Vines will grow in almost any sort of soil, but succeed the most perfectly in those of the good dry, loamy kind, and where there is a mixture of calcareous materials, or in those of other qualities which are dry and rich. However, where the land is of a wet retentive nature, or of the strong, stiff, clayey quality, it is quite improper for the growing of these kinds of plants, as though they may luxuriate strongly, they will produce an ill-flavoured fruit; and the notion of many gardeners of placing a layer or bed of stones, bricks, lime rubbish, or other similar materials, below their roots, in the view of checking their downward direction, and the over-luxuriance of the plants, thereby rendering them more fruitful, and promoting the ripening and flavour, though it may, in some measure, answer the purpose in particular instances, it is liable to stunt the growth of the trees, and cause the fruit to be small and of little value.

It is further remarked, that the best manure for vines is a mixture of vegetable mould, rotten spit-dung, and fresh loam (turf and all); this should be thrown in a heap, and frequently turned, for a year or two before it is made use of.

In regard to the proper situations for vines, they should constantly have a southern exposure as full to the influence of the sun as possible, never varying from the full south, or a very little to the south-west, as in this climate, this is necessary in order to the ripening and flavour of the fruit. In gardens they are usually trained against walls, or other erections of a similar nature; but in vineyards and other open places, against treillages, stakes, and other similar works, formed in rows on the south sides of them, where possible, choosing a rising ground for the purpose.

For final planting out in these situations, ready-raised plants of two, three, or more years' growth, procured in some of the above modes, are mostly used, being transplanted from the nursery. But in order to form bearers as soon as possible, ready-raised plants of the different varieties may be had at the public nursery-grounds in general, of a proper plantable size, and for immediate bearing, either in good-rooted plants in the full ground, or in pots fit for being planted out with balls of earth about them.

The proper season for performing the work of planting them out is the early autumn, or the very early spring months. The business should be done according to the nature and height of the material against which they are to be trained, in regard to the distance, and other circumstances: those against espaliers and stakes may be planted either together or in mixture with other kinds of fruit-trees,

in rows ten or twelve feet apart, choosing warm dry sandy situations: in all the cases setting the earth about the roots by proper watering.

In all the different sorts of vines, the fruit is produced on the young shoots of the same year, which arise directly from the eyes or buds of those shoots which were afforded in the former year. This is a matter of importance, and deserves much attention in the work of pruning.

Methods of Pruning and Training Vines.—In the management of the vines, after being thus raised and trained, as they rarely produce any bearing shoots from wood that is more than one year old, care should be taken to have such wood in every part of the trees; for the fruit is always produced upon the shoots of the same year, which come out from buds of the last year's wood, as has been already seen. The method practised by gardeners is to shorten the branches of the former year's growth down to three or four eyes at the time of pruning; though some leave these shoots much longer, and think that by this practice they obtain a greater quantity of fruit: but what is gained in quantity is probably lost in quality; therefore the best method is perhaps to shorten the bearing shoots to about four eyes in length, as the lowermost seldom is good, and three buds are sufficient, as each will produce a shoot, which generally has two or three bunches of grapes; so that from each of those shoots there may be expected six or eight bunches, which is a sufficient quantity. These shoots must be laid in about eighteen inches asunder, as where they are closer, when the side-shoots are produced, there will not be room enough to train them against the wall, which should always be provided for; and as their leaves are very large, the branches should be left at a proportionable distance from each other, that they may not crowd or shade the fruit too much.

In the winter pruning of the vines, it is advised to make the cut just above the eye, sloping it backward from it, that if it should bleed, the sap may not flow upon the bud; and where there is an opportunity of cutting down some young shoots to two eyes, in order to produce vigorous shoots for the next year's bearing, it should always be done, as in stopping of those shoots which have fruit upon them as soon as the grapes are formed, which is frequently practised, it often spoils the eyes for producing bearing branches the following year. The usual season for this pruning is the end of October. But about the end of April, or the beginning of the following month, when the vines begin to shoot, they should be carefully looked over, rubbing off all small buds which may come from the old wood, which only produce weak dangling branches; as also when two shoots are produced from the same bud, the weakest of them should be displaced, which will cause the others to be stronger; and the sooner this is done the better. And in the middle of the last month they should be gone over again, rubbing off and displacing all the dangling shoots as before, and at the same time fastening up all the strong branches, so that they may not hang from the wall; for if their shoots hang down, their leaves will be turned with their upper surfaces the wrong way, and when the shoots are afterwards trained upright, they will have their under surface upward; and until the leaves are turned again, and have taken their right position, the fruit will not thrive; so that the not observing this management will cause the grapes to be a fortnight or three weeks later before they ripen; besides, by suffering the fruit to hang from the wall, and be shaded with the closeness of the branches, it is generally retarded in its growth; therefore, during the growing season you should constantly look over the vines, displacing all dangling

branches and wild wood, and fasten up the other shoots regularly to the wall; and towards the middle of June the bearing branches should be stopped, which will improve the fruit, in doing which three eyes should always be left above the bunches. But though this is practised on those shoots which have fruit, it is not to be performed upon those which are intended for bearing the next year, as these must not be stopped until the middle of July, as by stopping them too soon, it may cause the eyes to shoot out strong lateral branches, and in that way injure them. In the summer season care should be taken to rub off all dangling branches, and train up the shoots regularly to the wall as before, which greatly accelerates the growth of the fruit, and admits the sun and air more freely to them, which is necessary to ripen and give the fruit a rich flavour; but the branches should not be too much divested of their leaves, as is the practice with some.

A late writer, Mr. Forfyth, has, however, attempted another mode of pruning and training vines, from trials made on vines planted against the piers of a fourth wall, among peaches, nectarines, and plums, &c. in which the fruit was so small and hard as to be unfit for the table. They had been trained upright, which induced such a luxuriance of growth, as made the sap to flow into the branches in the place of the fruit. He consequently let, it is remarked, in 1789, two strong branches grow to their full length without topping them in the summer, and in the following year trained them in a serpentine form, leaving about thirty eyes on each shoot, which produced one hundred and twenty fine bunches of grapes, weighing from one pound to a pound and a quarter each. Every one that saw them said that the large ones were as fine as forced grapes; while the small ones produced from branches of the same vine, trained and pruned in the old way, were bad natural grapes, and not above twice the size of large currants. And in order more fully to prove the success of the experiment, he next year trained five plants in the same way, allowing the shoots intended for bearing wood to run to their full length in summer, training them wherever there was a vacancy between the old trees; where there was none, he ran them along the top of the wall, without topping them. In winter he trained them in a serpentine manner, so as to fill the wall as regularly as possible; and they were, it is asserted, as productive as those in the former year. And after a three years' trial, he thought he was warranted to follow the same practice with the whole; when, in the year 1793, he sent, it is remarked, for the use of his majesty and the royal family, three hundred and seventy-eight baskets of grapes, each weighing about three pounds, without planting a single vine more than there were the preceding year, in which he was able to send only fifty-six baskets of the same weight; and those so bad and ill-ripened, that he was ashamed of them, as they were not fit to be sent to the table.

This, he thinks, sufficiently proves the great advantage that the serpentine method of training possesses over the common method. He advises, that the shoots should be brought as near as possible from the bottom of the vine, that the wall may be well covered. When the walls are high, and the shoots from the serpentine branches strong, they are sometimes let remain; but if the walls are low, and the serpentine branches produce weak shoots, they are cut out in the autumnal pruning, and the strongest of the young wood trained up in their room.

It is noticed, that as the size and fineness of the bunches of grapes depend in a great measure on the bearing wood being strong and well ripened, great attention should be paid

paid to these circumstances. Where the vines produce small bunches, they should be cut down to two or three eyes, in order to have strong wood for the ensuing year. And as it has been seen that vines bear their fruit on the wood that was produced the preceding year, when there is a great deal of old naked wood on them, as generally is the case, with some small weak shoots at the extremities, they should always be cut down as near to the ground as possible, in which case there will be no fruit for that year. But another mode is sometimes practised, which is, to cut every other shoot, leaving the old ones to produce some small grapes; when in the following year there will be plenty of fine wood, provided care be taken to nail in the strongest shoots, and pick off all the side-shoots that are produced from the eyes, pinching them off with the finger and thumb, or cutting them off with a sharp penknife close to the bud or eye; but never twisting them; as by twisting them, the bud that produces the grapes the next year is hurt; being always attentive to cut as near to a bud as possible, and taking care to lay in the wood very thin in the summer season, that the sun and air may be freely admitted to ripen it well, as by these means it will grow very strong. Great care should also be taken to keep the shoots nailed to the wall, which will prevent their being broken by high winds; picking off all the side-shoots every time they are nailed, which should be done several times during the summer months, according to the quickness of their growth. In fine weather they grow to very rapidly, that it is necessary to look them over once every fortnight or three weeks to have them in good order. The vines should never be suffered to run together in a cluster, and mat, as it infallibly ruins them for bearing the succeeding year. The shoots that have been trained in a serpentine manner, are advised by Mr. Forfyth to be topped, as soon as the grapes come to the size of very small green peas, at a joint or two above the fruit; but neither the leading shoot, nor that which is intended to bear fruit the next year, should ever be topped.

In the second year Mr. Forfyth never recommends the pruning of vines to be performed till the beginning of February, except in such seasons as are very forward. It is, however, the common practice with some to begin pruning soon after the fall of the leaf, before the wood becomes hard; but if a frost sets in before the wood is hard, in particular after wet summers and autumns, it is apt to be very much injured; he has frequently seen it almost killed after autumnal pruning. And he observes, that there is often fine weather in the months of October, November, and December, with sun and drying winds, which helps to ripen the wood after wet autumns.

It is likewise advised, when the vine-leaves begin to fall, to take a soft broom and sweep them off upwards in a gentle manner, which will be of great service in assisting to harden the wood. In beginning to prune in February, it is recommended always to make choice of the strongest and longest shoots, leaving them as long as the eyes are found good and plump, and the wood round; but by no means to leave them when they become flat, as in that case they seldom bear fruit; and if they do, it will be very small. Mr. Forfyth never lays in any that has less than fifteen, and from that to thirty good eyes, according to the strength of the shoot, which will produce two bunches from every good eye. He has had seventy bunches of grapes from one shoot. The shoots that have borne fruit in the preceding year should be cut out the next year, except where the wall is to be filled and the shoots are very strong. Plenty of fine healthy young wood is easily provided, if care be taken in the winter pruning; therefore, none should be left but the fine strong wood,

cutting constantly at the second, third, or fourth eye; rubbing the lowest bud off, and that which comes out at the joint between the new and last year's wood. By these means as much fruit will, he contends, be procured from these short shoots, as by the common way of pruning. It is necessary to leave two or three of the strongest shoots for next year's bearing wood, and never to top them. When there is not room to train them, they may be led over the tops of the other trees, if the vines are planted against piers; or be run behind the standards, if there be any, which is generally the case where the walls are high. In this way all the wall will be covered, which will have a very beautiful appearance when the fruit is ripe, besides furnishing a plentiful supply of fine grapes. The shoots at the bottom of the wall may be run behind the dwarf-trees, or be tacked down over the top of the wall on the other side where the walls are low. Mr. Forfyth has had very fine grapes on east and west walls, in good seasons, between peaches, plums, &c. particularly when the trees are young. In these cases he advises to keep cutting in the vines as the other trees grow and fill up the walls. He also trains them over the tops of trees on each side; which, he asserts, never does any harm to the trees below, provided they are kept nailed to the wall. He has also planted vines between trees on north and east aspects, and trained them over the tops of the south and west walls to fill the upper parts, till the peaches and nectarines cover them. He then cuts away part of the vines, leaving only as many shoots as he may think necessary.

Two years ago, he states, he removed some old apricots that covered a wall about 165 feet long, and planted them against a new wall, leaving five vines that were planted against the piers. These five plants have, in the course of two years, covered the above wall from top to bottom, and bear plenty of fine grapes every year. He remarks that he also moved an old vine on a wall near to the above, and cut it in pretty close, when it has in three years spread twenty-six yards, and bears very fine fruit. And against one of the piers had, he observes, been planted a black Hamburgh grape, and at the other side of the same pier a muscadine, at the distance of about two feet from each other; he pruned them both according to his method, and the second year after, they produced 1100 bunches of fine grapes. It is added, that he also tried an experiment by taking some shoots from a south wall, opening the ground deep enough to lay them in across the footpath at the distance of about four feet from the wall, and tied them to stakes, training them as espaliers, laying in the wood as directed for walls, and keeping them as low as possible, that they might not shade the bottom of the wall; he also pruned them as he does those against walls, laying the shoots in very long, except those that were intended to bear fruit next year, from which he took off all the side-shoots and runners against the wall and espaliers. In a favourable season these bear, he asserts, very fine fruit, better than what is got from the walls by the old method of pruning.

The use of the composition prepared by him is advised as soon after pruning as possible; for as the vine is very porous, it soon imbibes the wet and moisture, which brings it quickly to decay. He adds further, that if at any time a vine should be cut late in the season, it will be apt to bleed much; in which case the powder should be applied, repeating the application till the bleeding stops. He states, moreover, that he cut two strong vine-branches in the month of June, and three more in July, in very hot weather, on purpose to try the effect of the powder in stopping the bleeding. The sap rose so strong, that it worked out at the top in a froth; he applied the powder, which in a short time entirely stopped

VITIS.

it. These directions are chiefly for vines on the natural wall, though the same method has been advised to be practised for forced grapes. The situations in which they are placed should be towards the south, and the earth quite dry and light.

The above writer still further advises, that after the grapes are set and begin to swell, to water them with the barrow-engine, sprinkling them all over the leaves and fruit, pressing the fore-finger over the top of the pipe; by which the water can be thrown as fine as small rain, which will wash all the dust off the vine and leaves, that are frequently covered with it, especially where the garden is near a public road. The insects should likewise be washed off the trees. In fine weather he sprinkles all the wall-trees three times a week, which keeps them clear from insects, and promotes the swelling of the fruit; but this operation must never, he says, be performed when the nights are cold and frothy. The sprinkling of the trees should be begun when the sun is in an oblique direction, or gone off the wall, which may be about four o'clock on a south aspect; as by doing it at this period the leaves will have time to dry before night, and so prevent the frost, if there should be any in the night, from injuring them. In very hot and dry weather the trees should have a good bottom watering once a week, which will forward the swelling of the fruit. Vines require a great deal of watering; but when the fruit is fully swelled, you should leave it off, particularly when the nights begin to get cold, as it would hurt the flavour of the fruit.

In order to preserve the grapes, as soon as the large fly makes its appearance, plenty of bottles a little more than half filled with some sweet liquor should be provided to entice the flies to enter them, where they will be drowned. The bottles should be hung on the nails at proper distances all over the vines, and also some of them placed at the bottom of the walls. The blue fly comes much earlier than the wasp, and is no less destructive to the fruit. It is therefore necessary to hang up the bottles betimes, in order to destroy as many of them as possible before the wasp makes its appearance, to have the bottles ready for this second enemy.

And when the grapes begin to ripen, the birds begin to attack the fruit; when it is necessary to bag some of your fine handsome bunches, but to bag them all would be an endless trouble where there is a full crop and a large garden. Of course where the bunches are very thick, the quickest way is, he thinks, to cover the trees with nets, or buntine (a kind of stuff of which ships' colours are made), which will admit a free air to the grapes, and dry soon after rain. They will also in the spring, he thinks, be a good covering for the trees in cold, wet, or snowy weather. The bunches of grapes should always be kept under the shade of the leaves till they begin to ripen; when you may begin to pick off the leaves which cover the fruit (leaving those a little above it to be a shelter from the wet and frost in the nights): this will assist the ripening of the fruit; and take off only a few leaves at a time, according to the quantity of grapes to be gathered at once: by this means the fruit will continue three times as long in succession as it would if the leaves were picked off all at one time. He has often seen all the leaves taken off from the fruit soon after it was set, which prevents it from swelling, and it becomes hard and small, and generally cracks. When the leaves are not too thick, they admit, he asserts, the rays of the sun to pass through, and a warm glow of heat will be reflected from the wall.

Further, it is often convenient to let the grapes hang as long on the walls as possible; he has often let them hang till the middle of November, only covering them with nets, or buntine. But when the frost begins to set in sharp,

they should then be gathered. Where there are several bunches on one branch it may be cut off, leaving about six inches in length, or more, of the wood, according to the distance between the bunches, and a little on the outside of the fruit at each end; both ends being sealed with some common sealing-wax, such as wine-merchants use for sealing their bottles with, which you may buy at the wax-chandler's; then hang them across a line in a dry room, taking care to clip out with a pair of scissors any of the berries that begin to decay or become mouldy, which if left would taint the others. In this way he has kept grapes till the 6th of February; but if they are cut before the bunches are too ripe, they may be kept much longer than that period.

They may also be kept, he contends, by packing them in jars, (every bunch being first wrapped up in soft paper,) and covering every layer with bran, which should be well dried before it is used, laying a little in the bottom of the jar; then a layer of grapes alternately, till the jar is filled, then shaking it gently, and filling it to the top with bran, laying some paper over it, and covering the top with a bladder tied firmly on to exclude the air; when the top or cover of the jar should be put on, observing that it fits as close as possible, placing them in a room where a fire is kept in wet or damp weather.

Methods of forcing Vines.—This is performed in different sorts of buildings contrived for the purpose; such as hot-walls and vineries, as well as by hot-houses or stoves. See VINERY.

It is suggested by the Scotch Forcing Gardener, that in the former cases, when the borders have been prepared and made up in the manner directed under the head VINERY; when proper plants of one or two years' growth in pots cannot be procured, cuttings should be made use of. Others, however, prefer cuttings in all cases, planting two in each hole, to guard against failure, the weakest, where both grow, being afterwards removed. These should be planted about the beginning of April, being chosen from good-bearing vines, and such shoots as are well ripened, otherwise they never make good plants. The distance they should be allowed to remain is about six feet. In planting them out, holes should be opened with a spade, about eighteen inches deep; the cuttings being laid in the holes a little sloping, the earth being then filled into the holes, and gently pressed with the foot to them, and raised in a heap so as just to cover the uppermost eyes, afterwards applying a little mulch on the surface of the ground about them to prevent the sun and air from drying the earth; and when the spring is very dry, a little water should be given once a week.

Under this management they usually make strong shoots the first summer.

But the above writer, where rooted plants are employed, advises the pits to be half filled with vegetable mould, and the plants to be taken carefully out of the pots with their balls entire, and, unless when rooted, be placed in that manner in the pits, filling them in with vegetable mould, and settling them with a little water. This work, in his opinion, may be performed any time from the beginning of November to the 1st of March, with equal success. But though the above distance of planting may be proper when the vines are full grown, it may be beneficial to have them put in at half that distance at first; as a crop or two may be obtained before it is necessary to thin them out; two of a kind being placed together for the greater convenience of thinning.

The management of the vines, for the three first years after planting, is the same as practised for those against common

VITIS.

common walls, which has been described above, being, however, encouraged as much as possible, and the shoots not left too long, or too many in number on each root, that they may be duly ripened and prepared for bearing the fourth year, which is the soonest they should be forced; when any sorts of fruit-trees are forced by fire too young, they seldom continue long in health; so that what fruit they produce is small, and not well-flavoured. By the middle of June the grapes will be almost full grown, therefore the glasses may be kept off continually in the day-time, unless the season be very cold and wet, in which case they must be kept on, and only opened when the weather is favourable; for as the racy vinous flavour of these fruits is increased by a free air, so during the time of their ripening they should have as large a share as the season will admit to be given them. Mr. Nicol advises in the first and second seasons, to keep the border in a moderately moist state while the plants are growing; but, after their growth begins to abate, particularly the second season, to withhold the waterings by degrees till it is quite stopped, in order to make them harden and ripen their shoots for the production of a crop the third year. Water frequently with the drainings of a dunghill. And wash with the hand-engine twice or thrice a week in the evening, in order to refresh and keep the plants clean. Steaming is, he thinks, unnecessary.

And in the third season, keep the border also in a moderately moist state, till the fruit begin their last swelling. Then give large quantities till they begin to colour; after which, entirely withhold it till the crop is gathered; and then give two or three hearty waterings, to recover the state the border ought to remain in for the winter.

He likewise advises to wash twice or thrice a week till the flowers begin to open, then to withhold till the fruit is fairly set; washing again till they begin to colour, and then withhold entirely for the season. And in the interim of washing, to steam every night when the fire is at the strongest, by pouring water on the flues till you cannot see an object at the distance of two or three yards; and repeat this early in the morning, if the temperature of the house require the making of fires, or if there is a sufficient heat in the flues to produce it, even in a middling degree.

The insects which infest the grape-house are chiefly the green fly, thrips, red spider, and wasp. The two first are, Mr. Nicol conceives, easily destroyed by a fumigation of tobacco; the third is kept under by the engine in summer; and the last, by the destruction of their nests, phials filled with honey and water, or sugar and small beer, and bird-lime. All these methods are, however, sometimes ineffectual for the destruction of wasps, where they abound in great number; and their fondness for grapes renders it sometimes necessary to inclose the bunches in bags of gauze, or silken paper, which is a misfortune; as the grapes, by being so much excluded from the action of the sun and air, fall off very much in flavour. Birds must also be guarded against by some means or other.

All sorts of grapes should continue on the trees till fully ripe. It is advised by some, that these vines should not be forced every year, but under good management every other year, or every third year. Of course, in order to have a supply of fruit annually, there should be a sufficient extent of walling to contain as many vines as are necessary for two or three years; and by having the frames in front moveable, they may be shifted from one part of the wall to another, as the vines are alternately forced. These hot-walls are commonly planted with early kinds of grapes, in order to have them forward in the season; though some think it hardly worth the trouble, in order to have a few grapes earlier by

a month or six weeks, than those against common walls. The sorts of vines most useful in this mode of culture have been mentioned above.

After these vines are grown to full bearing, they must be pruned and managed after the same manner as has been directed for those against common walls, with this difference only, that in those seasons when they are not forced, they should be carefully managed in the summer for a supply of good wood, against the time of their being forced, divesting them of their fruit for the purpose.

But when the vines are forced, the only care is to encourage the fruit, without having much regard to the wood, so that every shoot should be pruned for fruit, and none of them shortened for a supply of young wood; as they may be so managed by pruning in the years of their resting, as to replenish the vines with new wood. Those which are designed for forcing in the spring, should be pruned early in the autumn before, that the buds which are left on the shoots may receive all possible nourishment from the root, and at the same time the shoots should be fastened to the trellis in the order they are to lie; but the glasses should not be placed before the vines till about the middle or end of January, at which time also the fires must be lighted; for if they are forced too early in the year, they will begin to shoot before the weather is warm enough to admit air to the vines, which causes the young shoots to draw out weak, and their joints too far asunder to afford a good and full supply of fruit.

When the fires are made at the above period, the vines begin to shoot the middle or latter end of February, which is six weeks earlier than they usually come out against the common walls; so that by the time that other vines are shooting, these will be in flower, which is early enough to ripen them. The fires should not be made very strong in these walls; as, if the air is heated about ten degrees above the temperate point of the gardener's thermometer, it will be sufficiently warm to force out the shoots leisurely, which is much better than to force them violently. These fires should not be continued all the day-time, unless the weather be very cold, and the sun does not shine to warm the air, at which time it will be proper to have small fires continued all the day; for where the walls are rightly contrived, a moderate fire made every evening, and continued till ten or eleven o'clock at night, will heat the wall, and warm the inclosed air to a proper temperature; and as these fires need not be continued longer than about the end of April, (unless the spring should prove very cold,) the expence of fuel will not be very great, because they may be contrived to burn coal, wood, turf, or almost any other sort of fuel: though where coal is to be had reasonable, it makes the event and best fires, and will not require so much attendance. When the vines begin to shoot, they must be frequently looked over, to fasten the new shoots to the trellis, and rub off all dangling shoots; in doing of which great care must be taken; for the shoots of these forced vines are very tender, and very subject to break when any violence is offered. The shoots should also be trained very regular, so as to lie as near as possible to the espalier, and at equal distances, that they may equally enjoy the benefit of the air and sun, which are absolutely necessary for the improvement of the fruit. When the grapes are formed, the shoots should be stopped at the second joint beyond the fruit, that the nourishment may not be drawn away from the fruit in useless shoots, which must be avoided as much as possible in these cases, no useless wood being left to shade the fruit, and exclude the air from it by the leaves.

In speaking of the temperature of the vineery, Mr. Nicol

Nicol recommends, that fire should not be lighted the first season, unless it proves cold or wet, and the wood is not ripened in good time; in which case, a moderate fire heat, from the 1st of September, would greatly encourage the growth, and promote the ripening of the wood. And as the plants will bear gentle forcing the third season, it will be advisable (for that purpose) to forward them the second in a moderate degree. For this purpose, let moderate fires be made about the 1st of April, (by which time the plants will begin to vegetate,) so as to raise the air of the house at six in the morning, and eight at night, to about 55° ; in the course of a fortnight increase it to 60° ; and in another fortnight to 70° ; at which let it continue till the 1st or middle of June, and then be totally discontinued for the season. But in the third season, the forcing may commence on the 1st of March, without injuring the plants; and, if carefully performed, a fair crop of fruit be obtained. Begin then by making and regulating the fires, so that the thermometer may not stand above 50° at seven in the morning, and eight or nine at night; keeping it so till every eye in the house is broken, and then gradually increase it to 60, 65, 70, and when the bloom begins to open, to 75° degrees. He has already hinted, that vegetation in forcing ought to be brought on as it were by stealth; which is the cause of his advising the above gradual and progressive rise in the climate of the house: and where this is not particularly attended to in the first stage of the operation, disappointments will follow, as the plants will not break their eyes (and of consequence not shew fruit) regularly. He advises to keep the air of the house as near to 75° , till the fruit is fairly set, as possible, as grapes in general are found to set best in a moist heat of about 75° . But he has found by experience that all the kinds of frontinacs require a much greater degree of heat, not only when in flower, but from the time the clusters are distinguishable; while those of the white sweet-water, and white royal muscadines, require a much less degree; the former being apt to curl up and become sterile for want of heat, and the latter to produce a greater quantity of small berries in consequence of too much. Therefore, where there is any difference of climate (which is sometimes occasioned by the placing of the fire-places) in the house, this hint should be taken advantage of. But it may then be let down to 70° or 72° ; at which endeavour to keep it till the crop is all gathered; after which, no further attention to the climate is necessary. It is added, that in the following season, the forcing may, when requisite, be begun a month or six weeks sooner; as about the middle of January, or 1st of February; in which early season great attention must be paid to the regulation of the fire-heat.

It is further observed, that a month may be gained every season (where there are two or three grape-houses; and it is required to have grapes at a very early season), until you begin to force the first so early as the 1st of October; but where there is but one or two houses, the 1st of March in the one case, and of January in the other, is, he thinks, quite soon enough.

It is advised in the same work, that as the season advances, and the weather becomes warm, there should be a proportionable share of free air admitted to the vines every day, which is absolutely necessary to promote the growth of the fruit; but the glasses should be shut close every night, unless in very hot weather, otherwise the cold dews in the night will retard it. The bunches in some of the sorts should be carefully looked over, and the small grapes cut out with very narrow-pointed scissors, in order to thin them. Mr. Nicol also recommends a due portion of

air to be admitted every day after planting, from sun-rise to sun-set, until the buds begin to break; after which a more punctual regulation should be observed, being guided much by the temperature of the weather, and the quantity of sun-shine, but admitting less or more every day, unless the severity of frosty winds renders it imprudent to do so. And as the summer advances, to be very liberal in this article in serene weather; as it greatly tends to the strengthening of the young shoots. It is, he thinks, a practice with many to uncover grape-houses in winter; this he never did, not so much disapproving of the practice, as owing to the expence attending it, not only in removing and putting on, but in breaking the glasses, and waisting the flues by the extremes of frost and blanching rains. His method is to admit an equal and free circulation of air, by opening the sashes alternately at top, bottom, and middle, to the extent of at least a third part of the whole covering, and letting them remain so day and night; never shutting up for any cause but that of too much wet. In the second season, much the same regulation should be observed as above; and, if fire is applied for the forwarding of the wood, due attention should be paid at that time, as the sudden breaking out of the sun in dull weather, when there is a good deal of fire-heat in the house, is attended with much danger. Supposing the plants to have made good wood for the production of a crop, and that they are to be forced from the 1st of March, let the house be shut up at night from the middle of February, and have the same quantity of air in the day it enjoyed all winter. From the time the fire is lighted, give a moderate quantity every day if possible, till the buds have all broke, to the extent that in sun-shine the thermometer may not rise more than ten degrees above the fire-heat medium; but after the buds have broke, and the temperature of the house is increased, be careful in the admission of frosty, or foul damp air. The latter may be entirely excluded, except perhaps for an hour or two in the middle of the day; and the bad effects of the former, by opening the top sashes *only* a little way, to pass off the rarefied air occasioned by the sun-heat, which is frequently very intense in clear frosty weather in the months of March and April. In clear sun-shining weather, his mode of practice is to give and take away air by degrees; that is, by giving half air about eight in the morning, full air about ten or eleven, reducing to half air about two or three, and shutting up about four or five in the afternoon, according to the season. It is necessary from the time the fruit begins to colour, to give large portions of air till the crop is all gathered, the flavour being much augmented by it; and afterwards to expose the house night and day for the winter, as directed above; shutting up, however, if much wet or hard frost should happen during the first ten or twelve days after the plants have been pruned for the winter season.

In the latter mode of forcing, or that in hot-houses or pine-stoves, after they have been properly prepared and rendered dry in the bottom parts, the area should be filled up with a compost-mould composed of one-fourth strong loam; one-fourth turf, from a pasture where the soil is a sandy loam; one-fourth sweepings or scrapings of pavements or hard roads; one-eighth rotten cow and stable-yard dung mixed; and one-eighth of vegetable mould from decayed oak-leaves: the grafts must be well rotted, and the whole worked together till it is uniformly mixed. Where sandy loam cannot be had, common sand may be used; and the mould of rotten sticks or old woods, or from hollow trees, may be substituted for the decayed leaves.

When the border has been prepared, if the weather permit

shoulders, as also the lefs projecting parts of the bunch, should be fufpended by small ftrings to the rafters, and every part raised to a horizontal pofition. In thinning the berries, great care fhould be taken to leave all the moft projecting ones on every fide of the bunch. In very clofe-growing bunches, it will be neceffary to clip out more than two-thirds of the berries; in fome one-half; but in the loofe-growing kinds, one-third is generally fufficient. By this means the remaining berries will fwell well, grow to a great fize, and not be fubject to rot; as they are apt to do in a hot-houfe, when they are wedged together in a clofe manner.

It is obferved too, that not only the rafters or roof of the hot-houfe, but the back wall alfo above the flue, may be furnifhed with fruit. For this purpofe, let every fourth or fifth vine-plant be trained in one fhoot quite to the top of the rafter, and then directed fideways ten or twelve feet along the top of the back wall. At the winter's pruning, bring down the part of the fhoot perpendicularly, and cut it off at one foot above the top of the flue. The next fpring encourage only two fhoots from the two extreme or lowermoft eyes of each fhoot fo brought down, and train them in a horizontal diretion one foot above the top of the flue. Thefe fhoots, however, will grow with greater readinefs, if they are trained upwards during the fummer; and they may eafily be brought to the defired pofition at the next winter's pruning. They will then form againft the back wall the figure of the letter T inverted. And in the next feafon the horizontal fhoots will produce new wood from almoft every eye, provided all the fhoots be pinched off from every other part as foon as they appear; laying in the fhoots from one to two feet apart, according to the kind of vine. And it is advifed in thefe cafes, to train all the fhoots in a perpendicular diretion, and, provided they are ftrong and vigorous, to fuffer them to grow to the length of five or fix feet before they are ftopped; but all thefe muft be cut down to two or three eyes at the next winter's pruning. And only one fhoot fhould be permitted to rife from each fpur the following feafon; and though they will in general be fufficiently ftrong, and produce two or three bunches a-piece, yet only one bunch fhould remain on each fhoot: thefe will then be large and fine, and the wood will be greatly benefited by fuch practice. But thefe fhoots muft be pruned next winter very differently. One fhoot muft be left four feet, that next it only a few inches long, and fo alternately. It is added that the vines on the rafters will require a management in future feafons nearly fimilar to that defcribed above; and though it may not be advifable to prune them alternately fo near to the bottom of the rafters as was directed for the two preceding feafons, it will be frequently found neceffary to cut an old fhoot down to the lowermoft fummer fhoot, as near to the bottom of the rafter as can be. The fide-shoot on the other rafters fhould not be permitted to ramble over the adjoining lights; but at the end of every feafon it will be proper to cut fuch fhoots down to the fecond or third eye next the old wood, provided the bottom eyes are bold and ftrong: this muft be done not only to ftrengthen the vines, but alfo to prevent the roof of the houfe from being too much crowded with old wood. Whilft the vines are young, one rafter will fuffice for a vine-plant; but when they become older, they will require a larger fpace; efpecially the ftrong-growing kinds, which produce large leaves and bunches of fruit. It will be proper therefore to train fhoots fideways on the wall-plate, from the ftem of the plant, immediately at its entrance into the houfe. Thefe fhoots fhould be carried up the adjoining rafters, and the plants growing againft fuch

rafters muft be taken entirely away; except it fhould happen that the plant growing againft fuch rafter is trained forward to furnifh the back wall. And when a vine-plant occupies two or more rafters, it will be right to prune occasionally, particularly whilft the vine is young, one or more of fuch fhoots down nearly to the bottom of the rafter, as this will not only contribute to ftrengthen the plant, but alfo afford means to furnifh the rafters with a fucceffion of young wood. When the fhoots are thus conducted to different rafters, every one may be confidered as a feparate plant, and be trained up in one fhoot; requiring management fimilar to that mentioned above. Mr. Nicol, however, rejects the method of planting the vines on the outside of the houfes, and his reafons are thefe: firft, he thinks it unnatural that one part of a plant fhould be as it were in Greenland, and the other in the Weft Indies; and fecondly, becaufe he is convinced that no plant (efpecially the pine) will live and thrive as well under the fhade of another, as when expofed to the free fun and air. To obviate thefe objections, he plants the vines in the lobbies between the ftoves and peach and grape houfes; introducing them through the partitions, and training them horizontally on trellifes fixed againft the back walls and upright falfies in front. By which means he renders each of the ftoves as good as any grape-houfe, without being in the leaft injurious to the pines.

In thefe cafes, he ftates that the front walls of the lobbies were built on pillars; and a border, both without and within, prepared for the plants, in the fame manner as for the grape-houfe. It is added, that in one trial, the fecond year after introduction into the ftove, the plants completely filled the whole trellis; and a fine crop, the third year, gave a luftre and richnefs to the houfe (in conjunction with a good crop of pines) highly gratifying.

He remarks farther, that the fame methods in regard of watering, wafhing, and fteaming, are to be practifed here as in the grape-houfe. Air is admitted folety for the fake, and to anfwer the nature, of the pines; the temperature of the houfe is alfo regulated for their fakes. But the mode of training and pruning is very different from that in the grape-houfe. Here, you have it not in your power to bring on vegetation in that flow manner as in the grape-houfe; and confequently, were the fhoots to be laid in at as great lengths, they would only break perhaps a few eyes at the extremities, and the reft remain naked. This he found from experience to be the cafe; although it did not happen for the firft three or four years, owing to the youth and vigour of the plants; but when they had exhaufted themfelves a little by bearing a few crops, they began to break their buds in the manner above flated. He therefore made it a practice to train them only to five or fix feet in fummer, and fhorten them down to one or two in the pruning feafon; by which they generally broke all their eyes, and produced plenty of fruit. He further ftates, that in one houfe he tried, for two feafons, to produce crops by laterals; but found that method attended with more inconvenience than the above, from the difficulty of procuring a proper fucceffion of ftrong fhoots to produce the laterals, without which they bear very insignificant clufters. He alfo, in the other houfe, produced a fecond crop, for two feafons; but finding it to exhauft the plants very much, he difcontinued it; the more efpecially, as, having fo many compartments for grapes, the practice of it was the lefs neceffary. The method is, he remarks, this: juft about the time the fruit is half ripe, and when the under part of the fhoot is alfo ripe to the length of about two or three feet, and the extremity of it in a growing ftate, fhorten it at about two or three feet above the ripe part. It will push

produce a few bunches on each plant. This method is now practised in many cases, and found to be very easy and convenient.

The second species requires artificial heat in this climate, and may be increased from seeds, obtained from abroad, which should be sown in small pots, and be plunged into a hot-bed of tanner's-bark. When the plants come up and are fit to remove, they should be each planted out into a separate small pot filled with light earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root; when they must be treated in the same way as other tender exotic plants, always continuing them in the stove, otherwise they will not succeed well.

The third should be planted against a wall, and treated in the same way as the common vine, being raised by cuttings or layers in the same manner.

The fourth sort is preserved in some gardens for variety; but it rarely produces flowers in this climate, and has not much beauty. It is increased by laying down the young branches in the spring, which mostly put out roots in one year fit to remove, when they may be taken off and planted out where they are to remain. These require support; and as their young branches are tender, and liable to be killed by frost, they should be planted against a wall, or pale, exposed to the south. The young shoots should be shortened down to two or three buds in the spring, which will cause the shoots of the following summer to be much stronger.

VITIS *Idea*, in *Botany*. See VACCINIUM.

VITISALTUS, a word used by some medical writers for *St. Vitus's* dance.

VITMANNIA, in *Botany*, so named by Vahl, in honour of the Rev. Fulgentius Vitman, professor of Botany at Milan, author of a kind of *Species Plantarum*, entitled *Summa Plantarum*, in 6 vols. 8vo.—Vahl Symb. v. 3. 51. Willd. Sp. Pl. v. 2. 320. Mart. Mill. Dict. v. 4. (*Samadra*; Cært. t. 156.)—Class and order, *Oëandria Monogynia*. Nat. Ord. akin to *Guttifera* of Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, short, in four rounded concave lobes. *Cor.* Petals four, oblong, equal, obtuse, fleshy, rather concave, externally hoary, many times longer than the calyx. Nectary a small obovate scale at the base of each filament, two opposite ones shortest. *Siam.* Filaments eight, thread-shaped, rather shorter than the petals, smooth; anthers linear, slightly cloven at the base. *Pist.* Germen superior, of four half-orbicular, compressed, slightly connected, lobes, three of which appear to be generally abortive; style central, awl-shaped, the length of the filaments; stigma acute. *Peric.* none? *Seed.* Nut semilunar, compressed, of one cell, with a solitary obovate kernel.

Ef. Ch. Calyx four-cleft. Petals four. Nectary a scale at the base of each filament. Nut crescent-shaped, compressed, with one seed.

1. *V. alpitica*. Oval-leaved Vitmannia. Vahl as above, t. 60. (*Samandara*; Herm. Zeyl. 5. Linn. Zeyl. 202.)—Native of Ceylon. A tree, with round, smooth, leafy branches. Leaves alternate, on short stalks, elliptical, obtuse, entire, coriaceous, smooth, with one rib, and many fine, transverse, branched veins. *Stipulas* none. *Flowers* in long-stalked lateral umbels, about the ends of the branches. *Petals* not an inch in length. *Nut* various in size, from two to four inches long, sharply two-edged, curved, at first described by Plukenet in his *Manitissa*, p. 12, as a sort of bitter almond. He has misled other authors to cite Rheede's *Nagam*, Hort. Malab. v. 6. 37. t. 21, which is *HERITIERA*, a very different plant. See that article.

VITODURUM, in *Ancient Geography*, a town placed

by the Itin. of Anton. between Vindomissa or Windisch and Fines or Pfin, which, without doubt, was Wintertur.

VITOSCHA, in *Geography*, a mountain of European Turkey, in Bulgaria, on the borders of Romania, at the foot of which are some warm baths.

VITRACO, in *Botany*, a species of plants, resembling that of which the glass is made. It is otherwise called *helvinc*.

VITREI, in *Geography*, a town of France, and principal place of a district, in the department of the Ille and Vilaine; 19 miles E. of Rennes. N. lat. 48° 8'. W. long. 1° 9'.

VITREA TABULA, a name given by some authors to the internal table of the cranium.

VITRESCIBLE, or VITRIFIABLE, formed of *vitrum*, *glass*, is a denomination applied to all stones which, joined to alkaline salts, can form glass. In the last century, those stones, which had before been called vitrescible, were called siliceous by Mr. Pott, and after him by Mr. Cronstedt. See *STONE*.

VITREUS HUMOR, or *Vitreous Humour*, in *Anatomy*. See *EYE*.

For the office of the vitreous humour, see *VISION*.

VITREY, in *Geography*, a town of France, in the department of the Upper Saône; 6 miles W. of Jussey.

VITRIACO, PHILIPPUS DE, in *Biography*, is mentioned with great encomiums by early writers on counterpoint. We found a tract of his writing in the Vatican library, N° 5321, of which we obtained a copy. He is the reputed inventor of the minim, and a composer of motets, which have been very much celebrated by old musical writers. His name very frequently occurs in ancient authors, particularly in England, where he has been commended both in verse and prose. "William Cornish, chapelman to the most famous and noble kynge Henry VII., in a parable between Trouth and Informacion, published in Skelton's works, 12mo. 1736, names him among the greatest musicians upon record.

"And the first principal, whose name was Tuballe, Guido, Boice, John de Muris, Vitryaco, and them all."

An anonymous Latin writer in the Cotton musical manuscript (Brit. Mus.) says he invented the minim, and was a musician universally approved and celebrated in his time. The author of the manuscript in the Bodleian library, attributed to Thomas of Tewkesbury, says the same. Morley, Ravencroft, and Butler, are of this opinion; and Morley tells us, that he used red notes in his motets to imply a change of mode, time, and prolation. Vitriaco, however, makes no mention of such in his tract on counterpoint; and his motets, if they could now be found, such is the transient state of music, would be utterly unintelligible; though Morley tells us, that "they were for some time of all others best esteemed and most used in the church." See *MOTET*.

VITRICIUM, in *Ancient Geography*, a town situated in the Alps, on the route from Italy into Germany, by the Graian Alps, between Eporodia and Augusta Prætoria. Anton. Itin.

VITRIFICATION, or VITRIFICATION, the act of converting a body into glass, by means of fire.

Of all bodies, sand, flints, and pebbles, with alkaline salts, vitrify the most easily: accordingly, it is of these that glass is principally made. See *GLASS*.

Gold held, by M. Homberg, near the focus of the duke of Orleans's large burning concave mirror, at first smoked, then changed, all of it that did not go off in fumes, into glass of a deep violet colour. This glass of gold weighs less than gold. *Memoirs of the Royal Academy, 1702.*

All metals, and even almost all natural bodies, sufficiently heated, vitrify; and this vitrification is the last effect of the fire: after which, the most intense heat of the largest burning-glass will make no farther alteration.

VITRING, in *Geography*, a town of the duchy of Carinthia, with an abbey of Cisterians, on the Wordsee; 4 miles S.W. of Clagenfurt.

VITRINGA, CAMPEGIUS, in *Biography*, an eminent Dutch divine, was born at Leewarden in the year 1659, and educated first at Frankfort, and afterwards at Leyden, where he took his doctoral degree in 1679. In 1680 he was admitted to the ministry, and in the same year became professor of the Oriental languages at Franeker. In 1682 he was promoted to the chair of theology; and in 1693, to that of sacred history, in the same university. An apoplectic stroke terminated his life in 1722. He was the author of many learned works in theology and scriptural history; of which one of the most esteemed is his "Observationes Sacre, Lib. VI." 4to. Franck. 1683, and two vols. 4to. 1712. But his most learned work is his "Commentary on Isaiah," in two vols. fol. Leeward. 1714-1720. Vitringa had two sons, *Horace* and *Campegius*, cut off at an early age. The former, who died at 18, published some animadversions on the work of Vorlius on the Hebraisms of the New Testament. The latter, who died in 1723 at the age of 31, was professor of theology at Franeker, and published several works, one of which was "A Summary of Natural Theology." After his decease was published a collection of "Several Dissertations" on criticism and theology. Moreri.

VITRIOL, NATIVE, in *Mineralogy*, is a substance of greyish or yellowish-white, apple or verdigris-green, or sky-blue colour; and when decomposed, covered with an ochrey crust. It occurs in mass, disseminated, stalactical, and capillary. Externally it is rough and dull; internally it is more or less shining, with a vitreous or silky structure. Its fracture is generally fine and straight fibrous, sometimes also lamellar and conchoidal. It is soft, brittle, and translucent, and has an acerb metallic flavour. It is more or less soluble in water, and is a mixture in various proportions of the sulphate of iron, copper, and zinc. It is not unfrequently found in caverns and shafts, in argillaceous schistus, and in old mines, especially such as abound in blende and pyrites. Aikin.

Some take the word *vitriolum* to be used *quasi vitri oleum*, because of its shining colour; but Menage rather derives it à *vitreo colore*: the Latins call it *atramentum sutorium*; and the Greeks, *chalcanthus*.

It acquires different names, according to the different places where it is dug; and the vitriols of those also differ from each other in denomination and colour; some being *white*, others *blue*, and others *green*.

Roman and Cyprus vitriol, for instance, is blue; and that of Sweden and Germany, commonly called English vitriol, is green; besides which there is also a white kind, called Gollar vitriol.

Vitriol is very commonly called by the manufacturers *copperas*; accordingly, we constantly hear of green, blue, and white copperas. The constituent parts of the different kinds of vitriols were not understood by the ancients so well as they are at present: they seem to have had an idea, that copper was the basis of them all: hence the Greek term for vitriol, *chalcanthus*, the efflorescence of copper, and the Latin one, *cuperose* or *cupri rosa*, the flower or efflorescence of copper; from which, says Dr. Watson, the French *couperose*, and our *copperas*, are evidently derived. See *CABBUSI*.

Some moderns take the *chalctis*, or *chalcanthus* of the ancients, which they supposed to be a native vitriol, that had acquired, according to their opinion, its full perfection in the entrails of the earth, and which is a kind of mineral stone, of a reddish colour, to be the same with that *chalcanthus* brought from Sweden and Germany; the best of which is of a brownish-red colour, and a vitriolic taste, and dissolves easily in water; and when broken, is of the colour of shining copper. See *VITRIOLIC Mineral*.

The vitriols which nature prepares are never to be met with in commerce; they serve to adorn the cabinets of the curious, but they are neither sufficiently pure for the purposes to which common vitriols are applied, nor are they found in sufficient quantities to answer the demand which is made for them.

VITRIOL, in *Chemistry*, is a term that is now applied to every combination of the acid of sulphur with any metallic substance: three of these combinations, however, are more particularly distinguished, being of great use in various manufactures; *viz.* green vitriol or sulphate of IRON (which see), blue vitriol or sulphate of copper (see COPPER and COPPERAS), and white vitriol or sulphate of zinc. (See ZINC.) The acid in all these vitriols is the same; the metallic basis of the green vitriol is iron, that of the blue vitriol is copper, and that of the white vitriol, zinc.

According to the analysis of sir Torbern Bergman, (*Essays*, by Cullen, vol. i. p. 180.) 100 parts of blue vitriol, or vitriolated copper, crystallized, contain 26 of copper, 46 of vitriolic or sulphuric acid, and 28 of water. According to Kirwan, 100 parts contain 30 of real acid, 27 of copper, and 43 of water. The taste is acerb, arruginous, and caustic; it calcines in heat; one part, in a moderate heat, requires nearly four parts of water, but much less of boiling water. Of white vitriol, or vitriolated zinc, 100 parts contain 20 of zinc, 40 of vitriolic acid, and 40 of water. According to Kirwan, 100 parts contain 22 of acid, 20 of zinc, and 58 of water. In a moderate heat, one part requires more than two of water, but much less of boiling water. Its taste is acerb, astringent, and caustic. Of green vitriol, or vitriolated iron, 100 parts contain 23 of iron, 39 of vitriolic acid, and 38 of water. According to Mr. Kirwan, 100 parts of it, recently crystallized, contain 20 of real acid, 25 of iron, and 55 of water. In moderate heat, one part requires six of water, but three-fourths of boiling water. In heat it splits into a yellow powder; in the fire, into a ferruginous powder. The taste is acerb, styptic, and caustic.

Green vitriol is often met with native in our coal-mines. From an old canal coal-pit, near Wigan in Lancashire, Dr. Watson procured a considerable quantity of it, very well crystallized; and Dr. Rutty has observed, that the vitriolic water at Haigh, in Lancashire, is the strongest in Britain, yielding 1920 grains of vitriol from a gallon of water. See *VITRIOLIC Waters*.

The green vitriol, or sulphate of iron, commonly called English vitriol or copperas, and the Roman vitriol of the Italian writers, is prepared at Deptford, near London, and many other places, from martial pyrites, which is a native sulphuret of iron, and is found in abundance on Sheppey isle, the isle of Wight, and various other parts of the Essex, Kentish, Suffex, and Dorsetshire coasts. By exposing this to the air in large beds, oxygen is absorbed; the sulphur becomes sulphuric acid, and the new-formed salt is separated by washing, &c.

Much after the same manner vitriol is made from the pyrites found among coal: there are manufactories of it near Wigan, at Whitehaven, at Newcastle-upon-Tyne, and in several

VITRIOL.

Several other parts of the kingdom. But all the vitriol works have sunk in value of late years; the home consumption of vitriol being much diminished, since the acid, which used to be procured from the distillation of vitriol, has been obtained from the burning of sulphur. For the ancient and modern method of obtaining this acid, we refer to the article *SULPHURIC Acid*.

It is not easy to determine when this method of making vitriol was introduced into England. In the beginning of the reign of queen Elizabeth, a patent was granted to Cornelius Devoz for making alum and copperas; but it was not till towards the end of the 17th century, that this art of making vitriol was brought to so great a perfection as to enable us to export any of it; and indeed Dr. Campbell (*Surv. of Brit. vol. ii. p. 21.*) assures us, that at the latter end of the 17th century we imported annually about five hundred tons of vitriol, and that we now export upwards of two thousand tons. It appears from Sir Charles Whitworth's Register of Trade, N^o 1, that there were exported, from the port of London alone, near four hundred tons of copperas in three months, in 1776. A small quantity of vitriol, perhaps to the annual amount of fifty or sixty tons, says Dr. Watson, is still imported into England; some particular dyers, and other artists, being of opinion, that the foreign vitriol, as containing a little copper, is more useful to them than the English vitriol. It may be easily known whether green vitriol contains any copper, by only rubbing the vitriol to be examined upon a moistened piece of polished iron; for if there is any copper in its composition, the iron will be changed into a copper colour.

Vitriol is also prepared from mineral waters that hold copper in solution, which is precipitated by iron: this solution of iron is afterwards crystallized, and always retains some copper. In Hungary it is prepared from pyritaceous schists, and in many places from a species of calamine; the vitriol of Goslar commonly contains a portion of zinc, as that of Hungary and Saxony does of copper; the English and French vitriols are purer, and yet sometimes contain a small proportion of alum. Turf and peat are sometimes impregnated with vitriol; other earths also often contain vitriol and alum. This vitriol is sometimes found of a white colour, on the borders of the mineral lakes of Tuscany.

Pure vitriol of iron is considerably transparent, of a fine bright, though not very deep, grass-green colour; of a nauseous, astringent taste, accompanied with a kind of sweetishness. Dissolved, and set to crystallize, it shoots into thick rhomboidal masses, a part generally rising at the same time in efflorescences about the sides of the vessel. The solution deposits, in standing, a considerable quantity, and in boiling a much larger one, of the metallic basis of the vitriol, in form of a rusty calx or ochre: iron seems to be the only metallic body that thus separates spontaneously, in any considerable quantity, from the vitriolic acid. On exposing the vitriol itself to a moist air, a similar resolution happens on its surface; which, sooner or later, according as the acid is more or less saturated with the metal, changes its green to a rusty hue. In a warm dry air, it loses a part of the phlegm or water, necessary to its crystalline form, and falls by degrees into a white powder. Exposed to a gentle fire, it liquefies and boils up; but soon changes, on the exhalation of the watery part that rendered it fluid, to a solid, opaque, whitish, or grey mass: this pulverized, and urged with a stronger fire, continues to emit fumes, becomes yellow, being the *vitriolum calcinatum* of the London and Edinburgh Dispensatories; afterwards red, and at length turns to a deep purplish-red calx, called *colcothar of vitriol*, and the *chalcitis factitia* of the Paris Pharmacopœia, revivable

by inflammable substances into iron. This colcothar was formerly sold at Paris for ten-pence a pound, and used for giving the last polish to plate-glass, at the great manufactory in the street St. Antoine. The plate of glass, when first cast, is an inch thick; its asperities are ground away with a coarse kind of grit-stone, with sand and emery, of different degrees of fineness, and it is at last polished by colcothar. Dr. Watson suggested to the proprietors of the plate-glass manufactory, near Prescot, in Lancashire, and to the patentees for polishing marble, at Ashford, in Derbyshire, that colcothar, which is very cheap, might perhaps render the use of putty, or calcined tin, less necessary. From the colcothar of vitriol is prepared the *ens venæris*.

From the green vitriol the vitriolic acid, now called sulphuric acid, has been generally extracted; by distilling the calcined vitriol in earthen long necks, with a strong fire continued for two days or longer; though it is now mostly obtained by collecting the vapour of burning sulphur.

The distilled spirit appears of a dark blackish colour, and contains a quantity of phlegm, greater or less, according as the vitriol has been less or more calcined. On committing it a second time to distillation, in a glass retort placed in a sand-heat, the phlegmatic parts rise first, together with a portion of the acid, and are kept apart under the name of *spirit, or weak spirit of vitriol, spiritus vitrioli tenuis* of the London Dispensatory: at the same time, the remaining *strong spirit, or oil*, as it is called, loses its black colour, and becomes clear; in which state it is the *acidum vitriolicum* of the Edinburgh Dispensatory, and the *spiritus vitrioli fortis* of that of London; and this is the usual mark for discontinuing the rectification.

The College of Edinburgh now directs a weak vitriolic acid of more certain strength, made by mixing one part of the strong acid with seven parts of water: this is called *acidum vitriolicum tenue, vulgò spiritus vitrioli tenuis*. See *SULPHURIC Acid*.

Blue vitriol, or vitriol of copper, is commonly called Roman or Cyprian vitriol, or blue-stone. After being long exposed to the air, it degenerates into a mixture of white and rusty yellow. It requires about four times its weight of water to dissolve it in the temperature of 60°. Its specific gravity is about 2.23. This salt rarely occurs crystallized, but is often found naturally dissolved in water, in Hungary, Sweden, and Ireland; from which water blue vitriol is generally prepared, by evaporating the water to a proper standard; after which it is let out into coolers, where it shoots into regular and beautiful crystals of a rhomboidal form. See *ZIMENT Water*.

It is also occasionally extracted from sulphurated copper ores after torrefaction, by the application of water, or washed out by rain or subterraneous waters. Mr. Cronstedt says it is seldom free from iron and zinc. If a piece of clean polished iron be dipped into the solution of this salt, it will almost immediately be covered with a cupreous coat: this, together with the deep blue colour arising from mixing it with a volatile alkali, discovers its basis; as its uniform mixture with other vitriolic salts does its acid. Hence it also appears, that the acid of vitriol has a greater affinity with iron than with copper, because it quits copper to unite itself with iron. This fact explains, in a very satisfactory manner, the nature of that transmutation of iron into copper, which was formerly considered as a perplexing phenomenon. Agricola speaks of waters in the neighbourhood of Newfol, in Hungary, which had the property of transmitting the iron which was put into them into copper. In the year 1673, our countryman, Dr. Brown, visited a famous coppermine at Herrn-Grundi, near Newfol; and he informs us, that

VITRIOL.

that he there saw two springs, called the old and new Ziment, which turned iron into copper. The iron in this case is taken up by the water, and remains suspended in it, in the place of the copper: so that this transmutation is nothing but a change of place; and as the copper is precipitated by the iron, so the iron might be precipitated by pot-ash, or any other substance which has a greater affinity with the acid of vitriol than iron has.

The cause of the impregnation of these copper waters in Germany is not difficult to be explained. Molt copper-ores contain sulphur, and when the sulphur is in any degree decomposed, its acid unites itself to the copper, and forms blue vitriol, which is the substance with which the waters issuing from the copper-mines are impregnated. The copper contained in these waters has been for some centuries collected in Germany, by putting old iron into pits filled with the coppery water; and thus the iron is dissolved, and the copper is precipitated, and being raked out in the form of mud, it is afterwards melted into very fine copper. The quantity of copper procured by an hundred tons of iron amounts sometimes to ninety tons, and seldom to less than eighty-four. Of late years some successful attempts of this kind have been made in England and Ireland. See COPPER.

In the Isle of Anglesey, near Paris mountain, which abounds in copper ore, the water in which the roasted ore is washed is so strongly impregnated with copper, that they have found it useful to adopt the German method of precipitating it by means of old iron, and they have obtained in one year near a hundred tons of copper, precipitated from this water. The water, after the copper has been precipitated by means of iron, is at present thrown away; whereas, by evaporation, it would yield green vitriol; and as above a hundred tons of iron must be employed in obtaining the forementioned quantity of copper, Dr. Watson suggests, whether a manufactory of green vitriol might not be established at this and at all other places where copper is obtained by precipitation. One hundred tons of iron would yield, at the least, two hundred tons of vitriol, which, at the low price of 3*l.* per ton, would defray the expence of extracting it; more especially as the watery solution might be evaporated by a proper application of part of that heat, which is now lost in all the great smelting houses.

The greatest part of the blue vitriol, now met with in the shops, is prepared in England, by artificially combining copper with its sulphur or its acid. The method of making the preparation by the glass-makers is this: Take little thin pieces of brass, and lay them stratum super stratum in a crucible, with powder of brimstone. When the vessel is full, set it luted and covered in an open wind-furnace, with burning coals over it, and let it stand two hours; then let the furnace cool of itself, and take out the crucible, the mass within will be of an obscure blackish-purple; powder it and sift it fine, and then mixing with every pound of it six ounces of powdered brimstone, take a round vessel of earth, that will bear the fire, place it upon iron bars set across in an open wind-furnace, fill it with coals, and then put in the powder; keep it burning and stirring about till all the brimstone is burnt up; then take out the pan, and powder the calcined mass again; sift it fine, and proceed with it thrice as before; the last time let it stand on the fire till it becomes red. Put a pound of this calcined copper into a glass body, with six pints of water; evaporate two pints or thereabout in a sand heat; the water is then of a fine blue, and must be poured off clear; then filtrate it. Evaporate the water from the remaining sediment of copper left in the glass, and with new sulphur calcine it again and

again; repeat this five or six times, and extract the blue tincture with water as before; filtrate all the waters, and put them together. Evaporate all to a fifth part, or thereabouts, and let it in a cool place, and fine pointed crystals will be formed, resembling emeralds; separate these crystals, and evaporate the water again, till all the crystals be procured. Then put a pound of them into a glass retort, well luted, and fitted to a capacious receiver; let the joints be well closed, and make a moderate fire for four hours; then make it violent for twenty hours, or till no more white fumes arise. The next day open the receiver, and separate the liquor into a glass, where it must be kept carefully sealed up. Neri's Art of Glass, p. 50.

Very great things are to be done in the glass art by means of this liquor; the remainder in the retort exposed to the air for a few days, will acquire a blue colour, and this, mixed with zaffer, will give glass a fine sea-green. The vitriol of copper is of an elegant sapphire blue colour; hard, compact, and semitransparent; when perfectly crystallized, of a flattish, rhomboidal decahedral figure; in taste extremely nauseous, styptic, and acrid. Exposed to a gentle heat, it first turns white, and then of a yellowish-red or orange colour; on increasing the fire, it parts, difficultly, with its acid, and changes at length to a very dark red calx, reducible, by fusion with inflammable fluxes, into copper.

Some writers hold vitriol to be the root or matrix of copper; because, in the copper-mines, they never dig deeper than the glebe, out of which the vitriol is drawn. For the use of blue vitriol in medicine, &c. see VITRIOL, in *Medicine*.

The *white vitriol*, or vitriol of zinc, is found native in the mines of Goslar, sometimes in transparent pieces, more commonly in white efflorescences; which are dissolved in water, and crystallized into large irregular masses, somewhat resembling fine sugar; it is also found dissolved in mineral waters, and generally with some proportion to the vitriol of iron and copper: it is in taste sweetish, nauseous, and styptic.

It has been disputed, whether white vitriol is any thing else than green vitriol calcined. But it seems that white vitriol is of a quite different species from either the green or the blue vitriols. Geoffroy, *Mat. Med. tom. i. p. 124*.

In the condition in which white vitriol is usually bought, it contains somewhat both of copper and iron; but being purified by solution, filtration, and crystallization, it is freed from both these metals, and appears to be a native vitriol *suâ generis*. See Cramer, *Elem. Art. Docim. vol. i. p. 302. ed. 2. Med. Ess. Edinb. Abr. vol. ii. p. 472*.

If four ounces of alum be put in concoction with two parts of cadmia fossilis pulverized, the earth of the alum precipitates, and its acid takes hold of the earth of zinc, so that a true white vitriol is the result.

This vitriol being precipitated by an alkaline ley, and dried, after its salts are separated in water, and then mixed with charcoal-dust, will give zinc.

The same thing happens in mixing vitriol of iron with two or three parts of lapis calamaris; but the operation is easier with alum and vitriol of copper. Marggraaf, in *Mem. de l'Acad. de Berlin, 1746*.

The white vitriol requires little more than twice its weight of water to dissolve it in the temperature of 60°; its specific gravity is about 2.000. It mixes uniformly with vitriolic neutral salts, but precipitates nitrous or marine selenites from their solutions, which ascertains its acid principle; it is itself precipitated whitish by alkalis and earths, but not by iron, copper, or zinc, which sufficiently indicates its basis: if it contains any other metallic principle, this may be precipitated

VITRIOL.

precipitated by adding more zinc, except iron, which will of itself precipitate by exposure to the air, or boiling in open air. That in common use is mostly prepared at Goslar, from an ore which contains zinc, copper, and lead, mineralized by sulphur and a little iron: the copper ore is first separated as much as possible, and the residuum, after torrefaction and distillation, is thrown red-hot into water, and lixivated: it is never free from iron.

The common white vitriol of the shops contains a quantity of ferruginous matter; of which, in keeping, a part is extricated from the acid, in an ochrey form, so as to tinge the mass of a yellow hue. On dissolving the whitest pieces in water, a considerable portion of ochre immediately separates: the filtered solution, transparent and colourless, becomes again turbid, and yellow, on being made to boil, and deposits a fresh ochrey sediment; and a like separation happens, though much more slowly, on standing without heat. Hence, when the solution is evaporated to the usual pitch, and set to crystallize, the crystals generally prove foul; unless some fresh acid be added (as an ounce of the strong spirit or oil of vitriol to a pound of the salt) to keep the ferruginous matter dissolved: this addition secures the whiteness of the crystals, and prevents their becoming soon yellow in the air. White vitriol generally contains also a small portion of copper distinguishable by the cupreous stain which it communicates to polished iron immersed in solutions of it, or rubbed with it in a moist state. The quantity of copper is, indeed, very small, and may, if it be thought necessary, be separated by boiling the solution for some time, along with bright pieces of iron, which will extricate all the copper: by continued or repeated coction, the greatest part of the ferruginous matter may also be separated. For the use of white vitriol in medicine and surgery, see *VITRIOL*, in *Medicine*, *infra*.

VITRIOL, in *Medicine* and the *Arts*, has various applications and uses. *White vitriol* is sometimes given, from five or six grains to half a drachm and more, as an emetic, and appears to be one of the quickest in operation of those that can be employed with safety. Its chief use is for external purposes, as a cooling refrigerant and desiccative: a dilute solution of it, as sixteen grains in eight ounces of water, with the addition of sixteen drops of weak vitrolic acid, or the *aqua vitriolica* of the Edinburgh Dispensatory, is an excellent collyrium in defluxions and slight inflammations of the eyes; and, after bleeding and purging, in the more violent ones. A solution of it with alum, in the proportion of two drachms of each to a pint of water, called the *aqua aluminosa Bateana*, is used as a repellent fomentation for some cutaneous eruptions, for cleansing foul ulcers, and as an injection in the fluor albus and gonorrhœa, when not accompanied with virulence. This vitriol is sometimes likewise employed as an emetic, and said to be a very effectual dissolvent of mucous matters; in which intention it is recommended, in the German Ephemerides, against obstructions of the nostrils in new-born infants. See *ZINC*.

Blue vitriol, like the other preparations of copper, acts, in doses of a few grains, as a most virulent emetic. Its use is chiefly external, as a detergent, escharotic, and for restraining hæmorrhages; for which last intention a strong styptic liquor used to be prepared in the shops, and called *aqua vitriolica cerulea*. Blue vitriol has of late been considerably employed as an emetic by some practitioners; and is said to be by no means an unsafe one, as it operates the instant it reaches the stomach, before it has time to injure by its corrosive quality. The peculiar advantage in using it is represented to be, that it has no tendency to become also purgative, and that its astringent power prevents the

tone of the stomach from being impaired after vomiting with it. It is much recommended in the early state of tubercles in the lungs; and the following method of exhibition directed. (See *Simmons* on the Treatment of Consumptions, p. 70.) Let the patient first swallow about half a pint of water, and immediately afterwards the vitriol, dissolved in a cupful of water. The dose may be varied according to age, constitution, &c. from two grains to ten, or even twenty; always taking care to begin with small ones. After the emetic is rejected, another half pint of water is to be drunk, which is likewise speedily thrown up, and this is commonly sufficient to remove the nausea. In still smaller doses, the blue vitriol has been much used by some as a tonic in intermittents, and other diseases. See *COPPER* and *SULPHATE of Copper*.

Pure green vitriol is in no respect different from the artificial *SAL Martis*; which see. It is one of the most certain of the chalybeate medicines, scarcely ever failing to take effect where the calces, and other indissoluble preparations, pass inactive through the intestinal tube. It may be conveniently given in a liquid form, largely diluted with aqueous fluids: two or three grains, or more, dissolved in a pint or quart of water, may be taken in a day, divided into different doses. This vitriol is used also, especially when calcined, as an external styptic: the styptic of Helvetius, and, as it is said, that of Eaton, is no other than French brandy impregnated with the calcined vitriol: a drachm of the vitriol is commonly directed to a quart of the spirit, but only a minute portion of the drachm dissolves in it. (See *STYPTIC*.) As French brandy has generally an astringent impregnation from the oaken casks in which it has been kept, the vitriol changes it, as it does the watery infusions of vegetable astringents, to a black colour; but makes no such change in spirituous liquors that have not received some astringent tincture. See *IRON*, *SULPHATE of Iron*, and *TINCTURE*.

The acid of vitriol, or sulphur (sulphuric acid), largely diluted, is the most salubrious of all the mineral acids. It is mixed with watery infusions, spirituous tinctures, and other liquids, as an antiplogistic; as a refrigerant in hæmorrhages; and as a stomachic and corroborant in weakness, loss of appetite, and decays of constitutions, accompanied with slow febrile symptoms, brought on by irregularities, or succeeding the suppression of intermittents by Peruvian bark. In several cases of this kind, after bitters and aromatics of themselves had availed nothing, a mixture of them with the vitrolic acid has taken effect: the form commonly made use of is that of a spirituous tincture; six ounces of oil of vitriol are drop by degrees into a quart of rectified spirit of wine; the mixture digested for three days in a very gentle heat, and afterwards digested for three days longer with an ounce and a half of cinnamon, and an ounce of ginger; this is the *elixir vitrioli* of the Edinburgh Dispensatory. Or, a pint of an aromatic tincture, drawn with proof spirit, is mixed with three ounces of the strong acid, so as to form the *acid elixir of vitriol* of the late London Dispensatory: these liquors are given from ten to thirty or forty drops, in any convenient vehicle, when the stomach is most empty. (See *ELIXIR*.) A mixture of oil of vitriol with spirits of wine alone, in the proportion of one part of the former to three of the latter, digested together for some time, has been used in France as a refrigerant in gonorrhœas, female fluors, and spittings of blood, under the denomination of *aqua Rabelliana*, and *eau de Rabel*. The acid of vitriol, diluted with water, has been given internally with great success in the itch. It was first used for this purpose in the Prussian army in 1756, and has since been much employed in several parts of Germany. The dose recommended is from an

VITRIOL.

an eighth to a fourth of a drachm of the pure acid twice or thrice a day. It is said to succeed equally in the dry and moist itch; and when given to nurses, to cure both themselves and their children.

When oil of vitriol, and rectified spirit of wine, are long digested together, or distilled, a part of the acid unites with the vinous spirit into a new compound, very volatile and inflammable, of no perceptible acidity, of a strong and very fragrant smell, and an aromatic kind of taste: this dulcified part, more volatile than the rest, separates and rises first in distillation, and may thus be collected by itself. The College of London directed this *spiritus vitrioli dulcis* to be made by cautiously and gradually mixing a pound of oil of vitriol, and a pint of rectified spirit of wine, and setting them to distil with a very gentle heat: that of Edinburgh ordered the same quantity of the oil of vitriol to be dropt into four times as much of the vinous spirit, and the mixture to be digested in a close vessel, for eight days, previously to the distillation, with a view of promoting the coalition of the two ingredients. The different proportions of the acid spirit to the vinous, in these prescriptions, make no material variation in the qualities of the product, provided the distillation be duly conducted; for the smallest of the above proportions of acid is much more than the vinous spirit can dulcify, and all the redundant acid remains in either case behind. The true dulcified spirit rises in thin subtile vapours, which condense upon the sides of the recipient in straight striz; these are succeeded by white fumes, which form either irregular striz, or large round drops like oil; at the first appearance of which, the process is either to be stopped, or the receiver changed. The spirit which these fumes afford, very different from the dulcified one, has a pungent acid smell, like the fumes of burning sulphur: on its surface is found a small quantity of oil, called the *sweet oil of vitriol* of Hoffman, of a strong, penetrating, and very agreeable smell, readily dissoluble in spirit of wine, to a large proportion of which it communicates the smell and taste of the aromatic or dulcified spirit. The College of Edinburgh, in order to secure against any acidity in the dulcified spirit, ordered it to be rectified, by mixing it with an equal measure of water, in every pint of which a drachm of falc of tartar has been dissolved, and drawing off the spirit again by a gentle heat. This College, in their last Pharmacopoeia, have manifestly shewn how little they conceive the acid to enter as a constituent part of this preparation, and at the same time have directed an effectual method of preventing its presence in it. They order the *acidum vitriolicum vinosum*, vulgò *spiritus vitrioli dulcis*, to be made by simply mixing one part of vitriolic ether with two of rectified spirit. See *Sulphuric ETHER*, and *SPiRiT of Ether*.

This spirit, taken from ten to eighty or ninety drops, strengthens the stomach and digestive powers, relieves flatulencies, promotes urine, and, in many cases, abates spasmodic strictures, and procures rest. It is not essentially different from the celebrated mineral anodyne liquor of Hoffman; to which it is frequently, by the author himself, directed as a substitute. See *Liquor mineralis anodynus*, *Ethereal SPiRiT*, and *Compound SPiRiT of Ether*.

The dulcified spirit is sometimes used as a menstruum for certain resinous and bituminous bodies, which are more difficultly and languidly acted upon by pure vinous spirits. It is often mixed with aromatic and stomatic tinctures, in cases where the stomach is too weak to bear the acid elixirs above-mentioned: eight ounces are commonly added to a pint of the officinal aromatic tincture; or the ingredients of the aromatic tincture are infused in the dulcified acid, instead of

common rectified spirit, in order to form the *sweet elixir of vitriol*. A medicine of this kind was formerly in great esteem, under the name of *Vigoni's volatile elixir of vitriol*, prepared by macerating, in some dulcified spirit of vitriol, free from acidity, a small quantity of mint-leaves carefully dried, till the spirit has acquired a fine green colour: and to prevent the necessity of filtration, during which the more volatile parts would exhale, the mint may be suspended in the spirit in a fine cloth. If the dulcified spirit, rectified from a solution of fixed alkaline salt, be shaken with equal its quantity of a like solution, and the mixture suffered to rest, an ethereal fluid rises to the surface, and great part of the dulcified spirit may be recovered again from the remainder by distillation. Dr. Hadley obtained the largest portion of ether, by using the strongest vitriolic acid of the shops with equal its quantity, by measure, of spirit of wine, and distilling immediately by a heat sufficient to make the mixture boil. By this management, from three pints of oil of vitriol, and six pints of rectified spirit of wine, he obtained two pints and a half of the ether.

The vitriolic acid saturates a larger quantity of fixed alkaline salts than any of the other acids, and dislodges from them such other acids as have been previously combined with them. Of the strong spirit, or oil of vitriol, about five parts are sufficient for eight of the common vegetable fixed alkalies. The neutral salt thus obtained is of a bitterish taste, very difficultly soluble in water, and scarcely fusible in the fire: in small doses, as a scruple, or half a drachm, it is an useful aperient: in larger ones, as four or five drachms, a mild cathartic. This salt has been commonly prepared with the alkali obtained from tartar, and hence called *vitriolated tartar*, and sometimes *sal enisum*, and *arcanum duplicatum*. Some dilute the oil of vitriol with six times the quantity of warm water, and drop into it a solution of the alkaline salt till no effervescence ensues: others use vitriol in substance, which being dissolved in boiling water, any alkaline salt, gradually superadded, till the effervescence ceases, absorbs the pure acid, and throws down the metallic basis of the vitriol: one part of the alkali is nearly sufficient for two of the vitriol.

With the mineral fixed alkali, this acid forms compound salts of a more bitter taste, somewhat less purgative, and much easier of solution, than that with vegetable alkalies: with volatile alkalies, a very pungent ammoniacal salt, whose medicinal effects are not well known. The strong acid, boiled on argillaceous earths to dryness, corrodes a portion of them, and concretes with them into an austere styptic salt. Calcareous earths it does not dissolve into a liquid state, but may be combined with them, by precipitation from other acids, into an indissoluble concrete, seemingly of no medicinal activity. Among metallic bodies, it dissolves zinc and iron readily; copper, silver, quicksilver, lead, and tin, very difficultly: it is fitted for acting on the two first by dilution with three or four times its quantity of water: the others require the undiluted acid, and a heat sufficient to make it boil; when, the more phlegmatic parts exhaling, so much of the pure acid matter remains combined with the metals as to render them, in part at least, dissoluble in water.

The principal use of green vitriol is in dyeing, and in the making of ink. When the vitriol is dissolved in water, the iron contained in it becomes black by the addition of an infusion of gall-nuts. Mr. Lemery, the younger, in order to account for this blackness, imagines, that as the vitriol, of which ink is made, is iron dissolved by an acid, and intimately mixed with it, and as galls are an alkali or absorbent, this alkali, meeting the acids which hold the iron dissolved,

unites with them, and makes them set the iron loose; which thereupon revivifies, and resumes its natural blackness: for that in strictness we write with the iron.

In the Swedish Transactions, vitriol is recommended as a yellow for house-painting: quicklime, made into a paste with water, is to be diluted with a solution of vitriol, more or less, according as the colour is required deeper or lighter: the mixture appears of a blueish-green colour, and does not become yellow till it is dry. One part of vitriol is said to go as far as two of the dearer yellow ochre. This salt is also recommended for preserving wood, as particularly the wheels of carriages, from decay: when all the pieces are fit to be joined together, they are directed to be boiled in a solution of vitriol for three or four hours, and then kept for some days in a warm place to dry. It is said that wood by this preparation becomes so hard and compact, that moisture cannot penetrate it. For the use of vitriol in agriculture, see *SULPHATE of Iron*. See on the subject of the preceding articles, Neumann's Chem. Works, by Lewis, p. 173, &c. Watson's Chem. Ess. vol. i. c. 6. Lewis's Mat. Med. art. *Vitriolum*. Bergman's Ess. vol. i. p. 180, &c. Kirwan's Elem. of Mineral. p. 189, &c.

VITRIOLS, Metallic. All metals, it is to be observed, may be converted into vitriols, by dissolving them with acid spirits, and letting them stand to crystallize.

Facitious vitriols, being only metals dissolved and crystallized in saline menstrua, are frequently called, by way of distinction, *metallic vitriols*, and *metallic salts*.

VITRIOL of Cobalt is found native in small pieces, mixed with a greenish efflorescence, in cobalt mines: it is difficultly soluble in water; and both it and its solution are red, which sufficiently distinguishes its basis. Its acid is known by the same taste as that of the other vitriols.

VITRIOL of Iron, Vitriolum Martis, is a preparation made by dissolving iron, or steel, in oil or spirit of vitriol; then evaporating or drawing off the moisture, and bringing the matter to crystallize, by setting it in a cool place. This is also called *sal martis*, or *salt of steel*.

VITRIOL of Lead. See **LEAD**.

VITRIOL of Luna, or the *Moon*, is the name given to a salt with a metallic basis, called also *Vitriol of SILVER*; which see.

VITRIOL of Nickel is found native, efflorescing on kupfer-nickel, and generally mixed with vitriol of iron. This is difficultly soluble in water: both it and its solution are of a green colour. See **NICKEL**.

VITRIOL of Quicksilver, the name of a chemical preparation of quicksilver, with acid spirits, the process of which is this: let to rich a solution of quicksilver be made in spirit of nitre, or aqua fortis, that no more can be contained; let this solution be made by the assistance of heat, and the liquor immediately afterwards poured off into a clean and cold glass. There will, on this, spontaneously shoot on the bottom of the glass a saline, white, transparent matter, from which the liquor being poured, it is found to be a sharp, moist, saline substance, or true vitriol of mercury, soluble in water, and not safe to be touched. If the liquor, poured off from this, be evaporated half way, and the remainder set in a cool place, more crystals of the same nature with the first will shoot.

Another method of making the vitriol of mercury is this: reduce to powder some decrepitated sea-salt, and with two parts of this mix one part of crude mercury; distil the whole in a glass body, with a strong fire continued five or six hours: when the vessels are cold, break them, and there will be found a solid dry mercury, sublimed to the top and sides of the

body, in form of vitriol. Nay, Boerhaave affirms, that the common mercury sublimate is a true vitriol of mercury, though semi-volatile. Boerh. Chem. part ii. p. 301.

VITRIOL of quicksilver is also a name given to a salt of mercury, mineralized by vitriolic acid, first discovered by Mr. Woulfe, together with the marine salt of mercury, at Obermoschel, in the duchy of Deux-Ponts: they have a spar-like appearance, and are either bright and white, or yellow or black, mixed with cinnabar in a stony matrix: these well mixed with one-third of their weight of vegetable alkali, afforded him cubic and octagonal crystals, that is, salt of Sylvius, and tartar vitriol. Phil. Trans. vol. lxxi. part ii. p. 618.

VITRIOL of Venus is a solution of copper in spirit of nitre, evaporated and crystallized, to gain the salt; called also *vitriol of copper*.

VITRIOL, Liqueum, or Wash of, is a name given to the ochrey matter remaining after successive evaporations of the mother of vitriol, which yields no more vitriol. Its taste is acid and fiery, and the quantity left from a gallon of the well-impregnated liquor from the bed is about a pound. From this may be procured a white pungent salt, by subsequent evaporations. This is the saline principle of vitriol, according to the chemists, and is contained in so large a quantity, that nearly thirteen ounces of it may be separated from a pound of the liquor; the remaining liquor, after this, is what is called *liquamen vitrioli* by some chemists, but not properly. It will never coagulate into salt, but is very fiery and acrid to the taste, and extremely ponderous, not less so than oil of vitriol, nor less pungent; and is the strongest liquor any way obtained from a natural substance without distillation. This liquor being exposed to the air in a vessel not closed, will in a little time attract double its weight of water from it. All corrosive and saline liquors have somewhat of this property of imbibing moisture from the air, and weakening themselves by it; but this liquor attracts it faster and in greater quantity than any other. This liquor receives most moisture, and increases most quickly in wet weather, less so in dry; and this may have given occasion to that error so common among uninformed chemists, that several preparations of vitriol derive moisture from the moon, and have more or less of it, according to her different phases. The changes of the constitution of the air have effected what, in this case, they supposed to be done by the different phases of the moon. Phil. Trans. No. 103.

VITRIOLIC, something that has the quality of vitriol, or that partakes of the nature of vitriol.

VITRIOLIC Acid. (See **SULPHURIC Acid**.) This acid, when first prepared by art, was distilled from dried sulphate of iron, or the common green vitriol, or coppers of commerce: it is still prepared in Saxony, and many other parts of

VITRIOLIC ACID.

of Germany, from the same substance, in the manner described under *SULPHURIC Acid*. Accordingly, when the component parts neither of the salt nor of the acid were known, it was very naturally called "oil of vitriol;" acquiring this denomination probably from its resemblance to oil in adhering to the sides of a vessel containing it, and from its passing gently, or with little noise, from one vessel to another. However, as the name tends to give erroneous ideas of the nature of the acid, which is now known to be formed only of sulphur, oxygen, and water, it ought to be expunged. On account of the inconvenience and expence attending the method of procuring this acid from sulphate of iron, and the time required for the process, the manufacturers were led to the base itself, or the sulphur; which, in conjunction with nitre, was burnt in very large globes of glass, and the product was concentrated by boiling it in retorts or other glass vessels, till the fluid was of a sufficient strength for sale. See *SULPHURIC Acid*.

Mr. Parkes informs us (*Chemical Essays*, vol. ii.) that the process of forming sulphuric acid by the combustion of sulphur, was first adopted in this country by Dr. Ward, well known by his anæsthetic pill, white drop, and some other nostrums which bore his name. Fourcroy, however, attributes this important discovery to two French chemists, Lefevre and Lemery. Dr. Ward obtained a patent for his method of preparing it, and the article which he procured was denominated, by way of distinction, "oil of vitriol made by the bell." It is needless to describe his method, though it gave him for some time a monopoly of this British manufacture: until at length chambers of lead were employed for the combustion of the sulphur and nitre, so contrived that the floor of each might be constantly covered with a sheet of water, capable of absorbing the sulphuric acid gas at the time of its formation. The introduction of this leaden apparatus served to facilitate the manufacture of this acid, and in a short time reduced the price to about a quarter of its former rate. This important improvement is ascribed by Mr. Parkes to the late Dr. Roebuck, an eminent physician of Birmingham, who, in conjunction with his partner, the late Mr. Samuel Garbett, erected, notwithstanding a violent opposition on the part of Dr. Ward, the first leaden chamber for this purpose at Birmingham, about the year 1746: and the same works are now (1815), says Mr. Parkes, in the occupation of their successors, Messrs. Alston and Armitage. The consumption, however, was at first restricted, on account of local circumstances, to Birmingham and its vicinity. The manufacturers, therefore, with a view to a more extensive demand, and to the introduction of the article produced for the purpose of bleaching in the linen manufactories of Scotland and Ireland, established, on an extensive scale, in the year 1749, works at Preston-Pans, on the eastern coast of Scotland. It is observed, however, that Dr. Roebuck was not the sole founder of the works at Preston-Pans, or of the great iron-works at Carron. (See *CARRON*.) Of Dr. Roebuck, an account of whom has been by accident omitted under his name, it will be sufficient to observe, that he was a man of very superior talents, very considerable acquirements, and very amiable manners, highly esteemed at Birmingham, where he resided, and honoured with a peculiar intimacy with the celebrated Dr. Black. He died, much regretted, on the 17th of July, 1794. After this digression, we proceed to relate, that the doctor and his three brothers, together with Mr. Garbett, and Messrs. Cadell and Sons, of Cocksenzie, near Preston-Pans, were the original projectors and founders of the vast works at Carron, to the great prejudice of their respective fortunes. This circumstance,

together with an unfortunate concern in a colliery at Bor-rowstoness, brought ruin on all the doctor's fair prospects in life. With respect to the manufacture of sulphuric acid, we observe, that for several years Messrs. Roebuck and Garbett carried on their works in England and Scotland successfully and unopposed; and, besides supplying the demands of Great Britain and Ireland, exported very large quantities of sulphuric acid to the continent. At length, in the year 1756, their prospects were clouded by the conduct of a servant, who had the art to induce a Mr. Rhodes, of Bridgenorth, to embark in the business. This person, abandoning Mr. Rhodes, connected himself with Mr. Skey, of Bewdley, who had commenced a manufactory of sulphuric acid on a much larger scale than that at Bridgenorth; and this was the third manufactory for producing the acid by the combustion of sulphur in leaden chambers. In the year 1772, a manufactory was established at Battersea, near London; and upon the failure of this, another manufactory was instituted at Pitworth-Moor, near Eccles, in Lancashire. Soon afterwards another work was established at Leeds; and at length similar works have been founded in various parts of England, Scotland, and Ireland: and it is said, that there are now no fewer than eight considerable manufactories of sulphuric acid at and near Birmingham. When the new method of bleaching by oxymuriatic acid was introduced, about the year 1788, the demand for sulphuric acid was very considerably augmented, so that chambers for the combustion of sulphur of much larger extent than those first constructed became necessary. Chaptal, in his "*Chemistry applied to the Arts*," (vol. iii.) says, that chambers about 20 feet broad, 25 long, and 15 high, seem to be the most advantageous: and it is observed, that the size of the leaden chamber in modern use, is from 20 feet in length and 12 feet in width, to 40 or 60 feet long and 16 or 18 feet wide. One manufacturer in Lancashire, however, says Mr. Parkes, has a leaden chamber of the enormous dimensions of 120 by 40 feet, and 20 feet high, thus forming a space of 96,000 cubic feet. These leaden chambers are technically called "houses," and in some districts "leaden vessels." The sulphuric acid annually consumed in these kingdoms is said to amount to upwards of 3000 tons, the greater part of which is used in a state of dilution, in which state it is consumed in large quantities by bleachers, and by calico-printers, for making what they call "sours;" and also for the purpose of dissolving iron or zinc when diluted with at least five or six times its weight of water.

The uses of sulphuric acid are very numerous. It is employed in large quantities for preparing the bleaching salt; by dyers for dissolving indigo, and for other purposes; by calico-printers for preparing sours; and by the manufacturing and the philosophical chemist, as a test for lead and barytes, and for a great variety of other purposes, some of which only can be enumerated.

The makers of the nitrous and muriatic acids are large consumers of sulphuric acid; as also are the makers of sulphate of zinc, sal ammoniac, phosphate of soda, Glauber and other salts; as well as the manufacturers of Roman vitriol, Prussian blue, and some other colours.

Sulphuric acid is likewise employed by some modern farmers in the preparation of their feed-wheat, to prevent what is called the smut; by the people who purify lemon-juice, when united to lime, in order to separate its acid in a crystalline form for the use of calico-printers and others; and by the makers of glass to convert the muriate of potash, which is one of their residuums, into sulphate of potash, and which has lately been used by them as a substitute for

soda. It is also consumed in large quantities by the makers of tin-plate, by brass-founders, button-makers, japanners and gilders; to all of whom this acid is become absolutely necessary for the removal of the oxyd which forms on the surface of the iron or the copper on which they work, and which, if not removed, would prevent or impede all their operations.

Sulphuric acid is likewise a necessary article to some paper-makers, to fell-mongers, and to tanners;—it is used in considerable quantities by the modern hatter in the operation of felting;—and it may be remarked that refiners use it in the process of stripping metals;—oil-merchants, in refining rape-oil, which it effects by carbonizing the farinaceous matter and the mucilage;—and brewers in fining what is called “gray beer:”—that the professors of pharmacy as well as the chemists are constant customers for sulphuric acid;—that it is employed in making the astringent and stomachic water of Rabel, and for other purposes of medicine, as well as surgery;—that distillers and rectifiers of ardent spirits consume it in still larger quantities;—that the makers of vinegar use it for the adulteration of that acid;—that many tons are annually consumed in the preparation of liquid blacking;—and that the aeronaut, at every ascension into the atmosphere, requires many hundred weights of sulphuric acid for the formation of the hydrogen gas, which renders the aerial machine buoyant in that subtle medium.

As the uses of sulphuric acid are become so various, cases may occur of its being taken into the stomach by mistake, and without immediate relief its corrosive properties would produce fatal effects. If magnesia should be at hand, that earth mixed with water and sweetened with sugar, would be the best possible antidote to the poison; but in case this could not be immediately procured, soap-water, which can be furnished by all families, and which is one of the next best remedies, should be drunk plentifully. Parkes, ubi supra.

For an account of the process of manufacturing this acid, and its properties, see the article *SULPHURIC Acid*. For tables, exhibiting the temperatures produced by the mixture of sulphuric acid and water, the specific gravities of the acid, when diluted with different portions of water, taken at the temperature of 60°; and of the variations in the specific gravity of concentrated sulphuric acid, by change of temperature, the barometer being at 29.5 inches, we refer to Parkes's Essays, vol. ii.

VITRIOLIC Acid, in *Agriculture*, is that which is now termed or known by the name of the sulphuric. It is noticed by the writer of the work on the Connection of Agriculture with Chemistry, that all acids are at present named from the peculiar bases or substances of which they are formed, by the combination of pure air or oxygen; the presence of which is necessary in all cases to constitute an acid. This is stated to be the most powerful of all the acids, and that it disengages or expels other acids, when in a state of combination with metallic, earthy, or alkaline substances in the soil or otherwise. When concentrated, it acts in a similar manner to that of alkaline salts, in the resolution or destruction of vegetable substances, as well as those of the animal kind, disengaging from them certain gases, and forming therewith certain saponaceous and saline compounds. These solutions or extracts are of a reddish-brown colour, similar to that produced by the action of alkaline salts on oxygenated peat or peaty earth. The vitriolic acid may, it is said, be used beneficially to decompose and bring into action the soluble matter accumulated in soils, by the combination

of the phosphoric and forline or oxalic acids with calcareous matter. In this case, the vitriolic acid will join with the calcareous matter, and form gypsum or sulphate of lime; while the phosphoric and forline or oxalic acids, in consequence of their disengagement, will combine with other matters in the soil, particularly with magnesia, if any be present, forming saline matters which are very soluble, and conducive to vegetation and the growth of plants. The business is to be accomplished by the use of such substances as contain much of this sort of acid in cases where the other sorts of acids prevail.

It is suggested, however, that the endless series of processes employed by nature doth not finish or end here; for, on a supposition that the phosphoric and forline or oxalic acids had been fully disengaged from the calcareous matter with which they had been formerly united, and that in the states of phosphate and oxalate of potash, soda, ammonia, or magnesia, they had expended themselves in the process of vegetation; still the gypsum or sulphate of lime remaining in the soil would, on a renewed application of dung, urine, animal or vegetable matter, be brought from the state of gypsum or sulphate of lime, which is insoluble, to a state approaching to that of a hepar of lime, which is soluble; and that as the vitriolic acid and calcareous matter are contained in, and form a part of, the compounded residuum of vegetable matters, it may hence be inferred, that these matters were not generated in, but were taken up, when in a state of solution, by the roots of plants. Thus, it is said, may the good effects of gypsum or sulphate of lime in America be accounted for without much difficulty. And to these beneficial effects, from the combination of inflammable substances with gypsum or sulphate of lime, forming what is called a hepar, or liver of sulphur, may be added the large share of nourishment which trees, and plants of a certain formation of stem and leaf somewhat of that kind, receive by the hepatic air disengaged from the hepars, when they, by the process of oxygenation, are again returned to the state of neutral salts, of which such hepars had been formed by the combination of inflammable or carbonaceous matter. See *OXYGENATION and SULPHATE of Lime*.

VITRIOLIC Minerals are compound fossil substances, formed of various stony and earthy particles, mixed with others of iron and copper, and that either separately or conjointly; so that, in effect, they are ores of vitriols.

The different kinds of these minerals are, 1. The chalcitis. 2. The misy. 3. Sory or rusina. 4. Melancitis. 5. Pyrites, or fire-stone. 6. Marcasites. See *CHALCITIS, MISY, &c.*

In Europe, the only use made of chalcitis is as an ingredient of Venice treacle, and even here its place is generally supplied with common green vitriol calcined to a redness. The ancient Greeks used it externally in hæmorrhages, and collyriums for the eyes; also for the herpes and erysipelas; but never ventured to give it internally.

The ancients used misy for the same purpose as chalcitis, being esteemed milder than this last.

At present it is no where put to any use, nor indeed does it merit it, as containing no other virtues than those of green vitriol, though we are not sure what pernicious substance it may be mixed with.

VITRIOLIC Waters. The countries which abound with mines of copper and iron usually afford a great many vitriolic waters. See *Blue Vitriol*, under *VITRIOL*.

One of the most remarkable springs of this kind, of which we have an account, is that near Paderborn, in Germany; this is a sort of treble spring, having three openings, and all three yielding very different waters. Two of these openings

openings are not more than a foot and a half distant from one another, and yet of so different qualities, that the one is limpid, bluish, milk-warm, and bubbling, and contains sal ammoniac, ochre, iron, vitriol, alum, sulphur, nitre, and orpiment; all these substances having been separated in its analysis. The other is cold as ice, and is turbid, whitish, and much heavier, and stronger to the taste than the other. This holds much orpiment, with some salt, alum, nitre, sal ammoniac, and vitriol. The first of these waters is taken by the people in the neighbourhood, against worms, and disorders of the spleen, as also against epilepsies; the other is poisonous to birds, all that drink of it dying in a very little time. The experiment has been tried on common hens, with the water brought from the springs into other places, and given them to drink.

Those to which salt is given, after the swallowing of this poisonous water, struggle longer before they die by it; and vinegar is found to save them very often from death, after drinking largely of it; but in this case they are sickly for seven or eight days after it, and have the pip, as the good women express it.

In the dissecting of those birds which have died by drinking this water, the lungs are always found quite shrivelled up.

The people of the country have not been deterred by this bad effect of the water from using it in medicine; they take small quantities of it diluted in water, to destroy the worms, and it performs this very well; but gives them a grievous sickness while it operates.

The third stream, or opening, of this remarkable spring, is about twenty paces distant from the others; the water is here very clear, of a greenish colour, and of a sour, but not very disagreeable taste. It is of a middle weight, and of middle qualities between the other two, and is evidently formed of the joining of those two springs with some other fresh water in the way; for a liquor exactly resembling this third kind may be prepared, by mixing equal quantities of the other two with a sufficient quantity of common well-water.

There is a spring in Basil discharging its water through the Tanners'-street, or Gerber-gasse, which is of a bluish colour, and somewhat turbid. This holds blue vitriol, that is copper, in the form of a salt, and with it bitumen and antimony; but a much larger proportion of the first ingredient than of either of the others. The analysis of it shews, that it contains three parts copper to one of bitumen, and two of antimony. It serves the tanners of the place to good purposes, their skins receiving one of their preparations from this native water.

The same town affords several other springs of peculiar qualities, all owing to the veins of metalline ores with which the earth of the place abounds. The one of these is called Bandulphi's well, and affords a water of great use in medicine, several being regularly and perfectly cured of hydropical distempers by it. And another very remarkable one contains, as is found by its analysis, sulphur, nitre, and some gold. These, however, are in such small quantity in it, as not to prevent its being fit for the common uses of life. It is very agreeable to the taste, and is much esteemed for drinking, and sent for all over the town.

Another vitriolic water runs out of a cavern, near Gelfbach, in Alsace. It is a fattish and oily liquor, and is used by the country-people for greasing their wheels, but it is fit for much better purposes. If it be boiled to the evaporation of a third part, there will remain very little water, but a fatty bituminous substance, like tar, will subside to the bottom, and there will swim at the top a yellow, thin, and

limpid liquor, very much resembling linseed-oil; and this, distilled in a sand-heat, yields an oily and watery liquor; the first very good for external uses, for burns and scalds; and the other a good internal medicine in consumptions, and other disteases of the lungs. Phil. Trans. N^o 8.

Some time ago there was a water discovered in England, that gave, on many experiments, an appearance of containing natural and perfect vitriol. This water was found near Eglingham, in Cumberland; and being examined, by adding galls to it, it became absolute ink, much deeper than any of the atramentous waters ever do; when one half the quantity was slowly evaporated, the remainder retained this quality to a higher degree than before; and on evaporating it yet farther, there concreted in it fair crystals of pure and genuine vitriol.

This was an appearance wholly new in England, and not easily accounted for, as we have no mineral, except the common pyrites, which contains vitriol; and it is very well known, that there requires a fermentation in the air, before the vitriol, contained in that stone, will be disentangled from its other principles, so as to be capable of appearing in its own form; and as this stone, lying under water, can never impregnate that water with its vitriol, it did not seem easy to conceive in what manner a genuine vitriol should be communicated to water, where there was no other substance which could give it. The suspicions that these thoughts gave the gentleman who examined this water, occasioned his making a visit to the place where it was produced, when he found that the supposed vitriolic spring was no other than an old drift made for the draining of the water from some old wrought coal-pits; the people who had worked in these remembered to have seen great quantities of pyrites there. This drift was sometimes dry for a considerable time together, and sometimes ran in a plentiful stream; and there is no doubt but that, in these dry seasons, the air acted upon the pyrites, and caused it to shoot its vitriol, which the next tide of water washed away, and it came off dissolved in it, and highly impregnating it.

This proved, therefore, no better a medicinal spring than some of a like kind, described by Mr. Leigh in his "Natural History of Lancashire;" and all these are very little better than the discovery of a medicated water in Old-freeet, from the remains of an old colour-shop, or Kircher's reckoning the common stores of Rome among the medicated springs of Italy.

The vitriolic spring which has been so much talked of near Haigh, in Lancashire, is no other than an accidental impregnation of common water, in the same manner; it being only the runnings of an old drift, or drain, made to carry off the water from the pits of cannel-coal; and this, like the other, as it sometimes has water, and at other times is dry, gives time for the pyrites to let go its vitriol while dry, and then imparts it to the waters that pass that way afterwards. These are not to be accounted medicated springs, since neither natural nor continual, and such may be any day made at home, by laying the common pyrites of our clay, or coal-pits, out to moulder in the air, and then pouring water upon it, and, after a short time standing, taking it off again. Phil. Trans. N^o 245. p. 380. See ZIMENT, and VITRIOL, in *Chemistry*.

VITRUM. See GLASS.

VITRUM, in *Botany*, a name given by some of the old writers to the plant we now call *glastum* or *wood*.

This plant has always been a native of England, and was in use among the savage inhabitants of this island, for painting their bodies. Those who have not understood this to be the name of that plant, have been strangely perplexed to

to account for those people painting their bodies with vitrum, glass, as they understood it : but the whole meaning of this plant obtaining the name of vitrum, seems to have been its staining the skin to a pale blue colour, or, as it was called by many, a glass-colour.

VITRUM Antimonii Ceratum, in *Pharmacy*. See **ANTIMONY**.

This is an insipid, inodorous powder, of a brownish colour : in its operation diaphoretic and cathartic, occasionally exciting nausea and vomiting.

The ordinary dose for adults is ten or twelve grains ; but it is sufficient to begin with six, or even with three or four grains. The quantity of a scruple has been given to a strong man, which wrought gently. The dose for a child of three or four years is two or three grains ; and for one of ten, three or four grains.

This medicine was for some time held a specific in dysenteries ; but the preparation and manner of giving it had been kept a secret, till Dr. Young made it public. Dr. (afterwards Sir John) Pringle says, he tried it in a dysentery of four years standing with surprising success ; and, indeed, to him we are principally indebted for the general introduction and use of this medicine ; as he collected and published several cases of its efficacy.

It has been given in dysenteries, with or without a fever, whether epidemic or otherwise, and whether bleeding and vomits have been premised or not. In its operation, it sometimes makes the patient sick, and vomits him ; it purges almost every person ; but it has been known to cure without any evacuation or sickness. It is to be given with an empty stomach, for then it operates most mildly. Nothing is to be drank after it for three hours, unless the patient is very sick, and disposed to vomit ; in which case warm water may be given, as in other vomits.

This medicine should not be given for diarrhæas in the end of consumptions. Other diarrhæas have been cured with large doses of it ; but in such cases it fails oftener than in dysenteries. During the use of this powder, fermented liquors should be abstained from, and a milk diet is proper. It may be given safely to women with child, and to children on the breast may be given half a grain. This preparation has also been found successful in uterine hæmorrhages, both in young and old.

It has also been tried in colic pains, from vicidities in the intestines, and found a safe and easy purgative, and sometimes a gentle emetic.

The method of giving it is in a bolus, with conserve of roses, diascordium, or theriaca Edinensis. An opiate, after the operation, is proper. (Med. Ess. Edinb. vol. v. art. 15. p. 162, &c.) See an account of its efficacy in bloody fluxes, diarrhæas, simple loosenesses, quartan agues, even the most obstinate, and in certain cases of the fluor albus, and observations on the mode of administering it, by M. Geoffroy, in *Phil. Trans.* vol. lxxvii. p. 273, &c.

Later experience, it is said, has proved that it possesses no advantages superior to other antimonials, properly dosed and combined, in the diseases above-mentioned ; and differs from the vitrum antimonii, or glass of antimony, only in its milder operation, owing to part of the oxygen being abstracted by the carbonaceous matter of the wax, which appears to answer no other purpose. Thomson's Disp.

VITRUM Archimedæum, *Archimedes's Glass*, a name given by Swedenborg to an instrument which he invented for the examination of mixed metals, and by means of which he could discover the quantities, without the trouble of the apparatus and calculation commonly used for this purpose.

VITRUM Morrbinum, *Morrhine*, or *Myrrhine Glass*, a name given by Pliny, and some of the ancients, to a sort of

manufacture made in Egypt, which, though truly no other than a kind of glass divested of its transparency, yet was made so nicely to imitate the *myrra* or *morra* of the Indies, so famous among the Romans, under the form of cups and vessels, called *murrhina vasa*, that it was called by some *murrha altera*, another sort of *murrha*, and the cups made of it honoured with the name of *murrhine vessels*. This serves to shew, that the *myrrhina vasa*, properly so called, were not of any precious stone, as vulgarly supposed, but a sort of porcelain. See **MURHINE**.

VITRUM Saturni. See **GLASS of Lead**.

VITRUVIUS, M. POLLIO, in *Biography*, a very distinguished writer on architecture, is supposed to have flourished in the times of Julius Cæsar and Augustus : of his parentage and place of nativity nothing certain is known. Verona claims him ; but the pretensions of Formia, now Mola de Gæta, are more generally allowed. Of his liberal education, and of his travels for information and improvement, we can have no doubt. By the exercise of his profession he had acquired some property ; though perhaps it was not very considerable, as he says of himself that he did not, like the emperor Augustus, or perhaps one of the succeeding princes, to whom he dedicated his work, he occupied the post of inspector of the military engines. But as Pliny the Elder mentions his name, among other authors, in his "Natural History," composed in the reign of Vespasian, his work must have been published before that period. Of edifices planned or constructed by him, one only is mentioned by himself, which was a Basilica at Fano. His work was discovered in MS. by Poggio in the 15th century, and it has ever since been held in high estimation. The ten books into which it is distributed, not only treat on every thing belonging to buildings, public and private, their site, materials, forms, ornaments, conveniences, and the like ; but include much of what would now be termed engineering, civil and military, and even digress to geometrical problems and astronomical inventions. Besides the instruction that may be derived from it, it has afforded much important matter to the antiquary relative to the state of art and science, and the detail of private life, among the Romans.

Some of the most esteemed editions of Vitruvius are "Dan. Barbari," Venet. fol. 1567 ; "J. de Lact," Amst. fol. 1649 ; "Galiani," Neap. fol. 1758 ; with an Italian translation and notes. "Claude Perrault" has given a good French translation, Paris, fol. 1684 ; and we have an English one by "Mr. Newton," Lond. 1791. Gen. Biog.

A magnificent edition of the *Civil Architecture* of Vitruvius, in two parts, royal folio, has been lately presented to the public by W. Wilkins, jun. A.M., F.R.S., &c. &c.

During the reign of Augustus, except Vitruvius, it does not appear that the Romans had one architect, sculptor, painter, or musician. Vitruvius has given Aristoxenus's system in Latin ; but was obliged to retain the Greek technica, as he was the first Roman writer on the subject of music, and used Greek technical terms as we do Italian. Vitruvius has described the theatrical *vasæ* used by the Greeks for the augmentation and continuation of sound (see **ECHÆIA**) ; and has given us a description of the organ of the ancients blown by the fall of water. See **ORGAN** and **HYDRAULICON**.

VITRY, JAMES DE. See **JAMES DE VITRY**.

VITRY, in *Geography*, a town of France, in the department of the Straits of Calais ; 9 miles N.E. of Arras.—Also, a town of France, in the department of Paris ; 4 miles S.E. of Paris.

VITRY le Brulé, a town of France, in the department of the

the Marne. This town was, in the 12th century, one of the principal places of the country, when Thibaut, count of Chartres, who took arms against Louis the Young, took it by assault, and set it on fire, by which many persons were burned, and great part of the town destroyed. It was on this account called *Brule*. The English and Burgundians in the war with Charles VII. set fire to Vitry, with sixty villages, in the year 1422. It was a third time burned and ruined by the troops of the emperor Charles V.; 3 miles N.E. of Vitry le François.

VITRY le François, a town of France, and principal place of a district, in the department of the Marne, on the Marne; built by Francis I. after the destruction of Vitry le Brulé by the emperor Charles V.; 16 miles S.E. of Châlons-sur-Marne. N. lat. 48° 43'. E. long. 4° 38'.

VITRY aux Loges, a town of France, in the department of the Loiret; 18 miles N.E. of Orleans.

VITTA, among the Romans, a fillet with which the women in Rome bound their hair. The matrons wore a double one, to distinguish them from the virgins, whose vittæ were single.

Vittæ were also worn by priests and poets, in which case they were made of branches of olive or laurel: the statues of the gods were likewise adorned with the vittæ, as were altars, the doors of temples, victims, and supplicants.

VITTA, among *Anatomists*, *fillet*, or *head-band*, is used for that part of the amnios which sticks to the infant's head when it is just born.

VITTA Cerulea, in *Conchology*, a species of dolium.

VITTA, in *Ichthyology*, a name given by Gaza and some others, to the fish called by others *tania*, and by the Italians *cepole*.

VITTARIA, in *Botany*, so called by the writer of this article, from *vitta*, a fillet, or ribbon, in allusion to the shape of the frond.—Sm. Mem. de l'Acad. de Turin, v. 5. 413. t. 9. f. 5. Tracts, 243. t. 1. f. 5. Willd. Sp. Pl. v. 5. 404. Swartz Syn. Fil. 109. Nov. Aët. Soc. Nat. Scrut. Berol. v. 2. 129. Sprengel Crypt. Engl. ed. 77, 114. Brown Prodr. Nov. Holl. v. 1. 153. Ait. Hort. Kew. v. 5. 522.—Clas and order, *Cryptogamia Filices*; sect. *annulata*. Nat. Ord. *Filices dorsifera*.

Eff. Ch. Fructification in longitudinal continued lines, parallel to the midrib at each side. Involucrum double, uninterrupted; one separating towards the margin, the other towards the rib.

This genus was at first supposed by its author to consist of a solitary species, *Pteris lineata* of Linnaeus; but Swartz and Willdenow have added several others, from their own discoveries or those of Bory de St. Vincent, so that eight in all are now known. Of these, Willdenow has given the most complete view. They are all of tropical origin. The frond is uniformly simple and entire, of a long nearly linear form, and either erect or pendulous; its texture generally coriaceous.

1. *V. lineata*. Linear Tape-fern. Swartz Syn. n. 1. Willd. n. v. Schkuhr Crypt. 93. t. 101, b. (*V. angustifrons*; Michaux Boreal-Amer. v. 2. 261. *Pteris lineata*; Linn. Sp. Pl. 1530. *Lingua cervina longifolia* et *angustifolia* foliis; Plum. Amer. 28. t. 41. Fil. 123. t. 143; copied in Petiv. Fil. t. 14. f. 3.)—Fronds linear, very long. Lines solitary, a little within the margin.—Native of many parts of the West Indies. The perennial root consists of numerous reddish fibres, intermixed with scales. Fronds several, about two or three feet long, and a quarter of an inch wide, acute, coriaceous, smooth, of a bright green. We find no authority for Swartz's character of "pendulous" in the specific definition, except he alludes to the reflexed posture of the upper half of each frond in Plumier's

figure, which seems contrived merely to admit the whole plant into the plate.

2. *V. ifoetifolia*. Quillwort Tape-fern. "Bory de St. Vincent Voy. v. 2. 325." Swartz Syn. n. 2. Willd. n. 2.—Fronds linear-thread-shaped, acute, pendulous, very straight; channelled at the top. Lines solitary, marginal.—Native of the isle of Bourbon, hanging from the trunks of aged trees. Stalks very scaly. Fronds rigid, from ten to eighteen inches long. Involucrum narrow. Capsules pale. Willdenow.

3. *V. filiformis*. Thread-shaped Tape-fern. Cavan. Leccion. 270. Swartz Syn. n. 3. Willd. n. 3.—Fronds thread-shaped, very long, glaucous.—Native of Peru. Fronds numerous, two or three feet in length, and half a line only in breadth. Cavanilles.

4. *V. elongata*. Long-leaved Tape-fern. Swartz Syn. n. 4. 302. Willd. n. 4. Brown n. 1.—Fronds linear, very long, coriaceous, ribbed, pendulous. Lines marginal.—Native of the East Indies, and the tropical part of New Holland. Roots creeping, rigid, with downy rusty fibres. Stalks covered with black, shining, reticulated, hair-pointed scales. Frond three or four feet long, two lines broad, flat, rather rigid, smooth, minutely veined. Swartz.

5. *V. zosterifolia*. Grass-wrack Tape-fern. Willd. n. 5. ("V. angustifrons"; Bory de St. Vincent Voy. v. 1. 238, and v. 2. 324.)—Fronds linear, very long, membranous, pendulous. Lines solitary, marginal.—Found on old trees, in the isle of Bourbon. Root creeping, scaly. Fronds five feet long, three or four lines broad, thin; tapering much at the base. Lines very narrow, close to the edges. The plant much resembles a *Zostera*. Willdenow.

