumana. By this river animals for labour and for the shambles are brought from Terra Firma to Trinidad; and through the same channel all the contraband articles consumed in this province can ascend with perfect convenience, or may be landed at several points without the least danger. In general, the cargoes which are destined for Barcelona proceed up this river: they are thence distributed to Caraccas and other cities. The mouths of the Oronoko, which cross the gulf of Paria from south and north, and which are compelled by Trinidad to discharge into the sea by the dragon mouths, open to this island the commerce of Guiana, whither the surplus goes by the river Apure to Barquisimeto, Truxillo, Varinas, Merida, &c. Dr. Anderson has given a particular account of a remarkable phenomenon in this island, which is a bituminous lake, or rather plain, denominated Tar-lake, and by the French La Brea, from its resemblance to ship-pitch, and from its answering a similar intention. It lies on the leeward side of the island, on a point of land extending into the sea about two miles, and opposite to the high mountains of Paria on the north side of the gulf. The headland, or cape, is about 50 feet above the level of the sea, and is the greatest elevation on this side of the island. From the sea it appears a mass of black vitrified rocks; but on closer examination, it is found to be a composition of bituminous scoria, vitrified sand, and earth, cemented together: in some parts, beds of cinders only are found. In approaching this cape, there is a strong sulphureous smell, sometimes disagreeable. This smell is prevalent in many parts of the ground to the distance of eight or ten miles from it. The point of land is about two miles, and falls with a declivity to the sea, the bituminous plain being on the highest part of it, and separated from the sea by a margin of wood which surrounds it. It appears at first like a lake of water; and in hot and dry weather its surface, about an inch deep, is liquid, whence it obtained the appellation of lake. Its form is circular, about three miles in circumference. Its more common consistence and appearance are those of pit-coal, the colour being rather greyer. No appearance of sulphur is discernible, though, in passing over it, a strong sulphureous smell was experienced. Dr. Anderson apprehended that this bituminous substance is the bitumen asphaltum of Linnæus. By a gentle heat it was rendered ductile; and mixed with grease or common pitch, it is much used for the bottoms of ships; and he conceives it to be a preservative against the insect called the borer, so destructive

destructive to ships in that part of the world. Every part of the country, he says, to the distance of 30 miles round, has the appearance of being formed by convulsions of nature from subterraneous fires; and the whole island, he thinks, is formed of an argillaceous earth, either in its primitive state, or under its different metamorphoses. This argillaceous earth is formed, as he conceives, from the sediment of the ocean, and its formation is easily accounted for from the situation of Trinidad. The great influx of currents into the gulf of Paria, from the coasts of Brasil and Andalusia, must bring down a vast quantity of light earthy particles from the mouths of the numerous large rivers which traverse those parts of the continent; but the currents being repelled by the sides of adjacent mountains, eddies and smooth water will be produced when they meet and oppose one another; and, therefore, the earthy particles would subside, and form banks of mud, and by the accession of fresh accumulations form dry land; and thus such a tract of country as Trinidad must be formed. The causes still operate, for the island is daily increasing on the leeward side, as is visible in the mud-beds that extend a great way into the gulf, and are there constantly augmented. But from the great influx from the ocean at the south end of the island, and its egress to the Atlantic again through the Bocas, a channel must ever exist between the continent and Trinidad. N. lat. $9^{\circ} 48'$ to $10^{\circ} 42'$. W. long. $60^{\circ} 6'$ to $61^{\circ} 36'$.

TRINIDAD, *La*, a town of South America, in the province of Moxes; 200 miles N.E. of La Plata. S. lat. $14^{\circ} 40'$. W. long. $65^{\circ} 50'$.

TRINIDAD, a sea-port town of the island of Cuba; situated in a bay on the south coast of the Havannah. N. lat. $51^{\circ} 56'$. W. long. $80^{\circ} 18'$.

TRINIDAD, *La*, or *Sonfonate*, a sea-port town of Mexico, in the province of Guatimala; 80 miles E.S.E. of Guatimala. N. lat. $14^{\circ} 3'$. W. long. $91^{\circ} 6'$.

TRINIDAD, *La*, a town of Mexico, in the province of Veragua, on a river which runs into the gulf of Mexico; 18 miles S.E. of La Concepcion.

TRINIDAD, *La*, a town of Mexico, in the province of Nicaragua, on the east coast of Nicaragua lake; 30 miles N.W. of St. Carlos.

TRINIDAD, a town of South America, in the province of Paraguay; 170 miles S.E. of Assumption.

TRINIDAD, a small island in the South Atlantic ocean, and one of those called "Martin Vas's Islands;" taken possession of by the Portuguese about the year 1783, who keep a small garrison here, but, according to M. Perouse, ill furnished. This island presents nothing to the eye but a rock, almost entirely sterile. A little verdure, and a few shrubs, are alone to be seen in the narrow passes between the mountains. It is in one of those vallies situated in the south-east quarter of the island, and about three hundred toises wide, that the Portuguese have formed their establishment. Nature certainly did not intend this rock to be inhabited: neither men nor animals being able to find a subsistence upon it; but the Portuguese were afraid lest some European nation should avail themselves of the vicinage, and carry on a contraband trade with the Brasils. S. lat. $20^{\circ} 31'$. W. long. of the south point $26^{\circ} 37'$.

TRINIDAD Bay, a small open bay or cove on the west coast of North America. N. lat. $41^{\circ} 3'$. E. long. $236^{\circ} 6'$.

TRINITARIANS, a term used very variously, and arbitrarily: frequently it stands as a common name for all persons who have sentiments on the mystery of the Trinity, different from those of the Catholic church.

Sometimes it is more immediately restrained to some one or other particular class of such persons.

It is now applied to the orthodox themselves, in contradistinction to the others who are then called *Antitrinitarians*, or *Unitarians*, who deny or impugn the doctrine of the Trinity.

Thus the Socinians and others called the Athanasians, *Trinitarians*.

The Trinitarians of the present age, and especially those who, in England, have written on the subject of the Trinity, are far from being agreed in their opinions, and, therefore, ought to be classed very differently from one another.