6. *V. ensiformis*. Sword-shaped Tape-fern. Swartz Syn. n. 5. Nov. Ac. Berol. n. 3. t. 7. f. 1. "Schkuhr Crypt. 94. t. 101, b." (*V. incurvata*; Cavan. Leccion. 270.)—Fronds linear-sword-shaped, somewhat falcate, erect. Lines solitary, marginal.—Native of the Philippine isles, the Mauritius, and the East Indies. The root resembles that of *V. lineata*. Fronds numerous, six or eight inches high, and two lines broad, curved. Cavanilles.

7. *V. plantaginica*. Plantain-leaved Tape-fern. "Bory de St. Vincent Voy. v. 2. 325." Willd. n. 7.—Fronds linear-lanceolate, erect. Lines solitary, marginal, in the middle part of the frond.—Native of the isle of Bourbon. Root tufted, clothed with blackish, tapering, most elegantly reticulated scales. Fronds from ten to eighteen inches high, from three to five lines broad, tapering much at each extremity. Lines of fructification thickish, pale brown, but four or five inches long. Willdenow.

8. *V. lanceolata*. Lanceolate Aggregate Tape-fern. Swartz Syn. n. 6. Nov. Aët. Berol. n. 2. t. 7. f. 2. Ind. Occ. 1603. "Schkuhr Crypt. 94. t. 101, b." (*Hemionitis lineata*; Swartz Prodr. 129.)—Fronds lanceolate-linear, erect. Lines numerous.—Found on old trees, on the mountains of Jamaica. Root fibrous, tufted, rusty, covered with shining reticulated scales. Fronds crowded, a foot high, acute, smooth, on short bordered stalks. Lines two, three, or four on each side of the rib, between it and the margin, reaching from top to bottom, each furnished with its double involucrum, though very narrow. Swartz.

VITTEAUX, in *Geography*, a town of France, in the department of the Côte d'Or; 9 miles S.E. of Semur en Auxois.

VITTEFLEUR, a town of France, in the department of the Lower Seine; 20 miles N. of Caudebec.

VITTEL, a town of France, in the department of the Vosges; 9 miles S.W. of Mirecourt.

VITTORIA, **LODOVICO**, in *Biography*, author of the most

most pompous publication of motets which we have seen. The parts are printed separate on the opposite pages, and without bars, in such large characters, that the performers of the several parts might sing out of the same choral book. The following is the Latin title of this work: "Thomæ Ludovici Vitoria Abulenſis Motecta Feſtorum totius Anni, cum Communi Sanctorum, a 4, 5, 6, 8 Vocibus." Romæ, 1585.

VITTORIA, in *Geography*, a town of Spain, in the province of Alava. This town was built by Don Sancho, king of Navarre, in memory of a victory obtained over the Moors on the spot. It contains five parishes, four convents, three hospitals, and a college. The inhabitants carry on a considerable traffic in wool and wine; but the principal article of commerce is in sword-blades, of which they manufacture a great number; 42 miles S.S.W. of St. Sebastian. N. lat. 42° 47'. W. long. 2° 41'.

VITTORIA, *La*, a town of Sicily, in the valley of Noto; 20 miles N.W. of Modica. N. lat. 36° 55'. E. long. 14° 38'.

VITTORIOSA, or *Città Vittoriosa*, or *Il Borgo*, a fortified town of the island of Malta, situated on a narrow neck of land, to the left of Valetta; on each side a broad natural canal runs up into the land, and surrounding the town, forms a fine harbour. This canal is on one side called Porto della Renella, and on the other Porto delle Galere. The strong castle of St. Angelo stands on a high rock, and has a communication with the town by a bridge. The number of inhabitants amounts to 3000; formerly the grand master resided here. The palace of the inquisition and the arsenal are reckoned among the principal buildings of this place.

VITULI AQUATICI, in the *History of Insects*, a name given by the German writers to the worms resembling animated horse-hairs. See *AMPHIBIENA Aquatica*.

VITULUS, *CALF*, in *Zoology*. See *CALF*.

VITULUS Marinus, the *Sea-calf*. See *SEA-CALF*.

VITUS'S DANCE, *St.*, in *Medicine*. See *CHOREA*.

VIU, in *Geography, a town of France, in the department of the Po, on the Stura; 14 miles N.W. of Turin.*

VIVA, or **VIVA**, in *Ancient Geography*, a town of Africa Propria, on the route from Carthage to Sufetula, between Carthage and Pulput. Anton. Itin.

VIVA Pecunia was anciently used for live cattle.

VIVA Voce, *q. d.* by word of mouth. See *ORAL*.

VIVACE, Ital. in *Music*, implies lively, gay, animated; not rapid, but an execution free and firm. See *VIF*.

VIVACITY of Style, in *Oratory*, a character of style, depending on the choice of words, their number, and their arrangement.

This quality of style is adapted to please the imagination, and consequently to awaken and fix the attention. With regard to words, they may be considered in three points of view; as proper terms, or rhetorical tropes, or as to the relation which the found may be made to bear to the sense. The chief importance and use of proper terms in their reference to the end proposed is their "speciality," or their being as particular and determinate in their signification as will suit the nature and scope of the discourse. To this purpose it is observed, that in composition, particularly of the descriptive kind, it invariably succeeds best for brightening the image, to advance from general expressions to more special, and thence again to more particular. This, in the language of philosophy, is called descending; but in the language of oratory, it is ascending. With regard to the use of tropes, we refer to that article. Words may farther be considered with regard to their found, and the affinity to the subject

of which the found is susceptible. When, as Pope expresses it, "found is made an echo to the sense," there is added, in a certain degree, to the association arising from custom, the influence of resemblance between the signs and the things signified; and this, without doubt, tends to strengthen the impression made by the discourse. In this connection it is natural to enquire, what kinds of things language is capable of imitating by its found, and in what degree? In reply we may observe, that the imitative power of language must be greatest, when the subjects themselves are things audible. When the subject is articulate found, the speaker or the writer may do more than produce a resemblance; for he may even render the expression an example of that which he affirms. Thus Pope affords an instance.

"These equal syllables alone require,
Tho' oft the ear the open vowels tire;
While expletives their feeble aid do join,
And ten loud words oft creep in one dull line."

As to founds inarticulate, the same author has tolerably succeeded in imitating them.

"Soft is the strain when Zephyr gently blows,
And the smooth stream in smoother numbers flows;
But when loud surges lash the founding shore,
The hoarse rough verse should like the torrent roar."

The same conformity of the found to the sense is too discernible in the following lines.

"O'er all the dreary coasts!
Dreadful gleams,
Dismal screams,
Fires that glow,
Shrieks of woe,
Sullen moans,
Hollow groans,
And cries of injur'd ghosts."

Nor can we here overlook Milton's description of the opening of hell-gates;—

"——— On a sudden open fly,
With impetuous recoil and jarring found,
Th' infernal doors, and on their hinges grate
Harsh thunder——"

The following is also an excellent specimen from the same author's "Lycidas:—

"Grate on their scarnel pipes of wretched straw."

Dyer has also made an excellent attempt in the same way, in his "Ruins of Rome:—

"——— The pilgrim oft
At dead of night mid his oration hears
Aghast the voice of time, departing towers,
Tumbling all precipitate down-dash'd,
Rattling around, loud thundering to the moon."

But the following lines of Pope furnish the best example of this kind:

"What! like fir Richard, rumbling, rough and fierce,
With arms, and George, and Brunwick crowd the verse,
Rend with tremendous sounds your ears asunder,
With gun, drum, trumpet, blunderbuss, and thunder?
Then all your Muse's softer art display,
Let Carolina smoothe the tuneful lay,
Lull with Amelia's liquid name the nine,
And sweetly flow through all the royal line."

There are other subjects beside found, to which language

is capable of bearing some resemblance. Time and motion, *e. g.* or whatever can admit the epithets of quick and slow, may in some degree be imitated by speech. This appears with particular advantage in verse, when, without any violation of the rules of prosody, a greater or a less number of syllables is made to suit the time. Thus Milton:—

“When the merry bells ring round,
And the jocund rebees found,
To many a youth and many a maid
Dancing in the chequer'd shade.”

The Greek and Latin have here an advantage, at least in their heroic measure, superior to all modern tongues; accordingly Homer and Virgil furnish excellent specimens in this way. Our own tongue and metre, however, afford instances not unworthy of notice. We shall select the translation by our English bard of the following much admired passage from Homer:

“——— Λαοὺς αὖτις ὠθεῖται πρὸς ἑλίκην—
Αὖτις; ἐπιείθε κλυτὰ τεύχεα λαοὺς ἀναιδέων.” Od.

“Up the high hill he heaves a huge round stone;
The huge round stone resulting with a bound,
Thunders impetuous down, and smokes along the ground.”

Vida, in his “Art of Poetry,” has well exemplified this beauty from his great master, Virgil:

“Ille autem membris, ac mole ignavius ingens
Incedit tardo molimine subsidendo.”

Slowness of motion is admirably exemplified by Pope, in the following lines:

“A needless Alexandrine ends the song,
That, like a wounded snake, drags its length along.”

In representing uncommon speed, he thus expresses himself:

“Not so when swift Camilla scours the plain,
Flies o'er th' unbending corn, and skims along the main.”

Thus Dryden:

“Which urg'd, and labour'd, and forc'd up with pain,
Recoils, and rolls impetuous down, and smokes along the plain.”

There are also other affections of motion, besides swiftness and slowness, which may, to a certain degree, be imitated in the sound of the description: but our limits will not allow us to introduce examples. Size or magnitude, difficulty and ease, are subjects of imitation in language. For an instance of difficulty, we produce the following couplet from Pope:

“When Ajax strives some rock's vast weight to throw,
The line too labours, and the words move slow.”

Moreover, the agreeable in things may be adumbrated to us by smooth and pleasant sounds, and the disagreeable by such as are harsh and grating.

With regard to the species of beauty which we have been describing and exemplifying, we may observe, that it is, in many cases, more the creature of the reader's fancy than the effect of the writer's ingenuity; and as it occupies the lowest rank in the scale of rhetorical excellence, it ought always to give place to the other virtues and ornaments of elocution, and not *vice versa*. The cases in which it ought to be aimed at are comparatively few.

Compositions in prose, those excepted which are intended to persuade, and which aim at a certain vehemence of style and sentiment, should hardly ever be allowed to exemplify the resemblance above-mentioned; and even in poetry, this beauty seems naturally adapted only to the most pathetic passages, and most descriptive parts. In poems in which it is most suitable, it should be admitted only in a few passages, when it is the author's intention to describe something that is peculiarly striking.

In the inquiry how far vivacity may be affected by the number of words that are used, our author concurs with others in laying it down as a maxim, that the fewer the words are, provided neither propriety nor perspicuity be violated, the expression is always the more vivid. “Brevity,” says Shakspeare (Hamlet), “is the soul of wit.” Of whatever kind the sentiment be, witty, humorous, grave, animated, or sublime, it is certain that the more briefly it is expressed, the energy is the greater, or the sentiment is the more enlivened, and the particular quality for which it is eminent the more displayed.

Among the Lacedaemonians, who were remarkable for conciseness, to use few words, to speak energetically, and to be laconic, were almost synonymous. Pope has in a peculiar degree studied conciseness, and rendered it conducive to vivacity. The following example will be sufficient:

“See how the world its veterans rewards!
A youth of frolics, an old age of cards;
Fair to no purpose, artful to no end;
Young without lovers, old without a friend:
A top their passion, but their prize a fot;
Alive ridiculous, and dead forgot.”

The principal offences against brevity of diction are, *tautology, pleonasm, and verbosity*; which see respectively.

Another circumstance upon which vivacity of elocution depends is the arrangement of words: and this might be considered as it respects simple and compound sentences. (See SENTENCE and PERIOD.) We shall here observe, that composition and arrangement in sentences, though nearly connected, are not entirely the same. Composition includes arrangement, and something more. When two sentences differ only in arrangement, the sense, the words, and the construction are the same; but when they differ also in other articles of composition, there must be some difference in the words themselves, or at least in the manner of constructing them. See Campbell's Philosophy of Rhetoric, vol. ii. p. 158, &c.

VIVALDI, DON ANTONIO, in *Biography*, the most popular composer for the violin, as well as player on that instrument, of his time. He was maestro di capella of the conservatorio of La Pietà, at Venice. (See CONSERVATORIO.) Besides sixteen operas which he set for the Venetian theatres, and several others for different parts of Italy, between the year 1714 and 1737, he published eleven different works for instruments, of which a list is given in Walther, without including his pieces called “Stravaganze,” which among flashy players, whose chief merit was rapid execution, occupied the highest place of favour. His Cuckoo concerto, during our youth, was the wonder and delight of all frequenters of country concerts; and Woodcock, one of the Hereford waits, was sent for far and near to perform it. If acute and rapid tones are evils, Vivaldi has much of the sin to answer for. His title of Don was derived from his clerical character. “It is very usual,” says Mr. Wright in his *Travels through Italy*, from 1720 to 1722, “to see priests play in the orchestra. The famous Vivaldi, whom they call the *Prete Rosso*, very well knows among

among us for his concertos, was a topping man among them at Venice."

VIVAR, in *Geography*, a town of Spain, in Old Castile; 6 miles from Burgos.—**Alfo**, a town of Italy, in Friuli; 5 miles N.E. of Aviano.

VIVARAIS, before the revolution a province of France, in Lower Languedoc, on the right side of the Rhône, of which Viviers was the capital; now the department of the Ardèche.

VIVARIO, a town of the island of Corfica; 10 miles S. of Corte.

VIVARO, a small island in the Mediterranean, a little to the east of Ichia.

VIVARY, **VIVARIUM**, in our *Larw-Books*, is sometimes used for a park, warren, or fish-pond, in which living creatures are kept.

VIVER, in *Geography*, a town of Spain, in the province of Valencia; 8 miles N.W. of Segorbe.

VIVERO, a town of Spain, in Galicia, on the river Vivero or Landrova; 18 miles N.W. of Mondonado.—**Alfo**, a river of Spain, in Galicia, which runs into the sea; 12 miles E. of Cape Ortegal.

VIVEROL, a town of France, in the department of the Puy de Dôme; 9 miles S.S.W. of Ambert.

VIVERON, a town of France, in the department of the Dora, on a lake; 10 miles S. of Ivrea.

VIVERRA, in *Zoology*. See **FERRER** and **MUSTELA**.

VIVERRA, in the *Linnaean System*, is a distinct genus of the order *Feræ* (though united by Pennant and Shaw to the genus *Mustela*; which see), the characters of which are, that it has six cutting-teeth, the intermediate being shorter; one of the canine teeth on each side longer than the rest; the grinders more than three; the tongue bending backwards, often aculeated; and the nails extended. Gmelin reckons twenty-seven species, which are as follow.

ICHNEUMON; **Grey Ichneumon**. With distant thumbs, and tail gradually tapering from a thick base, and tufted at the end. This is called the rat of Pharaoh. See **ICHNEUMON**.

MUNGO; **Rufous-grey Ichneumon**. With distant thumbs, and untufted tail, gradually tapering from a thick base; the Indian ichneumon of Edwards; the quil or quiopele of Ray; and the mangoutte of Buffon. Shaw suggests that this may be a variety of the former; and he observes, that the ichneumon is a species of which there seem to be two distinct varieties, one of which (*viz.* the latter) is a native of India, and the other (or former) of Africa: they are alike in general appearance, but the Egyptian variety is considerably larger than the Indian, and has its tail tufted at the end, and thus differing from the Indian. In India, as well as in Egypt, the ichneumon is regarded as one of the most useful and estimable of animals; as it is an inveterate enemy to serpents, rats, and other noxious creatures which infest those regions. (See **ICHNEUMON**.) In India, it attacks with great eagerness and courage that most dreadful reptile, the cobra de capello, or hooded snake, and easily destroys it. For such purposes it is domesticated as the cat is in Europe. It is said to swim and dive occasionally, like the otter, and to continue for a long time under water. This animal is found, not only in various parts of India, but in the Indian islands, as Ceylon and others. It occurs also in various parts of Africa besides Egypt, as in Barbary and the Cape of Good Hope, &c.

CAFRA; **Yellowish-brown Weasel**. With tail gradually tapering from a thick base, and black at the tip. This animal, resembling, in its general form, the pole-cat, and nearly the length of the otter, with blackish feet and very

short ears, covered with woolly fur, is a native of the Cape of Good Hope.

ZENIK; **Four-toed Grey Weasel**. With ten transverse black bands on the body, and deep chestnut-coloured tail, black towards the tip; it is about the size of a water-rat, with a long snout, and two incisive and six canine teeth in each jaw; it has five toes on each foot; the claws on the fore-feet being very long, and almost straight; and those on the hind-feet are small and crooked. It is described by Sonnerat as a Caffarian species, being found in the country of the Hottentots.

TETRAPACTYLA, or **SURIKATTE**; the **Grey-brown Weasel**. With four-toed feet, and long moveable snout, and ferruginous tail, black at the tip: the furcate of Buffon, and four-toed weasel of Pennant. It is an inhabitant of the Cape of Good Hope, where it is called Meer-rat. It feeds on flesh, and preys on mice and other small animals. It commonly sits erect like the squirrel, and when pleased, makes a rattling noise with its tail, from which circumstance it has obtained, among the Dutch inhabitants of the Cape, the name of Klappermaus. It is also found in the island of Java, where the Dutch call it Surikatje, on account of a peculiar acid scent which it is said to emit.

NASUA; **Rufous Weasel**. With tail annulated with white, and lengthened moveable snout: the coat of Marcgrave, and coati-mondi of others, and Brazilian weasel of Pennant. Its size is equal to that of a cat; its colour cinereous-brown, with a cast of reddish, and tail annulated with distinct circles of black. Like the pole-cat, it preys on the smaller quadrupeds, birds, &c. It is a native of South America. Some animals are distinguished by a prolongation of the skin at the back of the head into several horny processes, about a quarter of an inch in length; and the upper part of the tongue is marked with several furrows, disposed so as to resemble the fibres of a leaf.

NARICA; **Brownish Weasel**. With tail of the same colour, and lengthened moveable snout: the coati-brun of Buffon, and dusky weasel of Pennant; reckoned a variety of the former both by him and Shaw. However, it is larger than the former, of a browner colour, and without any very distinct variegations on the tail. It feeds on animals and vegetables; goes into the water, and also climbs trees. It is found in South America.

VULPECULA; **Dark-chestnut-coloured Weasel**. With lengthened snout: the coasse of Buffon, and stifling weasel of Pennant. It is about the size of the pole-cat, of a deep or blackish chocolate colour, that of the tail sometimes mixed with white. This animal is a native of Mexico, and many other parts of America, and when attacked or irritated in pursuit, emits very powerfully offensive effluvia.

QUASIE; **Chestnut-coloured Weasel**. Beneath yellowish, with prolonged snout and annulated tail; is found at Surinam, and feeds on worms, insects, and fruits, and is fetid. Probably a variety of the coati-mondi, or Brazilian weasel.

PUTORIUS; **Blackish Weasel**. With five parallel, white, dorsal stripes: the friated weasel of Pennant, and conepate of Buffon: supposed to be the female of the *V. vulpecula*. Found in North America. It is sometimes tamed, and rendered domestic. See **MUSTELA Putorius**.

CONEPATL; **Blackish Weasel**. With two white dorsal lines extending along the tail. It is a native of New Spain, and probably a variety of the preceding.

MEPHITIS; **Brown Weasel**. With white back, marked with a longitudinal black stripe: the skunk weasel of Pennant, and chinche of Buffon. In manners and smell this species resembles the two preceding.

The *V. Chinge* of Molina, or black weasel, with a changeable cast of blue, and a row of white spots from head to tail, resembles in shape and general form the *chinche* just mentioned; but its colour is black. It is a native of Chili. According to Molina, its smell proceeds from a greenish oil, ejected from a follicle or receptacle near the tail. The Indians are said to value the skin of this species on account of its beauty, and to use it for various purposes, quilts, &c.

ZORILLA. Weasel variegated with black and white: the zorilla of Buffon; the mapurito and mafutiquil of Gullilla, &c.; smaller than the three preceding. A native of Peru and other parts of South America. The ground-colour is black; the tail as bushy and elegant as that of the mephitic weasel. It possesses the same faculty with the three former species.

MAPURITO; Black Weasel. With snow-white band from the forehead to the middle of the back, and without any external ears. This is the *V. putorius* of Mutis. Its tail is nine inches long, and whitish at the tip. It inhabits New Spain, burrows under ground, feeds on worms and insects, and may, perhaps, be a variety of the mephitic weasel.

VITTATA; Blackish Weasel. With a broad white band from the forehead to each shoulder: the grifon of Buffon; a native of Surinam, and found at Pamplona, in New Spain, and probably in every part of South America.

ZEYLANICA; Cinereous Weasel. Mixed with brown; whitish beneath; resembling the martin, and suspected by Schreber to be the same with the Ceylonese dog of Vosmaer. It is found in Ceylon, and probably in the Philippine Isles.

CAPENSIS; Black Weasel. With grey back edged with white. This is the stinkbinkfen of Kolbe, and ratel weasel of Pennant. It is one of the larger animals of the genus; cinereous-grey above, and brownish-black below, the two colours being separated along the whole length of the animal, from the base of the nose to the tail, by a stripe of black and white; when pursued it ejects a fetid liquid, accompanied with the intolerable smell of that of the American weasels, or skunks, and producing the same effects. It is found at the Cape of Good Hope, and in Guinea.

MELLIVORA. With cinereous back, with a black lateral band; the abdomen black; the claws long, hollow beneath, and formed for burrowing. This is the ratel of Sparrmann, feeding principally on the honey of wild bees, and found about the Cape of Good Hope. This honey-weasel has a very tough and loose skin, with thick hair, supposed to be given to it as a natural defence against the stings of bees. Mr. Pennant seems to have confounded this animal with the *V. capensis*; both species feed on honey; but Mr. Sparrmann does not mention any offensive effluvia in his description.

CIVETTA; Ash-coloured Weasel. Spotted with black, with chestnut-coloured mane, and dusky tail spotted towards the base. This is the felis zibethi of Gesner and Aldrovand, and the civette of Buffon, and commonly known by the name of the civet cat. It is a native of several parts of Africa and India. It is of a mild disposition, preys on birds and small quadrupeds, and produces the drug called *civet*; which see.

ZIBETHA; Ash-grey Weasel. Striated with black undulations, and an annulated tail. It is the felis zibethi of Gesner, and zibet of Buffon. Pennant regards it as the same species with the former, but it is generally considered by modern naturalists as distinct. It is found in India, and the Indian islands, and may be called the Indian, whilst the former is denominated the African civet cat. In disposition

and manners they both seem to agree; as well as in the secretion of the perfume before-mentioned, which is collected from both animals in the same manner.

HERMAPHRODITA; Dark-grey Weasel. With three black dorsal stripes, and long tail with black tip. Schreber has described this species from Dr. Pallas. It is a native of Barbary.

GENETTA; Fulvous-grey Weasel. With the body marked with rows of black spots, and annulated tail. It is the genet of Buffon, and one of the most beautiful animals of the genus, and about the size of a small cat. Its disposition is mild, and it is easily tamed. In various parts of the East, and particularly at Constantinople, it is domesticated like the cat, and no less serviceable in clearing houses from rats and mice. It is a cleanly animal, and has a slight musky smell. It is a native of the western parts of Asia, and is said likewise to occur in Spain, and in some parts of France. The French variety, however, is less elegantly and distinctly spotted than the Oriental genet; and Mr. Pennant considers it as a distinct species, under the name of "Pilofello."

FOSSA; Ash-coloured Weasel. Spotted with black, and with annulated tail. This is the fossane of Buffon, and so nearly allied to the genet, and of the same size, that it might be taken for a variety of the same animal. It is a native of Madagascar, Guinea, Bengal, CochinChina, and the Philippine islands: it is fierce, and with difficulty tamed. It destroys poultry like the common weasel: when young, it is said to be good food.

TIGRINA; Yellowish-grey Weasel. With brown variegations; annulated tail tipped with black or brown, and a black stripe from head to tail. This is the chat-bizzaam of Vosmaer, and the blotched cat of Pennant; of the size of the cat, and of mild manners. Mr. Pennant has referred it to the genus Felis, but Mr. Schrader makes it a Viverra. It is found at the Cape of Good Hope. Gmelin suggests that it may be a variety of *V. fossa*.

CAUDIVOLVULA; Yellow Weasel. Shaded with dusky, with prehensile tail: the yellow macuaco and yellow weasel of Pennant, and le kinkajou potot of Buffon. It is an animal of gentle manners, active and playful, and hangs by its tail occasionally, like the prehensile-tailed monkeys. Supposed to be a native of Jamaica. The kinkajou of Buffon is supposed by Pennant to be a distinct species, and called Mexican weasel. It was brought from New Spain; and is described as fond of vegetables of various kinds, and delighted with sugar and different sweets; and would seize on birds, and suck the blood without tearing its prey. It slept much by day, and was lively during the night; exhibited the actions of a monkey, and had various cries, sometimes a kind of barking note, at other times hissing, or variously modified.

FASCIATA; Grey Weasel. With six longitudinal black bands, beneath white; the hairs of the tail long, black and reddish. This is the chat sauvage à bandes noires des Indes of Sonnerat, who first described and figured it. It is a native of India.

MALACCENSIS; Grey Weasel. Dotted above with black, with four round spots above the eyes, and three black bands on the neck and rump, and long tail annulated with black. It is a native of Malacca, described by Sonnerat; of the size of a domestic cat, and much allied to the genet and the fossane. It lives by chase, is nimble in climbing trees, and so fierce, that if it be only wounded when shot, it will turn back and attack the aggressor. It diffuses a powerful musky odour, from a receptacle like that of the civet cat. The Malays collect the fluid there secreted, and pretend that it is stimulant and stomachic. It is much

cillemed for these qualities by the Chinese, who purchase it of the Malays. Of this species there are some varieties.

For other species of weasel, we refer to *MUSTELA* and *WEASEL*.

VIVES, a disease of the glandular kind among animals, especially those of the horse kind. In it there is an inflammation of the glands under the ear, which produces a swelling, that gradually enlarges and forms a tumour, that sometimes terminates in suppuration. It is occasionally accompanied with a slight fever, but not constantly. It is mostly caused by cold and other circumstances which have a tendency to produce inflammation.

In these cases, when the inflammatory appearances and fever are moderate, the size of the tumour not large, but after suppurating discharges itself externally, there is little danger; while on the contrary, when the inflammation is more deeply seated, and the swelling breaks and discharges its contents internally, there is more danger to be apprehended.

In the removal of the disease, where the appearances of the fever and inflammation are rather high, it may sometimes be necessary to take away a little blood, as a pint or two, or more, according to the size of the animal, keeping the bowels properly open by the use of suitable food and clysters; and at the same time, the inflamed and swelled gland or part has a fomentation or wash of Goulard's water and camphorated spirit frequently applied to it, by means of a cloth of the flannel or other kind; or, in some cases, where there is a tendency to suppuration, a bran or linseed poultice made up with the same water may be more effectual. A powder composed of nitre and aniseed, in the quantity of an ounce or an ounce and a half of each, may likewise be given at night in a quart of oatmeal gruel.

In case matter be formed, and it can be plainly felt by the gentle pressure of the finger upon the part, the tumour may be opened with a lancet in the most depending part, which will prevent any ulceration of the skin. In cases where the tumours have been very large, a seton is sometimes introduced, in order to support the discharge until the cavity which contained the matter be filled up. In this case, the fomentation need only be continued a few days afterwards, when the wound may be dressed with common digestive ointment spread upon lint. As the wound begins to heal, the seton may be withdrawn.

Where the tumours break inwardly, the animals may often be greatly benefited by breathing occasionally for some time through a nose-bag of scalded bran.

When the animals do not recover their strength in a proper manner, but become weaker and weaker in consequence of the discharges from the opened tumours, bark of the oak or other similar kinds should be given in large quantities, with opium, and aromatic seeds in fine powder, for some length of time.

In the more early stages of the disease, the animals should have masses of bran and oatmeal, with warm water or thin gruel often given them, and in case the masses should be refused, the gruel should be more frequently given. And in the latter, when their strength will permit, they should have walking exercise daily, and be well taken care of in their whole management.

While the tumours tend towards suppuration, it is often useful and necessary to keep them warmly covered about the heads and necks, but in other cases this may sometimes be hurtful.

When their strength is fully restored, a dose or two of calomel is often beneficial in completely removing all danger of the complaint.

VIVES, *JOANNES LUDOVICUS*, in *Biography*, was born at

Valencia in Spain in 1492, and having laid the foundation of literature in his own country, went to Paris, where he studied the fashionable scholastic philosophy, which he afterwards condemned. From Paris he removed to Louvain, devoting himself there to the study of Greek and Latin literature, and publishing a work intitled "Contra Pseudo-Dialecticos." In this university he became professor of belles-lettres, and acquired a degree of reputation which caused him to be chosen preceptor to William de Croÿ, afterwards cardinal. He also studied divinity, and wrote a commentary on St. Augustine's book "De Civitate Dei," which he dedicated, in 1522, to Henry VIII. king of England. In consequence of this work he received an invitation, in 1523, to undertake the instruction of the princefs Mary, which he accepted. During his residence in England, he composed for the use of his pupil a tract, "De Ratione studii puerilis," and by command of queen Catharine, his treatise "De Institutione Fœminæ Christianæ." At Oxford, where he spent much of his time, he read lectures on law and also in the classics, and was admitted to the degree of D.L.L. Vives forfeited the king's regard by opposing in conversation and writing the divorce of queen Catharine, and was also confined for six months in prison. As soon as he was at liberty he left England, and settled at Bruges, where he married. He was highly esteemed by his contemporaries among men of literature; and so high was his reputation, that he was popularly named with Erasmus and Budæus, as one of the triumvirate at the head of literature at that period. From an epitaph it is inferred that he died after he had completed his 48th year. His works were both various and numerous. In divinity, his treatise "De Veritate Fidei Christianæ," in five books, is represented by Dupin as a learned and judicious performance. His Commentary on St. Augustine displays much erudition, but the Louvain doctors censured some passages as too bold and free, and in their edition of the commentary they were omitted. Dupin is of opinion that his other theological and devotional writings display more of the orator than of the divine; and that Erasmus excelled him in judgment. The principal of his grammatical and critical works were his "Exercitatio Linguae Latinae;" "De Corruptis Artibus;" "De tradendis disciplinis." Brucker says of these works; "they discover great strength of judgment, an extensive knowledge of philosophy, much enlargement of conception, uncommon sagacity in detecting the errors of ancient and modern philosophers, particularly of Aristotle and his followers, and, in fine, a mind capable of attempting things beyond the standard of the age in which he lived."

The works of Vives were printed collectively in 2 vols. fol. at Basil in 1555. Dupin. Moreri. Brucker by Enfield.

VIVIANI, *VINCENIO*, an eminent mathematician, was born of noble parents, at Florence, in the year 1622. Manifesting at an early period his genius for mathematics, he was recommended by Ferdinand II., grand duke of Tuscany, to Galileo, under whose tuition he made very rapid progress in geometry and the new philosophy. After his death, he was invited by Torricelli to assist him in his experiments on the barometer. But he was chiefly devoted to the study of geometry, and his attention was particularly directed to the ancient geometers. His first object, at the age of 23 years, was to supply the last work of a contemporary of Euclid, "De Locis Solidis;" and he then proceeded to accomplish the same design with regard to the "Conics of Apollonius;" for an account of which we refer to the article *APOLLONIUS*. Viviani projected the restoration of the 5th book; with this view he prosecuted his labour with great diligence, and in the year 1659 published his divination of Apollonius. When this work was afterwards

afterwards compared with that of the Greek mathematician, it was discovered that Viviani had not only formed new theories, but that he had discovered many new properties of the conic sections, so that his work may be considered as a supplement to the ancient theory of these curves. In the years 1664 and 1665, he was engaged, in concurrence with Caffini, in concerting means for preventing the inundations of the Tiber, by altering the course of certain rivers: and in their survey of the country for this purpose, they were led to a variety of collateral observations on the insects found in the gall-nut, on marine shells, partly petrified and partly in their natural state, dug up in the mountains, and also on Etruscan vases and inscriptions. In 1666, the grand duke of Tuscany honoured Viviani with the title of his mathematician, which had been previously enjoyed by Galileo; and in 1673 he commenced printing the work of Aristeus, an ancient mathematician, the restoration of which he had at an early period of his life contemplated: but infirmities and other engagements prevented his proceeding with it. In the following year he published, in a small quarto, some works of Galileo, and particularly his Treatise on Proportion, for illustrating the 5th book of Euclid. In 1676, three problems were proposed by M. de Comiers, provost of the collegiate church of Ternant, two of which related to the trisection of an angle, for the solution of which Viviani had discovered three methods, which he now determined to publish. His work on this subject, dedicated to the memory of his friend Chapelain, appeared in 1677. In 1692 he proposed, in the Acts of Leipzig, a problem relating to the art of piercing an hemispherical arch with four equal windows, in such a manner that the remainder of the surface should be absolutely squareable. This problem, which he called a geometrical enigma, was solved by Leibnitz, J. Bernouilli at Balle, the marquis de l'Hospital in France, and by Dr. Wallis and David Gregory in England. Viviani himself published the problem and his own geometrical solution of it in a work, in which he treats, both as a geometer and architect, of the arches of the ancient Romans, and proposes a new arch to be called the Florentine. In 1664 Louis XIV. had settled on him an annual pension, in consideration of his distinguished merit: and in 1669 he was appointed one of the eight foreign associates of the Academy of Sciences. Thus noticed, he was led in 1701 to publish his divination of Aristeus, in three books, dedicated to his benefactor. Part of his pension was devoted by him to the construction of a magnificent edifice at Florence, which he called "Ædes a Deo date;" and over the gate he placed a bust of Galileo, with several inscriptions in honour of him. In his old age he amused himself with the solution of several problems relating to chances on dice. He also published, for facilitating the study of geometry, an edition of Euclid's Elements, both plane and solid. Viviani, desirous of rendering mathematics in connection with the arts practically useful, was consulted both by his countrymen and foreigners on various public works; and it is stated, that, among other benefits which he conferred on his country, he contributed, by the introduction of new terms in his mathematical and philosophical writings, to render the Tuscan language more copious; but his style is said to be inferior in elegance to that of his master Galileo. After a life of usefulness and honour, prolonged to his 81st year, he died of an apoplexy, in October 1703.

Bayle has accused him of atheism: but Fabroni has refuted the charge. Fontenelle says, "he had that innocence and simplicity which are commonly preferred by persons who have more intercourse with books than with men,

without that haughtiness and boisterous rudeness which are often acquired by them. He was affable, modest, sincere, and faithful in his friendships; and what includes many virtues in one, he was grateful, in the highest degree, to those from whom he received favours." His works were numerous. To some of them we have already referred. Fabroni. Montucla. Fontenelle Eloges, &c. Gen. Biog.

VIVIEN, JOSEPH, a French painter, who, though a pupil of Le Brun, practised his art mostly in crayons, and obtained a degree of reputation, which few who have worked in those perishable materials have arrived at. He was born at Lyons, in 1657. His portraits were fresh and vigorous, and obtained for him considerable employment, and the favour of the elector of Bavaria, who made him his state painter, and gave him a pension. His portrait is among those of distinguished artists at Florence. He died in 1735.

VIVIER, LA, in *Geography*, a town of France, in the department of the Ille and Vilaine; 3 miles N. of Dol.

VIVIERS, a town of France, in the department of the Ardèche, on the right bank of the Rhône. Before the revolution, the see of a bishop, and capital of a province, called Vivarais, now the department of the Ardèche; 16 miles S.S.E. of Privas. N. lat. 44° 29'. E. long. 4° 46'.

VIVIFICATION, in *Medicine*, the art of *vivifying*, that is, of contributing to the action that gives life, or maintains life.

The chemists also use the word in speaking of the new force, vigour, and lustre, which, by their art, they give to natural bodies, particularly to mercury; which, after having been fixed, or amalgamated, they restore to its first state. See REVIVIFICATION.

VIVIPAROUS, VIVIPARUS, in *Natural History*, an epithet applied to such animals as bring forth their young alive and perfect; in contradistinction to such as lay eggs, which are called *oviparous* animals.

The females of all the quadruped class are *viviparous*, and those of the bird class are all *oviparous*.

The laws of nature in the larger animals are, therefore, in a great measure, fixed and certain; but it is not so in the insect tribes, nor in the fishes; for of these, some are *viviparous*, and others *oviparous*; and those of genera nearly allied to one another.

Among insects, the much greater number are *oviparous*; but there are many which are not so, as the pucerons, proglan insects, cochineal, &c. The millepedes and scorpions are also well known to be so; all the females of the butterfly, and of some other classes, lay only eggs; but the most singular and remarkable inconsistency in nature, if we may be allowed the expression, is that in the fly kingdom; the same class of insects, and even the same genus, will furnish us with some which are *viviparous*, and others which are *oviparous*: the two-winged flies give us instances of this; but these are not singular in that respect; for among the reptile world, there are other creatures which are subject to the same varieties; and Swammerdam has observed a *viviparous* snail.

The species of *viviparous* two-winged flies are much more rare than the *oviparous*; and among the four-winged class they are yet more uncommon. It is not certain, that any of the latter, beside the winged pucerons, are of this kind; but among the former there are six or seven species which are known always to produce living worms, and probably many more will be discovered, by a more close attention than has hitherto been given them.

It is easy to find about our houses one of these species of *viviparous*

viviparous flies; the creature is always buzzing about the places where meat is kept, and loves to deposit her young, as the common blue flesh-fly does its eggs, on meat. Its way of carrying its wings is the same with that of the blue fly, and its antennæ are of the same form. It at least equals the blue fly in length, but its body is less thick, and is a little bent at the hinder part; its colour is grey; its legs are black; its petty wings whitish, and its reticular eyes reddish.

There are, beside this species, two other of the viviparous flies, which are not uncommon. Both these, in a great measure, resemble the former, but their bodies are shorter, and, in the whole, they much more than the other approach to the form of the blue flesh-fly. They are also smaller than the former species: the one of them, however, on the whole, is not so much so, and, though shorter, yet is much thicker both in the corcelet and body. They are both, though smaller than that kind, yet tolerably large flies, and are bigger than the common horse-fly.

On the leaves of ivy also there are often seen, about autumn, two other species of viviparous flies, which are easily distinguished from all the others. Those of one of these species are larger than the great blue flesh-fly, and have a shorter and thicker body than that kind. The manner of carrying the wings is also the same in both; but though both have antennæ of the battledore kind, yet they are evidently distinguished by this, that the extremities of the one are lenticular, and those of the other prismatic. Near the origin of each wing these have a brownish spot, as have those oviparous flies which usually have in their body only two large eggs at a time, and which are produced of the yellow worms, so common in cow-dung. But these viviparous ones differ from those flies, in that they are larger, and of a deep, but dead brown; whereas the others are black, or nearly so.

The other species is not much unlike this in form, but is smaller, being not more than of the bigness of the blue flesh-fly, and of a blueish-black; so that it might easily be mistaken for one of the common flesh-flies, were it not for the two brown spots at the insertion of the wings; and both this and the former species are plainly distinguished from the cow-dung fly before described, by their wanting the gold-coloured down which has on the fore-part of its head. Reaumur, *Hist. Insect.* vol. iv. p. 405, seq.

Vipers are distinguished from snakes, in that the latter lay eggs in dunghills, to be hatched by the warmth of them; but the former are viviparous, that is, they keep their eggs within their bellies, and bring forth live vipers.

In the Philosophical Transactions we have an account of a viviparous fly of the cestrum or gad kind. Dr. Lister tells us, he opened several females of this class, and found, in each, two bags of live white worms. The like is hinted by Aldrovandus. Lister even suspects, that all in this tribe are, in some measure, viviparous.

VIVIPAROUS SHEEP FESCUE GRASS, in Agriculture, a sort which is found on the tops of high mountains, and which is particularly worthy of the notice of the flock-farmer, as it is of a very nutritious quality for sheep, and is said to abound in Spain, and to contribute in producing the fine wool of that country. See FESCUE and GRASS.

UJUM RAJAH POINT, in Geography, a cape on the north coast of Sumatra. N. lat. 4° 58'. E. long. 96° 31'.

VIVO, in Architecture, the shaft or fuit of a column.

The term is also used, in a more particular sense, for the raked of a column, or other part.

VIVOIN, in Geography, a town of France, in the department of the Sarthe; 14 miles N. of Le Mans.

VIVONNE, a town of France, in the department of the Vienne; 6 miles E. of Lufignan.

VIVUM LINUM. See LINUM.

VIVUM Sulphur. See SULPHUR.

VIX, in Geography, a town of France, in the department of the Vendée; 6 miles S. of Fontenay le Comte.

VIXEN, or FIXEN, among Sportsmen, denotes a fox's cub.

VIZA, or BIZIA, in Geography, a town of Romania; 50 miles W. of Adrianople.

VIZAPOUR, a town of Hindoostan, in Baglana; 13 miles S.E. of Chandor.

VIZARD, or VIZOR. See MASQUE.

VIZERABAD, in Geography, a town of Hindoostan, in Lahore; 16 miles N. of Ameenabad.

VIZERABY, a town of Hindoostan, in the Baglana country, celebrated for its hot springs; 20 miles N.E. of Baffeen.

VIZEROY, a town of Hindoostan, in the circar of Ellore; 10 miles N. of Ellore.

VIZIAMANGALUM, a town of Hindoostan, in Myfore; 13 miles S.W. of Errood.

VIZIANAGRAM, a town of Hindoostan, in the circar of Cicaole; 108 miles N.E. of Rajamundry. N. lat. 18° 5'. E. long. 83° 36'.

VIZIANAGUR, a town of Hindoostan, in the circar of Cicaole; 33 miles W.S.W. of Ganjam.

VIZIER. See VISIER.

VIZILLE, in Geography, a town of France, in the department of the Isère; 7 miles S.S.E. of Grenoble.

VIZINI, a town of Sicily, in the valley of Noto; 20 miles N.W. of Syracuse. N. lat. 37° 2'. E. long. 14° 53'.

UK, a river of Russia, which runs into the Uda, 16 miles N. of Udinsk.

UKDE, a town of Arabia, in the province of Yemen; 8 miles S. of Abu-Arifch.

UKELEY, a river of Brandenburg, which runs into the Rega, near Plate.

UKENSKOI, a town of Russia, in the government of Tobolsk, at the conflux of the Irtsch and the Oby; 196 miles N. of Tobolsk. N. lat. 61° 10'. E. long. 69° 14'.

UKERATH, a town of the duchy of Berg. In 1796, the Austrians established here a strong post.

UKIKITSCHA, a river of Russia, in the government of Irkutsk, which runs into the Olenck, N. lat. 69° 20'. E. long. 117° 21'.

UKINSKOI, a town of Russia, in the peninsula of Kamtschatka; 80 miles N. of Niznei Kamtschatkoi. N. lat. 57° 55'. E. long. 160° 14'.—Also, a cape of Russia, on the eastern coast of Kamtschatka; 60 miles N.E. of Udinskoi. N. lat. 58° 36'. E. long. 162°.

UKIPEN, a small island in the North Pacific ocean, so called by the Russians, probably the same with that called Sledge island by Capt. Cook. N. lat. 64° 22'. E. long. 211°.

UKKASS, a town of Algiers; 10 miles W. of Tipfa.

UKLI KARAGAISKAIJA, a fortress of Russia, in the government of Upha; 56 miles W. of Troitsk.

UKRAINE, a name given to a very fertile country, situated on both sides of the river Dnieper, and so fertile, that by the Poles it was always called the "Land of Milk and Honey." It forms now a part of the Russian government of Ekaterinoflav. See COSSACKS.

UKSA, a town of Russia, in the government of Viborg; 44 miles

44 miles N. of Serdopol.—Also, a river of Russia, which runs into lake Ladoga; 40 miles N.W. of Olonetz.

ULA, in *Surgery*, a gumboil, or a small abscess of the gums.

VLACO, ADRIAN, in *Biography*, a Flemish mathematician of Ghent, commenced with Napier and Briggs in facilitating, by means of logarithms, the application of trigonometry to scientific and practical purposes. The service which he rendered to this branch of science appears partly under the article BRIGGS. But besides his addition to the work of Briggs, he extended his tables to sines, tangents, and secants, and their logarithms from 10 to 10 seconds. These new and ample tables were published in 1633, with the logarithms of the natural numbers from unity to 20,000.

VLADIMIR, in *Geography*, a town of Russia, and capital of a government, at the conflux of the Kliazma and the Nerl; 100 miles E. of Moscow. N. lat. $55^{\circ} 50'$. E. long. $40^{\circ} 22'$.

VLADIMIR, *Order of St.*, or as it is expressed in the patents, of the prince equal to an apottle Vladimir, a Russian order of knighthood, founded by the empress Catharine II. on the 22d of September 1782, being her 20th coronation day, for men of merit in the civil or military stations. It has four classes, of which the senior knight receives a pension, in the first class 600, and in the fourth 100 rubles. Any person who has served faithfully for 35 years may apply for this order; it is worn to a ribband, red in the middle, and on each side a black stripe: the knights of the two first classes, as in the other high orders, wear a star on the breast. The star is of eight points, interchangeably of gold and silver, having a red area, bearing a cross, with the Russian letters C. P. K. B. "Swatogo Revnopolstelnago Knzha Vladimira," i. e. the holy apostle-like prince Vladimir. Round the badge are the words "Polja, Tichest i Slava," utility, honour and fame, with a ribband of two black and one red stripes. The chapter of this order is held in the church of St. Stephen. In 1790 the number of knights was 716.

VLADIMIRSKOE, in *Geography*, a government of Russia, bounded on the N. by the governments of Jaroslavl and Kostrom, on the E. by the government of Nizgorod, on the S. by the governments of Tambov and Riazan, on the W. by Moskovkaia, and on the N.W. by Tverkoie; about 160 miles from E. to W. and 80 from N. to S. N. lat. $55^{\circ} 20'$ to $57^{\circ} 10'$. E. long. 38° to 43° .

VLADISLAUS I., surnamed *Herman*, in *Biography*, king of Poland, succeeded his brother Boleslaus in the year 1082. As Boleslaus had been excommunicated by pope Gregory VII., and the kingdom laid under an interdict, the pope would allow Uladiflaus no other title than that of duke. The defection of Russia, Prussia, Pomerania, and other provinces at the commencement of this reign, obliged Uladiflaus to have recourse to arms; and he succeeded at length in subduing the Pomeranians. Soon afterwards, he was involved in a civil war by the rebellion of his sons; but the archbishop of Gnesna effected a reconciliation, and prince Boleslaus defeated the Prussians and Pomeranians who had taken a part against the king during the civil contests. In 1103 Uladiflaus died, at the age of fifty-nine, with the character of a pious and mild sovereign, too much under the dominion of parasites and favourites. Mod. Un. Hist. Moreri.

VLADISLAUS II., king of Poland, son of Boleslaus III. succeeded his father in 1139. Being under the influence of his queen Christina, sister of the emperor Henry V., she engaged him in a plan for gaining entire possession of Poland, part of it having been distributed among his brothers

in separate duchies by the testament of their father. He convened the states, but notwithstanding his eloquent harangue, they refused concurring in his project. At length Uladiflaus took up arms and attacked his brothers; he expelled two of them from their dominions; but uniting together, they fell suddenly on the royal army and totally defeated it. The king, deserted by the Russians who had engaged to assist him, retired into Germany to the emperor Conrad. At length he was solemnly deposed by the diet, after an inglorious reign of seven years, and succeeded by his brother Boleslaus. Uladiflaus, in consequence of the intercession of the emperor Frederic Barbarossa, obtained Silesia, which was thus separated from the crown of Poland, and has never been re-annexed to it. Uladiflaus died in 1159. Mod. Un. Hist. Moreri.

VLADISLAUS III., king of Poland, surnamed from his small stature *Loketak*, or cubit's length, having expelled Premislaus II. in 1296, obtained possession of the kingdom. But the people were so oppressed by his tyranny and the licentiousness of his soldiers, that the states deposed him in 1306, and elected Wencellaus, king of Bohemia, to supply his place. He retired first to Hungary, then to Rome; but hearing of the discontents that prevailed in Poland, he put himself at the head of a considerable army: and whilst he was making conquests, Wencellaus died, and he was restored to the throne in 1305; with powers limited and restrained. The Teutonic knights having taken possession of a great part of Pomerania, he commenced a war with them, which, after alternate defeats and victories, terminated in his recovery of the territories which they had usurped; Uladiflaus, during the progress of the contest, having displayed great military talents, combined with humanity and generosity. He then directed his attention to the arts of peace, and having in the course of fifteen years established his reputation, he indulged himself and his queen in a magnificent coronation, with the full consent of the states and of the see of Rome. Soon afterwards he fell into a chronic disease, which closed his life in 1333, the states having previously promised to elect his son Casimir as his successor. Mod. Un. Hist. Moreri.

VLADISLAUS IV., king of Poland, obtained the crown by the interest of his wife, Hedwiga, daughter of king Lewis, to whom the states had offered the crown on the death of her father, provided that she married with the consent of her subjects, and that her husband would reside in the kingdom. Jagello, duke of Lithuania, was the suitor of the princess, who consented to embrace the Christian religion, to oblige his subjects to be baptized, and to annex Lithuania inseparably to Poland, and to reconquer Pomerania and the territories usurped by the Teutonic order. The Poles approved his liberal offers, and interposed to gain the consent of Hedwiga, who was attached to William of Austria. At length Jagello's person and vivacity, together with the urgent persuasion of the people, overcame her reluctance, and she gave her hand to him in 1386, when he was baptized by the name of Uladiflaus and elevated to the throne. By this alliance, not only Lithuania, but the duchies of Samogitia and Black Russia, were annexed to the Polish crown. The Teutonic knights became indignant, and revolted; and having recourse to arms, took several fortresses before the king was aware of their designs. However, he soon expelled them, and reduced the palatine of Bosnia, who had revolted, to submission. He then undertook the conversion of the Lithuanians, who were gross idolaters. With this view he cut down their sacred forests, extinguished their fires, demolished their temples, established a body of Christian clergy, and erected an archbishopric at its capital, Wilna.

Wilna. Leaving his brother Skirgello as his viceroy, he returned to Poland. Skirgello by his barbarity, and the Teutonic knights by their unwarrantable practices, soon occasioned a rebellion, that was not terminated without much bloodshed. This event was followed by a war with the Tartars, in which the lieutenant of Lithuania was defeated by a lieutenant of Tamerlane, and by wars between Poland and Prussia, in which Uladiflaus took the field in person, and penetrating into Pomerania, gained a great victory over the knights near Marienburg. Failing to take the town, he consented to grant the knights an advantageous peace. The reputation of Uladiflaus induced the Hussites of Bohemia to offer him the crown, but he declined accepting it. After a reign of forty-eight years, generally prosperous and at length tranquil, he died at a very advanced age in the year 1434, highly honoured and much regretted. *Mod. Un. Hist. Moreri.*

ULADISLAUS V., king of Poland, was the son of the preceding. See LADISLAUS IV. king of Hungary.

ULÆ, in *Ancient Geography*, a people of Asiatic Sarmatia, upon the coast of the Caspian sea. *Ptol.*

ULAK, in *Geography*, a mountain of Bosnia; 20 miles S.S.W. of Zwoznick.

ULAMA, in *Ancient Geography*, a town of Palestine, S.E. of Dio Cæsarea, at the distance of about 12 miles.

ULAMIRSKA, in *Geography*, a town of Russia, in the government of Tobolsk; 48 miles E.S.E. of Yalutorovik.

VLARDINGEN, or VLAERDINGEN, a town of Holland, formerly the seat of the counts, situated on the N. side of the Meuse; 2 miles W. of Schiedam.

ULATHA, in *Ancient Geography*, a town placed by Josephus between Galilee and the Trachonitis.

ULAUN, in *Geography*, a town of Bengal; 45 miles W.N.W. of Rangur.

ULBACH, a river of the duchy of Baden, which runs into the Elzach, 4 miles N.W. of Elzach.

ULBO, a small island in the Adriatic, near the coast of Dalmatia; 4 miles W. of Pago.

ULCAMI, or ULCUMI, a kingdom of Africa, on the coast of Guinea, N. of Ardra.

ULCER, in *Surgery*. The word *ulcer*, as professor Thomson rightly observes, does not easily admit of a satisfactory definition. It has, says he, sometimes been used in a more extensive, and at other times in a more limited sense. By some it has been defined to be a solution of continuity in the solid parts of the body, accompanied with the discharge of a purulent fluid. According to this definition, the term ulcer is synonymous with the words *fore*, *suppurating wound*, and *open abscess*. Dr. Thomson thinks this use of the term ulcer too general and indefinite. By others, the term ulcer has been employed to express only those solutions of continuity, from which an ichorous, sanious, or vitiated matter is discharged, attended with a loss of substance in the part. Although professor Thomson thinks more favourably of this definition than the former, we confess our decided preference of the other, for the reasons which this judicious surgeon has himself explained. If we object to calling suppurating wounds, and such abscesses as have burst, ulcers, as long as they discharge healthy pus, what particular reason is there for approving of their receiving this name only when the matter from them happens to be of a bad quality? The healthy or unhealthy state of the discharge from a *fore* or an abscess, is an accidental circumstance, depending upon the favourable or unfavourable condition of the parts to admit of the process by which they are to be healed. If the preceding capricious method

of defining an ulcer were to be fashioned, every ulcer would cease to be one, when the discharge from it becomes healthy pus; nor could there be any such ulcer as that which has usually been described by the name of the *simple*, *purulent*, and *healthy ulcer*.

In all the foregoing cases, whether sores, suppurating wounds, or open abscesses, the parts can be healed only by one and the same process,—the formation of granulations; and the principal difference in these examples is, that in suppurating wounds and abscesses, there is not always a loss of substance, as in the instances of ulcers. In these, a chasm or breach is actually produced in the part affected by the action of the absorbent vessels in the process of *ulceration*; which fee.

The causes of ulcers, says Dr. Thomson, are extremely various. Some of these causes operate more, others less directly; some are limited in their operation to the parts to which they are immediately applied, while the influence of others extends to the general system; and hence a distinction of ulcers, which is in common use, and which must ever continue to be made of ulcers, into local and constitutional. It is only, however, within certain limits, as professor Thomson observes, that even this distinction is well founded; for an ulcer which was at first completely local, may in time affect the system so as to become constitutional; and ulcers which derived their origin from some general affection of the system, may remain after the constitutional affection has been removed, by which they were originally produced.

When an ulcer arises from an internal cause, it is, as professor Thomson has accurately explained, the immediate effect of the process of ulcerative absorption (see *ULCERATION*); but when a wound, a burn, or an abscess, becomes an ulcer, it is by no means necessary that the process of ulcerative absorption should in any degree whatever have taken place. A suppurating surface, when it is long in healing, or when it is changed from a healthy to an unhealthy state, may, according to the use that is at present made of the term ulcer, become an ulcer, without the process of ulceration having ever been induced. Every suppurating surface, or abscess of long continuance, may, in this extended sense, be regarded as an ulcer; at least, the period at which they cease to be wounds or abscesses, and when they become ulcers is not very distinctly marked. So true, indeed, is this, that in defining and classifying ulcers, authors have always found it necessary to set out from a healthy state of the suppurating surface, or, in other words, to begin the consideration of the subject of ulcers, with what they term a healthy or a simple purulent ulcer.

Ulcers, continues Dr. Thomson, have usually been distinguished from each other, as Fallopius very justly remarks in his treatise upon this subject, by the causes by which they are induced, by the symptoms which they exhibit, and by the parts of the body in which they occur. The want of a disposition to heal in a suppurating surface may depend upon some specific action in the cause from which it proceeds; upon something peculiar in the constitution of the patient in whom it exists; or merely upon an improper mode of management. Hence, the distinction that has long been made of ill-conditioned sores, or ulcers, into those which are specific in their nature, and into those which are simple.

Specific sores, or ulcers, may be occasioned by specific poisons, or by particular diatheses. The sores, or ulcers, which arise from specific poisons, may be either local, that is, confined, like a primary syphilitic ulcer, to one part; or constitutional, that is, liable to occur in any part, texture,

ULCER.

or organ, such as secondary syphilitic ulcers. Of diatheses predisposing to ulcers, we have examples in the scrophulous, scorbutic, and arthritic diatheses, and also in the syphilitic diathesis, or that which arises not unfrequently in those who have had syphilis, from the too free and injudicious use of mercury.

In addition to the foregoing observations, selected from the valuable lectures on inflammation, lately published by professor Thomson of Edinburgh, we subjoin from the same excellent authority a few more general remarks on the subject of ulcers.

The appearances, says Dr. Thomson, which different ulcers exhibit, seem at first view to afford an excellent foundation for distinctions among them; and so they undoubtedly do in many respects. Surgeons have accordingly endeavoured to observe, arrange, and classify, the various morbid appearances which occur in ulcers, and to give to these appearances appropriate and peculiar names. It is probable that every morbid affection, to which the human body is liable, possesses characters, or exhibits appearances, which are peculiar to itself. To discover these appearances in the symptoms of diseases, and in the various modes of their commencement, progress, and termination, is at all times the great object which the scientific practitioner proposes to himself. It is to be regretted, however, that the characters upon which the distinctions of ulcers, as well as of many other local diseases, are founded, are neither very uniform in their appearance, nor very easily distinguishable from one another. Not only are the local appearances, which present themselves in simple ulcers, liable to great variations in the different stages of the same individual affection, but they are often apparently the same with, or at least not easily distinguishable from, those which occur in specific diseases, and which require for their cure peculiar modes of treatment. It is this circumstance which renders it so necessary for us, in endeavouring to distinguish and to cure ulcers, to avail ourselves of all the information which we can procure from the history of the ulcer, from the nature of the exciting cause by which it has been induced, and from the effects of the remedies which have been employed, as well as from the particular appearances which the ulcer itself exhibits. But though the distinctions, which are taken from the appearances of ulcers, may not at all times enable us to distinguish those which are simple in their nature from others which arise from specific causes, they are not, says professor Thomson, to be regarded as unimportant or useless; for, he believes, it will be found, that similar appearances in ulcers require in general, though not always, the same local applications, and similar modes of management, whether the ulcers be of a simple or specific nature.

Specific diseases render some parts more liable than others to attacks of ulceration. Thus, secondary syphilis appears most frequently in the throat; scurvy in the gums; cancer in the lower lip; and lupous and scrophulous ulcerations in the upper lip, or in the nose. Cancer seldom or never appears primarily in the upper lip; but syphilis, when it attacks this part, puts on many of the appearances of cancer; a fact which professor Thomson first learned from Mr. Pearson, and which he has since had several opportunities of seeing confirmed.

Ulcers upon the lower extremity, *cæteris paribus*, are longer in healing than sores in other parts of the body. This comparative backwardness of ulcers of the legs to heal is probably owing to three principal circumstances: first, the distance of these parts from the source of the circulation; secondly, the retardation of the venous blood in them in the

erect position of the body; and, thirdly, the disturbance and irritation to which such ulcers are frequently exposed, by the patient imprudently walking about, and neglecting himself. The common position of the lower extremities is also very unfavourable to the quick passage of the lymph through the trunks of the absorbents; and this may be the reason why even the slightest injuries of the lower extremities are often accompanied with a considerable degree of œdematous swelling.

Sir Everard Home, in his Practical Observations on the treatment of ulcers of the legs, mentions several facts, which seem to prove that ulcers are more common in tall than in short men; and that ulcers of the legs heal with more or less difficulty, according as they are seated nearer to, or more remote from, the feet. Ulcers, unconnected with any specific disease in the constitution, may occur on the legs, as well as other parts of the body, from external or from internal causes. Among the external causes, says professor Thomson, we may rank contusions, wounds, burns, and the application of every substance capable of exciting inflammation. Among the internal causes we ought probably to rank the predisposing causes. Of these, we have not only the distance from the heart, and retrograde motion of the blood, but peculiarities of constitution, such as temperaments, diatheses, and idiosyncrasies; which often become manifest only from the effects to which they give rise. Thus, the slight scratch, or excoriation, which in one person will heal without any trouble; in another, though placed in circumstances precisely alike, becomes a disagreeable and troublesome ulcer. An ulcer, also, which is produced in the leg of a person of a scrophulous diathesis, though the disease may never have appeared in the general system, often discovers a backwardness to heal, and in some instances exhibits symptoms that are peculiar to itself. The age, mode of life, and habits of the patient, are circumstances also which will modify the appearances, and tend to increase the backwardness to heal and the obtusacy of ulcers. Thus, the aged, the sedentary, and the dissipated, are known to be more liable to ulcers of the lower extremities, than the young, active, and sober. See Thomson's Lectures on Inflammation, p. 426—433.

We shall next endeavour to describe the several principal varieties of ulcers, and the most approved methods of treatment.

Simple purulent or healthy Ulcers.—The ulcers, termed *simple purulent ulcers* by Mr. Benjamin Bell, sir Everard Home denominates *ulcers in parts, which have sufficient strength to carry on the actions necessary for their own recovery*. As Dr. Thomson has observed, the descriptions, which have been given of these ulcers by different authors, will soon apprise us, that they differ in no respect from healthy suppurating surfaces. The pus is of a white colour, thick consistence, and readily separates from the surface of the sore. When diluted, and examined with a microscope, it is found to be composed of small globules, which swim in a transparent fluid. The granulations of a healthy ulcer are small, florid, and pointed at the top. As soon as they have risen to the level of the surrounding skin, those which are next to the old skin become smooth, and covered with a thin, transparent film, which is afterwards rendered opaque, and converted into cuticle.

The main indications in the treatment of healthy ulcers are, to keep the surface, and especially the adjoining integuments, clean, and to prevent the natural processes from being interrupted. According to sir Everard Home, this will in general be best accomplished by the application of dry lint, in order to absorb and retain the secreted matter,

which serves as a soft covering for the granulations. A pledget of simple ointment must also be laid over the lint, for the purpose of hindering the evaporation of the fluid parts of the pus. By this means, the dressings will continue soft and moist, be prevented from becoming adherent to the surface of the sore, and kept in a state in which they can always be removed without pain, or irritation.

In some particular examples of healthy ulcers, sir Everard Home has found rollers or bandages disagree, causing uneasiness in the part, and making the sores lose their healthy appearance. This, however, is not the usual effect of a roller in such cases; but, whenever it is observed to be so, the bandage must of course be discontinued.

In a few other instances, ointments are found to irritate and inflame the neighbouring skin, so that it becomes necessary to leave them off. In such cases, the surgeon may apply over the lint a compress of fine linen, wet with water, or the lotio plumbi acetatis.

There are also certain superficial ulcers, which will not heal, while kept in a moist state, unexposed to the air; but which readily heal when allowed to become dry, and covered with a scab. Sir Everard Home has made the following general remarks on the subject of dressings for healthy ulcers.

1. Applications in the form of vapour, and fomentations, should never be employed, as they render the texture of the granulations looser, and diminish the disposition to form skin.

2. With respect to fluid applications, sir Everard Home also very properly condemns poultices, as well as fomentations. He speaks of alcohol, as being an application, which promotes the formation of a scab, when this mode of cure is chosen.

3. In regard to ointments, their only use, in cases of healthy ulcers, is to keep the matter from evaporating. The most simple ointments are the best for the purpose, particularly the one composed of white wax and olive oil.

The great objections to the common simple ointments are, that they sometimes disagree with the skin, even when recent, and free from all rancidity. When they have acquired the latter quality, they still more frequently create a greater degree of irritation.

4. With respect to applications in the form of powder, sir Everard Home remarks, that when it is desirable to form a scab on the ulcer, any inert powder may be sprinkled on the sore; but he prefers dry lint. Nothing should touch the powder, or lint; and to prevent this circumstance, sir E. Home recommends applying a little bolster on each side of the sore, and over them a roller, which will go from one bolster to the other, in the manner of a bridge.

For healthy ulcers, dry lint is to be regarded as being, upon the whole, the most eligible application. When the sore does not secrete pus enough in twenty-four hours to moisten the lint, the dressings are only to be changed every other day.

When a moderately tight bandage is not forbidden by constitutional peculiarities, it is useful, both in supporting the muscles and skin, which are often in a flabby state, from the unexercised state of the limb, and in defending the newly formed parts.

We shall presently have occasion to speak of Mr. Baynton's plan of dressing old ulcers of the leg with strips of adhesive plaster. This method is now not confined to old ulcers, but often adopted with advantage in cases of simple healthy sores upon the lower extremities.

Of irritable Ulcers.—These are called by Mr. Benjamin Bell *simple vitiated ulcers*; and by sir Everard Home, *ulcers*

in parts, whose actions are too violent to form healthy granulations, either from the state of the parts, or of the constitution. Mr. Bell characterizes this species of ulcer chiefly by the vitiated state of the discharge; while the other gentleman ranks all ulcers under the denomination of irritable, which require sedative applications for their cure.

According to the observations of the latter writer, an irritable and an indolent ulcer cannot always be distinguished from each other by mere appearances, though they can be so in a few instances. The disposition of an ulcer, like the disposition of a constitution, can only be accurately ascertained by determining the actions, which arise from the different impressions made upon it.

The following appearances, however, are said to afford a decisive indication of the irritable nature of an ulcer. The margin of the surrounding skin is jagged, and terminates in an edge, which is sharp and undermined. The bottom of the sore exhibits concavities of different sizes. There is no distinct appearance of granulations, but a whitish spongy substance is seen, covered with a thin ichorous discharge. Every thing which touches the surface gives pain, and very commonly occasions hemorrhage. The discharge is altered from common pus to a thin fluid, in proportion to the degree of irritability communicated to the sore by constitutional causes. The pain of an irritable sore in general gradually diminishes. When it is not constant, but comes on in paroxysms, chiefly in the evening, or night-time, with great violence, convulsive motions of the limb are apt to occur, and to extend to various other parts.

When the foregoing signs of an irritable ulcer are not present, we must form a judgment of the nature of the sore, by attending to the history of the case, and the effects of various applications upon the disease. But when such information cannot be obtained, it is the advice of sir Everard Home, that the treatment should always begin with the supposition of the ulcer being of an irritable nature.

When an ulcer occurs just over the malleolus externus, it is generally of an irritable kind, in consequence of the nature of the part on which it is situated, quite independently of any constitutional or local disposition to irritability. Sir Everard Home conceives that the periosteum, which here lies immediately under the skin, becomes the seat of the ulcer, is the cause of its being very difficult to heal, and gives it an irritable appearance. The fact, that sores situated upon the ligament of the patella, and over the periosteum of the anterior surface of the tibia, assume a similar appearance, and are equally difficult to heal, made the above gentleman more confirmed in his sentiment.

1. On the subject of applications to irritable ulcers, sir Everard Home entertains a favourable opinion of those which are in the form of vapour. The steam of warm water has very beneficial effects; but it is not often used alone; and, what seems curious, its utility is said to be greater in these cases, when the water is mixed with spirits. Fomentations, containing opium, are also described as producing considerable benefit. The tincture of opium, sprinkled on flannel wrung out of hot water, and flannels wet with a warm solution of the extract of opium, or with a decoction of poppy-heads, are enumerated as eligible applications. A decoction of chamomile flowers, the tops of wormwood, or henlock leaves, may also be used with advantage.

There are some particular irritable ulcers, however, specified by sir Everard Home, which are rendered more painful by warm applications. These sores are represented as being generally attended with a mottled purple discoloration of the limb for some distance from them, and a coldness

of the lower part of the leg. They are likewise said to have a tendency to mortification, and it is remarked that this disagreeable event seems to be promoted by warm applications.

2. With respect to moist applications, the linseed-meal poultice is the most simple, and most easily prepared; and as it does not necessarily require any addition of oil, it is to be prepared when the latter ingredient appears not to agree with the fore.

The lotio plumbi acetatis sometimes makes an useful fluid for the composition of poultices for irritable ulcers; but it does not always agree with these sores; and Sir Everard Home states, that if it be used a long time, it is apt to excite a kind of paralysis, known by the appellation of the lead colic, or colica pictonum.

In cases of irritable ulcers, the decoction of poppy-heads should not be forgotten, as it is a very excellent liquid for poultices. The carrot poultice is also found to agree better, than most other things, with a large number of irritable ulcers.

If poultices be employed, their use is to be continued as long as the granulations are small, and the ulcer is rapidly diminishing in size, even till the cicatrization is complete. When the granulations become large, and loose in their texture, poultices should no longer be used.

When the weight of a poultice cannot be borne, the surgeon may try the application of lint dipped in one of the following lotions, and covered with a pledget of any simple ointment:—a solution of the extract of opium; a decoction of poppies; the tincture of opium; a decoction of cicuta; the lotio plumbi acetatis composita; or a diluted solution of the nitrate of silver.

Professor Thomson observes with respect to poultices, that, notwithstanding all that has of late years been said against their use in the treatment of ulcers, he is still very partial to their employment in a great proportion of the morbidly inflamed and irritable states into which ulcers are so liable to pass. He declares, that he has often seen irritable ulcers, which had resisted all other means of cure, heal up under the continued use of these applications. Lectures, &c. P. 444.

3. Applications in the form of powders are generally found to be too stimulating for irritable ulcers. Carbon has sometimes been thought to do good; and so has powdered extract of opium, mixed with an equal quantity of carbon, or linseed flour. However, opium sometimes affects the constitution by being absorbed, and sometimes it produces a great deal of pain, irritation, and sloughing.

4. Ointments cannot be said to be frequently proper applications for irritable ulcers; as they are always more or less rancid, and generally disagree with the skin in such cases. Sir E. Home recommends cream as a very useful application, especially in those examples in which warmth is found to do harm. As a substitute for it, the same writer mentions an ointment, composed of hog's-lard, purified by repeated washing in spring water, and then mixed with a small quantity of white wax and rose-water.

The observations made respecting solutions of lead, apply to the unguentum plumbi acetatis.

5. If the horizontal position be necessary in the cure of simple ulcers of the leg, it is still more so in every instance of an inflamed or irritable fore.

6. Irritable sores cannot generally bear the pressure of bandages. According to Sir E. Home, however, a slight degree of pressure does good to certain ulcers which arise from weakness, and are somewhat irritable.

7. In the treatment of ulcers in general, and of irritable sores in particular, the surgeon will often find immense ad-

vantage from frequently changing the kind of dressing employed. Few cases will continue to heal favourably longer than a certain time under the employment of one sort of application. The surgeon ought therefore to be acquainted with the effects of many different kinds, in order that he may make an alteration as frequently as the state of the case requires.

Of the Fungous Ulcer.—In some cases, as Dr. Thomson observes, the inflammation of the surface of an ulcer is followed by an excess in the growth of granulations; in some, by the death or sloughing of the granulations, and of the parts which surround them; and in others, portions of the surface and edge of the ulcer are removed by the process of ulcerative absorption. The extremes of these states form sores, which are termed *fungous*, *putrid* or *sloughing*, and *ulcerative* or *phagedenic* ulcers. In most instances, however, the surface of an old sore upon the legs manifests but little disposition, after an attack of inflammation, to pass into the state of granulation, or of ulceration. It often remains long in a stationary condition, forming what has been termed an *indolent* or *callous* ulcer.

When the granulations of an ulcer, instead of being small, red, and firm, become large, pale, loose, soft, and flabby; and when, instead of rising to, and remaining on a level with, the surface of the surrounding skin, they rise much higher; the case is technically called a *fungous ulcer*, or *ulcer with hypersecretion*. This is the case which Sir Everard Home has chosen to name the *ulcer in parts*, which are too weak to carry on the actions necessary for their recovery. It is the disease which Mr. Burns describes under the name of the *over-acting* ulcer. We think that professor Thomson, of Edinburgh, is perfectly right in regarding the old name of *fungous*, as less exceptionable than those which have been more recently proposed as substitutes for it. The old name, as this gentleman observes, involves no hypothesis respecting the state or action of the vessels, and merely expresses the fact, that in some suppurating surfaces, the granulations are spongy in their consistence, and too luxuriant in their growth. Lectures, &c. p. 437, 438.

The granulations of these sores are larger, more round on their external surface, and of a less compact texture than those formed on ulcers in healthy parts. Sir E. Home has also noticed their semi-transparent appearance. When they have filled up the cavity of an ulcer to a level with the surface of the body, they do not readily form skin, but, rising up in a still higher manner, often lose altogether the power of producing new cutis. When the parts are still weaker, the granulations sometimes continue gradually to fill up the hollow of the ulcer, and then, all on a sudden, are suddenly absorbed, so as to leave the fore as deep as it was before.

Ulcers may be weak from the first, or become so in the progress of the case. Even granulations of the most healthy kind, if they are not skinned over in a certain time, gradually lose their primitive strength.

Sores on the legs are greatly under the influence of all natural peculiarities of the constitution, and every thing which affects the health. When the constitution becomes in the least weaker or stronger, the appearance of the granulations becomes changed accordingly, and this effect of constitutional weakness or strength on ulcers, is greater in proportion as the sores are further from the source of the circulation.

While the constitution is undergoing any kind of disturbance, the healing of an ulcer is suspended. Mental anxiety is very apt to retard cicatrization.

Such effects of the constitutional kind on ulcers are greater

greater in weak and delicate persons, than in the strong and robust. Change of weather has considerable influence over the healing of sores. Sir E. Home mentions, in proof of this fact, that when there were several hundreds of ulcers in the Naval Hospital at Plymouth, in 1778, every time the weather changed from a dry to a moist state, the ulcers universally assumed an unhealthy appearance; but put on a better aspect when the weather became dry again.

In the treatment of this kind of ulcer, tonics are to be exhibited, particularly bark and steel; and every thing which disagrees with the constitution is to be avoided. Wine and cordial medicines are also usually prescribed. Porter, however, is deemed better than wine, for working people.

Sir E. Home observes, that the first object in the local part of the treatment, is to keep the granulations from rising above the edge of the surrounding skin. This gentleman very judiciously represents the greater propriety of preventing the granulations from ever becoming too high by the employment of proper applications, than following the common plan of destroying the high granulations with escharotics, after they have risen to an improper height. There cannot be the smallest doubt, that if the granulations could always be prevented from rising up too much, the patient would suffer a great deal less pain.

Instead of applying to the surface of the ulcers, now under consideration, lunar caustic, blue vitriol, red precipitate, &c. Sir E. Home prefers mixing these escharotics with other substances, so as to render them only strong stimulants, and using them in this latter form. He conceives that, when the high granulations are destroyed with escharotics, the disposition of the surface underneath to reproduce them is increased, but that this is not the case when the luxuriant parts are only stimulated so as to become absorbed.

The same gentleman seems to think, that when animal substances grow with great rapidity, they are, like vegetable ones, weaker than when produced in a slower manner. Hence Sir E. Home is of opinion, that the growth of granulations ought to be checked in the early stage of their formation, by some resistance which they are just able to overcome, under which circumstances they derive strength from the limited increase of action which they are obliged to undergo.

On the same principle, according to Sir E. Home, the pressure of tight bandages is advantageous; and ulcers which heal while the patient is walking about, are not so apt to break out again as when healed while the parts are in a state of rest.

In the treatment of these ulcers, when the granulations have come to a proper height, and do not form a thin semi-transparent pellicle upon their surface, they are to be considered as weak parts, and treated accordingly. Sir E. Home thinks, that in this circumstance, the best plan, when no particularity of constitution forbids, is pressure made with a thin piece of lead over the dressings, and supported with a tight bandage.

Although, strictly, we have no topical applications which can directly communicate strength to granulations, there are certainly some which prevent the granulations from exhausting themselves by luxuriant growth, and stimulate them to draw more blood from the arteries, which effects, as Sir E. Home remarks, render such granulations stronger.

1. This gentleman very properly condemns, as applications to weak ulcers, all relaxing fomentations commonly employed; and recommends instead of them the use of

spirits of wine and the decoction of poppies, in equal proportions, not however to be applied hot.

2. With regard to moist applications, the same gentleman expresses his disapprobation of poultices, and mentions a weak solution of the argenti nitratum as the most eligible application in an aqueous form.

3. On the subject of powdered substances, as applications to weak ulcers, Sir E. Home says he has often tried bark, and the lapis calaminarius, without perceiving that the former had any power of strengthening granulations, or the latter any virtue in disposing them to form new skin; properties commonly imputed to these applications.

Sir E. Home entertains no better an opinion of plaster of Paris, or powdered chalk, employed with a view of promoting the formation of skin. Powdered carbon, he speaks of, as being more adapted to irritable, than weak ulcers. He praises powdered rhubarb, as particularly applicable to the latter kind of ulcer, because it represses the luxuriant growth of the granulations, renders them small and compact, and disposes them to form skin. When, however, the granulations have risen above the level of the skin, it is not powerful enough to reduce them. When the rhubarb is too stimulating, it is to be mixed with a fourth part of crude opium in powder.

A piece of lint, a little less than the sore, is always to be put over the powder, and covered with a pledget of simple ointment.

4. Ointments, according to Sir E. Home, are particularly apt to disagree with weak ulcers. When other applications fail, however, greasy ones may be tried, and the above gentleman gives a preference to the ung. hydrarg. nitrat. mixed with hog's-lard, in the proportion of one to five, or else to common cerate, blended with a small quantity of the hydrarg. nitrat. ruber.

Of Indolent or Callous Ulcers.—When the edges of the skin surrounding an ulcer become thick, prominent, smooth, and rounded, and when the bottom of the ulcer is covered with smooth and glossy raw flesh, which, as Dr. Thomson remarks, can scarcely be said to be raised into granulations, the case is called an *indolent* or *callous* ulcer. This is the disease which Sir E. Home has denominated an *ulcer in parts, whose actions are too indolent to form healthy granulations.*

Under the name of callous or indolent ulcer, as professor Thomson observes, authors have included by far the greater number of ulcers which affect the lower extremities. This is the ulcer which, of all the varieties to be mentioned, is perhaps the most deserving of attention; for the callous or indolent state is that into which almost all ulcers of the lower extremities have a tendency to pass, and in which they often continue stationary, or nearly so, for months or even for years. Most of the general rules which have been laid down by practical authors, respecting the treatment of ulcers of the legs, and most of the improvements which have of late years been introduced into this branch of surgery, relate chiefly, if not solely, to the treatment of the callous or indolent ulcer. The parts surrounding this ulcer may be inflamed or uninfamed. If uninfamed, the case is simply a callous ulcer; but if inflamed, it then becomes a callous ulcer in an inflamed, vitiated, or irritable state. This last is the state in which most patients, affected with ulcers of long standing, apply to medical men for advice and assistance. It is the state in which patients affected with this complaint are almost always found, upon their admission into public hospitals. Lectures, &c. p. 438, 439.

According to Sir E. Home, the indolent ulcer forms in

ULCER.

its appearance a complete contrast to the irritable one. The edges of the surrounding skin are thick, prominent, smooth, and rounded. The surface of the granulations is smooth and glossy. The pus is thin and watery, being composed of a mixture of pus and coagulating lymph. The lymph consists of flakes, which cannot be easily separated from the surface of the sore. The bottom of the ulcer forms quite a level, or nearly so, and the general aspect conveys an idea that a portion of skin and parts underneath has been for some time removed, without the exposed surface having begun any new action to fill up the cavity. When, however, the indolence of the ulcer is not so strongly marked, the sore does not correspond to the preceding description, but resembles in appearance the ulcer which possesses an inferior degree of irritability, and it can only be discriminated from it by the circumstance of its receiving no benefit from soothing applications.

When an indolent ulcer does form granulations, these in some cases are all on a sudden absorbed, and in the course of twenty-four hours the sore becomes as much increased in size, as it had been previously lessened in as many days or weeks.

Two varieties of indolent ulcers have received distinct names. In one of these cases, the ulcer is connected with one or more apertures, leading into hollow suppurating cavities: this forms what has been sometimes termed a *fistulous*, and at other times a *sinuous* ulcer. The other variety of callous or indolent ulcer is that which is accompanied with a permanently enlarged, or varicose state of the veins of the limb. This case is often called the *varicose* ulcer, and is frequently very difficult of cure. The practical observations which apply to this particular form of disease, will be found in another article. See *VARICOSE VEINS*.

In the treatment of indolent ulcers, the indication is not merely to heal them, but to render the cure as permanent as possible. This is to be effected by changing the nature of the granulations, and using such dressings as will give them a more vascular healthy appearance. When an ulcer, which has existed six months, has been dressed with poultices for a week, the granulations will have partly filled up the hollow of the sore; but they will be found to be large, loose, and glossy. Should the poultice be now discontinued, and some proper stimulating application be used for another week, the granulations at the expiration of this time will have become smaller, more compact, redder, and free from the glossy appearance. Now experience proves that the ulcer, when healed by the latter application, will not be so likely to break out again, as when healed with large, loose, flabby, glossy granulations. Indeed, Sir E. Home assures us, that the number of indolent sores which heal under the use of stimulating applications, and do not break out again, are, in comparison with similar cases treated with mild dressings, as four to one.

The callous, or indolent ulcer, as Dr. Thomson observes, changes very readily into an inflamed or irritable one; and the sore is generally in the latter state, when patients first apply to surgeons for relief. Their ulcers are commonly in a temporary state of irritation from neglect, exercise, excesses, &c.

We have already stated, that medicines, in the form of vapour, cannot heal indolent sores, so as to effect a durable cure. Such remedies, however, are proper, when these ulcers assume a foul appearance, and are in a temporary state of irritation. Hence, for the first few days after the commencement of regular surgical treatment, poultices and fomentations are the best applications.

The fomenting liquor may be a decoction of poppy-heads, or chamomile flowers, or simple warm water, which answers equally well. The best poultices are those of bread and milk, linseed meal, and oatmeal. The most advantageous time for fomenting the sore is while the poultice is preparing, which should be changed twice a day.

When an indolent ulcer does not appear to be attended with any particularity, a solution of the nitrate of silver is considered by Sir E. Home as one of the best watery applications. It stimulates the granulations, and makes them put on a more healthy appearance. Its strength is to be increased according to circumstances. An ulcer, which at first cannot bear this solution above a certain strength without pain, and an absorption of the granulations, becomes able, after the application has been used about ten days, or a fortnight, to bear it twice as strong: a proof of the granulations having acquired strength.

The tincture of myrrh, a decoction of walnut-tree leaves, and the diluted vitriolic acid, have all been tried as applications for indolent ulcers, and with advantage. A scruple of nitrous acid, mixed with eight ounces of water, forms also another useful local remedy, which, according to Sir E. Home, promotes, in a very uncommon manner, the progress of the cure. The first application of diluted nitrous acid gives a good deal of pain, which, however, ceases in about half an hour.

When an indolent sore heals with the diluted nitrous acid, the process of skinning is accomplished with more rapidity, than when other applications are employed; and the new skin is said by Sir E. Home to be more completely formed.

The only application, in the form of powder, ever much employed for indolent ulcers, is the pulv. hydrarg. nitrico-oxidi. It cannot be used, however, except for the most indolent sores, as in fact it is an escharotic, and, if applied too freely, destroys every attempt at the formation of granulations upon the surface of the ulcer. When too often used upon a sore of any material size, it will also sometimes produce a violent salivation of the patient. The writer of this article has seen many patients unintentionally salivated in this manner.

Ointments, containing ingredients which are more or less stimulating, have been at all times the favourite dressings for indolent ulcers. "Ointments containing resin, or oil of turpentine, in their composition, to which a small portion of some metallic oxyd, or metallic salt, has been added, were (as professor Thomson observes) till very lately the most approved applications in the management of callous ulcers. Every variety and form of these stimulating ointments had its partisans and recommenders among practitioners; but the truth is, that this kind of ulcer occasionally got well under every diversity in the form and composition of the ointments employed." (Lectures on Inflammation, p. 446.) According to Sir E. Home, one of the best ointments for indolent ulcers consists of one part of the unguentum hydrargyri nitrati, mixed with three of hog's-lard. Its strength, however, must be increased, after it has been used a certain time for the same ulcer. This ointment is said to have the good effect of quickly removing the thickening of the edges of indolent ulcers, and the surrounding dark red colour of the skin. It also seems to possess extraordinary efficacy in making the granulations assume a small healthy appearance, and the ulcer, when healed with such granulations, is less likely to break out again. Sir E. Home thinks that the resins and turpentine are not so powerful as the acids and metallic salts, in giving the granulations a healthy appearance, and a disposition to resist being absorbed. Camphorated

ULCER.

Camphorated ointments are represented as being particularly applicable to cafes, in which there is present a degree of indolent thickening.

Befides ointments somewhat stimulating in their nature, bandages have been found particularly serviceable to indolent ulcers. The laced stocking was much used, and is particularly recommended by Wifeman. As Dr. Thomson remarks, however, it is in appearance only, that this mode of bandaging in ulcerated, or varicose legs, has any advantage over that by the common circular roller. The use of the circular bandage, with dressings composed of unguentum resinofum and red oxyd of mercury, in different proportions, was some years ago recommended in a particular manner to the attention of the English public in a very useful treatise, which Dr. Underwood published upon the treatment of old ulcers of the legs. He allowed his patients to go about their ordinary occupations, under this mode of treatment, first, because it was inconvenient for many of them to be confined; and secondly, because it was found, that many of those patients whose ulcers were healed up during rest, broke out again as soon as they began to take exercise. It must be acknowledged, that many indolent ulcers do get well under the mode of management recommended by Dr. Underwood. In many persons the bandaging, and that degree of cleanliness which is occasioned by the regular dressing of their sores, are of infinite service; but it is a mode of treatment which does not answer in all old and indolent ulcers; for many of them, according to the experience of Dr. Thomson, become inflamed and irritable under its use. He observes, also, that the recurrence of ulcers in persons who begin to take exercise after being cured, has appeared to him to be often occasioned by their leaving off the bandaging, by their standing or walking too much, and by accidental injuries. The part which has been healed up during rest is weak, and requires support and careful defence, which it very seldom receives from the class of individuals who are most liable to this species of ulcer. Lectures on Inflammation, p. 447.

The treatment of ulcers with bandages has had of late years a very zealous advocate in Mr. Whateley, who, in the year 1799, published strongly in favour of the plan, in his Practical Observations on the Cure of Wounds and Ulcers on the Legs, without rest. In the cafes adduced in this essay, very little variety of dressing was employed; and, with some exceptions specified by the author, pressure was principally relied upon as the means of cure. This gentleman gives a preference to fine flannel rollers, somewhat less than four inches wide.

But of all the improvements which have of late years been introduced into the treatment of old indolent ulcers of the legs, that which was first proposed and practised by Mr. Baynton, of Bristol, is by far the most interesting and important.

Mr. Baynton acquaints us, that the means proposed by him will, in most instances, be found sufficient to accomplish cures in the worst cafes, without pain or confinement. After having been repeatedly disappointed in the cure of old ulcers, Mr. Baynton determined on *bringing the edges of old ulcers nearer together by means of slips of adhesive plasters*. To this he was chiefly led, from having frequently observed, that the probability of an ulcer continuing found, depended much on the size of the cicatrix which remained after the cure appeared to be accomplished; and from well knowing, that the true skin was a much more substantial support and defence, as well as a better covering, than the frail one which is obtained by the assistance of art. But when he had recourse to the adhesive plaster, with a view to lessen

the probability of those ulcers breaking out again, he little expected, that an application so simple would prove the easiest, most efficacious, and most agreeable means of treating ulcers.

Although the first cafes in which Mr. Baynton tried this practice were of an unfavourable nature, yet he had soon the satisfaction to perceive that it occasioned very little pain, and materially accelerated the cure, while the size of the cicatrices were much less than they would have been, had the cures been obtained by any of the common methods.

At first, however, the success was not quite perfect; as, in many instances, he was not able to remove the slips of plaster, without removing some portion of the adjacent skin, which, by occasioning a new wound, proved a disagreeable circumstance, in a part so disposed to inflame and ulcerate, as the vicinity of an old sore. He therefore endeavoured to obviate that inconvenience, by keeping the plasters and bandages well moistened with spring-water, for some time, before they were removed from the limb. He had soon the satisfaction to observe, that the inconvenience was not only prevented, but that every succeeding case justified the confidence which he now began to place in the remedy. He also discovered, that moistening the bandages was attended with advantages which he did not expect: while the parts were wet and cool, the patients were much more comfortable in their sensations, and the surrounding inflammation was sooner removed, than he had before observed it to be.

By the mode of treatment here recommended, Mr. Baynton found, that the discharge was lessened, the offensive smell removed, and the pain abated in a very short time. But besides these advantages, he also found, that the callous edges were in a few days level with the surface of the sore; that the growth of fungus was prevented, and the necessity of applying painful escharotics much lessened, if not entirely done away. Mr. Baynton gives the following description of his method.

"The parts should be first cleared of the hair, sometimes found in considerable quantities upon the legs, by means of a razor, that none of the discharge, by being retained, may become acrid, and inflame the skin, and that the dressings may be removed with ease at each time of their renewal, which, in some cafes, where the discharge is very profuse, and the ulcers very irritable, may perhaps be necessary twice in the twenty-four hours, but which I have, in every instance, been only under the necessity of performing once in that space of time.

"The plaster should be prepared by slowly melting, in an iron ladle, a sufficient quantity of litharge plaster, or diachylon, which, if too brittle, when cold, to adhere, may be rendered adhesive by melting half a drachm of resin with every ounce of the plaster: when melted, it should be stirred till it begins to cool, and then spread thinly upon slips of smooth porous calico, of a convenient length and breadth, by sweeping it quickly from the end, held by the left hand of the person who spreads it, to the other, held firmly by another person, with the common elastic spatula used by apothecaries; the uneven edges must be taken off, and the pieces cut into slips, about two inches in breadth, and of a length that will, after being passed round the limb, leave an end of about four or five inches. The middle of the piece so prepared, is to be applied to the sound part of the limb, opposite to the inferior part of the ulcer, so that the lower edge of the plaster may be placed about an inch below the lower edge of the sore, and the ends drawn over the ulcer with as much gradual extension as the patient can well bear; other slips are to be secured in the same way, each
above

above and in contact with the other, until the whole surface of the fore and the limb are completely covered, at least one inch below and two or three above the diseased part.

“The whole of the leg should then be equally defended with pieces of soft calico, three or four times doubled, and a bandage of the same, about three inches in breadth, and four or five yards in length, or rather, as much as will be sufficient to support the limb from the toes to the knee, should be applied as smoothly as can be possibly performed by the surgeon, and with as much firmness as can be borne by the patient, being first passed round the leg, at the ankle joint, then as many times round the foot as will cover and support every part of it, except the toes, and afterwards up the limb till it reaches the knee, observing that each turn of the bandage should have its lower edge so placed as to be about an inch above the lower edge of the fold next below.

“If the parts be much inflamed, or the discharge very profuse, they should be well moistened, and kept cool with cold spring-water poured upon them as often as the heat may indicate to be necessary, or, perhaps, at least, once every hour. The patient may take what exercise he pleases, and it will be always found, that an alleviation of his pain and the promotion of his cure will follow as its consequence, though, under other modes of treating the disease, it aggravates the pain, and prevents the cure.

“These means, when it can be made convenient, should be applied soon after rising in the morning, as the legs of persons affected with this disease are then found most free from tumefaction, and the advantages will be greater than when they are applied to limbs in a swollen state. But at whatever time the applications be made, or in whatever condition the parts be found, I believe it will always happen, that cures may be obtained by these means alone, except in one species of the disease, which seldom occurs, but which will hereafter be described. The first application will sometimes occasion pain, which, however, subsides in a short time, and is felt less sensibly at every succeeding dressing. The force with which the ends are drawn over the limb, must then be gradually increased, and when the parts are restored to their natural state of ease and sensibility, which will soon happen, as much may be applied as the calico will bear, or the surgeon can exert; especially if the limb be in that enlarged and incompressible state which has been denominated œdematous; or if the edges of the wound be widely separated from each other.”

In adopting the preceding method, Mr. Baynton sometimes observed a breaking of the skin near the ulcers; a circumstance which sometimes proved troublesome, and arose partly from the mechanical effect of the adhesive plasters, and partly from the irritating quality of the plaster. Mr. Baynton, however, only considers such sores of serious consequence, when they are situated over the tendon of Achilles, in which situation they are sometimes several weeks in getting well. In order to prevent them, Mr. Baynton recommends a little bit of soft leather to be applied to the parts which are in danger of being affected.

The cures will generally be accomplished very well by the mere application of the slips and bandage; but when the parts are much inflamed, the secretion great, or the scabion hot, Mr. Baynton states, that the frequent application of cold water will be found a valuable auxiliary. See A Descriptive Account of a New Method of Treating Old Ulcers of the Legs, by Thomas Baynton, 2d edit. 1799.

Of the Malignant or Putrid Ulcer; or Hospital Gangrene.
—This is a disease which is of a very peculiar nature, and its history must be highly interesting to every practitioner, whose avocations make him likely to have the care of a

large number of patients who are afflicted with ulcers or wounds, and collected together in one building. The surgeons of the army and navy in particular, and those of great hospitals and prisons, ought to be fully acquainted with the subject; for they are all liable to be suddenly called upon to exert their skill in checking the ravages of this severe complaint, the treatment of which is far from being either simple, or well determined.

The symptoms by which the malignant ulcer, or hospital gangrene, is characterized, are partly of a local, and partly of a constitutional nature. According to professor Thomson, these two classes of symptoms are not invariably in the order of their appearance; but his own observations lead him to believe, that the constitutional symptoms usually precede the local. He observes, that, in the progress of the constitutional symptoms, a general uneasiness is felt before any visible change takes place in the wound, or sore, which is attacked with hospital gangrene; the tongue becomes foul, with a sensation of bitterness in the mouth; the appetite decreases, and the patient begins to loathe his food; the pulse becomes very quick, but is in general rather weak than strong; the skin feels hot; and the patient in the progress of the disorder becomes affected with great anxiety and restlessness.

The local appearances of wounds, sores, and ulcers, are soon altered after the commencement of an attack of hospital gangrene. Their surfaces become pale; the discharge of pus becomes less copious and less healthy than formerly; their edges swell, inflame, and become exceedingly painful; they are sometimes ragged; at others reverted, and exhibit a soft spongy appearance. A dusky red-coloured circle of inflammation, having more or less of a livid tinge, extends from these edges into the surrounding integuments, and is often the forerunner of gangrene and sphacelus. Inflamed lymphatic absorbent vessels are sometimes to be observed, extending from the surfaces affected with hospital gangrene, to the contiguous, or communicating, cervical, inguinal, or axillary glands.

The local affection in hospital gangrene seldom occupies at first the whole surface of extensive wounds or sores. It more frequently appears in the form of dirty white ash-coloured sloughs, occupying only one, two, or more small spots, and from these, it gradually extends itself over the whole of the diseased surface. In some instances, hospital gangrene begins in the form of a small inflamed pimple, or vesicle, without our being able to perceive any previous injury of the part in which it appears. More frequently, however, it attacks parts which have been scratched, bruised, or wounded, or which have had the integuments injured by ulceration, burns, or blisters. Specific sores, or ulcers, seem to be less liable to attacks of hospital gangrene, than those which are of a simple nature. Dr. Thomson has seen it, however, repeatedly attack cancerous sores and venereal ulcers. In some instances, it has been said to have produced a cure of these diseases, destroying by mortification the parts on which they were situated. In severe cases of hospital gangrene, the surface of the wound, or sore, which it attacks, is soon changed into sphacelus, and covered with dirty white-coloured sloughs. During the separation of these sloughs, an ill-coloured and sanious discharge, having a peculiar fetid smell, takes place from the surface of the wound, or sore. This surface is often seen covered with a tenacious viscid pus, which firmly adheres to the surface from which it is secreted. In mild cases, the destructive effects of hospital gangrene are confined to the skin and subjacent cellular membrane; but it often extends its ravages beyond these textures, destroying tenacious
fibre,

fasciæ, muscles, ligaments, and tendons, together with the nerves and blood-vessels. Artery seems to be the texture which resists most powerfully the destructive action of hospital gangrene, as well as of most other species of mortification. When, in the progress of hospital gangrene, adhesive inflammation does not occur, hemorrhage is liable to take place, and, in some instances, to prove fatal. Even in cases in which distinct hemorrhage does not occur, a thin bloody sanies is often discharged, which has a very offensive smell; and the pus, which begins to appear during the separation of the slough, or mortified part, often continues for days to be reddened by an admixture of blood.

The severity and progress of the symptoms in hospital gangrene, as well as the duration of the disease, are extremely different in different individuals. In some, the fever continues with unabated violence for a period of one or two weeks. After suffering an abatement, it is liable to recur; and the patient sometimes sinks under a second or third attack. When the affection has been very severe, has continued long, or has returned frequently, the patient becomes at last generally affected with fever and oblitinate diarrhœa. This is a state, from which, if patients recover, it is always in a very slow and tedious manner. See Thomson's Lectures on Inflammation, p. 458—461.

Hospital gangrene (says Boyer) is a species of humid gangrene, which attacks in some degree *epidemically* the wounds and ulcers of patients, who happen to be crowded together in an unhealthy place.

Its occasional causes are; the situation of an hospital upon a low marshy ground; the vicinity of some source of infection; the uncleanness of the individuals, or of the articles for their use; the crowded state of the wards, especially when they are small and badly ventilated; lastly, every thing that tends to corrupt the air which the patients breathe. An infected atmosphere may produce in the moist simple wounds unfavourable changes, partly, as Boyer conceives, by its immediate action on the surface of the wound, but, no doubt, principally by its hurtful influence upon the whole animal economy. The foregoing causes have also sometimes produced alarming and oblitinate gangrenes of an epidemic kind, or, at least, a state of the constitution, under the influence of which all wounds and ulcers constantly took on a bad aspect, and were often complicated with the most gangrenous mischief. M. Vigaroux saw such an epidemic disease prevail for twenty months in the two hospitals of Montpellier, and he states, that the most powerful antiseptics were of little avail against the disorder, which often invaded the slightest scratches.

In general, this epidemic species of gangrene is not observed in new-built hospitals, nor in those which are erected out of the central parts of cities, upon high ground. Hospital gangrene may occur in any season; but it is most common after the sultry heat of summer. It complicates, without distinction, every kind of solution of continuity. However, it never attacks those of all the patients in the same ward. It manifests itself in different degrees on the majority of them, and it is remarked, that the more extensive the solution of continuity is, the more it is exposed to the disorder. But, occasionally, the disease is confined to a part of the surface of such solution of continuity, while the rest continues to make progress towards cicatrization. Patients, who have escaped infection once, are not on that account exempt from the danger in future.

A bilious constitution, mental trouble, unwholesome or insufficient food, a scorbutic diathesis, great debility, and fevers of a dangerous type, may become for many predisposing causes of hospital gangrene.

The observations of Pouteau, and those of some other practitioners, convincingly prove, that hospital gangrene may be communicated to the most simple wound, or ulcer, in a subject of the best constitution, and breathing the purest air, by merely putting into contact with such wound, or ulcer, sponges, lint, or charpie, impregnated with the infection of this peculiar disorder. But this inoculation is conceived to be more alarming, and to take effect the more quickly, in proportion as patients have been more exposed to the influence of such causes, as are themselves capable of producing the disease, and also in proportion as the kind of constitution predisposes to it.

Although the contagious nature of hospital gangrene has been generally admitted by all the best informed writers on the subject, we ought to notice, that the doctrine was not considered by Dr. Trotter as having a good foundation. Modern authors, however, have not joined this latter gentleman, and both Dr. J. Thomson and Delpech believe that the disorder is infectious. "The contagious nature of hospital gangrene (says professor Thomson) appears to me to be sufficiently proved, first, by the fact that it may be communicated by sponges, charpie, bandages, and clothing, to persons at a distance from those infected with it. Secondly; by its having been observed to attack the slight wounds of surgeons, or their mates, who were employed in dressing infected persons; and that even in circumstances where the medical men so employed did not live in the same apartment with the infected. Thirdly; by our being able often to trace its progress distinctly from a single individual through a succession of patients. Fourthly; by its attacking recent wounds as well as old sores, and that in a short time after they are brought near to a patient affected with the disease. Fifthly; by our being able to prevent the progress of the disease in particular situations, by removing the infected person, before the contagion, which his sores emit, has had time to operate. Sixthly; by its continuing long in one particular ward of an hospital, or in one particular ship, without appearing in other wards or ships, if pains be taken to prevent intercourse between the infected and uninfected." (Lectures on Inflammation, p. 484.) But although there can be no doubt of the disease spreading partly by its contagious nature, it appears to us equally certain, that the number of cases is also often increased by the continued operation of the same causes which produce the earliest instance of the disorder in any particular hospital. If this were not the case, upon what principle could we account for the origin of the disease at all, since the commencement of the first instance cannot possibly be referred to contagion?

It is alleged, that when once a patient has taken the infection, he cannot avoid the consequences, whatever precautions he may adopt. Thus, Boyer informs us that he has seen hospital gangrene take place in wounded patients, who, in the hope of escaping this epidemic affection, had quitted the infected hospital, and retired to elevated situations, where they breathed the most salubrious air. *Traité des Maladies Chir. tom. i. p. 322.*

The duration of hospital gangrene is various, according to the extent of the wound, or ulcer affected; the constitution of the patient; the impression made by the putrid effluvia on the animal economy; and the intensity of the disorder. Hospital gangrenes have been known to continue more than a month, in which circumstance, the patients seldom recover. In ordinary cases, the wound puts on a favourable appearance again between the sixth and ninth days; and in slight examples, the amendment is manifested between the third and fifth. Whatever may be the period

ULCER.

of the complaint, its wished-for termination is always announced by a diminution of pain; the pus acquiring a white colour and more confidence, and losing its fetid nauseous smell. The edges of the ulcer subside, while its surface becomes less irregular, and puts on more of the vermilion colour. The red, purplish, œdematous circle which surrounds the disease, assumes a true inflammatory nature, and the solution of continuity, restored to a simple state, heals up with tolerable quickness, even when the destruction of soft parts is somewhat considerable, unless any fresh untoward circumstances occur to interrupt cicatrization. But sometimes, when the patient is on the point of being completely well again, his condition is suddenly altered for the worse; ulcerated spots make their appearance on the cicatrix, and these spreading in different directions occasion a relapse, which may happen several times.

Hospital gangrene must be regarded as a serious complication of wounds and ulcers, since it considerably retards their cure. When, however, the solution of continuity is not extensive, and the constitution good, and in other respects healthy, the disease is not dangerous. In this case, as soon as the sloughs are detached, the ulcer heals up, and leaves a cicatrix accompanied with very little disfigurement. But when the solution of continuity is large, or of long standing, the disorder commits much greater ravages, renews its attacks repeatedly, and the relapses prove exceedingly obstinate. The same thing is said to happen when it affects persons labouring under scorbutic or venereal complaints, who are often put into great danger. Hospital gangrene proves particularly dangerous, and mostly fatal, when it complicates large contused wounds, attended with badly fractured bones. All the soft parts of the injured limb are then frequently observed to be progressively destroyed, and the unfortunate patient falls a victim, sometimes to typhoid symptoms attending the complaint, sometimes to frequent hemorrhages, but still more often to hectic complaints, the almost inevitable consequence of long-continued profuse suppuration.

The effects of hospital gangrene should be carefully discriminated from those of the scurvy. Ulcers, attacked with hospital gangrene, are not affected in any degree, like scorbutic ulcers, by the use of vegetable diet and lemon-juice, and they occur among men who are fed upon fresh meat and vegetables, as readily as they do upon those who have been fed altogether upon salt provisions. (Thomson's Lectures on Inflammation, p. 482.) Hospital gangrene is almost always accompanied with severe febrile symptoms; but, "as to fevers (says Dr. Lind), it may indeed be doubted whether there be any such as are purely and truly scorbutic. The disease is altogether of a chronic nature; and fevers may be justly reckoned amongst its adventitious symptoms." (Treatise on the Scurvy, p. 106.) We may also remark, that in cases of hospital gangrene, the general symptoms of scurvy are absent, such as soreness and bleeding of the gums, livid blotches and wheals on the fleshy part of the legs, œdematous ankles, &c.

The treatment of hospital gangrene is either preventive or curative.

With a view of preventing the disorder, it is essential to remove all the causes which have been specified as capable of producing it. Thus, the wards in which the wounded are placed should not be crowded; they ought to be freely ventilated; as much detached as possible; the utmost attention to cleanliness should be paid; and every source of infection obviated. The predisposition of the wounded to this species of gangrene may be lessened by a well-chosen diet, by drinks acidulated with vegetable acids, or with the

fulphuric acid, and by the moderate use of wine. The state of the stomach and bowels should be particularly attended to, and if found to be out of order, emetics and purgatives ought to be immediately employed, and repeated according to circumstances. In the beginning of the constitutional attack, Pouteau and Duffassois particularly recommended the use of emetics, and Mr. Briggs also found them highly useful. It is by the advantageous use of these remedies, that the tendency to bilious fevers is removed, to which all wounded patients are so liable, who have not been evacuated in time; and which (as Boyer observes) always retard cicatrization, and frequently impart to wounds the most fatal complications. After due evacuations, the surgeon should prescribe bitter aromatic decoctions proper to support the tone and functions of the stomach. The dressings should be applied with extreme attention and cleanliness, and too much care cannot be taken to prevent the infectious matter of one wound from coming into contact with another. All fatty resinous applications should likewise be abandoned in the treatment of wounds and ulcers threatened with hospital gangrene. The dressings, says Boyer, should be of a quality calculated to keep up the tone of the parts, without irritating them. According to this professor, such are the decoction, or simple infusion of aromatic plants in spirit of wine; diluted alkaline lotions, &c. Pledgets, kept constantly wet with these applications, are to be applied to the wound.

Such are the means, which, judiciously resorted to, will prevent hospital gangrene, or at least render its occurrence much less frequent. Let us next consider what can be done after the disorder has manifested itself, with a view of alluaging it, before it attains such a degree as puts the patient's life into danger.

No doubt the most certain mode of arresting the progress, or, at all events, of abridging the duration of the complaint, would be to transport the wounded into a more healthy situation, so as to remove them from an atmosphere contaminated by putrid contagious effluvia, and in which the disease has had its first formation. But, as Boyer observes, this change of place is generally impossible. In fact, where is the hospital in which can be found large well-ventilated wards in reserve, separated from every source of infection, and into which the patients can be directly moved on the very first appearance of the disorder? The best built hospitals offer no such accommodation. As then the patients cannot usually be transported into a different ward, the air which they breathe should be purified, by renewing it as much as possible, fixing ventilators, and especially by using the oxygenated muriatic acid fumigations, as recommended by Guyton-Morveau, or else those of the nitric acid.

The nitric acid fumigations are made by putting into a glass vessel on the ground, half an ounce of concentrated sulphuric acid, to which an equal quantity of nitre is to be added *gradatim*. The mixture is to be stirred with a glass tube, when an abundance of white vapour will be produced.

The oxygenated muriatic acid fumigations are made, by mixing three ounces two drachms of common salt, with five drachms of the black oxyd of manganese in powder. These two ingredients are to be triturated together; they are then to be put into a glass vessel; one ounce two drachms of water are to be added, and then, if the ward or chamber be uninhabited, one ounce seven drachms of sulphuric acid are to be poured upon the mixture all at once; or gradually, if the patients are there. This quantity will be sufficient for disinfecting a very large ward. See *Lassus Pathologie Chirurgicale*, tom. i. p. 38, 39.

When one or more of the patients afflicted with the disorder,

order, before it has become general, are lying in a badly ventilated part of the ward, or near some source of infection, the surgeon can partly counterbalance the disadvantage of not having a fresh ward, by causing the patients to be put into a more airy part of the ward, and as far as possible from the quarter in which they contracted the disease. Diet, internal medicines, and topical applications, form the three essential points in the treatment of hospital gangrene, after change of situation, or purification of the air, when that is impracticable.

When hospital gangrene attacks a large wound or ulcer, and the fever attending the complaint is considerable, no solid animal or vegetable food should be allowed. Where more nourishment is required than can be obtained from sops, tea, &c. thin rice-milk, weak gruels, &c. will agree better than broth or soup, which cannot be digested without considerable disorder. In proportion as the heat and irritation of the system diminish, the rice-milk and gruels may be made somewhat thicker, and when the patient can venture to eat solid food, new-laid eggs, baked or boiled fruits, vegetable dishes, fish, and even what are called white meats, may be given. The less meat, however, the patient eats, the less liable will he generally be to a relapse.

With regard to internal medicines, while irritation and febrile heat accompany hospital gangrene, diluent acid drinks are proper, such as nitrated whey sweetened with syrup of violets, lemonade, &c. Blood-letting is admissible in but few instances, not merely because the orifice made by the lancet is apt to become gangrenous, but because the fever which accompanies hospital gangrene is usually of the typhoid, or athenic character. Thomson, p. 493.

When the stomach appears much oppressed with bilious complaints, an emetic ought to be administered. When there is debility, good generous wine should be allowed, either by itself, or mixed with lemonade, according to circumstances. Bark, whose antiseptic qualities have been highly praised, is in general more hurtful than useful in this disorder. Boyer, however, allows that it may be beneficially given when the febrile heat has abated, and the debility is very great. He thinks also that the extract is the best preparation.

Acids are not liable to the same objections as bark: they are proper in all stages of the disease, and their efficacy, which has been proved in a vast number of instances, is the more marked, the greater the doses. The sulphuric acid is that which is given with most success; but the acidulous tartrate of potassa is also an excellent medicine. From two drachms to half an ounce may be given every day, and the best plan is to make with it an acid drink, which should be sweetened and strained.

In severe cases, attended with quick and feeble pulse, depression, restlessness, and anxiety, an opiate becomes necessary. "So long as we wish to excite a degree of moisture on the skin (says professor Thomson), Dover's powder, or laudanum with antimonial wine, form in general the best opiates." This gentleman, however, is not an advocate for the employment of opium in the early stage of hospital gangrene, while the heat and other febrile symptoms are at their height. (See *Lectures on Inflammation*, p. 494, 495.) For these cases, camphor was highly praised by Pouteau.

With respect to the local treatment, it is at least as important as the constitutional. Indeed, the French surgeons conceive that it is much more so. "I was told by several of the French surgeons," says a late visitor to Paris, "that they did not rely at all on internal means for stopping the progress of hospital gangrene, and that their experience had

proved them to be insufficient, if not wholly inefficacious. Dupuytren, in reply to the account I gave him of the practice and opinions of English surgeons on this subject, assured me, that he had no confidence but in local applications; and that internal remedies alone, as far as he had found, did almost nothing." The same remark has been made in a very recent publication on hospital gangrene (*Delpech Mém. sur la Complication des Plaies*, &c. 1815.), although it seems to be rather at variance with its being a constitutional and contagious disease, which the author has admitted. See *Sketches of the Medical Schools of Paris*, by J. Crofs, p. 83.

Perhaps there is not a single antiseptic application which has not been tried as a dressing for wounds or ulcers affected with hospital gangrene. All watery applications, and common poultices and fomentations, are generally condemned as inefficacious, and even hurtful, in the treatment of this disorder.

M. Dufflassio was convinced by the observation of numerous cases, that the best application is powder of bark. He recommends the wound to be covered with several layers of this powder, which are then to be moistened with turpentine. When this composition dries, it forms a fragile sort of coat, at the sides of which, and through which, the discharge escapes. After twenty-four hours, the first coat is to be removed, and a fresh one applied. In general, four or five such dressings are sufficient in simple cases, where the disorder is confined to the skin and cellular substance. Healthy inflammation then occurs, the sloughs come away, and the wound puts on a healing appearance. Dufflassio, in bad cases, sometimes added one-fifth of powdered muriate of ammonia to the powder of bark. In mild instances, as we learn from Mr. Crofs, the modern surgeons in France also employ with success vegetable and diluted mineral acids. P. 84.

But when, by the employment of these means, and of the other remedies which have been enumerated, the progress of the disorder cannot be checked, and all the surrounding soft parts are threatened with destruction, Pouteau, Dufflassio, and other French surgeons, even those of the present day, have immediate recourse to the actual cautery, and repeat the application of it, until the whole surface of the ulcer is converted into a firm hard eschar. Even the edges of the solution of continuity should not be spared,—"*ils doivent être torréfiés et rôtis pour ainsi dire.*" (*Boyer, Traité des Maladies Chir. t. i. p. 332.*) The eschar is then to be covered with a thick stratum of bark, moistened with turpentine. This application is to be removed in twenty-four, thirty-six, or forty-eight hours, and the surgeon is then to judge from the appearance of the flesh, and the quality of the discharge, whether a further repetition of the cautery will be necessary.

Although we thus find from the accounts of Boyer, Mr. Crofs, and others, that the modern French surgeons still regard the actual cautery as the only effectual means for stopping the progress of bad cases of hospital gangrene, their opinion has fortunately not been adopted in this country. Nothing can be a greater proof of such severe practice being at all events unnecessary, than the fact that many bad cases of hospital gangrene have done well without it, and even its greatest advocates cannot presume to assert that it will always effect a cure.

Instead of the actual cautery, the application of boiling oil has been proposed; but the advocates for red-hot irons maintain, that the heated oil does not extend its action to a sufficient depth.

A phlegmonous swelling at the circumference of the wound, or ulcer, evinces, that the ravages of the disease are stopped,

flopped, and that suppuration and the detachment of the sloughs are about to follow. In order to promote these desirable changes, Boyer recommends the inflamed parts to be covered with an emollient poultice; but as soon as pus is secreted, the poultice is to be discontinued, as it might relax too much, and some gently tonic application employed, such as the decoction of bark.

When the sloughs have separated, and the bottom of the ulcer appears firm and of a vermilion colour, the rest of the treatment ought to resemble that of a common wound, and the cure then generally follows with tolerable quickness. However, *cæteris paribus*, wounds and ulcers, after an attack of hospital gangrene, heal more slowly than other solutions of continuity.

But when, after the detachment of the eschars, the wound, instead of presenting a firm vermilion appearance, and discharging healthy pus, is covered with pale flabby granulations, the recurrence of hospital gangrene is to be apprehended. With a view of preventing it, the patient is to be purged with a decoction of tamarinds, which Boyer says is preferable to any thing else, and small doses of the acidulous tartrate of potassa are to be given every other day. But if the disease returns, the French surgeons direct the cautery to be used again, if the patient be not too much exhausted to bear it; for when he is, there is no hope from this or any other means. Relapses seldom happen, except in wounds and ulcers which are very large, and have confined the patients a long while in the hospital. A relapse, in these cases, is always an unfavourable omen; for it sometimes proves mortal, and if the patient gets over it, still the ulcers, or wounds, which have been repeatedly affected by it, are apt to degenerate into chronic sores, which it is extremely difficult, or even impossible, to heal. Boyer, *Traité des Maladies Chirurg.* t. i. p. 320, et seq.

By referring to the various publications, published by English surgeons on hospital gangrene, we shall find that they have succeeded in frequently stopping the disease, without having recourse to that heroic means, (as it is called by M. Roux,) the actual cautery. "The fermenting poultice, spirits, and turpentine, (says professor Thomson,) are certainly much milder applications, and will, I am convinced, when judiciously used, be found to be much more efficacious in effecting a cure. If attention to cleanliness in the dressing of sores and ulcers be at all times required, it is needless for me to remark to you, how much more imperiously it must be required in hospital gangrene, where the discharge from the sores, and probably the effluvia from the body of the patient, are of a contagious nature." See *Lect. on Inflammation*, p. 500.

Besides the fermenting poultice, camphorated spirits, and turpentine, the following local applications seem eligible; viz. decoction of bark; charcoal poultice, especially when the disease is stopped, and the sloughs are separating; the citric acid, with or without laudanum; vinegar; the diluted mineral acids; the vapours of the nitric, muriatic, and oxygenated muriatic acids; a solution of gum kino in equal quantities of claret and port wine.

Of Ulcers attended with some specific diseased Action, either constitutional or local.

1. *Ulcers which yield to Mercury.*—Here we shall exclude from consideration venereal ulcers, as this subject is treated of in the article *LUES VENEREA*. At present we shall only notice such sores as are produced by other diseases of the general system, or of the parts, and are capable of being cured by mercury.

Perhaps there is no greater source of error in the whole

practice of surgery, than the supposition, that a sore, when it yields to mercury, must be a syphilitic one. Surgeons, however, who run into this absurdity, can hardly be imagined to be unaware, that so potent a medicine must have effects on numerous diseases of very different descriptions. Sir E. Home very truly remarks, that many ulcers, unconnected with the venereal disease, which receive no benefit from other medicines, heal under a mercurial course, or yield to mercurial applications. In some cases, the ulcer remains in the same state while mercury is used; but begins to look better as soon as the medicine is discontinued, in consequence of the beneficial change produced in the system by the mercurial course. In these cases, mercurial frictions are the best, because they occasion least impairment of the constitution, in consequence of the stomach continuing undisturbed, and capable of digesting well.

Another description of ulcers noticed by sir E. Home, as deriving benefit from mercury, occur on the instep and foot, have a very thickened edge, and are attended with a diseased state of the surrounding skin, so as to bear some resemblance to elephantiasis. They are frequently observed affecting servants who live in opulent families in an indolent and luxurious way. Sir E. Home states, that fumigations with the hydrargyrus sulphuratus ruber heal these ulcers, and resolve in a great degree the swelling of the surrounding parts. In some instances, an ointment of calomel and hog's-lard; in others, the camphorated weak mercurial ointment, is the best application.

Many diseased ulcers, particularly superficial ones, with a thickened edge, may be healed, when they are dressed with a solution of one grain of the hydrargyrus muriatus, in an ounce of water, containing a little spirit.

2. *Ulcers which are curable by Hemlock.*—Sir E. Home places more reliance on hemlock as an external, than an internal remedy for ulcers. The ulcers which usually receive benefit from hemlock applications, look like those of an irritable sort; but the surrounding parts are thickened, in consequence of some diseased action. Such sores occur near the ankle; which joint is at the same time enlarged. Sometimes, but not so often, they take place over the ligaments of the knee. On account of their situation, and the swelling of the joint, they may be suspected to be scrophulous, though they are more sensible than strumous ulcers usually are. The sores just described are rendered less painful, their diseased disposition is checked, and the swelling of the joint diminished, by hemlock. Several irritable scrophulous ulcers are also particularly benefited by this medicine.

Sir E. Home gives the preference to hemlock poultices, unless their weight should be objectionable, in which cases, he advises lint to be dipped in a decoction of the herb, and put on the sore.

Of the ointment made with the inspissated juice, sir E. Home seems to say little in regard to its efficacy.

3. *Ulcers which may be cured by Salt Water.*—Sir E. Home takes notice of other specific ulcers which yield to this application, after resisting other remedies. Poultices made with sea-water are often employed; but this gentleman seems to prefer keeping the part immersed in the water in a tepid state, about a quarter of an hour, twice a day.

When sea-water poultices bring out pimples, in cases of scrophulous ulcers on the legs and feet, sir E. Home informs us, that this disagreeable circumstance may be obviated by diluting such water with an equal quantity of a decoction of poppies. After a time, the salt-water may be tried by itself again. While each fresh poultice is preparing, the part should also be immersed in such water warmed.

When there is a tendency to anasarca, or when there is

an unusual coldness in the limb, unattended with any propensity to mortification, tepid salt-water may be used with infinite advantage.

4. *Ulcers which may be cured by the Argentum Nitratum.*—Sir E. Home notices, under this head, an ulcer, which does not penetrate more deeply than the cutis; but spreads in all directions, producing ulceration on the surface of the skin, and often extending nearly through its whole thickness. The part first affected heals, while the skin beyond is in a state of ulceration.

Of this description are, a leprous eruption, mostly seen in men impressed in Ireland; a disease of the skin induced by bbooes, which have continued a great while after the venereal virus has been destroyed; and the ring-worm.

All these diseases are most easily cured by applying to them a solution of the argentum nitratum.

The leprous eruption is communicated by contact, and makes its appearance in the form of a boil. This is converted into an ulcer, which discharges a fetid fluid, by which the surrounding skin is excoriated, and the ulceration is extended over a large surface. The pain is the most severe, and the discharge greatest, in hot weather. The parts first diseased heal, while others are becoming ulcerated, and the disease is always rendered worse, by spirituous liquors, salt provisions, and catching cold.

Sir E. Home remarks, that the disease in the skin, produced by the effects of very irritable bbooes, in constitutions broken down by mercury, is attended with ulceration of a more violent, deep, and painful kind than the foregoing distemper. The progress of this disorder is, in other respects, very similar to that of the leprous eruption.

Although the ring-worm only occurs in the form of an ulcer in warm climates, a mild species of the affection takes place in summer-time in this country. It seems to be infectious; though it often occurs without infection. It commences with an efflorescence, which is attended with very trivial swelling, and spreads from a central point. The circumference of the efflorescence becomes raised into a welt, while the rest assumes a scurfy appearance. The welt becomes covered with a scab, which falls off, and leaves an ulcerated ring, in general not more than a quarter of an inch wide. The outer margin of this ring continues to ulcerate, while the inner one heals, so that the circle gets larger and larger. The discharge consists of a thin acrid fluid, which seems to have a great share in making the disease spread.

For all the three preceding diseases, a solution of the argentum nitratum is strongly recommended by sir E. Home.

5. *Ulcers which yield to Arsenic.*—The sores which are named *noli me tangere*, derive great benefit from this powerful remedy. Sir E. Home observes, that they are nearly allied to cancer, differing from it in not contaminating their neighbouring parts by absorption, and only spreading by immediate contact.

From some cases which fell under sir E. Home's observation, he discovered that arsenic was not only efficacious as an external, but also as an internal remedy. Indeed, experience proves, that, in all cases of lupus, or *noli me tangere*, if any medicine is entitled to more confidence than others, it is unquestionably arsenic.

Sir E. Home is an advocate for its employment, both internally and externally, for ulcers of untoward appearance on the legs. The fungated ulcer is particularly pointed out by this gentleman as being benefited by arsenic. This ulcer occurs on the calf of the leg, and on the sole of the foot. From its surface a fungus shoots out, which is entirely differ-

ent from common granulations. The new-formed substance is radiated in its structure, the bottom of the ulcer being the central point, and the external surface, which is continually increasing, the circumference. The substance of this fungus is very tender, and readily bleeds. The first stage of the disease sometimes has the appearance of a serophulous affection of the metatarsal bones; but the parts seem more enlarged, and when the skin ulcerates, a fungus shoots out, and betrays the nature of the case.

One species of the fungated ulcer is capable of contaminating the lymphatic glands, the other is not so. The first is represented by sir E. Home as being incurable by arsenic, or any other known medicine.

The second yields to this remedy. Sir E. Home uses a saturated solution, made by boiling white arsenic in water, for several hours, in a sand heat. He gives from three to ten drops internally; and, for outward use, dilutes a drachm with two pints of water, making it afterwards gradually stronger and stronger, till it is of double strength. The application may either be made in the form of a poultice, or by dipping lint in the lotion.

The best and safest preparation of arsenic, both for internal and external use, is the kali arsenicatum.

6. *Ulcers attended with Varicose Veins.*—A certain kind of ulcer is very apt to occur on the inside of the leg, and is equally difficult to cure, and liable to break out again. It has the look of a mild indolent sore; but the branches and trunk of the vena saphena are enlarged, and this varix of the veins keeps the ulcer from healing. The sore is seldom deep, usually spreads along the surface, and has an oval shape, the ends of which are vertically situated. There is a pain affecting the limb rather deeply, extending up in the course of the veins, and exasperated by keeping the leg a long while in an erect posture.

This is a kind of ulcer which derives immense benefit from a tight roller, applied from the toes to the knee, although the direct operation of the pressure of the bandage on the sore is itself productive of no particular good.

Sir E. Home found, however, that many patients could not bear to wear laced stockings or tight bandages, and that some received no relief from them. Hence, this gentleman was led to consider what else could be done for the cure of the varicose state of the veins. He represents, that, in consequence of the size of the vena saphena, and its numberless convolutions, the return of blood from the smaller branches is so impeded, as to retard the circulation in the smaller arteries, and to interfere with their action in forming healthy granulations. The coats and valves of the veins also become thickened, so that the latter parts (the valves) do not do their office of supporting the weight of the column of blood.

These reflections induced sir E. Home to think, that some benefit might be obtained by taking off a part of the pressure of this column of blood, by making a ligature round the vena saphena, where this vessel passes over the knee-joint. Thus the cavity of the vein at this part would be obliterated, and a kind of artificial valve would be formed.

This gentleman recommends the following way of performing the operation: "As the veins are only turgid in the erect posture, the operation should be performed while the patient is standing, and if placed upon a table, on which there is a chair, the back of the chair will serve him to rest upon; and he will have the knee-joint at a very convenient height for the surgeon. The leg to be operated upon must stand with the inner ankle facing the light, which will expose very advantageously the enlarged vena saphena passing over the knee-joint. While the patient is in this posture, if a fold

ULCER:

of the skin, which is very loose at this part, is pinched up transversely, and kept in that position by the finger and thumb of the surgeon on one side, and of an assistant on the other, this fold may be divided by a pointed scalpel, pushed through with the back of the knife towards the limb to prevent the vein being wounded; much in the same way as the skin is divided in making an issue. This will expose the vein sufficiently; but there is commonly a thin membranous fascia confining it in its situation; and when that is met with, the vein had better be laterally disengaged by the point of the knife. This is most expeditiously done by laying hold of the fascia with a pair of dissecting forceps, and dividing it; for it is difficult to cut upon parts which give little resistance, and there is a risk of wounding the vein. After this, a silver crooked needle, with the point rounded off, will readily force its way through the cellular membrane connected with the vein, without any danger of wounding the vessel, and carry a ligature round it. This part, or, indeed, what may be considered as the whole of the operation, being finished, the patient had better be put to bed, so as to allow the vein to be in its easiest state, before the ligature is tied, and then a knot is to be made upon the vein: this gives some pain, but it is by no means severe. The edges of the wound in the skin are now to be brought together by sticking-plaster, except where the ligature passes out, and a compress and bandage applied, so as to keep up a moderate degree of pressure on the veins, both above and below the part included in the ligature." See Home's Pract. Obs. on Ulcers, p. 296, edit. 2.

The foregoing method does not appear to possess novelty, as it was practised by Paré. What is of still more consequence, it is a plan which is not free from serious danger. We have seen several examples, in which the practice was followed by a violent degree of constitutional irritation, considerable disturbance of the nervous system and a tendency to convulsions.

Mr. Brodie has tried another method of operating, which is said to prove effectual, and to be milder in its consequences. Some account of it will be found in the article *VARTCOSE Veins*.

On the whole, we believe that there are few cases in which an operation is advisable, and that Default, Mr. Whately, and several other surgeons, have been perfectly right in giving a preference to the safer and more simple plan of making methodical pressure with a bandage.

ULCER, in animals of the domestic or live-stock kind, is a wound of some standing, arising from a solution of continuity in some fleshy part of the bodies of them with a loss of substance. The term is by some, in these as well as other cases, confined to that breach or erosion of the skin and parts immediately connected with it, which either proceeds directly from an internal cause, or at least is closely concerned with a peculiar state of the constitution. Others, however, divide ulcers into two classes, the simple and the compound: the former being a mere wound of some duration, which is capable of being restored by nature without the assistance of art, especially in the animals; while the latter is that which is attended with a bad state of the body. But although in these instances an ulcer may be supposed to proceed from a vitiated or diseased state of the habit of body in the animal, all common sores may likewise be reckoned ulcers, when they degenerate and contract an ill disposition, whether they take their origin from an internal or an external cause. They are, of course, of various kinds, according as they are owing to these different causes. Wounds, bruises, and other accidents, when ill-treated or neglected, often occasion ulcers; as well as a depraved state

of the blood and juices, which in the first instance only produce tumours. Of this kind are all those of the fistular and of other kinds in these sorts of animals.

Some ulcers too are internal, as in the lungs, liver, kidneys, and other viscera of animals, where they not unfrequently produce wastes and decays in them; and some are among the joints and ligaments, which are much more common. This is much the case in the legs of some animals.

There are other distinctions also occasionally made use of in describing ulcers in such animals; as those of *sinuous, fistulous, putrid, scrophulous, cancerous, varicous*, and some others, as their nature may be, and as may be seen under the same head in *Surgery*.

The simple ulcer is always superficial, and attended only with foulness, and hard or uneven edges raised above the surface of the common skin. A compound ulcer is, properly, when not only the flesh is ulcerated, but a caries or decay exists in the bone, with other bad appearances in the animal. A cavernous ulcer is that which has a small narrow entrance, with a wide spreading bottom part. The ulcers that run along, proceeding from abscesses between the muscles or their tendons, are called sinuous ulcers: the ulcers that are tubular, smooth, and callous on the inside, and run in several meanders, are called fistulous: and where there is a great efflux of fetid matter, with inflammation, swelling, and inward sickness in the animal, such ulcers are said to be putrid. Cancerous and scrophulous ulcers are usually seated on the glands, and may be distinguished by their particular appearances; the latter being more slow in its progress, and less offensive than the former, which extends rapidly, and makes great havoc on the parts, and seriously affects the whole constitution of the animal. Varicous ulcers are seated among the veins, and are always soft and dilated with blood in their parts. There are many of this kind that take place in the legs and other parts of animals of these different sorts.

It is found by experience, that simple and superficial ulcers on the skin in animals, are not, in general, difficult of cure; but sometimes their edges rise above the surface-skin, and grow callous, in which case they require some time before these can be reduced and cicatrized or healed. An ulcer or caries in the bone is necessarily more tedious and difficult to cure than one in the flesh, and the difficulty is more or less, in proportion to the nature of its situation, and the causes whence it proceeds. Cavernous ulcers often become so, merely by their situation being in places where compression or bandages cannot be applied; but they are not so troublesome as sinuous ulcers, especially when the sinuosities terminate near a joint, for then they are often attended with great difficulty and danger. Fistulous ulcers are attended with all the same, or rather greater difficulties, being often situated among the joints, and other inconvenient places; a circumstance which to animals of different sorts is of bad consequence, and, for the most part, renders them of little use, even when a cure is effected. Putrid ulcers are always dangerous, as proceeding from a bad state of the body in the animal; and when they discharge very great quantities of fetid matter, they are liable to end in mortification, and the destruction of the animals.

Cancerous ulcers are not of less ill consequence, only that there is more respite given; as the animals will live languishing a considerable time with these and other anomalous ulcers, as in some sorts of glanders or affections of the nostrils in horses, and sometimes in other disorders, until they are quite reduced, and the cure in most cases is impracticable.

ULCER.

practicable. Varicous ulcers among the blood-vessels of the legs or other parts of animals are of a spongy nature, and hard to manage, discharging, for the most part, a bloody sort of ichor. Of this kind too are some of those ulcerations that creep along the veins in the limbs, where they are equally troublesome and difficult of cure, on account of the exertions of the animals; but a simple and single ulcer of this kind may easily be healed by suitable applications, and a proper use of bandages or compression.

In the cure of these different sorts of ulcers, the methods that are directed below, may mostly be had recourse to with success in most kinds of domestic animals.

The first or *simple* kinds, it is thought by some, seldom need any other management than washing them with pure water a little warm, or with spirit of wine, and then dressing them with pledgets of lint or tow spread thinly with digestive ointment, composed of yellow wax, resin, common turpentine, and olive oil, in the proportion of two parts of the others to one of turpentine. However, if there be an itching, with small pimples, it is sometimes advised to mix in every four ounces of the digestive ointment a drachm of verdigris in very fine powder, and to apply dressings with it once a day, or once in two days, if the discharge be small. And if little papillæ arise in the bottoms of the ulcers, that are of a faint red colour, the dressing ointment should be mixed with red precipitate, in the quantity of a drachm of it in fine powder to every two ounces of the digestive ointment. Where the ulcers are deep, and do not fill up in a proper manner, as is the case sometimes in weak bad habits of body in the animals, bark, and strengthening remedies of other kinds, will likewise be necessary, as well as good keep; and the ulcers may be dressed with a mixture of common turpentine and myrrh in fine powder put on the pledgets every other day, washing them first with brandy, spirit of wine, or tincture of myrrh, or any other similar application.

The common black and yellow basilicons too, when made without lard, with oil, sometimes answer in these cases, as they tend to fill up the ulcers with granulations of good flesh; especially if proper remedies be at the same time given internally. It is advised also, that equal parts of antimony and gum guaiacum should be divided into ounce doses, and one of them be given every day, with plenty of good nourishing food, consisting of the best sorts of fodder and oats, with water-gruel for drink in some cases.

In cases where the ulcers fill up too fast, and produce a quantity of fungous flesh, it may be repressed by dressing with dry powders, such as myrrh and lapis calaminaris, or occasionally with red precipitate and burnt alum in fine powder, in equal proportions, mixed together; carefully avoiding all greasy applications. If the fungus continue troublesome, the dressing may be lint or tow, dipped in blue vitriol water, and wrung out dry, and then applied. If the edges be callous, so as to make a kind of rim round the ulcers, red precipitate dressings are always the best. This method has been found by some to succeed better, in some kinds of animals, as the horse, than either cutting the callous edges off, or eating them down by caustic, or destroying them by a hot iron. Although somewhat slower, it is supposed more safe, as not being so apt to produce inflammation, which, instead of destroying such callosities, frequently renders such ulcers more obitinate than before, and more liable to fungus.

These ulcers, in their simple states, may often be cured simply by drawing together, and supporting the parts by slips of sticking-plaster.

In the *cavernous* kind of ulcers, where they are deep, narrow at their entrances, and wide at their bottom parts,

they require to be laid open, or the small orifices of them to be widened by a caustic, so that no matter may be concealed. Where they are in such situations that they can be laid open with safety, and the habit of body in the animals is good, they may be cured with the same ease as almost a simple flesh wound, by merely observing the same methods as in the former cases. But when they do not fill up by such means as are directed above; and if they be found on probing to have sinuities, they must be managed as sinuous ulcers, as below.

The *sinuous* kinds of ulcers are a sort which should be laid open without loss of time, by incision, where it can be properly done, provided acid injections, such as the solutions of blue vitriol, alum, or corrosive sublimate, have been previously tried, and where bandage or compression cannot be used; as when they are suffered to continue long, they will run deeper and deeper, and often among the tendons and interstices of the muscles, so as at last to make their way to the bones, which become carious in consequence, and the cure in that case is rendered equally tedious and difficult.

The *fitulous* kinds of ulcers mostly take place by there being inflammations and tumours in the parts, which form abscesses or collections of matter, which, if not let out and removed by incision, and proper pressure applied, penetrate deeper, and become sinuous ulcers; which when they have existed long, or have occurred in unhealthy animals, several sinuses often form, and the matter makes its way from one to another by small tubes, or communicating passages; in which cases the sinuses are commonly lined with callous coats or membranes, so that no re-union can be effected until these connecting passages are laid into one, and their callosities are destroyed. This may mostly be accomplished by proper incisions being made, when the parts should be dressed with levigated red precipitate, or with pledgets of lint or tow dipped in a solution of blue vitriol, and phagedenic water, made by dissolving a drachm of corrosive sublimate in a pint of lime-water; or when made stronger in some obitinate cases.

Common abscesses, on some occasions, by injudicious treatment, are converted into sinuous and fitulous ulcers, where they would perhaps have no such tendency; as by the bad and absurd practice sometimes used, of introducing long hard tents, that separate the muscles in the same manner as a piece of timber is cleft by a wedge, and by thus tearing the membranes apart, the abscesses grow deeper, and even occasionally run into sinuses that lie out of the reach of common applications. The frequent and unnecessary use of the probe too, often promotes the same bad consequences. In abscesses, the weight of the collected matter in them occasions an easy separation of the contiguous cellular membrane, so as to give way readily to a slight force applied by a rude hand, and to form deep sinuities; to prevent which, in all such cases, the parts should be kept as firm and close by the use of a bandage as they are capable of bearing, or a depending opening may be formed for the passage of the matter in another direction; a seton too may sometimes be introduced for the same purpose: so that by one or other of these methods, most bad cases of this kind may be prevented or removed in these sorts of animals.

In *putrid* ulcers, as whatever may be their origin, they always exist under unfavourable states of the constitution of the animals, the cure of them will, of course, stand in need of internal means, such as the use of bark, opium, and good nourishing food, in as large quantities as they can be taken, with fomentations and cataplasms of the spirituous and opiate

opiate kinds applied in as powerful a manner as possible externally to the parts. By these means, steadily persevered in, they may often be removed without much difficulty.

The *cancerous* and *scrophulous* are sorts of ulcers that take place in the glandular parts of the bodies of animals. The first sort sometimes occurs in horses in bad cases of glanders and farcy; and horses have occasionally cancerous warts, which, when deep seated, are liable to become true cancerous ulcers. Some suppose too that ulcers of this nature take place from setons, in some cases, when improperly placed in glandular parts.

In neat cattle, they mostly begin by hard livid tumours forming themselves in glandular parts, some of which are moveable, others more fixed at first, and some inflame and quickly break out, discharging a thin acrid sort of ichor, while others are more slow in breaking, and discharge a more thick matter, being liable to fill up with fungous flesh. These latter often occur about the face, on the eye-lids, and in the glands about the jaws, being very difficult of healing. There is frequently a scrophulous disposition in the parts that keep them up.

In these cases the cure depends much on their situation. In some instances they can be readily removed by cutting the diseased parts wholly out. Some destroy the excrescences by the use of caustic. These modes are particularly used with neat cattle, and sometimes with other sorts. After the ulcers have been made clean in their parts, they may be touched all over with caustic of the lunar kind, or have red precipitate, in fine powder, dusted on them, and be afterwards dressed with small pledgets of tow or lint, dipped in a solution of sublimate in egyptiacum, to which a little tincture of myrrh and spirit of turpentine and of salt have been added, once a day; any rising flesh being kept down by the above caustic. In order to fill up such ulcers more readily, in some cases, as where they are clean, and without acrid discharge, it may be necessary to use digestive ointment wrought up with the above solution, on the dressings, once or twice a day.

Mild purges in these cases may sometimes be beneficially made use of to promote the healing of the ulcers, as well as medicines of some other kinds.

The hard glandular tumours that produce these ulcers may sometimes be dispersed at first, by the use of strong mercurial ointment mixed up with turpentine, well rubbed upon them once or twice a day for several days, and then leaving it off for a time, to be repeated again if necessary. The same ointment may likewise be employed with more advantage, in some cases, when combined with strong aqua-fortis and powdered cantharides. See TUMOUR.

In the cure of the *varicous* kind of ulcers, it has been advised by some to bathe the parts with astrigent fomentations prepared by oak and other such barks in proper proportions, or with alum and white vitriol dissolved in warm vinegar. The matter of these ulcers is generally, it is said, of a thin bloody watery nature, which will thicken or dry up by such applications. In case the vessels continue weak and relaxed after such ulcers are healed, firing will sometimes be useful and proper for strengthening the parts, by contracting the coats of the veins that cause and promote the ulcers: and in some cases it may be done so deeply as to cut off the communication of them. Ulcers of this watery kind, which have some affinity to the varicous, take place in horses in the farcy, and in some other diseases of them, as well as other animals.

In most cases of old ulcers in animals, it will be of much

use to have recourse occasionally to calomel, given in doses of from half a drachm to a whole one, with cooling purges, and good keep, as well as the frequent application of bandages where they can be employed.

By these different means properly applied, most of the ulcers in different sorts of domestic animals may be speedily removed.

ULCERATION. That the living body should possess a power of removing portions of itself, seems at first a proposition somewhat extraordinary; but when it is known that there exists in the animal body a system of vessels, whose peculiar function is to take away the old particles of matter, in proportion as new particles are deposited by the arteries, the disappearance of parts then readily admits of explanation by adverting to the power and action of the absorbent vessels. In fact, there can be no greater difficulty in conceiving how these vessels remove the particles of the body, than in conceiving how such particles are deposited by another order of vessels, named arteries. One of the most common examples of the absorption of particles of the living body in disease, is that which is every day exemplified in the process of ulceration, by which an actual breach or solution of continuity is produced. It was this process which Mr. Hunter used to distinguish by the name of *ulcerative absorption*.

Ulceration, or ulcerative absorption (as professor Thomson observes), is a morbid process which must have presented itself in every age, and with the appearances of which medical men must have been at all times very familiarly acquainted. The phenomena which it exhibits were denominated erosion by Galen. Since his time, it has usually been supposed that the solution of continuity which occurs in erosion is produced by the corrosive or solvent power of the fluids which are generated in that process.

Mr. Hunter was the first who ventured to call this opinion of Galen's in question, and who pointed out to future observers the state which the absorbent vessels have in this process.

In most instances of inflammation, in which the process of ulcerative absorption occurs, it usually begins at a single point, forming a small sore or ulcer; while in other examples it commences at several points, either at the same time or in succession. In many instances, its operation appears to be diffused over a considerable extent of surface; and in others again it is limited to a very narrow line, producing a chink or fissure, an appearance similar to that which occurs in the separation of mortified parts. The progress of ulcerative absorption is very various in different textures, and in the same texture in different individuals, according to the nature of the inflammation, the degree in which it exists, and perhaps, also, according to the particular constitution of the person in whom it occurs. In some instances the process of ulcerative absorption is exceedingly slow, or chronic in its progress, the sores which it forms remaining long open, without manifesting any disposition to extend themselves into the parts more immediately surrounding them. In other instances it acts with great rapidity, removing and destroying considerable portions of textures or organs in the course of a few hours.

Dr. Thomson then proceeds to notice, that pain of a pricking or lancinating nature is an almost constant attendant upon attacks of ulcerative absorption; but this varies exceedingly in different textures, in different kinds of inflammation, and according as the absorption is more rapid or slow.

Every organized part of the body seems liable to ulcerative

cerative absorption, but we see it occur more frequently in cutaneous texture, and in mucous membrane, than in any of the other textures of the body.

In all the parts in which it occurs (says Dr. Thomson), it is preceded by a certain degree of inflammation, and this inflammation is usually the adhesive; but ulcerative absorption may supervene in parts affected with suppurative or gangrenous inflammation. The inflammation which precedes and accompanies ulcerative absorption, may be either of a simple or of a specific nature, and great differences will be produced by this circumstance in the appearances and effects of the sores or ulcers which are formed.

Ulcerative absorption, in simple inflammation, may arise from a great number of causes, as from pressure upon parts in a state of inflammation. We see this effect daily produced in cases of simple and compound fractures, where the limbs are frequently kept a long while in one posture. It may be produced by the application of irritating substances to inflamed surfaces, or by the too long retention of excreted fluids upon surfaces in a state of suppuration.

Many specific inflammations seem to give a disposition to ulcerative absorption, and the sores or ulcers which are formed, are most of them very difficult to heal, if they are not in their nature absolutely incurable. This difficulty is often very remarkable in scrophulous, syphilitic, cancerous, and lupous ulcerations. The ulcerative absorption which occurs first in cutaneous texture, may in its progress be confined to that texture, removing a considerable portion of skin, and exposing the parts which lie under it; or, without extending far along the surface, it may penetrate into the interior parts of the body. In doing this, it often successively attacks and removes skin, cellular membrane, fascia, muscle, blood-vessel, absorbent, nerve, and bone. We have examples of this in the progress of cancerous and lupous ulceration. That inflammation constantly precedes ulceration, Dr. Thomson thinks is proved, not only by the occurrence of redness, pain, heat, and swelling in the parts which are contiguous to those in which the ulceration appears, but also by that closure (which is effected by adhesion) of the canals of the blood-vessels and absorbents divided in ulcerative absorption, and without which a certain degree of hemorrhage would be the never-failing and constant attendant upon the state of ulceration.

When, in the healing of sores, the skin which immediately surrounds them becomes red, hot, swollen, and painful, we have reason to dread an extension of the sore by the progress of ulcerative absorption. In some instances this process occurs in the whole circumference, producing an extremely irritable and painful ulcer; in others, the ulcerative absorption is confined in its operation to a particular spot, which is always more inflamed and painful than the other parts of the sore. Certain states and degrees of gangrenous inflammation have a tendency to terminate in ulcerative absorption; and when the ulcerating and sphacelating processes occur together in the same diseased surface, dreadful are the havoc and destruction of parts which they occasion. Mucous membrane, next to cutaneous texture, seems to be most liable to attacks of ulcerative absorption. In mucous membranes, the ulcerating process often appears in the form of small round sores, which are termed aphthæ when they appear in the mouth or fauces, and chancres when on the parts of generation. These, like the ulcerations in cutaneous texture, may be either of a simple or specific nature, and it is often extremely difficult, from the appearances which they exhibit, to determine to which division we ought to refer them.

Bone is another texture which seems very liable to ulceration, and the disorder here generally receives the appellation of caries.

Ulcerative absorption very seldom begins originally in muscle, tendon, fascia, blood-vessels, absorbents, or nerves, though, in the progress of disease, it may attack all these structures.

Synovial membranes are often the seat of ulceration, particularly in the progress of chronic inflammations, which attack the articulating surface of the joints. Here the ulcerative process begins most frequently in the synovial membrane, and from this extends to the articulating cartilage, and afterwards to the bone.

Of the internal viscera, there are none which seem so liable to ulcerative absorption as the stomach and intestinal canal. Death is almost always the speedy effect of ulceration, when it eats through the coats of these viscera, the contents of which escape into the cavity of the abdomen.

Healthy pus and the appearance of granulations are always agreeable occurrences in the progress of an ulcer, as they indicate that a stop has been put, at least for a time, to the process of ulcerative absorption.

It was particularly remarked by Mr. Hunter, that new-formed parts are more liable to ulcerative absorption than such as constitute original portions of the body. This is seen in the frequent absorption of granulations, cicatrices, and callus.

There is also a process in the animal body, very analogous to open ulceration, or, what Mr. Hunter called, ulcerative absorption: we allude to that peculiar operation which he thought proper to name progressive absorption. By this, abscesses, aneurisms, and various tumours, make their way to the surface of the body, the parts covering them being gradually rendered thinner and thinner by absorption. And it is by the same process that foreign bodies, such as pins, needles, bullets, &c. travel from one part of the body to another, and are at length brought to the surface. See Hunter's Treatise on the Blood, Inflammation, &c. and Thomson's Lectures on Inflammation, p. 369, &c.

ULCHUNSKOI, NIZNEI, in *Geography*, a town and fort of Russia, on the Amur; 56 miles S.S.W. of Doronink.

ULCHUNSKOI, *Verchnei*, a fort of Russia, on the Amur, on the borders of China; 100 miles S.W. of Doronink.

ULCI, in *Ancient Geography*, a town of Italy, in the interior of Lucania. Ptolemy.

ULEA, or ULABORG, in *Geography*, a sea-port of Sweden, capital of a government which comprehends a part of East Bothnia, situated in a peninsula, at the mouth of a river of the same name, which runs into the gulf of Bothnia. It was built in the year 1610, and is the largest town in all East Bothnia. It has very straight and long streets, a good school, a commodious harbour, and a fine salmon fishery. In the year 1714, this town was demolished by the Russians. The castle which stands near it on a small island, and is properly called Ulaborg, was built and fortified in the year 1590; but now lies in a ruinous condition; 320 miles N. of Abo. N. lat. 65° 40'. E. long. 25° 23'.

ULEA, a river of Sweden, which runs into the gulf of Bothnia, N. lat. 65° 2'. E. long. 25° 22'.—Also, a large lake of Sweden, in the province of Cajana.

ULEASALO, a town of Sweden; 4 miles S. of Ulea.

VLED DE NUN, a country of Africa, next to the province

province of Suz, or Sufe, in Morocco, and separated from it by sandy deserts. The emperor of Morocco arrogates to himself the sovereignty of Vled de Nun, but his real authority is here extremely feeble. This vast, but desert, province affords not a single harbour or anchoring-place along a coast of 60 leagues, or quite to Cape Bajador. It is inhabited by different tribes of Arabs, whose camps are scattered over such parts of the interior country as are capable of cultivation. The side next the sea is a sandy shore, lined with rocks under water, over which the waves break violently. Ships are often driven on this coast by rapid currents formed between the continent and the Canary islands, and Spanish, English, and French vessels are frequently shipwrecked. When these disastrous events occur, the unhappy mariners are immediately seized and stripped by the Arabs, exposed to every kind of privation, bought and sold, or exchanged for camels, or other beasts, in the markets of the deserts. The province of Vled de Nun has a considerable trade. After having passed the deserts that separate it from Morocco, we find many tracts of land capable of cultivation, and which produce gums and excellent wax. As these people are so far removed from the reach of tyranny as to live in a kind of independence, luxuries are more indulged among them; and they make use of many European commodities, especially linen. Several of these Arab tribes are more affable and honest than the other Moors. They trade to Mogodor, but with reserve and circumspection, that they may not expose their riches to the uncertainty of accident. It is probable they have a more immediate communication with the factories of Senegal, with which they may trade with less restraint; and it is only by their means that the westerly Moors have any intercourse with the people of Nigritia. If it were practicable to form settlements on the coast of Cape Bajador, a very profitable commerce might be established with these Arabs; and mariners, who might have the misfortune to be shipwrecked on the coast, would be able to obtain more certain and speedy assistance; but such a plan is exposed to too many difficulties ever to be realized. Chenier's Morocco, vol. i.

ULEMAS, the name by which the ministers and interpreters of religion are distinguished in the Ottoman empire. In Turkey they possess the most lucrative employments; they join judicial to religious power; they are at the same time interpreters of religion and judges of all civil and criminal affairs; they are secure from the extortions of the pachas and great men of the empire; they cannot be legally put to death without the consent of their chief: their property, after their decease, passes as a right to their heirs, so that the imperial treasury cannot appropriate it to itself. In short, they form a corporation, highly regarded, powerful, and sometimes formidable to the throne itself, from their having the direction almost always of public opinion, and because there is, perhaps, no government where public opinion is pronounced with so much strength and success as in Turkey. These magistrates and doctors of the law must not be confounded with the *imams* who serve the mosques, (see IMAM,) nor with the *muezzims*; which see. The order of ulemas, the most respectable and best informed in the Ottoman empire, comprehends the *mufti* or *muphti*, the *kadilefers* or *cadilefers*, the *stambol-effendi*, and the *muderis*; which see respectively. The immediate ministers of religion, though they make no part of the body of ulemas, may be admitted into it, either by undergoing examinations, and getting themselves received as *muderis*, or by obtaining through favour a place of provincial *mufti*, or *cadil*, or of *nab*. If, after having occupied these employments, they

be admitted into the body of the *muderis*, and with to pass to the mosque of Soliman, they may then arrive at the most eminent places of judicature. The first rank among them is that of *schick*, or preacher, whose function is to preach in the mosques every Friday after the noon prayer, and even oftener when there are foundations for that purpose. The *schicks* of the fourteen imperial mosques of Constantinople are the most considered in the empire, and are appointed by the *mufti*; those of the other mosques are named by the magistrate of the place or of the district. The *khatis* have no other employment besides that of discharging, in imitation of the prophet and of the first caliphs, and in the place of the sultan who represents them, the functions of *imameth*, or of the priesthood, at the solemn prayer which takes place on the Friday, and of reciting the *khoubé*, or public profession respecting the unity and the attributes of the Supreme Being, accompanied by a prayer for the preservation and prosperity of the sultan, and for the success of his arms against the infidels. They are appointed by a *khatty-scherif*, signed by the hand of the sultan. The imam recites in a loud voice, in the mosque, five times a day, except at the solemn Friday's prayer, the *namaz*, which the persons present repeat in a low tone: he at the same time performs the ceremonies which accompany that prayer; he assists at circumcision and interments: in a word, he discharges all the functions which worship requires. In the early ages of Mahometanism, *imam* signified and designated the pontiff, or the supreme chief of Islamism: the successors of the first four caliphs took only the title of *imam-ul-mustimin*, pontiff of the Mussulmans. The doctors and interpreters of the law were afterwards decorated with it, and for some time past it has no longer been given to any but the ministers of religion. In most villages, and some mosques of the towns, whose revenue is too limited, the imam discharges at the same time the functions of *schick*, *khatis*, *imam*, *muezzim*, and *cayim*. The mosques of the second order, called *mesjids*, have no need of a *khatis*, because they have not the right to celebrate the solemn prayer on a Friday. Olivier's Travels.

ULE-TREE, CASTILLA, in Botany, Mexican Elastic Gum, constitutes a new genus of plants, of which an account has been given by Don Vicente de Cervantes, in the supplement to the *Gazeta de Literatura*, published at Mexico, July 2, 1794. See Konig's Tracts relative to Botany, 229. This genus is named CASTILLA, in memory of the late Don Juan del Castillo, a native of Jaca, in the kingdom of Aragon, who at the age of twenty-seven was appointed chief botanist to the royal hospital at Porto-Rico. Seventeen years afterwards he was one of the naturalists chosen to investigate the productions of Mexico, where he died July 26, 1793, at the age of forty-nine years.—Class and order, *Monococia Icosandria*. Nat. Ord. *Scabride*, Linn. *Urticea*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, hemispherical, covered with imbricated, ovate, acute scales. *Cor.* none. *Stam.* Filaments numerous, thread-shaped, inserted into the inside of the calyx, the outermost gradually longer; anthers simple, roundish.

Female, on the same branch, alternate with the male, *Cal.* as in the male, but with rather broader and thicker scales, permanent, at length spreading. *Cor.* none. *Pist.* Germens numerous, fifteen to twenty, ovate; styles two, rarely three, to each germen, spreading, permanent; stigmas simple, revolute. *Peric.* Drupas from fifteen to twenty, combined at the base, obscurely triangular, excavated at the summit. *Seed.* Nut ovate, of one cell, with a kernel of the same shape.

Eff. Ch. Male, Calyx of one leaf, imbricated with scales. Corolla none. Stamens numerous.

Female, Calyx as in the male, permanent. Cor. none. Germens numerous. Styles two or three. Drupas numerous.

1. *C. elastica*. Cervantes as above, t. 9.—Native of the hot north-east coasts of Mexico, where it is one of the loftiest and most luxuriant of trees, much resembling *Annona muricata*. Stem three or four yards in circumference, very straight. Bark smooth, soft, three or four lines thick, ash-coloured, bitter and nauseous in taste, as is the milky juice issuing from every part when wounded. Branches alternate, horizontal, round, flexible; the younger ones clothed with stiff hairs. Leaves alternate, on short thick stalks, elliptic-oblong, acute, eighteen inches long and seven broad, veiny, downy on both sides, entire, though apparently toothed from the equidistant tufts of hair, ranged along the margin; heart-shaped at the base; reticulated with veins. Stipulas in pairs at the base of each footstalk, oblong, pointed, membranous, deciduous. Flowers axillary, solitary, nearly sessile, the male and female alternate in the lower part of each branch, but towards the end are male flowers only. Calyx straw-coloured. Stamens white, with deep-yellow anthers. Drupas larger than a pea, crowded together in the bottom of the extended calyx, orange-coloured, mucilaginous, almost tasteless.

The milky juice of this tree forms that kind of Elastic Gum, which the Mexicans call *Ule*. The *Cecropia peltata*, with some species of *Jatropha* and *Ficus*, yield a similar produce, valuable for divers economical purposes. See CAOUTCHOUC.

ULEX, the Furze-bush, a name in Pliny, which professor Martyn is disposed to derive from *ωλος*, *crisped* or *curled*; but De Theis traces the word to the Celtic *ec* or *ac*, a point, certainly applicable enough to its habit and appearance; this etymology being moreover supported by the French name of the shrub, *ajonc*, anciently *arjone*, or prickly rush.—Linn. Gen. 379. Schreb. 488. Willd. Sp. Pl. v. 3. 969. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 756. Ait. Hort. Kew. v. 4. 265. Brot. Lufit. v. 1. 78. Juss. 352. Lamarck Illustr. t. 621. Gærtn. t. 151.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. Cal. Perianth inferior, of two ovate-oblong, concave, straight, equal, permanent leaves, rather shorter than the keel; the upper one with two teeth; lower with three. Cor. papilionaceous, of five petals. Standard very large, inversely heart-shaped, emarginate, straight. Wings oblong, obtuse, shorter than the standard. Keel straight, obtuse, of two petals converging at their inner margin. Stam. Filaments in two sets combined at the base, one simple, the other in nine divisions; anthers simple. Pist. Germen oblong, cylindrical, hairy; style thread-shaped, ascending; stigma small, obtuse. Peric. Legume oblong, turgid, nearly covered by the calyx, straight, of one cell and two elastic valves. Seeds few, roundish, emarginate, with a fleshy appendage.

Eff. Ch. Calyx of two leaves. Legume scarcely longer than the calyx. Stamens all connected.

The few species of this genus are almost confined to the western more temperate parts of Europe, and are remarkable for their rigid thorny bushy habit. The leaves are simple, small and inconspicuous. Flowers numerous, deep yellow.

1. *U. europæus*. Common Furze, Whin, or Gorse. Linn. Sp. Pl. 1045. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 742. Fl. Dan. t. 608. Brot. n. 1. (*U. grandiflorus*;

florus; Pourret Act. Tolof. v. 3. 333. Genita spinosa vulgaris; Ger. Em. 1319. Scorpius primus; Cluf. Hist. v. 1. 106.)—Calyx-teeth obsolete, converging. Bractæas ovate, lax. Branches erect.—Native of gravelly or sandy heaths, in Denmark, Germany, Brabant, France, and Portugal, very frequent in England, flowering in May.—On Putney heath it is remarkably luxuriant, and very splendid when in blossom. Linnæus is recorded to have been peculiarly struck with the appearance of this shrub, when he visited England, and he complains in *Hort. Upsal.* 212, that he could never preserve it in his garden through the winter. With us it varies from two to six feet in height. The branches are excessively numerous, crowded, furrowed, hairy, tipped with strong, sharp, compound, permanent thorns, which bear at their base the leaves and sometimes flowers. Leaves solitary, awl-shaped, spinous-pointed, small, roughish or hairy, deciduous, chiefly on the youngest most vigorous branches. Flower-stalks axillary, solitary or in pairs, simple. Bractæas near the calyx, but not close-pressed, sometimes spreading, ovate, concave, silky. Calyx downy. Corolla near twice the length of the calyx, honey-scented, of a golden yellow. Legume downy, splitting with a crackling noise, in hot still weather.

2. *U. nanus*. Dwarf Furze. Forst. in Sym. Syn. 160. Fl. Brit. n. 2. Engl. Bot. t. 743. Willd. n. 2. Ait. n. 2. (*U. europæus* β; Linn. Sp. Pl. 1045. *U. geniftoides*; Brot. n. 2. Genita aculeata minor, five Nepa Theophrasti; Ger. Em. 1321.)—Calyx-teeth lanceolate, spreading. Bractæas minute, close-pressed. Branches reclining.—Found on rather mountainous or elevated heathy ground, in France, England, and Portugal, flowering in autumn; though it must be observed that both species are to be met with more or less in blossom, in all open weather. This is much smaller than the foregoing; flowers not only smaller but paler; branches more elongated and cylindrical; bractæas minute, brown; calyx yellower, with deeper more evident teeth.

U. capensis, Linn. Sp. Pl. 1046, being no other than *Polygala spinosa*, Linn. Sp. Pl. 989, is properly left out by Willdenow, though he ought to have referred to it under the said *Polygala*.

ULEX, in Gardening, furnishes shrubby plants of the thorny kind, among which the species cultivated are, the common furze, whin, or gorse (*U. europæus*); the dwarf furze (*U. nanus*); and the Cape or African berry-bearing furze (*U. capensis*).

The first is a well-known plant, frequently met with on wastes, commons, and heaths, spreading over large tracts of land.

There are several varieties, as the common yellow furze; the white-flowered furze; the long-spined furze; the short-spined furze; the large French furze; the small or dwarf furze; and the round-podded furze.

This sort and varieties of furze are remarkable for having all their young shoots, branches and spines of a lasting green colour, which, though they are deciduous in the leaf, which comes out in the spring, and soon falls off and disappears, yet from these numerous branches, shoots and spines remaining constantly green, they always appear in the manner of evergreens, and are mostly ranked under that head or class. See EVERGREEN.

The second sort is much lower than the common sort, having decumbent branches. It is found with the other kind chiefly on dry elevated heaths, but by no means so generally; flowering from August to October. It was formerly considered by some as a variety of the above.

The third, or Cape fort, has a woody hard item, which is covered

covered with a greenish bark when young, but afterwards becomes greyish: the branches are also slender and woody. It has not yet produced any flowers in this climate.

Method of Culture.—These plants may all be increased from seeds. These in the first fort should be sown in the autumn or spring, in any light mould, where the plants are to remain. They are likewise sometimes sown in drills in nursery-beds, to be transplanted afterwards while very young; but the first is the better practice, as they do not remove well, especially when grown of a large size. Hedges of this plant are best raised by sowing them in drills an inch deep where they are to remain, keeping them perfectly free from all sorts of weeds, &c. for two or three years, until a little advanced in growth.

In the second and third forts, in the latter of which the seed should be obtained from abroad, and be sown in pots of fine mould, plunging them in the hot-bed; when the plants are up a few inches in height, they should be removed into separate small pots, being afterwards managed as other shrubs of the greenhouse kind. But with the former, the same modes may be followed with the seeds as in the first fort and its varieties.

The last fort is difficult to raise, either by layers or cuttings.

The first fort and varieties afford ornament and variety in shrubberies, where a few plants of the different kinds may be admitted in such as are extensive, having a fine effect in their evergreen flowery appearance, and the two latter among potted plants of the greenhouse kind. The former also in borders and clumps.

ULEY, LA, in *Geography*, a town of Spain, in the province of Grenada; 10 miles W. of Vera.

ULFEN, a sea-port town of Sweden, in Angermanland, on the coast of the gulf of Bothnia; 25 miles N.N.E. of Herjolund.

ULFON, *North and South*, two small islands on the west side of the gulf of Bothnia. N. lat. 63° 2'. E. long. 18° 27'.

ULFSBY, a town of Sweden, in the government of Abo; 5 miles S.S.E. of Biorneborg.

ULIA, (*Monte Major*), in *Ancient Geography*, a town of Hispania, in Bætica, towards the N.E. By a medal of Gruter, it appears to have formed a small citate, and to have assumed the title of a republic.

ULIARUS, the *isle of Oleron*, an island on the coast of Gallia Aquitania.

VLIEGER, SIMON DE, in *Biography*, was born at Amsterdam about the year 1612. It is not known by whom this artist was educated, but his pictures are very deservedly esteemed for their force and brilliancy. He had the honour to be the instructor of the younger Vandevelde; and though the delicacy of the pencil enjoyed by the pupil surpassed that of the master, yet the works of the latter retain their power, and have a character of their own, which gives them a place in the best collections.

VLIELAND, or **VLIELANT**, in *Geography*, an island in the German sea, at the entrance of the Zuyder See, about eight miles long, and three in breadth; taken by the English in 1799; 5 miles N. from the Texel. N. lat. 53° 24'. E. long. 4° 25'.

ULIETEÀ, one of the Society islands, in the South Pacific ocean. On the east and west coasts of this island are some good harbours. One harbour or bay, called by the natives *Oopoa*, and capable of holding any number of ships, extends almost the whole length of the E. side of the island, and is defended from the sea by a reef of coral rocks; the southernmost opening in this reef, or channel into the har-

bour, is little more than a cable's length wide; it lies off the easternmost point of the island, and may be known by another small woody island, which lies a little to the S.E. of it, called by the people *Oatara*. Between three and four miles N.W. from this island lie two other islets, in the same direction as the reef of which they are a part, called *Opururu* and *Tamou*, between which lies another channel into the harbour, a quarter of a mile wide. Still farther to the N.W. are some small islands. On Ulietea there is a great Morai, called *Tapodebatea*, different in its construction from the Morais of Otaheite. Several jaw-bones are found, which lead scalps among the Indians of North America, are trophies of war. On this island they exhibit dances and dramatic exhibitions for the amusement of those who choose to attend them. The inhabitants in general are more superstitious than those of Otaheite. Oreo, the chief of this island, when Cook visited it in 1774, is a native of Bolabola, but is possessed of uhe-noos or lands at Ulietea, which he, as well as many of his countrymen, are supposed to have gotten at the conquest. He resides here as the lieutenant of Opoony of Bolabola, seeming to be vested with regal authority, and to be the supreme magistrate in the island. Oo-oo-rou, who is the earee by hereditary right, has little more left him than the bare title, and his own uhe-nooa or district, in which he is sovereign. Oreo was observed to pay him the respect due to his rank. The land is hilly, broken, and irregular, except on the sea-coast; yet the hills are green and pleasant, and in many parts abound with wood: the productions and manners of the inhabitants are similar to those of Otaheite. The principal refreshments that are to be procured at this island are plantains, cocoa-nuts, yams, hogs, and fowls: the hogs and fowls however are scarce; and the country appears to be neither so populous nor so rich in produce as Otaheite, or even Huahine. Wood and water may also be procured here, but the water cannot be conveniently got at; lying S.W. by S. distant 7 or 8 leagues from Huahine. See **SOCIETY ISLANDS**.

ULIETER, or *Flie Stroom*, a road in the north part of Zuyder See, near the coast of Friesland.

ULIGINOUS LAND, in *Agriculture*, a term sometimes applied to a dark-coloured fort of moilt, moorish, or fenny ground or soil.

ULISSING, in *Geography*. See **FLUSHING**.

ULIZIBIRRA, in *Ancient Geography*, a town of Africa Propria, towards the S. of Adrumetum. Ptol.

ULKANSKAIA, in *Geography*, a town of Russia, in the government of Irkutsk; 60 miles S. of Kirensk.

ULKORUNNE, three small islands on the east side of the gulf of Bothnia. N. lat. 65° 24'. E. long. 24° 14'.

ULKOKALLA, a small island on the east side of the gulf of Bothnia. N. lat. 64° 22'. E. long. 23° 31'.

ULLA, a river of Spain, which runs into the Atlantic, N. lat. 42° 40'. W. long. 8° 25'.

ULLAGE, in *Commerce*, a term denoting what a cask of liquor wants of being full.

ULLAPOOL, in *Geography*, a sea-port town of Scotland, in the county of Ross, situated at the mouth of a river which runs into Loch Broom; it was first founded in 1788, and is advantageously situated for fishing or commerce. The roadstead is safe and convenient for any number of vessels; and there is a good quay where goods may be loaded or unloaded with the greatest ease. N. lat. 57° 52'. W. long. 5° 1'.

ULLARED, a town of Sweden, in Halland; 30 miles N. of Halmstad.

ULLAVA, a town of Sweden, in the government of Wafa; 32 miles N. of Jacobstadt.

ULLERSDORF, a town of Silesia, in the principality of Neisse; 22 miles N.N.E. of Otmuchau.

ULLERUD, a town of Sweden, in the province of Warmeland; 12 miles N. of Carlstadt.

ULLESWATER, a lake of England, situated partly in the county of Westmoreland, and partly in Cumberland, whose waters run into the Eden, by the river Eimot, 3 miles S. of Penrith.

ULLO, a small island in the North sea, near the coast of Lapland. N. lat. $69^{\circ} 32'$.

ULLOA, ANTONIO DI, in *Biography*, a celebrated naval officer of Spain, was born at Seville in the year 1716, and so distinguished by talents and knowledge, that at the age of eighteen years he was appointed to accompany his friend Don George Juan to South America, to co-operate with the academicians Condamine, Bouguer, and Godin, in measuring a degree of the meridian. On the 26th of May, 1735, he sailed for Peru, and remained at Quito till the measurement was completed on the 12th of May, 1744. On his return home in a French ship he was captured, in August 1745, by two English men of war, and from Louisburg, in the island of Cape Breton, whither he was carried, he proceeded to London, where he was kindly received, particularly by Martin Folkes, esq. president of the Royal Society, of which he was admitted a member in December 1746. After his arrival in Spain, he and his friend Don Juan published an account of the voyage to America, in five small folio volumes, entitled "Relacion historica del Viage de Orden de S. Mag. para medir algunos Grados de Meridiano;" Mad. 1748. Translations of this work were printed, one in German, at Leipzig, and one in English, at London, in 2 vols. 8vo. 1758. Another in French, entitled "Voyage historique de l'Amerique Meridionale," Amst. 1757, 2 vols. 4to. is considered as the most complete, as the author approved the undertaking. His next object was to collect information with regard to the state of the arts and sciences, &c. in various parts of Europe, and with this view he made a tour, under the appointment of Ferdinand VI. through England, France, Holland, and various districts of Germany; and the result of this tour was that many young Spaniards were sent at the public expence to France, Holland, Geneva, and Italy, to acquire a knowledge of medicine, surgery, engraving, watch-making, and various other arts in which the Spaniards were at that time very deficient. Ulloa was also active in promoting the royal woollen manufactures, and in organizing the colleges of history and surgery; he also superintended and completed the canals and basins both at Carthagena and Ferrol. The famous quicksilver mines of Almaden were objects of his peculiar attention, and in 1759 he was deputed to visit those of Guancavellica in Peru. From this service he was removed, in 1766, to the government of Louisiana, which had been ceded to Spain, but the disturbances that ensued obliged him very soon to abandon that station. In 1776 he commanded the galleon fleet that sailed from Cadiz to Mexico, and having been charged with neglect in that service, he was honourably acquitted by a council of war at Cadiz. His second great work, which was a Physical and Historical Account of the Southern and North-eastern Part of America, and which contained a curious dissertation on the peopling of America, was published at Madrid, 4to. in 1772, under the title of "Entretencimientos Physicos-Historicos sobre la America Meridional y Septentrional Oriental;" the dissertation is entitled "Sobre el Modo en qual pasaron los primeros Profeladores." This work was translated into German by professor Diez, and published at Leipzig in 1781, 1782, in 2 vols. 8vo., and was enriched by the valuable additions of professor Schneider. Dr. Robertson estimated them fo

highly, that he procured a translation of them into English for his own use. Another eminent Spaniard related to the subject of this article, DON BERNARD D'ULLOA, published in 1740 an interesting work, entitled "Reftablamiento de las Fabricas y Comercio Maritimo di Efpagna," which was translated into French in 1753, and which contains several extracts from the work of Don Ant. Ulloa. This latter died in the isle de Leon, near Cadiz, on the 5th of July, 1795. The Transactions of the Royal Society contain several papers which he communicated to the Society. He was a knight and commander of the order of St. Jago, lieutenant-general of the royal navy of Spain, and director-general of the Spanish marine. Gen. Biog.

ULM, in *Geography*, an imperial city of Germany, in the circle of Swabia, situated on the Danube. This city is well fortified; and the magistracy and principal part of the inhabitants are Lutherans. The cathedral is one of the largest, and with respect to its Gothic tower, is esteemed one of the loftiest in Germany. N. lat. $48^{\circ} 24'$. E. long. $9^{\circ} 59'$.

ULMA, a town of Portugal, in Estremadura; 11 miles E. of Santarem.

ULMARIA, in *Botany*, so called, as Caspar Bauhin and all following writers inform us, from the shape of the leaves, though we confess ourselves unable to discover any striking resemblance therein to any kind of elm. See SPINÆA, n. 21.

ULMEN, or *Thal Ulmen*, in *Geography*, a town of France, in the department of the Sarre; 6 miles W. of Kayser's Esh.

ULMESFELD, a town of Austria; 18 miles E. of Steyr.

ULMI, in *Ancient Geography*, a town of Pannonia. Anton. Itin.

ULMIN, in *Chemistry*, a substance obtained from the elm-tree (*ulmus*), first made known by the celebrated Klaproth, and ranked by Dr. Thomson, in his "System of Chemistry," (vol. iv. p. 69. 4th ed.) as a distinct vegetable principle, on account of its peculiar and extraordinary qualities. This very intelligent chemist observes, that though in its original state it is easily soluble in water, and wholly insoluble in alcohol and ether, it changes, when nitric or oxymuriatic acid is poured into its solution, into a resinous substance, no longer soluble in water, but soluble in alcohol: and this singular alteration is attributed to its union with a small portion of oxygen, which it has acquired from these acids. It has been the subject of Mr. Smithson's particular examination, and he has observed facts which appear to warrant a different history of its phenomena, and opinion of its nature, from that which has been given of them. The ulmin used in his experiments had been freed from the fragments of bark by solution in water and filtration, and recovered in a dry state by the evaporation of the solution in a water-bath. In lumps, says this ingenious writer, ulmin appears black, but in thin pieces it is transparent, and of a deep red colour. In a dilute state, solution of ulmin is yellow; in a concentrated one, dark red, and not unlike blood. When this solution dries, the ulmin separates into long narrow strips, arranged in rays towards the centre, which curl up, and detach themselves from the vessel, and the fluid part seems to draw together and become protuberant. The solution feebly and slowly restores the colour of turnsole paper reddened by an acid.

If dilute nitric acid be poured into a solution of ulmin, a copious precipitate is immediately formed. When the mixture is thrown on a filter, the matter supposed to be a resin remained on the paper, and a clear yellow liquor passed

through it; which yellow solution, on evaporation, produced a number of prismatic crystals, having the appearance of nitrate of potash; and these were tinged yellow by some of the resin. The mixture, heated in a gold dish, deflagrated with violence, and left a large quantity of fixed alkali. Similar results were obtained by means of dilute muriatic acid. The filtered liquor afforded saline matter, which being freed by ignition from a portion of dissolved resin, shot into pure white cubes of muriate of potash. A similar precipitation was effected by sulphuric, phosphoric, oxalic, tartaric, and citric acids, in solution of ulmin. Distilled vinegar produced no turbidness, but the mixture, exhaled to dryness, at a gentle heat, was found to be again wholly soluble in water; and when it boiled, some decomposition occurred. On adding muriatic acid to a mixture of solution of ulmin and distilled vinegar, a precipitate was produced, as in an aqueous solution. The nitric and muriatic acids received from the ulmin a small quantity of lime and iron, and, as was supposed, of magnesia; which were conceived to be foreign admixtures. Some experiments were made in order to detect the quantity of potash in ulmin. When four grains of this substance were decomposed by nitric acid, 2.4 grains of resin-like matter were the result; and when the nitrate of potash obtained was heated to deflagration, in a platina crucible to free it from resin, the alkali produced was supersaturated with nitric acid, dried, and slightly fused; it then weighed 1.2 grain: so that if we admit $\frac{1}{2}$ of nitrate of potash to be alkali, this will denote $\frac{1}{10}$ of potash in ulmin. By decomposing five grains of ulmin by muriatic acid, the resinous matter weighed 3.3 grains; and the muriate of potash, ignited, separated from the charcoal, dried, and again made red-hot, weighed 1.4 grain. Supposing $\frac{1}{2}$ of muriate of potash to be alkali, we may infer that the ulmin had $\frac{1}{10}$. Two grains of ulmin were made red-hot in a gold crucible; and it then weighed only 1.05 grain. The flakes, retaining their form, appear to have acquired the blue and yellow colours of heated steel, with the metallic aspect and lustre; but the metallic appearance was immediately destroyed by water. Muriatic acid poured on, caused a strong effervescence, and formed muriate of potash, which freed from charcoal, and made red-hot, weighed 0.6 grain, corresponding to $\frac{1}{10}$ of potash in ulmin. From these experiments our author infers, that the quantity of potash in ulmin is about $\frac{1}{10}$.

The substance separated from ulmin by acids has the following qualities: it is glossy, and appears resinous: in lumps it appears black, in minute fragments transparent, and of a garnet-red colour: it burns with flame, and is reduced to white ashes: alcohol dissolves it in a very small quantity, which is also the case with water: acids cause a precipitate on the solution, though the resin-like matter appears neither to contain any alkali, nor to retain any of the acid: its watery solution seems to reddens turnsole paper: neither ammonia nor carbonate of soda promotes its solution in cold water: on adding a small quantity of potash to water, it dissolves immediately and abundantly. Upon the whole, it appears that ulmin is not a simple vegetable principle of anomalous qualities, but a combination with potash of a red, or more properly, a high yellow matter, which, if not of a peculiar genus, seems rather more related to the extractives than to the resins.

Our author made several experiments with a black shining substance, appearing like ulmin, collected from an elm-tree in Kensington gardens; and found that it differs in a variety of respects from that which he obtained from Palermo. The English ulmin had an excess of alkali, which he supposes to be owing to the tree from which it was collected having been affected with the disease which produces the

alkaline ulcer to which the elm is subject. Ulmin, he says, appears to be the product of old trees. The uses to which it is applicable, as an astringent, are still to be investigated. See Phil. Transf. for 1813, pt. 1.

ULMUS, in Botany, an old Latin name, generally left by etymologists unexplained, but deduced by De Theis from Elm, its synonym in Anglo-Saxon, as well as in all the dialects of the Celtic tongue; and which has remained unchanged in English to this day.—Linn. Gen. 123. Schreb. 173. Willd. Sp. Pl. v. 1. 1324. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 281. Prodr. Fl. Græc. Sibth. v. 1. 171. Ait. Hort. Kew. v. 2. 107. Pursh 199. Juss. 408. Tourn. t. 372. Lamarck Dict. v. 4. 609. Illustr. t. 185. Gært. t. 49.—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Scabridæ*, Linn. *Amentacæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, corrugated; its limb four or five-cleft, erect, internally coloured, permanent. Cor. none. Stam. Filaments four or five, awl-shaped, twice the length of the calyx; anthers erect, short, with four furrows. Pist. Germen orbicular, compressed, erect, somewhat stalked; styles two, shorter than the stamens, reflexed; stigmas stony. Peric. Capsule membranous, large, oval, compressed, winged, with the dilated styles, of one cell, not bursting. Seed solitary, roundish, slightly compressed.

Eff. Ch. Calyx four or five-cleft, inferior, permanent. Corolla none. Capsule membranous, compressed, nearly flat, with one seed.

Obs. The flowers in some species have only four segments and four stamens, in some occasionally six. Schkuhr is said to have met with eight stamens, which Willdenow confirms. The pericarp was called by Linnæus sometimes a dry drupa, sometimes a dry berry. Schreber adopted the latter. In more modern language it is a SAMARA; see that article.

The species of *Ulmus* have not been well defined. Linnæus confounded all the European ones together, under the name of *U. campestris*. The writer of this has distinguished five British species in his Engl. Bot., and Compendium, ed. 2. More may perhaps be made out hereafter. Characters formerly supposed accidental, such as the number of stamens and segments of the flower, have been found permanently to indicate a specific difference; and the different value of the several species, for ornamental planting, or for timber, renders their discrimination important. They are generally trees of lofty stature, with hard and tough wood; stalked, alternate, roughish leaves; and numerous, tufted, small, reddish or purplish, very early flowers, fading long before the foliage expands. The capsules are deciduous, copious, of a light chaffy aspect, scarcely ever perfecting their seed, at least in England.

1. *U. campestris*. Common Elm. Linn. Sp. Pl. 327. Bauh. Pin. 426? Fl. Brit. n. 1, a. Compend. 42. Engl. Bot. t. 1886, excluding the reference to Willdenow and Ehrhart. (U. minor, folio angusto fæbræ; Goodyer in Ger. Em. 1480. Raii Syn. 469. U. suberosa 2; Dryandr. in Ait. n. 2.)—Leaves doubly serrated, rough, unequal at the base. Flowers nearly sessile, four-cleft, with four stamens. Fruit oblong, naked.—Common in scattered woods and hedges, chiefly in the southern part of England, flowering in April, scattering its unprolific seeds in June. The tree attains a considerable height before it blossoms, with a rugged crooked trunk and branches, being of slower growth than our other wild species, with a harder, more durable, and consequently more valuable, wood, which is preferred for coffins, as resisting wet for a long while. Leaves on short stalks, ovate, somewhat rhomboid, unequal at the base, doubly

doubly ferrated, rough on both sides; most downy beneath, especially at the axillary glands of their veins: their length is from one to two inches, scarcely more. *Foosfalks* short. *Flowers* from separate, much more early, buds, in numerous, dense, round tufts, almost sessile, with oblong fringed *bracteas*. *Calyx* light red, in four ovate, obtuse, equal, fringed segments. *Stamens* four, opposite to each segment, smooth, with large purple *anthers*. *Stigmas* downy along their upper edge; at length dilated at the other, incurved, and running down into the membranous smooth wings of the *capsule*, whose oblong wedge-like shape essentially distinguishes this species from the next.—Whether this be Schkuhr's *U. tetrandra*, we have no means of knowing. It is certainly very erroneously combined with *suberosa* in Hort. Kew. Linnæus doubtless confounded it with *montana*; but the latter name having been long established, we prefer retaining *campestris* for the present species, authors having made so many mistakes, that no name can be chosen which does more authority or other does not contradict.

2. *U. suberosa*. Cork-barked Elm. Ehrh. Arb. 142. Willd. n. 2. Engl. Bot. t. 2161. Compend. 42. Ait. n. 2, B. (U. campestris B.; Fl. Brit. n. 1. Hudf. 109. U. vulgatissima, folio lato scabro; Goodyer in Ger. Em. 1480. Raii Syn. 468.)—Leaves pointed, doubly and short ferrated, rough, unequal at the base. Flowers on short stalks, four or five-cleft, with four or five stamens. Fruit rounded, deeply cleft, naked. Bark corky.—Found in woods, and about villages, in many parts of Europe. Very common in Suffolk, according to Mr. Borrer, flowering in March. The branches spread widely, and their bark of a year old is covered with a fine dense cork, divided by deep fissures. Leaves larger than in the foregoing, more pointed, as well as more sharply and finely ferrated. Flowers earlier, more hairy, on longer stalks, and often five-cleft; their segments obtuse. Capsule much shorter and nearly orbicular, more deeply cleft than in *montana*, to which species the present seems more akin than to *campestris*. The axillary tufts of hair to the veins beneath, are peculiarly broad in *U. suberosa*.

3. *U. major*. Dutch Elm. Engl. Bot. t. 2542. Compend. 43. (U. hollandicus; Mill. Dict. ed. 8. n. 5. U. major hollandica, angustis et magis acuminatis famaris, folio latissimo scabro; Pluk. Alm. 393.)—Leaves unequal, rather bluntly, ferrated, rough, unequal at the base. Flowers nearly sessile, four-cleft, with four stamens. Fruit obovate, naked, slightly cleft.—Native of Holland, and perhaps of England. We believe it may not be specifically distinct from what was pointed out to us by his grace the duke of Bedford, near Shugborough, Staffordshire, by the name of the Huntingdonshire Elm, but of that we have not seen either flowers or fruit. We originally confounded the *U. major* with *suberosa*, and this may have led to the still greater mistake in Hort. Kew. of uniting our *campestris* to the Dutch Elm, though the wood of the former is mentioned in Engl. Bot. as the most valuable of its genus, while that of the latter is declared by Miller to be "good for nothing." This author says his *U. hollandicus* was brought from Holland in king William's reign, and being recommended for its quick growth, was a fashionable tree for hedges in gardens, but afterwards fell into disuse. We prefer for this species the name of *major*, taken from Plukenet's synonym. It is intermediate between *suberosa* and *montana*, agreeing most with the latter in its broad, bluntly-ferrated rough leaves, and the large obovate fruit, which is much less deeply cleft than in *suberosa*. The branches spread widely, in a drooping manner, and their bark is more corky than even that of the species last mentioned.

4. *U. montana*. Broad-leaved Elm, or Wych Hazel. Bauh. Pin. 427. Camer. Epit. 70. With. 279. Fl. Brit. n. 2. Engl. Bot. t. 1887. (U. campestris; Willd. n. 1. Ait. n. 1. Woodv. Med. Bot. t. 197. Sm. Prodr. Fl. Græc. Sibth. n. 599? Fl. Dan. t. 632. U. nuda; Ehrh. Arb. n. 62. U. folio latissimo scabro; Goodyer in Ger. Em. 1481.)—Leaves doubly ferrated, pointed, rough, unequal at the base. Flowers on short stalks, five or six-cleft, with five or six stamens. Fruit rounded, naked, scarcely cloven.—This appears to be one of the most common species throughout Europe, from the south of Sweden. It is frequent in woods and hedges in Britain, flowering at the end of March, or early in April, and ripening feed, more perfectly than our first species, in June. The tree is large and spreading, with drooping or pendulous branches. The wood fetches about half the price of our Norfolk *campestris*. The bark is not corky. Leaves much larger than in *campestris*, and somewhat less rough, with longer points. Flowers larger, on rather longer stalks, their segments acute, from five to six, or even seven, with the same number of stamens. Fruit larger, more orbicular, slightly obovate, smooth at the edge, and very slightly cloven at the end.—Since the species of Elms have been more accurately investigated, botanists have differed about the names of this and our first described. That the present is *U. montana* of Bauhin, we well figured by Camerarius, and distinguished from what those authors term *campestris*, there can be no doubt. The latter is the *Ulmus* figured by Matthioli, Dodonæus, Lobel (in his Icones, v. 2. 189.), with a sort of gall, but no fructification, and we presume it to be either our *campestris* or *suberosa*, but most probably the former. However this part of the question may be decided, we conceive there can be no doubt as to the *montana*, which can never be justly taken for the true *campestris*, though confounded by Linnæus with other species under that name, and though it may be the Swedish plant. Both perhaps are indigenous in Greece, but we have no specimens from thence.

5. *U. glabra*. Smooth-leaved, or Wych Elm. Mill. Dict. ed. 8. n. 4. Cullum Fl. Angl. 97, unpublished. Sm. Compend. 43. Engl. Bot. t. 2248. (U. montana B.; Fl. Brit. n. 2. U. folio glabro; Ger. Em. 1481. Raii Syn. 469.)—Leaves doubly ferrated, smooth, unequal at the base. Flowers nearly sessile, five-cleft, with five stamens. Fruit obovate, naked, deeply cloven.—Native of England. Observed by Mr. Edward Forster to be the most abundant species of this genus in some parts of Essex, flowering in March. We have arranged Gerard's synonyms of this and the first two species, under the auspices of that accurate British botanist. The present is an elegant tree, with spreading drooping branches, whose bark is smooth and blackish. Leaves more oblong and rigid than those of *suberosa*, very unequal at the base; quite smooth to the touch on the upper side, and nearly so beneath, except the general downiness of the rib and veins. Flowers fringed, obtuse, with long stamens. Fruit small, cloven down to the feed. Goodyer in Gerard's Herbal says the wood is preferred for the naves of cart-wheels. If so, it perhaps equals our *campestris* in quality.

6. *U. effusa*. Loose-flowering Elm. Willd. n. 3, with many wrong synonyms. (U. ciliata; Ehrh. Arb. 72. U. pedunculata; Lamarck n. 2. U. folio latissimo, floribus in petiolis (pedunculis) pendentibus; Buxb. Halenf. 340. U. longioribus florum et feminum petiolis; Rupp. Jen. ed. Haler. 330.)—Leaves doubly ferrated, smooth, unequal at the base. Flowers octandrous, on drooping stalks. Fruit elliptical, cloven, densely fringed.—Native of Germany. Buxbaum speaks of it as growing about vil-
lages,

lages, affording a grateful shade. Ruppian gathered it near Leipzig, and Ehrhart at Hanover. We know nothing of this species in England. Its leaves are larger than the last, and not less unequal at the base; very smooth, with downy ribs and footstalks. Flower-stalks about an inch long, smooth, loosely pendulous. Calyx probably answering in its segments to the number of the stamens, which are said to be eight, but we do not always find the calyx more than five or six-cleft, with blunt shallow divisions. The fruit is elliptical, acute at each end, larger than the last, cloven, but not quite down to the seed; its margin densely woolly; by which last mark, and the long drooping flower-stalks, this species is very clearly distinguished. We cannot concur with Willdenow in thinking this *U. glabra* of Miller, or *montana* of Bauhin; it certainly does not answer to the cut of *montana* in Camerarius.

7. *U. americana*. American Elm. Linn. Sp. Pl. 327. Willd. n. 4. Ait. n. 3. Pursh n. 1.—Leaves acutely serrated, very rough, somewhat unequal at the base. Flowers on longish stalks. Fruit ovate, deeply cloven, densely fringed. Common in all low lands and woods, from New England to Carolina, flowering in April, and known by the name of White Elm. Pursh. There is a variety with red branches, another with white, and a third more pendulous, whose leaves are said to be smoother. In our specimens the leaves are large, long-pointed, unequally serrated, more or less rough, like a file, on short downy stalks; their ribs numerous, straight and parallel; their under side downy and hoary when young. *Stipulas* long, strap-shaped, reddish, deciduous, smooth. *Stamens* apparently more than five. *Fruit* reticulated, as densely fringed as the last, and more deeply cloven.

8. *U. nemoralis*. Hornbeam-leaved Elm. River Elm. Ait. n. 4. Willd. n. 5. Pursh n. 2. (*U. polyama*; Lamarc n. 5. *Rhamnus carpinifolius*; Pallas Ross. v. 1. part 2. 24. t. 60. *Planera Gmelini*; Michaux Boreal-Amer. v. 2. 248. *P. aquatica*; Willd. Sp. Pl. v. 4. 967. Pursh 115. *P. Richardi*; Michaux *ibid.*)—Leaves ovate, oblong, equally serrated, nearly smooth; scarcely unequal at the base; paler beneath. Fruit inflated, oblique.—Native of the banks of rivers in North America, flowering in April and May. Pallas found it in Siberia, and was justly doubtful of its genus. This tree is said to have been cultivated by the late Mr. Gordon, in 1760. It flowered in the royal French garden at Trianon, for the first time, in April 1779. The synonyms appear very paradoxical, and we hardly feel justified in supposing that Michaux as well as Pursh, have each described the plant twice over. Yet we never could meet with more than one species answerable to the above names. The tree is tall and handsome, with a white brittle wood. Leaves an inch and a half long, bright green, with large, broad, blunt, equal serratures. Foot-stalks downy, very short. Flowers nearly sessile, in lateral or axillary tufts, some of them occasionally male or female only. Calyx bell-shaped, usually five-cleft, with five stamens. Capsule ovate, oblique, gibbous, reticulated, bordered, not winged, very unlike an *Ulmus*, yet surely less like a *Rhamnus*, or a *Celtis*, to both of which it has been compared. Not having seen the fructification alive, to trace its progress, we must leave the genus of this remarkable tree in the uncertainty in which we find it.

9. *U. Abelicea*. Sandal-wood Elm. Sm. Prodr. Fl. Græc. Sibth. n. 600. (*Abelicea cretica*; P. Bald. 112, with a figure. Sm. Tr. of Linn. Soc. v. 9. 126. Bauh. Hist. v. 1. 490. *Pseudofantulum creticum*; Bauh. Pin. 393.)—Leaves elliptical, equally serrated, scarcely unequal at the base; downy and hoary beneath. Fruit inflated, oblique.—

Native of Crete, from whence its wood is said to have been formerly transported to Italy, as a sort of Sandal-wood. Honorio Belli communicated a figure of the branches and leaves to Pona, and we have the fruit from Dr. Sibthorp, but no specimen or account of the flowers. This species differs from the last chiefly in the hoary pubescence of its leaves on their under side. The fruit is very similar to that, but more compressed, and cloven like an Elm at the summit. The wood is harder, and denser.

10. *U. fulva*. Red, or Slippery, Elm. Michaux Boreal-Amer. v. 1. 172. Pursh n. 3.—Branches rough. Leaves ovate-oblong, pointed, unequally serrated, very rough, downy on both sides; scarcely unequal at the base. Buds densely woolly. Flowers sessile.—On mountains, from Canada to Pennsylvania, flowering in May. The viscid inner bark is used by the natives as a healing application for sores. Pursh. Leaves variable in shape and serratures, but more downy than those of other American Elms. Stamens from five to seven. *Stigmas* purplish. Young fruit downy on both sides. Michaux.

11. *U. alata*. Whaloo, or Cork-winged Elm. Michaux Boreal-Amer. v. 1. 173. Pursh n. 4.—Branches winged with cork at each side. Leaves oblong-oval, tapering to a point; nearly equal at the base. Fruit downy, densely fringed.—In sandy low woods of Virginia and Carolina, flowering in April. Pursh. A middle-sized tree, with leaves like horn-beam, and nearly the fructification of *U. americana*. Michaux. This is the *U. pumila* of Walter, Fl. Carolin. 111.

12. *U. pumila*. Dwarf Elm. Linn. Sp. Pl. 327. Willd. n. 6. Ait. n. 5. Pall. Ross. v. 1. part 1. 76. t. 48. (*U. humilis*; Amm. Ruth. 180.)—Leaves elliptic-lanceolate, equally serrated, very smooth; nearly equal at the base. Fruit roundish-ovate, cloven, smooth.—Native of Siberia and China. Hardy in England. A bushy shrub, with shining, veiny, neatly serrated leaves, smaller than in any of the former, except perhaps *U. Abelicea*. Flowers stalked, red.

13. *U. integrifolia*. Entire-leaved Elm. Roxb. Coromand. v. 1. 56. t. 78. Willd. n. 7.—Leaves entire. Fruit orbicular, emarginate.—Native of the Circar mountains of the East Indies, flowering during the cold season, and casting its leaves after the rainy season, but young ones come out in March. This is a large timber tree, whose wood serves for a variety of uses. The ovate, acute, entire leaves are near three inches long. Flowers small, sessile, deeply five-cleft; some of them male, with eight stamens; the rest with five. Fruit somewhat racemose, veiny, near an inch broad.

ULMUS, in Gardening, contains plants of the deciduous timber-tree and ornamental hedge-kind, and others, among which the species cultivated are, the common elm (*U. campestris*); the Dutch elm (*U. subserotina*); the broad-leaved elm, or Wych hazel (*U. montana*); the American elm (*U. americana*); the hornbeam-leaved elm (*U. nemoralis*); and the dwarf elm (*U. pumila*).

The first sort grows to a great high tree; the bark of which in the young trees and the boughs of the older ones is smooth and very tough, and will strip or peel from the wood a great length without breaking, being somewhat of an astringent quality, and probably capable of being employed in the business of tanning leather.

There is a variety called the narrow-leaved elm, which is like the other, but much less and lower: the leaves are usually about two inches and a half long, and an inch or an inch and quarter broad; indented about the edges, and having one side longer than the other, and being harsh on both sides.

sides like the other. It is called in the nurseries the English elm. It is stated by Dr. (now Sir James) Smith, as the opinion of Mr. Crowe, that this is the origin of all the cultivated varieties of the elm: and Miller asserts that there are several other varieties, but not worth noticing; among these is that with variegated or blotched leaves. Gilpin also makes mention of the weeping elm.

However, the varieties commonly noticed are, the common small-leaved English elm; the larger-rough-leaved English elm; the small-leaved Cornish elm; the smooth-barked or Wych elm; the narrow-leaved Wych or Scotch elm; the broad-leaved Wych elm; the smooth-leaved Wych elm; the rough-leaved Dutch elm, with large leaves; the yellow or golden-striped leaved elm; the silver-striped elm; and the silver-dusted elm.

The second species is chiefly remarkable for its quick growth and fungous rough bark. It is a native of Europe, and is often called the cork-barked or the Dutch elm, as it was introduced from Holland at the beginning of King William's reign: the wood is of very inferior quality.

The third fort has the bark of the branchlets smooth and even: the bark on the outside in this is blacker than in that of the first kind, and is also very tough; so that when there is plenty of sap, it will strip or peel from the wood of the boughs from one end to the other, a dozen feet in length, or more, without breaking: the timber is in colour nearly like the first: it is not so firm or strong for naves of wheels, but will more easily cleave: the branches or young boughs are grosser and bigger, and spread themselves broader, and hang more downwards; the leaves being much broader and longer than in any of the other kinds of elm.

The variety of it termed the smooth-leaved elm is in bigness and height like the first, but the boughs grow as those of the Wych hazel, hanging more downwards than those of the common elm: the bark is blacker than that of the first kind, but will also peel from the boughs: the flowers and seeds are like those of the first; the leaves also, in form, are like that, but smooth in handling on both sides: the wood is said to be more desired for naves of cart-wheels than that of the first fort.

The fourth kind has three varieties, according to the Kew catalogue: the first is the red, or Canada elm, which grows in its native country to a vast size; the leaves are ovate, wrinkled, and scabrous, broader than those of our Dutch or Wych elms, smoother, and of a much more lively green; the branches are red, whence it has the name of red elm: It grows very fast in this climate.

In the second variety, or the white elm, which is so named from the whiteness of the branches, the leaves are scabrous, but oblong; and, according to Gronovius, having narrower leaves than the red, and the trunk set at intervals with twigs closely clustered together below the boughs. Boats are said to be made from the bark of it.

The third, or the drooping or weeping variety of this sort of elm, is distinguished by its oblong smoothish leaves, and its pendent branches. Martyn observes that the American fort differs from the European elm, in having the leaves equally, or, as Gronovius expresses it, quite simply or singly serrate.

The fifth fort, or the hornbeam-leaved elm, is a North American sort of elm.

The last fort has the branches more slender than in the other kinds, divaricating, and of a greyish ash-colour: the wood is very hard and tough, grey, remarkably waved with transverse lines of a deeper colour, larger fibred, and when

exposed to the air becomes yellower than oak, and is preferable to it: the ashes exported from Riga, under the name of waidafche, are made entirely from the wood of this and other elms, burnt in brick-furnaces: the root is beautifully variegated, and fit for the use of the turner, &c.: the bark does not readily peel off, and therefore is not used for making ropes. It is said, in Southern Russia, to often contend with the oak in stature.

There is a variety with both young and old branches winged and rendered irregular with compressed fungous excrescences of the bark variously interrupted; and in mountain rocks there is a variety which has shorter thicker branches, winged with fungous excrescences of the bark.

Method of Culture.—In these trees it is effected in different ways; as by feed, suckers, layers, and grafting. The feed, when perfectly ripened, may be collected and sown in the autumn or spring, in four-foot wide beds, half an inch deep; that which is kept to the spring being preferred by drying it well, out of the sun, then putting it up close till towards autumn, when it should be mixed with sand, to preserve it more effectually through the winter; when about the middle of February it should be sown as above. The young plants should afterwards be carefully shaded, watered, and kept clear from weeds. They should have one or two years growth in the feed-bed, and then be planted out in nursery lines, in rows two or three feet asunder, and the plants fifteen or eighteen inches distant in each row, giving them the common nursery care, and training them for the purposes intended. If for standards, for timber, or ornamental plantations, they should be trained each to a single stem, and as they advance in height, clearing the stems from all lateral shoots, leaving only the very small twigs, just to draw and detain the sap, for the better increase of the stem; suffering the leading top-shoot to remain entire, as also the principal branches of the head; but those designed for hedge-work, &c. should be let branch out all the way, and become feathered to the bottom, or as low as may be requisite for the purposes intended, only trimming them occasionally with the knife or garden-shears, to give them the intended form. When the trees have had four or five years' growth, and are from four or five, to six, eight, or ten feet high, they are fit for planting out where they are to remain.

The feed method of raising the plants is the best practised with the Wych elm sorts, as they ripen their feeds better than the other kinds, during the spring and summer months; but when it can be obtained of a good quality from the other sorts, it may be used in the same way with equal success.

The suckers which most of the sorts send up from the roots, but especially the English and Dutch sorts, should be taken up carefully with root-fibres, in autumn, winter, or spring, trimming them for planting by cutting them down at top to six or eight inches, placing them in small trenches or drills five or six inches deep, one row in each, half a foot apart, and the drills about half a yard asunder; giving waterings in spring and summer; letting them remain two years, to form good roots, then planting them in wide nursery-rows, and managing them as directed for the seedlings.

The layers of all the sorts may easily be made by previously preparing a quantity of stools to produce shoots, situated near the ground: the proper season for laying them down is in the autumn, winter, or early in the spring, performing it by slit-laying; and as soon as the whole are laid and moulded in, every layer should be lopped with a knife,

down

down to one eye above the ground. In this way they readily take root in the spring and summer following, shooting at top sometimes two or three feet long by the autumn, when they should be detached from the stools, and be planted in nursery-rows, two feet or a yard asunder, and half a yard distant in the rows: when they begin to shoot, they should be trained with one leading shoot only, as the feeding elms, managing them in the same manner.

In the grafting method, all the varieties of elms may be increased and continued distinct, which should be done upon stocks of the Wych elm, raised from seed, suckers, or layers, though the feeding stocks are preferable. For which purpose, some rows of Wych elms should be allotted for stocks, which, after having two years' growth in the nursery lines, will be fit to graft on: when about the beginning of February, the cuttings of the young moderate shoots of the best English elm, or any other variety, should be inserted into the stocks by the method of whip-grafting, putting them in as low as possible, for which the earth should be removed away a little down to each root, then cutting off the head of the stock within two or three inches of the bottom; the grafts be inserted one in each stock, as above, binding them close, and claying them well; then drawing the earth up about and over the clay, the more effectually to secure it from falling off by the effects of the frost or other causes. When they begin to shoot, they should be trained with only one leading shoot, so that if they fork at top into two or more, the weakest should be taken off, leaving the best shoot for the leader, displacing all large side-shoots from the stems, and letting the tops or leading shoots remain always entire, as also the general upper branches of the heads.

It has been observed, that as the common elm produces no seeds in this country, it is best propagated by suckers, or cultivated by grafting. In the first case, when the old tree is cut down, or the roots wounded by any accident, young shoots are thrown out in great abundance. The raising of elms by layers is advised by some as better than by suckers, which it is said are more liable to breed suckers, and of course to injure the trees, and encumber the ground around them. Such statements are not, however, exactly true, as there are no better trees than those raised by suckers, when it is properly performed, and they are placed for two or three years in a good nursery-ground. Young trees growing as suckers, without transplanting, certainly breed and send up new ones, as they spring up from long horizontal roots, which being bruised by accident, or otherwise wounded, will, in all such places, throw up new plants; but if the young trees be cut and separated from such roots, and then planted out in good soils, they speedily become flourishing, and grow exactly in the same manner the larger trees grow.

On the examination of these roots, no deficiency will be found, it is asserted; but the case is widely different if the young trees remain attached to the parent roots, the decay in the stumps of which communicates with the young trees; and this is the reason, it is supposed, why so much of the hedge-row elm-timber in some places falls in an unsound state. Although apparently flourishing in the lower parts of the stocks, they all grow from suckers, which convey the rot from the parent to the offspring; and it is a rare thing, in some districts, to find two sound elms together that have sprung up spontaneously; though it is equally uncommon to find a planted tree unsound at the bottom. The plants, in all exposed situations, should be put down small and flourishing, being free from any sort of former check, as such plants answer the best in all cases.

VOL. XXXVII.

In order to prevent the above danger, the young plants should be early severed from the parent roots or trees; they will then almost immediately send down perpendicular roots into the soil, take firm hold of the ground, and become independent trees.

As the stumps of old trees decay in a few years, they become a sort of bowls filled with rain-water, which not only rots these stumps, and penetrates and destroys the interior of those roots that formerly nourished the trees, but which actually ascends the stems of the young elm-plants, that spring from such roots. It is contended, that in spite of luxuriant foliage and a clean bark, it will be found on the inspection of any plant so produced, that the mischief has already begun, which grows with its growth, and strengthens with its strength, until the tree becomes fit for felling. Specimens of suckers from decaying stumps, not an inch in diameter, have been met with and preserved, in which the heart was already injured; and this will continue, it is said, to increase, until the channel of communication is cut off. After separation the evil does not increase, as it is found, on the examination of suckers of this description, planted in a nursery, that they bid fair to make sound trees. The butt of a planted elm has never been seen to be unsound, unless from great age, or external injuries: it is consequently advised to plant, in the first place, trees of this sort from the nursery, when of proper size, and to constantly supply the nursery with suckers from the hedge-rows, as it may be done with little trouble and expense; and in the second place, to cut off the connection and communication of young promising trees with their parent roots or stools early, opening the hedge-rows at three or four feet distant from the stems or stumps; as by these means sound trees of this sort may be easily raised and provided for different purposes.

These trees are highly useful, both for timber and in the way of ornament, when planted out on large open spaces, or otherwise; likewise for being clipped, or cut into particular forms, and as forming hedges in various situations. These sorts of trees, in their larger or smaller growths, are used for supplying those and other intentions and purposes in many different methods. All the sorts and varieties of the elm are of hardy growth, and will succeed perfectly well in any common soil and exposure, but delight most in a rich deep earth of a stiffish loamy nature, which is rather inclined to moisture, the English sorts having the best situations and soil, and the Wych and Dutch kinds those which are inferior in these respects.

For most purposes, the plants of these sorts of trees should be planted out finally while they are in their young states of growth, as from four or five, to six, eight, or ten feet in height, in which they commonly take root, grow, and establish themselves the most freely, expeditiously, and in the fullest manner.

It may however be particularly noticed, that elms will bear removing when large, better than most other sorts of trees, as they are more furnished with superficial horizontal root-fibres. Thus, trees of fifteen or twenty feet in height may often be taken up with a large spread of roots and balls of earth about them, and be safely removed by being replanted in spacious pits or holes dug for them, where they readily strike new root, and grow strongly. But the removing and transplanting of these large trees is not by any means a proper or desirable practice for making plantations, or other sorts of field planting, but merely occasionally for particular uses and purposes, where shade, shelter, or a blind to some part is wanted.

The most proper and suitable time for planting out and removing all such plants and trees, is from the beginning of autumn

autumn until the early part of the following spring. See PLANTATION and PLANTING.

All these sorts of trees, but especially the common English, Cornish and Wych kinds and varieties, are highly proper for different denominations of forest and timber plantations in mixture with other sorts of trees, or as an ulmarium, and in groups, ranges, hedge-rows, or clumps, on the borders, sides, boundaries and corners of fields, large parks, avenues, pleasure-grounds, or other out-grounds, as growing freely, and forming large-sized valuable timber, for a number of strong uses, such as most kinds of wheel-wright work, pipes for conducting water under the ground, water-pumps, and various other under-water and durable purposes. Also in garden plantations, thickets, and other ways, for variety, diversity, ornament, shade and shelter, near walks and other places, to break and keep off the violence of storms and tempestuous blasts, letting them in all such cases assume their own natural growth, only trimming away the strong irregular lateral shoots and low straggling branches on the stems and in the leads. They are likewise admirable for training, by means of which beautiful lofty hedges, quite close from the top to the bottom, from the height of ten to more than forty feet, were formerly made and much valued on the confines of gardens and in other places, for screens and in other designs. They were frequently too trained as arches, porticoes, pilasters, galleries, and other forms, producing much effect in the ancient mode and style of ornamental gardening, but which at present is almost wholly exploded. The English and Cornish sorts are here by far the best, in consequence of their more thick and regularly branching growth, as well as their more close foliage.

ULNA, in *Anatomy*, one of the bones of the fore-arm. See EXTREMITIES.

ULNA, *Fracture and Luxation of the*, in *Surgery*. See FRACTURE and LUXATION.

ULNA, an ell in measure. See ELL and MEASURE.

ULNA *Ferrea*, denotes the standard iron ell, kept in the Exchequer.

ULNAGE. See ALNAGE.

ULNAR *Artery and Nerve*, in *Anatomy*. See ARTERY and NERVE.

ULNARIS, a name given to some muscles of the fore-arm.

ULNARIS *Gracilis*, the palmaris longus. See PALMARIS and FASCIA.

ULNARIS *Externus*,

ULNARIS *Internus*

ULNARIS, *Extensor Carpi*,

ULNARIS *Flexor Carpi*,

} Names given to certain muscles of the fore-arm. See CARPI.

ULOPHONUS, in *Botany*, is a name given by the ancients to a poisonous plant, since called the *chameleon thistle*, and even at that time known to Dioscorides, Galen, and others, under the name of the *black chameleon thistle*. See IXIAS.

ULOTA, a new genus of Mosses, established by the late Dr. Mohr, of Kiel, in Sims and König's *Annals of Botany*, v. 2. 540. t. 14. f. 3, 4 and 6, and named from *ωλος*, curled, in allusion to the curling of the leaves by drying. This character distinguishes the genus in question, as to habit, from *ORTHOTRICHUM*; see that article. The essential generic difference between these two genera consists in the structure of the *Calyptra*, or Veil. In *Orthotrichum*, that part is marked with broad furrows, separated by narrow ridges, which are cloven at the bottom: in *Ulotia*, the veil is furnished with broad convex ridges, separated by narrow furrows, which furrows are cloven, very deeply, at the bottom.

The author of this genus has wisely kept in view the Linnean maxim, *genus dabit characterem, non character genus*; but the meaning of this maxim he has totally misrepresented in a note, *Ann. of Bot.* v. 2. 533, as follows. "In the series of natural beings the genera are altogether natural, being as given by nature herself; in the system they must be artificially determined, but when we shall become true observers, we shall find means to make our genera natural also." We presume this note was written by Dr. Mohr, and not by his editor. If it be correctly translated, we are obliged to observe that the author has explained away the meaning of this great principle, on which the science of generic distinction absolutely depends. Linneus meant that an idea of each genus is to be conceived in the mind, from an enlarged contemplation of the natural habit, and predominant technical characters of the fructification, all considered together, in a number of plants nearly related to each other. As the natural genera thus present themselves to the mind of a learned observer, he will then be able to seize one or more essential characters of each, to discriminate them from each other. Genera thus established are independent of all system, whether natural or artificial. This is making the *genus give the character*. If we make the *character give the genus*, we might in many instances find as many genera as there are species. Dr. Mohr has followed the first rule in the formation of his genus *Ulotia*, of which he says he has, besides species already known, about a dozen exotic ones, mostly nondescript; all are characterized at first sight by their crisped foliage, and marked by the above character in the *calyptra*. But when Dr. Mohr, in p. 541, 542, of the same volume, expresses doubts of the propriety of having recourse to the form and structure of the capsules of mosses, in forming their generic characters, "because it will oblige us to divide *Polytrichum* and other genera into several new ones, and to make more such unnatural alterations," he forgets that this would be to make the *character give the genus*, the very principle which is prohibited by the Linnean rule. It is on this rule that we find ourselves perpetually obliged to insist. Botanists of the French school seem, by a sort of fatality, unable to comprehend it, or at least incompetent to follow it. Some have occasionally undertaken to demonstrate its "absolute falsehood;" but they were not such as could handle mathematical tools. No botanist can establish permanent genera, but by chance, without making this rule his only guide.

Dr. Mohr has not defined the species of his *Ulotia*, which he says are chiefly nondescript. We are therefore unable to give more than two or three examples of the genus. Its class and order are *Cryptogamia Musci*. Nat. Ord. *Musci*.

Ess. Ch. Capsule oblong. Outer fringe of sixteen teeth; inner variable, or wanting. Veil with convex ribs; the intermediate furrows cloven at the base.

U. *crispa*. Common Curling-moss. (*Orthotrichum crispum*; Hedw. *Crypt.* v. 2. 96. t. 35. Sm. *Fl. Brit.* 1266. *Engl. Bot.* t. 996. Turn. *Musc. Hib.* 93. *Bryum striatum* 3; Linn. *Sp. Pl.* 1580. *Polytrichum capillaceum crispum*, *calyptris acutis pilosissimis*; *Dill. Musc.* 433. t. 55. f. 11.)—Leaves linear; revolute when dry. Capsule cylindrical, furrowed. Veil hairy.—Native of various parts of Europe, growing on the trunks of trees. Not unfrequent in Britain, flowering very early in the spring, ripening fruit in April. The stems are branched from the bottom, forming dense leafy tufts. Leaves crowded, linear, acute, entire, single-ribbed; when dry rolled back in their whole length, and curled at the edges. *Fruit-stalk* rising about half its length above the leaves, twisted when dry, as is also the base of the capsule, whose whole length is marked with eight

eight strong furrows. *Fringe* of eight pairs of spreading combined teeth; inner one of eight simple capillary teeth. Hairs of the *veil* erect, finely jointed.

U. torquata. Spiral Curling-moss. (*Hypnum torquatum*; Swartz Prodr. 142. Hedw. Sp. Musc. 246. t. 63. f. 4—7. Neckera torta; Swartz Ind. Occ. 1800.)—Leaves lanceolate; spiral and close-pressed when dry. Capsule ovate, even. Veil naked.—Found on the mossy trunks of old trees in Jamaica, by Dr. Swartz; in New Zealand by Mr. Menzies. The trailing shoots throw up many erect, thick, subdivided branches, an inch high, densely clothed with leaves of a shining golden hue, turning brown with age; all spirally twisted, and somewhat undulated, pointed, entire, with a strong mid-rib. *Fruit-stalks* above an inch long, angular, red, shining, rising high above the branches, and at length spiral. *Capsule* erect, ovate rather than cylindrical, brown, turgid, quite smooth and even. *Veil* of a brilliant golden colour; brown at the tip; split at the base into many narrow convex segments; its surface quite naked.—Such are our specimens from Mr. Menzies, on whose authority we depend for the synonym of Swartz. Indeed Hedwig's figure, though rude, is expressive of our plant. Dr. Mohr's fig. 3, exactly represents its *calyptra*. This is said to belong to a moss nearly related to *Aniæangium cirrosum*, Hedw. Sp. Musc. 42. t. 5. f. 1—3. (Neckera cirrofa; Sw. Ind. Occ. 1802.) which may be what we have here described.

U. polytrichoides. Slender Curling-moss. (Neckera polytrichoides; Swartz Ind. Occ. 1796. Hypnum polytrichoides; Sw. Prodr. 141. Hedw. Sp. Musc. 244. t. 61. f. 7, 8.)—Leaves ovate, pointed, concave, twisted; two-ribbed at the base. Capsule oblong. Veil hairy.—Gathered by Dr. Swartz, on the branches of trees and shrubs, as well as on stones, in the mountainous parts of Jamaica. The shoots are three or four inches long, ascending, more or less crowded, somewhat branched. Leaves scattered, not imbricated, spreading, wavy, entire, except some fine serratures near the point; under a magnifier they prove finely reticulated. *Fruit-stalks* rather shorter than the leaves, three lines only in length, lateral, red. *Capsule* oblong, erect. *Veil* clothed with erect hairs.

ULOTHO, or ULOTHOW, in *Geography*, a town of Westphalia, in the county of Ravensberg, with a Lutheran and a Roman Catholic church; near it is a medicinal spring; 6 miles S. of Minden. N. lat. 52° 5'. E. long. 8° 45'.

ULPHA, a term used by some authors to express the muddy substance which falls off from whet-stones, grind-stones, and the like, which is sometimes ordered in medicines among the chemical writers, and is only the comminuted particles of the stone, with a very small portion of iron abraded from the things ground on them.

ULPHILAS, in *Biography*, a Gothic bishop, was a native of Cappadocia, referred by Philostorgius to the year 326, and highly honoured by Constantine the Great, who called him the Moses of his time. At this period he must, therefore, have arrived at maturity of age; and as he was employed in the year 375 by the emperor Valens to solicit a settlement for the Goths in Thrace, after they had been expelled by the Huns, and embraced Arianism in order to accomplish his object, he must have lived to a very advanced age. To him historians ascribe the invention of the Gothic characters and the translation of the Bible into that language. See ARGENTEUS Codex.

ULPIA CASTRA LEG. 30, in *Ancient Geography*, a town of Gallia Belgica, upon the banks of the Rhine, between Burginatum and Vetera. Anton. Itin.

ULPIANUM, a town of Upper Mæria, in Dardania

(Ptol.), said by Procopius to have been repaired and embellished by Justinian, and called "Justiniana secunda."—Also, one of the principal towns of Dacia. Ptol.

ULPIANUS, DOMITIUS, in *Biography*, an eminent lawyer, was a native of Tyre, a disciple of Papinian, and tutor, as well as friend and minister, of the Roman emperor Alexander. Heliogabalus exiled him from the court on account of his virtues, but when his pupil became emperor he was recalled, and placed at the head of sixteen senators, who formed a council of state. He was also secretary of state and inspector over the two pretorian prefects, whose jealousy of his authority produced a mutiny among the soldiery, that proved fatal to themselves; and occasioned his advancement to the dignity of sole prefect. His wife and virtuous administration engaged universal esteem, until the emperor, probably at his suggestion, undertook to reform the army. The soldiers mutinied, and occasioned, for three days, a kind of civil war at Rome, which terminated in the massacre of Ulpian, A.D. 228, notwithstanding all the attempts of the emperor and his mother Mammaea to save him. The Heathen writers have concurred in their eulogies of Ulpian, but the Christians have reproached him, not unjustly, as their enemy; for, observing the emperor's favourable inclination to them, he collected all the decrees and edicts of the preceding sovereigns against them. This hostility is ascribed to his professional attachment to the laws. Of Ulpian's writings there are extant twenty-nine titles of fragments, which are annexed to some editions of the civil law. Crevier. Gibbon's Hist.

ULPICUM, in *Botany*, a name by which Columella, and some other authors, have called the *allium*, or garlic.

ULRACH, a name given by some writers to the *sanguis draconis*, or dragon's blood.

ULRICHEN, in *Geography*, a village of the Valais, in the dioxin of Goms; famous in the history of the country for two battles fought here in 1211 and 1219, for the establishment of their freedom and independence; 8 miles N.E. of Munster.

ULRICHSKIRCHEN, a town of Austria; 7 miles N.E. of Korn Neuburg.

ULRICHSTEIN, a town of Upper Hesse; 18 miles W. of Fulda.

ULRICSHAMN, or ULRICAHAMN, a town of Sweden, in West Gothland. This town was anciently called Bogefund; the present name was given it in compliment to queen Ulrica Eleonora in the year 1741. The inhabitants carry on a considerable trade in cattle, provisions, tobacco, &c.; 47 miles E. of Gothenburg. N. lat. 57° 48'. E. long. 13° 19'.

ULSE, a river of France, which runs into the Moselle, 6 miles N. of Trarbach.

ULSEN, a town of Germany, in the county of Bentheim; 5 miles W. of Nienhaus.

ULSTADT, a town of the duchy of Baden, with a salt-spring; 9 miles E.S.E. of Spire.

ULSTER, a river of Hesse, which runs into the Werra, near Vacha.

ULSTER, one of the provinces of Ireland, forming the northern part of the kingdom; it contains nine counties, and is in general the most improved part of Ireland. It was mostly forfeited in the reign of James I. and divided amongst settlers from England and Scotland, which is called the plantation of Ulster.

ULSTER, a county of New York, in the United States, which, with Dutchess, had two delegates in the first legislative assembly of the colony, which met at New York in

1691. It was one of those formed by the general organization acts of 1738 and 1801, and has constituted one of the colony and state of New York ever since 1691, though the boundaries have been altered. Several towns have been annexed to Orange county, and Sullivan county has been erected from the northern part. It is bounded northerly by Delaware and Greene counties, E. by the Hudson, or by Columbia and Dutchess counties, S. by Orange, and W. by Sullivan county. The area is estimated at 966 square miles, or 617,440 acres. It is situated between 41° 33' and 42° 19' N. lat., and 66° E. and 47' W. long. from New York. Its towns are Elopus, Hurley, Kingtton the capital, Marletown, Marlborough, New-Paltz, Plattekill, Rochester, Saugerties, Shandakan, Shawangunk, Wawarsing and Woodstock. Its population consists of 26,576 persons. This county is considerably broken by the Catsbergs, or Catkill mountains. The soil is of various qualities. The channel of the Hudson forms the eastern boundary of Ulster, and the small streams are very numerous. The uplands are, in general, rich and productive; and the flats along its streams are very extensive, with considerable tracts of recent and rich alluvion, though interspersed with clay and argillaceous mould. The agriculture of this county is inferior to that of Dutchess. Its marble is very fine; the mill-stones of Elopus are in high estimation: lime-stone, slate, marble, and iron-ore are found in great abundance; and lead, native alum, plumbago, coal, peat, and a variety of pigments, have been found in this county. It has thirteen congregations and houses of worship belonging to the Dutch reformed, and several Quaker and Methodist meeting-houses; and at Kingtton there is a flourishing academy. The early inhabitants of this county were Germans and Dutch, and it was settled at a very early period of American history. Kingtton, the capital, is delightfully situated between Elopus and Wall creeks, and contains about 150 houses and stores. Many of the houses are of stone. Ulster, with Sullivan county, sends four members to the house of assembly.

ULSTER, a township of America, in the state of Pennsylvania, and county of Lycoming, containing 627 inhabitants.

ULTERIOR, in *Geography*, is applied to some part of a country or province, which, with regard to the rest of that country, is situate on the farther side of a river, mountain, or other boundary, which divides the country into two parts.

Thus Africa, with regard to Europe, is divided by Mount Atlas into exterior and ulterior, *i. e.* into two portions, the one on this side Mount Atlas, and the other on that.

ULTIMA BASIA, *Last Kisser*, is a phrase used among some painters, for last finishing touches with the pencil.

ULTIZURI, in *Ancient Geography*, a barbarous people, comprehended under the general name of Huns, who made themselves famous until the reign of the emperor Leon.

ULTRAMARINE, is a beautiful and durable sky-blue, formed of the mineral called lapis lazuli, and consisting, according to the analysis of Klaproth, of little else than oxyd of iron. It is separated from the earthy parts of the above-mentioned mineral in the following manner. Let the lapis lazuli be heated just to redness, and then suddenly quenched in cold water, and let this be repeated two or three times, till the stone becomes almost friable; then let it be ground down with a few drops of water in a clean iron mortar, or, still better, in an agate one, till it is reduced to a perfectly impalpable powder. Then take one pint of linseed oil, warm it over the fire in a clean vessel, and add one pound of bees-wax, one pound of turpentine, half a pound

of rosin, and half a pound of gum mastic: keep the ingredients over the fire, with constant stirring, till they are melted and thoroughly incorporated together; the result will be a tenacious adhesive mass. Of this take any quantity, six ounces for example, melt it and pour it into a warm clean mortar; then sprinkle upon it three ounces of pulverized lapis lazuli, and incorporate it thoroughly by long beating with the pestle; this being done, pour in some warm water, and again work it about in the same manner as before: in a short time the water will become charged with the blue colouring matter; it must then be poured into a clean tall glass, and replaced by fresh, proceeding in this manner till the paste will give out no more colour on the addition of fresh water. By standing a few days the colour will subside from the water in which it was suspended; the clear fluid being then decanted off, and the rest got rid of by evaporation, there will remain a deep-blue powder, which is ultramarine. See LAZULI Lapis.

ULTRAMARINE *Ashes*, is the name of a pigment which is the residuum of the lapis lazuli, after the ultramarine has been extracted from it. But as the coloured particles which remain are mixed with those of another kind contained in the lapis lazuli, these ashes must of course be much less valuable than even the worst ultramarine.

Their appearance is that of the ultramarine, a little tinged with red, and diluted with white. The adulteration to which they are subject, and gives them a better appearance than that of their genuine state, may be detected by the methods proposed for discovering the sophistication of the ultramarine. See LAZULI Lapis and BLUE.

ULTRAMONTANE, something beyond the mountains. The term is principally used in relation to Italy and France, which are separated by the mountains of the Alps.

In France, the opinions of the ultramontane canonists, *i. e.* of those of Italy, are not received.

The painters, particularly those of Italy, call all those that are not of that country ultramontanes, or simply, tramontanes. Poussin is the only tramontane painter that the Italians seem to envy.

ULTRAMUNDANE, ULTRAMUNDANUS, *Beyond the World*, is that part of the universe supposed to be without or beyond the limits of our world, or system.

ULTZEN, or Veltzen, in *Geography*, a town of Westphalia, in the principality of Luneburg, on the Ilmenau. It contains three churches, three hospitals, and about 330 houses; the principal articles of trade are wool, brandy, and meal. It was at one time Hanfeatic; 20 miles S.S.E. of Luneburg. N. lat. 52° 58'. E. long. 8° 22'.

ULVA, in *Botany*, a Latin word, occurring more frequently in the poets than any where else, and possessing a general, rather than a very precise or appropriate, meaning. Pliny has it not. Virgil and Ovid often mention it, with the epithets of *viridis, levis, mollis, palustris, glauca, fluminea*; and Vitruvius speaks of roofs made of "the marsh *Ulva*." Hence Cæfalpinus and others have been led to believe the *Typba*, or perhaps the whole tribe of Bulrushes, Sedges, &c. were understood by this appellation. Perhaps *Ulva* is simply synonymous with *aquatic plants* in general; which opinion is confirmed by the etymology pointed out by De Theis. He refers this word to the Celtic *ul*, water, the origin of *uligo*, ooze, and synonymous with *lu*, from whence comes *lutum*, mud, &c. Dillenius latterly rejected *Ulva* entirely, because of its uncertain meaning; adopting *Tremella*, which he considered as more expressive. Linnæus, distinguishing TREMELLA (see that article) as a freshwater genus, with less decided characters, retains *Ulva* for one chiefly of marine origin, more membranous in habit, and

and sufficiently well marked by the arrangement of its seeds, by which it differs from *Fucus*. The English name Laver is well applied to the genus before us.—Linn. Gen. 567. Schreb. 768. Mart. Mill. Dict. v. 4. Dill. in Raii Syn. 62. Sm. Prodr. Fl. Græc. Sibth. v. 2. 331. Hudf. 566. Roth Catal. v. 1. 204. Juss. 6. Lamarck Illustr. t. 880.—Class and order, *Cryptogamia Algae*, Linn. Nat. Ord. *Algae submersæ*.

Eff. Ch. Frond membranous or gelatinous. Seeds foliary, scattered throughout its substance, under the cuticle.

Fewer difficulties attend the generic character of *Ulva* than that of several other marine *Algae*, yet various things have been improperly referred to this genus. (See REVUE LITTÉRAIRE.) Some excellent remarks on this subject are given by Mr. Woodward, in Tr. of Linn. Soc. v. 3. 46; and the same is ably treated by Dr. Roth, in the first volume of his learned *Cataleña*, above cited. We shall follow the last-mentioned author in his leading principles; regretting that we are still deprived of a more complete view of the whole genus, long promised by Mr. Dawson Turner; who in his peculiar attention to this natural order of plants, has enjoyed more opportunities than any other botanist, for their complete elucidation. These opportunities however may perhaps have served to make him the more fully aware of the difficulties of the undertaking. With respect to the existence of species, in which, as Mr. Woodward observes, "no actual fructification has been hitherto discovered," we can only say that these are referred by analogy of habit to *Ulva*, with which they accord at least as well as with any thing else, the same defect which renders their place here doubtful, disabling us from removing them elsewhere. We shall enumerate all the known British *Ulvæ*, with such exotic ones as appear to be well determined, aiming rather at giving a general idea, than a complete view of the genus.

SECT. 1. Frond expanded, leafy.

1. *U. pavonia*. Turkey-feather Laver. Linn. Syst. Nat. ed. 12. v. 2. 719. Sm. Prodr. Fl. Græc. Sibth. n. 2515. Engl. Bot. t. 1276. (*Fucus maritimus*, gallo pavonis pennas referens; Raii Syn. 43. Tourn. Inst. 568. Ellis's Corallines, 88. t. 33. f. c. D. E. Morif. sect. 15. t. 8. f. 7.)—Frond membranous, flat, kidney-shaped, with a taper base. Seeds in transverse arched lines.—Found attached to submarine rocks and stones, on the southern coast of England, as well as throughout the Adriatic and Mediterranean seas, and on the shores of France, Spain, and Portugal. Several fronds, from one to three inches high, grow from one central root, spreading circularly and horizontally, each of them rounded at the extremity, either undivided or lobed, entire at the edges, of a light greenish-brown. The seeds are thickly lodged, in many brown, arched, transverse, continued lines, making an elegantly striped appearance, and resembling the feathers of a turkey-cock. This arrangement of the seeds can scarcely be thought to contradict the generic character; for it appears, in other species, that the expansion of the frond, after the first formation, and fixation, if we may so express it, of the seeds, cannot but separate them, more or less accurately, into patches or stripes. These stripes are nevertheless, as we must allow more determinate, from the very first, than in any other known species. The seeds are oval, about two rows in each stripe.

2. *U. flabelliformis*. Green Fan Laver. Wulfen Crypt. Aquat. n. 11. Decand. Fr. suppl. 4. Prodr. Fl. Græc. n. 2516. (*Conferva flabelliformis*; Desfont. Atlant. v. 2. 430. Flabellaria Desfontainensis; Lamouroux Ann. du Mus. v. 30. 274. t. 12. f. 4. Tufillagine dell' Adriatico; Giann. Adriat. v. 1. 25. t. 25. f. 56.)—Frond spongy,

filamentous, flat, fan-shaped, lacinated and jagged, with a taper base.—Native of the Adriatic and Ionian seas. Rather taller than the foregoing, of a light spongy texture, and uniform green colour, without any visible seeds. The genus of this plant is unquestionably very doubtful, yet a vague resemblance to *U. pavonia*, makes us more willing to place it here than any where else. With *Conferva* it ill accords, and few botanists will follow Ginanni in making it a *Tufillago*!

3. *U. atomaria*. Concentric-dotted Laver. Woodw. Tr. of Linn. Soc. v. 3. 53. Engl. Bot. t. 419.—Frond membranous, flat, dilated, palmate; segments linear, slightly branched; sometimes fringed.—Found washed up on the Yarmouth coast, by Mr. Lily Wigg. The root is a small, dilated, downy disk, bearing a pale olive-brown, thin, wedge-shaped, spreading frond, four or five inches high, deeply cut into numerous, unequal, irregularly jagged and perforated, oblong or linear, occasionally fringed, segments; the whole marked with many transverse concentric stripes, of a darker hue, full of minute brown seeds.

4. *U. ligulata*. Lacinated Red Laver. Woodw. Tr. of Linn. Soc. v. 3. 54. Engl. Bot. t. 420.—Frond membranous, flat, branched; branches dilated, somewhat forked, with obtuse sinuses; terminated and fringed with strap-shaped segments.—Found by Mr. Wigg, on the Yarmouth beach, along with the last; but Mr. Woodward met with it, in a growing state, on the rocks at Cromer, Norfolk. The root is a small callous disk. Fronds clustered, from three to six inches high, of a light rather bright red, membranous, but varying in density; their general outline wedge-shaped, deeply cut into a few principal branches, which subdivide into others, and are fringed about the bottom with many very narrow segments, rather blunt at their ends. Seeds extremely minute and abundant, scattered throughout the whole substance, in cloud-like spots or patches.

5. *U. lactuca*. Green Laver, or Oyster-green. Linn. Sp. Pl. 1632. Hudf. 566. Engl. Bot. t. 1551. Prodr. Fl. Græc. n. 2520. Roth. Catal. v. 1. 206. (*U. marina*, lactuceæ similis; Dill. in Raii Syn. 62. Tremella marina vulgaris, lactuceæ similis; Dill. Musc. 42. t. 8. f. 1.)—Frond membranous, pellucid, palmate, bright green; segments contracted below; dilated upwards, obtuse, plaited.—Native of most of the shores of Europe, and perhaps other parts of the world, growing on stones, pebbles, shells, and the larger sea-weeds, forming annual tufts of thin green leaves, uniform in colour and texture, but very various in figure and dimensions; being sometimes simple and undivided, but more frequently palmate, lobed, or proliferous. They always taper downward, and have no ribs nor veins. The very minute seeds are equally dispersed.—This is the Laver, so often introduced at fashionable tables, within a few years past, being stewed and seasoned with lemon juice, which moderates its salt bitterish flavour and "sea-weed scent;" nor is this dish unpleasant, after a short trial, to most palates. We suspect it to have been originally contrived with a medical intention, for the benefit of icterophilous patients, so numerous, alas! in the gay circles of the opulent and great. Where laxatives are useful or admissible, nothing can be better applied.

6. *U. lubrica*. Slippery Laver. Roth. Catal. v. 1. 204. t. 5. f. 7, excluding the synonyms.—Fronds tufted, oblong, convoluted, inflexed, undulated, rugose, interbranching, very thin and slippery.—Found in stagnant ditches of fresh water, in marshy parts of Germany. In the spring and beginning of summer, the plant is fixed to the bottom of the pool or ditch, in dense, roundish, deep-green patches, and is so excessively

cessively tender, gelatinous, and slippery, as scarcely to be gathered entire. The length of each frond is from two to five inches; the breadth, as far as the convoluted and entangled habit of the plant will allow that matter to be ascertained, is from one to three lines at most. *Roth.*

7. *U. terrestris*. Thin Ground Laver. Roth Catal. v. 1. 211. (*U. crispata*; Lightf. 972. Hudf. 661. *U. Laëuca* γ ; Hudf. 567. *Tremella terrestris tenera crispata*; Dill. Musc. 52. t. 10. f. 12.)—Fronds membranous, very thin, decumbent, clustered, curled and plaited.—Found on the ground, in shady places, on gravel walks, and sometimes on old thatched roofs, scarcely attached by any visible roots. It does not shrink up to nothing, in dry weather, like a *Tremella*, though most vigorous in wet. The fronds lie over each other, and are of a deep, though shining, green. No seeds are discernible.

8. *U. bullofa*. Cellular Green Laver. Roth Catal. v. 3. 329. Engl. Bot. t. 2320. (*U. Laëuca* β ; Hudf. 567. *Tremella palustris, vulgari marinæ fimbilis, sed minor et tenerior*; Dill. Musc. 44. t. 8. f. 2.)—Frond membranous, very tender, dilated upwards, variously sinuated, cellular, bright green.—Found in shallow stagnant ditches of fresh water, in Germany and England. Dillenius observed it in meadows behind Newington; Mr. W. Borrer at Herfield, Suffex, in July. The former remarked that as warm weather came on, the plants floated on the top, turned yellowish, and became full of air-bubbles, as if in fermentation. In this state perhaps the seeds are scattered. The whole plant is smaller than *U. Laëuca*; of which it has been thought a variety; much more slippery and slimy, so tender as scarcely to be gathered without breaking. The frond is variable in shape; cellular like a cabbage-leaf when full-grown; appearing beautifully dotted when examined with a microscope.

9. *U. plicata*. Plaited Firm Laver. Fl. Dan. t. 829. Roth Catal. v. 1. 208. Uit. Annal. v. 1. 5. (*Muscus marinus* after Plinius; Camer. Epit. 872. *Lichen marinus*; Ger. Em. 1566.)—Fronds green, plaited, lacinated, elongated; combined and imbricated at the base.—Found attached to submarine rocks, stones, and large shells. This varies in length from one to twelve inches. Dr. Roth distinguishes it from *U. Laëuca* by its more opaque green colour, and firmer more rigid substance. It is also more complicated in form, as well as more plaited longitudinally, and jagged at the edges. We have not been able to compare these two plants, but from the analogy of some others, should suspect them to be merely varieties.

10. *U. plantaginea*. Plantain-leaved Laver. Roth Catal. v. 2. 243. Engl. Bot. t. 2136. (*Tremella marina, calendula folio atro-virente et verrucoso*; Dill. Musc. 46. t. 9. f. 4.)—Fronds aggregate, membranous, simple, oblong, obtuse, flat, entire, minutely warty, brown; tapering at the base.—Native of the coasts of Italy and England. The fronds spring from a cartilaginous disk, and are from three to six or eight inches high, an inch broad, of a very dull olive-brown, firm, not adhering to paper in drying; the surface besprinkled with slightly prominent warts; the base of each tapering into a short stalk. This species is very generally found eroded by marine animals.

11. *U. umbilicalis*. Peltate Laver. Linn. Sp. Pl. 1633. Hudf. 567. Engl. Bot. t. 2286. (*Tremella marina umbilicata*; Dill. Musc. 45. t. 8. f. 3.)—Frond rather coriaceous, purplish-olive, orbicular, sessile, peltate, spreading nearly flat, variously lobed.—Frequent on the sea-coast, growing solitary or dispersed, attached to rocks or stones by its central root, and often washed up on the sandy beach. Its more coriaceous substance, and browner, somewhat

purplish, colour, distinguish this *Ulva* from the *Laëuca* and *plicata*. The surface is very smooth, and shining. Each plant is a span or more in diameter, orbicular, variously cut or lobed, even to the very centre; the edges and lobes crisped, wavy and jagged, not imbricated; the internal substance finely cellular, appearing dotted. Seeds dispersed in small masses, darker than the frond. Mr. Borrer conceives Roth's *U. purpurea*, Catal. v. 1. 209. t. 6. f. 1, which, according to Sir Thomas Frankland's specimen, is Hudfon's *fusca*, to be an oblong variety of *umbilicalis*. *U. laciniata*, Lightf. 974. t. 33, may be, as Hudfon suspects, another variety.

12. *U. mesenteriformis*. Mesenteric Laver. Roth Catal. v. 1. 210.—Frond solitary, oblong, broad, plaited, wavy, cellular and rugose, dark green.—Native of the northern seas of Europe, or of muddy salt-water ditches on the coasts of Oldenburgh and Bremen. Various in size and shape, ovate, roundish or oblong, eighteen inches or more in length, and sometimes a foot broad, in much plaited and corrugated that it cannot be laid flat, nor does it adhere to paper. Roth compares this to *U. latissima* of Linnaeus, which we find by the original specimen to be only *Fucus saccharinus*, more cellular than ordinary; and we are much inclined to believe Roth's *mesenteriformis* to be no other, the varieties of that *Fucus*, in size and configuration, according to its age, being almost endless.

13. *U. coccinea*. Scarlet Laver. Hudf. 567.—“Flat, roundish, membranous, sinuated, scarlet.”—On submarine rocks and stones, near Plymouth and Falmouth. Frond from six inches to a foot in diameter, wavy, pellucid and shining. Seeds numerous, small, roundish, dark purple. Hudfon. This may probably be *Fucus punctatus*, Engl. Bot. t. 1573.

14. *U. furcellata*. Reddish Forked Laver. Turner in Schrad. Journ. v. 3. 301. Engl. Bot. t. 1881.—Frond nearly cylindrical, gelatinous, repeatedly forked, reddish; ultimate segments flattened, lanceolate, cloven.—Gathered by Mr. Turner, at Sheringham, Norfolk, and by Miss Biddulph, at Southampton. Fronds several, from three to six inches high, tender, gelatinous, nearly of equal thickness throughout, except the flattened ends. Seeds large, sparingly scattered just under the cuticle. The colour of the whole is a pale brownish-red, sometimes greenish.

15. *U.?* *multifida*. Lacinated Brown Laver. Engl. Bot. t. 1913.—Frond rather cartilaginous, brown, compressed, repeatedly branched, somewhat palmate. Seeds irregularly scattered. Root smooth.—Found by Mr. Turner, in August 1804, on the beach at Yarmouth, where it is of very rare occurrence. This has much of the hue and general aspect of *U. atomaria*, n. 3, but the root is smooth; substance of the frond very much firmer and thicker; seeds not disposed in concentric lines, but thickly scattered over the frond in small round clusters. By Mr. Sowerby's drawing, they seem, when highly magnified, to be congeries of oblong, stalked seed-vesicles, with three or four seeds in each, rendering the plant a *Fucus* rather than an *Ulva*. However small, they give a palpable roughness to the frond.

16. *U. montana*. Red Mountain Laver. Lightf. 973. Hudf. 652. Engl. Bot. t. 2193.—Frond leathery, dark red, of numerous, ascending, rounded, flattish, finely granulated lobes.—This grows on the ground, amongst grais and moss, on the sides of mountains in Skye, Rosshire, Dumfriesshire, &c. being called Mountain Dulse by the highlanders, who make a thin pulp mixture, by rubbing the plant between their hands, into some water, with which they purge their calves. It has the smell of Common Dulse,

Dulse,

Dulle, or *Fucus palmatus*, to which, though growing in fo different a station, the present *Ulva* has much natural affinity. The colour of both is a deep dull red, seldom greenish, or brown; and their substance, when soaked, is alike pulpy and mucilaginous, with a sea-weed odour. Our present plant, however, is much the smallest, being rounded, not palmate, scarcely notched, each *frond* or *lobe* from half an inch to two or three inches wide, generally convex. Innumerable internal granulations, the feat, as we presume, of the *feeds*, raise the cuticle in such a manner as to give a roughness to the surface.

17. *U. rupestris*. Broad Rock Laver. Engl. Bot. t. 2194. — Frond leathery, depressed, very wide, indeterminate, smooth and slippery, of a dull red.—The only specimen of this remarkable vegetable that ever occurred to our notice, grew on the wet shady surface of a rock, above Tylogè bridge, by the river side, at Hafod, Cardiganhire; the fine feat of the celebrated Mr. Johnes, so well known by his translations of the old French historians, and now so much lamented by all who truly knew him. We can compare this plant to nothing better than a well-soaked skin of parchment, both in size and texture, though more tender, and jagged at the edges, so that it could not be stripped entire from the rock, nor could the form of its outline be ascertained. It dried speedily, slightly adhering to paper, and shrinking considerably in width; but recovered its original appearance many years afterwards, on the application of water, when numerous, minute, granular, dotted bodies, presumed to be *feeds*, were found imbedded in the fibrous substance under the cuticle, not projecting, so as to produce a roughness, like the *montana*. We cannot doubt the strict affinity of this to the last, though they must be specifically distinct.

18. *U. dichotoma*. Green Forked Laver. Hudf. 568. Lightf. 975. t. 34. Engl. Bot. t. 774. (*Fucus membranaceus dichotomus gramineus*; Raii Syn. 45, according to Hudson.) — Frond membranous, quite flat, repeatedly forked, reticulated, pale-green, with linear, obtuse segments. — Found on the coasts of Scotland and Cornwall, in summer time. The whole plant, three or four inches high, and of a wedge-shaped or fan-like figure, is thin and flat, curiously reticulated internally like a *Flystra*, or like our n. 2, *U. flabelliformis*. The segments are alternate, from one line to three in breadth, generally notched at the end, but otherwise very entire. *Seeds* blackish, dispersed, with a series of imbedded bladders, between them and the margin of the leaf.

19. *U. Linza*. Ribband Laver. Linn. Sp. Pl. 1633. Hudf. 568. Fl. Dan. t. 889. (*Tremella marina fasciata*; Dill. Musc. 46. t. 9. f. 6. *Linza*; Imperato It. Nat. 651.) — Frond oblong-lanceolate, folded, green, somewhat undulated and cellular. — Native of salt-water ditches, and recesses of the sea among rocks, in various parts of Europe. Its form is oblong, ribband-like, acute, when full-grown folded and wavy, always membranous and pellucid; its length a foot or more. Mr. Turner in Tr. of Linn. Soc. v. 7. 108, records, that he found the original specimen of this in the Dillenian herbarium to consist of two long narrow pieces of different things, *U. Lacinea* and *umbilicalis*. The figure however represents what we understand by *U. Linza*, and agrees with *Fl. Dan.* Mr. Turner affords us, in the place just cited, a still more curious piece of information, that the *U. lanceolata* of Linnaeus, taken up in his Syst. Nat. ed. 12. v. 2. 719, from Dillenius, is no other than *U. Linza*, the figure in Hist. Musc. t. 9. f. 5. representing several individuals of that species, as passed in the herbarium, with their tops downward, crowded together, and the roots upward!

These were communicated, it seems, by Mr. Brewer, from the Isle of Man, and appear to be young plants, not yet become wavy or folded.

SECT. 2. *Fronde concave, or tubular.*

20. *U. intestinalis*. Gut Laver. Linn. Sp. Pl. 1632. Hudf. 568. (*Tremella marina tubulosa, intestinorum figurâ*; Dill. Musc. 47. t. 9. f. 7. *Cava*; Imperato It. Nat. 651.) — Frond tubular, membranous, green, irregularly cellular. — Common in salt-water ditches and pools, throughout Europe, attached to stones and rocks. The *frond* is occasionally branched, according to Dillenius. Young plants hardly exceed a straw in thickness, and are even in surface, of a yellowish or brownish colour; but when full grown they become an inch or two in diameter, variously cellular, like a cabbage-leaf, and of a fine green; often floating to the surface, inflated with air, eighteen inches or two feet in length. In this state they resemble, except colour, the intestines of some animal. Nothing is known respecting the *feeds*, which are probably perfected and disseminated at the period just described.

21. *U. compressa*. Compressed Laver. Linn. Sp. Pl. 1632. Hudf. 569. Engl. Bot. t. 1739. (*Tremella marina tenuissima et compressa*; Dill. Musc. 48. t. 9 and 10. f. 3. *Conserva compressa*; Roth Catal. v. 1. 161.) — Frond tubular, more or less branched, compressed, irregularly constricted, green; the branches elongated. — Common on submarine rocks, stones and pots, as well as in salt ditches, throughout Europe. Dr. Sibthorp noticed this, along with the last, in the sea near Constantinople. The *fronds* grow in tufts, extremely variable in size, and from two inches to a foot or more in height, each of them very slender at the base, where also they are most branched; the *branches* are often greatly enlarged upwards, but frequently nearly cylindrical; they are interrupted here and there by strictures, at each of which the internal cavity seems divided by a transverse membrane. Hence Necker and Roth made this plant a *Conserva*, but surely without sufficient reason. The surface is even and smooth; the colour fine green.

22. *U. ramulosa*. Green Sharp-branched Laver. Engl. Bot. t. 2137. — Frond tubular, very much branched, somewhat compressed, green; ultimate branches scattered, extremely numerous, sharp-pointed. — Discovered by Miss Hutchins, in Bantry bay, Ireland. A very elegant species, remarkable for the innumerable little branches, scattered over each principal ramification, which give it the aspect of a *Conserva*. The height of the tufted *fronds* is three or four inches; their colour a beautiful green; and the surface, under a moderate magnifier, is found curiously and uniformly dotted, perhaps with *feeds*. The substance of the plant is a little gelatinous, being far less membranous than *U. compressa*.

23. *U. purpurascens*. Purplish Laver. Hudf. 569. Woodw. Tr. of Linn. Soc. v. 3. 52. Engl. Bot. t. 641. — Frond tubular, branched, nearly cylindrical, purplish-brown; branches mostly opposite, simple or compound, acute. — This grows on submarine rocks and stones, in various parts of the south coast of England, being in perfection about the middle of summer. Several *fronds*, about six inches high, spring from one small cartilaginous disk. Each, like its branches, tapers considerably at the top and bottom, swelling in the middle, to a line or two in diameter. The *branches* are two or three inches long, generally opposite, and in some degree two-ranked. Sir Thomas Frankland has favoured us with a repeatedly compound specimen, a foot long. The whole plant is juicy, of a light reddish-brown, smooth and even, with little black *feeds* scattered copiously and irregularly just under the cuticle. Light-

foot's *Fucus verticillatus*, Fl. Scot. t. 31, a plant we have never examined, is cited for this *Ulva* by Mr. Hudfon, p. 661; but the figure represents numerous strictures in the main branches, with compound, whorled, capillary subdivisions, nothing like which occurs in our specimens.

24. *U. fistulosa*. Pipe Laver. Hudf. 569. Woodw. Tr. of Linn. Soc. v. 3. 52. Engl. Bot. t. 642.—FronD tubular, uniform, simple, blunfish, a little zigzag, gelatinous, yellowish-brown.—Found at Falmouth, and other parts of our southern coast. Mr. Hudfon attributes to this species a creeping root. The fronds grow in clusters, erect, three or four inches high, being flouter than the last, and constantly unbranched; their surface uneven or gibbous, with some appearance of strictures; their base tapering; their termination abrupt and blunfish. Seeds very minute, scattered through the soft substance of the frond, visible by their dark colour, contrasted with its very pale brownish-yellow.

25. *U. Turneri*. Reticulated Laver. Engl. Bot. t. 2570.—FronD membranous, tubular, simple, blunfish, brown, finely reticulated. Seeds in little patches.—Found by Miss Hutchins, in Bantry bay, Ireland, and by Mr. Borrer, on the Suffex coast. The name is a manuscript one of Mr. Dillwyn, who is said to have been long preparing a treatise on *Ulva*, which, if we may judge by his excellent performance on *Conserva*, cannot but prove a great accession to cryptogamic botany. Several fronds grow together, but apparently not connected, bearing a great resemblance to the last in height, figure, and somewhat in colour, though darker, rather thicker, and, when cut across, displaying a more membranous substance, which is finely reticulated throughout. The seeds moreover differ essentially, being collected into little irregular patches.

26. *U. rugosa*. Corrugated Cape Laver. Linn. Mant. 311.—FronD membranous, tubular, branched, corrugated, tuberculated, dark brown; branches two-ranked, bursting at the extremity.—Gathered by Koenig in the sea near the Cape of Good Hope. The fronds are four or five inches long, and about half an inch thick, beset with many simple branches, spreading in two ranks, each branch from an inch and half to three inches in length, not so thick as the main stem; their point of insertion much contracted; their extremity mostly open and tubular; their rugged surface besprikled with slightly prominent, umbilicated, minute prominences, in every one of which a seed appears to be imbedded.

Seet. 3. *FronD fleshy, solid.*

27. *U. diaphana*. Pellucid Flethy Laver. Hudf. 570. (Alcyonium gelatinosum; Linn. Syst. Nat. v. 1. 1295. A. n. 5; Ellis Cor. 87. t. 32. f. d. *Fucus spongiosus nodosus*; Ger. Em. 1570. *Urtica marina nodosa*; Bocc. Mus. 260. t. 5. f. 13.)

β. U. flavescens; Hudf. 570. (*U. diaphana*; Engl. Bot. t. 263. *Alga minor flavescens, variè divisa*; Mart. Cent. t. 32.)

FronD gelatinous, solid, tumid, pellucid, roundish or compressed, with numerous irregular branches.

This singular marine production, referred by Linnæus and Pallas to the animal kingdom, seems by its scent rather of a vegetable nature, betraying no signs of animal life, and having the character of an *Ulva* very apparent, in the distribution of what we presume to be the seeds; to say nothing of its drying as well as any very juicy sea-weed, though its substance is so extremely spongy and watery. The common appearance of this *Ulva*, as found on our coasts, exactly resembles wet sea-sand in colour. Its length is several inches, the main stem, which swells upward, being beset with irre-

gular series of knobby branches, more or less acute. The very copious imbedded seeds are brown, very small. Our more uncommon variety *β*, erroneously figured in Engl. Bot. as the true *diaphana*, though the description comprehends both sorts, differs from the above-described, in its pale-yellow colour, resembling barley-fugar (or *succè brâlé*); the branches are said by Hudfon, who nevertheless suspected it might prove but a variety, to be more obtuse; this character however is variable.

28. *U. defrata*. Broken Laver. With. v. 4. 124. t. 18. Engl. Bot. t. 1626.—FronD thread-shaped, solid, unbranched, elastic, viscid, pellucid, with pale red dots.—Found by Mr. Brodie of Brodie, on the east coast of Scotland, and by the late colonel Velley on the beach at Weymouth, at low water. The tender delicate plants of this species grow entangled amongst other marine vegetables, twisted together like worms, of a very pale flesh-colour to the naked eye; each being from two to twelve inches long, simple, brittle, blunfish, very glutinous, shrinking up to nothing when dried. The minute pink dots, scattered over the white surface, and presumed to contain the seeds, change gradually to an orange hue.

29. *U. filiformis*. Thread-shaped Laver. Hudf. 570.—“FronD gelatinous, thread-shaped, much branched, purplish; branches scattered, distant, very long.”—Native of submarine rocks and stones, near Christchurch, Hampshire. Annual, occurring from April to September. FronD six inches long, the thickness of packthread; the branches obtuse. Hudfon. We are unacquainted with this species.

30. *U. capillaris*. Capillary Laver. Hudf. 571.—“FronD gelatinous, thread-shaped, much branched, pale; branches alternate, capillary, acute.”—Found in similar situations with the preceding, near Christchurch, and elsewhere, in Hampshire, as well as at Margate. Annual; from May to October. The frond is four inches long, solid. Hudfon. This should seem to be very little different from the last.

31. *U. rubens*. Reddish Short-branched Laver. Hudf. 571.—FronD gelatinous, thread-shaped, equal, reddish or greenish, much branched; branches scattered, horizontal, obtuse.—Found by Mr. Hudfon on submarine rocks and stones, in Portland island, and near Pool, Dorsetshire. Annual; from May to October. FronD four inches long, of nearly equal thickness throughout, of the diameter of small packthread, divided into several alternate or scattered principal branches, each of which is beset with numerous others, all horizontal, short and blunt. Little black seeds are scattered under the cuticle. An authentic specimen of this, and many other sea-weeds, described by Hudfon, were given to the younger Linnæus by sir Thomas Frankland. We are also possessed of another, found by the same gentleman at Scarborough, in August 1807, which is six inches high, green, with very copious branches of the same thickness as above described; the internal substance of the main stem, in the lower part, appearing very firm and horny, like a coralline. Notwithstanding the difference of colour, we cannot doubt the identity of the species.

32. *U. rubra*. Crimson Laver. Hudf. 571. Engl. Bot. t. 1627.—FronD gelatinous, much branched, forked, thread-shaped, unequal, somewhat flattened, bright red, smooth.—Found by Mr. Hudfon, near Christchurch, Hampshire, and by sir Thomas Frankland on the Scarborough coast, in August. Several fronds, from an inch and a half to three inches high, spring from a small callous disk. They are taper at the base, much branched and variously dilated, especially the principal stem, which is most flattened; the ultimate divisions forked, or aggregate. The colour

colour of the whole is either a full or pale crimson, sometimes tawny, or slightly variegated.

33. *U. plumosa*. Feathered Green Liver. Hudf. 571. Engl. Bot. t. 2375.—Froned gelatinous, green, thread-shaped, somewhat compressed, branched; branches pinnate, with numerous, parallel, linear, shining segments.—Gathered by Mr. Hudson on the Devonshire coast; by Mr. W. Borrer at Brightelmstone; and by Mr. Woodward at Cromer, in little rocky pools, filled daily by the sea. This species is supposed to be perennial; it occurs throughout the summer and autumn. The fronds are three inches high, erect; when fresh of a bright, uniform, very beautiful green; but the colouring matter soon collects towards the skin, leaving the middle part vacant, and of a glassy transparency. The branches are numerous; naked at their base; copiously feathered above, with crowded, two-ranked, linear, obtuse, entire segments, gradually shorter towards the point. Nothing is known of the fructification. The habit of the plant, and the mode in which the green colouring matter subsides, accord with one tribe of the *Conservae*; but there are no joints, nor internal partitions.

34. *U. protuberans*. Prominent-seeded Liver. Engl. Bot. t. 2583.—Froned gelatinous, thick, angular, green. Seeds elliptical, at length prominent and deciduous.—Discovered by Mr. W. Borrer, growing amongst moss, on wet shady parts of the sand-rocks, at Uckfield, Sussex, in September 1813. This is of singular a production, that much doubt may arise concerning its real genus. The whole is an assemblage of thick, fleshy, juicy, angular or wrinkled, obtuse lobes, about half an inch high, of a light, pellucid, grass green. Copious elliptical uniform seeds, about the size of red poppy-seed, are lodged separately throughout the whole substance, the external series projecting beyond the surface, and when ripe easily separating from it if touched. According to our present state of knowledge therefore, this plant can be referred only to *Ulva*, though, like a few other species, it is not of marine origin.

Some doubtful species require to be mentioned, and of these we shall take a compendious notice.

U. confervoides, Linn. Sp. Pl. 1632. (*Coarvea marina* fistulosa; Dill. Musc. 34. t. 6. f. 39.), has all the appearance of a branched *Conserva*, but Dillenius describes it as pervious throughout, admitting water freely along the stem and branches. Hence Linnæus made the plant an *Ulva*, but our knowledge of many *Conservae* renders the propriety of such a determination doubtful. He adopted this species solely on the authority of the *Historia Muscorum*, what he subsequently referred to it in his herbarium being very different.

U. latifolia, Linn. Sp. Pl. 1632, we have already mentioned under n. 12, as not at all different from *Fucus sacccharinus*, which the original Gothland specimen clearly shews.

U. labyrinthiformis, Linn. Sp. Pl. 1633, found by Vandell in warm baths near Padua, and described, with a good figure annexed, in that author's *Traçatus de Thermis Agri Patavini*, 120. t. 2, should seem to belong rather to *Tremella*, no seeds having been observed.

U. lumbricalis, Linn. Mant. 311, may be found under MERTENSIA.

U. papillofa, *ibid.*, is probably a *Fucus*, near to the Linnæan *F. spinosus*, and perhaps the same with *F. striatus*, Turn. Hist. Fucor. 32. t. 16.

U. pruniformis, Linn. Sp. Pl. 1633, and *U. incrassata*, Hudf. 572, are species of RIVULARIA; see that article.

VOL. XXXVII.

U. granulata, Linn. Sp. Pl. 1633, is *Tremella granulata*, Engl. Bot. t. 324.

U. stellata, Wulf. in Jacq. Coll. v. 1. 351. Prodr. Fl. Græc. n. 2522, very nearly related to *Lichenoidea gelatinosum tenue reticulatum*. Dill. Musc. 138. t. 19. f. 21, if not the very same; is likewise next akin to *Conserva umbilicata* of Col. Velley, Transf. of Linn. Soc. v. 5. 169. t. 7. These plants are so peculiar in structure, that their fructification, when discovered, will probably establish them as a genus by themselves. At least they could be referred to *Ulva*, or to *Conserva*, for the present only, nor are they reconcilable to the generic character, or habit, of either.

ULVA, in *Geography*, one of the Western islands of Scotland, about seven miles in circumference, near the W. coast of Mull. N. lat. 56° 28'. W. long. 6° 13'.

ULUA, a river of Honduras, which runs into the bay, N. lat. 15° 48'. W. long. 88° 38'.

ULUA, or Sol, a small island in the gulf of Mexico. N. lat. 15° 40'.

ULUBRÆ, in *Ancient Geography*, a borough of Italy, in Latium, in the vicinity of Velitræ and of Suefla Pometia; was a Roman colony. Horace says of it (Epist. ii. v. 28.)

“ ——— Navibus atque

Quadrigris petimus bene vivere; quod petis, hic est,
Et Ulubris; animus si te non deficit æquus.”

But we learn from Juvenal (Sat. x. v. 101.) that this place became desert:

“ Et de mensura jus dicere, vasa minora
Frangere pannosus vacuus Ædilis Ulubris.”

ULUCITRA, a town of Thrace, in the province of Rhodope.

ULVERSTON, in *Geography*, an ancient market-town in the hundred of North Lonsdale, and county palatine of Lancaster, England, is situated within the district of Furness, at the distance of 20 miles N.W. from the county-town, and 270 miles N.W. by N. from London. Edward I., in the eighth year of his reign, granted a charter to this town for a weekly market and annual fair: but the benefit derived from this grant was inconsiderable, while Furness abbey was inhabited by the monks, as the great mart of this district was Dalton, which, from its contiguity and connection with the abbey, superseeded all the vicinal towns. After the dissolution of that monastery, Dalton lost its importance, and Ulverston, from its convenient and central situation, became the emporium of the district. The fair granted by king Edward has grown into disuse, but two others are annually held. Monday is the market-day. The principal trade of this town is in iron-ore, pig and bar iron, lime-stone, blue slate, oats, barley, and beans: the manufactures are cotton, check, canvas, and hats. Within the last sixty years, great improvements have taken place in the appearance of the town; the streets are spacious and clean; and the houses, which, from the advance of trade, rapidly increase in number, are well built: in the return of the year 1811, they were estimated at 728, the population at 3378. At the intersection of two principal streets, in the centre of the most ancient part of the town, is an old cross. The church, which stands in a field at a small distance from the town, was almost wholly rebuilt in 1804: it is a plain, neat edifice; has three aisles and a square tower. A small theatre, an assembly-room, and a public subscription library, have been recently established. A canal, about a mile and a quarter in length, was cut in 1795, to form a communication from

the east side of the town to the channel of the river Leven: it is well supplied with water, has a spacious basin, with a warehousc, and has been navigated by ships of 400 tons burden. It was made after the plans of J. Rennie, esq.

In the vicinity of this town is Conifhead, the feat of Wilfon Bradyll, esq. The house stands on the site of the ancient priory of Conifhead: the south front is modern, with an ornamental arcade; the north front has a piazza and wings.

About half a mile from Ulverston is Swartmoor-Hall, to which some degree of celebrity has attached from its having been the residence and property of George Fox, one of the founders of the sect of Quakers. He made a convert of the former proprietor, Thomas Fell, one of the Welsh judges, and married his widow. Fox died in 1691.—*Beauties of England and Wales*, vol. ix. Lancashire, by J. Britton, F.S.A.

ULUGH-BEIGH, in *Biography*, a learned and powerful Tartarian prince, was born in the year 1393. He was the grandson of the celebrated Timur; and his real name was Mohammed Taragai, Ulugh-Beigh being an epithet which signifies a great lord or prince. He entered upon the government of Iran and Turan, that is of Persia and Tartary, during his father's life, in 1407, and conducted himself in a manner that secured universal esteem. His leisure hours he devoted to reading, and thus acquired a knowledge of various sciences. He was famed for a very retentive memory, and having written a book or journal of all the animals which he had killed in hunting, which book was accidentally lost, he dictated the contents of it to a transcriber; and upon comparing this transcript with the original when it was found, it was correct except in four places. Among other institutions for the promotion of science, he established a gymnasium at Samarcand, his capital, which accommodated a hundred students, received into it for education. His chief attention, however, was devoted to mathematics and astronomy; and for the improvement of the latter science, he invited to Samarcand a great number of astronomers, and constructed an observatory, which he furnished with the best astronomical instruments. Here he assisted in person, employing in his observations, as some have said, a gnomon one hundred and eighty Roman feet in height. His principal assistant was Salah-Eddin, his preceptor, and a Christian, who was the director of this astronomical academy, and who co-operated with Ulugh-Beigh in the construction of the tables which he intended to publish; but as he died before their completion, the prince himself engaged in the laborious undertaking, and selected for his coadjutors Alicufi, the son of Salah-Eddin, and the astronomer Ali Ben-Gaiat-Eddin Mohammed Jamchid. To this work, which has never been printed entire, we are indebted for those tables that pass under the name of Ulugh-Beigh. A fourth part of it was published by the learned Hyde, with an ample commentary. This was a catalogue of the fixed stars, formed upon the Observations made at Samarcand, and completed in 1437. Its title is "Tabulæ Longitudinis et Latitudinis Stellarum fixarum, ex Observationse Ulughbeighi, Tamerlanis M. Nepotis, Regionum ultra citraque Gihun (Oxum) Principis potentissimi, ex tribus invicem collatis MSS. Perfcis, jam primum luce et latio donavit, et Commentariis illustravit, Thomas Hyde, A. M. e Coll. Regin. Oxon.; in calce accesserunt Mohammedis Tizini Tabulæ Declinationum et Rectarum Ascensionum. Additur Elenchus Nominum Stellarum," Oxon. 1665, 4to. These astronomical tables were scarcely completed, when a difference occurred between

Ulugh-Beigh and his eldest son. Addicted, like other orientals, to astrology, he calculated his son's nativity; and hence portending some great misfortune, he gave the preference to his younger son, so that the eldest, being slighted, rebelled against him. A civil war took place, and in a bloody battle near Samarcand the father was defeated, and was obliged to save himself by flight. Returning afterwards to Samarcand, hoping that his son would have compassion upon him, he was at first kindly received; but soon afterwards a mandate was issued for his execution, which tragical event occurred near Samarcand, according to Flamstead, in the year 1449; but, as Herbelot says, in 1450.

Two other learned works, which serve for the illustration of the eastern geography and history, written by this prince, were published by Mr. Greaves; viz. "Binæ Tabulæ Geographicae, una Nafir Eddini, altera Ulugh-Beighi, Opera et Studio J. Grævii nunc primum publicatæ et Commentariis ex Abulfeda aliisque Arabum Geographis illustratæ," Lond. 1648, 4to.: and also "Epochæ celeberrimos Astronomis, Historicis, Chronologis, Chateiorum, Syro-Græcorum, Arabum, Perlarum, Chorasmiorum usitatæ; ex Traditione Ulugh-Beighi Indiæ citra extraque Gangem Principis, eas primum publicavit, recensuit, et Commentariis illustravit J. Grævius," Lond. 1650, combined, in Arabic and Latin, in J. Hudson Geogr. Vet. Script. Minores, tom. iii. Montucla. Gen. Biog.

ULVISON, in *Geography*, a river of Sweden, which runs into the Mæler lake.

ULULA, in *Ornithology*. See STRIX.

ULULEUS, in *Ancient Geography*, a river which furnished Dyrhachium with water; now called Argentea.

ULYSSEA, a town of Hispania, in Bætica, situated on the mountains, above Abdera, according to Strabo; who says that here was a temple dedicated to Minerva, and that it contained many monuments of the voyages of Ulysses.

ULYSSES, in *Geography*, a township of New York, in America, in the S.E. corner of Seneca county, 14 miles S.E. of Ovid, and 180 W. of Albany, with two post-offices, Ithaca and Tremain; bounded N. by Ovid, N.E. and E. by Cayuga county, S. by Cayuta in Tioga county, and W. by Hector. On the E. it embraces the half of the S. end of Cayuga lake, an extent of eight miles, where it receives Cayuga creek, or the main inlet; Six-mile and Fall creeks, which furnish many mill-feats in this part of the town; and it has some small streams that fall into the W. side, and supply mill-feats in the N. part of the town. The fourth part is hilly, and the soil less valuable than the north, which is sufficiently level, with a very good soil. It has been settled since the year 1789, at first by Yankees, or New England people, and since by Dutch from New Jersey. It has one Methodist meeting-house, and a congregation of Presbyterians. The town has a considerable quantity of white pine, which is very valuable. Ithaca is a handsome post-village at the S. end of Cayuga lake, containing 40 houses, with a considerable trade; and Tremain is a post-village, 11 miles N.W. of Ithaca, containing 10 or 12 houses.

ULYSSIS PORTUS, in *Ancient Geography*, a port on the eastern side of Sicily, near Catania. It was an ancient opinion that Ulysses had landed in this place. However, if we admit the recitals of Homer in the *Odyssæe*, Ulysses had landed on the promontory of Pachynum.

ULYSSOPOLIS, a town of Thrace, said to be the Odifus of Ptolemy.

ULZEN, in *Geography*. See ULTZEN.

UMA, in *Mythology*, a name of the Hindoo goddesses *Parvati*,

Parvati, under which article an ample account is given of this important many-named deity. Uma is stated to be an incarnation of Parvati.

Uma is a name still given to Hindoo females, in common with several others of this and other goddesses; such as Lakshmi, Parvati, Bhavani, &c.

UMAGNO, in *Geography*, a town of Etruria; 5 miles N. of Volterra.

UMAGO, a sea-port town of Istria. Here is a spacious harbour at the mouth of a river, but the situation being unhealthy, the town is but thinly inhabited; 16 miles E. of Venice. N. lat. $45^{\circ} 35'$. E. long. $13^{\circ} 43'$.

UMAPA, a town of Mexico, in the province of Culiacan; 10 miles E. of Culiacan.

UMARI, in *Botany*, the Brazilian name of a tree, rudely figured in Marcgrave's *Hist. Plant.* 121. See GEOFFREA.

UMARRAH, in *Geography*, a town of Nubia; 85 miles S. of Syene.

UMATAG, or UMATAY, a town of the island of Guam, in the East Indian sea, where vessels stop to refit.

UMBA, a town of Russia, in the government of Archangel, on the White sea. N. lat. $66^{\circ} 45'$. E. long. $29^{\circ} 14'$.

UMBA, *Lower*, a middle province of Matamba.

UMBA, *Upper*, the most northerly province of Matamba.

UMBAA, a town of Abyssinia; 100 miles S.S.W. of Gondar.

UMBAGOG LAKE, a lake of New Hampshire. N. lat. $44^{\circ} 38'$. W. long. $70^{\circ} 59'$.

UMBALLA, a town of Hindoostan, in the circar of Sirhind; 32 miles E.S.E. of Sirhind.

UMBEL, UMBELLA, in *Botany*, a Latin word, for a little shade, or umbrella, is used to designate a particular mode of inflorescence, thence called umbellate. (See UMBELLATE.) The *umbella* was formerly named in English *rundle*, probably from its *round* shape; but *umbel* is now universally adopted. This mode of inflorescence consists of several flower-stalks, or rays, nearly equal in length, spreading from a common point or centre, their summits forming a level, convex, sometimes globose, surface; more rarely, as in the Carrot, a concave one. When each ray is simple, and bears a solitary flower, the umbel is denominated simple, as in the Ivy and Cowslip, as well as in *Astrantia*, *Eriocalia*, and *Hydrocotyle*. A compound umbel, properly so called, has each of its principal rays terminating in another smaller umbel. Such, at least, is the case with those plants constituting the natural order of UMBELLATE; few of which, besides the three genera just mentioned, have simple umbels. Instances of compound ones are familiar in the Hemlock, Carrot, Parsley, &c. There are indeed other kinds of compound umbels, found in various other tribes of plants; as in *Euphorbia*, whose general umbel, in most of the species, is repeatedly subdivided, either in a threefold, or a forked manner. A CYME (see that article) is in the first instance a general umbel, though its partial stalks are irregularly subdivided. On the contrary, a panicle, whose primary ramifications are alternate, or irregular, sometimes has its ultimate ones umbellate, of which examples occur in *Vitis* and *Aralia*. We refer the reader to CYME, INFLORESCENCE, and GENUS, for remarks on the different conceptions of authors, respecting the nature of an umbel, referring further considerations of that kind for the article UMBELLATE. We have here only to add, that an umbel is sometimes naked, but much more generally accompanied by *bracteas*, or by a simple or compound involucre, not always constant, or uniformly present, even in the same species. The rays themselves are usually per-

manent, seldom deciduous, till long after the seeds have fallen.

UMBELLATE, a very natural order of plants, so named from its mode of inflorescence, (see UMBEL,) and constituting the forty-fifth order among the *Fragmenta* of Linnaeus. It is exactly equivalent to the *Umbellifera* of other writers, at least of such as are correct, being the sixtieth order in Jussieu's system, or the second of his twelfth class. The characters of that class are these. A superior *calyx* of one leaf. *Petals* several, definite, inserted upon the pistil, or upon the border of a gland crowning the germen. *Stamens* definite, distinct, inserted into the same part, being alternate with the petals, and equal to them in number. *Germen* inferior, simple; styles several, definite; stigmas as many. *Seeds* agreeing in number with the styles, either naked, or rarely inclosed in a seed-vessel, having a similar number of cells. *Coraculum* minute, oblong, at the top of a woody albumen. *Flowers* umbellate, that is, supported singly on numerous stalks, springing from the same point. *Umbel* either naked, or surrounded by a many-leaved involucre: and either simple, or composed of lesser, or partial, umbels, which likewise are sometimes naked, sometimes furnished with a partial involucre. The orders are two; 1. ARALIE, whose petals, styles, and seeds, are numerous, their fruit capsular or pulpy; and 2. UMBELLIFERE, of which we are about to treat.

Jussieu thus distinguishes the order in question. *Calyx* either entire or five-toothed. *Petals* five. *Stamens* five. *Styles* and *stigmas* two. *Fruit* perpendicularly separable into two seeds, various in shape, hanging by their summits to a central, thread-shaped, often deeply divided, axis or receptacle. *Flowers* disposed in little umbels, which are mostly collected into general umbels, each being either naked or furnished with involucre, and for the most part regular, in a few instances anomalous. The stem is often herbaceous, rarely shrubby. *Leaves* alternate, with sheathing footstalks; and either simple, or most frequently compound, with repeated subdivisions. The colour of the flowers is usually white, sometimes reddish or purplish; in a few instances yellow. *Lagoecia*, and we may add *Eriocalia*, are remarkable for a solitary seed, the style also being solitary in the former. We may add also, that *Eryngium* is singular for having the umbel condensed into a head, the flowers having no footstalks, forming the only exception to the umbellate inflorescence of the whole order.

Linnaeus fixes the character of his *Umbellate* in the five stamens, two styles, and two seeds, all umbellate flowers not being comprehended therein. But as *Eryngium* is not excluded, though destitute of a proper umbel, so neither are *Lagoecia* and *Eriocalia*, though having only solitary seeds. His general idea of the order agrees with Jussieu's, but he held a peculiar opinion of the umbel being in itself an aggregate flower. On this subject we have already said all that is necessary, under CYME. We proceed to the generic distinctions in this order, a subject of the greatest difficulty, because the order itself is so very natural. The species, as Haller observes, are easily discriminated. This author, and his pupil Crantz, follow Tournefort, in defining the genera by the seeds. Linnaeus holds this principle rather too cheap, adopting the plan of his friend Ardeii, who first suggested the use of the general and partial involucre for the purpose required. Hence he distributes the *Umbellate* into three sections. Those which have a general as well as partial involucre; those which have only a partial one; and those which have neither. Jussieu follows the same arrangement, only reversing the sections. The author of the *Flora Bri-*

lannica has not undertaken to reform this subject, though he has always objected to the principle on which it is founded. Like other Linnæan botanists, he adopts it, with many things besides, for present use. Gærtner, as might be expected, recurs to the seeds, but not with the happiest success.

Two ingenious writers have of late taken up this department of botany afresh, independent of each other; professor Hoffmann, late of Gottingen, now of Moscow; and professor Sprengel of Halle. The former finds his genera on the seeds and petals; the latter on the seeds alone, carrying into execution the principles of the late M. Cusson of Montpellier, whose premature death deprived the world of the fruit of his laborious studies on this subject.

Mr. Sprengel's sections are as follows. 1. Fruit compressed, flat. 2. Fruit rather solid, winged. 3. Fruit bladder. 4. Fruit coated. 5. Fruit armed. 6. Fruit solid, naked. This last section is subdivided into those whose fruit is linear-lanceolate, and those in which it is oblong-ovate, or quite ovate. Subordinate characters are afforded by the ribs of the seeds, and their interstices, which, after Cusson, are termed *vallæculæ*. *Latuscula* of these authors are the sloping sides of each seed, from the back to the *commisura*, or seam, where the edges of the two seeds meet. Professor Sprengel establishes 63 genera, and 371 species, in his *Prodromus*, published at Halle in 1813.

The *Umbellatæ* hitherto known are chiefly found in the temperate climates of the northern hemisphere, as Mr. Brown observes in his General Remarks on the Botany of Terra Australis, subjoined to captain Flinders's Voyage. Very few occur within the tropics, but the eminent botanist just quoted informs his readers, that those of Terra Australis, including a few *Araliæ*, exceed fifty species. These are mostly new. The singular genus *ERIOCALIA*, (see that article,) adopted in Sprengel's Prodr. 27, is one of them. Mr. Brown speaks of another genus, by the name of *Leucolena*, "worthy of notice on account of the great apparent differences of inflorescence, existing among its species;" which, however, prove, by his luminous explanation, to be only *apparent*.

We think it hardly necessary to mention the polygamous character of the flowers in some of this order, though that character is made to enter into the Linnæan generic distinctions. The central flowers, or central partial umbels, are most inclined to be male, the surrounding ones female, or at least most fertile. The petals of the latter are also most radiant, or dilated outwards.

Linnæus remarks, that the principal qualities of these plants reside in their roots, (often biennial,) and their seeds; the herbage, for the most part, being inactive. They contain an acrid aromatic, or caustic principle. Such as grow in dry places are most wholesome or safe, as well as most agreeable in flavour; those found in watery places are among the most virulent of all vegetable poisons; witness *Cicuta virosa* and *Oenanthe crocata*. Cultivation, in a dry or manured soil, renders some aquatic *umbellatæ* safe and wholesome, particularly the *Apium graveolens* of our ditches, which becomes, under proper treatment, the garden Celery.

UMBELLIFERÆ. See UMBELLATÆ.

UMBELLIFEROUS PLANTS, a name given to certain kinds, as all such as form and produce their flowers in the manner of an umbel, and which are principally of the herbaceous kinds, with some few of the tree sort, having the flowers in this mode either in the simple or compound form, rising with erect hollow stalks in the first description,

and mostly branching in the alternate method, and either simple-fingered, or winged. The chief sorts in the garden herb clafs are those of angelica, the different carrot kinds, the parsnip, parsley, the various kinds of celery, common fennel, dill, giant fennel, alexanders, coriander, carraway, Macedonian parsley, fampshire, eringo, &c. But besides these esculents for different culinary purposes, it belongs to some of the medicinal sort, and others which do not relate to the business of gardening. See KITCHEN-Garden Plants, and MEDICINAL Plants.

UMBELLUS, in *Ornithology*, a species of *Tetrao*; which see.

UMBER, OMBROS, or *Umbros*, in *Ancient Geography*, a lake of Italy, in Umbria; which, according to Scaliger, is the same with the *Vadimonis lacus* of Livy.

UMBER, or *Umbre*, in *Natural History*, a fofsil brown or blackish substance, used in painting, so called from *Ombria*, the ancient name of the duchy of Spoleto, in Italy, whence it was first obtained; diluted with water, it serves to make a dark-brown colour, usually called with us an hair-colour.

Dr. Hill and M. Da Costa consider it as an earth of the ochre kind. It is found in Egypt, Italy, Spain, and Germany; in Cyprus also it is found in large quantities; but what we have brought into England is principally from different parts of the Turkish dominions. But it might be found in considerable plenty also in England and Ireland, if properly looked after, several large masses of it having been thrown up in digging on Mendip-hills, in Somersetshire, and in the county of Wexford, in Ireland: it is also sometimes found in the veins of lead-ore, both in Derbyshire and Flintshire.

Mineralogists mention two kinds of umber; the one called "Cologne earth," which is a variety of peat or earthy-brown coal. In the vicinity of Cologne they work large beds of it, principally for fuel, and a considerable quantity is imported into Holland, where it is used for the adulteration of snuff, and a smaller quantity is employed by the paint-makers. Its colour is a somewhat pinkish-brown, and it is useful to the painter in water-colours. The second kind is known by the name of "Turkish umber," and appears to be a variety of the iron-ore, called brown iron-stone ochre. Klaproth analysed a specimen from Cyprus, and found that it contained

48	oxyd of iron.
20	oxyd of manganese.
13	filæ.
5	alumine.
14	water.

—

100

—

Wallerijs ranks the umber as a humus or mould, apprehending, by its immediately flaming in the fire, and by the smell which it emits, that it owes its colour to an admixture of bituminous parts. But M. le Baron de Hupfel (Berlin, Mem. 1771) has discovered it to be a fofsil wood, filled with a bituminous juice. It is found in two different states, first, as retaining the form of wood, which it has preserved by means of a bituminous matter that has prevented the rotting of the wood; and secondly, as a powder, like that into which the first kind, that still retains the form of the wood, easily crumbles.

It is certain, however, says Mr. Kirwan, that the name hath been also given to a sort of brown ochre, which becomes

comes red when slightly heated, but in a stronger heat is again brown and magnetic, and in a still stronger, melts into a black glass. It does not effervesce with acids before roasting, but after that the martial part is soluble. Elem. Mineral, p. 78.

This substance, when burnt, makes a good shade for gold. It need only be put into the naked fire in large lumps, which should not be taken out till they be thoroughly red-hot.

UMBER, or *Ombre*, in *Ichthyology*, an English name for a fish of the truttaceous kind, more commonly called the *grayling*, and by the authors in ichthyography, *thymallus*, a fresh-water fish of a very fine taste.

UMBERPATTONS, in *Geography*, a town of Hindoostan, in Boggricumd; 20 miles S.S.W. of Rewah.

UMBERSTON CREEK, a river of Virginia, which runs into the Potomack, N. lat. 39° 35'. W. long. 78° 6'.

UMBILICAL, in *Anatomy*, an epithet applied to the arteries and veins which pass through the umbilicus. See EMBRYO.

UMBILICAL *Region*, is that part of the abdomen lying round the umbilicus, or navel.

UMBILICAL *Rupture*, a rupture or protrusion of the bowels at the navel. The disease is frequently called by surgeons *exomphalos*; which see. Also see HERNIA.

UMBILICALIS *Funiculus*, popularly called the *navel-string*. See EMBRYO, FUNIS, and LAPOUR.

UMBILICAL *Points*, in *Mathematics*, the same with *foci*. See FOCUS.

UMBILICAL *Vessels of Vegetables*, in *Agriculture and Gardening*, a term lately applied by some writers, as Darwin, to the small vessels which pass from the heart part of the seed into the side seed-lobes, and there imbibe the solution of saccharine, farinaceous, or oily matter, which is prepared and deposited in them for the nourishment and support of the new vegetable in its germination and infant growth. They are consequently supposed to perform the important office of supplying nutrition to the young plant, and of oxygenating, or affording the oxygene principle of the air to the vegetable juice, sap, or blood, and thereby to be of very material use in the sprouting and vegetation of grain, seeds, and buds. See VEGETATION, and VITAL Air.

UMBILICARIA, in *Botany*, a genus of the *Lichen* family, so called by Hoffmann, from the rounded depressed figure of its frond, whose centre is firmly attached to the rocks, by a central root, like an umbilical cord. This genus consists of the *Lichenes umblicate* of Linnæus, and is now called *CYROPHORA*; see that article. Nineteen species are described in the most recent publication of professor Acharius, *Synopsis Methodi Lichenum*, p. 63—69.

UMBILICATED, in *Gardening*, a term which signifies and is applied to those sorts of fruit and leaves which are navel-shaped, or formed in the manner of that part. This is the case in fruit of the apple and pear kinds, as well as some others, in which one or both ends are hollowed in a navel-like manner. Also in some leaves, as those of the petlate or target-formed sort, which are fashioned or shaped in a manner somewhat similar to that of the navel, at the part or place where the footstalk is inserted, which is commonly about the middle, on the under side, but in some instances above.

UMBILICUS, in *Anatomy*, the navel, a round opening in the linea alba, for the passage of the umbilical vessels of the fœtus. Its situation is marked by a depression, after the cord has separated, produced by the inflection of the integuments. See OBLIQUUS.

UMBILICUS, in *Mathematics*, the same with *focus*.

UMBILICUS *Marinus*, a name given to a small oval body of a shelly matter, from its resemblance to the human navel. It is properly the operculum of a shell-fish, serving to close up the aperture of the shell in the buccinum, and other turbinated shells; and to that purpose it is fixed to the anterior extremity of the body of the animal; so that when it retracts its body into the shell, this naturally fills up the mouth of it: it is convex on one side, and flat on the other; the convex side is plain and white, the flat side is yellowish or reddish, and marked with a spiral line. See CONCHOLOGY.

It is said by authors to have great virtues as an abortif and astringent; but it is not used at present in the shops, though it holds a place in the catalogues of the *Materia Medica*, as well of our own as other nations.

UMBILICUS *Veneris*, in *Botany*. (See COTYLEDON.) The English name of the same import, Venus's Navel-wort, is applied to the *Cynoglossum linifolium*, on account of the little hollow, or depression, in each of its beautiful seeds.

UMBINUS, among the *Ancients*, a kind of coin current in Gallia Narbonensis.

UMBRA, or, as some write it, *Umbra*, in *Ichthyology*, the name of a fish of the truttaceous kind, and nearly allied to the falmon.

It is the *salmo umbra* of Linnæus, with the lateral lines bent upward, and a bifurcated tail. See SALMO.

There are four species of this fish mentioned among naturalists; but the *umbra prior* and *umbra altera* of Rondeletius, which are two of them, seem only to be the different sexes of the same fish. These are considerably large, very like the common falmon, but have blue backs and yellow bellies. The third is the fish commonly called the *salvelin*, or *salmo salvelinus* of Linnæus, with the upper jaw longer than the other: and the fourth is the *red charr*. Willughby's Hist. Pisc. p. 198.

UMBO, in *Antiquity*, the round protuberant part of a shield.

UMBO, in *Geography*, a lake of Russia, in the government of Archangel. N. lat. 67° 40'. E. long. 29° 14'.

UMBONE, or HORN, among *Florists*, signifies any pointed style, or pistil, in the middle of a flower.

There is also an umbone called *double-pointed*, or *biparted*, as in the prony; and sometimes the umbone has four sharp points, in which case it is termed, an umbone divided into so many heads, or cut into three or four parts.

UMBOYNA, in *Geography*, a town of Nubia; 50 miles S. of Gooz.

UMBRA, SHADOW. See LIGHT, SHADOW, PENUMBRA, &c.

UMBRA, in *Ancient Geography*, a small river of Italy, in Etruria.

UMBRA, in *Geography*, a river of America, which runs into the Wabash, N. lat. 38° 38'. W. long. 88° 12'.

UMBRA, in *Ichthyology*, the name of a sea-fish caught in the Mediterranean, and brought to the markets in Italy and other places; called by some *chromis*, and by the Venetians *carvo*.

Its usual size at market is about twelve or fourteen inches in length; but it grows to sixty pounds weight, and to the length of five or six feet. It is of a somewhat flattened figure, and its back is ridged and rises up from the head. It something resembles the carp in its general figure, but is broader. It is very elegantly coloured, for there are a number of long oblique lines covering its whole sides, which are alternately of a fine pale blue, and a beautiful yellow. Its scales are moderately large, and its coverings of the gills, and great part of its very head, as well as its body, are covered with these; its head is moderately large, but its mouth small, and

it has a single beard hanging down from its chin. Rondelet. de Pisc. p. 182. See SCIÆNA.

UMBRA, in *Zoology*, a species of lacerta. See LIZARD.

UMBRA TILIS PUGNA, the fighting with one's own shadow.

This was one of the kinds of exercise much recommended by the ancient physicians; they ordered the person who used it, not only to box, but to wrestle, with his shadow; that is, not only to use his arms, but his legs also, and often to put himself into a leaping posture, and throw his body violently forward, and often to retreat hastily backwards. The custom seems to have been of ancient date; Plato expressly mentions it, and St. Paul seems to allude to it in the passage where, glorying in the reality of his conflicts, he says he does not fight as one who beats the air. The physicians greatly recommended this exercise to people of sedentary lives, and to those who had weak nerves, and were afflicted with tremors. They esteemed it useful also in diseases of the kidneys, and of the thorax.

UMBRE, in *Minerology*. See UMBER.

UMBRE, in *Ornithology*. See SCOPUS.

UMBRELLA, in *Rural Economy*, a well-known shade or guard from the sun or rain, formed by stretching silk, canvas, or any other linen or woollen stuff, over elastic strips of whalebone, so disposed as to diverge from a central point and make a circular covering, which may be means of a rod or staff passing through the centre be held over the head, when occasion requires it, or which may be drawn up round this rod and conveniently carried in the hand. These temporary guards from heat or wet have not long been introduced into our country, but they have been found to be convenient and useful that they are now become very common. They seem to have been of much more ancient use in the East. M. de la Loubere, who was envoy extraordinary for the French king to the king of Siam, in the years 1687 and 1688, informs us in his "New Historical Relation of the Kingdom of Siam," a translation of which into English was printed at London in 1693, that the use of umbrellas, in Siamese Rour, was a favour which the king of Siam did not grant to all his subjects, although the umbrella be permitted to all the Europeans. Those which are like to ours, or which have only one round, were the least honourable, and were used by most of the Mandarins. Those that had more rounds about the same handle, as if they were several umbrellas fixed one upon another, were for the king alone. Those which the Siamese called "clot," and which had only one round, having two or three painted cloths suspended from them, one lower than the other, were granted by the king of Siam to the "Sanrats," or superiors of the "Talapoins." Those which he gave to the king's ambassadors were of this last sort, and had three cloth hangings. The Talapoins had umbrellas in the form of a screen, which they carried in their hands. They were formed of a kind of palmetto leaf cut round and folded, and the folds were tied with a thread near the stem, and the stem was made crooked like an S, and served for a handle. In the Siamese language they called them "Talapat," and it is probable, says Loubere, that from hence comes the name of "Talapai" or "Talapoins," which is in use only among foreigners, and which is unknown to the Talapoins themselves, whose Siamese name is "Tchaou-cou."

An umbrella, held in a proper position over the head, may serve to collect the force of a distant sound by reflection, in the manner of a hearing-trumpet; but its substance is too slight to reflect any sound very perfectly, unless the sound fall upon it in a very oblique direction. The whispering gallery at St. Paul's produces an effect nearly similar,

by a continual repetition of reflections. Mr. Charles's paradoxical exhibition of the invisible girl has also been said to depend on the reflection of sound; but the deception is really performed by conveying the sound through pipes, artfully concealed and opening opposite to the mouth of the trumpet from which it seems to proceed. Young's Philosophy.

UMBRELLA-Tree, in *Gardening*, the common English name of a very ornamental tree. See MAGNOLIA.

UMBRETTA, in *Ornithology*. See SCOPUS.

UMBRIA, in *Ancient Geography*, a large country of Italy, bounded on the N. by a part of Gallia Cispadana, on the N.E. by the Adriatic gulf, on the E. by Picenum, and on the W. by the Apennines, which separated it from Etruria. This country, which was very mountainous, contained in its northern part the Senonoi. It was divided into two parts by the Apennines, and took its name, as some have said, from the Greek *Ομβροσ*, *Imber*, because, as they say, without sufficient reason, rain inundates this country. Propertius says of it:

"Proxima supposito contingens Umbria campo
Me genuit terris fertilis uberibus."

Ptolemy mentions several towns as belonging to this country, the names of several of which are now unknown. To the N. of this country lies the Rubicon, which serves as a boundary to Italy, properly so called.

UMBRIA, in *Geography*. See SPOLETO.

UMBRIATICO, a town of Naples, in Calabria Citra, the see of a bishop, suffragan of St. Severina; 57 miles E. of Colofza. N. lat. 39° 27'. E. long. 17° 6'.

UMBRINO, in *Ichthyology*, a name used by some authors for the *coracinus*, or *umbra*, as some call it. The *umbri* has by some been esteemed a distinct species of fish from the *coracinus*; but they seem to differ no other way than as the one is the older, the other the younger fish. Willughby's Hist. Pisc. p. 330.

UMBRO, OMBRO, or OMBRONE, in *Ancient Geography*, a river of Italy, in Etruria, commencing N.E. of Seuz, and discharging itself into the sea near Rusellæ.

UMBUNCULUS, in *Natural History*, a name given by ancient authors to the small prominences on the surfaces of certain stones. It was originally derived from the word *umbo*, which expresses the prominent knob, or round lump in the centre of a shield; and its first use that we find in the naturalists is, in expressing a very familiar thing; that is, the prominent part of the *zmilampis*. This was a stone of the nature of what we call *oculis beli*, or *bellocbio*, and was of a white ground, and roundish figure, somewhat resembling an eye. It was found in the Euphrates, and other rivers, and had always an umbunculus of a glaucous or bluish colour. This umbunculus was a prominent round spot, such as we see in our *oculi beli*, and call the *pupil*. It was afterwards used to express the inequalities on the surfaces of flints and agates, which frequently are roundish and obtuse, and represent a kind of umbones.

UMDOOM, in *Geography*, a town of Nubia; 10 miles N. of Chiggré.

UMEA, a sea-port town of Sweden, in West Bothnia, at the mouth of a river of the same name, in the gulf of Bothnia, built by Gustavus Adolphus, with a good harbour. This town was twice burned by the Russians in the beginning of the 18th century. N. lat. 63° 52'. E. long. 20° 4'.

UMEABY, a town of Sweden; 60 miles N.W. of Umea.

UMELHEDEGI, a town of Africa, in the country of Tailet; 66 miles S.W. of Sugulmeffa.

UMEL-

UMELHEFEL, a town of Africa, in the country of Tafflet; 40 miles S.W. of Sugulmeffa.

UMEMGIVEAIBE, a town of Africa, in the kingdom of Fez.

UMENAK, an island on the W. coast of East Greenland. N. lat. $60^{\circ} 35'$. W. long. $45^{\circ} 30'$.—Also, an island on the S.W. coast of East Greenland. N. lat. $59^{\circ} 43'$. W. long. $43^{\circ} 20'$.—Also, an island near the W. coast of West Greenland. N. lat. $61^{\circ} 55'$. W. long. $48^{\circ} 25'$.

UMIAK, a river of Russia, which runs into the Viatka, 20 miles S. of Marmalisch, in the government of Kazan.

UMMA, or AMMA, in *Ancient Geography*, a town of Palestine, in the tribe of Apher. Josh. xix. 30.

UMMANTZ, in *Geography*, a small island in the Baltic, near the W. coast of the island of Rugen. N. lat. $54^{\circ} 30'$. E. long. $13^{\circ} 14'$.

UMMENDORF, a town of Westphalia, in the duchy of Magdeburg; 24 miles W. of Magdeburg.

UMMERSTADT, a town of the principality of Coburg; 5 miles W. of Coburg.

UMPIRE, a third person, chosen to decide a controversy, left to an arbitration, in case the arbitrators cannot agree. See ARBITRATOR.

Minfew supposes the word formed of the French *un père*, a father. Some call him a *sur-arbitrator*.

UMPLE, in our *Statutes*, signifies fine linen. 3 Ed. IV. cap. 5. Blount.

UMREVISKOI, in *Geography*, a town of Russia, in the government of Tobolsk, on the Oby; 88 miles S.W. of Tomsk.

UMRITA, or AMRITA, the Sanscrit name of a precious elixir, that, according to Hindoo fables, confers immortality on those who quaff it. This word, and the legends connected with it, remind us strongly of the Ambrosia of Western poets. There can, indeed, be little doubt of a common derivation, or of one being borrowed from the other. In the Sanscrit language its root is traceable to *mrit*, meaning mortality: *a* being a privative particle. Immortal is, therefore, a strict translation of the compound.

With the Hindoos, as with the Greeks, the subject of this article furnishes an endless source of poetical allusion. Both people had the notion that the moon was a vase of this quintessence, which both sometimes confound with amber and ambergis. (See SOMA.) Under our article KURMAVATARA, a brief relation is given of the churning of the ocean by gods and demons for the purpose of recovering the beverage of immortality, which appears to have been lost by the iniquities of the antediluvian world. For farther information as to the fabulous origin and history of the Amrita, we refer to the notes to Wilkins's *Gita*, and the second article of the 11th vol. of the *Asiatic Researches*, by major Wilford.

When the gods shared among themselves the precious things gained in the churning process above alluded to, Indra, regent of the firmament, obtained the Umrta, hence probably the name of his city Umravati; for we find several places still similarly named: Umrapura, the metropolis of Ava (see AVA); Umrutir, or Amritsar, the capital of the Sikh nations, and others, might be instanced. Perhaps too the cave and village of Amboly, on the island of Salfette, may be hence derived. This beautiful cavern temple is fast mouldering to decay, and no good description of it has yet been given. There is also a respectable town about 40 miles S.E. from Poonah called Amravaty.

UMRUT, in *Geography*, a town of Hindooistan, in Guzerat; 18 miles E. of Pennalla.

UMSEQUIR, a town of Africa, in the desert of Barca; 20 miles E. of Siwah.

UMSTADT, a town of Hesse Darmstadt; 10 miles E. of Darmstadt.

UNA, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana, the mouth of which, according to Ptolemy, is between Suriga and the outlet of the river Agna.

UNA, in *Geography*, a town of Hindooistan, in Guzerat; 20 miles S.S.E. of Chitpour.—Also, a town of Brazil, in the government of St. Paul; 50 miles S.E. of St. Paul.

UNADILLA, a post-township of America, in New York, situated in the extreme southern angle of Otsego county, 100 miles S. by W. from Albany; bounded N. by Butternuts and Otego; E. by Otego; S.E. by Susquehanna river, or the county of Delaware; and W. by the Unadilla, or the county of Chenango. Its area is supposed to be about 65 square miles. The surface is hilly and uneven, but along the streams that form the boundaries, and also some smaller ones, the land is very good and productive. The uplands and hills also afford fine grazing and meadow lands. Several small streams furnish mill-leats, which are numerous. Here are a quarry of stones used for grinding, sixteen saw-mills that prepare lumber conveyed to the Baltimore market on rafts upon the Susquehanna, five grain-mills, an oil-mill, and other water-works, and five distilleries of whiskey. Here are one episcopal church, and fourteen school-houses. In 1810, the whole population consisted of 1426 persons, with 116 senatorial electors, 341 taxable inhabitants, and 141,896 dollars of taxable property.

Unadilla Village is pleasantly situated on the Susquehanna, and contains an episcopal church and 30 dwellings, besides stores, &c.

UNALASHKA. See OONALASHKA.

UNALGA, one of the Fox islands; 15 miles S.E. of Unalaska.

UNAMAK. See OONAMAK.

UNAMIS, a tribe of Delaware Indians.

UNAMPELLY, a town of Hindooistan, in Mysore; 15 miles S.W. of Gooty.

UNANIMITY OF JURIES. See JURY.

UNANNEALED BOTTLES, or *Bologna Bottles*, a kind of unannealed glass bottles made at Bologna, and many other places, in the year 1742, which, though appearing very strong, yet are to be broken by a fragment of flint, scarce larger than a grain of lead, thrown into them. See *Annealing of GLASS*.

UNARA, in *Geography*, a river of South America, which serves for a line of division between the governments of Caraccas and Cumana. It is navigable as far as the village of San Antonia de Clarinas, six leagues from the sea. Its course extends about 30 leagues from S. to N.

UNAROTA, among the *Ancients*, a carriage with only one wheel.

UNAU, in *Zoology*, a name given by Buffon to the *BRADYPUS didactylus*; which see. See also SLOATH;

UNAWA, in *Geography*, a town of Hindooistan, in Guzerat; 12 miles S.E. of Puttan.

UNBALLAST, *To*, in *Sea Language*, is to discharge the ballast of a ship.

UNBENDING, generally implies the act of taking off the sails from their yards and stays; or of casting loose the anchors from their cables, or of untying one rope from another.

UNBIAK, or SEMISKOSCHNOI, in *Geography*, one of the Fox islands, in the North Pacific ocean, about 72 miles in circumference. N. lat. $53^{\circ} 40'$. E. long. $179^{\circ} 14'$.

UNBITTING, in *Sea Language*, denotes the operation of removing the turns of a cable from off the bits.

UNCARIA, in *Botany*, so named by Schreber, from *uncus*, a hook, alluding to the hooked prickles of the stem in one species. See NAUCLEA.

UNCASING, among *Hunters*, the cutting up or flaying of a fox.

UNCASTILLO, in *Geography*, a town of Spain, in Aragon, on the Rignel; 12 miles N. of Exea.

UNCATA, in *Botany*, a name given by some authors to the stramonium, or thorn-apple.

UNCEASESATH, in our *Old Writers*, an obsolete word, used where one killed a thief, and made oath that he did it as he was flying for the fact, and thereupon *parentibus ipsius occisi juret unceasesath*, viz. that his kindred would not revenge his death; or they swore that there should be no contention about it.

Du-Cange derives the word from the negative particle *un* and the Saxon *ceath*; which last signifies the same with *affirmation* in the law of Scotland.

UNCERTAIN, in the *Manege*. We call a horse uncertain that is naturally restless and turbulent, and is confounded in the manege he is put to, so that he works with trouble and uncertainty.

UNCHÆ, in *Ancient Geography*, a town of Asia, in Aſyria, about two stages from the road of the fraits at the entrance into this province. Quintus Curtius.

UNCHASAIR, in *Geography*, a town of Hindoostan, in the subah of Delhi; 10 miles S.S.E. of Secundara.

UNCIA, a term generally used for the twelfth part of a thing. In which sense it occurs in Latin writers, both for a weight called by us an *ounce*, and a measure called an *inch*. See OUNCE. See also MEASURE and WEIGHT.

UNCIA, in *Zoology*, a species of *Felis*; which see.

UNCIA *Terræ*, or *Agri*, is a phrase frequently met with in the ancient charters of the British kings; but what the quantity of ground was is a little obscure. All that we know for certain is, that it signified a large quantity, as much as twelve modii, which modius some conjecture to have been an hundred feet square.

UNCLÆ, in *Algebra*, are the numbers prefixed to the letter of the members of any power produced from a binomial, residual, or multinomial root: now usually called *co-efficients*.

Thus, in the fourth power of $a + b$, that is, $a^4 a a a + 4 a a a b + 6 a a b b + 4 a b b b + b b b b$, the unciæ are $\frac{4}{3}, 6, 4$.

Sir Isaac Newton gives a rule for finding the unciæ of any power arising from a binomial root. Thus: let the index of the power be called m , then will the unciæ arise

from such a continual multiplication as this, viz. $1 \times \frac{m-0}{1}$

$\times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5}$, &c. Thus, if the

unciæ of the biquadrate or fourth power were required;

the rule is, $1 \times \frac{4-0}{1} (= 4) \times \frac{4-1}{2} (= 6) \times \frac{4-2}{3}$

$(= 4) \times \frac{4-3}{4} (= 1)$; which shews that the unciæ are

$1, 4, 6, 4, 1$.

Or thus: The terms of any powers are compounded of certain little factums, with numbers, called unciæ, prefixed; and the factums are found by making two geometrical progressions; the first of them beginning from

the required power of the first part of the root, and ending in unity; and the second beginning with unity, and ending in the required power of the second part; thus, for a sixth power of $a + b$;

$$\begin{matrix} a^6 a^5 a^4 a^3 a^2 a^1 & \text{first series.} \\ 1 b b^2 b^3 b^4 b^5 b^6 & \text{second series.} \end{matrix}$$

And multiplying the terms of the same order in either series into one another; as $a^c + a^b + a^1 b^2 + a^1 b^3 + a^2 b^3 + a b^4 + b^6$, out of which the sixth power of $a + b$ is compounded.

The unciæ, then, are found by writing the exponents of the powers of the second series, *i. e.* of b , under the exponents of the powers of the first series, *i. e.* of a ; and taking the first figure of the upper series for the numerator, and the first of the lower for the denominator of a fraction, which is equal to the unciæ of the second term, and so for the rest. Thus, for the sixth power, we have,

$$\begin{matrix} 6 & 5 & 4 & 3 & 2 & 1 \\ 1 & 2 & 3 & 4 & 5 & 6 \end{matrix}$$

Accordingly, $\frac{6}{1} = 6$ is the unciæ of the second term of the

sixth power; $\frac{6 \cdot 5}{1 \cdot 2} = \frac{30}{2} = 15$, the unciæ of the third term;

$\frac{6 \cdot 5 \cdot 4}{1 \cdot 2 \cdot 3} = \frac{120}{6} = 20$, the unciæ of the fourth term;

$\frac{6 \cdot 5 \cdot 4 \cdot 3}{1 \cdot 2 \cdot 3 \cdot 4} = \frac{6 \cdot 5}{1 \cdot 2} = \frac{30}{2} = 15$, the unciæ of the fifth term;

$\frac{6 \cdot 5 \cdot 4 \cdot 3 \cdot 2}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} = \frac{6}{1} = 6$, the unciæ of the sixth term;

$\frac{6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5 \cdot 6} = 1$, the unciæ of the last power. See

BINOMIAL Theorem.

UNCIAL, UNCIALIS, an epithet which antiquaries give to certain large-sized letters, or characters, anciently used in inscriptions and epitaphs.

The word is formed from the Latin *uncia*, the twelfth part of any thing, and which, in geometrical measure, signified the twelfth part of a foot, viz. an inch; which was supposed to be the thickness of the stem of one of these letters.

UNCIFORME OS, in the carpus, is the fourth bone of the second row; it has its name from the Latin *uncus*, a hook, and is composed of a body, and a hooked, or unciform, apophysis. See *Carpus*, under EXTREMITIES.

UNCINARIA, in *Zoology*, a genus of the Vermes Intestina, the characters of which are, that the body is filiform and elastic, obsoletely nodulous forward; with angulated membranaceous lips; the tail of the female is aculeated, and that of the male armed with two cuspidated hooks inclosed in a pellicular bladder. There are two species, one lodging in the thick intestines of the badger, and the other in those of the fox.

UNCINIA, in *Botany*, from *uncus*, a hook, because of the barbed or hooked awn, on which the generic distinction is founded.—“*Perf. Syn. v. 2. 534.*” Brown Prodr. Nov. Holl. v. 1. 241.—Class and order, *Monocotyledonaria Triandria*. Nat. Ord. *Calamaria*, Linn. *Cyperoidea*, Juss. *Cyperaceae*, Brown.

Eff. Ch. Male, Glumes imbricated every way, single-flowered. Corolla none.

Female, in the lower part of the same spike, Glumes imbricated every way, single-flowered. Corolla of one leaf, capsular,

capful, contracted at the mouth, scarcely divided, permanent. Awn inserted into the receptacle, beneath the germen, longer than the corolla, hooked. Nut inclosed in the enlarged corolla.

Mr. Brown observes, that this genus differs from *Carex* merely in the presence of the awn, which by no means originates from the base of each scale, as described by Willdenow, Sp. Pl. v. 4. 209, and by Perton; but from the receptacle, within the corolla, termed by Mr. Brown perianth, on the outermost side. Hence, we would remark, a new difficulty occurs respecting the true denomination of the part here called by us corolla, which we have always taken for a tunic, *arillus*, but which cannot be such, if separated from the seed by the awn, a part belonging to the flower.

1. *U. compta*. Br. n. 1.—“Spike oblong, dense, many-flowered. Lowest scale awned. Fruit densely imbricated, perfectly smooth. Stem smooth. Leaves flat, straight.”—Found by Mr. Brown, in Van Diemen’s island.

2. *U. riparia*. Br. n. 2.—“Spike thread-shaped, rather loose, of few flowers. Lowest scale like the rest. Fruit alternate, half-imbricated, lanceolate, ribbed, perfectly smooth. Angles of the stem rough. Leaves flat, flaccid.”—From the same country.

3. *U. australis*. Br. under n. 2? (*Carex uncinata*; Linn. Suppl. 413. Willd. Sp. Pl. v. 4. 209. See *CAREX*, n. 12.)—Spike thread-shaped, dense, many-flowered. Lowest scale leafy-pointed. Fruit lanceolate, scarcely ribbed. Stem smooth. Leaves flat. Awn twice the length of the glume.—Native of New Zealand. We presume this must be what Mr. Brown means by *U. australis*, though we can find no pubescence about the top of the fruit, which he indicates as the chief distinction between this species and the last, except its longer spike.

4. *U. phleoides*. (*Carex phleoides*; Cavan. Ic. v. 5. 40. t. 464. f. 1. C. hamata; Swartz Prodr. 18. Willd. Sp. Pl. v. 4. 209. C. uncinata *b*; Swartz Ind. Occ. 84. Schkuhr Car. 13. t. G. f. 30. See *CAREX*, n. 11, by mistake printed *humata*.)—Spike thread-shaped, elongated, dense, many-flowered. Fruit oblong, with three fringed angles. Awn thrice the length of the glume.—Native of Jamaica, Chili, and the island of Mauritius.

5. *U. erinacea*. (*Carex erinacea*; Cavan. Ic. v. 5. 40. t. 464. f. 2. Willd. Sp. Pl. v. 4. 210. See *CAREX*, n. 13.)—Spike cylindrical, dense. Fruit roundish, triangular, smooth. Awn five times the length of the glume.—Native of Chili, and Brazil near Montevideo. The spike measures about an inch and a half, being only about one-third the length of the last, though full as thick as in that species.

6. *U. tenella*. Br. n. 3.—“Spike thread-shaped, of few flowers. Scales uniform, deciduous. Fruit somewhat imbricated, lanceolate, smooth. Stem slender, with smooth angles. Leaves flaccid, nearly bristle-shaped.”—Gathered by Mr. Brown, in the island of Van Diemen.

UNCINUS, in *Surgery*, the name of a small hooked instrument, serving for many purposes.

UNCKEL, in *Geography*, a town of Germany, on the right bank of the Rhine; 2 miles N. of Lintz.

UNCORE, or UNQUES *Prisb, still ready*, in *Law*, a plea for the defendant, being sued for a debt due on a bond at a day past, to save the forfeiture of his bond, &c. by affirming that he tendered the debt at the time and place, and that there was none to receive it; and that he is yet also ready to pay the same.

UNCTION, UNCTIO, the act of anointing, or rubbing with oil, or other fatty matter.

VOL. XXXVII.

Mercurial unction, properly applied, brings on a salivation. The furgeons cure divers wounds, ulcers, &c. by repeated unctions, with oils, unguents, cerates, &c.

UNCTION, in *Matters of Religion*, is used for the character conferred on sacred things by anointing them with oil.

Anciently in the eastern countries, which abounded so much in oil and odoriferous spices, it was the custom to separate persons and things designed for extraordinary offices or uses, by anointing them with ointments composed of such ingredients; symbolizing thereby, both an effusion of the necessary gifts to qualify them for their office, and a diffusion of the good and grateful effects expected from them.

There were three sorts of persons to whom this unction, or consecration, especially belonged, kings, priests, and prophets; who, therefore, are all of them (says Barrow) styled in scripture the *Lord’s anointed*.

The unction of kings is supposed to be a ceremony introduced very late among Christian princes: Onuphrius says, none of the emperors were ever anointed before Justinian, or Justin. The emperors of Germany took up the practice from those of the eastern empire. King Pepin of France was the first king who received the unction.

Unction, although we have no scripture warrant for it, is one of those rites that succeeded baptism in the ancient church. Of unction, or chrismation, Tertullian (*De Baptism.*) says, “as soon as we are baptized, we are anointed with the blessed unction,—an external unction is poured upon us, but it is spiritually profitable.” And Cyprian also says (*Epist.* 70. § 3.), “he that is baptized must of necessity be anointed, that having received the chrism or unction, he may be the anointed of God, and have in him the grace of Christ.” Under this chrismation was comprehended signation, or the signing of the baptized person with the sign of the cross, which the minister performed with this ointment or chrism. See Tertullian, *de Resurrect. Carnis*, and Cyprian, *de Unct. Eccles.* § 16. To signation succeeded imposition of hands, or that which is now termed *confirmation*; which see. The ceremony of unction was derived from the Jewish rites, and was employed in the installment of the high priest, to denote his sacerdotal consecration to the service of God. The unction of Christ by God the father, in consequence of which he was called Christ, or anointed, was urged as a plea for this carnal and external unction by Tertullian, *ubi supra*.

In the Romish church, besides an unction at baptism, on the forehead, and at confirmation, on the head (see *CHRISM*), they have an *extreme* unction, given to people in the pangs of death, on the parts where the five senses reside, being the parts by which the person is supposed to have sinned.

The first mention that is made of this ceremony is by pope Innocent I. Sacred oil, indeed, was held in great veneration so early as the fourth century, and esteemed as a universal remedy; for which purpose it was either prepared and dispensed by priests and monks, or was taken from the lamps which were kept burning before the relics of the martyrs. But in none of the lives of the saints before the ninth century is there any mention made of their receiving extreme unction, though their deaths are sometimes particularly related, and their receiving the eucharist is often mentioned. But from the seventh century to the twelfth, they began to use this anointing of the sick, and a peculiar office was made for it; but the prayer that was used in it plainly shews that it was with a view to their recovery, for which purpose it is still used in the Greek church. But because it failed so often, that the credit of

this rite was in danger of suffering much in the esteem of the world, they began, in the tenth century, to say that it did good to the soul, even when the body was no better for it; and then they applied it to the several parts of the body, after having originally applied it to the diseased parts only. In this manner was the rite performed in the eleventh century. In the twelfth, the prayers that had been made before for the soul of the sick person, though only as a part of the office (the pardon of sin being supposed to be preparatory to their recovery) came to be considered as the most essential part of it. After this the schoolmen brought it into shape, and then it was decreed to be a sacrament by pope Eugenius; and it was finally established at the council of Trent. Burnet on the Articles, p. 268. See *EXTREAM UNCTION*.

UNCTORES, among the Romans, servants whose employment it was to anoint their master when he batedh.

UNCTUARIUM, a room in the ancient baths, where people were anointed before they went away.

UNCUS, among the Romans, an instrument used in torturing criminals. It was a kind of club, bent and inclined to one side.

UNCUTH, *Unknown*, is used in the ancient Saxon laws, for him that comes to an inn, guest-wife, and lies there but one night. In which case, his host was not bound to answer for any offence he committed, of which he was guiltless himself.

“Prima nocte potest dici uncuth; secunda vero, guest; tertia nocte hoghenine.” *Bracton*, lib. iii. See *THIRD night awn hynd*.

UNDALUS, in *Ancient Geography*, a town, according to Strabo, of Gallia Narbonensis, at the place where the river Selge (Sorgue) discharges itself into the Rhône. Livy calls it Vindalium, which probably is the true name, and undalus a corruption.

UNDE, **UNDEE**, or *Undy*, in *Heraldry*. See *WAVED*. *UNDE nihil habet*, in *Law*, a writ of dower. See *DOTÉ unde nihil habet*.

UNDEARCORE, in *Geography*, a town of Hindoostan, in the eircar of Ruttunpour; 40 miles S.W. of Ruttunpour.

UNDECAGON, is a regular polygon of eleven sides.

UNDECIMVIR, a magistrate among the ancient Athenians, who had ten other colleagues, or associates, joined with him in the same commission.

The functions of the undecimviri at Athens were much the same as those of the prévôts de marcheau in France. They took care of the apprehending of criminals; secured them in the hands of justice; and when they were condemned, took them again into custody, that the sentence might be executed on them.

They were chosen by the tribes, each tribe naming its own; and as the number of tribes, after Callisthenes, was but ten, which made ten members, a scribe or notary was added, which made the number eleven.—Whence their name, α ἑνδεκά, or *undecimviri*, as Cornelius Nepos calls them in the life of Phocion. In Julius Pollux they are denominated ἑκατόνταροι, and ἑκατομύδαροι. See *NOMOPHYLACES*.

UNDENAS, in *Geography*, a town of Sweden, in West Gothland; 81 miles E.N.E. of Uddevalla.

UNDER the Sea, in the *Sea Language*. A ship is said to be fo, when she lies still, or waits for some other ships, with her helm lashed, or tied up a-lee. See *LYING under the Sea*.

UNDER-CHAMBERLAINS, or *Deputy-Chamberlains of the Exchequer*, officers there, who cleave the tallies, and read the same; so that the clerk of the pell, and the comptrollers of it, may fee that the entries are true.

They also make searches for all records in the treasury, and have the custody of Domeday-book.

UNDER-CURRENT. See *Under-CURRENTS*.

UNDERDENGARDE, in *Geography*, a town of Hindoostan, in Coimbetore; 40 miles W. of Ardenelli.

UNDER-DITCHING, in *Agriculture*, a term applied in some districts, as that of the county of Essex, to such ditches as are formed for the purpose of taking away the surface wetness of land. In some places it is called land-ditching by the farmers. It is said to be one of the most beneficial and permanent modes of improving land that is not commonly known. It is much practised in different parts of the above county, and with perfect success, there being no sort of husbandry from which the land derives greater advantage. So that it is not unusual for the farmer to extend the practice over almost the whole of his land, in this district. Where this practice is intended, it is first to be considered, whether the soil be sufficiently open and porous for receiving a benefit adequate to the expence of performing it, as in very strong land this sort of ditching is not found to answer. However, in cases where the wetness can sink in a ready manner to eighteen or twenty inches in the land, the farmer may safely draw a furrow from the highest to the lowest part of the field, then dig out a spit of earth below, and again with a tool three inches wide, contrived for the purpose, work fourteen or fifteen inches deeper, and with the bent scraper, for this use, take out all the loose earth at the bottom; thus making a narrow channel along the centre of the furrow, leaving sufficient support on each side to keep up the materials used in filling, and prevent the replaced earth from falling into the narrow opening left for taking off the wetness. This sort of ditching is done at different distances and depths, as there may be a necessity for them, and as the nature of the soil through which the wetness has to pass into them may be, making them so as to empty themselves into deep ditches at the bottoms of the fields; or where the fields are large, forming one or more leading ditches sufficiently large to receive the wetness from several of the smaller ones, which are so contrived as to fall into them. In order to make these ditches of the most permanent use, they should be cut perfectly straight, and the passage for the wetness be made of an equal depth throughout, otherwise it will be stopped in the lowest parts, and occasion the sides to fall in and choak up the ditch. In case the soil be adapted to it, this sort of work will last twenty years, but where there are squalls, with sand or drift gravel, the passages are liable to choak in a short time. The ploughs, carts, waggons, and other carriages, go over these ditches without injuring them in the least; and in park grounds, and old pastures, it is not uncommon merely to turn the sod over the water-channel, without using any other materials; and the ditches are seen to work, or *draw*, as it is termed, as well after running thirty years, as they did at first. The improved appearance and better state of the land are particularly evident after this method of ditching has been had recourse to, and sufficiently prove its utility and importance in different cases. The practice is more fully explained in the second volume of the Essex Report on Agriculture. See this work, and *SURFACE-Drain*. See also *SURFACE-Draining*.

UNDER-DRAIN and **DRAINING**, terms sometimes employed to signify that sort of drain, or opening and draining, which is cut and made to some considerable depth in the earth or soil, and calculated to convey and carry off internal water and wetness, or that proceeding from springs, in contradistinction to that of surface-drain and draining.

See

See *SPRING-Drain* and *SPRING-Draining*. See also *DRAINING of Land*.

UNDER-FURROW, a term used to signify any sort of operation or thing that is done under the furrow-slice of the plough which is just turned down or over, such, for instance, as the putting in certain kinds of grain, seeds, or other crops, in particular circumstances and sorts of soil or land, the turning in particular sorts of manure, green crops and other things, and many other processes of a similar nature.

UNDER-FURROW Sowing, a term applied to that mode of introducing the seed into the ground, which is performed by depositing it in the bottom of the preceding furrow of the plough, and turning the next furrow-slice upon it.

In all cases of under-furrow sowing, however, great care is to be taken that the seed be not deposited to too great a depth in the soil, so as by excluding it from the action of the oxygenic principle of the air, to prevent or retard its germination and early growth, and thereby incur the risk of its rotting and being destroyed. The depth of three or four inches, as the nature of the land may be, is, for the most part, fully sufficient for this sort of sowing. See the next article.

UNDER-FURROW Sowing-Plough, that sort of plough, tool, or machine, which is particularly contrived for this manner of putting seed into the ground. An implement of this kind was not long ago invented with seven shares, so set at suitable distances, as to correctly execute the work in that number of furrows at the same time. It is constructed with a roller somewhat on the same principle, and in the same manner, as the fowing roller; which is supposed to be an admirable mode of communicating motion in such sorts of machinery. See *SOWING-Roller*.

A plough of this nature has still more lately been invented and constructed, which is said to be simple and convenient, and to answer well in practice, but of the particular nature of its construction, or the manner of its operating in performing the work, we are not informed.

A tool of this sort, which would execute the business with sufficient accuracy, expedition, and exactness, would be a matter of great utility and importance to the farmer, and prevent much injury and inconvenience in different respects.

UNDERGROWTH, in *Rural Economy*, a term applied to any sort of young wood of the small or brush kind, which grows under any kind of trees, or tall plants of the wood sort. It is a description of wood which is constantly cut down, in what may be said to be the season or stage of youth, sooner or later, as the nature of the sort, and the purpose for which it is raised, may be. See *UNDERWOOD*.

UNDERHILL, in *Geography*, a town of America, in the state of Vermont, and county of Chittenden, containing 490 inhabitants; 24 miles N.N.E. of Newhaven.

UNDER-LEAF APPLE-TREE, a sort of apple-tree which is valuable, as producing good fruit for the purpose of cyder. It is said to be an excellent bearer, and in which the inside of the tree is mostly full of fruit. Some, however, think that the cyder afforded by it, though pleasant, is inclined to be rather thin and weak. A good tree of this sort is asserted to often carry twenty ffeam of apples. It is common in the apple-groves of Gloucestershire.

UNDERLETTING LAND, in *Agriculture*, the practice of reletting lands or farms, or the letting of them again by the tenants. It is a matter of much importance to the public, and to the advancement of husbandry, that tenants should have the power of underletting or assigning the farms

they may hold, in different circumstances and situations. And it has been remarked, in a late periodical work on farming, that, by the law of England, leases are not only assignable, but the proprietor of the land or farm must, on the assignment of the lease, declare his election, whether he inclines to hold the original lessee bound for his rent, or trusts to the assignee, as he cannot have both; and that, on the whole, a lease, whether granted for a long or a short term of years, seems to be held there under as ample powers as the proprietor could have possessed the ground himself by, for the period it has to run. But that in Scotland, from the present interpretation of the laws, by the decisions of the court of session, a lease or tack of lands there does not imply a power either to assign, or even to underlet or sublet; although, in the latter case, both the principal lessee and subtenant were always understood to be bound for the rent to the landlord.

It may be noticed, it is said, that these leases or tacks, in general, are, by the commentaries of their lawyers, considered as unassignable, from their being supposed to imply an election or choice of the person of the tenant by the landlord; yet it is admitted, that a life-rent lease or tack is assignable, which surely, it is thought, implies more of such election or choice than any other. That all leases or tacks, too, that are to subsist for a great length of time, are also assignable, as well as sublettable; but that, rather unfortunately, the length of indurance that is necessary for conferring this privilege has not been legally fixed. By a late decision, in one case, it was found, it is said, that a power of subletting was implied in a lease of thirty-eight years. With due submission to the opinions of others, however, there seems, it is contended, to be no solid ground for any distinction, in judging a lease or tack assignable or unassignable, as derived from the length of its duration merely. It is said in addition likewise, that, by the feudal law, this right of election or choice was carried so far, that even an heir was not permitted to enjoy the lease or tack of his father, unless it was so expressed in the lease-deed. What an obstacle was this to the improvement of the soil! And it is asked, does not the exclusion of assignees, in leases or tacks, still remain an obstacle of the same nature? What an incentive, on the other hand, would it be to industry, if a tenant, who had successfully improved one farm, had it in his power to assign his lease or tack, and remove to another, to a new and wider field for exercising his talents! Nor does there seem, it is said, to be any sound reason why a tenant, who now-a-days generally buys his lease or tack, as the highest bidder, at a public or private sale, should not have it in his power to sell it again, to avoid loss, or obtain profit, to any person able to pay the rent, as freely as a proprietor of lands sells his property, when he finds it does not suit his views. This plan, it is thought, would be much more reasonable, than that the law should force a tenant to remain in a farm he cannot manage, until he is utterly ruined; as is but too often the case. And that, moreover, if a tenant does become bankrupt, it is hardly to be expected that an adjudger, who enters to his farm from necessity, and is accountable as a factor, will do any thing for the improvement of it: for it is held as law, that a lease or tack, which bears no power to assign, may yet be adjudged by a creditor of the tenant. Expediency may, therefore, in every view, be strongly urged in favour of a more unlimited power in assigning leases or tacks in that part of the country.

The notion of the right of election, or choice of the tenant by the landlord, seems, it is thought, to have arisen from circumstances of a temporary nature, which are now no longer of any consequence: from the rudeness of the

age, landlords then relying more on the fidelity of their tenants and retainers than on the protection of the laws, from the municipal regulations of the country, which rendered proprietors of the land responsible for the conduct of those who resided upon their estates; and also from the nature of the *prestations* then exigible from tenants, which, consisting almost entirely of personal services, brought them nearer the state of menial servants than that of modern farmers. Hence it was, it is said, that a lease, during these periods, was considered as a contract *stricti juris*. If given to a woman, it fell by her subsequent marriage; if to a man, it became void by his death. It was alike incapable of voluntary, as of judicial transmission. But, for more than a century past, this contract having been treated by the legislature, and wisely enforced by the judges there, in conformity to the sense of the country, has, it is asserted, regained much of its original nature. It is no longer the personal services of the tenant, or his peculiar qualifications, but the rent in money which he can afford to pay, which a landlord has in view. Accordingly, the court of session there has found, that the principle of law, regarding leases or tacks not bearing to assignees, being unassignable without the consent of the heritor, does not apply to urban tenements, and made decisions in conformity to it. And that as to sub-tacks or leases, it has been observed, that there was not the same reason against sustaining them as against sustaining assignations; because, by a sublet or underletting there, the principal tenant or tackman is not changed. On that principle, the power of granting them seems to have been ever, until of late, recognised as implied in a lease, by the law of Scotland, as it was by that of the Roman. This power was, however, questioned in the years 1686 and 1687. The first case was that of a lease or tack of nineteen years let to a person, secluding his assignees. It was contended, that the exclusion of assignees implied the exclusion of subtenants, or underletting; but the court of session there decided that the lease or tack might be sublet. And it adhered to the same judgment, in a similar case, decided in the following year.

It may be noticed, that this implied power in leases or tacks, of subletting or underletting, appears to have been understood to be a settled principle of law there until lately; and that that material point of public policy was not altered by any act of the legislature, but by a decision of the above court. It was first considered on general grounds, it is said, in the case of a mislive of a lease or tack, to endure nineteen years, which made no mention of assignees or subtenants, and was found by it neither capable of being assigned or sublet. And there have since been several decisions to the same purpose; but that as none of them have probably yet been appealed, and received the judgment of the house of peers, until then it may be understood that the law is as interpreted in the above cases.

Upon the whole, it can hardly be doubted that it would be more conducive to the improvement of the country, and its agriculture, if all restrictions against assigning and subletting or underletting were abolished and done away with, than that the free disposal of property of the farm kind should receive, by implication, additional fetters. The necessity and utility of this must indeed be evident in a great many different points of consideration. See FARM, LEASE, and TACK.

UNDER-LOCKS, in *Sheep Husbandry*, the locks of soiled wool which hang under the bellies of the sheep, especially about their udders and tails. The operation of removing such locks is termed under-locking in most sheep districts. See SHEEP.

UNDERMINING. See SAP.

UNDER-RUN, *To*, in *Sea Language*, is to pass under, or examine any part of a cable or other rope, in order to discover whether it is damaged or entangled. It is usual to under-run the cables in particular harbours, as well to cleanse them with brooms and brushes from any filth, ooze, shells, &c. collected in the stream, as to examine whether they have sustained any injury under the surface of the water; as from rocky ground, or by the friction against other cables or anchors.

UNDER-RUN a Tackle, *To*, is to separate the several parts of which it is composed, and range them in order, from one block to the other; so that the general effort may not be interrupted, when it is put in motion. Falconer.

UNDER-SAIL, denotes the state of a ship when she is loosened from her moorings, and under the government of her sails and rudder.

UNDER-SHERIFF, *Sub-vice-comes*. See SHERIFF.

UNDER-SHOOT and SPROUT, in *Agriculture and Gardening*, that sort of shoot or sprout which rises from the under-part of a tree or vegetable of any kind. The under-shoots of trees and shrubs are often liable to be weak, and to want vigour, unless they are kept well thinned in their branches, and, of course, to be injurious and unsightly in the growth of the plants. But in some field and culinary vegetables, under-sprouts frequently form a sweet, tender, and useful food. See SHOOT and SPROUT.

UNDER-SHRUB. See SUFFRUTEX.

UNDER-SITTER, an inmate. See INMATES.

UNDERSTANDING, INTELECTUS, is defined, by the Peripatetics, to be a faculty of the reasonable soul, conversant about intelligible things, considered as intelligible. They also make it twofold; *viz.* *active* and *passive*.

UNDERSTANDING, *Active, Intellectus Agens*, they hold that faculty of the soul, by which the species and images of intelligible things are framed, on occasion of the presence of phantasms or appearances thereof. For, maintaining the intellect to be immaterial, they hold it impossible it should be disposed to think by any disproportionate phantasms of mere body; and, therefore, that it is obliged to frame other proportionate species of itself; and hence its denomination *active*.

UNDERSTANDING, *Passive, Intellectus Patiens*, is that which, receiving the species framed by the active understanding, breaks forth into actual knowledge.

The moderns set aside the Peripatetic notion of an active understanding. The Cartesians define the understanding to be that faculty, by which the mind, conversing with, and, as it were, intent on itself, evidently knows what is true in any thing not exceeding its capacity.

The Corpuscular philosophers define the understanding to be a faculty, expressive of things which strike on the external senses, either by their images, or their effects, and so enter the mind. Their great doctrine is, *Nihil esse in intellectu, quod non prius fuerit in sensu*; and to this doctrine our famous Mr. Locke, and most of the latest English philosophers, subscribe.

The Cartesians exclaim much against it; and between these and the Corpuscularians there is this farther difference, that the latter make the judgment to belong to the understanding; but the former to the will.

Hence, according to the most approved opinion of the Corpuscularians, the understanding has two offices, *viz.* *perception* and *judgment*; according to the Cartesians, it has only one, *viz.* *perception*.

UNDERSTANDING is also used for the act, exercise, or exertion,

exertion, of this faculty; or the action by the mind knows things, or represents them in idea to itself.

UNDERSTRATUM, in *Agriculture*, a term signifying much the same as subsoil and substratum. It is the bed or layer of some sort of material, upon which the surface or upper soil or mould rests, or is placed. It is of much use in many cases of land to have an open understratum. See **SOIL**.

UNDERTAKERS were anciently such persons as were employed by the king's purveyors, and acted as their deputies.

At present, the name is chiefly used for *upholders*, or persons who furnish out funerals; and also for such as undertake any great work, as the draining of fens, &c. Stat. 43 Eliz.

UNDER-TREASURER of England, Vice-treasurer Angliæ, an officer mentioned in stat. 39 Eliz. c. 7. and whom several other statutes confound with treasurer of the Exchequer.

He chested up the king's treasure at the end of every term, and noted the content of money in each chest, and saw it carried to the king's treasury in the Tower, for the ease of the lord treasurer, &c.

In the vacancy of the lord treasurer's office, he also did every thing in the receipt, that the lord treasurer himself does. See **TREASURER**.

UNDERWALDEN, or **UNTERWALDEN**, in *Geography*, a canton of Switzerland, bounded on the north by Lucern and Walldtatter lake, on the east by mountains which separate it from Uri, on the south by Bern, and on the west by Lucern. It measures about eight leagues each way, and is divided into two valleys, Upper and Lower, by a forest called "Kernwald," which crosses the canton from south to south. These valleys are called in German "Unterwald ob dem Wald," and "Unterwald nid dem Wald;" that is, "Underwald over the Forest," and "Underwald under the Forest." Each of them forms a separate regency. The canton itself is small, but abounds in fruit and cattle. The mountains are covered with rich pastures, and the fields in the fertile valleys, in one year, yield several advantages: for in spring time, when the snow is off the ground, they are full of cattle; afterwards, the cattle being driven up the Alps, the herbage shoots again in such a manner as often to be mowed twice in the summer; and in autumn, the cattle, on their return from the Alps, meet again with plenty of fodder in them, till the snow sets in a-new. All the lower parts of the country produce an exuberance of very fine fruits; and with wood this canton is so well provided, that without any detriment to it, several spots might be allotted and improved into meadow or arable land. Of what it has little or none, and grows no wine. The Underwalders are universally Roman Catholics, and have ever enjoyed the like liberties with the people of Uri and Schwitz. In conjunction also with them, in the year 1308, they shook off the Austrian yoke. Arnold de Melchtal, a native of this canton, was one of the four heroes who first reared the standard of Swiss liberty; and in 1315, they entered into a perpetual alliance with the said states. At the conclusion of the war with Charles the Bold, Friburgh and Soleure having contracted an alliance with Zurich, Bern, and Lucern, the treaty was considered by Uri, Schwitz, Underwalden, Zug, and Glarus, as a breach of the former union. After various disputes and fruitless conferences, the deputies of the eight confederate cantons assembled, in 1481, at Stantz, in order to compromise the differences. When the deputies failed to effect a reconciliation, and a civil war appeared to be inevitable, Nicholas de Flue, a celebrated saint and

patriot, born at Saxelon in 1417, quitted the hermitage to which, in his 50th year, he had retired, and in his 64th year, after having travelled during the night, arrived at Stantz just at the moment when the deputies were departing. The conference was renewed by his persuasion, and all differences were adjusted. Among the confederate body, they are reckoned the sixth; but among the six landern or lesser cantons, the third. The government of this canton is purely democratical, the landesgemeind being the depositary of the whole supreme power, and in which all males above sixteen have a right of admittance. As the country, however, consists of two vales, *viz.* Oberwald and Underwald, each of them forming a separate republic, so they have both their own particular landesgemeind and officers; but in the general affairs of the thirteen cantons they form only one. Of all the people of Switzerland, those of Underwald are the most honoured and most loved by the other cantons; their courage and love of liberty being joined by a strict concord, and an amiable simplicity of manners. In the late contest with the French, the inhabitants of Schwitz and Underwalden manifested a noble spirit, and an ardent desire of independence; and at length submitted with great reluctance. (See **SCHWITZ**.) Sarne or *Sarnen* (which see) is the capital burgh of the Upper Vale, or Oberwalden; and here the land-rath, as supreme court of judicature, assembles, for the purpose of deciding civil and criminal processes. This tribunal is composed of fifty-eight judges, chosen by the people, and continued in office for life. Stantz or *Stanz* (which see) is the capital of the Lower Vale, or Underwalden, and is the seat of civil and criminal judicature; and it is worthy of notice, that every male, of the age of thirty years, is permitted to give his vote for the acquittance or condemnation of a criminal. This town is situated in a beautiful plain of pasture, about two or three miles in breadth, at the foot of the Stantzberg, and at a little distance from the lake of Lucern. The town and environs, which are delightfully sprinkled with cottages, are extremely populous, containing perhaps not less than 5000 persons.

UNDERWICK, a town of Sweden, in Helplingland; 30 miles W.S.W. of Hudwickfwall.

UNDERWOOD, in *Rural Economy and Planting*, a term applied to small coppice, or any sort of low wood that is not accounted timber. It is mostly used for that which rises and grows under some sort of wood of the tree kind, and which is capable of being used for a great variety of little purposes, such as hoops, faggots, and many others, as will be seen below.

In Suffex, where wood is well known to grow remarkably well, the mode of managing the underwoods is, according to the Corrected Report on Agriculture for that county, to cut them at from eleven or twelve to fifteen or sixteen years' growth; as, upon favourable well-growing soils, from eleven to thirteen; and upon poor grounds, on which wood rises more imperfectly, from fifteen to eighteen. But as the age of cutting materially depends upon the qualities of the soil, and the application of the crop or produce, no fixed rule can evidently be laid down, other than the above stated general one. The underwoods of some, as those of the earl of Egremont, are cut at from twelve to sixteen years of age, in cases where the growth consists of oak, beech, alder, and willow: the underwood is then, it is said, the most valuable part of the conversion, except in the vicinity of hop-plantations, where the poles afford a much better price; but in the cases where the underwoods abound with birch, ash, hazel, and willow, of which hoops are usually made, at from ten to twelve years of age. Newly planted

UNDERWOOD.

planted grounds are always earlier cut; the shoots are more rapid and strong.

It is noticed as worthy of remark and deserving of attention, that underwoods, at twelve or thirteen years' growth, are as valuable upon some soils, as they would be, if cut down or over at a later age, especially if they are advantageously planted in the neighbourhood of hop-grounds; as poles of that age and size are equally as good, and answer all the purposes of larger: as when underwood has exceeded the size of poles, its utility, it is said, is there not otherwise essentially serviceable than as it is valuable for fuel. The younger, therefore, it is cut there, if fit for the market, the more productive it will turn out, and the sooner the succeeding crop will be ready for sale; for when underwoods are left too long before they are cut, besides growing slower, the interest of the money is lost for which they might have been sold. The under or small wood upon the most growing soils, as the difference that exists is considerable in this respect, is worth from eight to ten or eleven pounds the acre; but that to gain such a product, the land, it is observed, must be exceedingly kindly for the growth of wood.

The beech underwoods of the county of Oxford mostly consist of trees or plants growing on their own stems, produced by the falling of the beech mast; as very little is there permitted to grow on the old stools, which are commonly grubbed up. They are occasionally drawn out, but never felled all at one time, except in particular instances of converting the land into tillage, which is lately become more common. The beech underwood drawn in this manner is mostly either sold in long lengths, called poles, or, when cut short in billet lengths, for fuel. It requires considerable judgment, it is said, to thin these underwoods in such a way that the present stock may not hang too much over the young seedlings; at the same time, too, in a southern aspect, an injury may take place, by exposing the soil or surface of the land too much to the sun: for it is to be observed, that the north side of a hill will produce a better growth of beech than the south side; the very reverse of which is the case in regard to corn. In beech underwoods also, the succession of young trees is greatly injured by admitting sheep or other cattle into them; and though it is supposed by some, that sheep do no damage in winter, when the leaf is off, but find considerable feed from the grass and other plants abounding in such underwoods, yet it is the opinion of others, that the wool which is left hanging on the young stocks is prejudicial to their growth, allowing, what is doubtful, that the sheep do not crop them. Some improvement might probably be produced by keeping better fences, especially against commons, where a wide ditch is often an essential part of the mound; and also by transplanting the young beech from those parts of an underwood where they are too thick, so as that they would be destroyed, by the strongest overpowering the weakest, to those places where they may not stand sufficiently thick, there being mostly spots of both these sorts to be found in all underwoods of this kind.

In Cornwall and some other southern counties, the underwoods are mostly of the common oak, and are usually cut at from twenty to thirty years' growth, selling at from twenty to sixty pounds the acre, the chief profit depending upon the bark. Some of the wood is converted into poles, for farm and other purposes; but the greatest part is commonly charred, for the use of the blowing-houses, and domestic purposes; the brushwood being sold for fuel. Such are the advantages of this sort of wood for different uses in these places, that instances of the grubbing up of under-

woods are very rare. In the felling of underwoods, in these situations, a great advantage has lately been found, in more attention being paid to the reservation of saplings as standards, than was formerly the case. The land producing underwood of this kind, in these districts, is found to be more valuable than that in the state of tillage, in many cases.

In some of the more northern counties, much advantage is derived, in different cases, from underwoods of the ash kind, when cut at about fourteen years' growth, for various uses.

It may be noticed that underwoods, in many situations, are greatly neglected, and managed in a very indifferent manner; but they require a good deal of attention in different respects, to have them in good perfection; and it is necessary, in many cases, to grub up the old decayed stubs at every time of felling the wood, when fresh plants will come forth of the different kinds, before the next felling, which will keep the underwood in a perfect and proper state of cultivation and growth.

The proper soils for the growth of underwood must necessarily vary with the nature of the plants; but for the oak and ash, those of a rather strong stiff quality are found the most suitable. In Sussex, the former rises with astonishing rapidity in a sort of red clay. The chestnut, hazel, and some others, require a more light and free soil; and the willow, one that inclines to moisture. But they all allow of considerable variety in the qualities of the soils on which they grow.

Underwoods in many cases rise naturally from the stubs and seeds of the old wood, and they are formed and planted in different ways, according to circumstances, and the nature of the plants. For raising chestnut underwood, which is the best and most lasting wood for stakes, hop-poles, and some other uses, Mr. Foriyth advises the following method as the most advantageous. To prepare the land well by ploughing or trenching, and summer-fallowing, planting the young trees in the quincunx order, in rows six feet apart, and at the distance of six feet from plant to plant in the rows. In forming large extents of such underwoods, it is the most expeditious way to plant after the plough, treading the mould firmly about the roots of the plants. Basins should be formed round the plants on the surface, in order to mulch them, in case the first summer season after putting them in be dry. It may save time, too, to put the plants in loosely at first, in order to keep up with the plough, returning afterwards to tread the earth about them, and form the basins for mulching. When the trees are become fit for poles, every other one is to be cut down nearly close to the ground, throughout the whole, constantly cutting them in a sloping manner, and as near to an eye or bud as may be. Those intended to stand should be left in every other row, which will leave them twelve feet apart every way: if the soil be, however, rich and deep, they may be left twenty-four feet apart. As in many counties, particularly Hertfordshire, the underwood is more valuable than the other; in that case it will be most judicious, it is said, to leave but few standards; in the meantime the underwood will amply repay the expence of planting and other things, as well as the rent of the ground, while at the same time a sufficient produce of timber-trees is had upon the land. In the county of Kent, it is remarked, they commonly plant out chestnuts and ash for hop-poles at three years old, and cut them fourteen years afterwards, which makes in all seventeen years before they are fit to cut; and they bring from one guinea and a half to two guineas the hundred: but if they were raised from large stools, it is
said,

said, properly cut and prepared, they would be fit for cutting in less than one-third of that time; and consequently the value of the land be tripled.

In Suffex, it is remarked, that in the newly planted underwoods of the first cuttings, which are made at seven or eight years' growth, the profit is little or nothing: that in the second it is still inconsiderable; so that for fourteen or sixteen years the return from young planted underwoods is but trifling, which is not very encouraging to the planter of such wood: the third is the most profitable cutting, as the underwood has now reached its ultimate perfection: the fourth often equals the third; but after this the underwood advances no more. The effect of the young standard-trees is now visibly apparent to the prejudice of the underwood, which in sixty years, if the trees be left to stand so long, it is said, is destroyed.

The application and uses to which underwood is converted in the above, and some other districts, are various; as poles for hop-grounds, bays, spray-faggots for lime-kilns, cord-wood for coaling, and hoops for the use of the cooper, besides affording large supplies of wood for fuel and other purposes of that kind. Ash is supposed, of all the various species of underwood, with the exception perhaps of alder, to be the most profitable; the smallest pieces being of use in some shape or other, and suited to a greater number of purposes than most other sorts. But the point of view in which this sort of wood is considered as so particularly valuable, is the use to which the shivers convert it in quartering it into middlings, long and short hoops, as its value in these ways is perfectly well known. Birch is rapid in its growth, and pays well on poor moist soils; but on all soils, where the alder is in plenty, as it forms the best charcoal for the gunpowder-makers, it is the most valuable underwood, being converted to patten poles and powder-wood. Cutting of the former is paid two shillings for the hundred in the above county; they measure in common from three-fourths to a foot each, and sell for five-pence the foot. The cutting and stripping of the powder-wood are mostly three shillings and sixpence the load, which is sold for twenty-four shillings.

The value of underwoods, as in the case of most other products, has increased here, as well as in most other places, considerably in their price of late years. In some parts they have doubled their value in twenty years. Various new demands for them have been created; so that some think underwood lands are the most profitable of any whatever. See Woods.

UNDERWOOD, *Stealing of*. See LARCENY.

UNDERWRITERS are persons who subscribe their names to policies of insurance, and become answerable for the sums annexed, in case of loss or damage of the ship, goods, &c. thus insured by them to the owner.

Serjeant Marshall observes, that there are many reasons why an agent or broker ought not to be an insurer. He becomes too much interested to settle with fairness the rate of premium, the amount of partial losses, &c. And though he should not, himself, create any unnecessary delay or obstacle to the payment of a loss, he will not be over anxious to remove the doubts of others. Besides, he ought not, by underwriting the policy, to deprive the parties of his unbiassed testimony, in case of dispute. For though there may be no legal objection to his competency, as a witness for the other underwriters, it is impossible that his credit should be altogether free from suspicion. The principal, in short, can never place any reliance in one who makes himself an adverse party, and who is, at the same time, above all others, in a capacity to abuse his confidence.

It has been determined in general, that an underwriter cannot be a witness in an action on a policy; but if the broker, who effects a policy, subscribe it himself, after the other underwriters have subscribed it, he may be a witness for the other underwriters, if they release him from all contribution for costs, though an action be depending against him, and he has joined in a bill of equity against the insured, for a discovery. Marshall on the Law of Insurance.

UNDETERMINED, in *Mathematics*, is sometimes used for indeterminate.

UNDIMIA, in *Surgery*, the name of a kind of cedematous tumour, the matter contained in which is glutinous and ropy, like the white of an egg.

UNDIVIDED, in *Botany*, applied to leaves, or other parts of a plant, means that they are not lobed, cloven, or branched, this term having no reference to the margin of a leaf, which, when destitute of all notches or indentations, is called entire, *integerrimus*; the leaf itself being either undivided or lobed, as it may happen. The earlier translators of Linnæus, such as Mr. Rose, rendered *folia integra*, by *entire*, and *folia integerrima*, by *very entire*; which, though correct in language, is not the true meaning, the former being synonymous with *undivided*, and the latter regarding the margin only.

UNDRET, in *Geography*, a town of Baglana; 45 miles S. of Tolnani.

UNDULAGO, in *Natural History*, a name given by Mr. Lhuys to a species of fungus found fossil, and usually of a sort of undulated figure. See FUNGITE.

UNDULATED LEAF, among *Botanists*. See LEAF.

UNDULATION, in *Acoustics, Mechanics, Optics, &c.* is nearly synonymous with *Vibration*; which see.

Dr. Young, in the illustration and establishment of his theory of light and colours, uses the term undulation in preference to vibration; because vibration is generally understood as implying a motion which is continued alternately backwards and forwards, by a combination of the momentum of the body with an accelerating force, and which is naturally more or less permanent; but an undulation is supposed to consist in a vibratory motion, transmitted successively through different parts of a medium, without any tendency in each particle to continue its motion, except in consequence of the transmission of succeeding undulations, from a distinct vibrating body; as, in the air, the vibrations of a chord produce the undulations constituting sound.

Dr. Young commences the explanation of his theory with premising a number of hypotheses, and with shewing how far they agree with the system of Newton, and in what respects they differ from it. He assumes, 1st, with Newton, (see our article *ÆTHER*), that a luminiferous ether pervades the universe, which is in a high degree rare and elastic. 2dly. Undulations are excited in this ether, whenever a body becomes luminous. 3dly. The sensation of different colours depends on the different frequency of vibrations, excited by light in the retina. The three hypotheses above recited, and which, according to Young, may be called essential, are literally parts of the more complicated system of Newton. 4thly. All material bodies are to be considered, with respect to the phenomena of light, as consisting of particles so remote from each other, as to allow the ethereal medium to pervade them with perfect freedom, and either to retain it in a state of greater density and of equal elasticity, or to constitute, together with the medium, an aggregate, which may be considered as denser, but not more elastic. Our author next proceeds to unfold and establish his theory by a series of propositions, which our limits will allow us merely to transcribe.

PROP. I.

All impulses are propagated in a homogeneous elastic medium with an equable velocity. In different mediums, the velocity will vary in the subduplicate ratio of the force directly, and of the density inversely. From the phenomena of elastic bodies and of sounds it appears, that the undulations may cross each other without interruption.

PROP. II.

An undulation, conceived to originate from the vibration of a single particle, must expand through a homogeneous medium in a spherical form, but with different quantities of motion in different parts.

PROP. III.

A portion of a spherical undulation, admitted through an aperture into a quiescent medium, will proceed to be further propagated rectilinearly in concentric superficies, terminated laterally by weak and irregular portions of nearly diverging undulations. This proposition, though the principle of it is objected to by Newton, is, according to our author, perfectly consistent with analogy and experiment.

PROP. IV.

When an undulation arrives at a surface which is the limit of mediums of different densities, a partial reflection takes place, proportionate in force to the difference of the densities.

PROP. V.

When an undulation is transmitted through a surface terminating different mediums, it proceeds in such a direction, that the sines of the angles of incidence and refraction are in the constant ratio of the velocity of propagation in the two mediums. The demonstration of this proposition will prove the equality of the angles of reflection and incidence.

PROP. VI.

When an undulation falls on the surface of a rarer medium, so obliquely that it cannot be regularly refracted, it is totally reflected, at an angle equal to that of its incidence.

PROP. VII.

If equidistant undulations be supposed to pass through a medium, of which the parts are susceptible of permanent vibrations, somewhat slower than the undulations, their velocity will be somewhat lessened by their vibratory tendency; and in the same medium, the more, as the undulations are more frequent.

PROP. VIII.

When two undulations, from different origins, coincide either perfectly or very nearly in direction, their joint effect is a combination of the motions belonging to each.

PROP. IX.

Radiant light consists in undulations of the luminiferous ether. For the illustration and proof of these propositions, the corollaries deducible from them, as particularly applicable to the colours of striated surfaces, thin and thick plates, and those by inflection, and a reply to the objections that may be urged against the author's theory, we refer to Young's Philosophy, vol. ii. See also Phil. Trans. for 1800.

UNDULATION, in *Physics*, a kind of tremulous motion or vibration, observable in a liquid; by which it alternately rises and falls, like the waves of the sea; and hence it is that the term takes its rise, from *unda, wave*. See *WAVE*.

This undulatory motion, if the liquid be smooth, and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone, or other matter, upon the surface of a stagnant water, or even upon touching the surface of the water lightly with the finger, or the like.

The cause of these circular undulations is, that, by touching the surface with the finger, there is produced a depression of the water in the place of contact. By this depression, the subjacent parts are moved successively out of their place, and the other adjacent parts thrust upwards, which, lying successively on the descending liquid, follow it; and thus the parts of the liquid are alternately raised and depressed, and that circularly.

When a stone is thrown into the liquid, the reciprocal vibrations are more conspicuous: here the water in the place of immersion rising higher, by means of the impulse or rebound, till it comes to fall again, gives an impulse to the adjoining liquid, by which means that is likewise raised about the place of the stone, as about a centre, and forms the first undulous circle; this falling again, gives another impulse to the fluid next to it farther from the centre, which rises likewise in a circle; and thus, successively, greater and greater circles are produced.

UNDULATION, in *Medicine*, the term used by some to express an uneasy sensation in the heart, of an undulatory motion, which may sometimes be perceived externally.

UNDULATION, or *Beat*, in *Music*, is used for that rattling or jarring of sounds, which is observed, chiefly, when discordant notes are sounded together. See *BEATS*.

The phenomenon is more fully described thus, by Dr. Smith. In tuning musical instruments, especially organs, it is a known thing, that while a consonance is imperfect, it is not smooth and uniform, as when perfect, but interrupted with very sensible undulations or beats; which, while the two sounds continue at the same pitch, succeed one another in equal times, and in longer and longer times, while either of the sounds approach gradually to a perfect consonance with the other, till at last the undulations vanish, and leave smooth, uniform consonance. Smith's Harmonics, p. 107. See *HARMONICS*.

This learned author observes farther, that quicker undulations are beats, and are remarkably disagreeable in a concert of strong, treble voices, when some of them are out of tune; or in a ring of bells ill tuned, the hearer being near the steeple; or in a full organ badly tuned. Nor can the best tuning wholly prevent that disagreeable battering of the ears with a constant rattling noise of beats, quite different from all musical sounds, and destructive of them, and chiefly caused by the compound stops called the cornet and sesquialter, and by all other loud stops of a high pitch, when mixed with the rest. But if we be content with compositions of unisons and octaves to the diapason, whatever be the quality of their sounds, the best manner of tuning will render the noise of their beats inoffensive, if not imperceptible.

The doctor has with great ingenuity deduced the theory of these undulations from his principles, and has applied his doctrine to the tuning of instruments; by which he has shewn, that a person of no ear at all for music may soon learn to tune an organ, according to any proposed temperament of the scale, and to a nice degree of exactness, far beyond what the nicest ear, unassisted by theory, can possibly attain to. This may be done by counting the number of undulations in a certain time, such as fifteen seconds.

seconds. See the treatise before cited, prop. xv. p. 215. and the Table, p. 244. plate 20.

From this ingenious theory the learned author has demonstrated several errors in what monſieur Sauveur has delivered concerning thefe undulations or beats. See Harmonics, Scholium 2. p. 115.

In the ſame treatiſe we find ſome curious obſervations relating to the analogy of audible and viſible undulations. See p. 128. 273.

UNDULATION is alſo uſed in *Surgery*, for a motion enſuing in the matter contained in an abſceſs, upon ſqueezing it. A tumour is ſaid to be in a condition for opening, when one perceives the undulation.

UNDULATORY MOTION is applied to a motion in the air, by which its parts are agitated after the like manner as waves in the ſea; as is ſuppoſed to be the caſe when the ſtring of a muſical inſtrument is ſtruck.

This undulatory motion of the air is ſuppoſed the matter or cauſe of ſound; which ſee.

Inſtead of the *undulatory*, ſome authors chooſe to call this a *vibratory* motion.

UNDULATUM FOLIUM, in *Botany*. See LEAF.

UNDULLEE, in *Geography*, a town of Bengal; 5 miles S. of Doega.

UNDY, in *Heraldry*. See WAVED.

UNEDO, in *Botany*, the name of a fruit, ſo called, according to Pliny, book 25. chap. 24. becauſe one only was to be eaten. He gives *Arbutus* as a ſynonym. The meaning of the above name ſeems to be, that the fruit in queſtion might, by its beauty, tempt any perſon to eat it once, but that its infipidity would prevent any further inclination to taſte it. We have, nevertheleſs, found this fruit gratefully reſrefhing and wholeſome in our fatiguing botanical excuſions in the ſouth of France, and have eaten it plentifully. (See *ARBUTUS Unedo*.) This tree, figured in Engl. Bot. t. 2377. is found about the lake of Killarney, in Ireland, in a naturalized, if not a wild, ſtate. The *Comaron* of the Greeks, mentioned by Pliny, is not this, but *Arbutus Andrache*; ſee Prodr. Fl. Græc. v. 1. 274.

UNELLI, or VENELLI, in *Ancient Geography*, a people mentioned by Cæſar among other inhabitants of Armorica, and not belonging to Brittany. Ptolemy deſcribed their capital under the name of Crociatonum, the poſition of which is that of Valognes. In the Notitia of the provinces of Gaul, Civitas Conſtantia, from which the appellation of Coſtentin is derived, was the capital of the canton occupied by the Unelli.

UNEQUAL, in *Botany*, applied to a leaf, means that the two halves, ſeparated by the mid-rib, are of evidently different dimenſions, and eſpecially that their baſes are not parallel. Inſtances occur in the Elm, (ſee ULMUS,) as well as in the fine exotic genera of *Begonia* and *Eucalyptus*. The ſurface of a leaf or ſtem is termed unequal, when it is rugged, not even or ſmooth, without any reference to the pubeſcence. An unequal corolla has ſome ſegments, or petals, alternately ſmaller than the others, ſo as not to interfere with the regularity of its figure. This may occur in ſome ſpecies of a genus only, nor does it neceſſarily mark a generic difference. —Stamens are unequal in the claſſes *Didynamia* and *Tetradynamia*, with reſpect to their proportion only.

UNEQUAL Courſes. See MASONRY.

UNEQUAL Hours. See HOUR.

UNEVEN NUMBER. See NUMBER.

UNG, in *Geography*, a river of Hungary, which riſes in the Crapack mountains, and runs into the Latoreza, 7 miles N. of Zemplin.—Alſo, one of two ſmall ſtreams which form the river Laubach, in Carniola.

VOL. XXXVII.

UNGELD, compounded of the negative *un*, and *gildan*, to pay, in our *Ancient Cuſtoms*, a perſon out of the protection of the law; ſo that if he were murdered, no *geld*, or fine, was to be paid in the way of compenſation by him that killed him. See GELD, and ÆSTIMATIO capitis.

Si Fritibman, i. e. *homo pacis, fugiat et repugnans, et ſe noliſt indicare; ſi occidatur, jaceat ungeld*, i. e. no pecuniary compenſation ſhall be made for his death. Skinner.

Ungilda akere, mentioned in Brompton, has much the ſame ſignification; viz. where any man was killed, attempting any felony, he was to lie in the field unburied, and no pecuniary compenſation was to be made for his death.

UNGA, in *Geography*, a town and caſtle on the eaſt coaſt of Tunis, ſurrounded by morafles, but without a harbour, or road; 76 miles S. of Cairo.

UNGVAR, a town and fort of Hungary, on the Ung. This town was ſeized by the malecontents; but, in 1685, recovered by the Imperialiſts, with count Tekeli's treaſure and jewels; 22 miles N. of Munckacz.

UNGUENT, UNGUENTUM, Ointment, in *Surgery*, a topical remedy, or compoſition, chiefly uſed in the dreſſing of wounds and ulcers.

Unguent, liniments, and cerates, are external forms, applied on divers parts of the body, both to cure, and to eaſe and relieve them. They only differ from each other in their conſiſtence; with regard to which, unguents hold the medium; being ſtiſſer than liniments, but ſofter than cerates.

Oils are ordinarily the baſes of all three; to which are added wax, axungia, and ſeveral parts of plants, animals, and minerals; both on account of the virtues they furniſh, and to give a conſiſtence to the oils, and to keep them longer on the part, that they may have more time to act.

Many extravagant encomiums have been beſtowed on the efficacy of different preparations of this kind in the cure of wounds, ſores, &c. and yet it is unqueſtionable, that the moſt proper application to a green wound is dry lint. But though ointments do not heal wounds and ſores, they ſerve, however, to defend them from the external air, and to retain ſuch ſubſtances as may be neceſſary for drying, deteſting, deſtroying proud fleſh, and ſuch purpoſes.

We ſhall here enumerate and deſcribe the principal cerates.

The common cerate of the Lond. Pharm. is formed by adding four fluid-ounces of olive oil to four ounces of yellow wax, and mixing them.

For the *calamine cerate* of the Lond. Ph. ſee CERATUM *epuloticum*.

The *cerate of impure carbonate of zinc*, formerly cerate of calamine ſtone, Edinb. Ph., is compounded of five parts of ſimple cerate, and one part of prepared impure carbonate of zinc. Theſe cerates, long known in practice under the name of "Turner's cerate," are uſeful dreſſings in exoriations and ulcers; and as they are in a certain degree deſiccative, they are applied to burns after the inflammation is abated, and to the eye-lids in ophthalmia tarſi.

For *cerate of bliſſering flies*, ceratum Lyttæ, or ceratum cantharidis, ſee CERATUM. This cerate is intended to promote a purulent diſcharge from a bliſſered ſurface, and it generally anſwers this purpoſe without much irritation. But in ſome habits it occaſions ſtrangury, great pain of the part, ſwellings of the lymphatics, and ſuch a degree of general irritation, as to produce œdematous ſwellings, and eryſipelas of the neighbouring parts. It is obſerved, that cerates or ointments for keeping open iſſues are beſt ſpread on lint; and that the dreſſings ſhould in all caſes be renewed once in twenty-four hours.

Cerate of ſupercetate of lead of the Lond Ph. is prepared

of two drachms of superacetate of lead in powder, two ounces of white wax, and half a pint of olive oil, by melting the wax in seven fluid-ounces of the oil, then adding gradually the superacetate of lead, separately rubbed down with the remaining oil, and stirring with a wooden spatula, until they be thoroughly incorporated. This is an excellent cooling cerate for burns, excoriations, and other inflamed sores.

For the *compound cerate of lead*, see CERATUM *libargyri acetati compositum*. This is a mode of applying lead in the form of ointment, long known under the name of "Goulard's cerate," and is used in the same cases as the former cerate. The name, says Mr. B. T. Thomson, is very improper; and ought to have been *ceratum plumbi acetatis*, as the virtue of the composition altogether depends on the acetate of lead.

For the *mercurial cerate*, see CERATUM *mercuriale*.

The *resin cerate* of the Lond. Ph. is formed by mixing a pound of yellow resin and the same quantity of yellow wax together by a slow fire, and then adding a pint of olive oil, and straining the cerate while it is hot through a linen cloth. See CERATUM *resine flavae*.

Cerate of favine of Lond. Ph. is obtained by melting two pounds of prepared lard and half a pound of yellow wax together, and boiling a pound of the fresh leaves of favine, bruised, in the mixture, and then straining through a linen cloth.

The *simple cerate* of the Edinb. Ph. is prepared of six parts of olive oil, three parts of white wax, and one part of spermaceti.

For the *soap cerate*, see CERATUM *saponis*. The efficacy of this cerate depends on the acetate of lead, which is formed in the first stage of the process; the soap answering scarcely any other purpose than that of giving consistence and adhesiveness. It is occasionally used as a cooling dressing.

For *cerate of spermaceti*, see CERATUM *spermaceti ceti*. This and the simple cerate are soft cooling dressings.

Liniments are, in general, more active remedies than cerates or ointments; and act as local stimulants, relieving deep-seated inflammations and pains. For an account of the liniments of the Lond. Ph., see LINIMENT. See also OXYMEL *aruginis*.

The *ammoniated oil*, commonly called volatile liniment of Edinb. Ph., is prepared by mixing two ounces of olive oil with two drachms of water of ammonia.

The *liniment of ammonia* of the Dub. Ph. is obtained by mixing two fluid-drachms of caustic water of ammonia with two fluid-ounces of olive oil.

The *liniment of lime-water*, or oleum lini cum calce, Edinb. is prepared by mixing equal parts of linseed-oil and lime-water.

Liniment of lime of Dub. Ph. is formed by mixing lime-water and olive oil, of each three fluid-ounces. These are solutions of earthy soap, resulting from the chemical union of the lime and oil; and being devoid of acrimony, they are beneficially applied to burns and scalds. As the soapy matter separates from the water when it is kept for some time, it is always best to prepare this mixture when it is wanted.

The *camphorated oil* of the Edinb. Ph. is obtained by mixing two ounces of olive oil and half an ounce of camphor, so as to dissolve the camphor.

The *camphorated oil* of the Dub. Ph. is had by rubbing together half an ounce of camphor with two fluid-ounces of olive oil. (See LINIMENTUM *camphorae*.) These solutions of camphor in fixed oil are very useful embrocations to glan-

dular swellings, sprains, bruises, and to joints affected with rheumatic pains. The late Mr. Ware recommended it with the addition of half an ounce of the solution of subcarbonate of potash, to be applied to the eye-lids night and morning, in incipient amaurosis. The compound liniment of camphor is an useful stimulant application to sprains, bruises, and rheumatic pains. It is also an excellent vehicle for introducing opium into the habit by means of friction. An embrocation composed of fʒijss of this liniment, and fʒijss of tincture, warmed and rubbed over the surface of the abdomen, very quickly allays the pains of flatulent colic.

The *liniment of soap*, or tincture of soap of the Edinb. Ph., is prepared by digesting four ounces of soap sliced in two pounds of alcohol for three days, then adding two ounces of camphor, and half an ounce of volatile oil of rosemary, frequently shaking the mixture.

The *anodyne liniment*, or tincture of soap and opium, is made in the same manner, and of the same ingredients as the other tincture of soap, only adding, at the beginning of the process, an ounce of opium.

The principal unguents, or ointments, are enumerated in the sequel of this article. Pomatums are also ranked in the number of unguents. See POMATUM.

In the Edinburgh Pharmacopœia we have the following general rule for the preparation of unguents, applicable also to cerates: let the fatty matters and the resin be melted by a gentle heat, and then constantly stirred, sprinkling in the dry ingredients, if there be any, reduced to very fine powder, until the mixture, by cooling, becomes firm.

Unguentum acidi nitrosi, ointment of nitrous acid, Edinb. Ph., is obtained by mixing six drachms of nitrous acid gradually with one pound of melted hog's-lard, and beating the mixture assiduously as it cools. The Dub. College directs a pound of olive oil to be melted in a glass vessel, and an ounce by weight of nitrous acid to be added to it; then to expose them to a medium heat in a water-bath for a quarter of an hour; then to remove them from the bath, and to stir them constantly with a glass rod until they become firm. This ointment is said to have been invented by Alyon, who found it useful in syphilitic and herpetic ulcers. It has been occasionally used in this country for the same purposes; but it is less effectual than the ointment of nitrate of mercury.

U. album. See *U. oxidi plumbi albi*, infra.

U. ex erugine. See VERDEGREASE.

The *ointment of subacetate of copper*, formerly ointment of verdigris, Edinb. is compounded of fifteen parts of resinous ointment, and one part of subacetate of copper. The *U. aruginis*, or ointment of verdigris of Dub. Ph., is formed by making one pound of ointment of white wax and half an ounce of prepared verdigris into an ointment. These ointments are escharotic and detergent; they are occasionally used as dressings to foul, slabby ulcers, and as an application to scrophulous ulcerations of the tarSI. In the undiluted state they can scarcely be used, unless to act as a caustic for taking down fungous flesh.

U. arcei. See ELEMI and LINIMENTUM *arcei*.

U. basilicum viride, a form of medicine prescribed in the late London Pharmacopœia, and ordered to be made thus: Take of yellow basilicon, eight ounces; oil of olives, three ounces; verdigris, in fine powder, one ounce; mix the whole into an ointment.

U. basilicum flavum, or yellow basilicon ointment, may be made by melting yellow wax, white resin, and frankincense, of each a quarter of a pound, over a gentle fire; and then adding of hog's-lard prepared, one pound; strain the ointment while warm. This is employed for cleansing and glan-

UNGUENT.

ing wounds and ulcers. See BASILICON, CERATUM Resine, and U. rufine, &c.

U. calaminare, or epuloticum, commonly called *Turner's cerate*. See *Calamine cerate*, supra, and CERATUM epuloticum.

U. cere flavæ, ointment of yellow wax of Dub. Ph., consists of a pound of purified yellow wax, and four pounds of prepared hog's-lard, formed into an ointment.

U. cere albe, ointment of white wax of Dub. Ph., is prepared in the same manner as the former, with the substitution of white for yellow wax. These are useful dressings to benign ulcers and excoriations.

U. cetacei, or spermaceti ointment of the Lond. Ph., is prepared by mixing together six drachms of spermaceti and two drachms of white wax, over a slow fire, and stirring them continually till they be cold. The *U. spermatis ceti* of the Dub. Ph. is composed of half a pound of white wax, a pound of spermaceti, and three pounds of prepared lard, mixed into an ointment. These ointments form the ordinary dressings for healing blistered surfaces and excoriations.

U. citrinum is a mercurial ointment. See *U. nitratis hydrargyri fortius*, infra.

U. dialtheæ. See DIALTHEA.

U. elemi compoſitum, compound ointment of elemi of the Lond. Ph., is composed of a pound of elemi, ten ounces of common turpentine, two pounds of prepared fuet, and two fluid-ounces of olive oil. The elemi is melted with the fuet; then removed from the fire, and mixed immediately with the turpentine and the oil; and then the mixture is strained through a linen cloth. The *U. elemi* of the Dub. Ph. consists of a pound of elemi resin, half a pound of white wax, and four pounds of prepared hog's-lard: these are formed into an ointment, which is to be strained through a sieve while it is hot. These ointments are stimulant and digestive: they are used to keep open issues and fetons; and as a dressing to ulcers which do not admit of the application of the adhesive straps.

U. emolliens, or emollient ointment, may be made by taking of palm oil, two pounds; of olive oil, a pint and a half; of yellow wax, half a pound; and of Venice turpentine, a quarter of a pound; melting the wax in the oils over a gentle fire, then mixing in the turpentine, and straining the ointment. This supplies the place of althæa ointment, and may be used for anointing inflamed parts, &c.

U. epifpasticum. See *U. vesicatorium*, infra.

U. hydrargyri fortius, or strong mercurial ointment of the Lond. Ph., is prepared by first rubbing two pounds of purified mercury with an ounce of prepared fuet, and a small quantity of twenty-three ounces of prepared lard, until the globules disappear, and then adding the remainder of the fat and mixing. Two drachms of this ointment contain one drachm of mercury.

U. hydrargyri, or vulgarly, U. ceruleum, Edinb., mercurial ointment, is compounded of one part of mercury, one part of mutton fuet, and three parts of hog's-lard; and it is formed by rubbing the mercury diligently in a mortar with a little of the hog's-lard until the globules disappear, then adding the remainder of the lard. One drachm of this ointment contains twelve grains of mercury. It may also be made with double or triple the quantity of mercury. The Dublin College directs equal parts of purified mercury and prepared hog's-lard to be rubbed together in a marble or iron mortar, until the globules disappear. One drachm of this ointment contains thirty grains of mercury.

U. hydrargyri mitius of the Lond. and Dub. Ph., milder mercurial ointment, is prepared by taking of the stronger mercurial ointment, a pound; and prepared lard, two pounds; and mixing them. One drachm of this ointment contains

ten grains of mercury; but prepared according to the Dub. Ph., with two parts of lard to one of mercury, one drachm contains a scruple of mercury. The preparation of the stronger mercurial ointments requires much labour, care, and patience.

When newly prepared, mercurial ointment has a light grey or blueish colour, owing to its containing some unoxidized metal, which separates in globules when it is liquefied by a gentle heat: when kept for some time, the colour is much deepened, and less metallic mercury subfides, owing to the more complete oxidization of the metal. It is probable, therefore, that long kept mercurial ointment contains, besides the oxyd, a febate of mercury.

The strong mercurial ointment rubbed upon the skin is the ordinary mode of introducing a large quantity of oxyd of mercury into the system. About ʒj is rubbed upon the inside of the thighs, or any other part of the body where the cuticle is thin, every night and morning until the system is affected. The oxyd contained in the ointment is absorbed during the friction, and carried into the habit; where it produces the same effects as arise from taking the remedy by the mouth, without the unpleasant affection of the bowels that very commonly follows the introduction of preparations of mercury into the stomach. In order, however, to produce the full effect of the friction, it must be continued until every particle of the ointment disappears; and the operation should be performed by the patient himself. The stronger mercurial ointment is used in this form as an antisyphilitic, as a doebfruent in hepatic affections, and to excite the absorbents in hydrocephalus. The weaker ointment is used only as a topical dressing in venereal sores. During a course of mercurials the patient should be kept in a moderately warm and dry, but airy chamber; and his diet should be chiefly weak broths, milk, and gruel.

The following table, extracted from Thomson's Dispensatory, exhibits the quantity of mercury contained in each of the different ointments ordered by the British colleges.

One drachm	{	of the Lond.	{	stronger oint. contains of merc.	30	grs.
				weaker oint.	10	
		of the Edin.		common oint.	12	
		of the Dub.		stronger oint.	30	
				weaker oint.	20	

U. oxydi hydrargyri cinerei, or ointment of grey oxyd of mercury, Edinb. is prepared by mixing one part of grey oxyd of mercury with three parts of hog's-lard.

U. hydrargyri nitratis, or ointment of nitrate of mercury of the Lond. Ph., is composed of an ounce of purified mercury, two fluid-ounces of nitric acid, six ounces of prepared lard, and four fluid-ounces of olive oil; and is prepared by first dissolving the mercury in the acid, then mixing the solution, while it is hot, with the lard and oil melted together.

U. nitratis hydrargyri fortius, vulgò U. citrinum of Edinb. Ph., is obtained by dissolving one part of purified mercury in two parts of nitrous acid; then beating up the solution strongly with the lard and oil previously melted together, and nearly cold, in a glass mortar, so as to form an ointment.

U. supernitratis hydrargyri of Dub. Ph. is prepared by dissolving an ounce of purified mercury in two ounces by weight of nitrous acid; then mixing the solution with the oil and lard previously melted together, and forming an ointment in the same manner as the ointment of nitrous acid.

U. nitratis hydrargyri mitius, or milder ointment of nitrate of mercury of Edinb. Ph., is made in the same manner as the stronger ointment, with a triple proportion of oil and lard.

UNGUENT.

This ointment is stimulant and detergent. When moderately diluted with lard, it is a local remedy of great efficacy in herpetic eruptions, tinea capitis, and other cutaneous eruptions. The weaker ointment may almost be regarded as a specific in pterophthalmia, in the purulent ophthalmia of infants producing ectropium, and in ulcerations of the tarfi. It is applied by taking a little on the finger, liquefying it by the fire or the flame of a candle, and applying it along the inner part of the eye-lids.

U. hydrargyri nitrico-oxidii is obtained by melting together two ounces of white wax and six ounces of prepared lard, then adding to the mixture an ounce of the nitric oxyd of mercury in very fine powder, and mixing.

U. oxidii hydrargyri rubri, ointment of red oxyd of mercury of Edinb. Ph., is compounded of one part of red oxyd of mercury by nitric acid, and eight parts of hog's-lard.

U. subnitratis hydrargyri consists of half a pound of white wax and half an ounce of subnitrate of mercury, which are formed into an ointment. These are excellent stimulant ointments, well adapted for giving energy to indolent foul ulcers. They are also very beneficial in inflammation of the conjunctiva, with a thickening of the inner membrane of the palpebræ: and to specks of the cornea. They should be applied in the same manner as the ointment of nitrate of mercury.

U. hydrargyri præcipitati albi of Lond. Ph. is formed by adding a drachm of white precipitate of mercury to an ounce and a half of prepared lard, previously melted by a gentle heat, and mixing.

U. subnitratis hydrargyri ammoniati of Dub. Ph. is obtained by forming one pound of ointment of white wax, and an ounce and half of ammoniated submuriate of mercury, into an ointment. These ointments are stimulant and detergent. They are recommended by some German authors as a remedy for the itch, which may be safely used on infants: but they have not been employed in this country.

U. e japonica terra. See JAPAN Earth.

U. linariae. See ANTIRRHINUM.

U. mercuriale, or mercurial ointment. See *U. hydrargyri*, supra.

U. infusi meloes vesicatorii, ointment of infusion of blistering flies of Edinb. Ph., is prepared of blistering flies, resin, yellow wax, of each one part; Venice turpentine, hog's-lard, of each two parts; and boiling water, four parts; by macerating the flies in the water for a night, and straining the liquor, strongly expressing it; then adding the liquor to the fat, and boiling until the water be evaporated; afterwards adding the wax and the resin, and when these are melted, removing the mixture from the fire and adding the Venice turpentine.

This ointment is sufficiently mild, but does not always keep open a blistered surface, so that it does not answer the purpose for which it is designed. The acrimony of the flies is nearly destroyed by the heat employed for the evaporation of the water.

U. nardinum. See NARDINUM unguentum.

U. nutritum is the name of an ointment of lead, made by grinding two ounces of litharge, and adding alternately, and by little and little, two ounces of vinegar, and six of oil. This unguent, though now expunged from our Dispensatories, is an excellent application in many cases. It should not be long kept, but made fresh as wanted. Lewis. See *U. saturninum*.

U. oculi, or eye-ointment. See *U. oxidii zinci impuri*, &c. infra.

U. oxidii plumbi albi, vulgò, *U. album*, ointment of white

oxyd of lead of Edinb. Ph., consists of five parts of simple ointment, and one part of white oxyd of lead.

U. cerussa, five *subacatis plumbi*, ointment of cerussa, or subacetate of lead of Dub. Ph., is compounded by forming a pound of ointment of white wax and two ounces of cerussa, reduced to a very fine powder, into an ointment. These are cooling, desiccative ointments, chiefly employed as dressings for burns.

U. oxidii zinci impuri, olim, *U. tutie*, Edinb., ointment of impure oxyd of zinc, formerly ointment of tutty, is compounded of five parts of simple liniment, and one part of prepared impure oxyd of zinc.

U. tutie, ointment of tutty of Dub. Ph., is prepared by forming ten ounces of ointment of white wax, and two ounces of prepared tutty, into an ointment. These ointments were formerly much used in ophthalmia tarfi, but they are now seldom employed.

U. picis aridae, pitch ointment of the Lond. Ph., is prepared by melting together pitch, yellow wax, and yellow resin, of each nine ounces, and a pint of olive oil; and straining the mixture through a linen cloth.

U. picis liquidae, tar ointment of the Lond. Ph., is obtained by melting together tar and prepared suet, of each a pound, and straining the mixture through a linen cloth.

U. picis, tar ointment of the Edinb. Ph., is compounded of five parts of tar, and two parts of yellow wax.

U. picis liquidae, tar ointment of Dub. Ph. consists of tar and mutton suet, of each half a pound, which are melted together, and then the mixture is strained through a sieve. The pitch and tar ointments are applicable to the same purposes; being used with advantage as detergents in scabby foul eruptions and tinea capitis.

U. piperis nigri, ointment of black pepper, is obtained by forming a pound of prepared hog's-lard and four ounces of black pepper in powder, into an ointment.

U. populeum. See POPELUM.

U. pulveris meloes vesicatorii, olim, *U. epispasticum fortius*, ointment of the powder of blistering flies, formerly strong issue ointment, consists of seven parts of resinous ointment, and one part of powdered blistering flies.

U. cantharidis, ointment of blistering flies of Dub. Ph., is compounded of half a pound of ointment of yellow wax, and one ounce of blistering flies in powder, formed into an ointment. These ointments answer the purpose of promoting a purulent discharge from blistered surfaces, when the irritation excited by them, which is sometimes intolerable, can be endured. The flies should be very finely pulverized, and very intimately mixed with the ointment.

U. resinae albae, ointment of white resin of Dub. Ph., is composed of a pound of yellow wax, two pounds of white resin, and four pounds of prepared hog's-lard, which are made into an ointment, and this is to be strained, while it is hot, through a sieve.

U. resinosum, resinous ointment of Edinb. Ph., is compounded of eight parts of hog's-lard, five parts of resin, and two parts of yellow wax. (See CERATUM resinae.) These ointments are stimulant, digestive, and cleansing; and therefore form an excellent dressing for foul and indolent ulcers. See BASILICON.

U. fabinae, favine ointment of Dub. Ph., is obtained by taking fresh leaves of favine freed from the stalks and bruised, half a pound; prepared hog's-lard, two pounds; yellow wax, half a pound; boiling the leaves with the lard until they become crisp, then straining with expression, and lastly adding the wax, and melting them together. (See CERATUM fabinae.) This ointment is very difficult of preparation. The fresh leaves are preferable to those that are dry,

dry, because by drying their acrimony is impaired. When good, the colour of the ointment is a beautiful deep green, and its odour is that of the fresh bruised herb. It should be kept in closely covered pots, as it will soon lose its virtue by exposure to the air. Savine ointment, which is said by Mr. Thomson to have been first described by Mr. Crowther in his "Observations on White Swelling," serves for keeping up a purulent discharge from a blistered surface; and this it does as effectually and with much less irritation than the ointment of blustering flies.

U. sambuci, elder ointment of Lond. Ph., is formed by boiling two pounds of elder flowers in two pounds of prepared lard, until they become crisp, then straining the ointment through a linen cloth. The Dublin College directs three pounds of fresh elder flowers, four pounds of prepared hog's-lard, and two pounds of mutton suet, in the manner prescribed for the savine ointment.

These ointments are simply emollient, and possess no advantages superior to those of the simple ointment.

U. saturninum. See *Compound cerate of lead*, supra.

U. simplex, simple ointment of Edin. Ph., is formed of five parts of olive oil and two parts of white wax. This is an useful emollient ointment for softening the skin.

U. simplex is also a name given to the composition commonly called *pomatum*; which see.

U. subacetis cupri, olim, *U. eruginis* of the Edinb. Ph., is formed of fifteen parts of resinous ointment, and one part of subacetate of copper. See VERDEGREASE and LINIMENT.

U. sulphuris, sulphur ointment of the Lond. Ph., is obtained by mixing three ounces of sublimed sulphur, with half a pound of prepared lard. The Edinb. Ph. directs to take of hog's-lard four parts, and one part of sublimed sulphur; and to add to each pound of the ointment, of volatile oil of lemon or volatile oil of lavender, half a drachm. The Dub. College orders four pounds of prepared hog's-lard, and a pound of sublimed sulphur, to be formed into an ointment.

These ointments are specific in itch. They should be rubbed on the body every night until the disease be cured; but not more than one-fourth of the body should be rubbed with it at a time.

U. sulphuris compositum, compound ointment of sulphur of the Lond. Ph., is a composition of sublimed sulphur, half a pound; white hellebore root in powder, two ounces; nitrate of potash, a drachm; soft soap, half a pound; and prepared lard, a pound and a half; which ingredients are to be mixed. This ointment is employed like the simple one, and in the same cases; it is supposed to derive additional efficacy from the white hellebore; but it often excites too much irritation.

U. tripharmacum, is prepared by boiling and stirring over a gentle fire four ounces of the common plaster, with one of vinegar, and two of oil, where a thick unguent is required; or four of oil, for a softer liniment.

U. veratri, ointment of white hellebore of Lond. Ph., is obtained by mixing two ounces of white hellebore root powdered, eight ounces of prepared lard, and twenty minims of oil of lemon.

U. hellebori albi, ointment of white hellebore of Dub. Ph., is compounded of a pound of prepared lard, and three ounces of white hellebore root in powder, which are made into an ointment.

These ointments are sometimes used for the cure of psora, when there is an objection to the smell of the sulphur; but as remedies, they are less certain.

U. vesicatorium, blistering ointment. See the appropriate articles, supra.

U. viride, the green ointment, a form of medicine prescribed in the late Lond. Ph., and ordered to be made by melting ten ounces of yellow wax in three pounds of the *oleum viride*, or green oil of the fame Pharmacopoeia.

U. zinci, zinc ointment of the Lond. Ph., is formed by mixing an ounce of oxyd of zinc, with six ounces of prepared lard. See ZINC. Thomson's Dispensatory.

UNGUICULI, in *Botany*, is used for the ends of the petals of roses, or other flowers, where they adhere to the plant.

UNGUIN, a name given by the people of Guinea to a plant, of which they are very fond, on account of its medicinal virtues: they boil it in water, and give the decoction in large draughts for pains in the back. The leaves of this plant grow alternately on pedicles of an inch long, and have the exact shape and size of those of the common bay-tree; but they have neither its taste nor smell, nor any thing approaching to either. Phil. Trans. N° 232.

UNGUIN, or *Ungar*, in *Geography*, a small island near the W. coast of Alashka, in the North Pacific ocean; about 20 miles long, rising in the interior into lofty mountains, but near the sea more level, and covered with brushwood, producing no vegetable food, except berries, and a root from which the Russians make the liquor called quafs. The island abounds with deer. The settlement consists of one Russian and about thirty Indian families, which latter occupied huts constructed of mud, in the form of bee-hives, with a hole at the top instead of a door. They have no fire-places, but warm themselves by means of lamps made out of flat hollow stones, with rush wicks, which they placed under their frocks. This island is separated from the main land by a strait nearly ten miles wide at high water.

UNGUIS, a Latin term, signifying a nail of the hand or foot.

UNGUIS, in *Botany*, the claw, is the elongated base of a petal, conspicuous in the Pink, *Dianthus*, and in the Wall-flower and Stock, *Cheiranthus*, being distinguished by its taper form, and pale colour, from the border, *lamina*, which it supports. The claws of petals are, for the most part, inclosed in the perianth of the flower, though not invariably.

UNGUIS *Cati*, Cat's-claw, the name of a species of *Mimosa*, Linn. Sp. Pl. 1499, alluding to its sharp hooked thorns.

UNGUIS *Ossa*, in *Anatomy*, a small bone on each side of the head, situated in the inner corner of the eye. See CRANIUM.

UNGUIS, in *Surgery*, an abscess of the cornea, or of the anterior chamber of the eye, shaped like a nail.

UNGUIS, in *Natural History*, a name given by authors to a genus of shells, more usually called *solea*.

UNGUIS *Obrutus*, in the *Materia Medica*, a thin, flat, testaceous substance, of an oval or oblong figure, rounded at both ends, and marked on the surface with three or four concentric circles, or oval lines. Its colour is a dusky brown, with some mixture of the orange, sometimes of a purplish tinge. Its usual size is that of a full grown nail of a man's thumb; and its thickness rather less than that of the nail. It is tough, flexible, and elastic; and has no peculiar smell or taste.

The want of smell might seem to argue this to be a different substance from the *unguis odoratus* of the ancients, but the truth is, that their's owed all its sweet flavour to its being brought over among aromatic drugs.

There were two kinds of it, the largest of which they had from the Red sea, and the other from Babylon; and both were the opercula of two species of murex shells.

Dioscorides tells us, that this *unguis* was the operculum

or poma of the shell, which stopped the mouth at pleasure, and from under which the creature thrust out its tongue to feed; and he adds, that the shell-fish to which it belonged was taken in the marshes of India, when the waters were dried away; and that the Indian spikenard growing in great abundance in these marshes, the creature became sweet-scented in every part, by feeding on it. However, he concludes with telling us, that there were only two kinds brought into Greece in his time, the one from the Red sea, the other from Babylon.

The truth is, that spikenard grows neither in the Red sea, nor any where about Babylon, but only in India, beyond the Ganges, or about its banks. The spikenard also does not grow in the water, but only in marshy places, and therefore can never be in the way of feeding shell-fish. Avicenna, perceiving the absurdity and contradiction of Dioscorides's account, says that the shell-fish was found in an island in the Indies, on which island the spikenard also grew in great abundance. But this account supposes that the shell-fish, to which the unguis odoratus belongs, may be found on dry land; whereas it is certain, that no shell-fish, living in the water, can subsist without some means of closing up its cavity, so as to keep out the water at pleasure; this is done in the bivalve kinds, by closing the two valves; but in the sromboide ones, by drawing down this operculum, which is the unguis odoratus, to the mouth of the shell. A land-shell, therefore, can have no occasion for such a part as the poma or operculum, and no such drug as the unguis odoratus can be found about it. But it is to be observed, that Avicenna did not know that the unguis odoratus was a covering or operculum of the mouth of a shell, but thought that it was only a fragment cut or broken indeterminately from any part of the shell. This therefore might appear no absurdity to him; and the thin and flat unguis he saw might appear fragments artificially cut from some of the thin-shelled kind of land-snails. See *BLATTA Byzantina*.

UNGULA, in *Geometry*, is the section of a cylinder, cut off by a plane passing obliquely through the plane of the base, and part of the cylindric surface.

Or, more generally, an ungula, or hoof, is a part cut off a solid by a plane oblique to the base.—To find the curve surface of the ungula DEAGD of a cylinder (*Plate XV. Geometry, fig. 19.*) put b = the height AD, v = the versed sine of AE, d = the diameter AB, a = the arc EAG of the base, s = the right sine FG, and c = the cosine of the half arc; then $\frac{ds - ac}{v} \times b$ is the

convex surface: *i. e.* from the product of the diameter and sine, subtract the product of the arc and cosine, and multiply the difference by the height, and divide by the versed sine.

Note 1.—When F is the centre of the base, then $v = s = \frac{1}{2}d$, and $c = 0$; in which case the theorem becomes db , *viz.* the product of the diameter and height equal to the curve surface.

Note 2.—When AF exceeds $\frac{1}{2}AB$, then ac must be added.

For the demonstration of this theorem, draw HI, IK parallel to FA and AD respectively, and join the points H, K; since it is evident that the surface is generated by the motion of IK along the arc AIG, KI \times the fluxion of IA will be the fluxion of the surface. Therefore put $z = AI$, $x =$ its sine IL, and $y =$ its cosine; then HI $= y - c$; and, by similar triangles, FA : AD :: HI

: IK $= \frac{b}{v} \times (y - c)$; and hence the fluxion of the surface, or $z \times$ IK, is $\frac{b}{v} \times (y \dot{z} - c \dot{z}) = \frac{b}{v} \times (\frac{1}{2} \dot{d} x - c \dot{z})$: the fluent of which is $= \frac{b}{v} \times (\frac{1}{2} dx - cx) =$ (when

AI = AG) $\frac{b}{v} \times (\frac{1}{2} ds - \frac{1}{2} ac)$; the double of which is $\frac{b}{v} \times (ds - ac)$ = the whole convex surface DEAGD

Cor. 1.—If F be the centre; then $v = s = \frac{1}{2}d$, and $c = 0$; and then the theorem becomes barely $db = 4$ times the triangle FDA.

Cor. 2.—When AF exceeds $\frac{1}{2}d$, c is negative, and then $-ac$ becomes $+ac$.

Cor. 3.—If F coincide with B; then $s = 0$, and $c = -\frac{1}{2}v$; and the theorem becomes $\frac{1}{2}ab$ = the surface of the half cylinder.

Example 1.—Let the diameter AB (d) be 100, the height AD (b) 140, and the versed sine AF (v) 10. Then $\frac{1}{2}d - v = 50 - 10 = 40 = c$; and $\sqrt{\frac{1}{4}dd - cc} = \sqrt{2500 - 1600} = \sqrt{900} = 30 = s$. But $\frac{s}{\frac{1}{2}d} = \frac{30}{50} = \frac{3}{5} = .6$ is the sine reduced to the radius 1, to which, in a table of sines, belong $36^\circ 52.268'$ = 36.87113 degrees. Then by the rule given under *ARC of a Circle*, the length of the arc a will be $.01745329 \times 36.87113 \times 100 = 64.352252$. Whence

$\frac{ds - ac}{v} \times b = (3000 - 2574.09008) \times 14 = 425.90992 \times 14 = 5962.73888$ = the convex surface required.

Ex. 2.—If the diameter and height be 100 and 140, as before, and the section be made through the centre of the base, or $v = \frac{1}{2}d = 50$; what is the convex surface?

Here, by note 1, $db = 100 \times 140 = 14000$ = the convex surface required.

Ex. 3.—Supposing d and b still the same, and $v = 90$; to find the convex surface.

Here $\frac{1}{2}d - v = 50 - 90 = -40 = c$, $s = 30$, the same as before, but it is here the sine of the supplemental arc, which therefore is $180 - 36.87113 = 143.12887$ degrees. Hence $.01745329 \times 143.12887 \times 100 = 249.807013$ = the arc a . Or, the arc may be sooner found by only subtracting the arc in the first example, *viz.* 64.352252 , from 314.159265 , the whole circumference.

Then, by note 2, $\frac{ds + ac}{v} b = \frac{1}{5} (3000 + 9992.28052) = \frac{1}{5} \times 12992.28052 = 2598.456456$, the convex surface required.

To find the Solidity of the Hoof of a Cylinder.—From $\frac{1}{3}$ of the cube of the right sine, subtract the product of the base and cosine of half the arc of the base; then multiply the difference by the height, and divide by the versed sine, the quotient will be the solidity required. That is, putting, as before, b = the height AD, v = the versed sine AF, s = the right sine FG, c = the cosine = $\frac{1}{2}AB - AF$,

b = the base or area of the seg. GAEG; then $\frac{\frac{1}{3}s^3 - bc}{v}$

$\times b$ = the solidity.

Note 1.—If F be the centre, that is, if the base be equal to the semicircle, then $v = s$, and $c = 0$; and therefore $\frac{1}{3}bs = \frac{1}{6}d^2b$ is the solidity in that case.

Note 2.—If v exceed $\frac{1}{2}d$, that is, if the base exceed the semicircle, then c is negative, and bc must be added.

This theorem may be demonstrated in the following manner. The fluxion of the solid is = the Δ H I K drawn into the fluxion of L I, which fluxion will, therefore, be

$$\dot{x} \times \frac{b}{2v} \times H I^2 \text{ (using the same characters as in the demonstration of the last problem)} = \frac{b\dot{x}}{2v} \times (y - c)^2 = \frac{b\dot{x}}{2v} \times$$

$$(yy - 2cy + cc) = \frac{b\dot{x}}{2v} \times (\frac{1}{4}dd - xx - 2cy + cc) =$$

$$\frac{b\dot{x}}{2v} \times (\frac{1}{4}dd - xx - dc + 2c \times AL + cc) = \frac{b\dot{x}}{2v} \times$$

$$(ss - xx - 2c \times FL); \text{ whose fluent, } \frac{bx}{2v} \times (ss - \frac{1}{2}xx) -$$

$$\frac{bc}{v} \times \text{area FAIH, when I coincides with G, is } \frac{b}{2v} \times$$

$$(\frac{2}{3}s^3 - bc), \text{ the double of which is } \frac{b}{v} \times (\frac{2}{3}s^3 - bc) =$$

the content of the solid D E A G D required.

Cor. 1.—If F fall in the centre of the base, then $c = 0$, and $s = v = \frac{1}{2}d$, and the rule will be $\frac{1}{2}ddh$.

Cor. 2.—If A F exceed F B, c will be negative, and then $-bc$ will become $+bc$.

Cor. 3.—If F fall in B, $s = 0$, and $c = -\frac{1}{2}v$; and then the theorem becomes $\frac{1}{2}bh$ = half the cylinder.

Ex. 1.—If the diameter A B be 50, the height A D 120, and the verfed sine A F 10; what is the solidity of the hoof?

Or, supposing a cylindric vessel A B C D, containing a fluid, to be placed in such a position that the surface of the fluid, disposing itself parallel to the horizon, may cut the base in G E, leaving 40 inches of the diameter dry, and the side of the cylinder in D, 120 inches distant from the base; to find how many ale gallons are in it, the diameter of the base being 50 inches.

Here $b = 120$, $d = 50$, and $v = 10$. Then $\frac{1}{2}d - v = 25 - 10 = 15 = c$, and $\sqrt{\frac{1}{4}dd - cc} = \sqrt{25^2 - 15^2} = \sqrt{40 \times 10} = 20 = s$.

And, to find the base by the table of segments, $\frac{v}{d} =$

$\frac{10}{50} = .2$; this being found in the column of verfed sines, opposite to it is the area .1118238: hence $50 \times 50 \times .1118238 = 279.5595 = b$ is the segment or base.

Then $\frac{\frac{2}{3}s^3 - bc}{v} b = 12 \times (\frac{2}{3} \times 8000 - 15 \times 279.5595) = 12 \times (5333 \frac{1}{3} - 4193.3925) = 12 \times 1139.9408 = 13679.2896$ = the solidity in inches; which, divided by 282, the inches in a gallon, give 48.50939 ale gallons for the content.

Ex. 2.—Suppose the cylinder po placed, that the surface of the liquor may bisect the base, and rise up the side to the same distance of 120 inches from the base: to find the content.

Here, by note 1, we have $\frac{1}{2}ddh = 50 \times 50 \times 20 = 50000$ solid inches = 177.3049645 gallons, for the content in this case.

Ex. 3.—Suppose, now, the same vessel po placed, as that the surface of the liquor may leave only 10 inches of the diameter dry, still rising to the same distance of 120 inches along the side; to find the content.

Here the part of the cylinder's base left dry, is equal to the base in the first example, *viz.* 279.5595, which, therefore, taken from $50 \times 50 \times .78539816 = 1963.4954$, the whole circle, leaves 1683.9359 = b , the base of the ungula in this example.

Now $v = 40$, $c = -15$, and $s = 20$.

Whence $\frac{\frac{2}{3}s^3 - bc}{v} b = (\frac{2}{3} \times 8000 + 25259.0385) \frac{1}{40} b = 30592.3718 \times 3 = 91777.1154$ solid inches = 325.45076 gallons, the content in this case.

For the method of finding the solidity of the ungulae or hoofs of other solids, we must refer to Hutton's Mensuration, part iii. § 1.

UNGULA, in *Natural History*, the claw, or hoof, of a quadruped.

UNGULA *Alcis*, the elk's claw. See ELK.

UNGULA, a technical name formerly applied to an abscess of the cornea, when the disease was fancied to resemble a hoof in its shape.

UNGULA, or *Hamus*, among *Surgeons*, a sort of hooked instrument, with which to extract a dead fetus out of the womb.

UNGULUS, in *Antiquity*, a remarkable kind of bracelet.

UNHACA, in *Geography*, a small island in the Indian sea, at the entrance of the bay of Lorenzo Marques. N. lat. 26° 5'.

UNHALTER, in the *Manege*. A horse is said to unhalter himself that turns off his halter.

UNHOST, or AUNHOST, in *Geography*, a town of Bohemia, in the circle of Schlan; 8 miles S. of Schlan. N. lat. 50° 6'. E. long. 14° 15'.

UNIA, a small island in the Adriatic, W. of Ofero. N. lat. 44° 52'. E. long. 14° 26'.

UNIAR, or UNIMAK. See OGONEMAK.

UNIARA, a town of Hindoostan, in the circle of Rantampour; 18 miles S. of Rantampour.

UNICORN, in *Astronomy*. See MONOCEROS.

UNICORN, in *Geography*, a post-town of Pennsylvania, in Lancaster county; 124 miles from Washington.

UNICORN, in *Natural History*, an animal famous among the Greek authors, under the name of *μονοκερας*; and among the Latins, under that of *unicorn*.

Both these names it takes from its distinguishing characteristic, the having one horn only. See RHINOCEROS.

The first author who wrote of the unicorn, was one Ctesius, whom Aristotle mentions as a very suspicious author. Ælian speaks of it in very doubtful terms. The other writers on the subject are Philostratus and Solinus; Æneas Sylvius, who is pope Pius II; Marcus Paulus, Aleofius, Gefner, Garcias ab Orta, And. Marinus, &c. Of these, some say it resembles a horse, others an ass, others a goat, by its beard; others an elephant, others a rhinoceros, others a greyhound, &c.

Munier and Thevet will have it an amphibious animal, and its horn to be moveable at pleasure. Others make all its strength to consist in its horn; and add, that when pursued by the hunters, it precipitates itself from the tops of the highest rocks, and pitches upon its horn; which sustains the whole effort of its fall, so that it receives no damage thereby. In reality, the several authors do all give different accounts of the figure and colour, both of the animal and of its horn, and all its parts. And hence many among the moderns have supposed it to be a merely fabulous animal.

The legend adds, that it is wonderfully fond of chaste persons; and therefore, in order to take it, a virgin is placed

in its way; whom when the unicorn spies, he lies down by her, and lays his head on her lap, and soon falls asleep; upon which the virgin makes a signal, the hunters come in, and take the beast; which could never be caught any other way, because it would either cast itself headlong from the rock, or die. For an account of the animal to which the appellation of the unicorn has been applied, see RHINOCEROS.

What ordinarily passes among us for unicorn's horn, and is shewn for such in the collection of curiosities, and used for such by several physicians, we are assured by Pereyra, in his account of Greenland, &c. is the tooth of a large fish of the whale kind, called by the islanders *narwal*; frequent enough in the icy sea. The tooth or horn, turned, channelled, and terminating in a point, as it is, springs out of the middle of the fore-part of the upper jaw, where it has a root a foot long, as thick as the horn itself: it is the only tooth the animal has in the upper jaw, and serves it as a weapon of defence, with which it dares to attack the largest whale. There is a fine horn of this kind preserved in the repository of St. Denis at Paris, given by And. Thevet, and pretended to have been a present to him from the king of Monomotapa, who carried him to hunt the unicorn; which is frequent in that country: this horn some have suspected to be an elephant's tooth, carved in that manner. At Strafburgh there is another between seven and eight feet long. In the repository at Venice there is a good number; all different from each other.

The ancients held the unicorn's horn to be a counter-poison; and that the animal used to dip it in the water, to purify and sweeten it, ere it would drink: it is added, that for the same reason other beasts wait to see this creature drink before them. Thence, as also from the rarity of the thing, people have taken occasion to attribute divers medicinal virtues to it.

But Amb. Paré has proved it a mere piece of charletanery, and all the virtues attributed to it to be false; and yet the price it has borne is almost incredible. Andrea Racci, a physician of Florence, affirms the pound of sixteen ounces to have been at one time sold, in the apothecaries' shops, for fifteen hundred and thirty-six crowns, when the same weight of gold was only worth one hundred and forty-eight crowns. See RHINOCEROS.

The unicorn is one of the supporters of the arms of England. This beast is represented, by heralds, passant, and sometimes rampant. When in this last action, as in the English arms, it is properly said to be *passant*. Argent, an unicorn sejant sable, armed and unguled, or, borne by the name of *Harding*.

UNICORN, *Sea*, the name of a fish of the whale kind, called also *narbual*, or *narwal*, remarkable for having a horn growing out at its nose, in the manner of the supposed unicorn's horn, as described by many too credulous authors. It is the only species of monodon in the Linnæan system.

This fish feeds on flesh, or other fish, and is not only found in the main sea, but sometimes gets up into large rivers. In the year 1736 there was a large one caught in the river Oste, near its discharging itself into the Elbe, in the duchy of Bremen; this place is four German miles from the sea. The skin of this fish was spotted with dark-brown spots upon a white ground; the epidermis was transparent; and under it was another skin very thin and spotted; but the true skin was brown, and near an inch in thickness. On the top of the head there is only a semi-lunar hole, as in the porpoises; this hole opens into the two channels, which run through the skull to the palate, and are called the ductus hydragogi. The people who examined this

creature were not able to find any aperture in the body for the discharge of the excrements; whence it has been generally believed, that the creature voids them through this passage in the head.

Authors have differed in the name of the process issuing from the head; some calling it a horn, others a tooth; some are of opinion that it serves to break the ice for air; but others pretend that it is an offensive weapon, with which it wounds the common whale, and other large fish; and that when it has plunged it up to the head in the whale's body, it sucks the juices of that animal.

The fish was near twenty feet long, and about four feet in diameter. The horn stood on the fore-part of the head, just above the mouth, and was six feet long, white like ivory, and curiously wreathed or twisted. The body was smooth and slippery, like that of an eel; the head, in proportion to the body, was small, not exceeding sixteen inches in length, and the same in diameter; the eyes not larger than a sixpence. It had, on each side of the neck, two black fins, one above another at a small distance; these were two feet long, of the breadth of a hand, and about half an inch in thickness. See the account of this fish by Dr. Steigertahl, and Dr. Hampe, in Phil. Trans. N^o 447. p. 157, and p. 149. or Abr. vol. ix. p. 71, &c.

This unicorn's horn has been so common in the Danish and neighbouring seas, that there was a magnificent throne built only of them in that kingdom; the horns are from ten to fifteen feet in length, and are all white, and furrowed with a spiral line.

Unicorn's horn has the same medicinal virtues with hart's horn and ivory; but at present is only kept as an ornament in druggists' shops.

UNICORN, *Sea*, is also a name given to two sorts of small fish caught in the American seas, and known among authors under the name of *Monoceros pisces*.

UNICORNU Fossile, Fossile Unicorn's Horn, the name of a substance much used in medicine in some parts of the world, but which seems to have been very little understood by many who have written of it. Dr. Hill, from the examination of the several varieties of shapes it is found in, and trying it by the several tests which fix the criterions of fossils, has determined it to be no other than a terrene crustaceous spar, not very different from the osteocolla, and other bodies of that genus, which he has called the *cibdeloplacia*; and has distinguished this peculiar species by the name *cibdeloplacium albidofubcinereum, friabile, superficis lævis*, or the whitish-grey friable crustaceous spar, with a smooth surface.

It differs principally from the osteocolla in its softness, and the smoothness of its surface; but from its having, like many other of the crustaceous terrene spars, the property of encrusting, and sometimes even permeating the pores of bodies, and in a manner petrifying them, it has obtained the names of the things it thus lodges itself in and about, which being usually bone, and some of them bones of an extraordinary size and figure, have been taken for the bones and horns of unicorns; and the name and nature of the body itself wholly lost and neglected, and that of the horn, with that of its imaginary animal, only preserved.

They are, however, now sensible in Germany, that it is not the horn, but this substance, which is lodged about it, which is the medicine; for they never use the fossil bones which are petrified in the common way, but only such as are impregnated with this sparry substance; and even use all substances whatever, which are impregnated with this, whether bones or wood, under the same name, calling the

natural tubular pieces of it, which are very common, and also the pieces of branches of trees impregnated with it, by the common name of unicorn's horn, while they allow plain bones, petrified in the common way, no such name. So that the word is now become a mere technical term, and signifies either this spar in its pure state, or any substance whatever which is impregnated with it.

It is a lax and spongy terrene spar, and is naturally of a regular form, in some degree like that of the osteocolla, being always found, where it has concreted pure, and not been in the way of any extraneous substance, an oblong and moderately thick, cylindrical, tubular body, frequently narrower at one end than the other, and approaching to a conic form. Usually its hollow is empty, but sometimes it is found filled up with a substance of the same nature with itself, only composed of a larger proportion of earth with less spar, and therefore more crumbly and soft. These are found of various sizes, from an inch to three feet long. The larger specimens are most frequent; and it is very probable, that the ignorance of the first ages, which brought it into use in medicine, might take these natural concretions for unicorns' horns.

It is found in other parts of the world besides Germany, and is in great esteem in many places as a sudorific and astringent; and is given in fevers, attended with diarrhoea, with great success. Hill.

Dr. Ebreus, in his Natural History of Hartz Forest, in Germany, gives a particular account of this fossil. He says that it is dug up of different shapes; sometimes like a straight horn, skull, jaw-bone, shoulder-blade, back-bone, rib, tooth, thigh-bones, or other bones of men and beasts; and sometimes like an unshaped lump or mass of stone, having no resemblance to bone. Conrigius, and Otto Guericke, have maintained that this fossil is petrified bone; others, as Sennertus, Schræder, Baucusius, &c. not being able to comprehend how bones of such size and in such quantities should be collected together, and dissatisfied with the account given by naturalists of the manner of their petrification, reckon it among the minerals. Some think, with Labavius, that it is a bituminous earth; others say that it is a kind of agate; but Dr. Ebreus apprehends, that it is formed of a clayey or fatshy earth, called *marga* or marle, common in that country, hardened by petrifying water, and assuming different shapes and sizes, according to the situation in which this earth lies under ground. It is commonly of a light grey, black, or yellowish colour, and seldom perfectly white; sometimes it is as hard as a stone, and sometimes soft as clay, and hardens by being exposed to the air. It has commonly neither smell nor taste; though in some cases it has been found with a scent like that of quinces, which Dr. Ebreus ascribes to a bituminous substance mixed with the petrifying water. The whitest and mellowest is reckoned the best for medical purposes. It operates, he says, like the terra sigillata, absorbing, astringing, and promoting perspiration; and is one of the ingredients of the bezoardic powder, described by Ludovici in his "Pharmacopœia Moderna sæculo applicanda," and produces a very good effect, unless a symptomatic costiveness forbids the use of it. Externally it serves in pustular eruptions and erosions about the pudendum and fundament in children, and in eye-waters. Hoffman advises people to try the fossil unicorn first upon a dog, before it is used in medicine; because he thinks it is sometimes of a poisonous nature, but this is never observed in any fossil of this kind found in or near Hartz Forest.

UNICZOW, or MAHRISH NEUSTADT, in *Geography*,
VOL. XXXVII.

a town of Moravia, in the circle of Olmutz; 12 miles N.N.W. of Olmutz. N. lat. 49° 42'. E. long. 17°.

UNIEGOW, a town of the duchy of Warsaw; 18 miles S.W. of Lenciez.

UNIEH, a town of Asiatic Turkey, in Natolia; 40 miles E. of Samfoun.

UNIEJOW, a town of the duchy of Warsaw; 15 miles N.N.E. of Siradia.

UNIENOW, a town of the duchy of Warsaw; 20 miles S.E. of Kalisch.

UNIFOLIUM, in *Botany*, Dill. Nov. Gen. 138. t. 7, is so called, not because it bears a single leaf only, which is not the case, but because it springs out of the ground with a solitary leaf, and is some time before it acquires more. The plant in question is *Convallaria bifolia* of Linnæus, whose flowers are four-cleft, or rather have four petals and four stamens only.

UNIFORM, UNIFORMIS, denotes a thing to be similar, or consistent either with another thing, or with itself, in respect of figure, structure, proportion, and the like. In which sense it stands opposed to *difform*.

UNIFORM, in a *Military Sense*, signifies the ornamental parts of a soldier's dress, by which one regiment is distinguished from another. See REGIMENTALS.

UNIFORM or *Equable Motion*. See MOTION.

UNIFORM *Flowers of Plants*. See POLYPETALOUS *Flowers*.

UNIFORM *Matter*, in *Natural Philosophy*, that which is all of the same kind and texture.

UNIFORM *Temperament*. See TEMPERAMENT.

UNIFORMITY, REGULARITY, a similitude or resemblance between the parts of a whole. Such is that we meet with in figures of many sides, and angles respectively equal, and answerable to each other.

A late ingenious author makes beauty to consist in uniformity, joined or combined with variety.

Where the uniformity is equal in two objects, the beauty, he contends, is as the variety; and where the variety is equal, the beauty is as the uniformity. See BEAUTY.

UNIFORMITY is particularly used for one and the same form of public prayers, and administration of sacraments, and other rites, &c. of the church of England, prescribed by the famous stat. 1 Eliz. and 13 & 14 Car. II. cap. 4. called the "Act of Uniformity." See LITURGY.

Although it is declared in the Act of Uniformity, "that nothing conduceth more to the settling of the peace of the nation, nor to the honour of our religion, and the propagation thereof, than an universal agreement in the public worship of God," it has been contended, that strict uniformity with regard to points of doctrine and forms of worship is not essential to the peace of society, and to the honour and prevalence of true religion; and that such an uniformity is inconsistent with the present state of mankind, possessing different faculties and talents, and different opportunities and means of inquiry; and that it is, therefore, altogether unattainable. It has been also maintained, that, in the province of religion, every man has a right to exercise his own judgment, and to satisfy his own conscience, under the best illumination which he is able to obtain; and that the civil magistrate, however exalted his rank and extensive his influence in the community over which he presides, ought not to interfere in controuling this right, and obstructing the exercise of it. It has been alleged, that every attempt to enforce uniformity of religious faith and worship by privations and penalties of a civil and secular nature, is a misapplication of the authority with which he is invested, and an extension of it beyond its proper province, inconsistent with

UNIFORMITY.

the doctrines and spirit of Christianity, and injurious to the rights and claims of peaceable and loyal subjects. Those persons to whom we now refer object to the fundamental principle and professed design of the Act of Uniformity, and they concur with many others in disapproving and condemning the mode and time of its introduction, its pernicious influence in causing a schism or separation among British Protestants, and the indignance and distress to which it reduced a great number of meritorious persons, whose conscientious scruples, exemplary character, and useful services, entitled them to protection and encouragement. To this purpose it has been said, that the conditions of exercising the Christian ministry, which the Act of Uniformity imposed, are such as no civil authority can justifiably enjoin; and that it requires subscription to articles of faith, which Christ, who, as they say, is the supreme head of the Christian church, never established; and unfeigned assent and consent to rites and forms of worship, which neither he nor his apostles ever ordained. Besides, this Act required the clergy to subscribe and declare, "that it is not lawful, upon any pretence whatsoever, to take arms against the king, or any commissioned by him;" a position, as it has been conceived, absolutely subversive of the British constitution, and which the nation, soon after the act of king Charles II., openly acknowledged to be traitorous, detestable, scandalous, and false; and which, if admitted, would have precluded us from enjoying the benefits of the glorious revolution, and our present happy government. By this Act the Puritans, extolled even by Hume as a sect, though their principles appear, in his view of them, so frivolous, and habits so ridiculous, to which the English owe the whole freedom of their constitution, were lamentably separated from the English church; and many of them were thus recompensed by Charles II. for their activity and zeal in restoring them to the British throne.

When Charles II. came to Scotland, says lord Clarendon, (Hist. of the Rebellion, vol. vi. p. 374, 375, 733, 734.) expecting force from that kingdom to restore him "to his father's throne, and the parliament of England resolved to send an army against him, all the Presbyterian party greatly opposed it: they were bold in contradicting Cromwell in the house, and crossing all his designs in the city." See Rapin's Hist. of England, vol. xiii. p. 227, 241, 242.

Bishop Burnet says, "these five following persons, all Presbyterians, had the chief hand in the restoration: sir Ant. Ashley Cooper, afterwards earl of Shaftesbury; sir Arthur Annesley, afterwards earl of Anglesey; Denzil Hollis, created lord Hollis; the earl of Manchester; and lord Roberts."—"The Presbyterians and the Royalists," says Hume, "being united, formed the voice of the nation, which called for the king's restoration."

Moreover, the Presbyterians, (whom the king, with too much truth perhaps, used to call *God's silly people*), trusting to his declaration from Breda, solemnly promising "liberty to tender consciences, and that no man should be disqualified for differences of opinion in matters of religion, which did not disturb the peace of the kingdom;" and, relying upon the fair speeches and assurances of his friends, and some of them perhaps duped by the low cunning of the king, who (a committee of their ministers being sent to him at Breda) ordered them to be in waiting whilst he hypocritically withdrew to perform his private devotions, in which his heart was so enlarged, that his voice was distinctly heard, as he intended it should be, by the ministers in the ante-chamber, devoutly thanking God that he was a covenanted king, (alluding to the solemn league and covenant, to which he had bound

himself by the most sacred of oaths,) and that he hoped the Lord would give him a humble, meek, and forgiving spirit. Whether the Presbyterians were deluded by the fair promises of the king and his treacherous friends, or were pressed by the civil discord which at that time subsisted, and alarmed at the dreadful disorders into which they apprehended the nation was again running,—be this as it may, they were so infatuated as to trust to the honour of Charles II., and, without previously settling any conditions, they were highly instrumental in restoring him to the throne. Their folly was only equalled by the base ingratitude with which he requited them.

Two years had scarcely elapsed before the Act of Uniformity was, by a small majority, passed into a law, which not only cast out of their livings two thousand ministers, some of whom had helped forward his restoration, but exposed them and their distressed families to numerous sufferings. The goals were soon filled with the unhappy restorers of this ungrateful king; their houses were pillaged; their families reduced to beggary and want. An estimate was published of near eight thousand Protestant dissenters, who perished in prison by their sufferings on a religious account, in the reign of this perjured, perfidious prince; and, by the severe penalties inflicted on them, for no other crime but that of assembling to worship God, they suffered in their trades and estates, in the compass of a few years, at least, it is said, two millions. Crit. Hist. of England. Neal's Hist. of the Puritans, vol. iv.

This was the king who had himself three several times taken the Scots covenant, declared solemnly his detestation of Popery and Prelacy, vowed never to tolerate them in any part of his dominions, and, in the most solemn manner, swore, by the eternal and almighty God, who liveth and reigneth for ever, that he would not only enjoy the covenant, but fully establish Presbyterian government, and their directory for worship, and observe them in his own practice and family, and never oppose them, nor endeavour any change.

Besides, we may here adduce the historical fact, that the Puritan or Presbyterian clergy were the only body of men in the whole kingdom, who had the courage to oppose and to protest openly against the trial and condemnation of Charles I. Their long and spirited protest was signed by above fifty of the principal Presbyterian ministers in and about London, and presented Jan. 18, 1648-9. See Burnet's Hist. of his own Times, vol. ii. p. 31. Echard's Hist. of England, p. 654, 708. See also the histories of Clarendon, Rapin, &c. &c.

"Bartholomew day," says Mr. Locke, "was fatal to our church and religion, by throwing out a very great number (about two thousand) of worthy, learned, pious, orthodox divines, who could not come up to this oath, and other things in that act. And so great was the zeal in carrying on this church affair, and so blind in the obedience required, that if you compute the time of passing this act with that allowed for the clergy to subscribe the book of Common Prayer thereby established, you will find it could not be printed and distributed so as that one man in forty could have seen and read the book they did so perfectly assent and consent to."—"The matter was driven on," says bishop Burnet (Hist. of his Times, vol. i. p. 212, 8vo.) "with so much precipitation, that it seemed expected the clergy should subscribe implicitly to a book they had never seen. This was done by too many, as the bishops themselves informed me." Among these were several, who, according to Mr. Locke's description of them, were "taught rather to obey than to understand."

It has been much lamented by many, eminently learned and strictly conscientious, members of the church, both clergy and laity, that the obligation to subscribe assent and consent to a variety of articles of faith and forms of worship, of doubtful and disputable evidence and utility, enjoined and enforced by the Act of Uniformity, should still remain as an indispensable condition of obtaining honourable and useful offices both in the church and state; more especially at a period when liberal sentiments, with regard to controversial subjects, are generally entertained both by clergy and laity; when the right of private judgment and free inquiry is universally acknowledged; and when the governors of the church and the legislature of the state seem disposed to uphold and promote the interests of religious liberty. Attempts have been made to widen the door of admission into the church, and to remove the impediments that lie in the way of advancement to civil offices of trust and profit. Hitherto they have proved ineffectual; but when it shall be perceived that neither the established religion of the country nor the safety of the state can suffer any detriment from a greater latitude in this respect, scrupulous consciences will be relieved, the church will gain an accession of ornament and support, and an union of many interests and services give strength and stability to the constitution and government of the country. On the general subject which has now engaged attention, different opinions have been maintained; and the Editor hopes that the candid reader will find them impartially stated, as far as the limits of this work allow, under the articles CHURCH, CLERGY, LITURGY, RELIGION, SUBSCRIPTION, TEST, TOLERATION, &c. &c.

UNIGENITUS, called also the *Constitution*, in *Ecclesiastical History*, a famous bull, deriving its denomination from the first word of it, which was issued in 1713 by pope Clement XI., and in which Queen's book, entitled "Moral Reflections on the New Testament," was condemned, and a hundred and one propositions contained in it were pronounced heretical. This bull gave a favourable turn to the affairs of the Jesuits; but it was highly detrimental to the interests of the Romish church, as many of the wiser members of that community candidly acknowledge. For it not only confirmed the Protestants in their separation, by convincing them that the church of Rome was resolved to adhere to its ancient superstitions and corruptions, but also offended many of the Roman Catholics, who had no peculiar attachment to the doctrines of Janfenius, against which this bull was levelled, and were only bent on the pursuit of truth, and the advancement of piety. See JANSENIISM.

The dissensions and tumults excited in France by this edict were in the highest degree violent. A considerable number of bishops, among whom was the cardinal de Noailles, archbishop of Paris, and a large body, composed of persons eminently distinguished for their piety and erudition, both among the clergy and laity, appealed from the bull to a general council; and hence those who reject the authority of the bull are called *appellants*; which see. However, the issue of this famous contest was favourable to the bull, which was at length rendered valid by the authority of the parliament, and was registered among the laws of the state. Moheim's *Ecll. Hist.* vol. v. 8vo.

UNJIGAH, or *Peace River*, in *Geography*. See PEACE RIVER.

UNILOCULAR CAPSULE, among *Botanists*. See CAPSULE.

UNIOLA, was so named by LINNÆUS, as he himself informs us, *Phil. Bot.* 166, from the union, or rather the aggregation, of several glumes in the calyx; of which, in

Hort. Cliff. 23, he speaks as the very remarkable character of this genus of grasses, one species only of which had then come under his notice.—*Linn. Gen.* 35. *Am. Acad.* v. 7. 195. t. 3. f. 40. Schreb. 49. Willd. *Sp. Pl.* v. 1. 406. Mart. *Mill. Dict.* v. 4. Ait. *Hort. Kew.* v. 1. 159. Pursh 82. *Juss.* 32. Beauvois *Agrofl.* 74. t. 15. f. 6. Poiret in Lamarck *Dict.* v. 8. 183. (Briza; Lamarck *Illustr. t.* 45. f. 3.)—Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume many-flowered, of from three to six nearly awl-shaped, compressed, boat-like, minutely keeled valves, alternately imbricated in two rows, each valve closely embracing the next, the upper pair largest, subtending the many-flowered, ovate, greatly compressed, sharp-edged spikelet. *Cor.* of two lanceolate, compressed valves, resembling the calyx, but larger, cloven, acute, without awns. Nectary of two wedge-shaped cloven scales. *Stam.* Filaments three, rarely but one, capillary; anthers oblong, linear. *Pistl.* Germen superior, conical; styles two, erect, simple; stigmas downy. *Peric.* none, except the permanent corolla. *Seed* solitary, ovate-oblong, somewhat cylindrical, unconnected with the corolla.

Efl. Ch. Calyx of several valves, many-flowered. Spikelet ovate, awnless, keeled. Seed somewhat cylindrical, unconnected.

1. *U. paniculata*. Paniced Spike-grafs. *Linn. Sp. Pl.* 103. Willd. p. 1, excluding Catesby's synonym. Pursh n. 2. Muhlenb. *Cat.* 12. (*U. maritima*; Michaux *Boreal-Amer.* v. 1. 71. Uniola; *Linn. Hort. Cliff.* 23. *Gramen μολοκοφορον οξυρριζωλον carolinianum*; *Pluk. Phyt.* t. 32. f. 6.)—Panicle repeatedly compound; partial stalks shorter than the spikelets. Calyx of six valves. Keel of the florets smooth. Leaves involute.—Native of the sandy sea-shores of North America, from Virginia to Florida, perennial, flowering in June and July. *Pursh.* One of the largest and most magnificent of grasses. The stem is from four to six feet high, erect, round, jointed, smooth, leafy in the lower part, terminating in an ample panicle eighteen inches long, whose drooping, smooth, compound branches spread in every direction, and bear innumerable, pendent, light brown, or straw-coloured, shining, ovate, very flat spikelets, full an inch long, half an inch broad; some of them nearly sessile. Florets about fourteen; the inner valve of their corolla a little downy at the edges; keel of the outer sometimes, though rarely, a little rough, not fringed.

2. *U. latifolia*. Broad-leaved Spike-grafs. Michaux *Boreal-Amer.* v. 1. 70. Muhlenb. *Cat.* 12. Pursh n. 1. (*U. paniculata*; Ait. n. 1. *Gramen microporphoron oxyphyllon carolinianum*; Catesb. *Car.* v. 1. t. 32.)—Panicle loose, with capillary stalks, mostly longer than the spikelets. Calyx of three valves. Keel of the florets fringed. Stamen solitary. Leaves lanceolate, flat.—Native of shady woods among rocks, on the Alleghany mountains, perennial, flowering in June. Michaux, *Pursh.* Near Lancaster, Pennsylvania, flowering in August. Muhlenb. One of Catesby's original specimens, now in our hands, settles his synonym, hitherto always applied to the foregoing, and is inscribed, in his hand-writing, as follows. "This odd plant or grass grown in a rich bottom, by a creek-side up the west branch of Susqueannah river. I observed but a little spot of it in all my journey." Nothing can be more distinct from the real *paniculata* above described, which is a sea-side plant. The specific characters are abundantly clear. The present is of more slender and less elevated growth, with broad, many-ribbed leaves, glaucous beneath. Panicle capillary, much less branched. Spikelets green or glaucous, of fewer and broader florets, which, according to Michaux, are

are monandrous: their keel is rough with short hairs, as well as fringed more or less with longer ones. The *calyx* consists of three unequal valves.

3. *U. racemosa*. Jamaica Spike-grafs.—Cluster cylindrical, compound. Spikelets nearly sessile. Calyx of about four valves. Keel of the florets minutely downy. Leaves involute, taper-pointed.—Gathered in Jamaica by Mr. Masson, one of whose specimens was communicated, probably by sir Joseph Banks, to the younger Linnæus. We know not how so fine a species of this elegant genus escaped the notice of Dr. Swartz. It has the aspect of a sea-side grafs, having a very stout *stem*, leafy to the very summit. The *leaves* are involute, rigid, with a long very slender point, and broad sheathing base, crowned with a hairy *stipula*: the upper ones, two feet in length, rise high above the flowers. The *panicle* is terminal, solitary, cylindrical, six inches long, with numerous, short, toothed, simple, downy, many-flowered *branches*, each bearing six or eight alternate, nearly sessile, flat, ovate *spikelets*, half an inch long, variegated with green and white. The *florets* are about twelve, ovate, compressed, finely downy at the edges and keel, having three green ribs at each side extending half way down from their point.

4. *U. mucronata*. Pointed Spike-grafs. Linn. Sp. Pl. 104. Willd. n. 2.—“Spike two-ranked. Spikelets ovate. Calyx somewhat awned.”—Native of the East Indies. *Burmans*. *Stem* a foot high, smooth. *Leaves* narrow, smooth, with striated sheaths. *Spike* of eleven or twelve *spikelets*, which are alternate, in two rows, nearly sessile, ovate, smooth, seven-flowered. The *calyx* is so much pointed as to be almost awned. Linnæus. We have seen no specimen. The description was probably made from Burmann’s herbarium.

5. *U. spicata*. Two-ranked Spike-grafs. Linn. Sp. Pl. 104. Willd. n. 3. Bigelow Bot. 23. Ait. n. 2. (Fesuca distichophylla; Michaux Boreal-Amer. v. 1. 67. Pursh 84, excluding the reference to Plukenet.)—Spike unilateral, dense. Spikelets tumid, sessile, smooth. Leaves involute, pointed, rigid.—Native of salt meadows in North America; common along the coast from Canada to Florida; perennial, flowering in July and August. *Pursh*. The *stem* is much branched, and thickly clothed with rigid, pungent, smooth, sheathing, alternate *leaves*, two or three inches long, rising above the *spikes*, which are terminal, solitary, sessile, about an inch in length. Each *spikelet* consists of four or five broad close *florets*, and the two principal *calyx-valves* are sometimes accompanied by one or two smaller external glumes, which may excuse Linnæus for placing this species here, but we confess it to be a bad *Uniola*. Plukenet’s t. 33. f. 4, cited doubtfully by Pursh, bears much resemblance to our plant, but is an English *Triticum*!

6. *U. gracilis*. Slender Spike-grafs. Michaux Boreal-Amer. v. 1. 71. Pursh n. 3. (Holecus laxus; Linn. Sp. Pl. 1486. Willd. Sp. Pl. v. 4. 934.)—“Panicle elongated, somewhat spiked, with short close-pressed branches. Spikelets nearly sessile. Florets monandrous, divaricated, pointed, smooth. Calyx of three valves. Leaves flattish; their sheaths smooth and compressed, like the stem.”—In shady rocky situations, from Virginia to Georgia; perennial, flowering in July. *Pursh*. Linnæus compares the habit of the grafs to *Aira*, or *Melica*, *cærulea*. The *stems* are weak, two feet high, a little drooping.

Labillardiere, Nov. Holl. v. 1. 21. t. 24, has an *U. distichophylla*, very nearly related to our *spicata*, but referred to *Poa* by Mr. Brown, Prodr. Nov. Holl. v. 1. 182.

UNION, a junction, coalition, or assemblage of two or

more different things in one. Philosophers are much perplexed in accounting for the manner of the union of soul and body, or by what medium it is that such two heterogeneous beings are kept closely together.

It is one of the great laws of this union, that such and such an impression on the brain be followed by such and such a sensation, or perception, in the soul.

UNION, in a philosophical sense, is used by Dr. Grew for one of the three ways of mixture; being the joining together of atoms, or insensible particles, so as to touch in a plane; as is supposed to be the case in the crystallizations of salts and the like bodies.

UNION, among *Painters*, expresses a symmetry and agreement between the several parts of a painting; when, *e. gr.* there is a considerable degree of relation and connection between them, both as to the figuring and the colouring; so that they apparently conspire to form one thing.

UNION, in *Architecture*, may denote a harmony between the colours in the materials of a building.

UNION, in an ecclesiastical sense, denotes a combining or consolidating of two or more churches into one.

This is not to be done without the consent both of the bishop, the patron, and the incumbent.

The canonists distinguish three kinds of union; that of *accession*, that of *confusion*, and that of *equality*.

UNION of *Accession* is the most usual; by this the united benefice becomes a member, and accessory of the principal.

UNION by *Confusion*, is that where the two titles are suppressed, and a new one created, including both.

UNION of *Equality*, is that where the two titles subsist, but are equal and independent.

The union or consolidation of churches ought to be founded upon good canonical reasons; and the principal reasons assigned by the canon law are, for hospitality, nearness of the places, want of inhabitants, poverty or smallness of the living. These several circumstances must be inquired into before the union; and some, or all of them, are recited in the preamble to the act of union.

In such case, by the common law of the realm, the ordinaries, patrons, and incumbents, may make a consolidation or union of the two churches into one. (1 Salk. 165. Hughes, c. 28.) Moreover, in such case, it is said, that the consent of the king is not at all necessary, although he hath an interest in the churches in the case of lapse. For by the ancient canon law, the licence of the pope was not necessary; nor has the licence of the king been thought necessary since the reformation. In some instances, however, it has been desired and obtained for the greater caution. Cro. Eliz. 500. Gibbon. Watson.

By stat. 37 Hen. VIII. c. 21. it is enacted, that an union or consolidation of two churches, or of a church and chapel, into one, may be admitted, provided the annual value of one of them, in the king’s books, doth not exceed 6*l.*, and the distance between them be not above one mile.

This union supposes the assent of the ordinary and ordinaries of the diocese where such churches and chapels stand, and the assent of the incumbents of them, and of all such as have a just right, title, and interest to the patronage of the same churches and chapels, being then of full age. This union shall be available in the law, to continue for ever; provided that where the inhabitants of any such poor parish, or the more part of them, within one year next after the union or consolidation of the same parish by their writing sufficient in the law, shall assure the incumbent of the said parish, for the yearly payment of so much money as with the sum that the said parish is rated and valued at in the court of first fruits and tenths, shall amount to the full sum

of 8*l.*, to be levied and paid yearly by the said inhabitants to the said incumbent and his successors; all such unions or consolidations made of any such poor parish as aforesaid, shall be void and of none effect.

By the same statute, it is provided, that all unions and consolidations, to be made of any church or chapel within any city or town corporate, without the assent of the mayor, sheriffs, and commonalty of such city, or without the assent of the body corporate of other towns corporate, by the names of their corporations in writing under their common seal, shall be void.

By 21 Hen. VIII. c. 13. s. 9. if any person having one benefice with cure, of the yearly value of 8*l.*, or above, take any other with cure, and be inducted in possession of the same; then immediately after such possession, the first benefice shall be void. And by s. 10. it shall be lawful for the patron to present; any licence, union, or other dispensation, to the contrary thereof notwithstanding. By which word *union* there is meant not a perpetual, but a temporary union during the life of an incumbent. (Gibf. Cod. 970. art. 7.) And this is there clearly proved, first by the words of the union, and also by the case of Page v. Bp. of London. Cro. El. 719, 720.

And by another stat. 17 Car. II. c. 3. it is enacted, that the union of two churches, or chapels, in any city or town, by the bishop, patron, and chief magistrate of the town, shall be valid, unless the value of the churches so united exceed 100*l.*

By the union the two churches are become so much one, that a second benefice may be taken by dispensation within the statute of pluralities. (Cro. Eliz. 720. Gibson 920.) If any question arise concerning the union, after it is established, this may not be tried in the temporal, but only in the spiritual court; unless it be such union as is restrained by the aforesaid statutes. Watf. c. 16.

UNION, *Hypostatical*. See *HYPOSTACIAL*.

UNION, or *The Union*, by way of eminence, is more particularly used, among us, to express the act by which the two separate kingdoms of England and Scotland were incorporated into one, under the title of the *Kingdom of Great Britain*.

The kingdom of Scotland, notwithstanding the union of the crowns on the accession of their king James VI. to that of England in 1603, continued an entirely separate and distinct kingdom for above a century more, though an union had been long projected; which was judged to be the more easy to be done, as both kingdoms were anciently under the same government, and still retained a very great resemblance, though far from an identity, in their laws. By an act of parliament (1 Jac. I. cap. 1.) it is declared, that these two mighty, famous, and ancient kingdoms, were formerly one. And sir Edward Coke observes, how marvellous a conformity there was, not only in the religion and language of the two nations, but also in their ancient laws, the descent of the crown, their parliaments, their titles of nobility, their officers of state and of justice, their writs, their customs, and even the language of their laws: upon which account he supposes the common law of each to have been originally the same. However, sir Edward Coke, and the politicians of that time, conceived great difficulties in carrying on the projected union; but these were at length overcome, and the great work was happily effected in the year 1707, by the general consent of the queen, and the estates of each realm.

The act or treaty of union consists of twenty-five articles; which eleven English commissioners, and eleven Scotch

ones, examined, approved, and signed on the 3d of August 1706. The parliament of Scotland approved it on the 4th of February 1707, and the parliament of England on the 10th of March in the same year. On the 17th following the queen went to parliament, where she approved the same treaty, with the act of ratification.

The purport of the most considerable articles is as follows: 1. That on the 1st of May, 1707, and for ever after the kingdoms of England and Scotland shall be united into one kingdom, by the name of Great Britain. 2. The succession to the monarchy of Great Britain shall be the same as was before settled with regard to that of England. 3. The united kingdom shall be represented by one parliament. 4. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. 9. When England raises 2,000,000*l.* by a land-tax, Scotland shall raise 48,000*l.* 16, 17. The standards of the coin, of weights and measures, shall be reduced to those of England throughout the united kingdoms. 18. The laws relating to trade, customs, and the excise, shall be the same in Scotland as in England, But all the other laws in Scotland shall remain in force, but alterable by the parliament of Great Britain; yet with this caution, that laws relating to public policy are alterable at the discretion of the parliament; laws relating to private right are not to be altered, but for the evident utility of the people of Scotland. 22. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the house of commons. 23. The sixteen peers of Scotland shall have all privileges of parliament; and all peers of Scotland shall be peers of Great Britain, and rank next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.

These are the principal of the twenty-five articles of union, which are ratified and confirmed by statute 5 Anne, cap. 8. in which statute there are also two acts of parliament recited; the one of Scotland, by which the church of Scotland, and all the four universities of that kingdom, are established for ever, and all succeeding sovereigns are to take an oath inviolably to maintain the same; the other of England, 5 Anne, cap. 6. by which the acts of uniformity of 13 Eliz. and 13 Car. II. (except as the same had been altered by parliament at that time), and all other acts then in force for the preservation of the church of England, be declared perpetual; and it is stipulated, that every subordinate king and queen shall take an oath inviolably to maintain the same within England, Ireland, Wales, and the town of Berwick-upon-Tweed; and it is enacted, that these two acts shall for ever be observed as fundamental and essential conditions of the union.

The great officers of the crown of Scotland, before the union, were, the lord high chancellor, lord high treasurer, or treasurer, lord privy seal, and lord register, or secretary. Their less officers of state were, the lord register, lord advocate, lord treasurer deputy, and lord justice clerk.

Since the union, the officers of state in Scotland are the keeper of the great seal, lord privy seal, lord register, lord vice-admiral, lord justice general, lord president, lord chief baron of the exchequer, lord advocate, lord justice clerk, lord high constable, heretable royal standard bearer, knight marechal, heretable keeper of the king's household, heretable carver, and heretable usher of the white rod. The privy council of Scotland is sunk in the parliament and privy council of Great Britain, and the civil and criminal causes are chiefly cognizable

UNION.

ognizable by two courts of judicature, *viz.* the college of justice, or the court of session, and the judiciary court, under the direction of the lord justice general, the lord justice clerk, five commissioners, his majesty's advocate, three deputy advocates, a solicitor-general, &c. Besides these two great courts of law, the Scots, by the articles of union, have a court of exchequer, under the direction of a lord chief baron, and four barons. The court of admiralty in Scotland is a supreme court in all cases competent to its jurisdiction, and under the direction of the lord vice-admiral, a judge, procurator fiscal, &c. The courts of commissaries in Scotland answer to those of the English diocesan chancellors; the highest of which is kept at Edinburgh, in which, before four judges, actions are pleaded concerning wills, the right of patronage to ecclesiastical benefices, tithes, divorces, and such causes. The office of privy seal is under the direction of the lord privy seal, a deputy writer to the privy seal, and his deputy. The great seal office is under the direction of the lord keeper, and deputy and king's writer. The lord register's office is under the superintendance of the lord register, and six deputies. The chancery is under the administration of a director, deputy, and principal clerk. See *COLLEGE of Heralds*, and *UNIVERSITY*.

Under this article of union we may observe, with respect to Wales, that very early in our history, we find its princes doing homage to the crown of England; till at length, in the reign of Edward I. the line of its ancient princes was abolished; and the king of England's eldest son became, as a matter of course, their titular prince; the territory of Wales being then entirely annexed (by a kind of feudal redemption) to the dominion of the crown of England. (10 Edw. I.) By 12 Edw. I. and other subsequent statutes, their provincial immunities were farther abridged; but the finishing stroke to their independency was given by the statute 27 Hen. VIII. cap. 26. which at the same time admitted them to a thorough communication of laws with the subjects of England. By this statute it is enacted, 1. That the dominion of Wales shall be for ever united to the kingdom of England. 2. That all Welshmen born shall have the same liberties as the other king's subjects. 3. That lands in Wales shall be inheritable according to the English tenures and rules of descent. 4. That the laws of England, and no other, shall be used in Wales; besides many other regulations of the police of the principality. And the statute 34 & 35 Hen. VIII. cap. 26. confirms the same, adds farther regulations, divides it into twelve shires, and, in short, reduces it into the same order in which it stands at this day; differing from the kingdom of England in only a few particulars, and those too of the nature of privileges (such as having courts within itself, independent of the process of Westminster-hall), and some other immaterial peculiarities, hardly more than are to be found in many counties of England itself.

The town of Berwick-upon-Tweed was originally part of the kingdom of Scotland; and as such was for a time reduced by king Edward I. into the possession of the crown of England; and during its subjection, it received from that prince a charter, which (after its subsequent cession by Edward Balliol, to be for ever united to the crown and realm of England) was confirmed by king Edward III. with some additions, particularly that it should be governed by the laws and usages which it enjoyed before its reduction by Edward I. Its constitution was new-modelled, and put on an English footing by a charter of king James I.; and all its liberties, franchises, and customs, were confirmed in par-

liament by the statutes 22 Edw. IV. cap. 8, and 2 Jac. I. cap. 28. Though, therefore, it has some local peculiarities, derived from the ancient laws of Scotland, yet it is clearly part of the realm of England, being represented by burgesses in the house of commons, and bound by all acts of the British parliament, whether specially named or otherwise. Accordingly it was declared by statute 20 Geo. II. cap. 24. that, where England is only mentioned in any act of parliament, the same notwithstanding hath and shall be deemed to comprehend the dominion of Wales, and town of Berwick-upon-Tweed. And though certain of the king's writs or processes of the courts of Westminster do not usually run into Berwick, any more than the principality of Wales, yet it hath been solemnly adjudged, that all prerogative writs (as those of mandamus, prohibition, habeas corpus, certiorari, &c.) may issue to Berwick, as well as to every other of the dominions of the crown of England; and that indictments, and other local matters arising in the town of Berwick, may be tried by a jury in the county of Northumberland.

UNION, Legislative, between Great Britain and Ireland. Amongst the important events which will in future times distinguish the reign of George III. and the administration of William Pitt, is the legislative union which this statesman effected between Great Britain and Ireland; a measure which, in the opinion of its advocates, has consolidated the strength of the empire, and thus contributed to its prosperity; whilst by others it is supposed to have destroyed the independence of one country, and to have added to the influence of the crown or its ministers in the other. To pass over such a measure without some account of the circumstances which attended it, would be a defect in a work of this nature; yet to treat it so as to give general satisfaction cannot be expected, whilst many who took an active part in promoting or opposing it are still alive, and whilst all the measures likely to result from it have not yet taken effect.

The first consideration in forming an opinion on this question, is the previous state of legislation in Ireland, and the nature of the connection between the two countries. Under the article *IRELAND* there is a brief historical detail of the manner in which Ireland became connected with England, and of the succeeding events, to which the reader is referred. From this account it is evident that Ireland was always considered as a *dependent* country; and whether the right was derived from voluntary submission, from conquest, or from colonization, it has been long regarded as an axiom in Irish politics, that whosoever is king of England, the same is *ipso facto* king of Ireland. It was entitled the dominion, or lordship of Ireland, *stat. Hiberniæ*, 14 Hen. III. and the king's style was no other than *dominus Hiberniæ*, lord of Ireland, till the 33d year of king Henry VIII. when he assumed the title of king, which is recognized by act of parliament 35 Hen. VIII. cap. 3. With a view to secure this authority in its fullest extent, Poyning's law was established in the reign of Henry VII. by which no law could be enacted in Ireland, which had not been previously submitted to the king and his council in England, approved by them, and certified under the great seal of the realm. (See *POYNINGS' Law*.) This was found necessary at first to check the king's representatives, who had often a private interest at variance with that of their master; and it was afterwards thought expedient to prevent the descendants of the English colonists from pursuing their own interest at the expence of that of the mother-country. But though the dependance of Ireland, in a political point of view, was thus apparent, it was reserved for the reign of George I. to assert legislative authority,

UNION.

authority, which was done first by the reversion of a sentence of the Irish house of lords by the English house, as a superior court of judicature, and then by a solemn declaration of a right, not only to make such reversions in all cases of appeal, but also that the king's majesty, with the consent of the lords and commons of Great Britain in parliament, had power to make laws to bind the people of Ireland. When the present king, George III., ascended the throne in 1760, two-thirds of the people of Ireland, depressed by severe penal laws, not only were not represented in the parliament by which they were taxed, but were considered as aliens, undefending of any protection. The remaining third was represented by three hundred members, of which about one hundred were chosen by counties or large towns, and the remainder by boroughs, most of which had been constituted in the time of the Stewarts, to create a Protestant majority of the house of commons, and had become the property of a few individuals. The members thus chosen sat for their own lives, or that of the sovereign; no general election taking place except on the demise of the crown. The executive government was committed nominally to a viceroy, but essentially to lords justices, selected from the principal state officers of the country, who were entrusted with the conduct of what was called the king's business, but which might with more propriety have been called the business of the lords justices. The viceroy came to Ireland for a few months only in two years, and the lords justices in his absence had the means of consolidating an aristocratic influence, which made them the necessary instruments of the English government. As no acts could pass without the previous approbation of the king in his English council, it was usual to agree with some of the Irish leaders on a compromise that the minister would forward their local objects, provided they undertook to carry through parliament those bills which he required. What could be expected from such a system of government? What but a system of speculation and oppression, such as perhaps was scarcely ever witnessed in any other country? The object, it may be said the mistaken policy of the British government, was, in the words of Mr. Pitt, "to debar Ireland from the enjoyment and use of her own resources, and to make her completely subservient to the interests and opulence of Britain;" and whatever resistance might be occasionally shewn, the general tenor of conduct of the Irish parliament was to promote the destructive views of Britain, which the members made conducive to their own individual interests. "The inevitable final result of this unpropitious combination," to use the words of Mr. Newenham in his *View of the Natural, Political, and Commercial Circumstances of Ireland*, published in 1809, "was a very scanty and disproportionate acquisition of commercial wealth on the part of Ireland, and an almost utter extinction of a spirit of industry therein. To cramp, obstruct, and render abortive the industry of the Irish, were the objects of the British trader. To gratify commercial avarice, to serve Britain at the expence of Ireland, or to facilitate the government of the latter, were the varying objects of the British minister. To keep down the Papists, cost what it would, and to augment their own revenues by the public moneys, instead of urging the adoption of wise, liberal, and patriotic measures calculated to quadruple the rents of their estates, were the objects of the reputed representatives of the Irish people; and to secure themselves from retaliations on the part of the Roman Catholics, whom they were encouraged to persecute and taught to dread, was the general object of the Irish gentry." To this deplorable state of Ire-

land, we have to add the non-residence of the principal landed proprietors, and the frequent disturbances which under various pretences were raised in different parts of the country. In short, Ireland was in a state which could hardly be rendered worse, and which required some speedy melioration.

The measure of a legislative union had occurred to several as the best mode of rendering Ireland a valuable part of the British empire. Oliver Cromwell, during the period of his usurped power, actually carried it into effect: in the reign of queen Anne, the Irish house of lords petitioned for such an incorporation; and the great earl of Chatham is said to have regarded it as a favourite object. Now, though he and others might have had the interest of England immediately in view, yet it is an undoubted fact, that the interests of both countries are so closely united, that it is impossible to make Ireland contribute to the welfare of England without promoting its internal prosperity. The avowed object, it is said, was an object of taxation; but he must be a statesman of a very different cast from lord Chatham, who could expect to derive revenue from an impoverished country like Ireland, until he had awakened a spirit of industry, had civilized, improved, and enriched the people. Those, however, who derived benefit from the system then acted on, such as the parliamentary leaders, were not backward in expressing their dislike of a union, and they were supported by those whose vanity was pleased by the name of an independent legislature, as well as by those unfriendly to British connection. So odious was the measure, that in 1759, at a time when Ireland was threatened by a French invasion, the bare suspicion of its being in contemplation caused a spirit of dissatisfaction to break out with extraordinary violence among the populace of Dublin. It was represented that Ireland would be deprived of its parliament and independence, and be subjected to the same taxes that are levied upon the people of England. On this occasion both houses of parliament, especially the lords, were grossly insulted; the members were compelled to take an oath that they would never consent to such a measure; and, at last, military interference was found necessary to the restoration of order. This mode of influencing parliamentary proceedings by the threatenings of a mob, which was not unusual at a much later period in the Irish capital, proves the necessity of some change in the system of legislation. In the reign of George III. many measures were adopted which contributed to give weight to the anti-union party, and which certainly promoted the improvement and prosperity of the country. Parliaments were rendered octennial, and their sessions annual; many penal laws were repealed or modified; agriculture was encouraged; and a spirit of industry excited. In the mean time, Britain was weakened by its contest with its American colonies; and the demands of the Irish parliament, backed by 40,000 volunteers, procured a liberation of trade from unjust restrictions, and the establishment of legislative independence. This independence, however, was merely nominal; the influence of the British minister still directed the measures of the Irish parliament at a greater expence to the nation, and there were many difficulties from the want of some regular mode of considering the commercial interests of both countries: "some general superintending authority," as Mr. Fox said, "to embrace and comprehend the whole system of the navigation of the empire." In 1785, Mr. Pitt attempted to remedy this evil by a commercial arrangement, which, whilst it held out great advantages to Ireland, stipulated that so long as Ireland continued to trade with the British colonies and plantations, she would adopt the regulations of trade
and

and navigation imposed by the British parliament on British subjects in carrying on the same trade. This interference with the independence of Ireland defeated the measure of the British minister, though he was assisted on this occasion by the talents and knowledge of Mr. Foster, then chancellor of the Irish exchequer. On this occasion, lord Sackville, better known perhaps as lord George Germaine, the title he bore when in office, earnestly recommended a legislative union as the only mode of settling the jarring interests of the two countries; and it is thought that from that time the measure became a favourite object of the British ministry. Several political writers had indeed warmly recommended it. Dean Tucker observed, that "to incorporate both the British isles together, and make one kingdom, in all respects, as to parliament, trade, and taxes, had long been the wish of every generous disinterested patriot of both kingdoms:" and in 1785, after the rejection of the commercial propositions, he said, "respecting Ireland, one or other of the same consequences (union or separation) must inevitably follow. For after tropes and figures have been let off without number, after torrents of eloquence have been poured forth, much paper blotted, and much ink spilled,—recourse must be had, at last, either to a *separation*, or to a *union*; for plainly there is no other alternative; no other medium to be discovered, or cement which can last for any length of time." The result of Arthur Young's examination into the state of Ireland, seems to have been a similar conviction; and the distinguished author of the *Inquiry into the Nature and Causes of the Wealth of Nations*, book v. chap. 3, after speaking of the commercial advantages resulting from a union, says, that Ireland would gain other advantages much more important. "The greater part of the people of all ranks would gain a complete deliverance from an aristocracy, not founded in the natural and respectable distinctions of birth and fortune, but in those of religious and political prejudices; distinctions which, more than any other, animate both the insolence of the oppressors, and the hatred and indignation of the oppressed; and which commonly render the inhabitants of the same country more hostile to one another, than those of different countries ever are.—The spirit of party prevails less in Scotland than in England. In the case of a union, it would probably prevail less in Ireland than in Scotland. Without a union with Great Britain, the inhabitants of Ireland are not likely for many ages to consider themselves as one people." From an anecdote recorded by sir John Dalrymple, and quoted by Mr. Goold, one of the many writers against the union, it appears that in 1776, the earl of Rochford being offered the lord lieutenancy of Ireland, was willing to accept the office if he could do some great good there, and get some great fame, and that two objects occurred to him, the one to procure a repeal of the penal laws against Roman Catholics, and the other to bring about a union with England. He sent to consult lord Harcourt, then lord lieutenant, and his intimate friend, about these measures; and though lord Rochford had at first deemed them visionary, and lord Harcourt pointed out such difficulties as prevented his friend from undertaking them, still it is evident that both noblemen regarded them as measures calculated to promote the general welfare. The opposition to a union, which lord Harcourt apprehended in 1776, would have been greater in 1785.—"To carry this into effect," says Mr. Newenham, "was an achievement which required much time; much address; much vigilance, with regard to opportunities; much discernment, with regard to selection; much promptitude, and much energy during the season of

action; for the parliament of Ireland had become attached to its aristocracy; and the people of Ireland had been rendered enthusiastic in behalf of national independence, and exemption from the paralyzing controul of Britain. Indeed, as the writer well remembers, it was considered as almost amounting to treason against the nation, to utter a syllable in favour of a union. The parliament was studious to preserve independence, chiefly on account of its tendency to enhance the services of individual members. The people were studious to preserve it, because it afforded them a better prospect of patriotic measures than they had before. But they were also anxious to reform the parliament, in order to insure the adoption of those measures which the private interests of a majority of the members induced them to oppose."

In 1785, then, all parties would have joined in rejecting a union with abhorrence; and the minister found it necessary to give up his commercial system, though beneficial to Ireland, because it involved a partial surrender of legislative independence. Circumstances however occurred, which rendered some means of strengthening the connection between the two countries absolutely necessary.

In 1788 it pleased God to afflict our good and beloved king with a malady which disabled him from exercising his royal functions. The parliament of Great Britain determined, after long deliberations, to appoint the prince of Wales regent, with restrictions; and whilst their deliberations depended, the parliament of Ireland met, and almost instantaneously resolved that an address should be presented to the prince, requesting him to take upon himself the government during his majesty's indisposition, under the style and title of prince regent of Ireland. There was here a choice of a regent before the British parliament had come to a decision, and though the choice fell on the same personage, yet that personage would have had different powers in the two kingdoms. It was a proof indeed of independence, but it was inconsistent with the connection; for if Ireland could choose her regent, her choice might fall on a different individual from the regent of Great Britain. The convalescence of the king prevented any evil; but the conduct of the Irish parliament supplied the advocates of union with a powerful argument; and if Mr. Pitt had been before undecided, this would probably determine him to take the first opportunity of carrying it into effect. In the mean time many circumstances prepared the way. The disturbances respecting tithes contributed to religious dissensions; the Protestants became alarmed at the idea of a Popish parliament; and the Catholics were irritated at what they conceived their just rights being withheld. In 1792 the Catholics presented two petitions to the house of commons, the first of which was withdrawn, and the second was rejected on a division of 228 to 25; and it was complained that the Catholics of Ireland had not influence to induce any one member of parliament to patronize their petition, so faint was the support given to it, even by those who voted for receiving it. Yet in the next session of parliament, without any change of circumstances in the country, the same house of commons, which had refused to allow the petition of three-fourths of their countrymen to lie on their table, on the recommendation of the crown passed a bill, granting every privilege for which the Catholics had petitioned, and even without the restrictions on the right of voting, which they had themselves proposed. Could any proceeding have tended more to destroy the confidence of the people in their representatives?

In 1795, during the viceroyalty of lord Fitzwilliam, the Catholics

UNION.

Catholics were led by the friends of that nobleman in Ireland to bring forward their demand for a full emancipation with a prospect of success; and soon after, in consequence either of the English cabinet having changed their opinion, or of his lordship having gone beyond his agreement with them, he was recalled, and a considerable irritation of the Catholic body was the consequence. This was taken advantage of by those who had revolutionary feelings, and who well knew how to avail themselves of the popular ferment. Incited by the success of the French, and maintaining a secret communication with the republican government, an organization of the people took place; a directory was formed, which consisted of leading members of the society of united Irishmen; and in 1798, a rebellion broke out, which, though soon subdued, was attended by circumstances that left the country in a very distracted state. If the first French expedition, in 1796, had not been dispersed by a storm; and the second, in 1798, been too late to act in concert with the rebels, Ireland would, in all probability, have felt the evils of separation from England, and of French connection, and the people would have learned from bitter experience to value the privileges of British subjects; but disappointed of foreign aid, the rebels were shortly reduced, and it became the arduous task of government, by a combination of vigour and of mercy, to restore tranquillity. It has indeed been asserted, that government could have suppressed the rebellion without any effort, or rather have entirely prevented it; but that they facilitated its growth, and accelerated its explosion, with a view to bring about their favourite measure of union. The confession of the members of the Irish directory, and other leaders, afford ample proof to every candid person that such a charge is unfounded; and that if ministers had acted in the manner recommended by their parliamentary opponents, all exertion to save the country would have been in vain. Such a charge is equally the result of party virulence, as that which attributed to Mr. Grattan and his Whig friends a participation in the rebellion. But though it would be uncandid to suppose that government excited or facilitated the rebellion with a view of bringing about the union, it is certain, that when this auspicious conjuncture did occur, the minister lost no time in bringing it forward. The rebellion took place in 1798, and in the succeeding session of parliament the union was discussed.

Previous, however, to the meeting of parliament, a pamphlet published in favour of the measure, which was attributed to Edward Cooke, esq. one of the under-secretaries, produced a controversy, which was carried on with much spirit. The repugnance to the measure was very great; some of the principal officers of the crown declared their determination to oppose it, and lost their situations in consequence; the majority of the gentlemen of the bar took the same side, and several meetings of counties and large towns were held for the purpose of instructing their representatives to oppose it. Some of these were influenced by the utter incompatibility of the union with their private interests, and others by high notions of Irish independence, as settled in 1782.

On the 22d of January, 1799, the question of union was regularly brought before parliament by the marquis Cornwallis, the lord lieutenant, who concluded his speech from the throne in these words; "The more I have reflected on the situation and circumstances of this kingdom, considering on the one hand the strength and stability of Great Britain, and on the other those divisions which have shaken Ireland to its foundation, the more anxious I am for some permanent adjustment, which may extend the advantages enjoyed by our

after kingdom to every part of this island. The unremitting industry with which our enemies persevere in their avowed design of endeavouring to effect a separation of this kingdom from Great Britain, must have engaged your particular attention; and his majesty commands me to express his anxious hope that this confederation, joined to the sentiment of mutual affection and common interest, may dispose the parliaments in both kingdoms to provide the most effectual means of maintaining and improving a connection, essential to their common security, and of consolidating, as far as possible, into one firm and lasting fabric, the strength, the power, and the resources of the British empire."

The address, which was moved by the earl of Tyrone, eldest son of the marquis of Waterford, the head of the Beresford family, and seconded by colonel Uniacke Fitzgerald, one of the members for the county of Cork, only intimated a readiness to discuss any measure likely to cement and strengthen the connection, but the opposers of it would not allow even of this. An amendment was accordingly moved by Mr. George Ponsonby, an eminent barrister, who since filled the high office of lord chancellor of Ireland during the lieutenancy of the duke of Bedford, and on retiring from it, became leader of the opposition in the British parliament, a man of great talents united with great moderation and judgment, and seconded by sir Laurence Parsons, now earl of Ross, and one of the postmasters-general. The amendment was, that after the passage which declares the willingness of the house to enter on a consideration of what measures may best tend to confirm the common strength of the empire, should be inserted, "maintaining, however, the undoubted birth-right of the people of Ireland to have a resident and independent legislature, such as it was recognized by the British legislature in 1782, and was finally settled at the adjustment of all differences between the two countries." This amendment was supported by sir John Parnell and Mr. J. Fitzgerald, who had been just removed from the offices of chancellor of the exchequer and prime serjeant, by the friends of Mr. Foster, the speaker, by Mr. Plunket, and many others, distinguished for their talents, or their influence in the country. A legislative union was however approved by several who could not be justly suspected of improper motives, and amongst others by the right honourable Thomas Conolly, who used the strong expression, "that the constitution of 1782 could not work, two independent legislatures in one empire being as absurd and monstrous as two heads on one pair of shoulders." This was indeed a striking reason for a union of legislatures, or some other expedient, if any other could be devised, which would preclude all possible future collisions of supposed national interests, especially with regard to commercial matters. In this debate, however, the advocates for a union chiefly confined themselves to urging the propriety of discussing the measure coolly and impartially, when it had been recommended by the crown. The opposers of it took a wider range. Almost all the lawyers who spoke denied the competence of parliament to entertain the question. In 1785, Mr. Grattan had maintained "that parliament was not omnipotent to accomplish their own destruction, and propagate death to their successors; that they, the limited trustees of delegated powers, born for a particular purpose, confined to a particular time, and bearing an inviolable relationship to the people who sent them to parliament, could not break that relationship, counteract that purpose, or derogate from those privileges they lived but to preserve." This opinion was maintained by several, and Mr. Plunket, one of the most eloquent speakers, as well as one of the ablest lawyers the country has produced, in express terms denied

the competency of parliament. "I warn you," said he, "do not dare to lay your hand on the constitution; I tell you, that if, circumstanced as you are, you pass this act, it will be a mere nullity, and that no man in Ireland will be bound to obey it; I make the assertion deliberately, I repeat it, and I call on any man who hears me to take down my words; you have not been elected for this purpose; you are appointed to make laws and not legislatures; you are appointed to act under the constitution, and not to alter it; you are appointed to exercise the functions of legislators, and not to transfer them; and if you do so, your act is a dissolution of the government; you resolve society into its original elements, and no man in the land is bound to obey you." Such is the strong language with which this gentleman is reported to have opposed the union; yet since it has taken place, he has not disdained to be a representative of Ireland in the imperial parliament, and has been heard with that attention and admiration to which he is entitled. The ablest advocate for the competency of parliament was Mr. William Smith, son of the master of the rolls, and since one of the barons of the exchequer, who maintained that a contrary "doctrine would not only impugn the express authority of Coke and Blackstone, and other constitutional writers, but would shake the fabric of our rights and liberties to its foundation; would go to cancel the title-deed of 1706, by virtue of which his majesty holds his Scottish crown; would question the legitimacy of that mixed assembly, which was formed by the coalition of the Scotch and English legislatures; and impeach the force of every statute which has been enacted since their junction; and would confound and violate the very elements of our constitution, by transferring the supreme authority from the parliament to the people." Whilst on this particular subject it may be observed, that the competency of parliament was also maintained by that eminent lawyer Barry, lord Yelverton, who had taken a lead in the measures of 1782. "Union," says he, "is only a law common to two states; and to say that the parliaments of both are incompetent to frame such a law, is to say that they are incompetent to answer the ends of their institution. For a distinction is to be made between the physical and moral power of parliaments. They can do any act, but there are certain acts which they ought not to do; and therefore every question of *competence*, ultimately resolves itself into a question of *expediency*. And surely it will not be argued, that though Great Britain and Ireland should stand on the precipice of destruction; that though their distinctness must be productive of misery in the extreme, and union be ever so necessary to their happiness; that they must continue distinct for want of power to unite: in other words, that though the measure should be ever so expedient, the parliaments of the two countries are yet incompetent to enact it. It is a wretched argument, and such as no man in his senses can contend for. 'The bare idea of a state,' says judge Blackstone, 'without a power somewhere vested to alter every part of its laws, (and it is the laws of every country which make its constitution,) is the height of political absurdity.'" When men of the greatest knowledge and abilities have held such opposite opinions on this question, it would be presumptuous in the writer of this article to do more than record their opinions; but he may be permitted to inquire how it has happened that such difference could exist. It appears to him, that those who deny the competence, refer to some original compact or constitution, such as the National Convention established in France, from which there is no power of departing, without the consent of an assembly, chosen for this purpose; but where is such compact to be found? Was there ever a period when the government of England

or of Ireland was to be set up anew, and when it was referred to any single person, or assembly or committee to frame a charter for the future government of the country, or when a constitution so prepared and digested, was by common consent received and established? The advocates of the competence of parliament, on the other hand, evidently consider the constitution to be founded on acts of parliament, on decisions of courts of law, and on immemorial usages. As therefore parliaments had united Wales and Scotland to England, and as the power of parliament to do whatever it deemed expedient had not been questioned in former times, they saw no solid objection to the competence of the independent parliaments of Great Britain and Ireland to form a junction for the common benefit. The constitution of England has grown out of occasion and emergency, from the fluctuating policy of different ages; from the contentions, successes, interests, and opportunities of different orders and parties of men in the community. There is no regular plan to be referred to, and therefore Paine said that we had no constitution. To return to the debate on Mr. Ponsonby's amendment, after seventy-three members had given their opinion for or against it, a division took place, and it was lost by a majority of one only. Encouraged by such a close division, the opposition used greater exertions; and when, two days after, the amendment was again moved on this report, it was carried by 109 to 104. This prevented the further direct discussion of the question during that session, the minister declaring it would not be again brought forward until its introduction should be justified by public sentiment. In the house of lords, several amendments were proposed, but the original address was carried by 52 to 17. In the minority was James, earl of Charlemont, a nobleman whose conduct was ever guided by what he deemed the interest of Ireland, and whom no selfish motives could swerve. The protest he signed on this occasion was one of the last acts of his public life, as he died on the 4th of August, 1799, before the measure could be again brought forward. As one of the arguments in favour of a union was the conduct of the Irish parliament during the king's illness, which might have led to two separate and distinct governments, Mr. Ponsonby brought in a bill to regulate the appointment of a regent, the discussions on which included the question of union. This bill went to enact that the regal power of the two kingdoms should reside in the same person, and that the regent of Ireland should be subject to the same restrictions as the regent of England, thus giving up the supremacy of the Irish legislature. The bill was opposed by lord Castlereagh, on the ground that it was incomplete, and that the danger of separation could not be cured by half-measures, and it was finally lost. In the committee on it, however, the speaker, Mr. Foster, had the first opportunity of delivering his sentiments against the union, which he availed himself of in a speech which was published, and which by its able details contributed very much to confirm members in their opposition to the measure. At the close of the session, the lord lieutenant again introduced the subject; and, after noticing the joint address of the two houses of parliament of Great Britain, recommending a complete and entire union between Great Britain and Ireland, said, "that his majesty, as the common father of his people, must look forward with earnest anxiety to the moment when, in conformity to the sentiments, wishes, and real interests of his subjects in Great Britain and Ireland, they may all be inseparably united in the full enjoyment of the blessings of a free constitution, in the support of the honour and dignity of his majesty's crown, and in the preservation and advancement of the welfare and prosperity of the whole British empire."

UNION.

The proceedings in the parliament of Great Britain will now demand our attention. On the 22d of January, 1799, the same day on which it was brought before the Irish parliament, a message from the king was delivered to the house of lords, by lord Grenville, one of the secretaries of state, and to the house of commons by Mr. Dundas, the other secretary, recommending it to both houses to consider of the most effectual means of finally defeating the design of separating Ireland from England, and of settling such a complete and final adjustment as would best tend to improve and perpetuate a connection essential for their common security, and to consolidate the strength, power, and resources of the British empire. In the lords, an address expressing a readiness to concur in any measure which might be found necessary or expedient towards the consolidation of the general interests of the British empire, was carried without opposition; but in the commons, a similar address was warmly opposed by Mr. Sheridan, who used arguments of the same nature as those of the Irish opposition. He particularly dwelt upon its being a breach of what he called the *final* arrangement in 1782, and it was much disputed, whether this had been intended to be final or not. General Fitzpatrick, who had been secretary to the duke of Portland, lord lieutenant at that time, as well as Mr. Grattan and others, maintained that it was so understood; whilst the duke of Portland himself and lord Yelverton asserted that further measures were in contemplation. It seems a matter of little consequence in what manner it was regarded at that time, but as the veracity of neither party can be called in question, it affords a striking proof of the difficulty of ascertaining the views by which public men are actuated. Mr. Sheridan moved an amendment, but it was feebly supported, and finally withdrawn. On the 31st of January, notwithstanding the amendment adverse to a union, which had been carried in Ireland, Mr. Pitt brought forward eight resolutions in a committee of the house, which were to form a ground-work for articles of union. He did not dispute the competence of the parliament of Ireland to accept or reject any proposition, but he had a right, as a member of the parliament of Great Britain, "to express the general nature and outline of the plan, which, in his estimation, would tend to insure the safety and the happiness of the two kingdoms." In the course of a very eloquent speech, Mr. Pitt said, "in answer to the question, what are the positive advantages that Ireland is to derive from a union, I might enumerate the general advantages which Ireland would derive from the effects of the arrangement, the protection which she will secure to herself in the hour of danger; the most effectual means of increasing her commerce, and improving her agriculture; the command of English capital; the infusion of English manners and English industry, necessarily tending to ameliorate her condition, to accelerate the progress of internal civilization, and to terminate those feuds and dissensions which now distract the country, and which she does not possess, within herself, the power either to controul or to extinguish. She would see the avenue to honours, to distinctions, and exalted situations in the general seat of empire, opened to all those whose abilities and talents enable them to indulge an honourable and laudable ambition. But, independent of all these advantages, I might also answer, that the question is not what Ireland is to gain, but what she is to preserve; not merely how she may best improve her situation, but how she is to avert a pressing and immediate danger. In this view, what she gains is the preservation of all those blessings arising from the British constitution, and which are inseparable from her connection with Great Britain."

The right honourable gentleman then proceeded to state, that a union would be the means of securing permanently to Ireland the great commercial advantages which she then held at the discretion of Great Britain, while it would open a more free and complete commercial intercourse; and intimated, that "if ever the overbearing power of prejudice and passion should produce that fatal consequence (separation), it would too late be perceived and acknowledged, that all the great commercial advantages which Ireland at present enjoys, and which are continually increasing, were to be ascribed to the liberal conduct, the fostering care, of the British empire, extended to the sister kingdom as to a part of ourselves, and not to any thing which had been done, or could be done, by the independent power of her own separate legislature." After enlarging upon some other points, and replying to some objections, he concluded with moving that the resolutions be referred to a committee of the whole house. Mr. Sheridan urged that, "under the present circumstances of the convulsed and disordered system of policy and general government of Ireland, it was not only impolitic, but even unsafe, to agitate the discussion of topics, the issues of which were to lay the most hardy and stout-hearted prostrate at the feet of a British minister." This indeed seemed to be the principal objection urged against the resolutions, that the discussion would tend to inflame Ireland, already in a state of considerable irritation. When the house divided on the question of the speaker's leaving the chair, the ayes were 140, the noes 15. On the 7th of February, the day fixed for considering the resolutions, Mr. Sheridan, after some prefatory remarks on the state of Ireland, in the course of which he asserted that all the advantages proposed might take place without a union, moved the following resolutions:

"That no measures could have a tendency to improve and perpetuate the ties of amity and connection, now existing between Great Britain and Ireland, which have not for their basis the manifest, fair, and free consent of the two countries. That whoever shall endeavour to obtain the appearance of such consent and approbation, in either country, by employing the influence of government for the purposes of corruption and intimidation, is an enemy to his majesty and the constitution."

In the latter resolution, Mr. Sheridan particularly alluded to the dismissal of the chancellor of the exchequer and prime serjeant, because they would not support the union; but Mr. Pitt maintained, that if many gentlemen were connected together with the fair intention of acting for the service of their country, it would be necessary, in order to preserve a unity of action, that they should agree in their system. The previous question was carried by 141 to 25. In the debate which followed on the motion for the speaker's leaving the chair, Mr. Grey (now earl Grey) urged, that the calamities of Ireland were not caused by the independence of her legislature, but had been in great measure owing to the conduct of government. "Look," said he, "at the history of Ireland, and you will find, that if it had not been for the interference of British councils, and of British intrigue, none, or but few of the evils which were felt would ever have taken place: evils of which government was the parent, and which were now made the reason for taking away all the semblance of liberty among the Irish people. All the feuds and religious animosities and dissensions which had distracted Ireland had been caused by government, and yet government was making use of these evils as a pretext for taking away the liberty of the people of Ireland." The motion was carried by 149 to 24; but from the latencies

of the hour, the consideration of the resolutions was deferred. On the 11th of February another long debate took place, in which the topics chiefly discussed were, the conduct of the minister to the Catholics in 1795, and the settlement of 1782, which rendered it necessary to put off the main subject till the following day, on which the house went into a committee. The first resolution, stating the utility of uniting the two kingdoms, was opposed by Mr. (now Sir B.) Hobhouse, and Mr. Bankes, and supported in a very able speech by the speaker (now Lord Viscount Sidmouth). The debate was not long, and all the resolutions were adopted without any division. On the 16th of February, on the question being put that the report be brought up, there was an animated debate, in which several members delivered their opinions, chiefly in favour of the measure: after which the resolutions were agreed to *feriatim*, and sent to the house of lords. The arguments used in that house were similar to those in the commons; the opposition was chiefly made by the earls Fitzwilliam and Moira, and Lord Holland, but no division took place. Several able speeches were delivered in favour of a union, some of which, particularly those of lords Auckland and Minto, were printed separately, and circulated throughout Ireland. The marquis of Lansdowne, and the bishop of Llandaff (Dr. Watson), though not in the habit of supporting ministers, were favourable to the measure. On the resolutions being returned by the house of lords, with an address to his majesty, in which the concurrence of the commons was requested, Mr. Pitt moved that concurrence on the 22d of April, and after a debate, in which nothing was advanced, the address was agreed to.

The resolutions thus agreed to were, 1. "That in order to promote and secure the essential interests of Great Britain and Ireland, and to consolidate the strength, power, and resources of the British empire, it will be advisable to concur in such measures as may best tend to unite the two kingdoms of Great Britain and Ireland into one kingdom, in such manner, and on such terms and conditions, as may be established by acts of the respective parliaments of his majesty's said kingdoms. 2. That it would be fit to propose, as the first article, to serve as a basis of the said union, that the said kingdoms of Great Britain and Ireland shall, upon a day to be agreed upon, be united into one kingdom, by the name of the *United Kingdom of Great Britain and Ireland*. 3. That for the same purpose it would be fit to propose, that the succession to the monarchy and the imperial crown of the said united kingdom, shall continue limited and settled in the same manner as the imperial crown of the said kingdoms of Great Britain and Ireland now stands limited and settled, according to the existing laws, and to the terms of the union between England and Scotland. 4. That for the same purpose it would be fit to propose, that the said united kingdom be represented in one and the same parliament, to be styled the *Parliament of the United Kingdom of Great Britain and Ireland*; and that such a number of lords, spiritual and temporal, and such a number of members of the house of commons, as shall be hereafter agreed upon by acts of the respective parliaments as aforesaid, shall sit and vote in the said parliament on the part of Ireland, and shall be summoned, chosen, and returned, in such manner as shall be fixed by an act of parliament of Ireland previous to the said union; and that every member hereafter to sit and vote in the said parliament of the united kingdom shall, until the said parliament shall otherwise provide, take and subscribe the same oaths, and make the same declarations, as are by law required to be taken, subscribed, and made by the members of the parliaments of Great Britain and

Ireland. 5. That for the same purpose it would be fit to propose, that the churches of that part of Great Britain called England, and of that part of Great Britain called Scotland, and of Ireland, and the doctrine, worship, discipline, and government thereof, shall be preferred as now by law established. 6. That for the same purpose it would be fit to propose, that his majesty's subjects in Ireland shall at all times hereafter be entitled to the same privileges, and be on the same footing in respect of trade and navigation in all ports and places belonging to Great Britain, and in all cases with respect to which treaties shall be made by his majesty, his heirs and successors, with any foreign power, as his majesty's subjects in Great Britain; that no duty shall be imposed on the import or export between Great Britain and Ireland, of any articles now duty free; and that on other articles there shall be established, for a time to be limited, such a moderate rate of equal duties, as shall, previous to the union, be agreed upon and approved by the respective parliaments, subject, after the expiration of such limited time, to be diminished equally with respect to both kingdoms, but in no case to be increased; that all articles which may at any time hereafter be imported into Great Britain from foreign parts, shall be importable through either kingdom into the other, subject to the like duties and regulations, as if the same were imported directly from foreign parts: that where any articles, the growth, produce, or manufacture of either kingdom, are subject to any internal duty in one kingdom, such countervailing duties (over and above any duties on import, to be fixed as aforesaid) shall be imposed as shall be necessary, to prevent any inequality in that respect. And that all other matters of trade and commerce, other than the foregoing, and than such others as may before the union be specially agreed upon for the due encouragement of the agriculture and manufactures of the respective kingdoms, shall remain to be regulated from time to time by the united parliament. 7. That for the same purpose it would be fit to propose, that the charge arising from the payment of the interest or sinking fund for the reduction of the principal of the debt incurred in either kingdom before the union, shall continue to be separately defrayed by Great Britain and Ireland respectively. That for a number of years to be limited, the future expences of the united kingdom, in peace or war, shall be defrayed by Great Britain and Ireland jointly, according to such proportions as shall be established by the respective parliaments previous to the union; and that after the expiration of the time to be so limited, the mode of jointly defraying such expences shall be regulated according to such rules and principles as shall be in like manner agreed upon previous to the union, for the purpose of establishing gradually an uniform system of taxation through every part of the united kingdom. 8. That for the same purpose it would be fit to propose, that all laws in force at the time of the union, and all the courts of civil or ecclesiastical jurisdiction within the respective kingdoms, shall remain as now by law established within the same, subject only to such alterations or regulations, from time to time, as circumstances may appear to the parliament of the united kingdom to require."

Such were the resolutions submitted by the lords and commons of Great Britain to the king, as best calculated to form the basis of a union, and which were afterwards laid before the Irish parliament. The sixth and seventh propositions contain much matter for discussion, in settling the duties and proportions; but the general outline appears to be founded on equal and liberal principles. The next object was to secure such a majority in the Irish house of commons, and such declarations in favour of it, as would enable the Irish

UNION.

government to bring it before parliament in the ensuing session. During the summer of 1799, the lord lieutenant visited many parts of Ireland, with a view to conciliate jarring interests, and was received with great marks of respect.

This nobleman had, by his conciliating humanity, engaged the affections, and by his exalted virtues and great military talents, had attracted the esteem and the confidence of the nation. He was therefore peculiarly qualified for such a purpose. Addresses were presented to him by public bodies, wherever he directed his course, most of which expressed or implied approbation of a union, and the papers were crowded with declarations in favour of that measure, signed by the principal landed proprietors. The secretary, lord Castlereagh, also, was not idle; several who had been adverse to the union were induced either to change their opinion, or to resign their seats; and it was generally supposed that the minister would not be again in a minority. Much has been said of the corruption used on this occasion; it has been charged repeatedly in parliament, and but faintly denied, yet charges of this kind are not easily established. This is certain, that either from gratitude for their support, or by a previous arrangement, the relatives of many gentlemen who voted for this measure were promoted in various ways; and that for years after, what were called *union engagements* obstructed almost any other preferment at the bar, in the church, or in the revenue and state offices. Some have vindicated this as necessary to the attainment of a great benefit, but the true patriot will never admit that a good end will justify dishonest means; and whatever posterity may think of the measure itself, the impartial inquirer will be compelled to acknowledge that it had not the *unbiased* support of a majority of the two houses of parliament, and that it was regarded with abhorrence by the great body of the people. At the same time, no exertions were spared by the opposers of the measure; seats were vacated to bring in active combatants; money was said to be subscribed to purchase boroughs; and other means, perhaps not strictly constitutional, were resorted to. Forty-eight members were brought in by one side or the other, in place of gentlemen who retired, and eight or nine were re-elected, on being appointed to lucrative places under the crown.

On the 15th of January, 1800, the lord lieutenant opened the session, by a speech from the throne, in which no mention was made of the union, and of course it was unnoticed in the address proposed by the friends of administration; but Mr. Ponsonby, having required the speech of the lord lieutenant at the close of the last session, in which he noticed the proceedings of the British parliament, to be read, moved as an amendment to the address, "humbly to assure his majesty, that this kingdom is inseparably united with Great Britain, and that it is the sentiments, wishes, and real interests of all his majesty's subjects, that it ever shall continue so united, in the full enjoyment of the blessings of a free constitution, in the support of the honour and dignity of his majesty's crown, and in the preservation and advancement of the welfare and prosperity of the whole empire, which blessings of a free constitution we owe to the spirited assertion of this kingdom of its birth-right to a free and independent parliament resident within it, and to the parental kindness of your majesty, and the liberality of the British parliament, ratifying the same in the year 1782, and which we have at all times felt, and do now particularly feel it our bounden duty to maintain." Ninety-six members voted for this amendment, and one hundred and thirty-eight against it, so that the minister had a majority of *forty-two*, on that

question, on which, in the preceding session, there was a majority of *five* against him. On the 5th of February, after a number of petitions against the union had been laid on the table, the business was formally introduced by a message from the lord lieutenant, in which his excellency stated that he had it in command from his majesty to lay before both houses of legislature the resolutions of the British parliament, and to recommend to their consideration the great objects they embrace.

A long and spirited debate took place, in consequence of which the house did not adjourn till half past twelve on the following day, when a motion for referring the lord lieutenant's message to a committee was carried by a majority of 43; the ayes, including the tellers, being 158, and the noes 117; so that, reckoning the speaker, 276 members were present at the division. The great abilities of Mr. Grattan, which had been voluntarily cast into obscurity, by his retiring from parliament, were once more brought before the public on this interesting occasion. Mr. Saurin and Mr. Bushe, who now fill the important situations of attorney and solicitor general, also distinguished themselves in opposition to the measure, in addition to the gentlemen who spoke in the preceding session; so that lord Castlereagh, with very inadequate support, had to withstand a combination of men of talents, such as have seldom co-operated on any other occasion. It seemed as if in this last struggle for independence, Ireland had united all her powers of eloquence, sarcasm, and invective, to resist her supposed enemies. In a debate which took place in the committee of the whole house, on the first article of the union, Mr. Grattan opposed the measure with such a degree of vehemence, that the chancellor of the exchequer (Mr. Isaac Corry) accused him of associating with traitors, and of disaffection to the government. The reply of Mr. Grattan to this harsh and unwarrantable charge was so pointed and severe, that Mr. Corry conceived himself under a necessity of resenting it by a challenge. A meeting ensued, and Mr. Corry was wounded. The question, however, was carried by a majority of 161 against 115; and as the discussion proceeded, the numbers of opposition appeared to diminish. There was, however, no relaxation of the energy with which the union was opposed. The table of the house was crowded with petitions, the debates were frequently protracted through the whole night, and the minister was harassed by frequent divisions. On the 13th of March, before the committee had gone through the resolutions, sir John Parnell moved, "That an humble address be presented to his majesty, praying that he will be graciously pleased to dissolve the present parliament, and call a new one, before any final measure shall be concluded respecting a legislative union between Great Britain and Ireland." This motion was, of course, supported by all the force of the anti-unionists; but on the division it was lost by a majority of 46. A similar division, after a very long debate, took place on the question for receiving the report of the committee, which was delivered on the 21st of March, and being agreed to by the house, was sent to the lords for their concurrence. On the 27th of March, the resolutions were returned with some amendments, the leading articles having been carried in the upper house by a majority of 75 to 26. On the 2d of April, the resolutions, as they finally passed the Irish parliament, were laid before the British house, in which, though there were several spirited debates, the measure was carried by a great majority. In the lords, the principle was carried by 82 to 3, and the final division was 75 for and 7 against. In the commons, a motion of Mr. Grey's for an address to his majesty, "That he would be

be graciously pleased to suspend all proceedings on the Irish union till the sentiments of the Irish people respecting that measure could be ascertained;" was rejected by 236 to 30. The bill founded on these resolutions received the royal assent in England on the 2d of July, and in Ireland on the 1st of August, when the lord lieutenant, on proroguing parliament, congratulated it on the accomplishment of this great work.

As the general outline of the measure, already stated in the resolutions of the British parliament, was not departed from, and as much of the detail must be uninteresting, it will be sufficient here briefly to state the articles, enlarged only on those points which have not been before noticed. The first article was, That the two kingdoms should be united for ever from 1st Jan. 1801; the second, That the succession to the crown should continue as at present; the third, That the united kingdom should be represented in one parliament; the fourth, That four lords spiritual, by rotation of sessions, and twenty-eight lords temporal, elected for life by the peers of Ireland, should sit in the house of lords of the parliament of the united kingdom; and that one hundred commoners (two for each county of Ireland, two for the city of Dublin, two for the city of Cork, one for the university of Dublin, and one for each of the thirty-one most considerable cities, towns, and boroughs,) should be the number to sit and vote on the part of Ireland in the house of commons of the united kingdom. Under the fourth article were contained provisions, that the Representation Act of the Irish parliament should form part of the treaty of union; that the rotation and election of the lords spiritual and temporal should be according to a form prescribed; that Irish peers, who are not elected to serve as peers, may serve as British commoners, during which time they are not to have any privilege of peerage; that the crown may create new Irish peers on the extinction of others, under certain regulations, so that one hundred may be kept up over and above those entitled to an hereditary seat in the house of lords of the united kingdom; that peerages in abeyance shall be considered as existing peerages; that questions touching the election of Irish commoners shall be decided in the same manner as those touching English ones, subject to such particular regulations as local circumstances may require, and the united parliament deem expedient; that qualifications as to property shall be the same in both parts of the united kingdom; that the king may constitute the lords and commons of the present parliament of Great Britain, members of the respective houses of the first parliament of the united kingdom, on the part of Great Britain, to sit with those returned for Ireland; that no more than twenty Irish commoners holding places shall sit in the united parliament; that the lords of parliament on the part of Ireland, shall have the same privileges as those of Great Britain, and take precedence next to those of the same rank; and that the peers of Ireland, not representatives, shall have all privileges of peerage, except the right and privilege of sitting in the house of lords, and on the trial of peers. The fifth article provided for the union of the churches of England and Ireland, so that the preservation of the said united church should be deemed an essential and fundamental part of the union. By the sixth article, his majesty's subjects of Great Britain and Ireland are from the 1st of January, 1801, entitled to the same privileges, and are to be on the same footing as to encouragements and bounties on the like articles, and in respect of trade and navigation in all places in the united kingdom and its dependencies; there is to be no duty or bounty on exportation of the produce of one country

to the other; but there shall be countervailing duties on several articles enumerated, some for twenty years only, and others as the united parliament may direct, but never to exceed those paid at the time of the union. By the seventh article, the charges for debts incurred by either kingdom before the union shall be separately defrayed; for twenty years the contribution towards the expenditure of Great Britain and Ireland shall be as fifteen to two, after which the expenditure shall be defrayed in such proportion as the parliament of the united kingdom shall deem just and reasonable, according to a system detailed in the article; the revenues of Ireland shall be a consolidated fund, which shall be charged in the first instance with the interest of the debt of Ireland, and with the sinking fund applicable to the reduction of the said debt, and the remainder shall be applied towards defraying the proportion of the expenditure of the united kingdom to which Ireland may be liable in each year. Under this head it is provided, that no article shall be more highly taxed in Ireland than in England; that any surplus of the revenues of Ireland shall be applied to the peculiar benefit of that country; that all monies raised after the union shall be a joint debt; and that premiums for the internal encouragement of agriculture or manufactures, or for maintaining institutions for pious and charitable purposes, shall be continued for twenty years in Ireland. By the eighth article, all civil and ecclesiastical laws and courts shall remain as established at the time, subject to future alterations; all writs of error and appeals shall be decided by the lords of the united kingdom; and there shall be a court of admiralty in Ireland, with an appeal to the court of chancery in Ireland. Such were the provisions of the Act of Union, as it was finally passed. We shall now add an address moved in the house of commons of Ireland on the 6th of June 1800, the purpose of which was to record the objections to this measure on the journals of parliament. When we consider the great abilities of the members who drew up and supported it, a Grattan, a Foster, a Ponsonby, a Plunket, and many others of distinguished talents, we may suppose that every thing has been urged which ingenuity could devise, or an acquaintance with the affairs and interests of Ireland could suggest; and, therefore, it should be read by every person wishing to form an opinion on the subject. It was moved that the following address be presented to his majesty.

"We, your majesty's loyal and dutiful subjects, the commons of Ireland, at all times sensible of the numerous and essential advantages which we, in common with your subjects in Ireland, have derived under your auspicious reign, beg leave to assure you, that none have more impressed the hearts of your majesty's subjects, than the adjustment, at your majesty's gracious recommendation, entered into by the parliaments of Great Britain and Ireland in 1782, thereby forming the most solemn compact which can subsist between two countries under a common sovereign; that the result of that compact was the increase of our trade and of our revenue, together with the harmony of the two parliaments, and the support of the connection; that the said compact on the part of your majesty's parliament of Ireland has been religiously and beneficially adhered to, inasmuch that a final termination of all constitutional questions between the two nations took place, and the commercial points which at that time remained to be settled, have since, without agitation or ferment, been gradually and satisfactorily disposed of.

"That under these circumstances, it is with the deepest concern and the greatest surprize we have seen a measure propounded, under the name of Union, to set aside this
moit

UNION.

most important and sacred covenant, to deprive this country of her parliament in time to come, and in lieu thereof to introduce an innovation, consisting of a separate Irish government without an Irish parliament, whose power is to be transferred to a British parliament without an availing Irish representation therein, an innovation such as may impair and corrupt the constitution of Britain, without preserving the liberties of Ireland, so that this country shall be in time to come taxed without being duly represented, and legislated for by a body out of the realm, incapable of applying proper remedies, and remote from the means of knowing her wants, her wishes, and her interests.

“That giving the name of Union to the measure is a delusion; the two kingdoms are already united to each other in one common empire, one in unity of interest, and unity of constitution, as has been emphatically pronounced from the throne by your majesty's former viceroy; bound together by law, and, what is more effectual than law, by mutual interest, mutual affection, and mutual duty, to promote the common prosperity of the empire, and it is our glory and our happiness that we form an inseparable part of it.

“That this union has stood the test of ages, unbroken by the many foreign wars, civil commotions, and rebellions which have assailed it; and we dread the rash and desperate innovation which now would wantonly and unnecessarily put it to the hazard, an innovation which does not affect to strengthen the unalterable interest of each country in supporting the revolution that placed your majesty's illustrious family on the throne, for that interest cannot be increased by any law; it is implanted in our hearts, it is interwoven with our prosperity, it grows with our growth, and strengthens with our strength.

“Neither does it profess to create an interest in either country to preserve their connection together, because that interest already exists, and we know and feel that such connection includes all that is dear to us, and is essential to the common happiness, and to the existence of both nations. We therefore do, with all humility, implore your majesty's protection of that glorious revolution, and of that essential connection against the perseverance of your majesty's ministers in their endeavours to force this ruinous measure.

“Their avowed object is a union of the two nations, but the only union they attempt is a union of the two parliaments, and the articles which are to attend their partial and defective union are all so many enumerations of existing distinct interests in the two kingdoms, which it cannot identify, and which require separate parliaments resident in each duly to attend to them. In respect to taxes, the purse of each nation is vested in its own house of commons by the principles of the constitution; the security of our liberty, and the great constitutional balance of the powers of the state, lie in its being left there; but the articles acknowledge a separate purse, and a separate interest in that purse, by providing for a separate proportion of expence, separate modes and laws of taxation, separate debts, separate sinking funds, separate treasury, separate exchequer, separate accounts of revenue to be kept, and separate articles of produce to be placed in the way of debtor and creditor between the two kingdoms, as between two unconnected parties; and though they state, acknowledge, and attempt to form regulations for all these many distinct interests, which no laws can identify or consolidate; and though even the legal interest of money remains different in the two kingdoms without their attempting to assimilate it, yet they take away the Irish parliament, which these distinctnesses ought rather to have suggested the creation of,

if it did not exist, and they lay the foundation of distress, discontent, and jealousies in this kingdom, if not of worse evils, and tend to familiarize ideas of separation instead of union, to the utter ruin of this your ancient kingdom, and your loyal subjects therein.

“In regard to manufactures, they acknowledge the interests in them to be so distinct, that they are forced to provide in express terms against a free intercourse being allowed between the two kingdoms, in more than twenty general denominations, and they establish countervailing duties on the mutual import of at least twenty-four species of goods, on account of the necessary difference in taxation, and the distinctness of revenue, which, from the separate interests of the two kingdoms in them, will not admit of consolidation.

“On the mutual interchange of corn, that great necessary of life, they not only continue duties, but they provide for retaining prohibitions and bounties, and instead of even alleging an identity of interest in so important and general an article, they avow such separate interests to exist in it as law cannot remove; and an interdict is necessary to be laid on its free communication between the two kingdoms, which your majesty's ministers have at the same time the hardiness to tell us, their project is to unite, identify, and consolidate, throughout all their interests.

“We see with them that these interests are distinct, and we, therefore, raise up our voices to your majesty against their impracticable attempt to consolidate them; an attempt which they themselves acknowledge to be so, by their many provisions, all intended to secure a continuance of their distinctness.

“But however separate these interests are in taxes, in revenue, in trade, and in manufactures; and however incapable of being identified, we have the happiness of knowing that in the great point of constitution no difference exists: both nations have a full right to all the blessings of the British constitution; and we have an identity, not a distinctness of interest, in the possession of it. Yet such is the strange passion of your majesty's ministers for innovation, that not finding any such distinctness, they do by these articles create several highly alarming to us, and to all your majesty's subjects of this kingdom, who claim an equal right with Great Britain in the full and free enjoyment of that constitution. All the Irish temporal lords, except twenty-eight, are to be incapacitated by this measure from exercising their rights and duties as peers and hereditary counsellors, while every British temporal lord is to retain his full functions. Four spiritual lords only are to have a share in the legislature, while all the British spiritual lords are to continue theirs; and two-thirds of the Irish commoners are to be disqualified, while every British commoner remains. The articles further declare, that all Irish peerages shall be considered as peerages of the united kingdom, whereby the Irish peers, who are to be incapacitated from legislating as peers, are to continue peers, and may legislate as commoners, against every known principle and established practice of the constitution: nay, even when chosen commoners, they are not to represent any place in Ireland, the country from which they derive their honours, although their voices as commoners will extend equally with that of every other commoner to all the concerns of this kingdom; and thus the Irish purse will be eventually put into the hands of the Irish peerage, in direct defiance of a great and fundamental principle of the constitution.

“All these degrading, dangerous, and unconstitutional distinctions are not only created in the Irish peerage, but are to remain for ever, without power of alteration, by a provision being made in the articles for a constant creation of

peers

peers for Ireland. That the Irish peerage is to be kept for ever a distinct body from the British, though the project professes a union of the two kingdoms of Britain and Ireland, and attempts a union of the two parliaments, of which the peerage is a constituent part; and this continuance of a separate Irish peerage, stripped as it will be of all parliamentary function, perpetuates a distinction insulting and degrading to this kingdom, which our ministers, if they had solely in view, without any regard to influence, a lasting union of the parliaments, to which this continuance no way contributes, would have avoided, by providing that the Irish peers, when reduced to the proposed number of twenty-eight, should be declared peers of the united empire equally with the British; and thus would have dissolved all national distinctions between them for the time to come.

“But it is not in trade, revenue, and manufactures only that distinct interests are declared to exist, nor in constitution alone that separate interests are to be created; the same distinctions is to be preserved in the administration of justice: every difference of law, every variation of practice and of regulation which now prevails, is to be allowed to distinguish the civil and ecclesiastical courts, with this one exception only, that, in the ultimate appeal, every Irish suitor is to be again at the expence and hazard of going to Westminster, instead of having a court in Dublin to resort to.

“We enlarge the more on these several enumerations of separate interests, avowed or created by your majesty’s ministers, because the many provisions they propose for their future regulation are so many acknowledgments that no force of law can identify them, so as to admit of their consolidation; provisions all in themselves presumptuous and insufficient, inasmuch as it is not in the power of human wisdom to foresee the events of time, and provide now, by a system declared immutable, for the varying changes which must naturally take place in the lapse of years.

“Under the same conviction, though they profess a union of the two parliaments, they do not attempt to form out of them one with equal and common powers for both kingdoms: it is to be free in all its functions in respect to Britain, but shackled and bound up by restrictions as to Ireland. In this they deprive your majesty’s Irish subjects of a parliament, such only as the British constitution acknowledges, free in its deliberations for every part of the empire it is to legislate for; such as we have a right to enjoy, equally unrestrained in its powers, and unfettered in its proceedings, as to the interests of this your majesty’s kingdom; and such a one, free and independent in all its functions, as we solemnly claimed to be our birth-right in 1782, and as your majesty, in your wisdom and justice, did then graciously confirm to this kingdom for ever; but which elaim and gracious confirmation your ministers now seek to take away from the kingdom for ever.

“That having thus shewn to your majesty how very inefficient the project of your ministers is to answer even the purpose it avows, and how very ruinous its operation must be, if you shall not be graciously pleased to interfere, we feel it our further duty to expose fully to your majesty’s view, not only the artful delusions which those ministers have presumed to hold out of supposed advantages in commerce, in revenue, in taxes, and in manufactures, to deceive the people into an approbation of their scheme, but the corrupt and unconstitutional means which they have used, the undue manner in which they have employed the influence of the crown, and the misrepresentations which they have made of the sense of your majesty’s people of Ireland on the measure. Were all the advantages, which without any foundation they have declared that this measure offers, to be

its instant and immediate consequence, we do not hesitate to say expressly, that we could not harbour the thought of accepting them in exchange for our parliament, or that we could or would barter our freedom for commerce, or our constitution for revenue. But the offers are mere impositions; and we flate with the firmest confidence, that in commerce or trade their measure confers no one advantage, nor can it confer any: for by your majesty’s gracious and paternal attention to this your ancient realm of Ireland, every restriction under which its commerce laboured has been removed during your majesty’s auspicious reign, and we are now as free to trade to all the world as Britain is.

“In manufactures, any attempt it makes to offer any benefit which we do not now enjoy is vain and delusive; and wherever it is to have effect, that effect will be to our injury. Most of the duties on import, which operate as protections to our manufactures, are under its provisions, either to be removed or reduced immediately; and those which will be reduced are to cease entirely at a limited time; though many of our manufactures owe their existence to the protection of those duties, and though it is not in the power of human wisdom to foresee any precise time when they may be able to thrive without them.

“Your majesty’s faithful commons feel more than an ordinary interest in laying this fact before you, because they have, under your majesty’s approbation, raised up and nursed many of those manufactures; and by so doing, have encouraged much capital to be vested in them, the proprietors of which are now to be left unprotected, and to be deprived of the parliament on whose faith they embarked themselves, their families, and properties, in the undertaking.

“In revenue we shall not only lose the amount of the duties which are thus to be removed or lowered, and which the papers, laid before us by the lord lieutenant, shew to amount to the immediate annual sum of 50,000*l.*, but we shall be deprived of nearly as much more by the annihilation of various export duties, which have subsisted for above a century on other articles of intercourse, without being felt or complained of by us; and this whole revenue of 50,000*l.*, which operated beneficially to our manufacture, and of near 50,000*l.* more, which oppressed no manufacture, is to be wantonly given up, without the desire or wish of either nation, at a time when our income is more than ever unequal to our expences, and when the difficulty of raising new taxes to supply its place is alarmingly increased, by our having been obliged, in this very session, to impose new burthens to the estimated amount of 300,000*l.* a year; and we cannot but remark, that in this arrangement, while we give up this revenue of near 100,000*l.* a year, Great Britain is to give up one not amounting quite to 40,000*l.*; an inequality no way consonant with the impartiality or justice professed by your majesty’s ministers, nor any wise consistent with the comparative abilities of the two countries to replace the loss.

“But the imposition of your majesty’s ministers is still more glaring, in their having presumed to fix a proportion of contribution towards the general future expences, to be observed by the two kingdoms, in the ratio of one part by Ireland for every seven parts and a half by Britain. If they had any plausible grounds whereon they calculated this proportion, they have not deigned to lay them before your parliament; and the usual and established forms of committees, to investigate into matters of such intricate and extended calculation, have been superseded by them. Your majesty’s faithful commons are satisfied that the calculation is extremely erroneous, and that, on a just and fair inquiry

inquiry into the comparative means of each country, this kingdom ought not and is not able to contribute in any thing like that proportion. They feel it a duty, too, to protest most solemnly against any arrangement of taxation, on which they have had no documents, or made any inquiry to guide their judgment, and in which they understand no consideration whatever has been had to the different legal interest of money in this kingdom, which causes a disadvantage of *20l. per cent.* in procuring capital, nor to the relative quantity of shipping possessed and used by each country, nor to the export trade in foreign articles, nor to the extent of manufacture for home consumption, nor to the balance of trade, which shews the annual increase of its clear profit, and of course the annual increase of the fund it creates to contribute from; in all of which, the means of Britain very far exceed the foregoing proportion, and particularly in the balance of trade, which in Ireland amounts to little more than half a million with all the world, but is stated by authority to have amounted to fourteen millions eight hundred thousand pounds in Britain, exclusive of an annual influx of money from the East and West Indies to the amount of four millions to the proprietors resident in Britain, and of two millions from Ireland to the proprietors of Irish estates resident there, and of another million from Ireland for the charges of her debt due in Britain; whereas the only known or visible influx of money into Ireland is the above balance of trade of half a million only: and these two sums of two millions and one million, while they add to the means and wealth of Britain, unfortunately take away in the same amount from the ability of Ireland.

“ Thus, had a due investigation been made, and a fair inquiry gone into, with a view to obtain a true knowledge of facts whereon to ground a just calculation, it would have appeared that this proportion for Ireland is not only unjust, but far beyond what it will be in her power to discharge; and the rashness of your majesty’s ministers, in hazarding such a measure, is the more to be lamented or wondered at, because should Ireland engage to pay more than she is able to answer, the necessary consequence must be a rapid decrease of her capital, the decline of her trade, a failure in the produce of her taxes, and, in the end, her total bankruptcy. But under such circumstances, she cannot be alone a bankrupt; and should she fatally become so, by an injudicious or avaricious apportionment of constitution, Great Britain must share in her ruin, and our great and glorious empire be brought to the brink of destruction, by an innovating attempt to take from Ireland its constitution, and substitute a theoretic, visionary, and untried system in its room. We should, therefore, earnestly supplicate your majesty to oblige your ministers to defer the measure, until a full and satisfactory investigation should be made, if we did not feel that it ought to be entirely relinquished, and that the injuries and dangers attending on it could not be removed by any change of that proportion, or reconciled by any modification of detail whatsoever. Subordinate, however, as the consideration of it is, we cannot omit remarking to your majesty, that there is cunningly and insidiously annexed to it a provision for its ceasing, even within the short period of three years, should the war continue so long; and that when we shall increase our debt, so as that it shall bear the like proportion to the permanent debt of Britain, all the delusive benefit held out by this proportion is to cease, and we are to undergo common taxes with Britain. We lament that such delusion should be resorted to; it is too palpable not to be seen; and instead of the confidence which ought to attend every arrangement between the kingdoms, such conduct must excite diffidence and distrust.

“ This proportion of their respective permanent debts is to be attained by increasing our debt, which we must do, and by Britain lessening hers, which she is in the actual course of reducing, as rapidly at least as that of Ireland increases. The absurdity, therefore, of the position is self-evident; for it says, that Ireland by increasing her debt, and its annual charges, will become more wealthy, and more able to bear equal taxes with Britain; but that Britain, by decreasing hers, will be left able to defray her contribution, and can only pay equal taxes. Another delusion (omitted, however, in the articles proposed) has been also plausibly offered, still further to deceive your majesty’s subjects of Ireland into an approbation of this destructive measure, and a promise has been authoritatively announced or artfully insinuated by your ministers in this kingdom, that Ireland is to save by it, or that Great Britain is to give her a million a year of revenue in time of war, and half a million a year in time of peace. But we know that during a war like the present, such a promise is impracticable; and both kingdoms must strain every nerve, and draw forth every resource. We seek not to load our sister kingdom unnecessarily, by lessening our own burden; and our loyalty forbids us to listen to arguments, which offer to save our purse at the expence of Britain. But it is all a delusion, for we see nothing in the uniting of the two parliaments, which can change the course of the war, or lessen the total mass of expence of both nations; and we assert most confidently, that no gift can be made, or saving ensue in our expences, by the union, however they may be attempted to be increased by the unfounded and unfair proportion ascertained for us to bear of the general expenture. But were the offer founded, were it effectual and desirable, its advantages rest on the misfortunes of war; and we should feel ourselves unworthy of the trust reposed in us, if we could suffer a hope, arising from the continuation of such a dreadful calamity, to direct our conduct in any measure, much less in one which calls on us to give up our constitution for ever.

“ Neither can we look forward to any proposed saving from the union in peace; for we are not told, nor could we believe it, if your majesty’s ministers did tell us, that a bill professing to unite the two kingdoms, inseparably united without a bill, can have an influence on the situation of the affairs of Europe, or that it can allow us, during the next peace, to dispense with keeping up the same military force as during the last; and we are further given to understand, that your majesty’s royal court, and all its establishments, the courts of law, the exchequer, and all the revenue expences, are to be continued without the parliament equally as with it. But were the saving practicable, we feel it is our own duty to make it without a union; and we know that no parliament can do it for Ireland with the same knowledge, the same efficacy, and the same safety, as the resident parliament of Ireland.

“ But it is not only in respect to these delusions held out as to trade and revenue, that we feel it our duty to lay before your majesty the conduct of your ministers on this measure: we must state the means by which they have endeavoured to carry it. That in the first instance, admitting the necessity of conforming to the sense of the parliament and the people, they took the sense of the commons, and found that sense to be against it; that they then affected to appeal against the parliament to the people, at the same time endeavouring by their choice of sheriffs to obstruct the regular and constitutional mode whereby the sense of the people has been usually collected: that, on the contrary, they did use or abet and encourage the using of various arts and stratagems to procure from individuals of the lowest

UNION.

order, some of whom were their prisoners and felons, scandalous signatures against the constitution: that, notwithstanding these attempts to procure a fallacious appearance of strength and muster against parliament, the people have expressed their sentiments decidedly against the union; and twenty-one counties at public meetings legally convened, and also many other counties by petitions signed by the freeholders, and many cities and towns, have expressed either to your majesty, or to this house, or to both, their decided and unalterable hostility to this union; yet your ministers have, as we believe, taken upon them to state to your majesty and your ministers in Britain, in defiance of all these facts, that the sense of the nation is not adverse to the measure: that if there could be any doubt that your majesty's ministers in the appointment of sheriffs did consider how they might obstruct the people in delivering their opinion regarding the union, that doubt is fully explained by their continuing in office the sheriff of the former year in more than one instance, whence it also appears how decidedly the sense of the country is against this measure, when your majesty's ministers found it difficult to procure any person to serve the office of sheriff who was properly qualified, and was also a friend to the measure: that, finding the sense of the people as well as the parliament to be against it, your majesty's ministers attempted to change the parliament itself, and refusing to take the sense of the nation by a general election, they procured a partial dissolution, and did so publicly abuse the disqualifying clause in the place-bill (which was enacted for the express purpose of preserving the freedom and independence of parliament), that by vacating seats under its authority, very many new returns were made to this house for the purpose of carrying it; and thus did they change the parliament without resorting to the people: that before the ministry had perverted the place-bill, the sense of parliament was against their union; and if that bill had not been so perverted, that sense had remained unaltered: that of those who voted for the union, we beg leave to inform your majesty, seventy-six had places or pensions under the crown, and others were under the immediate influence of constituents who held great offices under the crown: that the practices of influence above-mentioned, were accompanied by the removal from office of various servants of the crown who had seats in parliament, particularly the chancellor of the exchequer, the prime serjeant, three commissioners of the revenue, a commissioner of accounts, a commissioner of barracks, and the custos of the court of chancery, because they would not vote away the parliament; also by their withdrawing their confidence from others of your majesty's faithful and able counsellors for the same reason: that they procured or encouraged the purchase of seats in this house to return members to vote for the union; also the introduction of persons unconnected with this country to vote away her parliament: that they have also attempted to prostitute the peerage by promising to persons, not even commoners in parliament, her sacred honours, if they would come into this house and vote for the union: and that, finally, they have annexed to their plan of union an artful device, whereby a million and a half of money is to be given to private persons possessing returns, who are to receive said sum on the event of the union, for the carrying of which to such an amount said persons are to be paid; and this nation is to make good the sale by which she is thus disinherited of her parliament, and is to be taxed for ever to raise the whole amount, although, if your ministers shall persevere in such a flagrant, unconstitutional scheme, and the money is to be raised, it is for the union, and being therefore an imperial concern, ought to be borne in the pro-

portion already laid down for imperial expences, that is, two seventeenths by Ireland, and fifteen seventeenths by Britain: that under these unconstitutional circumstances your majesty's ministers have endeavoured, against the declared sense of the people, to impose upon them a new constitution, subverting the old one.

"That when we consider the peculiar situation of this kingdom, with the annual drains of money from it by persons possessing property in it, who do not reside, to the estimated amount of at least two millions annually; when we advert to the further inevitable drain of a million a year by the public revenue, to be remitted to Britain for the annual charges of our public debt; and that to countervail these great and tremendous issues of money, amounting to three millions, we have only our general balance of trade, not 600,000*l.* a year, to set against them; we look with dread at a measure which must on the one hand necessarily add to those drains, by adding a new and large portion of our wealthiest fellow-subjects to the present absentees, and which must on the other hand decrease that balance, by encouraging and promoting new imports of manufacture in the room of those which will decline here. We look to it with the more dread, because, notwithstanding the great loans from England, to the amount of six millions in the last three years, we have not been able to counterbalance the existing drains from hence, and the exchange has been and still continues regularly and uniformly against us. And further, because our inability to raise the necessary loans within this kingdom, even to the small extent that has been expected, is unfortunately now too evident; and the continuing to supply our treasury by loans from Britain, though it may afford some temporary relief, will regularly increase the evil. Your majesty's ministers, therefore, if they promise to themselves or to the British nation any easement to their own taxes, from the supposed accession of power over our wealth and over our resources, will find themselves most thoroughly disappointed; and if the difficulty of remittance shall increase, the manufacturers of Britain, who have hitherto supplied this kingdom, will find the demand for their goods decrease in proportion as that difficulty shall rise.

"That we understand one benefit which they hold out from the proposed measure is, what your ministers affect to call tranquillizing Ireland; but that when we look to our parliament, and see with what efficacy and promptness it has contributed to put down the late unfortunate rebellion, how inadequate a parliament not resident would have been; when we reflect that in a kingdom containing four and a half millions of people, a resident parliament must possess the quick and authoritative means of giving energy to the executive, which a parliament in another country cannot have; that the removing of the parliament tends to remove with it from the kingdom those men of large property and influence, of talents and respectability, whose presence is at all times essential to tranquillity, and may at some conjuncture be alone capable of preserving it; that their absence will leave room for political agitators and men of talents, without principle or property, to disturb and irritate the public mind; we tremble for the consequences of a measure at once the most rash and unnecessary, that ever was brought forward by any ministers, and at a time most fitted to produce every evil dreaded, and least fitted to promote any one benefit held forth.

"That when we consider the time chosen to introduce such a measure, we feel additional repugnance, it being the moment of our weakness and distress, when the country is of course less free to deliver its full and heartfelt sentiments against the illiberality of such an attempt; peculiarly mortifying

tifying to those of your majesty's subjects who had recently exerted themselves in defence of that constitution which they are now called upon to surrender, and at a time too when the spirit of innovation is abroad, and likely to be much encouraged by the example of your majesty's ministers in this their proceeding against the ancient liberties of the people, who may be rendered an unprofitable or dangerous part of the British empire, whether in consequence of this union they become slavish and abject, or restless and dissatisfied.

"That when we reflect on the great value of the acts for trying controverted elections, how eminently and effectually they have been framed for preserving the purity of election, without which the purity of parliament cannot exist; and when we see that your ministers, well knowing the value we set on them, have proposed various means to continue those benefits to us in the few elections which will remain to be held here after the union, and have withdrawn them all from their inefficacy and insufficiency almost as soon as they were proposed, and have now abandoned all hope of framing any; we foresee and dread the formidable power which the measure of union will give to the minister in all Irish elections, by destroying the beneficial operation of these acts; for the expence, trouble, and delay of trying controverted Irish elections in London, will deter many candidates entitled to be returned from seeking redress; the sheriffs, who are all appointed by the minister, will in fact nominate the members, and many of them having already obeyed the wishes of the minister in endeavouring to tithe the constitutional voice of the people, give us too sure an omen of the conduct which may be expected from them in elections.

"That whether we rest on this incontrovertible and self-evident truth, that no parliament in another kingdom can have the local information or knowledge of the manners, habits, wants or wishes of the nation, which its own parliament naturally possesses, and which is necessary for beneficial legislation, nor can be supplied with the necessary information, either as promptly or accurately; or whether we look to the clear proofs of that truth which the progress of this measure has afforded, by your ministers having called to their assistance in London the great officers of this kingdom most likely from their station to give full information for framing their measure, and though all their talents and all their own information, and what they obtained by letters while it was pending, were employed for months there, yet when they brought it back, a few hours or rather a few minutes inquiry on the spot in Dublin, forced them to alter their project in very many articles, complete and perfect as they thought it; we have strong additional reason to feel and to represent the manifest and irreparable injuries which this kingdom must sustain by the want of a resident parliament, and the impossibility of legislation being carried on for it as it ought to be.

"Therefore, inasmuch as the measure of a union is an unnecessary innovation, and innovation at all times hazardous, and rendered peculiarly so now by the awful situation of the times; inasmuch too, as far from being an innocent experiment, it is replete with changes injurious to our trade and manufactures and our revenues; inasmuch also, as it destroys our constitution which has worked well, and substitutes a new one, the benefits of which we cannot feel, but the numerous evils and dangers of which are apparent, and which in every change it offers militates against some known and established principle of the British constitution; inasmuch also, as it so far endangers the constitution of Britain, as not to leave us the certainty of enjoying a free constitution there when our own shall be destroyed; inasmuch as it tends to impoverish and subjugate Ireland, without giving

wealth or strength to Britain; inasmuch as it tends to raise and perpetuate discontent and jealousies, to create new and strengthen old distinctions of interests in our concerns of trade, manufactures, revenue, and constitution; and instead of increasing the connection between the two kingdoms, may tend to their separation, to our consequent ruin, and to the destruction or dismemberment of the empire; inasmuch as it endangers instead of promoting or securing the tranquillity of Ireland, as it degrades the national pride and character, debases its rank from a kingdom to that of a dependant province, yet leaves us every expence and mark of a kingdom but the great essential one of a parliament; inasmuch as it has been proposed and hitherto carried against the decided and expressed sense of the people, notwithstanding the improper means resorted to, to prevent that sense being declared and to misrepresent it when known; inasmuch as it is not grounded in all its intricate and momentous parts on that solemn and full investigation which ought to attend every measure of great moment, and has been introduced and conducted with various delusions and impositions, and with an unbecoming and suspicious haste; inasmuch as it provides for sending one hundred of the present representatives to legislate in another kingdom, though elected only to sit in the parliament in this, and does not give the people an opportunity, by a new election, to exercise their discretion in a new choice of persons for such a new altered and increased trust; inasmuch as it leaves to the chance of drawing lots the choice of thirty-two members to represent as many great cities and towns with a levity which tends to turn into ridicule the sacred and serious trust of a representative; and while it commits to one person the office which the constitution commits to two, of speaking the voice of the people and granting their money, it does not allow the electors to choose which of the two they will intrust with that power; and inasmuch as means the most unconstitutional, influence the most undue, and bribes openly avowed, have been resorted to, to carry it against the known sense of the commons and people during the existence of martial law throughout the land;—we feel it our bounden duty to ourselves, our country, and our posterity, to lay this our most solemn protest and prayer before your majesty, that you will be graciously pleased to extend your paternal protection to your faithful and loyal subjects, and to save them from the danger threatened by your majesty's ministers in this their ruinous and destructive project, humbly declaring, with the most cordial and warm sincerity, that we are actuated therein by an irresistible sense of duty, by an unshaken loyalty to your majesty, by a veneration for the British name, by an ardent attachment to the British nation, with whom we have so often declared we will stand or fall, and by a determination to preserve for ever the connection between the two kingdoms on which the happiness, the power and the strength of each irrevocably and unalterably depend."

Such was the protest which the Irish parliamentary opposition had recorded on the journals of the house; a protest which deserves the attention of the political enquirer, as well on account of the objections it dwells upon, as on account of the weakness of some of its arguments, shewing how men of the first talents and information may be misled by prejudice and passion. To this it will be useful to add an extract from a work already referred to, (Mr. Newenham's View of the Circumstances of Ireland,) a work which may be safely recommended, as containing much valuable statistical information respecting the country, being the production of a gentleman who spares no exertions to obtain the most authentic accounts, and whose honourable character

places him far above the suspicion of wilful misrepresentation. Mr. Newenham was in parliament when the measure was brought forward and discussed, and from his connections had the best means of knowing the sentiments of many leading persons at that time. "Of those who supported the union," says he, "few appeared to be duly impressed with the real expediency of that measure; which consisted, rather in precluding all possible future collisions of supposed national interests, especially with regard to commercial matters; and in the admission of the Roman Catholics to an equal participation with the Protestants of all the political benefits of the constitution, without endangering the political power of the latter, or even affording them the smallest ground for apprehension, than in any other considerations. And yet that a legislative union of the two kingdoms, or some compact, involving a limited and occasional acquiescence of the legislature of one in the decisions of that of the other, was requisite to preclude the hostile effects which might very possibly result from those accidental collisions; and that an incorporation of the British and Irish legislatures was necessary to remove those groundless, but prevailing apprehensions which operated in excluding the Roman Catholics from parliament, and consequently had the effect of keeping them in a perpetual and dangerous state of discontent and irritation, were truths by which, it might reasonably have been expected, every unbiassed man, after due reflection, would be sufficiently governed. In opposing or supporting such a measure, a man who had the welfare of his country, and also that of the empire at heart, would naturally have been governed entirely by his perception of the benefit or inconvenience likely to accrue from the different articles proposed as constituent parts thereof. If these articles did not appear equally beneficial to both of the contracting countries; if they were not strictly suited to the respective circumstances of each; if they were not susceptible of such modifications as future variations of these circumstances might require; if they appeared calculated to create or continue dissatisfaction in either country; if they were not such as to ensure the permanence of the contract, the dissolution whereof might occasion much more extensive and serious mischiefs than those which the projectors of it aimed at precluding,—the duty of every true Irish patriot, and of every sincere advocate for the welfare of the empire, certainly required him to oppose it. On the contrary, if these articles were evidently calculated to diffuse future general satisfaction, by securing, under all changes and emergencies, an equitable participation of commercial and political benefits to the people of both countries, true patriotism unquestionably required the sacrifice of that ridiculous national pride which was to be outraged by a surrender of legislative independence.

"Instead of patiently and prudently discussing the proposed contract, with reference to its constituent stipulations, which positively was the only method by which its real eligibility could be ascertained, the Irish house of commons precipitously entered, in the first stage of the business, into violent and declamatory debates on the measure in the abstract; and suffered themselves to be governed more by national pride, individual interest, and speculative political notions, than by considerations of national benefit. The consequence of which was, that the minister, having a majority in favour of the measure in the abstract, found it eventually an easy matter to secure a sufficient concurrence in its several articles; for those who had been swayed to support it at large, and had pledged themselves to do so, would have been guilty of unusual tergiversation by resisting it in detail. Had the assent of parliament been suf-

pended, until the different articles of the contract were thoroughly investigated, in all their bearings and effects; had each article been made the subject of a separate debate; it is not unreasonable to suppose that the union might have been rendered much more advantageous to Ireland; and, in the end, more beneficial to the empire. For, sooner than have his long meditated and indeed expedient project defeated, the minister of Britain would probably have conceded much to the desires of the Irish parliament, as he had before done to the British opposition, in the case of the commercial propositions. To the impatience and precipitancy therefore of the parliament of Ireland, which the minister ought, in prudence, rather to have restrained than encouraged, we must impute the defects of the act of union, and the probable future dissatisfaction of the Irish, consequent thereon."

These defects, in Mr. Newenham's opinion, are, 1. That Ireland should have had some appropriate advantages in compensation for the loss of a local legislature. 2. That the commercial arrangement between the two countries ought to have been regulated by the consideration that much of the wealth acquired in Ireland would necessarily flow into Britain and remain there, while none of that acquired by the latter would finally be fixed in the former. 3. That Ireland should have had some indemnification for the increased pressure of taxes from the increase of absentees. 4. That there should have been the same protection to other manufactures as to the cotton manufacture. 5. That the Catholics should by an article of the union have acquired the right of sitting in parliament; and lastly, That the number of representatives was not as great as it ought, on fair principles, to have been. It is a melancholy fact that domestic tranquillity has not hitherto been produced by the union, but it would be unfair to attribute the continuance of disturbance to that measure, and it would be perhaps too soon to despair of those advantages resulting which many unbiassed men expected from it, and which in a great degree reconciled them to the objectionable manner in which it was carried. One effect it has produced; we see Irishmen filling the highest departments of the united kingdom; and we must allow that government has shewn a general disposition to promote the interests of Ireland. It is to be desired that English members may not be prevented by false delicacy or indifference, from taking a part in the internal regulations of Ireland, as it was a benefit which many looked for from the union, that it would take legislation out of the hands of an Irish party. On the whole, it may be said that the union might have been and still may be rendered extremely beneficial to Ireland, consistently with the welfare of Britain, but that hitherto it cannot be considered, even by its most sanguine advocates, as having afforded matter of congratulation to the people of Ireland. Journals of the Lords and Commons of Ireland. Various Pamphlets respecting the Union. Newenham's View of the Natural, Political, and Commercial Circumstances of Ireland. Annual Register. Wakefield's Account of Ireland, &c. &c.

UNION, in the *Manege*, denotes the action by which a horse draws together and assembles the parts of his body, and his strength, in distributing it equally upon his fore-legs, and in reuniting and drawing them together; as we ourselves do when we are going to jump, or perform any other action which demands strength and agility. This posture alone is sufficient to settle and place the head of the animal, to lighten and render his shoulders and legs active, which, from the fracture of his body, support and govern the greatest part of his weight. Being then, by these means, made steady, and his head well placed, you will perceive in every motion which he makes a surprising correspondence

respondence of the parts of the whole. The legs and shoulders of a horse support, as we have said, the greatest part of his weight; and, therefore, his fore-part, either when he is in motion, or in a state of rest, is always employed, and consequently needs the assistance of art to ease it; and in this consists the union or putting together, which, by setting the horse upon his haunches, counterbalances and relieves his fore-part. Besides, the union not only helps and relieves the part of the horse that is the weakest, but it is so necessary to every horse, that no horse that is disabled can go freely: he can neither leap nor gallop with agility and lightness, nor run without being in manifest danger of falling, and pitching himself headlong; because his motions have no harmony nor agreement with one another. The trot is very efficacious in bringing a horse to this union; *i. e.* the trot, in which he is supported and kept together, and yet suppled at the same time: this compels the horse to put himself together, and to collect and unite his strength. In order to support the horse in this trot, the horseman should hold his hand near his body, keeping his horse together a little, and having his legs near his sides. The effect of the hand is to confine and raise the fore-parts of the horse; the effect of the legs is to push and drive forward the hinder parts. Now, if the fore-parts are kept back or confined, and the hinder parts are driven forward, the horse, in a quick motion, such as the trot, must necessarily sit down upon his haunches, and unite and put himself together. For the same reason, the making of your horse to launch out vigorously in his trot, and the quickening of his cadence from time to time, the putting of him to make pefades, the stopping of him, and making him to go backward, will all contribute towards his acquiring the union. If your horse trots, prefers him a little; in the instant when he redoubles and quickens his action, moderate and shorten the hurry of his pace; and the more he presses to go forward, the more will his being checked and confined tend to unite his limbs, and the union will be owing to opposite causes; *viz.* on the one hand, to the ardour of the horse who presses to go forward, and to the diligence and attention of the horseman on the other, who, by holding him in, slackens the pace, and raises the fore-parts of the creature, and at the same time distributes his strength equally to all his limbs. The action of a horse, when going backward, is directly opposite to his abandoning himself upon his shoulders: by this he is compelled to put himself upon his haunches; and this lesson is so much the more effectual, as the cause of a horse's being disabled is often owing to the pain he feels in bending his haunches.

The pefades have not less effect, especially upon horses that are clumsy and heavy-shouldered; because they are thus taught to use them and raise them up; and when they raise them up, it necessarily follows, that their whole weight must be thrown upon their haunches. A light and gentle hand, then, and the aids of the legs, judiciously managed, are capable of giving a horse the union; but before a horse is put upon his haunches, his fore-part must be lightened, and he must acquire that suppleness, which is the source of light and free action. Nothing can supple the shoulder more than the working of a horse upon large circles; walk him first round the circle, in order to make him know his ground; afterwards try to draw his head in, or towards the centre, by means of your inner rein and inner leg: *e. gr.* I work my horse upon a circle; and I go to the right; I draw his head to the right, by pulling the right rein; I bring *in* his outward shoulder by means of the left rein; and I support him at the same time with my inner leg. Thus the horse has his head in the centre, although the

croupe is at liberty. The right leg crosses over the left leg; and the right shoulder is suppled, while the left leg supports the whole weight of the horse in the action. In working him to the left hand, and following the same method, the left shoulder is suppled, and the right is pressed and confined. When this lesson, which tends not only to supple the shoulders, but likewise to give an appui, is well comprehended by the horse, let him be led along the side of the wall. Having placed his head, the horseman is to make use of the inner rein, which draws in his head, and to bring in his outward shoulder by means of the other rein. In this posture the horseman supports him with his inner leg, and he goes along the wall; his croupe being *out*, and at liberty, and his inner leg passing over and crossing his outward leg at every step he makes. By this his neck and shoulders are suppled, his haunches worked, and he is taught to know the heels. The haunches are thus worked, though the croupe of the horse is at liberty; because it is from the fore-parts only that a horse can be upon his haunches. In effect, after having placed his head, draw it *in*, and you will lengthen his croupe: if you raise him higher before than behind, his legs come under his belly, and consequently he bends his haunches. It is the same when he comes down hill, his croupe, being higher than his fore-parts, is pushed under him, and the horse is upon his haunches; since it is evident, that the hinder support all the fore-parts; therefore, in going along the side of the wall, by means of the inner rein, the horse is put together and united. When a horse has acquired union, he becomes able to undertake and execute, with justness and grace, whatever the horseman demands of him, conformably to his strength and disposition. Berenger's Art of Horsemanship, vol. ii. chap. 7.

UNION by the first Intention, in Surgery, denotes the process by which the opposite surfaces of recent wounds grow together and unite without suppuration, when they are kept in contact with each other. It is observed by professor Thomson, that among the various powers inherent in living animals, there is none more interesting to the surgeon, nor more remarkable in the eyes of a philosophical observer, than that by which wounds are healed, or by which the different parts of animal bodies, that have been recently divided, either by accident or design, are made to reunite with each other. This is a power, the effects of which in the human body are so obvious and important, that it would not fail at a very early period to attract, in some degree, the attention of every observer of nature; and accordingly we find, from the records of medicine, that the various circumstances which promote, retard, or prevent the healing of wounds, have at all times been more or less known to the practitioners of the healing art. A very slight degree of observation, however, must soon have been sufficient to convince them, that the phenomena which the healing of wounds exhibits, are neither simple in their nature, nor uniform in the order of their appearance; but variable according to the kind of wound, and the mode of treatment, which, in the different external and internal conditions of the body, is employed for its cure.

In slight wounds, inflicted by the sharper kinds of instruments, says the same author, even the most inattentive medical practitioners must have seen, that a reunion is often speedily effected merely by keeping the edges of the wound in contact with each other; whereas in wounds in which the divided surfaces are much torn or bruised, or where, from retraction, or loss of substance, they cannot be brought into contact, the healing is always accomplished in a much slower, more uncertain, and more complicated manner. These diversities in the process of reunion (continues Dr. Thomson), are

are taken notice of by the earliest writers upon physic and surgery; and distinguished from one another by different appellations or terms of art. Union by the first intention was the term which Galen employed to express that mode of healing wounds, in which the union is speedily produced merely by keeping their edges in contact: an operation of nature, now frequently denominated healing by the process of adhesion; while union by the second intention was a term employed by the same physician to indicate the series of phenomena which occur in that slower mode of healing wounds, in which their edges coalesce more slowly; phenomena to which modern surgeons now usually give the name of healing by the process of granulation. See Lectures on Inflammation, p. 206, 207.

We have also examples of an union, very similar to that by the first intention, in bones which have been fractured; in tendons which have been ruptured; and even sometimes in muscles which have been wholly or partially torn asunder, without any division having been produced in the skin which covers such parts. In the sudden and violent division of these textures, a greater or less quantity of blood is always effused into the line of separation between the divided parts, and a quantity of that fluid is at the same time poured out also into the cellular membrane contiguous to or immediately surrounding the solution of continuity. When the blood which is effused is not very considerable in quantity, and when the parts from which it has been effused have not been too severely injured, it is observed to be gradually absorbed; and in proportion as the effused blood is absorbed, the divided parts seem to approach nearer together. If the divided surfaces be examined a few hours after the division, or solution of continuity, has been produced, they will be found to be covered with a substance, which, in its appearance and other properties, resembles very exactly the coagulable lymph, or, as it is now often termed, the fibrin of the blood.

This coagulable lymph appears to be effused very soon after the injury. Professor Thomson found, that in animals, a distinct layer of it was effused over their wounds in less than four hours. (P. 209.) But, says he, whatever may be the period at which it is first formed, it is now well ascertained, that in healthy subjects, when fractured, torn, or ruptured surfaces, to which the external air has not been admitted, are properly covered with this layer of coagulable lymph, and come into contact, they speedily coalesce, and that, by this lymph becoming a living intermedium, the continuity of the divided part is at length restored.

Appearances, precisely similar to those occurring in divisions without communication with the external air, take place in simple incised wounds, the edges of which have been brought together before, or soon after the bleeding from the divided vessels has ceased. If a wound of this kind be torn open soon after its reunion, the surfaces which had been united are seen covered with a substance resembling an animal jelly. This is the coagulable lymph or fibrin of the blood. It has been supposed, that the lymph is poured out from the smaller vessels which are divided; but professor Thomson thinks it more probable that it is chiefly, if not wholly, formed by the secreting action of the capillary vessels of divided surfaces.

The coagulable lymph, soon after its exudation, becomes penetrated with blood-vessels, which proceed from the divided surfaces, appear to join in the process of reunion by open extremities, or, in other words, to inosculate with one another. The blood now circulates freely through the newly formed channels of communication established between the vessels which penetrate the lymph effused upon the surfaces

formerly divided. This is the state or stage of reunion, which Mr. Hunter has denominated the adhesive inflammation. The vessels which shoot into the coagulable lymph often acquire, in the course of a few hours, a size rendering them capable of being injected.

The precise manner in which the vessels are extended into the coagulable lymph is still unknown. It has not been positively settled, whether it is the divided vessels which penetrate the lymph. The extremities of the larger branches are closed with the effused lymph, and removed by means of it, and their natural elasticity, to a distance from each other. Dr. Thomson conceives, that these circumstances are insurmountable bars to their immediate inosulation; and he observes, that if it be the closed vessels which are prolonged into the lymph, each small artery, it is obvious, must have its corresponding vein. And though the vessels from the opposite divided surfaces may by prolongation pass each other in a wound, it is not easy to conceive the manner in which they will join, or inosculate, nor how the artery becomes afterwards connected with the vein. But the inosulation, or direct union of the small blood-vessels, from the opposite surfaces of wounds, however difficult to conceive or explain, is a truth undeniably established. Thomson, p. 212.

Duhamel made an experiment, which fully proves, that in the reunion of parts which have been divided, the blood-vessels from the opposite surfaces inosculate directly, and do not merely pass one another. He broke the legs of six chickens, and after the bones had reunited, he cut through about one-third of the soft parts, covering the callus, or new bone. When the wound had healed up, he divided another third part, and, in the same manner, the remaining third part, sparing neither blood-vessel, tendon, nor nerve. Only one of the six chickens survived these cruel operations; but upon injecting the artery at the upper part of the thigh, the injection was found to have penetrated to the lowest part of the leg. "I cannot say (Duhamel remarks) whether the large vessels, filled by the injection, were dilated capillary vessels, or the large vessel of the leg itself, which had been reunited; but the experiment proves irrefragably the inosulation of the blood-vessels." Later observations than those of Duhamel (says professor Thomson) have shewn that it is by the small vessels, and not by the larger trunks, that the inosulations are formed by which the divided parts in a limb are supplied with blood.

Mr. Hunter conceived that he had certainly succeeded in observing inosulation on the tunica conjunctiva of the eye, the vessels of which are frequently divided by surgeons in cases of ophthalmia. He states, that the two ends of the cut vessel are seen to shrink; but, after a little while, they are perceived to unite, and the circulation is carried on as before. (Hunter on the Blood, &c. p. 193.) Dr. Thomson's experiments and observations lead him, however, to believe, that it is not the divided extremities of the arteries that again unite, but the folds of small branches, that are prolonged into the intermediate space, which become the channels of communication between the larger trunks that had been divided, but the extremities of which had been previously closed.

Mr. Hunter was of opinion that blood sometimes served as a medium of reunion, or vital bond of connection between parts which have been divided, and that blood-vessels formed and inosculated with each other in this effused or extravasated blood. The practical surgeon, however, finds the interposition of this fluid between the surfaces of a wound disadvantageous, and if any material quantity be so situated, it always becomes a certain impediment to union by the first intention. There are, it is true, some instances in which

this process is not prevented by the presence of inconsiderable effusion of blood; but even in these cases, professor Thomson doubts whether the blood be not absorbed before adhesion takes place.

The lymph which is thrown out during adhesive inflammation, professor Thomson and the generality of modern surgical writers consider to be invariably formed by a process analogous to secretion or exhalation.

Our knowledge of the process of adhesion, or of union by the first intention, has been considerably extended by the attempts which have at different times been made to repair and improve those parts of the human body which had been cut off, or otherwise mutilated. Celsus treats professedly of the method of repairing mutilations of the ears, lips, and nose; but the only practice of this kind with which he was acquainted, consisted simply in paring off the callous edges of mutilated parts, in raising these edges by dissection from the parts below them, in drawing them nearer to each other, and retaining them together with sutures and adhesive plasters.

Early in the sixteenth century, a new mode of repairing mutilated parts began to be first practised in Italy. Alexander Benedictus, who published about the year 1527, particularly mentions, that some ingenious men had discovered a way of correcting the deformities occasioned by the mutilations of the nose. The plan consisted in raising a flap of skin from the arm, stitching it to the mutilated part, and after dividing this flap from the arm, modelling it as much as possible into the shape of the nose. These new noses, Benedictus remarks, bear ill the cold of winter, and he gives some wholesome advice about not rashly or severely pulling them, lest they yield and come away.

This curious subject was afterwards noticed by Gourmelin in 1566, by Vesalius in 1569, and by Ambrose Paré in 1582. The two latter erred in supposing it a necessary part of the operation to cut out a portion of the biceps muscle.

But, says professor Thomson, the best, and by far the most interesting account that is any where to be found of this mode of repairing mutilated parts, is that which is contained in the elaborate and not inelegant, though certainly prolix work of the celebrated Gaspar Taliacotius, entitled "De Curtorum Chirurgia per Infusionem," printed at Venice 1597. He describes most minutely and circumstantially his manner of restoring, by engraftment, noses, lips, and ears, which had been cut off. He gives a full account of the mode of preparing the flap of skin upon the arm; the manner in which it was to be marked out, and a slip of cloth inserted under it for some days; of the division of the upper extremity of this flap from the arm; of paring the mutilated part, and sewing, with mathematical precision, the flap to the nose; of the apparatus necessary for retaining it in this position; of the division of the lower end of the flap from the arm, after a union had taken place between the nose and the flap; of the modelling, or configuration of the septum; of the plasters and bandages to be applied in this stage of the process; and of the means to be used for some time to defend the nose from accidental injury. He then treats, in separate chapters, of the repair of the upper and lower lips, and of the formation of new ears. The instruments to be employed, and the progress of the artist in the different stages of his work, are likewise illustrated in twenty-two plates.

In the repair of the upper lip, this part was joined, like the nose, to the upper extremity of the flap; but in that of the lower lip, it became necessary to divide the lower end of the flap first from the arm, and connect it with the lip, so that the skin of the engrafted part might always be outermost.

The occasions for imitating the mode of practice so fully described by Taliacotius, now seldom occur in Europe; but in India, where the punishments are in some places similar to those which were inflicted in Europe in the time of Taliacotius, the art of restoring noses is still held in considerable repute. The Indian method differs from the Taliacotian chiefly in taking the flap of skin of which the new nose is to be formed, from the forehead instead of the arm. See *Cent. Mag.* Oct. 1794. Also, *An Account of Two successful Operations for reitoring a lost Nose from the Integuments of the Forehead*, &c. by J. C. Carpus.

Boyer mentions, that the late M. Chopard had employed a piece of the skin of the neck to fill up a void space left after an operation for a cancerous lip. The union took place, and a tolerably well-formed lip was procured.

It has been a question, whether parts which have been completely separated from the rest of the body can be again united. This reunion, says professor Thomson, was long conceived to be in every instance impossible; but the success which in some cases has attended the transplantation of the teeth, has clearly shewn, that in one instance at least, in the human body, this reunion is possible. Of the possibility of this mode of reunion in brute animals, numerous examples are to be found in authors.

Duhamel mentions, that it was a very common practice in the poultry yards in France, to engraft the spurs of young cocks upon their combs, and that, in this situation, the spurs were observed to grow to a larger size than when they were allowed to remain on their legs. From a variety of experiments and dissections, Duhamel deduces the following conclusions. "We see then (says he) that an organized part, detached from the leg of a cock, when it was not bigger than a hemp-seed, and placed upon the head of the same animal, forms there an union sufficiently intimate to become several inches in length, while it preserves in this new situation its original organization in every respect, except in the mere circumstance of becoming larger. This, therefore, is a true engraftment performed upon an animal. Secondly; we see a bony nucleus, covered first with a periosteum, and then with a horny substance; in a word, a horn similar to that of oxen, and which grows in the same manner, connected to the cartilaginous ring by the ligamentous bands which have been already mentioned. Thirdly; this horn, by its size, and by the continual motions of the head, being prevented from uniting firmly, or, in other words, from anchylosing with the cranium, forms a kind of joint, furnished with several ligaments sufficiently strong to support it. But these organs are not to be found in the natural state, either under the comb of the cock, or in the neighbourhood of their spurs; at least, I have never been able to perceive them there. Nature in this manner chooses to supply her own wants by the development of new organs." Duhamel in *Mem. de l'Acad. des Sciences*, 1746.

The experiments of Duhamel were repeated by Mr. Hunter with similar results; and he even prosecuted the enquiry further. Amongst other points, he endeavoured to ascertain whether parts peculiar to the male would grow on the female; and if the parts of the female, on the contrary, would grow on the male. He took the spur from the leg of a young cock, and placed it in the situation of a spur in the leg of a hen chicken; it took root: the chicken grew to a hen; but, at first, no spur grew; while the spur which was left on the other leg of the cock grew as usual. "This experiment (says Mr. Hunter) I have repeated several times in the same summer with the same effects, which led me to conceive, that the spur of a cock would not grow upon a hen, and that they were therefore to be considered as distinct

tinct animals, having very distinct powers. In order to ascertain this, I took the spurs of hen chickens, and placed them on the legs of young cocks. I found that those which took root grew nearly as fast, and to as large a size as the natural spur on the other leg, which appeared to be a contradiction to my former experiments. Upon another examination of my hens, however, I found that the spurs had grown considerably, although they had taken several years to do it; for I found that the same quantity of growth in the spur of the cock, while on the cock, during one year, was as much as that of the cock's spur on the hen in the course of three or four years; or as three or four to one." Mr. Hunter also inserted a human tooth into the comb of a cock, and there are preparations in his museum, fully proving that a vascular union was formed between these parts, as the membrane of the cavity of the tooth is seen beautifully coloured with red injection. The same distinguished observer likewise undertook experiments, with a view of learning whether the testicles of the cock would unite to the inner surface of the peritoneum of the abdomen of the hen. The attempt often failed; but four specimens are preserved in his museum, marked N^o 54, 5, 6, and 7, in which a vascular union has actually taken place; and in which, though the size of the testicles does not appear to have received any addition after their attachment to the parietes of the abdomen of the hen, still their vitality had been completely preserved by the communication of blood-vessels which had been formed.

The experiment of engrafting the parts of one animal upon another, has been frequently performed on the human body in the well-known practice of transplanting teeth. That a vascular reunion may take place between the vessels of the tooth and those of the socket, seems proved by the experiments of Mr. Hunter and Mr. A. Cooper, in which the vessels of the membrane lining the cavity of the tooth, and probably the only vessels which the tooth has, were filled from the vessels of the comb, into which the tooth had been inserted.

From some facts related in the article CRANIUM, however, it appears, that if a dead tooth, or, in other words, one that has been for a long time pulled, be inserted into the comb of a cock, it will adhere, as well as a living or recently pulled tooth. The ingenious author of that article had seen an example of a dead tooth adhering firmly in the comb of a cock, where it had been placed by the late Mr. Moore, a dentist and lecturer in London. It is known, also, that a tooth dead in every respect may be fixed without any external mechanical means in the living socket, so as not only to remain there for months, or for years, but to become so firmly fixed as not to admit of being readily pulled out, and to serve very well for the purpose of mastication. Professor Thomson informs us, that this fact was first mentioned by M. Fauchard, and the observation has been confirmed by cases, related by M. Bourdet in his book on the Art of the Dentist, p. 199. The union of the dead tooth to the living socket must be effected in all probability by the contraction of the socket around the inequalities of the fang and neck of the tooth: for the art of fixing a dry tooth principally consists in making several notches on its root with a file, before it is introduced into the socket. Bourdet remarks, that though this operation often succeeds, it does so less frequently than the transplantation of fresh teeth.

If we exclude from consideration the transplantation of teeth, the instances of the reunion of parts which have been entirely separated, are very rare in the human body; so rare indeed, says Dr. Thomson, that most practitioners still treat with disbelief and ridicule the few instances which

have been put upon record. But, he properly observes, that the different facts which have been learned respecting the transplantation of the teeth, together with the experiments of Duhamel and Mr. Hunter, prove indisputably the possibility of parts being reunited, which have been completely separated from the animal system, to which they belonged, and in which the circulation of the blood must necessarily have ceased for a time. The reader will find a variety of cases, proving the accuracy of this statement, collected in professor Thomson's valuable Lectures on Inflammation, p. 239, &c. It is to be acknowledged, at the same time, that when surgeons have attempted to reunite parts which had been entirely separated from the body, they have generally failed. But should the part retain the connection of only a few fibres, before it is replaced for the purpose of union, the circumstance makes an important difference; and union is then more frequently accomplished. The writer of this article was lately informed of a case, in which an ear, entirely separated, with the exception of a very slender piece of skin, was successfully reunited to the head again.

For most of the preceding observations, we are indebted to professor Thomson's Lectures, a work which displays a profound knowledge of all the most important doctrines of surgery.

Some additional observations on union by the first intention, and on the best means of promoting it, will be found in the article WOUNDS.

UNION, in *Geography*, one of the Grenadine islands, in the West Indies. N. lat. 12° 30'. W. long. 61° 20'.

UNION, a town of America, in the district of Maine and county of Lincoln, containing 1266 inhabitants; 50 miles N.E. of Brunswick.—Also, a town of the state of Connecticut, in the county of Tolland, containing 752 inhabitants; 12 miles E. of Tolland.—Also, a village of New York, in the township of Nassau, and county of Rensselaer, situated on the turnpike road to New Lebanon, 11½ miles about S.E. from Albany; with 50 houses and stores, a church, and a post-office of the same name, and incorporated as a village.—Also, a village of New York, in Greenwich, Washington county, situated on the Battenkill, 34 miles N. of Albany, and incorporated as a village; containing 48 houses and stores, two meeting-houses, an academy, two extensive cotton, and 12 woollen manufactures, several mills, a trip-hammer, a manufactory of files and of cast-steel, and about 500 inhabitants.—Also, a village of Albany county, in the township of Bern, 21 miles from Albany, on the road to Schoharie, from which it is distant 14 miles. It contains about 26 dwellings, several stores, &c. and a Presbyterian meeting-house.—Also, a village of New York, in Clinton county, pleasantly situated on a handsome plain, in the township of Para, 3 miles N. of the bridge across the Table river; 150 miles N. of Albany; in which are a post-office, 45 houses and stores, a Quaker meeting-house, and some other buildings.—Also, a town of Essex county, in New Jersey, containing 1428 inhabitants.—Also, a township of Berks county, in Pennsylvania, containing 766 inhabitants.—Also, a township of Huntingdon county, in Pennsylvania, containing 706 inhabitants.—Also, a township of Fayette county, containing 1821 inhabitants.—Also, a township of Mifflin county, Pennsylvania, containing 1114 inhabitants.—Also, a township of Belmont county, in Ohio, containing 1514 inhabitants.—Also, a township of Champaign county, in Ohio, containing 861 inhabitants.—Also, a township of Delaware county, in Ohio, containing 165 inhabitants.—Also, a township of Fayette county, in Ohio, containing 503 inhabitants.—Also, a township in Gallia county, Ohio, containing 367 inhabitants.

bitants.—Alfo, a township of Highland county, Ohio, containing 744 inhabitants.—Alfo, a township in Knox county, Ohio, containing 431 inhabitants.—Alfo, a township in Licking county, Ohio, containing 375 inhabitants.—Alfo, a township in Madison county, Ohio, containing 250 inhabitants.—Alfo, a township in Miami county, Ohio, containing 683 inhabitants.—Alfo, a township in Mufkingum county, containing 430 inhabitants.—Alfo, a township in Rofs county, Ohio, containing 2273 inhabitants.—Alfo, a township in Scioto county, Ohio, containing 541 inhabitants.—Alfo, a diftrict of South Carolina, containing 10,995 inhabitants.

UNION *Borough*, a town in Fayette county, Pennsylvania, containing 999 inhabitants.

UNION *River*, a river of the diftrict of Maine, which runs into Penobscot bay.

UNION *Springs*, a post-office in the fouth-west corner of Aurelius, in Cayuga county.

UNION *Fire-Office*. See INSURANCE.

UNIONS, UNIONES, in *Phyfiology*, the fame with *margarite*, or *pearls*. See PEARL.

UNIQUE is fometimes anglicifed, and ufed to denote a thing which is the only one of its kind.

UNISETA, in *Natural Hiftory*, the name of a fpecies of *Az*, found frequently fitting on the ammi or bifhops weed, and diftinguifhed by having one long hair or bristle growing out at its tail. See HENOTHRIX.

UNISON, in *Music*, is the effect of two founds, which are equal, in degree of tune, or in point of gravity and acutenefs.

Unifon may be defined a confonance of two founds, produced by two ftrings, or other bodies of the fame matter, length, thicknefs, and tenfion, equally ftruck and at the fame time; fo that they yield the fame tone or note.

Or it is the union of two founds, fo like each other, that the ear, perceiving no difference, receives them as one and the fame found. See SOUND.

What conftitutes *unifonance* is the equality of the number of vibrations of the two fonorous bodies in equal times; where there is an inequality in that refpect, and, of confequence, an inequality in degree of tune, the unequal founds conftitute an interval.

Since ifochronous vibrations produce founds that are musical, and that are faid to continue at the fame pitch, and flower vibrations produce graver, flatter, or lower founds, and quicker vibrations produce founds that are acuter, fharper, or higher; it follows, that if feveral ftrings, however different in length, thicknefs, denfity, and tenfion, or other founding bodies, vibrate all together in equal times, their founds will have one and the fame pitch, however they may differ in loudnefs, or other qualities, and are, therefore, called unifons; and, on the contrary, the vibrations of unifons are ifochronous. This obfervation reduces the theory of all forts of musical founds to that of the founds of a fingle ftring, with refpect to gravity or acutenefs. Confequently, the wider and narrower vibrations of a musical ftring, or of any other body founding mufically, are all ifochronous very nearly: otherwife, while the vibrations decrease in breadth till they ceafe, the pitch of the found could not continue the fame as we perceive it does, if the fift vibrations be not too large; in which cafe, the found is a little acuter at the beginning than afterwards. In like manner, fince the pitch of the found of a ftring or bell, or other vibrating body, does not fenfibly alter, while the hearer varies his diftance from it; it follows, that the larger and leffer vibrations of the particles of air, at fmaller and greater diftances from the founding body, are all ifochronous; and confequently, that the little fpaces defcribed

by the vibrating particles are every where proportional to the celerity and force of their motions, as in a pendulum; and this difference of force, at different diftances from the founding body, caufes a difference in the loudnefs of the found, but not in its pitch. It follows alfo, that the harmony of two or more founds, according as it is perfect or imperfect at any one diftance, will alfo be perfect or imperfect at any other diftance; and this is a known fact, *e. gr.* in a ring of bells. If two musical ftrings (fee STRANGE) have the fame thicknefs, denfity, and tenfion, and differ in length only, mathematicians have demonftrated, that the times of their fingle vibrations are proportional to their lengths. Hence, if a ftring of a musical instrument be ftopped in the middle, and the found of the half be compared with that of the whole, we may acquire the idea of the interval of two founds, whose fingle vibrations (*i. e.* the times) are in the ratio of 1 to 2; and by comparing the founds of $\frac{2}{3}$, $\frac{3}{4}$, $\frac{4}{5}$, $\frac{5}{6}$, $\frac{6}{7}$, $\frac{7}{8}$, &c. of the ftring with the found of the whole, we may acquire the ideas of the intervals of two founds, whose fingle vibrations are in the ratio of 2 to 3, 3 to 4, 3 to 5, 4 to 5, 5 to 6, 8 to 9, and 9 to 10, &c. See CHORD. Smith's Harmonics, p. 2, &c.

Unifon is the firt and greateft of concords, and the foundation, or, as fome call it, the *mother* of all the reft; yet others deny it to be any concord at all, maintaining it to be only that in founds, which unity is in numbers.

Thefe refrain the word *concord* to intervals, and make it include a difference of tune: but this is precarious; for as the word *concord* fignifies an agreement of founds, it is certainly applicable to unifons in the firt degree.

But though *unifonance*, or an equality of tune, makes the moft perfect agreement of found, it is not true that the nearer any two founds come to an equality of tune, they are the more agreeable. The mind is delighted with variety; and the reafon of the agreeablenefs or difagreeablenefs of two founds muft be afcribed to fome other caufe than the equality or inequality of the number of their vibrations.

It is a famed phenomenon in mufic, that an intenfed found being raifed, either with the voice, or a fonorous body, another fonorous body near it, whose tune is either unifon, or octave to that found, will found its proper note unifon, or octave, to the given note.

The experiment is eafily tried by the ftrings of two instruments; or by a voice and an harpfichord; or a bell, or even a drinking-glafs.

This our philofophers account for thus: one ftring being ftruck, and the air put in motion thereby; every other ftring, within the reach of that motion, will receive fome impreffion therefrom: but each ftring can only move with a determinate velocity of recourfes or vibrations; and all unifons proceed from equal, or equidurnal vibrations; and other concords from other proportions. The unifon ftring, then, keeping equal pace with the founded ftring, as having the fame meafure of vibrations, muft have its motion continued, and ftill improved, till its motion become fenfible, and it give a diftinct found. Other concurring ftrings have their motions propagated in different degrees, according to the frequency of the coincidence of their vibrations with thofe of the founded ftring: the octave, therefore, moft fenfibly; then the fifth; after which, the croffing of the motions prevents any effect.

This they illuftrate (as Galileo firt fuggested) by the pendulum, which being fet a moving, the motion may be continued and augmented, by making frequent, light, coincident impulfes; as blowing on it when the vibration is juft finifhed: but if it be touched by any crofs or oppofite motion, and this, too, frequently, the motion will be interrupted, and ceafe altogether. So of two unifon ftrings, if

the one be forcibly struck, it communicates motion, by the air, to the other; and both being equidurnal in their vibrations, that is, finishing them precisely together, the motion of that other will be improved and heightened, by the frequent impulses received from the vibrations of the first, because given precisely when that other has finished its vibration, and is ready to return: but if the vibration of the chords be unequal in duration, there will be a crossing of motions, less or more, according to the proportion of the inequality; by which the motion of the untouched string will be checked, as never to be sensible. And this we find to be the case in all consonances, except unison, octave, and the fifth. See CHORD.

UNISSONI, Ital. This word written at full length, or abridged over an empty staff in a score, if over the second violin, implies that it is to play in unison with the first; if over the first violin in vocal music, that it is to play in unison with the voice.

UNIT, UNITE, or *Unity*, in *Arithmetic*, the number *one*, or one single individual part of discrete quantity. See NUMBER.

If a number consists of four or five places, that which is outermost towards the right end, is called the place of units.

Number, in general, is by Euclid defined to be *μεγαλὸν ποσότης*, a multitude, or aggregate of units; but, in this sense, unity is not a number.

UNITARIANS, in *Ecclesiastical History*, a name given to those who confine the glory and attribute of divinity to the *One*, only great and supreme God, and father of our Lord Jesus Christ; and who maintain, that this one supreme God is the only object of religious worship.

This denomination is sometimes applied to those that are otherwise called Arians; but it is now more commonly appropriated to the Socinians, who maintain that the Father alone is the God of the universe, the only true God; that our Lord Jesus Christ was a mere man, with a reasonable soul and human body, who had no existence before he was born, either in the ordinary course of nature, or by the immediate operation and miraculous power of God, at Bethlehem, and who, in the course of his life and ministry, death, resurrection, and exaltation, was honoured with peculiar and extraordinary tokens of the divine influence and favour; and that the Holy Spirit was not a person, or distinct intelligent agent, but only the power, influence, and energy of God. Some, in imitation of Socinus, allow that Christ is an object of worship; but most of the modern Unitarians restrict prayer and divine worship to God alone: and this constitutes the distinction between Unitarians and other Christians, though many of the modern Socinians, renouncing that discriminating distinction, have appropriated the appellation, without sufficient reason, to themselves.

For an account of the progress of Unitarianism in our own country, see an Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times, by Mr. Lindsey, 8vo. 1783.

UNITAS FRATRUM, or *United Brethren*, a name distinguishing those Christians who are frequently called abroad Herrnhuters, and with us Moravians.

To those who are acquainted with the history of this sect, it is well known, that their most approved writers have taken great pains to derive their origin from those formerly distinguished by the appellation of Moravian or Bohemian Brethren, and who were afterwards denominated Hufites.

Mosheim, however, observes, that they may be said with more propriety to imitate the example of that famous community, than to descend from those who composed it: for, he adds, it is well known, that there are very few Bohemians and Moravians in the fraternity of the Herrnhuters; and it is extremely doubtful, whether even this small number should

be considered as the posterity of the ancient Bohemian brethren that distinguished themselves so early by their zeal for the Reformation. But from the Moravian writers, and from Crantz in particular, *ubi infra*, we are furnished with a circumstantial account of the rise and progress of this sect from the ninth century, when the Bohemians and Moravians, and the whole Slavonian nation, were first proselyted to the faith of Christianity, to the revival of it by count Zinzendorf. To this purpose they allege, that when by the instrumentality of Methodius and Cyrillus, two Greek monks, Bogaris, king of Bulgaria, and king Suatopluck, in Moravia, were converted, they and their respective countries united with the Greek church; Methodius being the first bishop, and Cyrillus having translated the bible into the Slavonian language. After various struggles, the Greek Christians were constrained to submit to the see of Rome. Some few, however, still adhered to the rites of the Greek church, who, in 1176, being joined by the Waldenses and instructed by them, associated in acts of worship, and sent missionaries into many countries. In this state they continued for more than two hundred years, till a severe persecution was commenced against them in 1391. In the beginning of the next century they acquired the denomination of Hufites, and were also called at different periods *Frater Legis Christi*, or Brethren of the Law of Christ; *Unitas Fratrum*, or the Unity of the Brethren; or *Frater Unitatis*, United Brethren. Notwithstanding very severe treatment, they maintained strict church discipline among themselves; and, at the synod of Lhota in 1467, chose twenty, and out of these nine persons, of whom they appointed three by lot for elders.

Having, at this time, no bishops of the Bohemian church who had not submitted to the see of Rome, they obtained consecration for three of their priests of Stephen, bishop of the Waldenses in Austria; and these, on their return, ordained ten co-bishops, or consensiors, from among the rest of the presbyters. After many intervals of persecution and of peace, towards the beginning of the sixteenth century, there were two hundred congregations in Bohemia and Moravia, which had the bible translated into the Bohemian tongue, first from the Vulgate, and afterwards another from the original text.

In 1523, after the dawn of the Reformation, a friendly correspondence commenced between the Brethren and Luther, and afterwards with Calvin, and others of the reformers. This correspondence involved them in a severe persecution, which greatly oppressed and dispersed them. The dissensions also that prevailed amongst themselves threatened their ruin, which were, at length, happily terminated at the synod of Sandomir, in 1570, when the three *Tropusses*, (*i. e.* those who held different tenets and rites with regard to non-essentials,) *viz.* the episcopal brethren, the Lutheran, and reformed, or followers of Calvin, agreed that they would perform divine service and communicate together. In 1575 they obtained an edict for the public exercise of their religion, which was confirmed in 1609, when they obtained leave to erect new churches. But, in 1612, a civil war broke out in Bohemia; and, in 1621, a violent persecution occasioned the dispersion of their ministers, and great distress to the Brethren in general. Among the ministers was one John Amos Comenius, bishop of the church of the Brethren. Crantz has given the succession of the Bohemian, Moravian, and Polish bishops from Stephen, in 1467, to the renewal of the church of the United Brethren in this century. In 1662, Comenius consecrated Peter Figulus, commonly called Jablonsky; and, in 1699, his son, Daniel Ernest Jablonsky, was consecrated bishop; and by him, it is said, the episcopal ordination has been

committed to the present Unity of the Brethren, adhering to the Augsburg confession, renewed by the emigration of many out of Bohemia and Moravia. This emigration was so considerable, and such numbers of others conformed to the rites of the church of Rome, that, at the close of the seventeenth century, it was apprehended that this ancient church was become utterly extinct.

Several, however, it is said, continued in Bohemia and Moravia, and retained their principles in secret; and from these the Moravian writers derive the present church, known by the name of *Unitas Fratrum*, or *United Brethren*, which, they say, is a renewal and continuation of the ancient church. About the year 1720, the revival commenced among the posterity of the Brethren about Fulneck in Moravia, and Leutomischel in Bohemia. In Moravia, one Christian David had been the chief instrument of the edification of his brethren, and the instructions which he received from ministers, whose names were Schoefer and Schwedler, he communicated, in 1717, to the descendants of the ancient Brethren. But being persecuted in their native country, some of them migrated under the conduct of Christian David, and, in 1722, put themselves under the protection of Nicholas Lewis, count of Zinzendorf, in Upper Lusatia; where they built houses upon the hill called the *Hutberg*, *Huth des Herrn*, i. e. the Watch Hill, and hence the new settlement was called *Herrnhut*, i. e. the Watch of the Lord, and the Brethren were denominated *Herrnhuters*. The count soon after removed to Bertholdsdorf, and superintended their rising settlement. Count Zinzendorf says of himself, that he had formed a design, when only ten years old, of collecting a small society of believers, who should altogether employ themselves in exercises of devotion under his direction. Accordingly, when he became of age, in the year 1721, he settled at Bertholdsdorf, and was soon after joined by a number of proselytes. In 1724, more emigrants arrived at Herrnhut from Moravia, just as the Brethren were beginning to lay the foundation of an edifice intended for the education of the children of the noblesse, for printing cheap bibles, and preparing medicines for their neighbours, in which building was also to be a chapel.

It would far exceed our limits to recount the successive emigrations to Herrnhut, and the additions that were made by the means of the preaching of the Rev. Mr. Rothe, minister at Bertholdsdorf, and the zeal of Christian David. Among these settlers there were persons of different opinions, which engaged the attention of count Zinzendorf, who endeavoured to establish an union among them in the fundamental truths of the Protestant religion, and, in 1727, formed statutes for their government in conformity to these truths.

From this period in particular, when elders and wardens were chosen, and an union established between the Brethren from Moravia, both among themselves, and with their Lutheran and reformed Brethren, the Moravian writers date the renewal of the Unity of the Brethren. The whole congregation was divided into classes of married men, married women, widowers, widows, maids, bachelors, and children, called choirs; and one of their own sex and station in life appointed to have the special care of each choir, under the inspection of the elders. The officers were appointed by lot, which has continued to be the case to the present day.

Particular attention was paid by these several classes to the instruction of youth; and as a great part of their worship consisted in singing, they proposed to instruct their children in their religion by hymns. There are some persons of both sexes appointed by rotation to pray for the society, who are said to be admonished of their duty by an inward feeling; and to determine the divine will in particular cases by casting lots. All matrimonial contracts are subject

to the direction and approbation of the elders. Such was the origin of the new sect, denominated *Herrnhuters*; or, as others say, the revival of that of the Moravian Brethren. In process of time, however, it became very considerable and extensive; and it adopted tenets and practices of a very singular kind. Some have charged it with adopting very pernicious notions, and with recommending very unwarrantable practices; such as disfigure the truths of the gospel, and sap the foundations of morality. The count is accused of speaking in very derogatory terms of the scripture, and with expressly asserting that the reading of the scripture appears to him to be more dangerous than useful to the society. To avoid idolatry, he says, people ought to be taken from the Father and Holy Ghost, and conducted to Christ, with whom alone we have to do. The Holy Ghost is called by the *Herrnhuters* the eternal wife of God, the mother of Christ, the mother of the faithful, and of the church. The language of their devotion has been charged with obscenity, and with exciting ideas not very chaste and decorous. Count Zinzendorf has incurred just censure by declaring, that the law is not a rule of life to a believer; that the word now belongs only to the Jews; and that a converted person cannot sin against light. It has been said, that no example can be found of a fanaticism more extravagant, and a mysticism more gross and scandalous, than those of the *Herrnhuters*. These charges principally depend upon the authority of Rimius, in his *Candid Narrative of the Rise and Progress of the Herrnhuters*, commonly called *Moravians*, or *Unitas Fratrum*, &c. 1753, and Supplement, &c. published in 1755, sanctioned by the recital of Moshem (Ecl. Hist. vol. v.), and bishop Warburton, in his "Doctrines of Grace," vol. ii. We are persuaded, however, by unquestionable testimonies communicated to us by the Rev. B. Latrobe, a very respectable minister among the Moravians in London, that the irregularities in principle and practice that have been charged upon them are much exaggerated; and that the accusation has been chiefly owing to some unguarded expressions introduced into their discourses and forms of devotion, which, as Mr. Crantz, their historian, candidly acknowledges, "being not clear and determinate enough, and in part unrestrained, proved offensive to many divines both in and out of their congregations."

From the year 1727 to 1731, deputations were sent from Herrnhut to Denmark, Sweden, England, Livonia, Switzerland, and other places in Germany; and thus the renewed unity of the Brethren became more known.

In 1729, a deed was signed by several, and ratified by the count and Mr. Rothe, in which they declare that they are neither Separatists, nor a new sect, but descendants of the Moravian Brethren, &c.

We acknowledge, say they, no visible congregation of Christ, but where the word of God is taught in simplicity and purity, and the members lead a holy life; yet we will not separate from any one of any other Christian denomination who truly believes in Christ, though he gives a different exposition to this or the other text of Scripture, &c.

They guard against latitudinarianism in religion; they determine to maintain their ancient church discipline, without forsaking divine service in the Protestant parish church at Bertholdsdorf; they agree to the confession of Augsburg; they will not be called *Hussites* or *Lutherans*, but retain their ancient name, *The Brethren*; thus hoping for the protection of their sovereign, and that their whole case might be examined by government.

The count's journey to Copenhagen to the coronation of Christian VI. in 1731, where he heard of the miserable condition of the negroes in the island of St. Thomas, was the occasion of the first mission of the Brethren among the

UNITAS FRATRUM.

heathen, so that two Brethren went thither in the year 1732, and the mission to Greenland commenced in 1733. In 1732, the count determined to devote himself to the ministry of the gospel, and accepted the office of warden, which he had held before, in 1733. In 1734, the first Brethren went to America. The count having been examined and received into the clerical order, by the theological faculty of Tubingen, corresponded with Jablonfsky, eldest bishop of the Brethren's unity, about the renewal of episcopal ordination; and he consecrated a bishop for the church of the Brethren of Berlin, with the concurrence of his colleague, the senior, or bishop of Liſſa, in Poland, in 1735. And in 1737, the count himself was consecrated a bishop of the Unitas Fratrum by these three bishops; having previously obtained the opinion of Dr. Potter, archbishop of Canterbury, that the Moravian Brethren were an apostolical and episcopal church, not maintaining any doctrines repugnant to the thirty-nine articles of the church of England: and he afterwards received a congratulatory letter from the archbishop on his consecration. From this time the count is called the ordinary of the Brethren. The count seems to have been zealous and indefatigable in his labours; and it appears that, in 1739, the Brethren were dispersed in about forty places, most of which were missionaries among the heathen. New settlements were made in Europe and America; institutions for the education of children were established in many places; and many regulations were adopted for mutual edification, in conformity to the constitution of the ancient church of the Brethren. In 1748, a formal and very respectable commission, consisting of three counts, two doctors of law, and three divines, was appointed to examine the charges that had been urged against the principles and practice of the Brethren, the result of which was very favourable to them. In consequence of the report of the commissioners, the bailwick and palace of Barby, where the college and seminary of the Brethren are now established, were ceded in lease to count Henry, twenty-eighth Reus, and his consorts, and the chapel of the palace given to the Brethren.

In 1749, a royal mandate was published, importing, that the congregations of the Protestant Moravian Brethren, avowing the unaltered Augustan confession, should be received in all Saxony, in the same manner as in Upper Lusatia and the county of Barby.

An eminent divine of Saxony, dean of the king's chapel, became this year, with the approbation of the sovereign, honorary president of the Lutheran Tropolis in the Unity of the Brethren; Dr. Cochius, dean of the king of Prussia's chapel, was, with the approbation of the king, introduced as honorary president of the reformed Tropolis in the Unity, to which he had been appointed in 1746, and after his death, in 1749, was succeeded in that office by Dr. Thomas Wilson, bishop of Sodor and Man. After the state of the Brethren's church had been deliberately examined by the British parliament, an act passed on the 6th of June, 1749, in behalf of the ancient episcopal church known by the name of Unitas Fratrum.

In the mean time, as their number increased, and their local congregations became more numerous, men of different connections and principles were introduced among them; some of whom had imbibed extravagant notions, which they zealously propagated. This occasioned what they called a time of sitting in doctrine and in conduct. Their phraseology in expounding divine truths often bordered upon error; and the passions being warmed, a kind of joy took place, which produced extravagant actions. Crantz, however, observes, that this sitting did not arise from irreligious principles, nor did it end in immoral practices. Many among

the Brethren were offended, and their adversaries took occasion to reproach them. The count, it is said, interposed with such success, that in the years 1750 and 1751, almost all that had been chargeable with these excesses, in doctrine and practice, acknowledged their error with shame; those who did not retract deserted them; and those, whose relapse was dreaded, were dismissed from their offices. The consequence of these excesses was, indeed, in another respect, more serious and alarming; for the count of Buedingen was so prejudiced against them, that an edict was published, requiring the inhabitants of Herrnhag, who would not renounce the count and the ministers of the Brethren's church, to leave the country; whereas those who complied were allowed to remain in their habitations, under the protection of the reigning count. On this occasion, more than a thousand persons, from 1750 to 1753, left a beautiful village, which they had erected at a great expence, and were dispersed in other congregations in Germany, Holland, England, and America; and the French reformed Brethren and Sisters, who lived at Herrnhag, formed a settlement at Neuwied, which is now in a flourishing condition.

The increase of the Brethren, their new settlements, and numerous journeys and missions, involved the society in a great expence, and threatened ruin. Their debts were many and great, discouraged their friends, and gave their enemies occasion for censure. The count, however, became security for their whole debt, which, at a stipulated time, was discharged. As soon as they were extricated from these difficulties, new regulations were adopted to prevent future distress of a similar kind. We can only add, that the count lived to see congregations and missions settled in the four quarters of the globe; and these, it has been urged, were the most effectual apologies and defences of the principles and practice of the Brethren.

In 1760 the count died, with a memorial among the Brethren of having been their patron, and the instrument by whom God restored and built up the church of the Brethren.

But though they counted him a distinguished servant of God, yet they did not regard him as their head; for they acknowledged, from the beginning, no other head and elder but the Lord Jesus Christ, and no other father but the Father in heaven.

At the first synod of the Unity, after his decease, in 1764, a number of Brethren were chosen to have collectively the superintendency of the whole Unity; and, in the following synods, the arrangement then made was continued with some amendments. This company is called the Elders Conference of the Unity, and consists of thirteen Brethren, who are chosen at every synod of the whole Unity.

The Brethren appeal to their lives for a refutation of the calumnies that have been circulated against them, professing themselves to be a people who walk in honesty and godliness as followers of the Lord Jesus Christ: and, as to doctrine, they avowedly adhere to the Augsburg, or Augustinian confession; and, with respect to this, the public, we are informed, may read an exposition of Christian doctrine as taught in the church known by the name of Unitas Fratrum.

In England, the congregations belonging to the Unitas Fratrum are the following: viz. two in London; one at Bedford, where are houses belonging to the single Brethren and single Sisters, to which belong their chapels and societies at Northampton, Rifeley, &c.; one at Ockbrook, near Derby; one at Fulneck, near Pudsey, in Yorkshire, where are houses for the single Brethren, and Sisters, and widows, and schools for children; to this the members of the societies near Leeds and Bradford belong; one at Wyke, near Halifax, another at Merfield, and another at Little Gumerfeld; one at Duckenfield, in Cheshire, where they have

two choir houses, one for the single Brethren, and one for the single Sisters; one at Leominster, in Herefordshire; one at Bristol, where are houses for the single Brethren and Sisters, to which belongs that at Kingswood; one at Bath; one at Tetherton, in Wiltshire, to which the chapel at Malmesbury belongs: a congregation was also collected, in 1759, at Haverfordwell, in Pembrokehire. Besides these congregations, the Brethren have chapels in several parts of England; *viz.* at Apperly, in Gloucestershire; Frome, in Somersetshire; Plymouth, in Devonshire; Eden and Culworth, in Northamptonshire.

The wild enthusiasm of this sect forms as singular a contrast with the wisdom and perseverance of their attempts to convert and civilize the heathens, as the smallness of their own numbers does with the variety and distant scenes of their missionary undertakings. Their numbers did not exceed 600, when they first began their attempt to convert the heathens; and, in the period of eight or nine years, they sent missionaries to Greenland, to St. Thomas's, to St. Croix, to Surinam, to the Rio de Berbice, to the Indians of North America, to the negroes of South Carolina, to Lapland, to Tartary, to Algiers, to Guinea, to the Cape of Good Hope, and to the island of Ceylon. We cannot follow Dr. Brown (*ubi infra*) through his details of these missions, which he has derived from the well-known works of Crantz, and the periodical accounts. In Greenland, where they have three settlements, *viz.* at New Hernhuth, Lichtenfels, and Lichtenau, the number of Christians, in the year 1810, was 998; but it appears to be diminishing, not so much from their defection to Paganism, as from a general decrease in the population of this inhospitable region. In St. Thomas's, where their number, in 1812, was 2285, and St. Croix, where they have three congregations, consisting in 1812 of 8443 persons, they have been favoured by the ruling powers, and have been very successful; in Jamaica, their undertaking has been viewed with jealousy, and they have made little progress; while in Antigua they have established the most flourishing of all their missions, and reckon 11,824 members of their different congregations. Their efforts on the continent of America, both North and South, have been almost uniformly unsuccessful; at Berbice the settlement was broken up in 1763, by a rebellion of the negroes; at Hope, on the river Corentyne, in Surinam, after several partial calamities, they were dispersed in 1808, in consequence of the burning of their settlement; and at Bamby and Paramaribo their establishments appear to be on the point of dissolution. The missions to North America have been almost without exception disastrous. However, they have five settlements among the Indians.

Their late missions, excepting the one that went to the Cape, appear to have been undertaken with very little prudence, and attended with no success. In the year 1812, according to an estimate by Mr. Latrobe, they had 33 settlements among the heathen, under whose care were 27,000 converts. From the account given of their method of conversion, it should seem that argument and evidence have nothing to do with it; since they never enter into any discussions concerning the several truths or doctrines of religion, till the savages appear to believe in *Christ*, and to feel the transforming influence of the gospel on their hearts and lives. Stripped of its technical language, the meaning of this statement is that the passions, and not the judgment, are the channel by which conviction is brought to the mind; and that conversion must begin by exciting terror or sympathy, before any knowledge of the cause of either can be acquired. The ultimate effect, however, is good, though the process is absurd; and perhaps no alternative presents itself but that of beginning, like the Quakers in America, with cultivating the understanding before the evidence of

Christianity is proposed to it; or operating by impassioned oratory and awful denunciations, on those feelings and sympathies which man in every condition carries within him, and which are even most powerful where the least of intellectual culture exists.

For other particulars relating to the sentiments, discipline, mode of worship, &c. of the Unitas Fratrum, we must refer to Crantz's Ancient and Modern History of the Brethren, 8vo. published in 1780, by the Rev. B. Latrobe; and to a Concise Historical Account of the present Constitution of the Unitas Fratrum, translated from a work entitled *Neueste Religions Geschichte*, by Dr. Walch, of Goettingen, and published in 1775, by Mr. Latrobe. See also Crantz's History of Greenland, &c. published in 2 vols. 8vo. 1767. A Succinct View of the Missions established among the Heathen by the Church of the Brethren, in a Letter to a Friend, by M. Latrobe, in 1771; and a Brief Account of the Mission established among the Esquimaux Indians, on the Coast of Labrador, in 1774. Brown's History of the Propagation of Christianity among the Heathen, since the Reformation, 2 vols. 8vo. London, 1817.

UNITE, in the *Manege*. See UNION.

UNITED AFFECTION. See AFFECTION.

UNITED *Flovers*, in *Botany* and *Vegetable Physiology*, are such as are furnished with stamens and pistils in the same flower. This term has been thought more commodious and unexceptionable, in English, than any translation of the Greek *ἑταροφλόγος*, however just and proper the latter may be in scientific or learned works. Most flowers come under the above description, the separation of the stamens and pistils, either in distinct flowers on the same plant, or upon different plants, of the same species, being far less common. Such a separation, however, when it does occur, presents one of the strongest evidences in favour of the Linnaean doctrine of impregnation; and decidedly refutes the opinion of Tournefort, that the anthers were destined to carry off excrementitious matter from the germs and young seeds, as the kidneys of animals secrete urine. The reniform structure of the anthers, in many cases, may offer an *apology*, it cannot be called a *raison*, in favour of such a doctrine. See FERTILIZATION of *Plants*.

The advantage of the union of both organs of impregnation in the same flower, as vegetables are not endowed with voluntary motion, is obvious. But nature seems occasionally under some disadvantage in bringing both to perfection; and one or other is rendered, by circumstances, deficient in its usual power. Thus in *Mentha* and *Lilium*, the increase by root being inordinate, the stamens become imperfect in some flowers, the pistils in others. In *Rhodiola*, which scarcely differs in any material respect from *Sedum*, they are always so, on distinct plants. Polygamous flowers (see POLYGAMIA) exhibit a sort of precaution in nature, to guard against any casual imperfection, from starvation, in either organ of united flowers. This is effected by providing a superfluous stock of stamens, for these generally predominate, in separate individuals, whose vigour is not impeded by the maintenance of any pistil of their own, and which are, therefore, at full liberty to supply the deficiencies of their neighbours.

UNITED *Provinces*, in *Geography*, a name given to the seven Protestant states of the Netherlands, which threw off the yoke of Spain, and became independent. (See HOLLAND and NETHERLANDS.) These now form a distinct kingdom, and by an arrangement which has taken place since the French revolution, William Frederick, grand duke of Luxemburgh, and prince of Orange and Nassau, is king of the Netherlands. This prince married princess Frederica Sophia of Prussia, October 14, 1791, by whom

he has issue, William Frederick, hereditary prince, a general in the British army, married Feb. 21, 1816, to the grand duchess Anne, sister to the emperor of Russia; and Frederick.

UNITED STATES, comprehend an extensive portion of North America, situated between $25^{\circ} 50'$ and $49^{\circ} 37'$ N. lat., and between 10° E. and $48^{\circ} 20'$ W. long. from Washington. The most northern part is bounded by a line running due W. from the N.W. corner of the Lake of the Woods, and the southern extremity is the outlet of the Rio del Norte. The eastern extremity is the great Menan island, on the coast of Maine, and the western is Cape Flattery, N. of Columbia river, on the Pacific ocean. The greatest extent of the country from N. to S. is 1650 miles, and from E. to W. 2700. The area is about 2,379,350 square miles, or 1,522,784,000 acres. The population by the last census was 7,239,903, being less than three to each square mile of territory, so that every inhabitant has nearly 200 acres of land. The United States are bounded on the E. by the Atlantic ocean, and the British province of New Brunswick; on the N. by the British possessions of Lower and Upper Canada, and the large unsettled country to the westward of those provinces; on the W. by the Pacific ocean; on the S.W. by the Spanish internal provinces and the Rio del Norte; and on the S. by the gulf of Mexico and Florida. In the definitive treaty of peace between the United States and Britain, executed at Paris on the 3d of September, 1783, the northern and eastern boundaries are described as follows, *viz.* "From the N.W. angle of Nova Scotia; *viz.* that angle which is formed by a line drawn due N. from the source of St. Croix river to the Highlands; along the said Highlands which divide those rivers that empty themselves into the river St. Lawrence, from those which fall into the Atlantic ocean, to the north-westernmost head of Connecticut river; thence down along the middle of that river, to the 45th degree of N. lat.; from thence by a line due west on said latitude, until it strikes the river Iroquois or Cataraguy; thence along the middle of said river into lake Ontario, through the middle of said lake until it strikes the communication by water between that lake and lake Erie; thence along the middle of said communication into lake Erie, through the middle of said lake until it arrives at the water communication between that lake and lake Huron; thence along the middle of said water communication into lake Huron; thence through the middle of said lake to the water communication between that lake and lake Superior; thence through lake Superior northward of the isles Royal and Philippeaux, to the Long Lake; thence through the middle of said Long Lake and the water communication between it and the Lake of the Woods, to the said Lake of the Woods; thence through the said lake to the most north-western point thereof, and from thence on a due west course to the river Mississippi. East by a line to be drawn along the middle of the river St. Croix, from its mouth in the Bay of Fundy to its source, and from its source directly N. to the aforesaid Highlands which divide the rivers that fall into the Atlantic ocean from those which fall into the river St. Lawrence; comprehending all islands within twenty leagues of any part of the shores of the United States, and lying between lines to be drawn due E. from the points where the aforesaid boundaries between Nova Scotia on the one part, and East Florida on the other, shall respectively touch the bay of Fundy and the Atlantic ocean; excepting such islands as now are, or heretofore have been, within the limits of the said province of Nova Scotia."

As to the country west of the Lake of the Woods, it is evident that the commissioners were of opinion, that it should be part of the territory of the United States, as

high as a line to be run due W. from the N.W. corner of that lake until it reached as far W. as the Mississippi; which was at that period the western boundary of the United States. Subsequent events have annexed the whole of Louisiana to the country, so that the northern boundary of it behoves to be ascertained, as it was possessed by France; but the country never having been settled, the boundary has not been accurately defined. The best course, says Mr. Melish, in the construction of his map, has appeared to be to run the boundary line due W. from the N.W. corner of the Lake of the Woods to the gulf of Georgia, and thence along that gulf, and the straits of Juan de Fuco, to the Pacific ocean. As the French were the first settlers in Louisiana, maps founded on their claims furnish evidence as to the western limits of Louisiana of undoubted authority, and fix the boundary line on the W. side of the Rio del Norte, to the Rio Salado, corresponding to the Rio Puerco of more modern maps: and it is continued along that river nearly to its source. From thence it passes to the E. of Santa Fé, to between the 37th and 38th degrees of N. lat., where it crosses the Rio del Norte, and is so continued to about half a degree W. of that river; then along that river to its source, where the limits of Louisiana are undefined. Towards the Pacific ocean, we have no very correct data, says Mr. Melish, for forming an opinion as to the boundaries. The following view of the subject, he says, is the result of the best information that can be obtained.

The Missouri and its waters are unquestionably part of the United States territory, in virtue of the purchase of Louisiana; and it is presumed, that the title is equally unquestionable as to the Columbia and its waters, to a line drawn due W. from the N.W. corner of the Lake of the Woods. This includes the Multnomah on the S., but leaves the question undetermined in the unexplored country between that river and the bay of St. Francisco. From the latest accounts, it appears that the Spaniards have no settlements above that bay, and probably will have none, so that the country may be considered virtually a part of the United States territory, provided they should consider it of importance to take possession, and settle it.

The face of the country in the United States presents every variety. The north-eastern part on the coast is broken and hilly; and is remarkably indented with numerous bays and inlets. Towards the S., and along the gulf of Mexico, the land is level and sandy, interspersed with many swamps, and numerous islands and inlets. At the outlets of many of the rivers, there is a large portion of alluvial land, which is particularly the case along the Mississippi. Beyond the head of tide waters, there is a tolerably rich and agreeably uneven country, which extends to the mountains. The mountainous district, on the Atlantic side of the country, is about 150 miles in breadth, and 1200 miles in length; extending in large ridges from N.E. to S.W. These ridges are generally known by the name of the Allegany mountains, and are of various elevations, from 2000 to 4000 feet. The highest point seems to be the White Hills, in New Hampshire, which rises to the elevation of nearly 9000 feet. Beyond the mountains we have a view of the great valley of the Mississippi and its tributary streams, presenting a body of the finest land in the world, and possessing great natural advantages. To the westward of this valley are the mountains of Louisiana, presenting features singularly bold and grand. The rocky mountains, in particular, are very majestic; and the vast variety produced by the great mass of waters forming the tributary streams of the Missouri and Columbia, must render the scenery in that region singularly interesting. Beyond these principal

UNITED STATES.

principal feature is the great confluence of waters at the outlet of the Columbia river, and the bold shores of the Pacific ocean.

The principal rivers of the United States are the St. Lawrence and its waters, the Columbia and its waters, the St. Francisco, the Rio del Norte, and the Missouri and Mississippi, and the waters that flow into them. The river St. Lawrence is formed by the waters that are collected about lake Superior, from which they issue into lake Huron through the fraits of St. Mary, and from it, by the fraits of that name about forty miles long, into lake St. Clair. From this lake the waters pass into lake Erie, through the fraits of Detroit, an important and beautiful passage, about 30 miles long. (See DETROIT.) Between Buffalo on one side and Fort Erie on the other, the water is discharged from the lake, and by a rapid course runs towards lake Ontario, through the passage called Niagara river. About five miles below lake Erie, the stream is divided by Grand island, below which is Navy island, where it expands to a considerable breadth, above the falls of *Niagara*; which see. Below the falls the river runs very rapidly for nine miles, through a deep chasm, and is navigable to lake Ontario, a distance of seven miles. From lake Ontario the river issues through a great number of islands, situated between Kingdon and Sackett's Harbour. Here it assumes the name of St. Lawrence, though from the lake to Montreal it is frequently denominated Cadaraqui. In its progress it expands into a considerable lake, called St. Francis; and when it reaches Montreal, it receives the Utawas, or Grand river, which forms the boundary between the two Canadas. Below Montreal, it receives the Richelieu, or Sorel river, from lake Champlain, and in succession the St. Francis, St. Maurice, and Chaudiere, below which, at a small distance, stands Quebec, and below this city the river is divided into two branches by the island of Orleans. Beyond this island it gradually expands into the spacious bay and gulf of St. Lawrence, which communicates with the ocean by the fraits of Belleisle, and what is called the South Entrance. See *St. LAWRENCE*.

Columbia river is supposed to take its rise about 300 miles N.E. of the point at which it interlocks with the head waters of the Unjigah or Peace river. It was first discovered by the enterprising British traveller, Mr. M'Kenzie, in N. lat. $54^{\circ} 40'$, W. long. $120^{\circ} 25'$, from London; and he descended it about 150 miles, and then leaving it, traversed the country to the ocean. From the point where he left it, its course is unknown till it is joined by Clark's river, where it is a large stream. About seventy miles below Clark's river, after receiving some tributary streams, the Columbia forms a junction with Lewis's river, formed of many branches, which rise in the Rocky mountains, where, like Clark's river, they interlock with the head waters of the Missouri. Below Lewis's river, the Columbia bends to the S. and E., and then passes through the mountains; and about 300 miles below are the Great Falls. About twenty miles below the falls, the river makes a considerable bend, and passes through another chain of mountains; below which, about 60 miles, it receives from the S.E. the large and important river called the Multnomah. From the Multnomah, supposed to rise near the head waters of the Rio del Norte, to the ocean, which is a distance of about 90 miles, it is all tide-water, through good land, with many Indian settlements. The waters of the Columbia are clear, and abound with every variety of fish.

The *St. Francisco* river is a very large stream, 270 miles in the interior of the country; a part of it being formed by the Rio Buenaventura, and its waters, which interlock with the waters of the Rio del Norte and La Platte, and open-

ing, in process of time, an excellent communication with the settlements on the W. coast of America.

The *Rio del Norte* rises among the mountains between N. lat. 44° and 42° , and 33° and 34° W. long. Its head waters interlock with those of the Missouri, Columbia, La Platte, Arkansas, Multnomah, and Francisco: and the waters of the Rio Colorado of the west, which fall into the gulf of California, approach near it. In a progress of about 300 miles to the point where the traveller Pike and his party first encamped upon it, it is presumed to be the S.W. boundary of Louisiana. About 100 miles below this is Santa Fé, an interesting Spanish settlement: below Santa Fé, the river runs about 450 miles in a direction E. of S., without any material augmentation, when the Rio Conchos falls into it from the S.W. Below this it makes a bend of about 100 miles, and receives the Rio Puerco from the N. At this river the Rio del Norte again becomes the S.W. boundary of Louisiana. Below this it pursues an E. course of between 50 and 60 miles, when it receives a considerable stream from the N.; and from hence, without much increase, its course is nearly S.E., about 400 miles, to the gulf of Mexico. See *Rio*.

The Missouri and Mississippi, with their numerous branches, water the interior of the United States. The highest source of the *Missouri* (which see) lies on Jefferson's river, a little above the 44^{th} degree of latitude, and near the 37^{th} degree of W. longitude, 3000 miles from the Mississippi. From this point, in descending it, we arrive in succession at Philanthropy river, Wisdom river, Philosophy river, Madison's river, Gallatin's river, Ordway river, Dearborn's river, and Smith's river, and then reach the falls of the Missouri, which are perpendicular descents, and partly rapids, the river falling no less than $36\frac{1}{2}$ feet in the course of 18 miles. The highest pitch is 87 feet, the next 47, and the next 26. Passing the falls, we arrive at Portage river, Snow river, Maria's river, Stone-wall creek, Slaughter river, Big Horn river, Judith river, Turtle creek, Windfor creek, North Mountain creek, others of less note, Bralton's creek, Milk creek, Porcupine creek, and Martha's creek, and then come to the Yellowstone river, which flows in from the S.W. The Yellowstone is a large river, the main branch of which rises in lake Enstus, and after receiving numerous tributary streams, the Big Horn, a river nearly equal to it in size, which rises in lake Biddle, falls in from the southward; and the streams thus united and augmented by others, particularly the Tongue river, form a confluence with the Missouri, in N. lat. 48° W. long. 27° . Beyond this, at a small distance, the Missouri reaches its northern extremity in N. lat. $48^{\circ} 22'$, where it receives the White-earth river, and beyond this the head waters of the Moose river approach within one mile of the main stream of the Missouri. Below this, the river is augmented by the Little Missouri, and after passing the Knife river, we arrive at Fort Mandan. Between 43° and 44° , there is a great bend in the river; and below it the river receives a number of pretty large streams, before we reach the La Platte, a little above N. lat. 41° . This is a very large stream, extending through several ridges of the rocky mountains, the head waters of which are higher than either the Arkansas or Rio del Norte. Passing the La Platte, the Missouri receives many tributary streams, before it reaches the Kanfas, a large river, which falls in from the W., a little above the 39^{th} degree of N. lat. Below this it is augmented by some important streams from the N., and afterwards the beautiful Ogage river falls in from the S.W. Below this river, about 120 miles, the Missouri joins the Mississippi, above St. Louis; from whence the united streams flow with majestic rapidity to the ocean.

UNITED STATES.

The *Mississippi* (which see) rises, says Mr. Melish, in Turtle lake, N. lat. $47^{\circ} 47'$, and after receiving several tributary streams, reaches the falls of St. Anthony in N. lat. 44° , which falls are 16 feet perpendicular, with a rapid below of 58 feet. Below the falls, St. Peter's river forms a junction with the Mississippi from the W., and a little further, St. Croix river falls in from the E. About 15 miles below this, the river spreads out into a beautiful sheet of water, called lake Pepin, at the lower end of which it receives the waters of the Chippewa river. About 90 miles below this river, the Ouifconfin falls in from the eastward, which river approaches within $1\frac{1}{2}$ mile of the Fox river, which falls into lake Michigan. At the mouth of the Ouifconfin river is Prairie du Chien, where the United States have lately formed a military establishment, which will undoubtedly be very important to the settlements of this part of the country. After passing the Ouifconfin river, the Mississippi makes a considerable bend to the eastward, and meets the northern boundary of the Illinois territory; then bending westward about 30 miles, it receives Stony river. About 80 or 90 miles below this, the Riviere des Moines falls in from the westward, and then the Illinois falls in from the eastward, a little above the junction of the Mississippi and the Missouri. The Illinois is a large river, the head waters of which interlock so closely with those falling into lake Michigan, that canoes, it is said, have sometimes in the wet season passed from the one to the other. About 12 miles below the confluence of the Illinois with the Mississippi, we arrive at the junction of the Mississippi and Missouri: the former of which is, according to Mr. Melish, inferior in importance to the latter. The Missouri, he says, is the main stream, and the Mississippi only a tributary branch. The former is in length double the latter, and receives before its junction with it, the waters of many streams, one of which, the La Platte, is longer than the Mississippi. The Arkansas and Red river are also much longer; and the Ohio, allowing for its great bends, is also longer; and taken in connection with the Cumberland and Tennessee, is a river of much greater importance.

After leaving St. Louis, we pass along the Mississippi about 80 miles to Kaskaskia, where the Kaskaskia, a considerable stream, falls in from the eastward; and about 90 miles further below this, the Ohio river, augmented by its numerous branches, joins the Mississippi. About 350 miles below the Ohio, the White river, a beautiful stream, falls in from the westward: 14 miles below this river, the Arkansas, a very large and important river, having its sources in the mountains above Santa Fé, falls in from the westward. Below the Arkansas river, 190 miles, the Yazoo falls in from the eastward: the Big Black river also falls into the Mississippi 63 miles by water, but only 30 in a direct line by land, below the Yazoo. A few miles below this, we pass the 31st degree of N. lat., which forms the boundary between the state of Louisiana and the Mississippi territory; after which the river bends to the westward, and receives the waters of the Red river. The Red river rises in the mountains, E. of Santa Fé, between 37° and 38° of N. lat., and pursuing mostly a S.E. course, makes several bends, and receives no considerable streams until it joins the Wachitta, and its great mass of waters, a few miles before it reaches the Mississippi. The latter passes to the sea by New Orleans and the Red river, through the Atchafalaya. As this river receives no streams of importance after passing the Atchafalaya, it may be considered as having reached its maximum; and it may be viewed in its progress from hence to the ocean, as having an average breadth of 800 yards, its depth about 120 feet, and the velocity of its current about one mile *per* hour. Accordingly, it runs on with majestic

sway, and passes St. Francisville, Baton-Rouge, Donaldsonville, Manchac, and, 250 miles below the Atchafalaya, reaches New Orleans, where it makes a considerable bend to the S. and E. After passing the English Turn, a considerable bend in the river, 16 miles below New Orleans, situated on its northern bank, we next meet fort St. Philip, or Plaquemines, distant 54 miles. Below this, at the interval of 19 miles, the river separates into three grand divisions, *viz.* the South-east or Main Pass, the South Pass, and the South-west Pass. Four miles below the Forks, on the Main Pass, a stream issues to the N.E., called Pass à la Louvre, and the Main Pass is divided into two parts at the outlet, one called the North and the other the South-east Pass. The South-west Pass is also divided into two parts at the outlet; the western one being called the West Pass. On all these passes there are bars at the outlet, with the water comparatively shallow: the Main Pass has about 13 feet; the South-west Pass 12; the West Pass 9; and the South Pass 8. The course of the river may be traced to a considerable distance from the shore, when it is finally lost in the mass of waters forming the gulf of Mexico.

Mr. Darby, in his valuable work on Louisiana, has given the following calculation of the quantity of water discharged by the Mississippi. In one foot longitudinal section of the river, it is estimated that there are 141,372 cubic feet of water, the mean velocity being one mile *per* hour; and as the mile contains 5280 feet, the river will of course discharge 5280 times 141,372, or 746,444,160 cubic feet of water every hour. This being reduced to gallons, gives 4,573,938,000, being upwards of 76 millions of gallons in a minute, and of 1270 thousand gallons in every second of time. The magnitude and importance of this river are exhibited by Mr. Melish in another point of view, thus: the eastern extremity of the waters of this river is the head waters of the Allegany, which are situated in Pennsylvania, about 190 miles N.W. of Philadelphia: the western extremity is the head waters of Jefferson's river, about 540 miles from the Pacific ocean; and the distance between these two extremities, in a direct line, is about 1700 miles. The northern extremity is a branch of the Missouri, in $50^{\circ} 42'$ N. lat., 550 miles W. by N. of the Lake of the Woods: the southern extremity is the fourth pass into the gulf of Mexico, 29° N. lat., 90 miles below New Orleans; and the distance between these two extremities, in a direct line, is 1680 miles. Hence it appears, by a subjoined statement, that the river and its branches spread over nearly 1,500,000 square miles, or above two-thirds of the whole territory of the United States.

The lakes of the United States are some of the largest in the world. The principal of these lie in a chain along their northern boundary, upon the Canada line, and are, lakes Superior, Michigan, Huron, St. Clair, Erie, and Ontario, Champlain, George, Memphremagog, Umbagog, Chilmacook, and Mooshead, &c. &c. The chief of these are described under their appropriate names, and others under the account of the states to which they belong.

Of the minerals, soil, produce, and climate of the United States, it is needless to give in this place more than a general statement, as they are mentioned under the appellations of the respective states and territories to which they pertain.

As to *minerals*, iron, lime-stone, and free-stone abound through the country. Coal is plentiful in the western territories, and is found in several districts in the Atlantic states. Lead abounds in the district near St. Louis, where the mines are extensive and valuable. Copper mines are also found in several places, and it is said that gold and silver, in great profusion, exist in Upper Louisiana. In this province marble

ble is abundant, and forms the bed of the White river for 300 miles. In the neighbourhood of Philadelphia, and in other places, the benefit derived from the marble quarries is very considerable. Quicksilver, zinc, saltpetre, and sulphur, are plentiful. Upper Louisiana affords great quantities of antimony, and the whole western territory abounds with salt-springs. The soil in this extensive country is various. On the Atlantic coast, to the N. and E., it is stony, and towards the S. sandy; but in both situations, intermixed with much alluvial land. Towards the mountains the soil improves, and is in many places very fertile. On the mountains it is light and thin, but in the valleys rich. Beyond the mountains, in the valleys of Ohio, Mississippi, and Missouri, several tracts of land are exceedingly rich and fertile. Towards the S.W. parts of the Missouri territory, the soil is light, thin, and sandy. The mountainous region to the N.W. is similar to the Allegany mountains, but the hills are more lofty, and the soil more variable. Beyond these mountains there is much good soil, as far as the Pacific ocean.

The produce consists of every variety that can be named; wheat, maize, rye, oats, barley, rice, and other grain; apples, pears, cherries, peaches, grapes, currants, gooseberries, plums, and other fruit, and a vast variety of vegetables. Lemons, oranges, and some other tropical fruits, are raised in Louisiana and some of the other southern countries. Hops, flax, and hemp are abundant. Tobacco is an article of extensive cultivation in Virginia, Maryland, and other districts. Cotton is a staple commodity in the southern states. Indigo is produced in Louisiana, and sugar is a commodity much cultivated in that country, and in some places along the Atlantic coast. The northern and eastern states, and the mountains in the interior, are fine grazing countries, and furnish a great number of cattle and sheep, and abundance of butter and cheese. The Merino breed of sheep have been introduced, and are said to thrive as well as they do in Spain. Horses for draught and saddle abound, and some of them are excellent, particularly in Pennsylvania. Other domestic animals, as asses, goats, hogs and dogs, are plentiful. Of tame fowl, the United States have turkeys, geese, ducks, common poultry, pigeons, peacocks, and guinea fowls. The wild animals are numerous; among which may be enumerated the bison or wild ox, moose, deer, bear, wolf, fox, lynx, panther, weasel, ermine, martin, mink, otter, opossum, hare, squirrel, mouse, bat, rat, beaver, seal, &c. The game and wild fowl peculiar to the country are turkeys, pheasants, partridges, woodcocks, snipes, wild swans, wild geese, wild ducks, pigeons, teal, plovers, widgeons, rail, &c. The other birds are eagles, hawks, vultures, turkey-buzzards, starlings, blue birds, red birds, humming-birds, &c. Of fishes, these states have the whale, dolphin, porpoise, grampus, skate, shark, sturgeon, cod, flounder, perch, whiting, salmon, trout, roach, sniad, drum, black fish, and many others, with which the seas, interior lakes, and rivers are abound. Among the amphibious reptiles we may reckon the tortoise, frog, lizards of various species, the alligator, &c. To the class of serpents belong the snakes and vipers, which abound in the United States. Of natural timber the United States have various kinds; but some of the most useful are the elm, cherry, locust, oak, beech, pine, cedar, cypress, willow, hickory, ash, walnut, chestnut, birch, maple, &c.

The climate must vary in the different parts of the United States. In the N.E. parts the winters are very cold, and the summers hot, changing as you proceed southward. In the S.E. and along the gulf of Mexico, the summers are very hot, and the winters mild and pleasant. Among the mountains it is cold towards the N., and temperate in the S. Beyond the mountains, in the rich valleys of Ohio, Mississippi,

and Missouri, the climate is temperate and delightful, till we approach the Rocky mountains, when it is subject to extremes, the winters being very cold. The climate must be chilled among mountains constantly covered with snow. West of these mountains the climate changes, until we reach the shores of the Pacific ocean, where it resembles that of the western parts of Europe. The prevailing winds are from the west, and as they pass over a wide expanse of water, they cool the air in summer, and in winter deluge the country with frequent rain.

The history of the United States has been already given, during the rise and progress, and to the termination of that dispute which separated them from this country, under AMERICA. From the time of their first settlement to July 1776, they continued to be British colonies; but in that month Congress declared them to be independent states. At this period their number was thirteen, and they contained about three millions of inhabitants. Since that time they have increased in an astonishing degree, and now amount to nineteen states, and five territories, containing, by the census of 1810, 7,239,903 inhabitants: and it is said by Melish (1816) that about 233,400 may be added as the annual increase since that year. This writer observes, that the progress of agriculture, manufactures, and the mechanic arts, is more remarkable than that of the population. At the period of the revolution the settlements were almost wholly confined to the eastward of the mountains, and principally along the sea-board, depending on Britain for manufactures, and many of the necessaries of life. The settlements now extend across the Mississippi, the interior being fludded with towns, villages, and farm-houses; and abounding with grist-mills, fulling-mills, carding and roving machines, paper-mills, cotton-mills, iron foundries and forges, tan-works, glass-works, in such profusion, and increasing so rapidly, that the internal manufactures will soon be sufficient not only to supply the demand at home, but to furnish vast quantities of cotton yarn and cloth, and of hemp articles, for exportation. The estimated amount of manufactures in 1810, was 120,000,000 dollars. The increase since that time has been so great, that they may be now estimated at upwards of 200,000,000. The United States have heretofore exported flour, wheat, Indian corn, rice, asses, cotton, indigo, tobacco, timber, fish, live-stock, tar, turpentine, &c. In 1812, the amount was 45,294,043 dollars. They have imported dry goods, groceries, tea, coffee, sugar, wine, brandy, &c. In 1812, the amount of the imports was nearly equal to the exports. The state of commerce, it is said, is rapidly changing from external to internal trade.

The government of the United States is a federal republic. Each state has a constitution for the management of its internal affairs, and they are all formed into one united body by the "federal constitution." By this constitution the legislative power is vested in a congress of delegates from the several states, divided into two distinct bodies, the "senate," and "house of representatives." The members of the latter are elected every two years by the people, and the senators are elected every six years by the state legislatures. The executive power is vested in a president (which see), chosen every four years, by a number of delegates in each state, appointed in such manner as the state legislatures may direct, and equal to the number of members which they respectively send to both branches of congress. The constitution guarantees for ever freedom of speech and liberty of the press. In the eye of the law all the inhabitants are equal. All must bear arms, or pay an equivalent; and all are equally interested in the defence of the country. The military strength of the country is a well-disciplined militia; and here is also an in-

creasing navy, to the maintenance of which the fishing trade is peculiarly important. Trial by jury is to be preferred inviolate. A republican form of government is guaranteed to all the states, and hereditary titles and distinctions are prohibited.

With regard to the religion of the United States, it is stipulated that no law shall ever be passed to establish any particular form of religion, or to prevent the free exercise of it: and no religious test shall be required as a qualification to any office of public trust under the United States. The following denominations of Christians are more or less numerous; *viz.* Congregationalists, Presbyterians, Episcopalians, Dutch reformed church, Baptists, Quakers or Friends, Methodists, Roman Catholics, German Lutherans, German Calvinists, Moravians, or brethren of the episcopal church. The Congregationalists are said to be the most numerous, particularly in New England, and also in the middle and southern states. Next to these are the Presbyterians, who inhabit chiefly the middle and southern states, and they are united under the same constitution. In 1796 these were divided into five synods, *viz.* those of New York, Philadelphia, Virginia, Carolinas, each of which four meet annually: and besides, they have a joint meeting, by their commissioners, once a year, in general assembly at Philadelphia. The Presbyterian churches are governed by congregational, presbyterial, and synodical assemblies; but these assemblies possess no civil jurisdiction. The Dutch reformed churches maintain the doctrine of the synod of Dort, held in 1618, and constitute six classes, which form one synod, styled "the Dutch reformed Synod of New York and New Jersey." The classes consist of ministers and ruling elders; each class delegating two ministers and an elder, to represent them in synod. The number of Protestant episcopal churches is not ascertained. There are some in New England, but they are most numerous in the southern states. The Baptists are chiefly upon the Calvinistic plan as to doctrines, and Independents as to church government and discipline. The Friends or Quakers went to America about the year 1656; the first settlers of Pennsylvania being of this description. The Methodists are Arminian and Calvinistic. The Roman Catholics are principally settled in Maryland, where they have a bishop. The German inhabitants in these states principally belong to Pennsylvania and New York, and are divided into a variety of sects, the principal of which are Lutherans, Calvinists, Moravians, Tunkers, and Mennonites. But the German Lutherans are the most numerous. The Moravians are dispersed over Pennsylvania, at Bethlehem, Nazareth, and Lititz; and they have also other settlements in New Jersey, North Carolina, Rhode island, New York, &c. The Tunkers appeared in 1719, and landing in Philadelphia, dispersed themselves in various parts of Pennsylvania; they are General Baptists, and believe in universal redemption and salvation. Their principal settlement is at Ephrata, called Tunker's-town, in Lancaster county. The Mennonites are chiefly settled in Pennsylvania. The Universalists, who maintain the doctrine of the ultimate salvation of all men, are said not to be numerous. The Unitarians are an increasing body. The Shakers form a small body. There are some few Jews, and many Deists. Provision is made for education and the improvement of the mind throughout the United States.

Accounts in the United States were formerly kept in pounds, shillings, and pence currency, which practice is still retained on some occasions; but the value of the currency is not the same in different states.

In Pennsylvania, New Jersey, Delaware, and Maryland, the ratio of currency to sterling is as 3 to 5: and therefore

1*l.* sterling = 1*l.* 13*s.* 4*d.* currency; or 1*l.* currency = 12*s.* sterling.

In New Hampshire, Massachusetts, Connecticut, Rhode Island, and Virginia, the ratio is as 3 to 4; and therefore 1*l.* sterling = 1*l.* 6*s.* 8*d.* currency; or 1*l.* currency = 15*s.* sterling.

In New York and North Carolina, the ratio is as 9 to 16; and therefore 1*l.* sterling = 1*l.* 15*s.* 6½*d.* currency; or 1*l.* currency = 11*s.* 3*d.* sterling.

In South Carolina and Georgia, the ratio is as 27 to 28; and therefore 1*l.* sterling = 1*l.* 0*s.* 8¾*d.* currency; or 1*l.* currency = 19*s.* 3½*d.* sterling.

Hence the exchange between England and the United States is at par, when, for every 100*l.* sterling, Pennsylvania, Maryland, &c. give 166*l.* 13*s.* 4*d.* currency; New England and Virginia, 133*l.* 6*s.* 8*d.* do.; New York and North Carolina, 177*l.* 15*s.* 6½*d.* do.; Georgia and South Carolina, 103*l.* 14*s.* 0½*d.*

Most of the European coins pass in the United States, but Spanish dollars are most common: hence the value of other European monies is commonly expressed in dollars, and hundredth parts of a dollar, called cents.

The dollar is valued in the different states according to the currency of each place. Thus in Pennsylvania, Maryland, Delaware, and Jersey, it passes for 7*s.* 6*d.*; in New England and Virginia, for 6*s.*; in New York and North Carolina, for 8*s.*; in South Carolina and Georgia, for 4*s.* 8*d.*

An uniform way of keeping accounts has been established in the United States (by an act of Congress in 1789) namely, in dollars of 10 dimes, 100 cents, or 1000 mills; and this method is used in all public accounts.

The American government, at the same time, established a mint, and ordered money to be coined, in gold, silver, and copper, according to the following denominations and values; *viz.*

Eagles, each to be of the value of 10 dollars, or units, and to contain 247½ grains of pure, or 270 grains of standard, gold, the standard being 22 carats, or 1½ fine. Its intrinsic value in English gold is, therefore, 2*l.* 3*s.* 8*d.* nearly. Half eagles and quarter eagles were also ordered to be coined in the same proportion.

Dollars or units, each to be of the value of a Spanish milled dollar, and to contain 371½ grains of pure, or 416 grains of standard, silver, the standard being 1½ fine, or 10 oz. 14 dwts. nearly. Its intrinsic value in English silver is, therefore, 4*s.* 3½*d.* nearly. Half dollars, quarter dollars, dimes, or tenths of dollars, and half dimes, were also ordered to be coined in the same proportion. Hence the proportion of gold to silver is as 4160 to 270, or as 15½ to 1.

Cents, each to be of the value of the one-hundredth part of a dollar, and to contain 208 grains of copper. Half cents were ordered to be coined in the same proportion.

The remedy of the mint is one part in 144.

In the public bank established at Philadelphia in 1790, chartered by Congress, and empowered to appoint branch-banks in the different states, the capital was fixed at ten millions of dollars, and divided into 25,000 shares, of 400 dollars each; none of the subscribers were to hold more than 1000 shares; one-fourth of the subscription was to be paid in specie, and three-fourths in public stock. These shares are transferrable, and yield a dividend, payable half yearly, of 7 or 8 per cent. per ann. The constitution and government of this bank are nearly on the plan of the bank of England.

The bank discounts, at 6 per cent per ann., bills and notes that have no more than 65 days to run; the three days of grace are included, and discount allowed for them. Bills

UNITED STATES.

or notes intended to be offered for discount must be delivered at the bank on the preceding day, inclosed under a cover, and directed to the cashier, mentioning the name of the holder of the bill.

Money deposited in the bank may be drawn out again at pleasure, free of expence; but no money is paid to any person beyond the balance of his account.

Other banks have been established in Philadelphia, as well as in Boston, New York, Baltimore, Alexandria, and Charlestown, some of which were prior to the bank of Philadelphia, called the "United States' Bank;" but they are chartered only by their respective states. Kelly's Cambiit.

The United States comprise three grand divisions: denominated *Northern*, or more properly *Eastern, Middle*, and *Southern* states.

The first division (the Northern or Eastern States) comprehends

- | | |
|------------------------------|-----------------------|
| Vermont, | Massachusetts Proper, |
| New Hampshire, | Rhode Island, |
| District of Maine, | Connecticut. |
| (belonging to Massachusetts) | |

These are called the New England States, and comprehend that part of America which, since the year 1614, has been known by the name of New England.

The second division (the Middle States) comprehends

- | | |
|---------------|---------------------|
| New York, | Ohio, |
| New Jersey, | Indiana Territory, |
| Pennsylvania, | Michigan Territory. |
| Delaware, | |

The third division (the Southern States) comprehends

- | | |
|-----------------|------------------------|
| Maryland, | Tennessee, |
| Virginia, | South Carolina, |
| Kentucky, | Georgia, |
| North Carolina, | Mississippi Territory. |

To which we may now add Louisiana.
The states, districts, and territories of the United States are described under their appropriate appellations: but the area, extent, population, chief towns, &c. of each, are exhibited in one view of them in the following

TOPOGRAPHICAL TABLE.

States and Territories.	Medium.		Area in Square Miles.	Population last Census.	Seat of Government.	Membr. to Congress.

Each state sends two senators						182
Total legislature						36
Total legislature						218

* Indiana is about to be constituted into a state, when it will send two senators, and one representative.

UNITED STATES.

From this table it appears, that if we refer the district of Maine to Massachusetts, and admit Indiana, the number of states is now nineteen; of districts, two; and of territories, four. Their respective topographical tables, extracted from Mr. Melish's valuable publication, appear either in the sequel of this article, or under the appellation to which we refer.

The district of *Maine*, according to the statement of Melish, is situated between $43^{\circ} 5'$ and $47^{\circ} 45'$ N. lat., and $5^{\circ} 55'$ and 10° E. long. from Washington; extending from N. to S. about 216 miles, from E. to W. 162, and comprehending about 31,750 square miles, or 19,720,000 acres. For other particulars, see MAINE.

Topographical Table.

Counties.	Townships.	Population.	Chief Towns.
Cumberland	24	42,831	PORTLAND 7,169
Hancock	76	30,031	Castine 1,036
Kennebec	33	32,564	Hallowell 2,068
Lincoln	36	42,992	Wiscasset 2,083
Oxford	37	17,630	Paris.
Somerfet	37	12,910	Norridgewock 880
Washington	24	7,870	Machias 1,570
York	21	41,877	York 3,046
	288	228,705	

The state of *Massachusetts* is situated between $41^{\circ} 13'$ and $42^{\circ} 52'$ N. lat., and $3^{\circ} 20'$ and $6^{\circ} 55'$ E. long. from Washington, extending from N. to S. 70 miles, from E. to W. 140 miles, and comprehending 8500 square miles, or 5,440,000 acres. See MASSACHUSETTS.

The state of *Louisiana* is divided into twenty-five parishes, whose natural positions are, six north of 31° N. lat.; three south of 31° N. lat. and west of Atchafalaya river; and sixteen east of Atchafalaya. Their respective extent in square miles, and population in 1810, is exhibited by the following table.

Statistical TABLE of the Extent of the Parishes of the State of Louisiana, and their Population in 1810.

Parishes.	Square Miles.	Acres.	Arpens.	Population in 1810.

The territory of *Orleans* comprehends the county of Orleans, the German coast, Acadia, Lafourche, Iberville, Point Coupée, Concordia, Ouachitta, Rapides, Natchitoches, Opelousas, and Attacapan; and by the census of 1810, its whole population consisted of 76,556 persons. (See ORLEANS and LOUISIANA). Melish's Geographical Description of the United States. Philadelphia. 1816. Morfe's Geography.

To the preceding general account of the United States, the Editor subjoins the pleasing information with which he is furnished by the 13th report of the British and Foreign Bible Society (1817), that 130, or upwards, of such societies have been established in these States, among which are numerous female institutions: and that, in consequence of a convention of delegates from different Bible societies, held in the city of New York, in May 1816, a society was instituted under the name of "The American Bible Society," of which the sole object should be to encourage a wider circulation of the Holy Scriptures, without note or comment. Several of the American societies have received pecuniary aid from the British and Foreign Bible Society.

UNITED STATES' SALINE, a township of the Illinois territory, in the county of Randolph, containing 845 inhabitants.

UNITY, UNITAS, the abstract, or quality, which constitutes, or denominates a thing *unum*, or one.

The school philosophers generally define unity, by a thing's being undivided in itself, and divided from every thing else. Others, more accurately, define it, a mode of being, by which it agrees to any particular being, once: these make two kinds of unity, *viz.* unity of simplicity, which is both undivided and indivisible; such as that of God, angels, and human souls: the other, *union of composition*, which, though undivided, is divisible in the being, as consisting of divers parts; such is that of man, &c.

Hence, unity is also divided into that *per se*, which agrees to any being whose parts are collected into one substratum: and unity *per accidens*, whose parts are not united into one substratum, as that of a flock of sheep, &c.

Some also make a *singular*, or *numerical* unity, and an *universal* unity; a *real*, and an *imaginary* unity, &c.

It is disputed among mathematicians, whether or not unity be a number? The generality of authors hold the negative, and make unity to be only inceptive of number, or the principle of it; as a point is of magnitude, and an union of concord.

Stevinus is very angry with the maintainers of this opinion: and yet, if number be defined a multitude of units joined together, as many authors define it, it is evident that unity is not itself a number.

It is to be observed in algebra, that unity itself has three different expressions of its cube root, one real, and the other two impossible, or imaginary. Thus the three cube roots of 1, are 1, $\frac{-1 + \sqrt{-3}}{2}$, and $\frac{-1 - \sqrt{-3}}{2}$.

This is, sometimes of use in finding the cube roots of quantities, appearing under impossible expressions.

The two impossible expressions of the $\sqrt{-1}$ may be thus found: let $x = 1$, then $x^2 = 1$, or $x^2 - 1 = 0$, and $x - 1 = 0$. Divide $x^2 - 1$ by $x - 1$, the quotient is $x + x + 1 = 0$, or $x + x + x = -1$. Resolve this quadratic equation, by adding $\frac{1}{4}$ to both sides. Then $x + x + \frac{1}{4} = -\frac{3}{4}$, and extracting the square root, $x + \frac{1}{2} = \sqrt{-\frac{3}{4}} = \frac{\sqrt{-3}}{2}$.

Therefore $x = -\frac{1}{2} + \sqrt{-\frac{3}{4}} = \frac{-1 \pm \sqrt{-3}}{2}$. That is,

$x = \frac{-1 + \sqrt{-3}}{2}$, and $x = \frac{-1 - \sqrt{-3}}{2}$. See Mac-

laurin's Algebra, p. 128. 226.

UNITY, among *Divines*. The Romanists, and the reformed, dispute, whether or not the church be one single body, all the members of which are joined together, either really, or in inclination; so that whatever does not appertain to that body, is no part of the church; which is what they call the *unity of the church*; and which the Romanists maintain to be refrained to one single society, or one communion, under one visible head; and out of which the Protestants are excluded. These last, on the contrary, hold, that the unity of the church may still subsist, without the members being united under any one visible head; it being sufficient, that all Christians be united by the bonds of mutual love and charity; and that they be agreed in the fundamental points of religion.

All the difficulty is, to fix what those fundamentals are; some inclining to make the door of the church wider than others. See UNIFORMITY.

UNITY, in *Poetry*. In the drama there are three unities to be observed; the unity of *action*, that of *time*, and that of *place*.

In the epic poem, the great and almost only unity is that of the action. Some regard, indeed, ought to be had to that of time: but that of place there is no room for. The unity of character is not reckoned among the unities.

The unity of the dramatic action consists in the unity of the intrigue in comedy, and that of the danger in tragedy; and this not only in the plan of the fable, but also in the fable extended and filled with episodes.

The episodes are to be worked in, without corrupting the unity, or forming a double action; and the several members are to be so connected together, as to be consistent with that continuity of action so necessary to the body; and which Horace prescribes, when he says, "sit quodvis simplex duntaxat et unum."

The unity of the epic action, M. Dacier observes, does not consist in the unity of the hero, or in the unity of his character and manners; though those be circumstances necessary to it. The *unity of action* requires, that there be but one principal action, of which all the rest are to be incidents, or dependencies.

F. Boffu assigns three things requisite to it: the first, that no episode be used, but what is fetched from the plan and ground of the action, and which is a natural member of that body: the second, that these episodes and members be well connected with each other: the third is, not to finish any episode, so as it may appear a whole action; but to let each be always seen in its quality of member of the body, and an unfinished part.

The same excellent critic examines the *Æneid*, *Iliad*, and *Odyssey*, with respect to these rules, and finds them strictly observed. Indeed, it was from the conduct of those divine poems, that he took the hint of the rules themselves. In-

stances in which these rules are all neglected, he gives us 10 Statius's Thebaid.

To the *unity of time*, it is required, in the drama, that the action be included in the space of a day. Aristotle says expressly, it must not exceed the time the sun employs in making one revolution, which is a natural day, under pain of irregularity: some critics will even have it included in the space of twelve hours, or an artificial day.

Indeed, the ancient tragic poets sometimes dispensed with this rule; and many of the modern English ones disallow it: and very few of them practise it.

In the epic poem, the unity of time is still less established. In effect, there is no fixing the time of its duration; in regard, the warmer and more violent the action is, the less must be its continuance; whence it is, that the *Iliad*, representing the anger of Achilles, only contains forty-seven days at most; whereas the action of the *Odyssey* holds eight years and a half, and that of the *Æneid* almost seven years.

But the length of the poem Aristotle gives us a rule for; which is, that it be such as that it may be read over in one day: pretending, that if it exceeds that compass, the imagination will be bewildered in it, and that one cannot see the end, without having lost the idea of the beginning.

As to the *unity of place and scene*, neither Horace nor Aristotle give us any rules relating to them. It were to be wished, indeed, that what is presented to the audience on the same stage, which is never shifted, might be supposed to have passed in the same house, and the same apartment. But as such a constraint would cramp the poet too much; and as such a uniformity would suit very ill with abundance of subjects; it has been agreed, that what passes any where in the same town or city, shall be allowed for unity of place. At least, if two different places be unavoidable; yet the place is never to be changed in the same act.

Shakspere, it is well known, paid no regard to the unities of time and place. On this subject Dr. Johnson observes, in the preface to his edition of Shakspere's plays, that perhaps a nearer view of the principles on which they stand will diminish their value, and withdraw from them the veneration which, from the time of Corneille, they have very generally received, by discovering that they have given more trouble to the poet than pleasure to the auditor.

As nothing is essential to the fable but unity of action, and as the unities of time and place arise evidently from false assumptions, and by circumscribing the extent of the drama, lessens its variety, Dr. Johnson does not think we need much lament their not being known or not observed by Shakspere.

He adds, as the result of his enquiries, that the unities of time and place are not essential to a just drama; that though they may sometimes conduce to pleasure, they are always to be sacrificed to the nobler beauties of variety and instruction; and that a play written with nice observations of critical rules, is to be contemplated as an elaborate curiosity, as the product of superfluous and ostentatious art, by which is shewn rather what is possible than what is necessary.

He that, without diminution of any other excellence, shall preserve all the unities unbroken, deserves the like applause with the architect, who shall display all the orders of architecture in a citadel, without any deduction from its strength; but the principal beauty of a citadel is to exclude the enemy; and the greatest graces of a play are to copy nature and instruct life.

UNITY of *Possession*, in *Law*, signifies a joint possession of two rights, by several titles.

Thus,

Thus, if I take a lease of land upon a certain rent, and afterwards buy the fee simple; this is an unity of possession, by which the lease is extinguished: by reason I, who before had only the occupation for my rent, am now become lord of the same, and am to pay rent to none but myself.

Unity of possession amounts to the same with what civilians called *consolidation*; which fee.

The unity of a joint estate is fourfold, *viz.* unity of interest, the unity of title, the unity of time, and the unity of possession; or, in other words, joint-tenants have one and the same interest, accruing by one and the same conveyance, commencing at one and the same time, and held by one and the same undivided possession. See Blackf. Com. b. ii.

UNITY of a Sentence, in *Grammar and Rhetoric*. See STYLE.

UNITY of Melody. This is an ingenious idea, which we think merits a place among musical desiderata: it was first suggested and recommended by Rousseau, in his Letter on French Music, 1751, and afterwards enforced in his Musical Dictionary, in the following manner. "There is in all the fine arts some object of unity, or symmetry, the source of intellectual pleasure: for attention divided by two different objects, has no repose; and when two objects occupy us at once, it is a proof that the mind is satisfied with neither. (Baretti used to say that two misfortunes were better than one, because they divided the attention.) There is in music a successive unity with respect to the subject, by which all the parts well combined constitute a whole, whence we perceive the *ensemble* and all its relations.

"But there is another more refined and more simultaneous object of unity, whence there insensibly arises the energy of music and force of its expressions.

"When I hear our palms sung in four parts, I begin to listen with great delight at the full and nervous harmony; and the first chords, when they are perfectly in tune, affect me even to shivering; but before I have listened many minutes to the rest, my attention diminishes, till by degrees I am stunned with the noise; I become indifferent, and, at length, tired with hearing nothing but chords.

"This does not happen when I hear good modern music, though the harmony is not so vigorous; and I remember at the opera in Venice, a beautiful air well executed never tired me, whatever was its length; and if repeated, my attention was renewed, and I heard it with more interest the second time than the first.

"This difference arises from the character of the two musics, of which one is only a succession of chords, and the other a series of single sounds in melody. Now the pleasure which we receive from harmony, is only that of pure sensation, and the enjoyment of the senses is always short. Satiation and fatigue follow each other very closely; but the pleasure from melody, is an interesting pleasure of sentiment which speaks to the heart, and which an artist may always sustain and renew by force of genius.

"Music ought therefore necessarily to sing, in order to interest, please, and support the attention. But in our systems of chords and mere harmony, can music sing, or have any interesting melody? If each part has its own melody, all these melodies heard at once, mutually destroy each other, and annihilate all melody: if all the parts perform the same melody, we shall have no harmony, and the concert will be wholly in unison.

"The manner in which a musical instinct, a certain impulse of genius, has vanquished this difficulty without seeing it, and at the same time turned it to advantage, is very remarkable. Harmony, which, abused, would suffocate me-

lody, animates, enforces, and gives it a character: the different parts, judiciously arranged, concur in producing the same effect, and though each seems to have a melody of its own, from all these parts united, we hear only one and the same melody. This is what I call *unity of melody*.

"Let us now explain how harmony itself, far from injuring, concurs in supporting this unity. Our melodies are characterized by our keys and measures, and our keys are governed by harmony. Whenever the harmony enforces and determines the sentiment of the mode or key and the modulation, it adds to the expression of the melody, provided it does not cover and render it insignificant.

"The composer's art, therefore, after rendering himself a master of harmony and modulation, should be principally pointed to the unity of melody. 1. When the key is not sufficiently determined in the melody, to render it more certain by the harmony. 2. To select and use his chords in such a manner, that the most interesting found should be always in the principal melody, and that its interest should arise from the base. 3. To add to the energy of each passage by harsh chords, if the expression is harsh, and by pleasing chords, if the expression is sweet. 4. To pay attention in the style of the accompaniment to the piano and forte of the melody: and 5. To contrive that the melody of the parts of accompaniment do not counteract the principal, but sustain, second, and give it a more lively and marked accent.

"The unity of melody particularly requires that two melodies equally interesting should not be heard at the same time, but not that the melody should never pass from one part to another. (In the quartets of Haydn, Mozart and Pleyel, there is nothing more amusing to the hearers, or more flattering to the performers, than giving the melody alternately to the different parts, in the way of dialogue.) But a treatise would be necessary to shew in detail the application of this principle to duos, trios, quartets, choruses, and symphonies. Men of genius will discover its extent and use, and their works will instruct others. I therefore conclude by asserting, upon the principle which I have been trying to establish; first, that all music which does not sing is tiresome, in whatever harmony it may be clothed; secondly, that all music in which many different simultaneous parts are distinguished, is bad, and that there results from it the same effect as from two or more people speaking upon different subjects at the same time. From this opinion, which admits of no exception, will be pointed out what we ought to think of those wonderful compositions, where one air serves for an accompaniment to another.

"It is from this principle of the unity of melody, which the Italians have felt and followed without knowing it, but which the French have neither known nor followed; it is, I repeat it, from this grand principle, that the essential difference of the two musics arises; and it is, I believe, what every impartial judge will allow, who shall listen to both with equal attention; if however that is possible."

UNITY, in *Geography*, a town of America, in the district of Maine and county of Kennebeck, containing 793 inhabitants; 60 miles N. of Brunswick.—Also, a town of New Hampshire, in the county of Cheshire, containing 1044 inhabitants: N.E. of Charlestown.—Also, a township of Pennsylvania, in Westmoreland county, containing 2174 inhabitants.—Also, a township of Ohio, in the county of Columbiana, containing 827 inhabitants.

UNITY Bay, a bay on the E. coast of Labrador. N. lat. 57° 8'. W. long. 61° 30'.

UNIVALVE, in *Conchology*, a genus of shells. See CONCHOLOGY and SHELLS.

UNIVERSAL, something that is common to many things; or, it is one thing belonging to many, or all things.

The word, according to some, is compounded of *unum* *versus alia*.

There are universal instruments, for measuring all kinds of distances, as heights, lengths, &c. called also *pantometers* and *holometers*.

An universal dial is that by which the hour may be found by the sun all over the earth; or under any elevation of the pole. See *UNIVERSAL DIAL*.

Several learned authors have had it in view to establish an universal character; by which the different nations might understand each other's writings, without learning their language. See *UNIVERSAL CHARACTER*.

The Romanists are divided among themselves about the title of *universal bishop*, which some of the popes have arrogated to themselves; though others of them have declined it. Baronius holds the appellation to belong to the pope *jure divino*; and yet St. Gregory, opposing the same quality given by a council in 586 to John, patriarch of Constantinople, asserted expressly, that it did not belong to any bishop; and that the bishops of Rome neither could, nor ought to take it. Accordingly, St. Leo refused to accept it, when offered him by the council of Chalcedon; for fear, lest, giving something particular to one bishop, they should take from all the rest; since there could not be an universal bishop, but the authority of the rest must be diminished.

UNIVERSAL, *Universale*, in *Logic*, is either *complex* or *incomplex*. A *complex* universal, is either an universal proposition, as, "Every whole is greater than its parts;" or whatever raises a manifold conception in the mind; as the definition of a reasonable animal.

An *incomplex* universal, is what produces one only conception in the mind, and is a simple thing, respecting many; as human nature, which relates to every individual in which it is found.

Now in an universal, two things are distinguished; the *matter*, called the *material universal*, *universale materiale*, which is the one nature multiplicable into many; as humanity in Peter, Paul, &c.; and the *form*, called the *formal universal*, which is the unity of that nature.

Wherefore, to constitute an universal, it is requisite the nature be one, yet multipliable; but what such a nature is has proved matter of great controversy, both among the ancient and modern philosophers.

The Platonists will have universals to be nothing but divine ideas. By idea, they mean the pattern or form which the artificer has in view when he makes any thing; but as this is twofold; *internal*, which is a sort of image of the thing to be done, which the artificer frames in himself; and *external*, which is something out of himself, which the artificer imitates; the philosophers have been infinitely perplexed to find which of the two Plato meant. The Peripatetics insist he meant the *external*; but the Platonists, and most of the Christian divines, were advocates for the *internal*.

The Peripatetic system of species and phantasms, as well as the Platonic system of ideas, is grounded, says Dr. Reid, in his reasoning against the ideal theory (see *IDEA*), upon this principle, that in every kind of thought, there must be some object that really exists; in every operation of the will, something to work upon. Whether this immediate object be called an idea with Plato, or a phantom or species with Aristotle; whether it be eternal and uncreated, or produced by the impressions of external objects, is, as he thinks, of no consequence in the present argument.

The Stoics and Nominalists maintain this in common with the Platonists, that universals are not in the things themselves, but out of them. The Stoics particularly, for universals, put a kind of formal conceptions, or acts of knowing; by reason they represent many things at the same time; e. g. knowledge, representing all men, is, according to the Stoics, an universal.

The Nominalists make words universals; because the same word represents many things, as the word *man* represents all men; but both Stoics and Nominalists make universals to be something extrinsic to things themselves; alleging that whatever exists, or is produced, is singular; so that there is no universal really in things. See *NOMINALS* and *REALISTS*.

The Peripatetics, however, contend, that there are universal and common natures in things themselves; or that things and natures like each other form a material universal. But as to the manner in which they are universal, or whence they derive their universality, that is, their unity and aptitude of being in many, whether from nature, or from our understanding, is great matter of dispute among them. If they derive that unity in which their universal form is placed from nature, then there is an universal *à parte rei*; which is the opinion of the Scotists.

If they do not derive it from nature, but only from our minds or understandings, then the doctrine of the Thomists is allowed, who contend, that a formal universal has no other existence, but by an act of the intellect.

"As in all the ancient metaphysical systems," says the ingenious professor Dugald Stewart, "it was taken for granted, that every exertion of thought implies the existence of an object distinct from the thinking being; it naturally occurred, as a curious question, What is the immediate object of our attention, when we are engaged in any general speculation? or, in other words, what is the nature of the idea corresponding to a general term?"—"In answer to this question," says the professor, "the Platonists, and, at an earlier period, the Pythagoreans, taught, that although these universal ideas are not copied from any objects perceivable by sense, yet that they have an existence independent of the human mind, and are no more to be confounded with the understanding, of which they are the proper objects, than material things are to be confounded with our powers of external perception; that as all the individuals which compose a genus, must possess something in common; and as it is in consequence of this, that they belong to that genus, and are distinguished by that name, the common thing forms the essence of each; and is the object of the understanding, when we reason concerning the genus. They maintained also, that this common essence, notwithstanding its inseparable union with a multitude of different individuals, is in itself one and indivisible." Our author substitutes the term *essence* for *idea*, as more intelligible to the modern reader, and more suited to convey the true import of Plato's expressions. (See *ESSENCE*.) On most of these points, the philosophy of Aristotle very nearly agreed with that of Plato; though they used different language in developing their respective opinions. Plato, fond of the marvellous and mysterious, maintained the incomprehensible union of the same idea or essence, with a number of individuals, without multiplication or division. Aristotle, aiming at greater perspicuity, contented himself with saying, that all individuals are composed of matter and form; and that in consequence of possessing a common form, different individuals belong to the same genus. "But they both agreed, that, as the matter, or the individual natures of objects were perceived by sense; so the general idea, or essence, or

UNIVERSALS.

or form, was perceived by the intellect; and that, as the attention of the vulgar was chiefly engrossed with the former, so the latter furnished to the philosopher the materials of his speculations.

"The chief difference between the opinions of Plato and Aristotle on the subject of ideas, related to the mode of their existence. That the matter of which all things are made, existed from eternity, was a principle which both admitted; but Plato farther taught, that, of every species of things, there is an idea or form which also existed from eternity; and that this idea is the exemplar or model according to which the individuals of the species were made; whereas Aristotle held, that, although matter may exist without form, yet that forms could not exist without matter.

"The doctrine of the Stoics concerning universals, differed widely from those both of Plato and Aristotle, and seems to have approached to a speculation which is commonly supposed to be of a more recent origin, and which an eminent philosopher of the present age has ranked among the discoveries which do the greatest honour to modern genius." See Hume's Treatise of Human Nature, book i. part i. sect. 7.

Our author's preceding statement of Aristotle's doctrine, as far as it is commonly supposed to differ from that of Plato, is founded on the authority of Brucker, whom we have cited under the appropriate titles; though Harris, in his "Hermes," and the author of the "Origin and Progress of Language," give a different account of the difference subsisting between them.

The opinion which generally prevailed among the Scholastics in the dark ages was, "that universals do not exist before things, nor after things, but in things; that is, universal ideas have not (as Plato thought) an existence separable from individual objects; and, therefore, they could not have existed prior to them in the order of time; nor yet, (according to the doctrine of the Stoics,) are they mere conceptions of the mind, formed in consequence of an examination and comparison of particulars; but these ideas or forms are from eternity united inseparably with that matter of which things consist; or, as the Aristotelians sometimes express themselves, the forms of things are from eternity immersed in matter."

This opinion concerning the nature of universals was generally maintained till the eleventh century, when a new doctrine, borrowed from the school of Zeno, was propounded by Roscelinus, and propagated by Abelard. According to these philosophers, there are no existences in nature corresponding to general terms, and the objects of our attention in all our general speculations, are not ideas, but words. The Scholastics from this time formed themselves into two sects, viz. the Nominalists and Realists: the former attaching itself to the opinions of Roscelinus and Abelard, and the latter to the principles of Aristotle. See NOMINALS and REALISTS.

Our author's opinion coincides with that of the Nominalists; and from his elaborate statement of the process of the mind, in pursuing general speculations, he infers, "that idea, which the ancient philosophers considered as the essence of an individual, is nothing more than the particular quality or qualities in which it resembles other individuals of the same class; and in consequence of which, a generic name is applied to it. It is the possession of this quality, that entitles the individual to the generic appellation; and which, therefore, may be said to be essential to its classification with that particular genus; but as all classifications are to a certain degree arbitrary, it does not necessarily follow, that it

is more essential to its existence as an individual, than various other qualities which we are accustomed to regard as accidental. In other words (if I may borrow the language of modern philosophy), this quality forms its nominal, but not its real essence." See CLASSIFICATION, ABSTRACTION, and GENERALIZATION.

After the death of Abelard, the Realists began to revive; the sect of the Nominalists declined, and in the fourteenth century was almost completely extinct. Their doctrine was equally reprobated by the two great parties which then divided the schools; the followers of Duns Scotus and of Thomas Aquinas. (See SCOTISTS and THOMISTS.) At length, William Occam vindicated the long-abandoned philosophy of Roscelinus. See NOMINALS.

Although the names of the contending parties no longer exist, the subject of controversy between them has at a very late period interested the attention of philosophers. The most distinguished advocates for the doctrine of the Nominalists, since the revival of letters, are Hobbes, Berkeley, and Hume.

"The universality of one name to many things," says Hobbes (Tripos, chap. v. § 6), "hath been the cause that men think the things themselves are universal; and so feverishly contend, that besides Peter and John, and all the rest of the men that are, have been, or shall be, in the world, there is yet something else that we call man, viz. man in general; deceiving themselves, by taking the universal, or general appellation, for the thing it signifieth: for if one should desire the painter to make him the picture of a man, which is as much as to say, of a man in general; he meant no more, but that the painter should chuse what man he pleased to draw, which must needs be some of them that are, or have been, or may be; none of which are universal. But when he would have him to draw the picture of the king, or any particular person, he limiteth the painter to that one person he chuses. It is plain, therefore, that there is nothing universal but names; which are therefore called indefinite, because we limit them not ourselves, but leave them to be applied by the hearer: whereas a singular name is limited and restrained to one of the many things it signifieth; as when we say, this man, pointing to him, or giving him his proper name, or by some such other way."

Berkeley and Hume do not materially differ from one another. "A very natural question," says the latter, (Treatise of Human Nature, book i. part i. § 7.), "has been started concerning abstract or general ideas: Whether they be general or particular in the mind's conception of them? A great philosopher has disputed the received opinion in this particular; and has asserted, that all general ideas are nothing but particular ones annexed to a certain term, which gives them a more extensive signification, and makes them recall, upon occasion, other individuals, which are similar to them. As I look upon this to be one of the greatest and most valuable discoveries that have been made of late years in the republic of letters, I shall here endeavour to confirm it by some arguments, which, I hope, will put it beyond all doubt and controversy."

Leibnitz has also declared himself a partisan of this sect, in a dissertation entitled "De Stilo Philosophico Marii Nizolii." Dr. Campbell, in his "Philosophy of Rhetoric," has founded an interesting speculation on the principles of Berkeley and Hume. See ABSTRACTION.

Attempts have been made, says our author, for reviving the system of the Realists; and he reckons among the ablest of these that of the excellent Dr. Price, to whom he pays a tribute of merited respect. This approved writer employed, he says, his ingenuity in support of some of the

old tenets of the Platonic school, and has even gone so far as to follow Plato's example, in connecting the speculation about universals, with the sublime questions of natural theology. His reasonings, he adds, "in proof of the existence of universals, are the more curious, as he acquiesces in some of Dr. Reid's conclusions with regard to the ideal theory of perception. That there are in the mind images or resemblances of things external, he grants to be impossible; but still he seems to suppose, that in every exertion of thought, there is *something* immediately present to the mind, which is the object of its attention." To this purpose, Dr. Price reasons in the following manner: "The word *idea* is sometimes used to signify the immediate object of the mind in thinking, considered as something in the mind, which represents the real object, but is different from it. This sense of an idea is derived from the notion, that when we think of any external existence, there is something immediately present to the mind, which it contemplates distinct from the object itself, that being at a distance. But what is this? It is bad language to call it an image in the mind of the object. Shall we say then, that there is indeed no such thing? But would not this be the same as to say that, when the mind is employed in viewing and examining any object, which is either not present to it, or does not exist, it is employed in viewing and examining nothing, and therefore does not then think at all? When abstract truth is contemplated, is not the very object itself present to the mind? When millions of intellects contemplate the equality of every angle in a semicircle to a right angle, have they not all the same object in view? Is this object nothing? Or is it only an image or kind of shadow?—These inquiries carry our thoughts high."

To the difficulty suggested by Dr. Price, our author says, "I have no answer to make, but by repeating the fact which I have already endeavoured to establish; that there are only two ways in which we can possibly speculate about classes of objects; the one, by means of a word or generic term; the other, by means of one particular individual of the class which we consider as the representative of the rest; and that these two methods of carrying on our general speculations, are at bottom so much the same, as to authorise us to lay down as a principle, that, without the use of signs, all our thoughts must have related to individuals. When we reason, therefore, concerning classes or genera, the objects of our attention are merely signs; or if, in any instance, the generic word should recall some individual, this circumstance is to be regarded only as the consequence of an accidental association, which has rather a tendency to disturb, than to assist us in our reasoning."

For the opinions of a sect that may be regarded as intermediate between the Nominalists and Realists, we refer to CONCEPTUALISTS. See Stewart's Elements of the Philosophy of the Human Mind. See also *Mental Philosophy*.

UNIVERSAL CAUSE, *Characters, Consumption, Geography, Gravity, Joint, Maps, Palsy, Proposition, Rheumatism, Ring-dial, System, and Theorem*. See the substantives.

UNIVERSALISTS, in *Polemical Divinity*, an appellation given to such as hold an universal grace; in like manner as the denomination Particularists is given to those who hold a particular and efficacious grace.

The Arminians are particularly denominated Universalists.

UNIVERSALISTS, *Hypothetical, in Ecclesiastical History*, an appellation given to those doctors of Saumur, who attempted to reconcile the doctrine of predestination, as it had been taught at Geneva, and confirmed at Dort, with the sentiments of those who represent the Deity as offering the displays of his goodness and mercy to all mankind. The first person who

made this attempt was John Cameron (see CAMERONIANS), whose sentiments were supported, and farther illustrated, by Moses Amyraut, a man of uncommon sagacity and erudition. The latter applied himself, from 1634, with such zeal to this work, that he produced no small changes in the doctrine commonly received among the reformed in France. The form of doctrine which he propounded with this view may be summed up in the following propositions; viz. that God desires the happiness of all men, and that no mortal is excluded, by any divine decree, from the benefits that are procured by the death, sufferings, and gospel of Christ; that, however, no one can be made a partaker of the blessings of the Gospel, and of eternal salvation, unless he believe in Jesus Christ; that such is the immense and universal goodness of the Supreme Being, that he refuses to none the power of believing; though he does not grant unto all his assistance and succour, that they may wisely improve this power to the attainment of everlasting salvation; and that, in consequence of this, multitudes perish through their own fault, and not from any want of goodness in God. Those who embraced this doctrine were called Universalists, because they represented God as willing to shew mercy to all mankind; and hypothetical Universalists, because the condition of faith in Christ was necessary to render them objects of his mercy. Mosh. Eccl. Hist. vol. iv. 8vo.

UNIVERSALITY, the quality that denominates a thing universal.

The Catholics assert the universality of their church, both as to time and persons; and maintain this to be a note or mark of the true church, which distinguishes it from all other societies that pretend to the name.

UNIVERSITY, in the *Schools*. Logicians made two kinds of universality, the one *metaphysical*, the other *moral*.

UNIVERSITY, *Metaphysical*, is that which excepts nothing; as this proposition, "Every man is mortal."

UNIVERSITY, *Moral*, is that which admits of some exception; as, "All old men praise the times past." In such like propositions, it is enough that the thing be ordinarily so; it not being strictly required, that every old man should be of that disposition. See PREDICABLE.

UNIVERSE, a collective name, signifying the assemblage of heaven and earth, with all things in them, called by the Greeks *κοσμος*, and by the Latins *mundus*.

The ancients, and after them the Cartesians, imagine the universe to be infinite. The reason they give is, that it implies a contradiction to suppose it finite or bounded; since it is impossible not to conceive space beyond any limits that can be assigned it; which space, according to the Cartesians, is body, and consequently part of the universe. But that the universe is finite, appears from the two following considerations: 1. That whatever consists of parts cannot be infinite, since the parts that compose it must be finite, either in number or magnitude; which, if they be, what they compose must be too; or, 2. They must be infinite, either in number or magnitude; but an infinite number is a contradiction; and to suppose the parts infinitely big, is to suppose several infinities, one bigger than another; which, though it may pass among mathematicians, who only argue about infinities, *in posse*, or in imagination, will not be allowed in philosophy.

UNIVERSITY, UNIVERSITAS, a collective term, applied to an assemblage of several colleges established in a city, or town, in which are professors in the several sciences, appointed to teach them to students; and where degrees, or certificates of study in the divers faculties, are taken up.

In each university four faculties are usually taught; theology, medicine, law, and the arts and sciences.

They are called *universities*, or *universal schools*, because the four faculties are supposed to make the grand world, or whole compass of study; or rather, because they form one whole out of many individuals.

In the eye of the law, an university is held a mere lay body, or community; though, in reality, it be a mixed body, composed partly of laymen, and partly of ecclesiastics. See CORPORATION.

The definition of the term *universitas*, by foreign civilians, answers nearly to our common law term of body politic or corporate; and such towns as had this appellation in Germany, &c. might hold lands and rents in common, and do all other acts as one aggregate body. And in this sense, the word *universitas* came to be applied to such academies for learning as were incorporated, which archbishop Usher thinks began about the year 1250.

Universities had their first rise in the twelfth and thirteenth centuries. Those of Paris and Bologna pretend to be the first that were set on foot; but then they were on a very different footing from the universities among us.

The university of Paris is said to have commenced under Charlemagne, and to owe its rise to four Englishmen, disciples of Venerable Bede, who, going to that city, made a proposal to set up and sell learning, and accordingly held their first lectures in places assigned them by that prince: such is the account given by Gaguin, Gilles, De Bauvais, &c. Though the authors who wrote in those days, as Eginhard, Aimon, Reginon, Sigebert, &c. make not the least mention of this memorable fact.

Add, that Pasquier, Du Tillet, &c. declare openly against the opinion; and assert, that the first foundations were not laid till the time of Lewis the Young, and Philip Auguste, in the twelfth century. The earliest mention we find made of the university of Paris, is in Regordus, who lived in that age, and who was contemporary with Peter Lombard, the master of the sentences, the great glory of that university; in memory of whom an anniversary has been long observed by that body in the church of St. Marcel, where he lies buried.

But it is certain it was not established all at once; it appears to have been at first no other than a public school in the cathedral church; from which it grew, by little and little, under the favour and protection of the kings, into a regular body.

Our own universities, Oxford and Cambridge, seem intitled to the greatest antiquity of any in the world; and University, Balol, and Merton colleges in Oxford, and Peter's in Cambridge, all made colleges in the thirteenth century, may be said to be the first regular endowments of this kind in Europe.

For though University college in Oxford had been a place for students ever since the year 872, yet this, like many of the other ancient colleges beyond sea, and Leyden to this day, was no proper college; but the students, without any distinction of habits, lived in citizen's houses, having only meeting-places to hear lectures, and to dispute.

In after-times, there were houses built for the students to live in society; only each to be at his own charge, as in the inns of court. These, at first, were called *inns*, but now *halls*.

At last plentiful revenues were settled on several of these halls, to maintain the students in diet, apparel, &c. and these were then called *colleges*.

The universities of Oxford and Cambridge are governed, next under the king, by a chancellor, who is to take care of the government of the whole university, to maintain its liberties, &c.

Under the chancellor is the high-steward, whose office is to assist the chancellor, and other officers, when required, in the execution of their offices, and to hear and determine capital causes, according to the laws of the land, and the privileges of the university. See *UNIVERSITY COURT*.

The next officer is the vice-chancellor, who officiates for the chancellor in his absence.

In the university of Oxford there are four pro-vice-chancellors: in the university of Cambridge, the vice-chancellor, and five others, constitute the *caput*, which every university graces mult pabs before it can be introduced into the senate.

There are also two professors, who assist in the government of the university, particularly in the business of school-exercise, the taking up degrees, punishing violators of the statutes, &c.

In the university of Cambridge there are also two moderators, two scrutators, and two taxors. In this university there are nineteen professors, besides lady Margaret's preacher: in that of Oxford there are twenty-one professors, including the readers in anatomy and chemistry. Add to these a public orator, keeper of records, librarians, register, esquire and yeoman beadles, clerk, and vergers. See COLLEGE. See also CAMBRIDGE and OXFORD.

For the degrees taken up in each faculty, with the exercises, &c. requisite to them, see DEGREE.

The universities of Scotland are four, *viz.* that of St. Andrew's, that of Glasgow, that of Aberdeen, and that of Edinburgh. See each place respectively, and also SCOTLAND.

In noticing the different European universities, under the names of the respective cities and towns in which they are established, we have detailed the histories and prominent events of each. Under the present head it was our intention to have inquired into the progressive and present state of classical learning and science, as these have been ostensibly influenced by the universities; and at the time of writing the account of Oxford, for a previous volume, it was our wish to have investigated, with caution and candour, the state of discipline and tuition of the most eminent universities of Europe. The subject is certainly of interest and importance; and it is rather singular, that in the vast range of literary inquiry and disquisition which characterizes the present age, we have not a work devoted to a comparative view and impartial elucidation of the practical systems of the national schools. For some centuries past these have been regarded as essential to complete the studies of the scholar and gentleman: to these nearly all the national establishments, and even the legislative assemblies, have looked with respect bordering on reverence. Laws have conferred on them many important dignities, privileges, and immunities; their riches and influence have progressively increased; and their powers of directing the minds and talents of their respective pupils, and consequently the countries in which they are placed, are of the highest responsibility. To elucidate these facts with any degree of satisfaction, would occupy a large volume. We must despair of effecting it in a work like the present, and therefore content ourselves with a few remarks and references. By examining the constitutions of the British universities, and the statutes of the different colleges, we shall observe that a laudable and liberal spirit actuated the original founders; and we shall also readily perceive that they have produced great and good effects on the morals and literature of the country. But it will also appear, that many of their ordinances and laws, having been adapted to an age and state of society very different from the present, are now become either obsolete, useless, or, what is much worse, injurious. These should be remodelled: for as the natural tendency of mankind is to advance in know-

ledge, it should be the practice of organized learned bodies to direct the youthful mind in the best and readiest way to learning; to point out the path that should be pursued, rather than follow in a beaten track. An university has been long regarded as the fountain of science and literature, and hence it becomes an imperious duty of its guardians to preserve its streams fresh and pure.

Within the last half century many great revolutions and changes have been produced in the civilized world. Empires, kingdoms, and subordinate states, have been created and have fallen; have been dismembered, torn asunder, overrun with armies, and, in various degrees, affected by political causes. Universities and academies must have been materially influenced by these events: and hence it is not the least difficulty of the historian to ascertain their recent and present states. In some of the cities on the continent they have been entirely altered. Their old foundations have been either abrogated, or remodelled on a new and broader basis. The revolution of France was not merely political, but it produced extensive effects on the old establishments in arts, science, and literature. Many pamphlets and essays were, soon after that event, published on the latter subjects: some vindicating and recommending the old systems, others urging the necessity of modifications, and others contending for the adoption of entirely new establishments. These controversies produced the "National Institute," the constitution and novelties of which have excited much general attention, and produced great changes in the discipline of public schools. (See PARIS, *Literary Institutions*.) Other universities on the continent have been roused by the shock of that revolution, and have endeavoured to adapt their routine of studies, and the subjects of them, to the demands of the age. "All the north of Germany," observes baroness Stael, in her recent work on Germany, "is filled with the most learned universities in Europe. In no country, not even in England, have the people so many means of instructing themselves, and bringing their faculties to perfection. Intellectual education is perfect in Germany; but every thing passes into theory: practical education depends solely on things actually existing: it is by action alone that the character acquires that firmness which is necessary to direct the conduct of life. The German universities possess an ancient reputation, of a date several ages antecedent to the Reformation. Since that epoch the Protestant universities have been incontestibly superior to the Catholic, and the literary glory of Germany depends altogether upon these institutions. A sketch of these is presented in a work just published by M. de Villers, an author who is always found at the head of all noble and generous opinions. The English universities have singularly contributed to diffuse among the people of England that knowledge of ancient languages and literature which gives to their orators and statesmen an information so liberal and so brilliant. It is a mark of good taste to be acquainted with other things besides matters of business, when one is thoroughly acquainted with them; and, besides, the eloquence of free nations attaches itself to the history of the Greeks and Romans, as to that of ancient fellow-countrymen. But the German universities, although founded on principles analogous to those of Oxford and Cambridge, yet differ from them in many respects: the multitude of students assembled together in Gottingen, Halle, Jena, &c. formed a kind of free body in the state: the rich and poor scholars were distinguished from each other only by personal merit; and the strangers, who repaired from all parts of the world, submitted themselves with pleasure to an equality which natural superiority alone could disturb."

Although there are no universities in Belgium, yet the college of Ghent is instituted for the same purpose, and calculated to produce very beneficial effects. Its plan of education, and general regulations, are worthy of imitation. The functionaries consist of a regent, two sub-regents, and six professors in Greek and Latin poetry, and in rhetoric; besides six other professors in French, English, German, drawing, and mathematics. These have not only the charge of educating the pupils, but of watching their morals and manners. They are required to make monthly reports to the mayor, and to the parents of the respective children. See a full and interesting account of this seminary in Mitchell's "Tour through Belgium," &c. 8vo. 1816; in which work is also contained, a review of the system of education in the college of Brussels, the central schools of France, the university of Leyden, and the university of Utrecht.

In Great Britain, some useful and essential improvements have been adopted in the present century: but they do not appear to have been produced so much from rivalry with foreign schools, as by the general emulation excited by metropolitan and provincial institutions. Within the last twenty years, London has presented nearly all the advantages, without any of the fetters, of established universities; for in this vast city, many literary and scientific institutions have been formed, and many courses of lectures delivered, all calculated to improve the rising generation. (See LONDON, *Literary Institutions*; LIVERPOOL, and MANCHESTER.) Hence the emulous mind has exhausted sources of learning: and hence a new era has been created in the annals of England.

In no one subject, perhaps, is the advantage of a free press more apparent than in that now under consideration. But for this, many useful plans would never have been carried into effect; many errors of the dark ages would have continued and increased; many establishments would have descended in utility, whilst they ascended in wealth and power. Public discussion on these subjects occasions a minute investigation into the principles and practices of old establishments; places them in a state of comparison with new; and causes a deliberate enquiry into the utility and practicability of new theories, before they have gone through the routine of experience. Many authors have thus been induced to publish their opinions and animadversions on the discipline and practices of the old universities of England; and these have produced useful effects. Still, however, some of the writers contend that the old establishments do not sufficiently attend to the demands and improvements of the age; but that they persist in studies which are useless and obsolete, to the neglect of those which are necessary, and which are calculated to be practically useful. Gibbon, in his "Life and Opinions," says, "The schools of Oxford and Cambridge were founded in a dark age of false and barbarous science; and they are still tainted with the vices of their origin. Their primitive discipline was adapted to the education of priests and monks; and the government still remains in the hands of the clergy, an order of men whose manners are remote from the present world, and whose eyes are dazzled by the light of philosophy." The same learned and eloquent writer enters into a disquisition on the prejudices, errors, and wrong discipline of these schools.

Dr. Knox also, in his "Moral and Literary Essays," the Edinburgh Review, vol. xvi. and other writers, have published their opinions on the same subject. In reply to which, and in vindication of the present practice, Mr. Copplestone of Oxford published a pamphlet in 1810. Other members of the respective universities have also come forward in defence of their schools: and hence the subject is brought

brought before the public tribunal, the ultimate decision of which is generally just and found. See also Monthly Review, vol. lxxviii. p. 277. The Oxford and Cambridge University Calendars, for 1816 and 1817. Chalmers's Account of the Colleges and Halls of Oxford, 2 vols. 8vo. Dyer's History of the University and Colleges of Cambridge, 2 vols. 8vo.

The chief foreign universities are those of Abo, in Finland, frequented by students from Russia, and, in number, equalling that of Upsal; of Austria, at Vienna, founded in 1237, and improved since 1752; at Prague, founded in 1347; at Inspruck, dated from 1677; and at Gratz, from 1585; of Benares, in Hindoostan; of Buda, in Hungary; and of Calcutta, established by the marquis of Wellesley, the plan of which is extensive and liberal. Besides Hindoo, Mahomedan, and English law, and the local regulations, it was designed to have professors of civil jurisprudence, political economy, geography, history, &c. The languages to be taught were Arabic, Persian, Sanscrit, Hindoostannee, Bengal, Telinga, Maratta, Tamula, and Canara. But this institution has declined. We may mention also the universities of Coimbra in Portugal, of Copenhagen, of Debritzin, and of Erlau. France formerly boasted of twenty-one universities; viz. in the North Douay, Caen, Paris, Rheims, Nancy, Strasbourg; in the middle provinces, Nantes, Angers, Poitiers, Orleans, Bourges, Dijon, Befançon; and in the south, Bourdeaux, Pau, Perpignan, Toulouse, Montpellier, Aix, Orange, and Valence. Of these, the Sorbonne of Paris was the most celebrated, though somewhat degraded by its tendency to prolong the reign of scholastic theology. The university of Georgia, in America, founded at Louisville in 1801, though Dr. Morse says it had its charter in 1785, and possessing funds to the amount of 50,000 acres of land. The university of Gottingen, in Hanover, was founded by George II. in 1734, solemnly opened in 1737, and has acquired considerable celebrity. Harvard university, in Cambridge, Massachusetts, founded in 1638, is the most ancient literary establishment in North America. The universities of Holland are those of Leyden, formerly much celebrated and frequented, but somewhat declined, on account of certain commercial regulations; of Utrecht, of Harderwyck, of Franche, and Groningen. Ingolstadt has an university, and so has Kiel, in Denmark. The university of St. Mark, in Lima, was founded in 1576, and is conducted on the plan of the Spanish universities. The university of Lunden, in Sweden, accommodates about 300 students. The universities of Hesse, in Germany, are those of Marburg and Rindeln, and that of Giessen, belonging to Hesse-Darmstadt. In Mexico an university was founded in 1551, and it is styled royal and pontifical; and the cloister is composed of 251 doctors, of all sorts of faculties. Its library was collected about forty years ago, and consists of many old books of divinity, but few modern publications. The universities of the Netherlands were formerly numerous, considering the extent of the country. Exclusive of Tournay (Dornick), which has been long subject to the French, there were others at Douay and St. Omer, much frequented by the English Catholics; and one of still greater celebrity at Louvain, founded in 1425. Their illustrious professors, though celebrated by Guicciardini, nephew of the great historian, have been long since forgotten. The universities of Parma and Placentia need only be mentioned. The university of Pavia is in high reputation, and is regarded as the first in Italy. Its professors have distinguished themselves in natural history. The university of Pennsylvania was founded at Philadelphia during the war,

VOL. XXXVII.

and having been since united with the college, is become a respectable seat of learning. Rostock, in the duchy of Mecklenburg, has an university. In Portugal, besides the university of Coimbra already mentioned, there is that of Evora, founded in 1553. Prussia has several universities, that of Frankfort on the Oder, founded in 1516, and that of Konigsberg, in 1544. Of the Polish universities, Cracow, founded in 1364, has fallen to Austria; and Wilna, founded in 1570, to Russia. Pofna or Posen has become subject to Prussia. The university of Peterburgh was founded by the late empress Catharine II. The universities of Spain are computed at upwards of 20; but the most noted is that of Salamanca, founded in 1200. The universities of Sweden are those of Upsal, Lunden, and Abo. The university of Tubingen on the Neckar was founded in 1477; that of Turin was founded in 1405; that of Vienna has been already mentioned. In the province of Yemen, in Arabia, there are two universities or celebrated academics, one at Zebid, for the Sunnis, and another at Damar, for the Zeidites.

UNIVERSITY Courts. See *UNIVERSITY COURT*, and *UNIVERSITY*, supra.

UNIUM, the *Odiel*, in *Ancient Geography*, a river of Hispania, in Bœtica, which united with the Luxia.

UNIVOCAL, in the *Schools*, is applied to two or more names, or terms, that have but one signification: in opposition to *equivocal*, which is, where one term has two or more significations.

Or, univocal terms are such whose name, as well as nature, is the same; in opposition to *equivocals*, whose names are the same, but their natures very different.

For a thing to be predicated univocally of any others, it is to be attributed to all of them alike, and in the same proper sense. See *PREDICATE* and *PREDICABLE*.

UNIVOCAL Generation. The doctrine of the ancients, with respect to propagation, was, that all perfect animals were produced by univocal generation, that is, by the sole union, or copulation, of a male and female of the same species, or denomination; and that insects were produced by equivocal generation, without any seed, and merely of the corruption of the earth exalted, and, as it were, impregnated by the sun's rays; but this is wholly erroneous.

Some philosophers make a kind of intermediate generation between equivocal and univocal, which they call *analogous generation*. See *GENERATION*.

UNIVOCAL Action. See *ACTION*.

UNIVOCAL Cause. See *CAUSE*.

UNIVOCALS, called by the Greeks *synonyma*, are defined by Aristotle to be those things whose name is common, and also the reason corresponding to the name; that is, the definition of the idea affixed to it the same.

Thus, under the name and definition of *animal*, man and brute are equally included; and circle and square, in the reason or definition of a *figure*.

Here, the word, as *figure*, they use to call *univocum univocans*, or *univocating univocal*; and the things included under the univocal name, as circle and square, *univoca univocata*, *univocated univocals*.

UNIVOCATION, in *Logic* and *Metaphysics*. The schoolmen have long disputed about the univocation of being, *i. e.* whether the general idea of *being* agree in the same manner, and in the same sense, to the substance, and the accident, to God and the creature?

UNIVOCQUE, Fr., in *Musick*. Univocal concords are the octave, and its recurrences or repetitions above or below, as they never change their name or effect. Ptolemy was the first who gave them this appellation.

UNKA, in *Geography*, a town of Sweden, in the province of Smaland; 85 miles N. of Calmar.

UNKEI-TENKY, a town of Hindoostan, in Baglana; 7 miles N.E. of Chandor.

UNKEL. See UNKREL.

UNKENACH, a town of Austria; 6 miles W. of Schwanastatt.

UNLACING, in *Sea Language*, the act of loosening and taking off the bonnet of a sail from its principal part.

UNLAWFUL, ILLEGAL, something prohibited by, or contrary to the terms of a law, either divine or human.

UNLAWFUL *Assembly*, the meeting of three or more persons together, by force to commit some unlawful act; as, to assault any person, to enter his house, or land, &c. and thus abiding together, whether they attempt the execution or not. See REBELLIOUS *Assembly*, RIOT, and ROUT.

By the stat. 16 Car. II. if five persons, or more, shall be assembled together, above those of the family, at any conventicle, or meeting, under colour of any exercise of religion, it is unlawful, and punishable by fines, and otherwise, as in that statute is provided. See CONVENTICLE.

UNLIKE *Quantities and Signs*, in *Algebra*. See LIKE *Signs and Quantities*.

UNLIMITED, or *Indeterminate Problem*, is such a one as is capable of infinite solutions. As, to divide a triangle given into two equal parts; to make a circle pass through two points assigned, &c. See DIOPHANTINE and INDETERMINATE.

UNLUTING, in *Chemistry*, the taking away of the lute, loam, or clay, with which a vessel was before closed, joined to another, or covered.

UNMOOR, *To*, in *Sea Language*, is to reduce a ship to the state of riding by a single anchor and cable, after she has been moored or fastened by two or more cables.

UNNA, in *Geography*, a river which rises in Bosnia, on the borders of Croatia; 28 miles S. of Bihacs, and runs into the Save, 16 miles N.W. of Gradisca.—Also, a town of Germany, in the county of Mark. This place is in rank the second town of the county, and lies in a fine plain, on a rivulet named the Kottelbecke. It has a Lutheran parish-church, and a hospital church, which the Calvinists use for their worship, but in which also on Saturdays worship is performed by a Lutheran preacher; as also a nunnery, together with a chapel, and a Lutheran school. This town is possessed of a very extensive and profitable territory. Formerly it constituted one of the Hanse towns. So early as the year 1032, Unna was a considerable village, and, together with its extent of territory, belonged to the archbishop of Cologne. In the year 1250, it was environed with walls, and endowed with the immunities of a town; 23 miles S. of Munster. N. lat. 51° 33'. E. long. 7° 48'.

UNNAP-POUPPY, a town of Meckley; 75 miles S.S.E. of Munnypour.

UNNARY, a town of Sweden, in the province of Smaland; 43 miles W. of Wexio.

UNONA, in *Botany*, a name evidently contrived to preserve an analogy with *Annona*, to which the genus which bears it is nearly related. Perhaps Linnæus had in view the union of the stamens with the germen, in the formation of this name.—Linn. Suppl. 44. Schreb. Gen. 375, 834. Willd. Sp. Pl. v. 2. 1271. Mart. Mill. Dict. v. 4. Juss. 283.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Coadunata*, Linn. *Annonæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three small, acute, close-pressed leaves. *Cor.* Petals six, lanceolate, sessile, gibbous at the base externally, and concave at the same part

within. *Stam.* Filaments none; anthers unnumbered, oblong, collected into a dense ball, within the hollow of the base of the corolla. *Pist.* Germens several, closely covered by the anthers; styles about ten, bristle-shaped, crowded, rather longer than the anthers; stigmas . . . *Peric.* Berries several, stalked, ovate, gibbous, composing a spreading umbel. *Seeds* two, one above the other, ovate, very smooth, abrupt at the base.

Eff. Ch. Calyx three-leaved. Petals six. Berries several, stalked, each with two seeds.

Obf. Linnæus suggests that this genus ought to be referred to *Gynandria*, and he has led the writer of the present article into the same mistake, concerning *Nymphaea*, in Prodr. Fl. Græc. v. 1. 360, corrected in v. 2. 359, of the same work. We are now convinced, that no genus can be safely termed gynandrous, except the stamens are inserted into the pistil above the germen. *Unona* is closely connected in character and habit with *Uvaria*, and perhaps ought to be united therewith. Willdenow has referred hither two species of *Desmos* of Loureiro, and *Uvaria seyalnica* of Aublet; but having no original information relative to these three plants, we prefer retaining the Linnæan *Unona* by itself.

1. *U. difcreta*. Linn. Suppl. 270.—Gathered by Dahlberg in Surinam, where it is called *Peyricboom*. This is a tree with slender, flexible, round, alternate branches, clothed when young with rusty down. Leaves alternate, willow-like, on short stalks, lanceolate, two inches long, taper-pointed, bluntish, entire; smooth above; beautifully silky beneath. Flowers axillary, solitary, on short stalks. Petals externally silky. Fruit the size of a large pea. In a dried state it seems rather a capsule than a berry.

UN POCO, in *Italian Music*, a little; as, *un poco piu allegro*, a little quicker; *un poco piu largo*, a little slower.

UNQUES PRIST, *Always ready*. See UNCORE *Priest*.

UNRECLAIMED HAWK, one that is untamed.

UNREEVING a Rope. See REEVING.

UNREST, in *Geography*. See ONRUST.

UNRIGGING of a Ship, is the taking away of the standing and running rigging.

UNSEELING, in *Falconry*, a taking away of the thread that runs through the hawk's eye-lids, and hinders her sight. See HAWK.

Drawing the strings of the hood, to be in readiness to pull off, is called *unstriking the hood*.

UNSER FRAU, in *Geography*, a town of Austria; 1 mile N. of Weitra.

UNS FRAU NAZARETH, a town of the duchy of Stiria; 10 miles S.W. of Windisch Gratz.

UNS FRAU WEISTEN, a town of the duchy of Stiria; 11 miles W. of Marburg.

UNST, is the most northern of the Shetland isles, and the most northern territory of the British empire, being situated in the latitude of 61°. Its form is of an irregular oblong square, extending in length about ten miles, and in breadth from two to four. In comparison with the other Shetland isles, Unst may be considered level, yet its surface is diversified by several extensive ridges of hills; the most remarkable are, Vallafeld, which rises to the height of 600 feet, and Saxaforth, elevated 700 feet above the level of the sea. The island is not intersected by rivers, but contains several fresh-water lakes; Loch Cliff, the largest, is two miles long, and about half a mile in breadth. The seashores are remarkably indented with bays and creeks, having many small islands and pasture holmes scattered around. Along the coast are several natural caves, of considerable extent;

extent; one of which, under a promontory of the hill of Saxaforth, penetrates at least 300 feet under ground. In general, the soil is tolerably fertile, even under the worst modes of culture; and the pasture-grounds are mostly covered with a short tender heath, which affords excellent feeding for sheep, of which about 7000 are kept here, with about 2000 cows, and 1000 horses. Hogs are also fed in great numbers; and rabbits are very abundant. Fishing is an important branch of the industry of the inhabitants, and about eighty tons of cured fish are annually exported. Unst abounds in iron-stone, and possesses many large veins of Jasper: rock-crystals have sometimes been found, and free-stone is abundant. The parish-church, which was built in 1764, stands at a place called Balcafa, at the distance of three miles from the minister's residence. Formerly there were twenty-four chapels on the island, the remains of which may still be distinctly traced. Unst constitutes a parish of itself; and according to the return of the year 1811, contains a population of 2288, occupying 385 houses. Here is no post-office; the only office in Shetland is forty miles distant from hence: so that, from its remote situation, and its little intercourse, especially during winter, with the mother country, the inhabitants of Unst are frequently strangers, for many weeks, to the greatest national occurrences. In this island, the longest day is nineteen hours fifteen minutes, and consequently, the shortest day is four hours forty-five minutes.—Beauties of Scotland, vol. v. Shetland, 1808. Gazetteer of Scotland, 1806. Carlisle's Topographical Dictionary of Scotland, 1813.

UNSTRUT, a river which rises four miles W. of Dingelstadt, in the territory of Eichsfeld, and joins the Saal, about two miles N. of Naumburg.

UNSUMMED, a term used by falconers for a hawk's feathers before they have arrived at their full length.

UNTERART, or **ART**, in *Geography*, a town of Switzerland, in the canton of Schwitz, at the southern extremity of the lake of Zug; 7 miles N. of Schwitz.

UNTERBERG, a town of Saxony, in the Vogtland; 1 mile S. of Plauen.

UNTERMDORFF, a town of Austria; 6 miles N. of Aggsbach.

UNTERSEE, a lake in the duchy of Carinthia; 10 miles W. of Velach.

UNTERSEEN, a town of the duchy of Holstein; 5 miles N.W. of Pinnenberg.—Also, a town of Switzerland, in the canton of Berne, purchased of the counts of Hohenzollern. This town is situated between the lakes of Brienz and Thun; 26 miles S.E. of Berne.

UNTOORAH, a town of Hindoostan, in Goondwana; 60 miles W. of Nagpore.

UNTZINA, a town of Wallachia; 30 miles N.E. of Bucharest.

UNUCA, in *Ancient Geography*, a town of Africa Propria, upon the route from Carthage to Cæsarea, between Carthage and Sicilibræ. Antou. Itin.

UNUNGE, in *Geography*, a town of Sweden, in the province of Upland; 28 miles E. of Upfal.

UNXIA, in *Botany*, from *ungo*, *unxi*, to *ainoit*, because of its fave-like odour, and its external, as well as internal, use as a sudorific.—Linn. Suppl. Schreb. Gen. 554. Willd. Sp. Pl. v. 3. 2339. Mart. Mill. Dict. v. 4. Juss. 186. Lamarck Illust. t. 699. Gært. v. 2. 421.—Class and order, *Syngenesia Polygamia-necessaria*. Nat. Ord. *Compositæ oppositifoliæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* roundish, of five ovate, nearly equal, concave leaves, in a simple row. *Cor.* compound, radiated; florets of the disk five, or more, male, funnel-

shaped, in five equal segments; those of the radius five, or more, female, small, lanceolate. *Stam.* Filaments, in the florets of the disk, five, capillary; anthers united into a pentagonal tube, rather longer than the corolla. *Pist.* in the same florets imperfect; in those of the radius, German ovate; style simple; stigma cloven. *Peric.* none, except the permanent calyx. *Seeds* in the circumference only, ovate, abrupt, hard, without any feed-down, or crown. *Recept.* naked, flat.

Eff. Ch. *Receptacle* naked, flat. *Seed-down* none. *Calyx* of five leaves, simple.

Obs. Schreber was led by the disagreement between the description of this genus, and the place allotted to it by Linnæus in his system, to make some corrections, without seeing the plant. The above, taken from the original specimen, will be found nearer the truth. *Unxia*, in fact, belongs, as truly as *Calendula*, to the order of *Polygamia-necessaria*, the florets of the disk having no more of a germin than is necessary to serve as a partial stalk.

1. *U. camphorata*. Camphorated Balm-weed. Linn. Suppl. 368. Willd. n. 1.—Leaves lanceolate. Young branches downy.—Gathered by Dahlberg, in sandy situations in Surinam, where it goes by the name of *Camphor-plant*, being remarkable for a strong camphor-like smell. A watery decoction of this herb, taken internally, is esteemed an excellent and powerful sudorific, in the obstinate lumbago which prevails at Surinam. The dry plant, applied outwardly, is supposed useful in restoring perspiration. The root is probably annual. *Stem* herbaceous, two feet high, round, slender, striated, forked; the young branches shaggy, with soft hairs. *Leaves* opposite at each fork of the stem, sessile, lanceolate, an inch and a half long, sparingly toothed, five-ribbed, clothed on both sides with soft hoary hairs. *Flowers* from the forks of the stem, mostly solitary, on hairy stalks of various lengths. *Calyx* the size of a pea, nearly smooth. *Corolla* yellow. *Seeds* tumid, angular, half the length of the calyx, of a pale grey. Lamarck's figure is the only one extant of this genus, and is sufficiently expressive of the original species here described. With the following we are unacquainted.

2. *U. bisulca*. Hairy Balm-weed. Richard Aftes de la Soc. d'Hist. Nat. de Paris, v. 1. 112. (not 105.) Willd. n. 2.—“Leaves oblong, somewhat heart-shaped, hairy. Stem villous.”—Native of Cayenne. This is found to be extremely hairy in every part. *Leaves* bluntish, somewhat ovate. *Florets* numerous. *Root* annual.

The habit and characters of *Unxia* approach *Eclipta*; see that article.

UNZA, in *Geography*, a town of Russia, in the government of Koltrom; and capital of a province on a river of the same name; 92 miles E.N.E. of Koltrom. N. lat. 57° 56'. E. long. 44° 14'.—Also, a province of Russia, forming a part, and the largest part, of the government of Koltrom, 160 miles in length, and from 80 to 112 in breadth; bounded on the north by the government of Vologda, on the east by the government of Viatka, on the south by the government of Nizgorod, and on the west by the province of Koltrom.—Also, a river of Russia, which runs into the Volga, near Jurev Povolskoi, in the government of Koltrom.

VOAM-TCHIM HOTUN, a town of Corea; 642 miles E.N.E. of Peking. N. lat. 43° 3'. E. long. 129° 44'.

VOAN-TSUNENFA, a city of China, of the second rank, in Pe-tche-li; 22 miles N.N.W. of Suen-hoa.

VOARCHADUMIA, a kind of cabala, or enigmatic art relative to metals, which professes the exaltation of gold

by cementations, and other methods; among which, charms made of the Hebrew letters have their place.

VOBARNO, in *Geography*, a town of Italy, in the department of the Benaco; 5 miles N.W. of Salo.

VOBERGA, or **VOBISCA**, in *Ancient Geography*, a town of Hispania Citerior, in a hunting country, according to Martial, l. i. epig. 52. v. 14.

“Præstabit illie ipsa fingendas prope,
Vobisca pranditi feras.”

VOBERNA, or **VOBERNUM**, a town of Gallia Transpadana, upon the banks of the river Clusius (the Chiefa).

VOBRIX, a town of Africa, in the interior of Mauritania Tingitana; now said to be Lempta, in the kingdom of Fez, with considerable ruins.

VOCA, a town of Hispania Citerior, belonging to the Callæici Lucenses. Ptolemy.

Voca, in *Ichthyology*, a name given by Gaza, and some other writers, to the fish called *boops* by the generality of writers. It is a species of the *spari*, and is distinguished from the rest by having four longitudinal parallel lines of a bright yellow and white colour, resembling gold and silver, on its sides.

VOCABULARY, **VOCABULARIUM**, formed of *vocabulum*, *vord*, in *Grammar*, denotes the collection of the words of a language, with their significations; otherwise called a *dictionary*, *lexicon*, or *nomenclature*.

The vocabulary is, properly, a less kind of dictionary, which does not enter so minutely into the origins, and different acceptations of words. Though the Italian vocabulary of the Academy de la Crusca seems to be an exception from this distinction, as being a copious and exact work, in three volumes folio, said to have been forty years in compiling. And the like holds of the *Vocabulario* Portuguez of F. Bluteau, in ten volumes folio: in the titles of both these books the word is used in a larger sense.

VOCAL, something that relates to the voice or speech. Thus, *vocal prayer* is that which is spoken out, or delivered in words, in contradistinction to *mental prayer*.

In our ancient customs, *vocalis* is frequently used for *so called*: “post hæc Merغانus de tribu Walensium, &c. alter nomine Madocus vocalis princeps eorum.” Matt. Paris.

VOCAL is sometimes also used substantively, in speaking of matters of election, to signify a person who has a right to vote. Thus the Romanists say, a man must have been a religious a certain number of years to be vocal.

VOCAL Music, is music set to words, especially verses, and to be performed with the voice: in contradistinction to *instrumental music*, composed only for instruments, without singing.

Poetry then makes a necessary part of vocal music; and this appears to have been the chief, if not the only practice of the ancients, from the definitions which they give us of music.

Their vocal music seems to have had some advantage over ours, in that the Greek and Latin languages were better contrived to please the ear than the modern ones. In effect, Vossius taxes all the later languages as unfit for music; and says, “We shall never have any good vocal music till our poets learn to make verses on the model of the ancients;” i. e. till the ancient metrical feet and quantities are restored.

But it is to be observed, that the rhythmus of their vocal music was only that of their poetry, and had no other forms and mutations than what the metrical art afforded.

Their changes were no other than from one kind of me-

trum or verse to another, as from iambic to choric. See **MEASURE** and **RHYTHMUS**.

Their vocal music, then, consisted of verses set to musical tunes, and sung by one or more voices, in chorus, or alternately; sometimes with, and sometimes without the accompaniments of instruments.

As for instrumental music, in the manner we have defined it, it is not very clear that they ever had any. See **SYNAULIA**, &c.

VOCANUS AGER, in *Ancient Geography*, a territory of Africa Propria, in the vicinity of the town of Acholla, and of that of Thapfus. Livy.

VOCATES, a people of Gallia Aquitania, of the number of those who were subjugated by Crassus, according to Cæsar.

VOCATION, **CALLING**, among *Divines*, the grace or favour which God does any one in calling him out of the way of death, and putting him into the way of salvation.

In this sense we say, the *vocation of the Jews*, the *vocation of the Gentiles*, &c. There are two kinds of vocation, the one *external*, the other *internal*. The first consists in a simple and naked proposing of objects to the will; the second is that which renders the first effectual, by disposing our faculties to receive those objects.

VOCATION is also used for a destination to any state or profession. It is a rule that none are to enter the ecclesiastic or monastic state, without a particular vocation, or call.

The Romanists hold the vocation of the reformed divines null and invalid. Among ourselves, some hold an uninterrupted succession necessary to the validity of the vocation of a priest.

VOCATIVE, in *Grammar*, the fifth case, or state of nouns.

When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun or name acquires a new relation, which the Latins and Greeks express by a new termination, called the *vocative*.

Thus, of *Dominus*, *Lord*, in the nominative, the Latins have made *Dominæ*, *O Lord*, in the vocative; of *Antonius*, *Antoni*, &c. But as this was a thing not absolutely necessary, and as the nominative case might very well serve on such occasions, this new case, or termination, was not universal: in the plural, for instance, it was the same with the nominative; and even in the singular, it was only practised in the second declension among the Latins; and in Greek, where it is the most common, it is frequently neglected, and the nominative used instead of it; as in that passage in the Greek Psalms, quoted by St. Paul, θεος ας ο θεος, *thy throne, O God*.

In English, and most of the modern tongues, this case is ordinarily expressed in nouns that have an article in the nominative, by suppressing that article; as, the *Lord is my hope*.—*Lord, thou art my hope!* though on many occasions we use an interjection.

VOCATORES, among the *Romans*, were servants whose business it was to call the guests, receive them, and assign every one a place according to his dignity.

VOCAYAMO, in *Geography*, a town of Japan, in the island of Nippon; 15 miles N.W. of Meaco.

VOCE SOLA, in the *Italian Music*, denotes a piece composed for a single voice, generally accompanied with a thorough-bass on the harpsichord or organ, without other instruments. But if, besides that it is to be accompanied by other instruments, they add, *con violini*, with violins; *duo violini*, *e violoncello*, *e basso per l'organo*, i. e. with two violins,

a bafe violin, and a thorough-bafe on the organ; *con violini o Stromenti*, i. e. with violins or instruments; *parti con, parti senza violini*, i. e. part with, part without violins, &c.

VOCETIUS MONS, in *Ancient Geography*, a mountain mentioned by Tacitus, in Helvetia, applicable to a branch of mount Jura, which approaches the Rhine above Augusta Rauracorum.

VOCHY, in *Botany*, Aubl. Guian. v. 1. 18. t. 6. Poir. in Lam. Dict. v. 8. 681, the Caribbean name of a fine tree in Guiana. (See *CUCELLARIA*.) It is scarcely credible that Jussieu and Lamarck should have attempted to render the above name admissible, or have thought they improved it, by changing it to *Vochifia*; Juss. Gen. 424. Lamarck Illustr. t. 11. The natural order of this genus remains doubtful.

VOCIFERATIO, in our old *Law-Books*, the same with *hue and cry*.

“—Qui furem plegi tum dimiserit, qui ei obviaverit, et gratis sine vociferatione dimiserit, &c.” Leg. Hen. 1.

VOCLADE, in *Ancient Geography*, a place of Gallia Aquitania, belonging to the Pictavi, celebrated by the defeat of Alaric, slain by Clovis.

VOKIURA, in *Geography*, a town of Japan, in the island of Ximo; 33 miles N. of Nangafaki.

VOCONIAN LAW, in *Roman Antiquity*, a testamentary law prepared by Q. Voconius, tribune of the people, which prohibited every citizen from making any woman universal legatee, not excepting an only daughter, and enjoined a daughter's fortune, after her father's death, to be proportioned to his estate, according to the estimation of prudent men; and this proportion was usually one-fourth of her father's estate; and, moreover, that all the legacies of the testator should not exceed one half of his estate. This was intended as a supplement to the Furian law; the time of its passing is fixed by Cicero, de Senect. to the year of Rome 584, when Q. Marcius Philippus, and Cn. Servilius Cæpio, were consuls. It was revoked by Augustus in favour of Livia, to whom he was resolved to devise by will a great part of his estate. However, though, by the abrogation of this law, married women were not restrained from receiving any legacies above a certain sum, yet Augustus bestowed on such women as had vowed perpetual virginity the same rewards and privileges as upon mothers.

VOCONTII, in *Ancient Geography*, a people of Gallia Narbonensis, N. of the Mæmini. According to Strabo, they extended themselves to the frontier of the Allobroges, in valleys that were deep and difficult of access. Mela mentions them, and Vasio their capital. The Vocontii were governed by their own peculiar laws. They appear to have occupied not only the dioceses of Vaïson and of Die, but a part of the diocese of Gap and of that of Sisteron.

VODABLE, in *Geography*, a town of France, in the department of the Puy de Dôme; 4 miles S.W. of Iffoire.

VODANA, a town of Arabia, in the province of Oman, on the Moiesur; 40 miles S.W. of Oman.

VODERKAMP, a town of the duchy of Holstein; 31 miles E. of Lutkenborg.

VODLA, a river of Russia, which runs from lake Vodlo, and enters lake Onezkoë, near Pudoga.

VODLITZA, a river of Russia, which runs into lake Ladoga; 16 miles N.W. of Olonetz.

VODLO, a lake of Russia, in the government of Olonetz; 16 miles N. of Pudoga.

VOECA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Callici Lucenses. Ptolemy.

VOEGLARBY, in *Geography*, a town of Sweden, in Dalcarlia; 17 miles S. of Fahlun.

VOEN, a river of China, which runs into the Hoai, 10 miles E.N.E. of Ngan-kieou, in the province of Chantong.

VOERDEN. See VORDEN.

VOET, GISEBERT, in *Biography*, an eminent Dutch divine, was born at Heuften in the year 1589; and after having pursued his studies at Leyden for seven years, and superintending some churches taken from the Catholics, he settled in 1617 in his native place, where he exercised his ministry with exemplary diligence. In 1634 he was advanced to the chair of theology and the oriental languages in the university of Utrecht, and became co-pastor in one of the churches. About this time the Cartesian philosophy engaged attention, and its progress so alarmed Voet, that, in 1639, he made a public attack upon its principles, charging them with an atheistical tendency; and in this attack, though Des Cartes defended himself with acuteness, and not without treating his adversary with some degree of contempt, Voet was supported by the majority of the Dutch clergy, and also by the States of Holland. Besides his writings against Des Cartes, he wrote also several theological works; and continued in the exercise of his various functions at Utrecht till his death in 1677, at the advanced age of eighty-eight years. His son, PAUL VOET, was born in 1619, and became professor of law at Utrecht, where he published various works in the department of his profession. He died in 1667. JOHN VOET, the son of Paul, was a professor of law at Leyden, and the author of a highly valued “Commentary on the Pandects,” 2 vols. folio, 1698—1704. He died in 1714. Moreri. Mosheim.

VOG, in *Commerce*, a weight in Denmark, containing three bismersponds, or thirty-six pounds.

VOGEL, in *Geography*, a small island in the East Indian sea. S. lat. 5° 12'. E. long. 130° 46'.—Also, a river of Austria, which runs into the Traun, 8 miles S.W. of Wels.

VOGEL Islands, a cluster of small islands near the W. coast of Siam. N. lat. 7° 38'. E. long. 98° 55'.

VOGELIA, in *Botany*, bears that name, doubtless, in memory either of Benedict Christian Vogel, professor at Altorf, born in 1744, who published in 1768, a small academic essay, on the Generation of Plants; or of Rudolph Augustin Vogel, professor at Gottingen, who died in 1774, aged 50, having written on the sleep of plants, on the balsam of Mecca, and on various mineralogical subjects.—Lamarck Illustr. v. 1. 376. t. 149.—Class and order, *Pentandria Monogynia*.

Ess. Ch. Calyx inferior, of five ovate, folded, transversely corrugated leaves. Corolla of one petal, tubular, plaited, five-cleft. Stigma in five capillary segments.

The figure represents a branched plant, with small, alternate, nearly sessile, inversely heart-shaped, entire leaves, each tipped with a small point, and dotted on the surface. Flowers in solitary terminal spikes near two inches long. Corolla an inch long. Stamens within the tube, equal, capillary. Germen ovate. Style capillary.—The letter-press of Lamarck's work has not extended to this, his 405th genus, except so far as to give its essential character, nor do we find any traces of *Vogelia* in his or Poir. part of their Dictionary. We are therefore in the dark as to the number of species of this genus, its native country, or any other particular in its history. The plate above quoted is in Plumier's style.

Vogelia is also a synonym of TRITERELLA; see that article.

VOGELSANG, in *Geography*, a town of Prussia, on the Frisch Nering; 13 miles N. of Elbing.

VOGESUS,,

VOGESUS, or VOSEGS, MONS, in *Ancient Geography*, a chain of mountains, which commenced on the confines of the Lingones; and after having covered the northern part of the country of the Sequani, prolonged itself towards the N., between the Leuci and Mediomatrici on one side, and the Triboci and Nemetes on the other.

VOGHERA, in *Geography*, a town of Italy, in the Pavese; 12 miles S. of Pavia.

VOGLIA, in *Ancient Geography*, a town of Hispania, in the interior of Bœtica, belonging to the Turduli. Ptol.

VOGLABRUCK, in *Geography*, a town of Austria, on the river Vogel. This place enjoys the privilege of granting protection to all slaves, and its burghers and merchants, together with their wares, are toll free throughout all the Austrian countries; 27 miles S.S.E. of Passau. N. lat. 48° 1'. E. long. 13° 35'.

VOGLAMARCK, a town of Austria; 3 miles S.W. of Voglabruck.

VOGLER, GEORGE JOSEPH, the *Abbé*, in *Biography*, honoured by the pope with the order of the *Speron d'oro*, or golden spur, was born at Murzburg in 1749. He studied composition at Padua under Padre Valotti, and became early in his life a very learned and ingenious practical musician. He travelled all over Europe, exhibiting in almost every capital and great city his talents on the organ, an instrument which he had made his peculiar study, particularly in the use of the pedals, and in producing new effects by the *crescendo* and *diminuendo*, not by the usual method of a common swell with pipes inclosed in a particular chest, but by boxing up the whole instrument, and increasing and diminishing the tone, not only of single stops, but of the entire chorus or full organ.

In 1776, he opened a music-school at Manheim, for organ-playing, for the harpsichord, and for composition. In 1780 he began his travels, went to Paris, performed to the king, queen, and royal family at Versailles, composed operas, and had several of his choral compositions performed at the concert spirituel. In 1786 he was appointed maestro di capella to the king of Sweden at Stockholm. But in 1790, after visiting Denmark, Germany, and Holland, he arrived in London, where he had pedals put to the organ in the Pantheon, before that beautiful building was burned down, and a general swell contrived for the whole instrument; and in a series of morning performances on that organ, shewed his dexterity in the use of the pedals, not only in the *crescendo* and *diminuendo*, but in innumerable imitations, many of which were thought imaginary, and but for the ample promises and description in his bills of fare, would perhaps not have been discovered.

The science of this extraordinary musician was thought by some to degenerate into pedantry, and the splendid promises in his advertisements to border on *charlatanerie*; so that his success was not equal in our country to his real merit. Had he promised and attempted less, the public would have been more just and even generous in the estimation of his talents; but having injudiciously promised seeming impossibilities, what was possible, and what he really did perform, was fully heard with an unwillingness to be pleased. What he really did achieve was often uncommon and well deserving of applause, though perhaps not so much as he expected.

His publications in different parts of Europe are innumerable; but those in theory favour so much of the marvellous, that, on the continent, they are become proverbial. So that when any thing extraordinary in music was propounded or advertised, musicians used to cry out, oh! this is à la Vogler!

His advertisement in Holland, concerning an organ of his own construction, which he denominated an *orchestrian*, surpasses the marvellous of all the magnificent musical promises that we remember.

“The abbé Vogler, director of the Royal Academy of Music to his Swedish majesty, has constructed, after his own invention and design, (and at his own expence,) an organ with four rows of keys, sixty-three stops, thirty-nine pedals, and three swells, with proper resources to modify the sound: of which the first opens and shuts the general case of the pipes; the second, which is a pneumatic measure, stops the wind; the third divides and reunites the resources proportionably to the harmonic progression. The breadth, height, and depth of this organ is nine feet; the temperament of it is beyond conception exact. With respect to the body of tone, when in full chorus, it is equal to a church organ of sixteen feet. In depth of sound, it surpasses those of thirty-two feet; in sweetness, the *armonica*. Its *crescendo* governs all it plays; its *diminuendo* is qualified by the most minute gradations; and with respect to variety, the connoisseurs have declared, that a concert given by the abbé on his *orchestrian*, being a combination of all the instruments in Europe, and the result of thirty years' travelling, is the utmost extent of perfection possible in the art of playing and constructing organs.”

His theoretical works are the following: 1. The Knowledge of Harmony, and its Use in Concert, Manheim, 1776, 8vo. 2. The Tuning Art, or System of Temperament. 3. His Course of Lectures delivered in his Harmonic School during three years. 4. A practical work for the Catholic church, entitled “*Paradigma Modorum Ecclesiasticarum*.” 5. *Ecce Pisanus*, Chorus. 6. German Mafs for the Organ. 7. *Suscipit Israel*, composed for the Concert Spirituel at Paris. 8. Four-part Fugues, upon the *Stabat Mater* of Pergolesi. 9. *Plalmum Miserere decantandus* 4 Vocib. cum Organ. et Bassis. S.D. Pio VI. pontifici composuit. Spire. 10. *Vesperæ Chorales*. Spire. For the theatre, *The Merchant of Smyrna*, an operette; and six more operas, serious and comic, to French words, at Paris. And works for the organ and piano forte, published throughout Europe, innumerable.

We believe that this active and indefatigable musician has at length become stationary in Denmark, and in the capital of that kingdom has been some time projecting new plans for the cultivation and improvement of music as a science, as well as a liberal and practical art.

VOGOGNA, in *Geography*. See UGOGNA.

VOGTLAND, a country inclosed in the kingdom of Saxony, situated between the territory of Erzgebirg, Bohemia, the electorate of Saxony, and the principality of Culmbach. It is very hilly, and abounds in woods, but the former cannot be said to be altogether unfruitful, as producing either trees and plants, or being improved by tillage. In some parts likewise they yield copper, iron, lead, and silver, with other minerals, such as alum. Here is also no want of any kind of provisions; the fields affording grain and esculent herbs; the fine pastures in the valleys droves of excellent cattle, the woods plenty of venison and game, and the waters a variety of fish. The principal rivers are the Elster and the Saal. The name of Vogtland signifies the country possessed by the ancient advocates of the empire, who were predecessors to the present counts of Reussen. But the counts of Reussen at present enjoy only a part of it. The greatest part of this country belongs to the electoral house of Saxony. The margraves of Brandenburg Culmbach are possessed of the lordship of Hof, and the lordship of Ronneburg is vested in the house of

Saxæ Gothæ. What the name and dignity of a vogt imported in those ancient vogts of the empire is not yet agreed among the learned. One of the most probable conjectures is, that this dignity of a vogt was an hereditary office belonging to the empire, and the vogts themselves subordinate to the palace of the Rhine, as arch-vogt of the empire. No less uncertainty exists concerning the epocha of this title, though it appears to have been used in the 11th century, the ancient statutes of the town of Weyda having been given to it in the year 1027, by Henry, vogt of Weyda. Towards the middle of the 14th century this title was discontinued.

VOGULES, a tribe or nation of Finns, who inhabit the western, and, in a greater degree, the eastern part of the northern Ural, and nomadize chiefly about the rivers which unite with the Irtysh and the Oby to the Frozen ocean, or with the Kama and the Volga into the Caspian, and therefore principally in the governments of Perma and Tobolsk: they call themselves *Voguli*, or according to M. Georgi Mansi, and are denominated by the Russians *Vogulitschi*. They allege their traditions in evidence of their having always resided where they are now found: and they came under the Russian sovereignty previously to the conquest of Siberia, at which time they were fo brave and warlike, that they were with difficulty subdued. For some time they were thought to be the same with the Oiliaks; but in existing documents, which are more than 300 years old, they are specified as a distinct nation. All the stems of the Vogules, dispersed in various districts, taken collectively, compose a numerous nation, of unascertained population. The Vogules nomadizing in the circle of Tcherdyn, in the government of Perma, amounted in the year 1783 to no more than 111 persons, composing nine families, and so nearly related in consanguinity, that they were obliged to fetch women to be their wives from other races. Tooke's Russia, vol. i.

VOHBURG, a town of Bavaria; 10 miles E. of Ingoldstadt.

VOHEMARE BAY, a bay on the island of Madagascar. S. lat. $12^{\circ} 25'$. E. long. $51^{\circ} 8'$.

VOHENSTRAUS, or FOHENSTRAUS, a town of Bavaria, in the principality of Sulzbach; 8 miles E. of Weiden.

VOHIRIA, in *Botany*, Juss. Gen. 141, a barbarous name, altered, if not improved, from Aublet's *Voyria*. See LITA.

VOHL, or VOHLE, in *Geography*, a town of Hesse Cassel; 5 miles W. of Waldeck.

VOHLENBACH, a river which runs into the Lauenburg, 2 miles N. of Voringen, in the principality of Hohenzollern.

VOICE, Vox, in *Physiology*, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose: or, it is the sound produced by the passage of the air through the rima glottidis of the larynx.

Voices are either *articulate* or *inarticulate*.

Voices, *Articulate*, are those of which several conspire together to form some assemblage, or little system of sounds. Such are the voices expressing the letters of an alphabet, numbers of which, joined together, form words.

Voices, *Inarticulate*, are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all its varieties observed in speech, music, &c. makes a very curious article

of investigation; and the apparatus and organism of the vocal parts which contribute to the formation of musical tones, constitute a very complicated and surprising anatomical article of enquiry.

The structure and mechanism of the larynx adapted to this purpose are described under LARYNX; which see. But as the subject is curious and important, we shall here resume it, and furnish the reader with a connected detail of some observations, that may serve farther to elucidate this operation of nature. The human voice depends principally on the vibrations of the membranes of the glottis, excited by a current of air, which they alternately interrupt and suffer to pass; the sounds being also modified in their subsequent progress through the mouth. The parts subservient to the formation of sound are, the *trachea*, or wind-pipe, through which the air passes and repasses into the lungs; and which serves, as it were, for a bellows; the *larynx*, which is a short cylindrical canal, at the head of the trachea, particularly described, with its cartilages, &c. under that article: and the *glottis*, which is a little oval cleft, or chink, over which the epiglottis inclines backwards, as it ascends from its origin at the upper part of the thyroid cartilage. Within the glottis are extended its ligaments, contiguous to each other before, where they are inserted into the thyroid cartilage, and capable of diverging considerably behind whenever the aretynoid cartilages separate. These ligaments, as they vary their tension, in consequence of the motions of the aretynoid cartilages, are susceptible of vibrations of various frequency, and as they vibrate, produce a continuous sound. Properly speaking, there are two ligaments on each side; but this mode of operation is not fully understood; probably one pair only performs the vibrations, and the other assists, by means of the little cavity interposed, in enabling the air to act readily on them, and in communicating the vibrations again to the air.

The long canal of the trachea, terminated at the top with the glottis, appears so like a flute, that the ancients made no doubt but the trachea contributed the same to the voice, as the body of the flute does to the sound of that instrument. Galen himself fell, in some measure, into the mistake: he perceived, indeed, that the principal organ of voice was the glottis; but he still allowed the trachea a considerable share in the production of sound.

Galen's opinion was followed by all the ancients after him, and even by all the moderns, before M. Dodart. But that author observes, that we do not either speak or sing, when we inspire, or take in the air, but only when we expire, or expel it; and that the air, coming out of the lungs, passes always out of the minute vesicles of that part into larger; and at last into the trachea itself, which is the largest of all: that thus its passage becoming still more free and easy, and this more than ever in the trachea, it can never undergo such a violence, and acquire such a velocity in that canal, as is required to the production of sound; but that, as the aperture of the glottis is very small, in comparison with the width of the trachea, the air can never get out of the trachea by the glottis, without a vast compression, and augmentation of its velocity; and that, by this means, in passing, it communicates a brisk agitation to the minute parts of the two lips of the glottis, and gives them a kind of spring, and occasions them to make vibrations; which, communicated to the passing air, are what really occasion the sound.

This sound, thus formed, proceeds into the cavity of the mouth and nostrils, where it is reflected and rebounds; and on this resonance, M. Dodart shews, it is, that the agreeableness of the voice entirely depends. The different con-

fitnencies, forms, &c. of the divers parts of the mouth, contribute to the resonance, each in their way; and from this mixture of so many different resonances in their due proportion, there results a melody in the human voice superior and more affecting than it is in the power of the greatest musician to equal upon instruments. Hence it is, that when any of these parts are disordered, *e. gr.* when the nose is stopped, the voice becomes displeasing.

The resonance in the cavity of the mouth does not seem to consist in a simple reflection, such as that of a vault, &c. but in a resonance proportionate to the tones of the sound sent into the mouth from the glottis; and, accordingly, we find this cavity to lengthen and shorten itself, according to the depth, or acuteness, of the tone.

Now, for the trachea to effect this resonance, as it was the common opinion it did, it would be required, that the air, after its being modified, and turned into sound, by the glottis, instead of continuing its course from within outwards, should return from without inwards, and thus strike on the side of the trachea; which can never happen, except in those who have a violent cough, and in ventriquoous persons. Indeed, in most river-fowl, which have a very strong voice, the trachea does refund; but the reason is, that in them the glottis is placed at the bottom of the trachea, and not at the top, as in men.

The canal, then, which at first passed for the principal organ of voice, is now found not to be so much as the secondary one, *i. e.* not that which occasions the resonance. It does not serve the glottis, as the body of the flute does its plug; but, instead of that, the mouth serves the glottis, as the body of some other wind-instrument not yet known in music. In effect, the office of the trachea is no other than that of the port-vent in an organ; *viz.* to furnish wind.

The vowels and femivowels are continuous sounds, chiefly formed by this apparatus in the glottis, and modified either in their origin or in their progress by the various arrangements of the different parts of the mouth. Of simple vowels, sixteen or eighteen may be enumerated in different languages: in the French nasal vowels, the found is in part transmitted through the nostrils, by means of the depression of the soft palate: the perfect femivowels differ from the vowels only in the greater resistance which the air undergoes in its passage through the mouth; there are also nasal and feminal femivowels. The perfect consonants may be either explosive, fufurrant, or mute; the explosive consonants begin or end with a found formed in the larynx, the others are either whippers, or mere noises, without any vocal found. By attending to the various positions of the organ, and by making experiments on the effects of pipes of different forms, it is possible to construct a machine which shall imitate very accurately many of the founds of the human voice; and this has indeed been actually performed by Kratzenstein and by Kemplen.

A kind of experimental analysis of the voice may be thus exhibited. By drawing in the breath, and at the same time properly contracting the larynx, a slow vibration of the ligaments of the glottis may be produced, making a distinct clicking found: upon increasing the tension, and the velocity of the breath, this clicking is lost, and the found becomes continuous, but of an extremely grave pitch: it may, by a good ear, be distinguished two octaves below the lowest A of a common base voice, consisting in that case of about twenty-six vibrations in a second. The same found may be raised nearly to the pitch of the common voice; but it is never smooth and clear, except perhaps in some of those persons called ventriquoists. When the pitch is raised still

higher, the upper orifice of the larynx, formed by the summits of the aretynoid cartilages and the epiglottis, seems to succeed to the office of the ligaments of the glottis, and to produce a retrograde falsetto, which is capable of a very great degree of acuteness. The same difference probably takes place between the natural voice and the common falsetto: the rimula glottidis being too long to admit of a sufficient degree of tension for very acute founds, either the upper orifice of the larynx supplies its place, or some other similar change is produced; hence, taking a note within the compass of either voice, it may be held, with the same expence of air, two or three times as long in a falsetto as in a natural voice; hence, too, arises the difficulty of passing smoothly from the one voice to the other. It has been remarked, that the larynx is always elevated when the found is acute: but this elevation is only necessary in rapid transitions, as in a shake; and then probably because, by the contraction of the capacity of the trachea, an increase of the pressure of the breath can be more rapidly affected this way, than by the action of the abdominal muscles alone. The reflection of the found, thus produced from the various parts of the cavity of the mouth and nostrils, mixing at various intervals with the portions of the vibrations directly proceeding from the larynx, must, according to the temporary form of the parts, variously affect the laws of the motion of the air in each vibration; or, according to Euler's expression, the equation of the curve conceived to correspond with this motion, and thus produce the various characters of the vowels and femivowels. The principal founding-board seems to be the bony palate: the nose, except in nasal letters, affords but little resonance; for the nasal passage may be closed, by applying the finger to the soft palate, without much altering the found of vowels not nasal. A good ear may distinctly observe, especially in a loud base voice, besides the fundamental note, at least four harmonic founds, in the order of the natural numbers; and, the more ready the tone of the voice, the more easily they are heard. Faint as they are, their origin is by no means easy to be explained. This observation is precisely confirmed, in a late dissertation of M. Knecht, published in the musical newspaper of Leipzig. Perhaps, by a close attention to the harmonics entering into the constitution of various founds, more may be done in their analysis than could otherwise be expected. Young's *Philosophy*, vols. i. and ii.

Voice, For the Cause of the different Tones of. As the organs that form the voice make a kind of wind-instrument, we might expect to find in this instrument some provision answerable to that which produces the differences of tones in some other wind-instruments. The tone, therefore, must be attributed either to the mouth and nostrils, which occasion the resonance, or to the glottis, which produces the found; and as all the different tones are produced in man by the same instrument, it follows, that the part which produces them must be capable of similar instrumental changes.

Now, for a grave tone, we know there is more air required than for an acute one. The trachea, therefore, to let this greater quantity pass, must dilate and shorten itself; by which shortening, the external canal, that is, the canal of the mouth and nose, reckoned from the glottis to the lips, or nostrils, is lengthened. For, the shortening of the internal canal, *i. e.* of the trachea, brings the larynx and glottis lower down; and, of consequence, makes its distance from the mouth, &c. greater; and there is a change in the length of each canal, for every change of tone and femitone. Accordingly, it is easy to observe, that the knot of the larynx accurately rises and falls in all divisions, shakes,

shakes, or rapid changes of intervals in singing, however small may be the difference of tone.

Hence, as the depth of the tone of an hautbois is answerable to the length of the instrument; the longest fibres of the wood, whose vibrations make the resonance, making always the slowest vibrations, and consequently the deepest tone, it may appear probable, that the concavity of the mouth, by its lengthening for grave tones, and shortening for acute ones, might serve very well for the production of the divers tones; but M. Dodart observes, that in the stop of the organ called the *human voice*, the longest pipe is six inches; and yet, with all that length, it does not make any difference of tone; but the tone of the pipe is precisely that of the plug: whereas the concavity of the mouth of a man of the gravest voice, not being above six inches deep, it is evident that cannot modify, vary, and give the tone.

It is the glottis, then, that forms the tone, as well as the sound; and the manner of forming the various tones is by varying its aperture: a piece of mechanism too admirable not to be here particularly inquired into.

The human glottis, then, represented in *Plate XXIV. Miscellaneous, fig. 9.* is only capable of one proper motion; viz. that of an approach of its lips A D B, and A D B. Accordingly, the dotted lines A E B, A F B, A G B, exhibit three different degrees of approach. These different apertures of the glottis anatomists usually attribute to the action of the muscles of the larynx; but M. Dodart shews, from their position, direction, &c. that they have other uses; and that the opening and shutting of the glottis is effected by other means, viz. by two tendinous cords, or fringes, inclosed in the two lips of that aperture.

In effect, each of the two semicircular membranes, whose interstice forms the glottis, is doubled back upon itself; and within each duplicate there is a cord, or string, which is fastened at one end of the fore-part of the larynx, and to the hind-part at the other. It is true, they appear more like ligaments than muscles, as consisting of white and membranous fibres, not of red and fleshy ones; but the vast number of minute changes in this aperture necessary to form the vast variety of tones, make an extraordinary kind of muscle, by whose contraction they should be effected, absolutely necessary. Common fleshy fibres, in which the blood is received in large quantity, had been infinitely too coarse for such delicate motions.

These frings, which, in their state of relaxation, make each a little arc of an ellipsis, as they contract more and more, become longer, but less and less curve; and at last, with the greatest contraction they are capable of, they degenerate into two right lines, applied close to each other; so close, and so firm, that an atom of air cannot escape out of the lungs, how full soever they may be, and how great an effort soever all the muscles of the lower venter may make against the diaphragm, and, by the diaphragm, against these two little muscles.

The different apertures of the lips of the glottis, then, produce all the different tones in the several vocal parts of music; viz. *bass, baritone, tenor, counter-tenor, and trebles*; and the manner is thus:

The voice, we have shewn, can only be formed by the glottis; but the tones of the voice are modifications of the voice; and these can only be produced by the modifications of the glottis. Now the glottis is only capable of one modification, which is the mutual approach, or recess of its lips: it is this, therefore, that produces the different tones. Now that modification includes two circumstances: the first and principal is, that the lips are stretched more and more, from

the lowest tone to the highest; the second is, that the more they are stretched, the nearer they approach.

From the first it follows, that their vibrations will be so much the quicker, as they come nearer their highest tone; and that the voice will be just, when the two lips are equally stretched; and false, when they are unequal; which agrees perfectly well with the nature of stringed-instruments.

From the second it follows, that the higher the tones are, the nearer will they approach to each other; which agrees perfectly well with wind-instruments governed by reeds or plugs.

The degrees of tension of the lips are the first and principal cause of tones; but their differences are insensible. The degrees of approach are only consequences of that tension; but their differences are more easily assigned.

To give a precise idea of the thing, therefore, we had best keep to that, and say, that this modification consists in a tension, from whence results a very numerous subdivision of a very small interval: which yet, small as it is, is capable, physically speaking, of being subdivided infinitely.

The doctrine is confirmed from the different apertures found in differing persons of different ages, of both sexes. The aperture is less, and the exterior canal always shallower, in the sex and ages fittest to sing treble. Add, that the reed of a hautbois, separated from the body of the instrument, being a little pressed between the lips, will yield a tone somewhat higher than its natural one; and if pressed still more, will yield another still higher: and thus an able musician may run successively through all the tones and semitones of an octave. They are different apertures, then, that produce, or, at least, that accompany, different tones, both in natural wind-instruments and artificial ones; and the diminution of the aperture raises the tones both of the glottis, and the reed.

The reason why lessening the aperture heightens the tone is, that the wind passes through it with the greater velocity; and from the same cause it is, that if any reed or plug, of an instrument, be too weakly blown, its tone will be lower than ordinary.

Indeed the contractions and dilations of the glottis must be infinitely delicate: by an exact calculation of the ingenious author above-mentioned, it appears, that to perform all the tones and semitones of a common voice, which is computed to reach twelve tones; to perform all the particles and subdivisions of those tones into commas, and other minuter, though still sensible parts; to perform all the shakes, or the differences in a tone when sounded more or less strong, without changing the tone; the little diameter of the glottis, which does not exceed one-tenth of an inch, but which varies within that extent at every change, must be actually divided into 9632 parts; which parts are yet very unequal, and, therefore, many of them much less than the $\frac{1}{100000}$ th part of an inch: a delicacy scarcely to be matched by any thing but a good ear, which has so just a sense of sound, as, naked, to perceive differences in all these tones; even those whose origin is much less than the $\frac{1}{9632000}$ th part of an inch.

With respect to the organ of voice, Rousseau, in 1768, when he published his Musical Dictionary, was able to find no more satisfactory account than that which he has given from Duclos and Dodart; nor have we since been able to find that any further progress has been made into this mystery of nature. We have conversed with the late Dr. William Hunter, and his brother, the great anatomist, Mr. John Hunter, on the subject, who agreed that there was no work of nature more subtle and inexplicable than the form-

ation of a fine musical voice; and agreed, that it was impossible, from any external appearance or dissection, to discover the least difference in the vocal organ of an individual who had been possessed of a fine voice, and of one who had no voice at all, but for speech; of a voice of high pitch or low; of a voice of extensive or contracted compass.

The great Haller combated the system of Dodart, and gave a very scientific and anatomical theory of his own; but not more intelligible and satisfactory to common readers than that of Dodart.

Buffon was of opinion, that those who sung out of tune heard better with one ear than the other; that those who sung in falset closed the larynx, and narrowed the passage of the voice; by which means octaves were produced, as in the flute and hautbois, by blowing with more force for the high notes than the low, with the same ventages open or closed.

The falset voice is literally *voce da testa*, and formed in the throat; never like the notes formed in the chest, called *voce di petto*.

This subject, one of the most curious in physiology, has tempted us to extend the article beyond our intention or usual limits: we must not yet, however, quit the subject.

The organ of voice had been always regarded by anatomists and natural philosophers as a wind-instrument, till the time of M. Ferrein, who, in 1741, presented a memoir to the Academy of Sciences at Paris, to prove it to be a stringed instrument, played on by the wind, which serves as a bow. An allusion, however, to the Æolian harp would have been more happy, than to a violin. The Æolian harp (see *ÆOLUS'S Harp*) was well known in England about this time. An idea of it, too, might have been seen in Kircher's *Musurgia*, quoted by M. Ferrein for other purposes; and it was thence that Thomson the poet took it, who wrote an ode on this aerial instrument, which was set to music, and performed at a morning concert at viscountess Townshend's, mother of the present marquis. The ode is in Dodsley's Collection, and in Thomson's Works. Oswald, the celebrated player of old Scots tunes on the violoncello, and composer of many new, passed for the inventor of the Æolian harp; but as he was unable to read the account of it in the *Musurgia*, written in Latin, Thomson gave him the description of it in English, and let it pass for his invention, in order to give him a better title to the sale of the instrument at his music-shop in St. Martin's Church-yard.

M. Ferrein was of opinion, that there are strings in the lips of the glottis, capable of lengthening and shortening, and vibrating and sounding, like those of stringed instruments. His opinion surprises at first, and seems paradoxical; but he has supported it by experiments, which cannot easily be eluded. According to him, the organ of voice is at once a stringed and a wind-instrument. The air which comes from the lungs, and which passes through the glottis, performing the office of a bow upon the tendinous fibres of its lips, M. Ferrein calls *vocal strings* or *ribands* of the glottis. By the violent collision of the air against these vocal strings, they are put in motion; and it is by their quick and slow vibrations that they produce tones differing in gravity and acuteness, in proportion as they are more or less extended, according to the common and well-known laws of stringed instruments.

M. Ferrein has made a thousand experiments before the Academy, and individuals, in confirmation of his doctrine, as well upon the human subject as upon different animals. He took the *trachea arteria* from the dead body of a man

defined for dissection, with his larynx, and blew into the *trachea*, holding at the same time the ribands, as he calls them, of the glottis lengthened or shortened, and the human voice was heard to rise or fall in tone, or remain stationary, in proportion to these circumstances.

And it is very remarkable, that, contrary to the expectation of M. Ferrein, the different voices produced, in the course of these experiments, were so like those of the particular animals upon whose organs they were made, that they were always to be discovered and distinguished one from the other. The roaring of a bull, the cry of a dog in pain, &c. were constantly discoverable, notwithstanding the want of innumerable parts used in modifying these sounds in living animals, such as the palate, the teeth, lips, &c. The larynx torn from the animal was usually mutilated, and sometimes without the epiglottis, as well as all the bits of cartilages surrounding or covering the glottis and vocal strings, which were removed in order to exhibit more plainly the visible play and vibrations of these strings; and notwithstanding all these defects, the voice of each animal preserved almost every peculiarity of sound which distinguishes it from that of other animals.

M. Ferrein says, that the necessary tension, or lengthening and shortening of the vocal strings, for the purpose of forming the whole extent of the human voice, is not above two or three lines, or twelfth parts of an inch.

In common stringed instruments, lengthening a string makes it flatter, or of a tone more grave; and shortening it has a contrary effect: but with respect to these vocal strings it is quite different; for they are rendered more acute by being lengthened, as at the same time their tension is increased.

Many have gone through M. Ferrein's experiments with success; though Haller says that he himself was not so happy, not having been able to produce different voices of animals, as others had done, by blowing on the ribands. (See *Eloge de M. Ferrein*, in the *Hist. de l'Acad. Royal des Sciences* for the year 1769, published 1772, p. 15.) M. Ferrein was a physician and professor of anatomy and surgery, who died at Paris in 1769.

If a pipe could be formed to resemble the vocal organ, as described by M. Ferrein, we might hope for a true and exact imitation of the human voice, which has never yet been attained, owing perhaps to the mistaken notion of the voice being a kind of flute or mere wind-instrument.

VOICE, in *Grammar*, is a circumstance in verbs, by which they come to be considered as either active or passive, *i. e.* either as expressing an action impressed on another subject; as, *I beat*; or receiving it from another; as, *I am beaten*.

The Greeks have a third voice, called *medial*, because it has sometimes an active, and sometimes a passive signification.

VOICE, in matters of election, denotes a *vote*, or *suffrage*. In this sense, a man is said to have a *deliberative* voice, when he has a right to give his advice and opinion in a matter of debate, and his suffrage is taken; an *active* voice, when he gives his vote for the election of any one; and a *passive* voice, when the suffrages may fall on himself to be elected; an *excitative* voice, when he may act to procure another to be elected; a *consultative* voice, when he can only offer reasons and remonstrances, on which the chief, or head, determines at his own discretion: such the cardinals have, with regard to the pope; and the masters in chancery, with regard to the lord chancellor, &c.

VOICE, in *Oratory*, is one of the parts of pronunciation, upon the proper regulation of which much of the orator's success

success depends. For this purpose it will be right to observe, in general, what nature does, when free and unconstrained. As persons are differently affected when they speak, so they naturally alter the tone of their voice: it rises, sinks, and has various inflexions given it, according to the present state and disposition of the mind. When the mind is calm and sedate, the voice is moderate and even; when the former is dejected with sorrow, the latter is languid; and when that is inflamed by passion, this is raised and elevated. It is the orator's business, therefore, to follow nature, and to endeavour that the tone of his voice appear natural and unaffected; and for this end, he must take care to suit it to the nature of the subject; but still so as to be always grave and decent.

The principal affections or properties of the voice may be referred either to *quantity* or *quality*. The quantity of the voice consists in its highness or lowness, swiftness or slowness, and the intermediate degrees between them. Every person who speaks in public should endeavour, if he can, to fill the place where he speaks, without exceeding the natural key of his voice; in which case it will be either harsh and rough, or too shrill and squeaking; nor will he be able to give every syllable its full and distinct sound, and to infect it properly. He should also take care, that it does not sink too low, which will give him pain to raise it again to its proper pitch, and be no less offensive to the hearers. The last word of a sentence ought, in a particular manner, to be expressed distinctly, because the meaning of the whole sentence often depends upon it. The medium between these two is a moderate and even voice, which every person must regulate by the natural key of his own voice. But this equality of voice must be accompanied with a variety of inflexions and changes within the same pitch; and the gradations, whether higher or lower, must be gentle and regular; the voice moving from one key to another, so as regular to glide like a gentle stream than pour down like a rapid torrent; and the degree of these inflexions and various tones of voice should differ according to the nature of the subject, and design of the speaker.

The next property of the voice is *swiftness*; and with regard to this, care should be taken to avoid the two extremes of hurrying precipitately without pausing, which destroys not only the necessary distinction between sentence and sentence, but likewise between the several words of the same sentence; and of speaking so slowly, as to argue a heaviness in the speaker, and to render the discourse flat and lifeless.

In order to avoid both these extremes, the voice ought to be sedate and distinct; for which purpose it is necessary, not only that each word and syllable should have its full and just sound, both as to time and accent, but likewise that every sentence, and part of a sentence, should be separated by its proper pause and interval. See *PAUSE*.

Those properties of the voice, that respect its *qualities*, are chiefly strength or weakness, clearness or obscurity, fullness or smallness, smoothness or roughness. Temperance is a great preservative of the voice in all these respects, and all excess is highly prejudicial to it. A strong voice is very serviceable to the orator, because, if he wants some other advantages, he is however able to make himself heard; and if he is forced to strain it, he is less in danger of its failing him, before he has finished his discourse. But he who has a weak voice should be careful not to strain it, especially at first: he ought to begin low, and rise gradually to such a pitch, as the key of his voice will carry him, without being obliged to sink again afterwards. Frequent inflexions of the voice will likewise relieve him; and he should speak de-

liberately, and ease his voice, by allowing due time for respiration at all the proper pauses.

A voice is said to be clear, when the organs of speech are suited to give every single letter, and all the combinations of them in syllables and words, their proper and distinct sound. Such a voice is agreeable to the hearers, and advantageous to the speaker; as by speaking moderately, he may be distinctly heard, and thus be able to modulate his voice at pleasure.

An obscure and confused voice is sometimes owing to a deficiency in the organ, but often it is the effect of bad habit, acquired either by misplacing the accent, confounding the sound of the letters, or huddling the syllables one upon another, so as to render what is said unintelligible. When this confused voice arises from a natural defect, it may be remedied, as well as weakness of voice, in the manner pursued by Demosthenes. See *PONUNCIATION*.

But the most likely way of mending faults proceeding from bad habit, is to speak deliberately.

A full voice is not the same as a strong or a loud voice; it fills the ear, but it is often not pleasant; and, therefore, to render it so, as well as audible, it should be frequently varied. Those who have the misfortune of a very small voice, should be cautious of raising it to too high a pitch, especially at once; because the sudden compression of the organ is apt to occasion a squeaking and very disagreeable sound. A soft and smooth voice is of all the most musical, especially if it be flexible; and, on the contrary, nothing is less harmonious than a voice that is harsh and rough.

Upon the whole, we may conclude that voice to be the best or fittest for an orator, which is moderate, distinct, firm, clear, and smooth, and also easily flexible to the several degrees and variations of sound, which every part of the discourse may require. The different parts of a discourse require corresponding modulations of the voice. The orator should speak low at first, because this has the appearance of modesty, engages attention, and is best for the voice. In the narration, the voice ought to be raised to somewhat a higher pitch. The proposition, or subject of the discourse, should be delivered with a very clear and audible voice. The confirmation admits of great variety, both of the voice and gestures: in reasoning, the voice is quick and pungent, and should be enforced with suitable actions; and in descriptions, whilst the orator is pointing out the images of things, he should so endeavour to adapt both his voice, and the motions of his body, particularly the turn of his eyes, and action of his hands, as may best help the imagination of his hearers. Where he introduces another person speaking, or addresses an absent person, it should be with some degree of imitation; and in dialogue, the voice should alter with the parts. When he diverts from his subject by any digression, his voice should be lively and cheerful; since that is rather designed for entertainment than instruction. In confutation, the arguments of the adverse party ought first to be repeated in a plain and distinct manner, unless they appear unworthy of a serious answer; and then a facetious manner, both of expression and gesture, may be the most proper way to confute them. In the conclusion, both the voice and gesture should be brisk and sprightly.

There are sometimes certain words, which require an emphasis and distinction of the voice: such are often pronouns, as *this is the man*; and many words that denote the circumstances and qualities of a thing, some of which heightening or magnifying the idea of the thing to which they are joined, elevate the voice, and others debasing or lessening it, depress the voice, or at least protract the tone.

Some tropes likewise, as metaphors, and verbal figures, which consist in the repetition of a single word, should have a particular emphasis.

In sentences, regard should be had to their length, and the number of their parts, in order to distinguish them by proper pauses. The frame and structure of the period ought likewise to be considered, that the voice may be so managed, as to give it the most musical accent. Unless there be some special reason for the contrary, it should end louder than it begins. In an antithesis, one contrary must be louder than the other; in a climax, or gradation, the voice should rise with it.

As to the passions, it is evident that each of them requires a different voice and action. Love and esteem are expressed in a smooth and cheerful tone; but anger and resentment with a rough, harsh, and interrupted voice. Joy raises and dilates the voice; as sorrow sinks and contracts it. Fear occasions a tremor and hesitation of the voice; and assurance gives it strength and firmness. Admiration elevates the voice, and should be expressed with pomp and magnificence; the expression of it being often accompanied with an elevation both of the eyes and hands: on the contrary, contempt sinks and protracts the voice.

All exclamations should be violent. When we address inanimate things, the voice should be higher than when we address animated beings; and appeals to heaven must be made in a loftier tone than those to men.

After all, it is impossible to gain a just and decent pronunciation of voice and gesture, merely from rules, without practice, and an imitation of the best examples. Ward's *Orat.* vol. ii. lect. 48. and lect. 50.

VOICE, *Part of the, in Music.* See *PART*.

VOICE of a *Singer, Accidents and Disorders to which it is liable.* The air received in the lungs, and expelled by compression of the chest, passing through the aperture of the larynx gently closed, produces a sound, which afterwards, by the modulation of the tongue and other parts of the mouth, form the voice of a singer; and as many things concur in this formation, such as the breast, the diaphragm, the lungs, the wind-pipe, the uvula, or palate, the tongue, the teeth, and the mucosity which lubricates the several parts, all subject to a number of acute and chronic disorders, which, though it may not be necessary to specify here, it seems expedient that vocal performers should be apprised of the accidents to which the voice is liable, to put them on their guard; and the public, to incline them to pity and tolerate what the utmost care cannot always avoid.

Natural defects in the voice are incurable, such as being of a coarse quality, husky, inflexible, and out of tune.

VOID, in *Geography*, a town of France, in the department of the Meuse; 10 miles W. of Toul.

VOID, in *Common Law*. See *ANNULING*.

VOID *Bastion*. See *BASTION*.

VOID *Space*, in *Physics*. See *VACUUM*, &c.

VOIDANCE, VACANCY, in the *Canon Law*, a want of an incumbent upon a benefice. See *VACANCY*, &c.

This is twofold; either in law, *de jure*; as when one holds several benefices that are incompatible; or *de facto*, in deed; as when the incumbent is dead, or resigns, or is actually deprived.

VOIDED, VUIDE, in *Heraldry*, is understood of an ordinary whose inner or middle part is cut out, leaving nothing but its edges to shew its form; so that the field appears through it. Hence, it is needless to express the colour, or metal, of the voided part; because it must, of course, be that of the field.

VOIDED, *The Cross*, differs from the cross *fimbriated*, in

that this latter does not shew the field through it, as the other does. And the same obtains in other ordinaries.

VOIDER, one of the ordinaries, whose figure is much like that of the flaque, or flanch; only that it doth not bend so much.

This armoury, they say, is properly the reward of a gentlewoman that has well served her prince. It is always borne by pairs.

VOIDER, in *Agriculture*, a term provincially applied, in some instances, to a sort of open-work shallow basket or sieve, in which different articles of farm produce are put, in order to be out of the way.

VOIDING, EVACUATING, in *Medicine*. (See *EVACUATION*.) In the Philosophical Transactions we have an account of one Matt. Milford, who voided a worm by urine, supposed to have come from the kidneys.

Dr. Lister mentions true caterpillars voided by a boy of nine years old. Mr. Jessop saw hexapods vomited up by a girl. Catharina Geilaria, who died in 1662, in the hospital of Altenburg, for twenty years voided, they say, by vomit and stool, toads and lizards. *Ephem. German. tom. i. obs. 103.*

In the same *Ephem.* is also a story of a kitten, bred in the stomach, and vomited up; and others of whelps, frogs, lacertæ aquaticæ, and other animals, bred and voided the like way. Bartholine gives us an instance of a worm bred in the brain, and voided by the nose of O. W. See *WORMS*.

VOIGTIA, in *Botany*, Roth in *Roem. and Ulf. Mag. fasc. 10. 17. 196.* Poiret in *Lamarck Dict. v. 8. 683*; see *ROTHIA*.

VOIGTSBERG, in *Geography*, a town and citadel of Saxony, which gives name to a prefecture in the Vogtland; 1 mile N. of O.-nitz.

VOIR DIRE, in *Law*. When, upon a trial at law, it is prayed, that a witness may be sworn upon a *voir dire*, the meaning is, that he shall, upon his oath, speak or declare the truth, whether he shall get or lose by the matter in controversy. If he be unconcerned, his testimony is allowed, otherwise not.

VOIRE, in *Geography*, a river of France, which runs into the Aube, near Chalette.

VOIRON, a town of France, in the department of the Ière; 10 miles N.W. of Grenoble.

VOISENON, CLAUDE HENRY DE FUSÉE DU, in *Bio-graphy*, a literary person of singular character, was born at the chateau of Voisenon, near Melun, in 1708, and educated for the ecclesiastical profession. He commenced his career of advancement by being grand-vicar to the see of Boulogne; but having fought a duel, he afterwards contented himself with the abbacy of Jardy, which was probably a family benefice. He was of a lively, humorous disposition, and as he knew how to trifle agreeably, he was admitted into fashionable society. As a writer, he published several romances, the best of which is said to be a kind of moral tale, entitled "L'Histoire de la Félicité." His comedies of "Mariages assortis," 1744, and "La Coquette fixée," 1746, are reckoned to contain strokes of humour which would not have been disfavoured even by Moliere. He was also the author of many fugitive pieces. His literary reputation caused him to be elected into the French Academy; and the duke of Choiseul settled on him a pension of 6000 livres to write a French history. He died in 1775, and his works were collected in 1782 by his friend, Mad. de Turpin, in 5 vols. 8vo. *Nonv. Dict. Hist.*

VOISEY, in *Geography*, a town of France, in the department of the Upper Marne; 6 miles S.E. of Bourbon les Bains.

VOISHA, a town of Servia; 48 miles W. of Jenibafar.

VOISIN, JOSEPH DE, in *Biography*, a theological writer, was born at Bourdeaux, of a family distinguished in the department of law, but his disposition being devotional, he abandoned the legal for the ecclesiastical profession, and obtained priest's orders, and the degree of doctor in theology. He was a good Hebrew scholar, and very conversant with Rabbinical literature. In 1635 he published a Latin translation of a Rabbinical work on the soul; and in 1647 he gave to the public "Theology of the Jews," in Latin, 4to., and afterwards a "Treatise on the Jewish Jubilee," and other works of a similar kind. He was the editor, and partly author, of the work of the prince of Conti against theatrical spectacles, 1666; and after the death of that prince, of a defence of it against the abbé d'Aubignac. His translation of the Roman Missal into French was printed in 1660; but at the instigation of cardinal Mazarin, it was condemned by an assembly of the French clergy, though it had obtained the sanction of some bishops and doctors in theology. The plea urged against it was its being an attempt to prepare for the celebration of mass in French, and it was suppressed by a decree of the council. The grand-vicar of Paris sanctioned the printing and sale of the work; but the king enforced the pope's brief, which prohibited a translation of the Missal. Voisin afterwards obtained a royal privilege for its impression. This learned and pious person died in 1685. *Moreri*.

VOISINNES, in *Geography*, a town of France, in the department of the Upper Marne; 6 miles W. of Langres.

VOITEUR, a town of France, in the department of the Jura; 6 miles N. of Lons le Saunier.

VOITTSBERG, or **WOITTSBERG**, a town of the duchy of Stiria, on the Kainach; 20 miles W.S.W. of Gratz. N. lat. 47° 4'. E. long. 15°.

VOITURE, VINCENT, in *Biography*, born at Amiens in the year 1598, was a lively French writer, and an agreeable companion in the fashionable circles. At the court of Lewis XIII. he was well received, whose brother, Gaston, duke of Orleans, made him master of the ceremonies, and introduced foreign ambassadors, and whom he followed in his retirement to Languedoc. In 1634 he was admitted into the French Academy, of which he was a distinguished member, as he was well acquainted with the Latin, Italian, and Spanish languages. He held the office of interpreter to the queen-mother, and was employed in several court commissions. At Madrid he ingratiated himself with the count d'Olivares, and for the gratification of his curiosity made a tour to Africa. His Spanish verses were taken for those of Lopez de Vega; and at Rome he was elected, on account of his Italian literature, a member of the Academy degli Umoristi. On his return to France, he was appointed maitre d'hotel to the king; and M. d'Avaux, superintendent of the finances, gave him the lucrative place of his "commis." But all his preferments and pensions were not a sufficient fund for supplying him with the means of gaming and of gallantry. Being naturally feeble in his constitution, his various indulgencies were the occasion of terminating his life, in 1648, at the age of 50 years. His heart was good, but he was vain and irritable; and he had the means to be ashamed of his descent from a father who was a wine-merchant, so that he could not bear pleasantries that referred to his origin: and it was therefore said of him, that "wine, which raised other people's spirits, flattened his." Against those whom he provoked by his sarcasms, he had not courage to defend himself; and therefore, when he once offended a court lord, and was ordered

to draw his sword, he replied, "the match is not equal: you are tall, and I am short; you are brave, and I am a poltroon; you want to kill me: well then! I reckon myself dead." By this kind of apology he disarmed his antagonists. His peculiar excellence, like that of Balzac, consisted in letter-writing, which he was very slow in executing, and in which he displayed much wit and pleasantry, often degenerating into affectation, and sometimes into imbecility. His letters, however, notwithstanding their imperfections and faults, were much admired, and served as a passport into the polite companies. His poems were of a similar character to that of his letters. They consist of epistles, elegies, sonnets, rondeaux, ballads, and songs. For want of nature and correct taste, his works have sunk into oblivion. The latest edition is that of Paris, in 2 vols. 12mo. 1759. *Moreri*.

VOIVRE, LA, in *Geography*, a town of France, in the department of the Vosges; 9 miles E. of Remberiviller.

VOJUSSA, a river of European Turkey, which runs into the Adriatic; 7 miles N. of Valona.

VOKINOSAMA, a town of Japan, in the island of Ximo; 18 miles N. of Funai.

VOKSA, a river of Russia, which runs from lake Saima to lake Ladoga, in the government of Viborg.

VOKSCHA, a river of Russia, which rises in the province of Utiug, and joins the Mezen, in the government of Archangel; 16 miles N. of Olenkoi.

VOIX CELESTINE, in *Music*, a stop in the organ, an octave above the *vox humana*.

VOL, in *Ancient Geography*, a town of Africa Propria, S. of Carthage, between the rivers Bagradas and Triton. Ptolemy.

VOL, among *Heralds*, signifies the two wings of a fowl joined together, borne in armoury; as being the whole that makes the flight. Accordingly, a *demi-vol* is a single wing.

VOLA, the palm, or inside of the hand, comprehended between the fingers and the wrist.

VOLANA, in *Ancient Geography*, a river of Gallia Cispalina, called also Podi Volana.—Also, a town of Italy, in Samnium.

VOLANDUM, a fortified place of Asia, in Armenia, and the strongest in the country. It was taken by Corbulo without the loss of a single man, and all the inhabitants above the age of fourteen years were confined to the edge of the sword.

VOLANO, in *Geography*, a sea-port town of Italy, in the Ferrarese, at the mouth of the southern branch of the Po, which is called Po di Volano; 23 miles E. of Ferrara.

VOLANS. See **DRACO**, and **PISCIS**.

VOLANT, in *Heraldry*, is when a bird, in a coat of arms, is drawn flying, or having its wings spread out.

VOLANT, Pass. See **PASS-VOLANT**.

VOLANT, Pont. See **PONT-VOLANT**.

VOLAR, in *Geography*, a town of Transylvania; 4 miles S. of Hunyad.

VOLATA, Ital., in *Music*, a slight, rapid division, a rapid extemporaneous passage at a cloic, or pause.

VOLATERRÆ, in *Ancient Geography*, a town of Italy, in Etruria, at a certain distance from the sea, situated on a mountain, which, according to Strabo, was fifteen stadia in height. It is placed by some authors in the rank of the twelve cities of Etruria. After its subjection to the Romans, it remained faithful. In the time of Sylla's proscriptions, it was unsuccessfully besieged for two years. Its inhabitants obtained the right of Roman citizenship. At the fall of the empire it passed under the power of the Vandals, Huns, and Goths; but was retaken by Narfes, in the year

553. Some authors say that for a certain time the Lombards fixed their court there.

VOLATERRANA VADA, a town or borough of Italy, in Etruria, with a port at the mouth of the Cecinna, according to Pliny. It is now called Vadi.

VOLATICA, in *Medicine*, a name given by authors to a sort of wandering pain, attended with a tumour, and affecting, at different times, different parts of the body. It is by some accounted a species of the scurvy; by others, of the leprosy.

VOLATILE, in *Physics*, is commonly used to denote a mixt body, whose integral parts are easily dissipated by fire or heat; but it is more properly used for bodies whose elements, or first component parts, are easily separated from each other, and dispersed in air.

As those bodies which by heat suffer no diminution of their weight are said to be fixed, so those which do lose of their weight are said to be volatile; and they are said to be more or less volatile, according as a greater or less degree of heat is requisite for producing a separation of their parts. Perhaps, indeed, every body is, rigorously speaking, volatile: but as there are some, the volatility of which can be only rendered sensible by the action of a fire much more violent than any which we can produce, we consider these bodies as being fixed, or not volatile.

Minerals, for the generality, are less volatile than vegetables; and vegetables are less so than animals.

The chemists distinguish between volatile salts and fixt salts. The capitals of aludels stop and collect the volatile parts of substances, in sublimation, and make what we call *flowers*.

“The particles of fluids which do not cohere very strongly together, and are of such smallness as renders them most susceptible of those agitations which keep liquors in a flux, are easily rarefied into vapour; and, in the language of the chemists, are volatile. Those which are grosser, and by that means less susceptible of alterations, or which cohere by a stronger heat, or, perhaps, not without fermentation; these are what the chemists call fixt bodies.” Newton’s *Optics*, p. 371.

VOLATILE Alkali. See **ALKALI**.

VOLATILE Salt of Amber. See **AMBER**.

VOLATILE Oil, in *Rural Economy*, is that sort which has a fragrant aromatic smell, and which is sometimes called *essential oil*. It is stated by sir Humphrey Davy to differ from fixed oil, in being capable of evaporation by a much lower degree of heat, in being soluble in alcohol, and in possessing a very slight degree of solubility in water. There is a great number of this sort of oils, distinguished by their smell, their taste, their specific gravity, and other sensible qualities. A strong and peculiar odour may, however, be considered as the great characteristic of each sort; the volatile oils inflame with more facility than the fixed oils, and afford by their combustion different proportions of the same substances, water, carbonic acid, and carbon.

It is said that the peculiar odours of plants seem, in almost all cases, to depend upon the peculiar oils of this sort they contain. All the perfumed distilled waters owe their peculiar properties to the volatile oils they hold in solution. By collecting the aromatic oils, the fragrance of flowers, so fugitive in the common course of nature, is as it were embodied and made permanent. It cannot be doubted, it is said, that the volatile oils consist of carbon, hydrogen, and oxygen; but no accurate experiments have as yet been made on the proportions in which these elements are combined. As the fragrance of flowers depends upon the volatile oils they contain; and these oils, by their constant evaporation,

surround the flower with a kind of odorous atmosphere; which, at the same time that it entices larger insects, may probably preserve the parts of fructification in the ravages of smaller ones; volatile oils, or odorous substances, seem, it is said, particularly destructive to these minute insects and animalcules which feed on the substance of vegetables: thousands of aphides may be usually seen in the stalk and leaves of the rose; but none of them are ever observed on the flower. Camphor is the substance used to preserve the collections of naturalists. The woods that contain aromatic oils are remarkable for their destructibility, and for their exemption from the attacks of insects: this is particularly the case with the cedar, rose-wood, and cypress. The gates of Constantinople, which were made of this last sort of wood, stood entire, it is said, from the time of Constantine, their founder, to that of pope Eugene IV., a period of 1100 years.

This sort of oils is afforded by distillation, coming over with the water, and floating on the top of it in small globules. It is collected by pouring a quantity of the distilled water with the oil, as it comes over into a vessel, so constructed as to suffer the watery part to escape by a stopcock near the bottom; the vessel or apparatus is again filled, and when settled, the water is again let out; in this manner the oil is collected in great quantities, floating as above. This essential or ethereal oil resides, it is supposed by some, in a particular part of the plant, but which is different in different sorts. And it is said that the oils vary in their nature or properties in different sorts of plants.

It is noticed by the above writer, that the volatile oils have never been used as articles of food; many of them are employed in the arts, in the manufacture of pigments and varnishes; but that their most extensive application is as perfumes in the hands of the perfumer, and manufacturer in that way. On the contrary, the fixed oils are very nutritive substances, and are of great importance in their applications to the purposes of life. See **OIL**.

VOLATILE, Sal Oleosum. See **SAL**.

VOLATILE Salt. See **SALT**.

VOLATILIZATION, or **VOLATILIZATION**, the act of rendering fixt bodies volatile, or resolving them, by fire, into a fine, subtle vapour, or spirit, which easily dissipates, and flies away.

All bodies, even the most fixt, as gold, may be volatilized, either of themselves, or with the admixture of some volatile substance, or spirit; by distillation, or sublimation.

In the Memoirs of the Royal Academy we have a discourse on the volatilization of the fixed salts of plants, by M. Homberg.

VOLATILITY, in *Chemistry*, is a property that many bodies have of being reduced into light vapours, which exhale when they are exposed to the action of fire. This quality is opposed to fixity, and is owing to the greater or less dilatibility which bodies have, when exposed to fire. See **VOLATILE**, **SUBLIMATION**, &c.

VOLCÆ ARECOMICI, in *Ancient Geography*, contradistinguished from the *Tectosages*, were a branch of a people, who occupied, in the Narbonne province, the whole space that lies between the Rhone and the Garonne. The Arecomici were situated near the Rhone, and extended along the sea in that territory which is now called Lower Languedoc. When Hannibal traversed the southern part of Gaul, in his way to Italy, the Arecomici were not bounded by the Rhone, but possessed territory on both sides of the river. The chain of Mons Aberna separated the Arecomici from the Ruteni and the Gabatii. But their limits with regard to the Tectosages are not easily ascertained. According

cording to Strabo, Narbonne was a part of the territory of the *Arecomici*; but Ptolemy extends the territory of the *Tectosages*, so as to assign to them the towns of Narbonne, Beziers, and Cessero upon the *Arur*. Before the Romans made Narbonne the capital of their first province conquered in Gaul, this city might have belonged to the *Arecomici* rather than to the *Tectosages*, agreeably to Strabo's account. But when Narbonne was elevated to this dignity, it found itself independent of both classes of the *Volcæ*, and appropriated to itself a distinct and separate territory. This territory is indicated by the position of *Fines*, between *Carcaffonne* and *Toulouse*. Ptolemy, however, not duly regarding the distinction between these several people, adjudged Narbonne and some other towns to the *Tectosages* rather than to the *Arecomici*, whose district was thus reduced to that of the capital, or of *Nemausus* in particular. The *Volcæ Tectosages* merit a particular distinction on account of the expeditions in which they engaged. They penetrated, according to *Cæsar*, into Germany, and established themselves in cantons of the forest of *Herinia*, acquiring the reputation of justice as well as of courage in war. *Julius* reports that a body of the *Tectosages* penetrated into *Illyria*, and fixed itself in *Pannonia*. But their most celebrated establishment was that in *Phrygia*, where they preserved their own name. They also occupied *Ancyra*, the principal town of the country, which took the name of *Galatia*. The *Tectosages* of the *Narbonnois*, according to Strabo, approached the *Pyrenées*, and attained one extreme of the declivity of mount *Commenus* or *Cebanna*. Their limit, with regard to the *Arecomici*, seems to have been determined by the position of *Fines*, of which we have already spoken.

VOLCANO, in *Geography*. See **VULCANO**.

VOLCANO, in *Geology*, is an opening made by subterranean fire in the surface of the earth, through which vapour, smoke, flames, and stones are ejected, with streams of melted stone, called *lava*. Some volcanoes throw out boiling water and mud.

Of all geological phenomena, volcanoes are the most impressive, as they not unfrequently change the appearance of a whole district in the course of a few days; and the only instances we have of the formation of rocks in our own times, are those produced by the agency of volcanic fires. In a former state of the globe, these fires appear to have been still more actively and extensively operative: this is proved by the numerous remains of extinct volcanoes of immense size, scattered over various parts of the world, and by the existence of rocks nearly resembling volcanic products, found in almost every country that has yet been explored. It is only within a short period that these phenomena have been attentively and accurately examined. We shall commence our account with a description of the external structure of volcanoes.

Many volcanoes are lofty mountains, surmounted by a truncated cone, having an aperture at the summit, nearly circular, and of greater or less depth, called the crater, from which the eruptions issue; but not unfrequently the eruptions burst from the side or the foot of the mountain, and they sometimes break forth at a great depth under the sea. The greatest number of active volcanoes are situated near the sea or large lakes, from which circumstance it has been supposed, by some geologists, that water is an agent in all volcanic eruptions. Most isolated volcanic mountains have a pyramidal or conical form, ascending at a moderate angle of inclination from the base to an elevated plain, from the centre of which rises the cone in which the principal crater is situated. The sides of this cone are generally steep, and are covered with volcanic sand, pumice,

or scoriae. The matter of which it is composed, as well as the shape, evidently indicate that it has been formed by substances thrown out of the volcano in a perpendicular direction, which in their descent have accumulated round the aperture, and from the laws of gravity have assumed a conical form. The shape of the cone is changed during great eruptions, sometimes they have been known to sink down and disappear, new volcanic cones forming in other parts of the mountain. A considerable part of the cone of *Vesuvius* fell down during the eruption of 1794. In 1727, when *M. d'Orville* visited *Vulcano*, one of the *Lipari* or *Æolian* isles, there were two distinct volcanic cones, each placed on an eminence, and containing a crater in a state of active eruption; whereas, at present, there is but one cone conspicuous in the island, the summit being single. *Spallanzani*, who visited these islands about sixty years after *M. d'Orville*, made inquiries of some of the oldest inhabitants respecting the double cone and crater of *Vulcano*, and he found some few persons who retained a recollection of it. The regular conical form does not characterize all volcanoes. The volcanic mountains in America, according to *Humboldt*, present a considerable diversity, both in shape and situation, from those in the old world.

In Europe and in Asia, as far as the interior of the latter continent is known, no burning volcano is situated in a chain of mountains; all being at a greater or less distance from these chains. In the new world, on the contrary, the volcanoes, the most stupendous for their masses, form a part of the *Cordilleras* themselves. The mountains of mica-slate and gneiss, in Peru and New Granada, immediately touch the volcanic porphyries of the province of *Quito* and *Pasto*. To the south and north of these countries, in *Chili* and in the kingdom of *Guatemala*, the active volcanoes are grouped in rows. They are the continuation of the chains of primitive rocks; and if the volcanic fire has broken out in some plains far from the *Cordilleras*, as in mount *Sangay* and *Jorullo*, we must consider this phenomenon as an exception to the law which nature seems to have imposed on these regions.

The Peak of *Teneriffe* forms a pyramidal mass like *Etna*, *Tungurahua*, and *Popocatepetl*, but this character is far from being common to all volcanoes. We have seen, says *Humboldt*, some in the southern hemisphere, which, instead of having the form of a cone or bell, are lengthened in one direction, having the ridge sometimes smooth, at others rough, with small pointed rocks. This structure is peculiar to *Antisan* and *Pichinca*, two burning mountains of the province of *Quito*, and the absence of the conical form ought never to be considered as opposed to a volcanic origin.

M. Humboldt deduces the following inferences from his observations on the shape of different volcanoes. That mountains with slender conical peaks, are those which are subject to eruptions of the greatest violence, and at the nearest periods to each other. Mountains with lengthened summits, rugged, with small stony masses, are very old volcanoes nearly extinguished. Rounded summits, in the form of domes or bells, indicate those doubtful kinds of porphyries which are supposed to have been heated in their original place, and forced up in a softened state without ever having flowed as lavas. To the first of these mountains belong *Cotopaxi*, the Peak of *Teneriffe*, and that of *Orizava*, in Mexico. The second is common to *Carguarazo* and *Pichinca*, in the province of *Quito*, and to the volcano of *Puracey*, near *Popayan*, and perhaps also to *Hecla*, in *Iceland*. The third and last form is seen in the majestic figure of *Chimborazo*, and in the great *Sarcony*, in *Auvergne*.

VOLCANO.

In order to form a more exact idea of the external structure of volcanoes, it is important to compare their perpendicular height with their circumference; but this can only be done with isolated mountains placed on a plain which is nearly on a level with the sea. The height of the Peak of Teneriffe is one twenty-eighth of the circumference of its base; that of Vefuvius, according to Von Buch, is a thirty-third; and of Etna, a thirty-fourth. Isolated volcanoes, in the most distant regions, are very analogous in their external structure. All have elevated plains, in the middle of which rises a cone perfectly circular. The greater the quantity of matter that has issued from the crater of a volcano, the more elevated is its cone of ashes, in proportion to the perpendicular height of the mountain. Nothing is more striking than the difference in this respect, says Humboldt, between Vefuvius, the Peak of Teneriffe, and Pichinea. The cone of Cotopaxi, the form of which is the most regular and elegant of any hitherto known, is 540 toises in height, but it is impossible to decide whether the whole of this mass is covered with ashes.

	Cone covered with Ashes.		
	Toises.	Toises.	
Vefuvius, height of	606	200	$\frac{1}{3}$
Peak of Teneriffe	1904	84	$\frac{1}{22}$
Pichinea	2490	240	$\frac{1}{10}$

The latter column shews the proportion of the cone to the total height of the mountain.

In most volcanic mountains, the cone, or fugar-loaf, as it has been not unaptly called, preserves its conic figure to the very summit; the whole of the declivity is inclined the same number of degrees, and is uniformly covered with layers of volcanic sand or powder. When we reach the top, nothing obstructs the view of the bottom of the crater. The Peak of Teneriffe and Cotopaxi, on the contrary, have a different construction. Their summits have a circular wall, surrounding the brink of the crater, which appears at a distance like a small cylinder placed on a truncated cone. According to Humboldt, this peculiar construction of Cotopaxi, is visible to the naked eye at the distance of nearly three leagues. No person has reached the crater of this volcano. On the Peak of Teneriffe, the wall that surrounds the crater is so high, that it would be impossible to enter, if there were not a breach which seems to have been made by the flowing of an ancient current of lava.

The shape of volcanic craters is generally that of a funnel, either circular or elliptical, the sides shelving down to the bottom, which is a plain of greater or less extent, having apertures or fissures, through which smoke and heated vapour are exhaled. At the bottom of many volcanic craters are one or more small cones, which during eruptions enlarge, and sometimes fill up the crater, and rise above its brim. The present cone of Vefuvius is supposed to have been raised within a crater of much larger size, of which mount Somma forms part of the remaining wall. (See VESUVIUS.) The size of the crater does not depend on the height and mass of the mountain, of which it forms the principal vent. Vefuvius, which is but a small hill compared with the Peak of Teneriffe, has a crater with a diameter five times larger than that of the latter mountain; and the present crater of Vulcano equals or exceeds that of Vefuvius, though the height of the cone is not more than 1500 feet above the level of the sea. When we reflect, says Humboldt, that very lofty volcanoes throw out less matter by their summits than by lateral openings, we should be led to conclude that the lower volcanoes are, their force and activity being the same, the more considerable

ought to be the size of their craters. There are immense volcanoes in the Andes, which have but very small openings, and we might establish it as a geological principle, that the most lofty volcanoes have craters of small extent at their summits, if the Cordilleras did not offer many instances to the contrary. The great volcanoes of Cotopaxi and Rucupichinea have craters, which, according to the admeasurement of this indefatigable traveller, exceed half and three-quarters of a mile in diameter.

In a volcano like Vefuvius, the activity of which is principally directed towards the summit, the depth of the crater varies before and after every eruption; but at the Peak of Teneriffe, the depth of the crater appears to have been stationary for a long time. In 1715, it was estimated by Mr. Eden at one hundred and fifteen feet; in 1805, by M. Cordier, at one hundred and ten feet; and subsequently, by Humboldt, it was conjectured to have rather less depth. The inside of the crater indicates a volcano, which for a long period has emitted no fire at the summit. From the lapse of time, and the action of vapours, the inside walls have fallen in, and have covered the basin with great blocks of lava.

For an account of the cone and crater of mount *Ætna*, see *ÆTNA*.

Among the various changes that have taken place in this volcano, it is highly probable that the partition between the upper and lower crater may have been frequently removed. Lieut.-general Cockburn, who visited *Ætna* in 1810, describes only one crater, though he ascended the highest pinnacle. This crater, he estimates at nearly two miles in circumference. At that time the bottom of the crater, which he distinctly saw, was not flat; it contained several minor mountains and their craters, some smoking like the most violent glass-furnace, or steam-engine. Cockburn's Travels in Sicily, vol. i. p. 137.

The whole cone of a volcano is sometimes swallowed up during an eruption, leaving a circular crater of a larger diameter and at a much lower level; which, when the volcanic fire becomes extinct, or remains dormant for ages, may form a lake. The celebrated lake of Avernus, near Naples, and the neighbouring lake Agano, are the craters of extinct volcanoes, the cones of which have probably been buried after a great eruption, or by an earthquake. Numerous circular lakes exist in volcanic countries which have had the same origin. Nor need we be surprised at the disappearance of a volcanic cone, however large, as it must stand and have its foundation on the brink of a much larger abyss, from which it has been thrown out, as we shall have occasion to remark in describing the formation of some of these cones, which have taken place in modern times.

The crater of a volcano can only be approached when the fire is in a dormant or nearly quiescent state; but as the intervals between volcanic eruptions sometimes last for many years, and even centuries, opportunities are offered for exploring their structure. The floor of the crater appears in many instances to be only a thin congealed crust, and returns a hollow sound when struck upon with a stone or any hard substance. This is the case at the Solfaterra, which appears to be the floor of an extinct crater. See *SOLFATERRA*.

When M. de Luc walked over the bottom of the crater of Vulcano in 1757, it returned a hollow sound. The largest diameter of the crater was then above three-quarters of a mile, and the depth nearly a thousand feet. In 1781 it was visited by M. Dolomieu, who found it impossible to enter the crater; its depth he estimated at half a mile from the brink, and the bottom not more than two hundred and fifty feet in diameter. He threw in some large stones from

the edge of the crater, which he perceived sunk in some fluid when they reached the bottom. This fluid could not be aqueous, since it would soon have been evaporated by excessive heat; he supposed it to be melted sulphur, as he saw that substance trickle down the sides, against which it had sublimed. With a good telescope he could discover at the bottom two small pools, which he supposed to be full of the same combustible matter. He likewise observed, that the fumes which in the day-time appeared white, were by night splendid, but placid flames, that rose above the mountain, and diffused their light to some distance.

Spallanzani, who visited Vulcano seven years after Dolomieu, found the bottom only about a quarter of a mile deep, but intolerably hot.

The changes which took place in this interval, were probably occasioned by a violent commotion which occurred in the month of March 1786, during which the crater threw out a prodigious quantity of volcanic powder or sand with immense volumes of smoke and flame. This eruption lasted fifteen days.

That the bottom of the crater should vary considerably in depth after every eruption will not appear surprising, if we reflect that this bottom is a crust of congealed lava, more or less covered with loose materials, which have fallen upon it. When the lava which has been forced up near to the brink of the crater, remains stationary at the close of an eruption, and solidifies, the melted lava will gradually sink down as the intensity of the volcanic fire diminishes at the surface, thus leaving a crust of greater or less thickness over a hollow space below. The depth of this floor from the brink will depend on the quantity of lava which remains in the crater towards the end of an eruption.

The phenomena preceding and attending volcanic eruptions, vary according to the situation in which they break forth, and the magnitude or intensity of the volcanic fire. An eruption may proceed from ancient volcanoes, which have been dormant for a longer or shorter period, or it may break out from a new opening or from under the sea. The phenomena most common to each of these situations we shall briefly describe. The indications of an approaching eruption from a dormant volcano, are the increase of smoke from the summit of the crater, which sometimes rises to a vast height, branching in the form of a pine-tree. This was the case in the memorable eruption of Vesuvius, described by Pliny, in the year 79 of the Christian era. The cause of this appearance is probably the violent escape of elastic gas driving up the volatile materials into the higher regions of the atmosphere, which in their descent float at different heights, according to their specific gravity, the heaviest stratum floating over a larger space. Tremendous explosions, like the firing of artillery, commence after the increase of smoke, accompanied with tremors of the earth, more or less violent, and by eruptions of red-coloured flame and stones from the crater; after which, in most violent eruptions, currents of melted stone, called lava, flow either over the brink of the crater, or break through the sides of the mountain. These currents, when consolidated by cooling, frequently form a stratum thirty or forty miles in length, several miles broad, and several yards thick, equalling in extent any continuous stratum, among the regular formations of secondary strata. The eruption of lava has been known to continue for several months. Black clouds, composed of dark-coloured sand or powder, improperly called ashes, are thrown out of the crater after the lava ceases to flow. During one eruption of Etna, a space of one hundred and fifty square miles was covered with this sand twelve feet thick. Stones or globiform masses of melted lava are

thrown out at the same time, and fall at a greater or less distance, according to their size, and the force with which they are ejected, the larger masses falling nearest to the mouth of the volcano. The smoke and vapour are highly electrical, and vivid violent flashes of lightning dart from it, which frequently occasion much mischief. Towards the conclusion of the eruption, the colour of the volcanic sand changes to white; it consists of pumice in a finely comminuted state. It is observed, that when the lava flows freely, the tremors of the earth and the explosion become less frequent, which proves that they were occasioned by the confinement of the gaseous and solid matter that is afterwards discharged.

Most of the phenomena here mentioned occur in the eruptions of mount Vesuvius, near Naples. The first eruption of this mountain recorded in history, is that which happened in the time of Vespasian, A.D. 79; on which occasion, says Dion Cassius, great quantities of ashes and sulphureous smoke were carried not only to Rome, but also beyond the Mediterranean, into Africa, and even to Egypt. Birds were suffocated in the air, and fell down dead upon the ground, and fishes perished in the neighbouring waters, which were made hot, and infected by it. Sir William Hamilton reckons, that the eruption in 1767 was the twenty-seventh from that in the time of Titus. Since 1767 the eruptions have been frequent.

Bishop Berkeley has given a particular account of the eruption in 1717; for which, see Phil. Transf. N^o 354. p. 708, or the Life of Berkeley, in the Biographia Britannica, by Dr. Kippis.

We have an account of mount Vesuvius, and of the eruption from it in 1737, by the prince of Cassano, in the Philosophical Transactions, N^o 435. sect. 1, 2.

The matter thrown out flowed like melted lead, and moved about half a mile in an hour, which was then considered as an unusual velocity. The trees touched by this matter, immediately took fire, and fell. Glass in houses was melted into a paste.

Sir William Hamilton has given an accurate and circumstantial description of the eruptions in 1766, 1767, and 1770. See Phil. Transf. vol. lvii. p. 192, vol. lviii. p. 1, &c. vol. lix. p. 18, &c. vol. lxx. part i. p. 42, &c. We shall select his account of the latter. During the whole month of July the mountain continued in a state of fermentation. Subterraneous explosions and rumbling noises were heard, quantities of smoke were thrown up with great violence, sometimes with red-hot stones, scoriz, and ashes; and towards the end of the month these symptoms increased to such a degree, as to exhibit in the night-time the most beautiful fire-works that can be imagined.

On Thursday, the 5th of August, the volcano appeared most violently agitated; a white and sulphureous smoke issued continually and impetuously from its crater, one puff seeming to impel another, so that a mass of them was soon accumulated, to appearance four times the height and size of the volcano itself. These clouds of smoke were exceedingly white, so that the whole resembled an immense accumulation of bales of the whitest cotton. In the midst of this very white smoke, vast quantities of stones, scoriz, and ashes were thrown up to the height of two thousand feet, and a quantity of liquid lava, seemingly very heavy, was lifted up just high enough to clear the rim of the crater, and take its way down the sides of the mountain. This lava having run violently for some hours, suddenly ceased, just before it had reached the cultivated parts of the mountain, near four miles from the spot whence it issued. The heat all this day was intolerable at the towns of Somma and

Ottaiano, and was fenfibly felt at Palma and Lauri, which are much farther off. Reddish afhes fell fo thick on the two former towns, that the air was darkened, fo that objects could not be diftinguifhed at the diftance of ten feet.

Long filaments of a vitrified matter, like fpon glafs, were mixed and fell with thefe afhes; feveral birds in cages were fuffocated, and the leaves of the trees in the neighbourhood of Somma were covered with a white and very corrofive falt.

About twelve at night on the 7th, the fermentation of the mountain feemed greatly to increafe. Our author was watching the motion of the volcano from the mole at Naples, which has a full view of it. Several glorious picturefque effects had been obferved from the reflection of the deep red fire within the crater of Vefuvius, and which mounted high amongft thofe huge clouds on the top of it; when a funimer form (called in that country a tropea), came on fuddenly, and blended its heavy watery clouds with the fulphureous and mineral ones, which were already like fo many other mountains, piled up on the top of the volcano. At this moment a fountain of fire was fhot up to an incredible height, cafting fo bright a light, that the fmalleft objects were clearly diftinguifhable, at any place within fix miles or more from Vefuvius. The black ftormy clouds paffing fwiftly over, and at times covering the whole or a part of the bright column of fire, at other times clearing away and giving a full view of it, with the various tints produced by its reverberated light on the white clouds above it, in contraft with the pale flafhes of forked lightning that attended the tropea, formed fuch a fcene as no power of art can exprefs. One of his Sicilian majefty's game-keepers, who was out in the fields near Ottaiano whilft the ftorm was at its height, was furprifed to find the drops of rain fcald his face and hands, a phenomenon probably occafioned by the clouds having acquired a great degree of heat in paffing through the above-mentioned column of fire.

On the 8th, the mountain was quiet till towards fix o'clock in the evening, when a great fmoke began to gather over its crater; and about an hour afterwards, a fubterraneous noife was heard in the neighbourhood of the volcano; the ufual throws of red-hot ftones and fcoriaz began and increafed every infant. The crater, viewed through a telefcopce, feemed much enlarged by the violence of laft night's explofions, and the little mountain on the top was entirely gone. About nine o'clock a moft violent report was heard at Portici and its neighbourhood, which fhook the houfes to fuch a degree, as made the inhabitants run out into the ftreets. Many windows were broken and walls cracked by the concussion of the air on this occafion, though the noife was but faintly heard at Naples. In an infant, a fountain of liquid transparent fire began to rife, and gradually increafing, arrived at laft at the amazing height of ten thoufand feet and upwards. Puffs of fmoke, as black as can poffibly be imagined, fucceeded one another haftily, and accompanied the red-hot transparent and liquid lava, interrupting its fplendid brightnefs here and there, by patches of the darkeft hue. Within thefe puffs of fmoke, at the very moment of emiffion, a bright but pale electrical fire was obferved playing briskly about in zig-zag lines. The wind was fouth-weft, and though gentle, was fufficient to carry thefe puffs of fmoke out of the column of fire, and a collection of them by degrees formed a black and extenfive curtain behind it. In other parts of the fky it was perfectly clear, and the ftars bright. The fiery fountain, of fuch immense magnitude, on the dark ground juft mentioned, made the fineft contraft imaginable; and the blaze of it reflected from the furface of the fea, which was at that time perfectly fmooth, added greatly to this fublime view.

The lava, mixed with ftones and fcoriaz, having rifea to the amazing height already mentioned, was partly directed by the wind towards Ottaiano, and partly falling, ftill red-hot and liquid, upon the top of Vefuvius, covered its whole cone, part of the fummit of Somma, and the valley between them. The falling matter, being nearly as much inflamed and vivid as that which was continually iffuing freft from the crater, formed with it one complete body of fire, which could not be lefs than two miles and a half in breadth, and at the extraordinary height above ftated, caft a heat to the diftance of at leaft fix miles round. The brush-wood on the mountain of Somma was foon in a blaze, and the flame being of a different colour from the deep red thrown out by the volcano, and from the filvery blue of the electrical fire, ftill added to the contraft of this moft extraordinary fcene.

The black cloud, increafing greatly, once bent towards Naples, and threatened the city with fpeedy deftruction; for it was charged with electrical fire, which kept continually darting about in bright zigzag lines, like thofe defcribed by Pliny the younger, in his letter to Tacitus, and which accompanied the great eruption of Vefuvius that proved fatal to his uncle. This fire, however, rarely quitted the cloud, but ufually returned to the great column of fire whence it proceeded; though once or twice it was feen to fall on the top of Somma. Fortunately the wind carried back the cloud, juft as it reached the city, and had begun to occafion great alarm. The column of fire, however, ftill continued, and diffufed fuch a ftrong light, that the moft minute objects could be difcerned at the diftance of ten miles or more from the mountain.

Mr. Morris informed our author, that at Sorrento, which is twelve miles diftant from Vefuvius, he read the title-page of a book by that volcanic light.

Whilft the eruption lafted, a mixed fmell, like that of fulphur, with the vapours of an iron-foundry, was fenfible. The air, after one day's eruption, was filled at night for many hours with meteors, fuch as are vulgarly called falling ftars, which fhot generally in a horizontal direction, leaving behind them a luminous trace, which quickly difappeared. Many fmall volcanic ftones and cinders were afterwards found to have fallen more than thirty miles from Vefuvius, and minute afhes fell in great abundance at the diftance of a hundred miles.

During the eruption, the miferable inhabitants of Ottaiano were involved in the utmoft diftreff and danger, by the fhowers of ftones which fell upon them, and which, had the eruption continued for a longer time, would moft certainly have reduced their town to the fame fituation with Herкулaneum and Pompeii. The mountain of Somma, at the foot of which the town of Ottaiano is fituated, hides Vefuvius from the view of its inhabitants; fo that till the eruption became confiderable, it was not vifible to them. On Sunday night, when the noife increafed, and the fire began to appear above the mountain of Somma, many of the inhabitants flew to the churches, and others were preparing to quit the town, when a fudden and violent report was heard, foon after which they found themfelves involved in a thick cloud of fmoke and afhes; a horrid clafhing noife was heard in the air, and prefently fell a vaft fhower of ftones and large pieces of fcoriaz, fome of which were of the diameter of feven or eight feet, and mult have weighed more than a hundred pounds before they were broken, as fome of the fragments which fir W. Hamilton found in the ftreets ftill weighed upwards of fixty pounds. When thofe large vitrified mafes either ftruck againft one another in the air, or fell on the ground, they broke in many pieces, and covered a large fpace of ground with vivid fparks of fire, which

VOLCANO.

which ignited every thing that was combustible. These masses were formed of liquid lava: their exterior parts were become black and porous, by cooling during their fall through such a vast space, whilst the interior retained an extreme heat, and were perfectly red. To add to the horror of the scene, incessant volcanic lightning darted from the black clouds that surrounded the inhabitants, and the sulphureous smell and heat would scarcely allow them to breathe. In this situation they remained about twenty-five minutes, when the volcanic storm ceased all at once, and Vesuvius remained fullen and silent.

Most volcanoes are observed to have intervals of repose of longer or shorter duration. Vesuvius has been known to remain inactive for many centuries. (See VESUVIUS.) The periods of intermission of Etna and the Peak of Teneriffe have extended to near a century. According to Humboldt, the long intervals of repose appear to characterize volcanoes highly elevated; and he adduces several instances in favour of this opinion; but other instances might be stated which oppose it: thus, the periods of repose of Vesuvius have been much longer than those of Etna; and Vulcano, which is far lower than Vesuvius, had no eruption from the fourth to the fifteenth century, or during a period of eleven hundred years.

The volcano of Stromboli is the only one at present known, which appears to be in a state of constant activity. The most ancient accounts of the conflagrations of Stromboli, transmitted by history, are prior to the Christian era about two hundred and ninety-two years; but at what time the eruptions first commenced we are entirely ignorant. Stromboli was burning in the time of Augustus and Tiberius; but for want of documents, we are unacquainted with the state of this volcano for a series of years afterwards. We know, however, from various public testimonies, that the continued eruptions have lasted some centuries. The crater is situated on the side of the mountain. Spallanzani, who looked into it from an eminence immediately above it, says that it has a circular conical form, and is about three hundred and forty feet in circumference at the brink. To a certain height the crater is filled with liquid red-hot matter, resembling melted brass: this is the fluid lava. It appeared to be agitated by two distinct motions: the one intestine, whirling, and tumultuous; by the other motion it was impelled upwards. The liquid matter is raised sometimes with more and sometimes with less rapidity within the crater; and when it has reached the distance of twenty-five feet from the upper edge, a sound is heard not unlike a very short clap of thunder; while, at the same instant, a portion of the lava, separated into a thousand pieces, is thrown up with indescribable swiftness, accompanied with copious eruptions of smoke and sand.

A few moments before the report, the surface of the lava is inflated and covered with large bubbles, some of which are several feet in diameter. On the bursting of these bubbles, the detonation and fiery shower take place. After the explosion, the lava sinks within the crater, but soon rises as before, and new bubbles appear, which again burst, and produce new explosions. When the lava sinks, it produces little or no sound; but when it rises, and begins to be inflated with bubbles, it is accompanied with a sound like that of liquor boiling vehemently in a cauldron, but greater in proportion to the magnitude of the crater. In the smaller and moderate ejections, the stones fell into the crater, and, at their collision with the lava, produced a sound similar to that of water struck by a number of staves; but in the greater ejections, a considerable quantity of them fell without the mouth of the crater. The redness of the larger

stones was visible in the air, notwithstanding the light of the sun. The lava, when it rose or fell, emitted but little smoke; but a great quantity issued from the fissures, when it exploded. This disappeared almost instantly after the explosion, like the smoke from the firing of gunpowder. Though the ejection of the larger and heavier stones have short intermissions, those of the lesser have scarcely any. Did not the eye perceive from whence these showers of stone originate, they might be supposed to fall from the sky. The noise of the more violent eruptions, and the darkness from the ascending smoke, present together the image of a tempest. During the night, the red-hot stones spread like a sheaf, and have the appearance of a beautiful fire-work.

It has been observed of Stromboli, that the inflammation is in general more considerable in winter than in summer, and more intense on the approach of, or during, storms than in calm weather. The materials which supply the eruptions appear to be inexhaustible; and there is reason to believe that the volcanic fires of Stromboli and Vulcano have an internal communication with those of Etna and more distant countries, as we shall presently have occasion to notice.

Boiling water and mud are occasionally thrown out of volcanoes, but more frequently from the American volcanoes than from those in Europe. This phenomenon is very different from that of mud volcanoes, more properly so called, the water ejected from which is cold.

The water ejected from fire volcanoes is probably what finds access to the deep mass of melted lava, either from the sea in the vicinity, or from the neighbouring lakes. Vesuvius is stated at one time to have thrown out a considerable quantity of salt water.

The most remarkable circumstance attending the volcanic eruptions in America is that stated by Humboldt, who informs us that great quantities of fish are sometimes ejected from the crater at the top, and sometimes from the sides of the mountain, through lateral openings; but always from an elevation more than fifteen thousand feet above the level of the sea. M. Humboldt has given the name of *pimelodus cyclopus* to this species of fish. Some of them are found living in the rivers on the sides of the mountains, and in all probability they exist in subterranean lakes, the sides of which are broken down during violent commotions, or melted by heat: hence the water finds its way to the crater, and is ejected with other materials. From this access of water, the mud or slime thrown out, called by the Indians *moya*, is probably formed.

In many instances, however, the torrents of water which issue from volcanoes arise from the rapid thawing of the snow on the summit. According to Humboldt, the colossal volcanic cones in the Andes, covered with snow, have become so hot in a single night as to melt the whole of the snow, and occasion the most extensive and fatal inundations. Torrents of water issued from Etna, in the eruption of 1755; but, according to Ferrara, they did not flow out of the crater, but from the snow and ice on the surface suddenly thawed by the lava. A mass of this ice, partially melted by the lava, left a pile in the midst standing like a superb palace of crystal.

It is only by observations made in or near the crater, when a volcano is in a quiescent state, that we can gain any knowledge of the saline or inflammable matter, which may either have served as fuel to the volcano, or have been produced by the eruption, or been subsequently sublimed. Of these we shall speak more particularly, in describing *Volcanic Products*, infra. The rapidity and extent of a current of

lava will depend on its fluidity, the quantity thrown out, and on the more or less rapid declivity of the mountain.

From various experiments made by Spallanzani and others, on the melting of lavas, it appears that they are susceptible of different degrees of fluidity, according to the degrees of temperature to which they are subjected. These gradations of fluidity, proportioned to the degree of heat, take place in other stones or substances fusible by fire, as may be observed in the slag from our furnaces. In some instances, the lava appears to have the perfect fluidity of water. According to professor Bottis, who was an eye-witness in 1776, the lava spouted from three small cones or apertures on Vesuvius, precisely like water, forming three beautiful fountains of fire, which described curves of different dimensions as they fell. He says also, that he has twice seen the inflamed matter break forth and disgorge in the Atrio del Cavallo, at the foot of the volcanic cone of Vesuvius. From its great fluidity, it resembled water issuing with violence from under the earth, and inundating the adjacent country. The current of lava, which flowed from this mountain in 1776, struck upon the lava of 1771, and rebounded into the air, congealing in various figures, terminating in thin sharp points like needles. In the eruption of 1754, the lava formed two branches, which flowed thirty feet in forty-five seconds, or above half a mile an hour; and uniting lower down, proceeded at the rate of thirty-three feet in fifty seconds. In 1765, the lava is stated to have flowed at the rate of a mile an hour. Another branch of the same lava is said by Sir William Hamilton to have had a velocity equal to that of the river Severn at Bristol. In 1776, a torrent of lava from the summit of Vesuvius was observed to flow a mile and a half in fourteen minutes. When the declivity is very gentle, the motion is slow, if the current is not pressed forward by new supplies of melted matter. Notwithstanding the velocity of torrents of lava, their tenacity is much greater than might at first have been expected. Sir William Hamilton informs us, that the lava of Vesuvius in 1765, which flowed a mile an hour, almost resisted any impression made on it with a long pole; and some large stones, thrown upon it with great force, did not sink, but making only a slight impression, swam upon its surface. The tenacity and resistance of lavas, even when flowing, is, says Spallanzani, an evident consequence of the action of the cold atmosphere. The loss of heat so occasioned is incomparably greater on the surface than in the internal parts, in which the lava still retains a considerable degree of fluidity, as appears on breaking the crust. The different currents of lava from Etna have flowed to the distance of fifteen, twenty, and even thirty miles from their source; and the current of lava, which flowed during the volcanic eruption of 1783 in Iceland, extended nearly sixty miles in length.

New Volcanoes.—When a volcano breaks out in a new situation, the phenomena are generally somewhat different; but it may be proper to remark, that we have no instances of volcanoes breaking out on land, in countries that are not or have not formerly been volcanic. New openings have indeed been made, at the distance of several miles from any existing volcano; but they have taken place in a volcanic or basaltic soil. From present appearances we are warranted in the conclusion, that all volcanoes were originally submarine. The most remarkable instance of the formation of a range of volcanic mountains in a new situation is that recorded by Humboldt of the volcano of Jorullo, and the adjoining hills, in the intendency of Valladolid, or Mechoacan, in New Spain, on the 29th of September, 1759.

A vast plain extends from the hills of Aguafarco nearly

to the villages of Teipa and Petatlan. This plain is in some parts not more than two thousand six hundred feet above the level of the sea: it contains various conical hills of basalt and porphyry, crowned with evergreen oaks and palm-trees. Till the middle of the eighteenth century, part of the plain was cultivated with sugar-canes and indigo. It was bounded by basaltic mountains, the structure of which indicated that, at a very remote period, this country had several times been convulsed by volcanoes. These fields, watered by artificial means, belonged to the plantation of San Pedro de Jorullo, one of the largest and richest in the country. In the month of June, 1759, hollow subterranean noises of a most alarming kind were accompanied by earthquakes, which succeeded each other for sixty days, to the great consternation of the inhabitants. After the commencement of September, tranquillity appeared re-established; but on the nights of the 29th and 30th, the horrible subterranean noises were renewed. The affrighted inhabitants fled to the mountains of Aguafarco.

A tract of ground, ten English miles in extent, rose up in the shape of a bladder above the old level of the plain. Near the edges it is only thirty-nine feet above the plain; but towards the centre, the convexity of the ground rises to the height of five hundred and thirty-four feet above its former level. This part of the ground is called *Malpays*. Those who witnessed the scene from the top of Aguafarco assert that flames were seen to issue forth from an extent of more than half a league, that fragments of burning rocks were thrown to a prodigious height, and that the softened surface of the earth seemed to swell like an agitated sea. The rivers Cuitambo and San Pedro precipitated themselves into the burning abyss, and appeared to invigorate the flames. Torrents of mud and clay, enveloping balls of basalt in concentric layers, were thrown out. Thousands of small cones rose up in the Malpays, from each of which a thick vapour ascended. In the midst of these cones was opened a large chafn, from which were thrown out six large masses or mountains, from thirteen to sixteen hundred feet in height above the level of the plain: the most elevated of these is the volcano of Jorullo. Here we have a range of volcanic hills formed in a few days, in the same manner as the Monte Nuovo near Naples, but of an extent and elevation exceeding that of the Malvern hills in Worcester-shire, or the Pentland hills near Edinburgh.

The volcano of Jorullo is still continually burning, and according to M. Humboldt's account, who visited it in 1803, it has thrown up on the north side an immense quantity of scoræe and basaltic lavas, containing fragments of primitive rocks. The first great eruption continued to the year 1760; in the following years, the explosions became gradually less frequent. The traveller is still shewn where the rivers Cuitambo and San Pedro disappeared on the night of September 29, 1759. About one mile and a half lower down now rise up two rivers, impregnated with mineral matter, having a temperature of 126° Fahrenheit.

There is one circumstance attending this great eruption, which seems peculiar to the formation of new volcanoes or volcanic cones. An immense rent is made in the surface, through the whole of which the matter is ejected, until the chafn becomes choked up in different parts, and the eruptions are confined to a few openings, round which the matter is accumulated, forming a series of craters or mountains, ranged in one line. A similar range of volcanic cones was formed on the side of Etna, nearest Lingua Grossa, in the year 1809. In this eruption, nine new boccas or craters were formed in the same line, near to each other. The ancient volcanoes in Auvergne, which are ranged in a line of

sixty miles, and also other volcanic ranges of great extent, have probably been formed by enormous chasms, partially choaked up in the same manner. Indeed the new volcanic range, of which Jorullo forms a part, is placed in the direct line of a volcanic range of vast extent, which this eruption appears to have partially re-opened. Humboldt observes, that in New Spain there is a narrow zone placed between latitude $18^{\circ} 59'$ and $19^{\circ} 12'$, in which the lofty volcanoes that still continue to burn, or which from their form and the nature of the rocks may be inferred to have been once volcanic, are situated. In receding from the Atlantic, we find in the same line, ranging east and west, the Pic d'Orizaba, the two volcanoes of Le Puebla, the Nevada de Toluca, and the volcano of Colima. The parallel of their greatest elevation ranges nearly at right angles with the chain of mountains that form the Cordillera of Anahuac; and it is worthy of observation, that the volcano of Jorullo forms a prolongation of that line, on the same parallel with the ancient Mexican volcanoes. Do not these analogies, he adds, entitle us to suppose that in this part of Mexico there exists, at a great depth in the earth, a chasm, extending in a direction from east to west one hundred and thirty-seven leagues, along which the volcanic fire, at different epochs, has burst through the porphyritic crust, from the gulf of Mexico to the South sea? This chasm may also extend to the group of islands called the Archipelago of Revelgado, placed in the same parallel of latitude, around which pumice-stone has been seen floating.

For an account of the volcanic eruption which formed Monte Rosso on Etna, see *ÆTNA*.

A tremendous noise and violent concussions of the earth preceded the repeated discharges of scorice and sand in this eruption; yet during all these convulsions, the summit of Etna was perfectly quiet, and only emitted a light smoke, which had issued with the same tranquillity before the eruption. A range of volcanic hills was formed in a similar manner near the foot of Vesuvius, in 1760. After repeated concussions of the earth, which were felt fifteen miles round the mountain, a vast opening was made in the territory of Torre del Greco, from which fifteen volcanoes arose; eight of these were soon covered by a torrent of lava, which rushed from one of them; the other seven remaining entire, and incessantly ejecting from their mouths vast quantities of ignited substances, which falling almost perpendicularly round the new volcanoes, produced in ten days seven small mountains of various heights, disposed in a right line. During the eruption, the noises sometimes resembled violent thunder, at others the discharge of artillery; large stones were thrown to the height of nine hundred and sixty feet. After the tenth day, the eruption ceased, and the newly-formed mountains gradually cooling, permitted a nearer approach; some of them had at their summits a cavity resembling a funnel, others a hollow of greater or less depth.

The Lipari islands extend in a right line about fifty miles from east to west, except Vulcano, which makes a small angle. These islands, as well as the volcanic isles of the Moluccas, which form a chain in the Indian ocean, probably originated from enormous chasms, like those which formed Jorullo, and the ranges on the sides of Etna and Vesuvius. These chasms were in all probability first opened under the ocean.

When a volcano opens in a new situation, the commotions which precede it will be greater than when the eruption takes place from craters already formed. The resistance occasioned by the congelation of lava in the mouth and passages of the principal crater, may be greater than

from other parts of the surface, in which case the liquid lava, confined and compressed by the expansive force of heat and elastic vapour, may be driven laterally to a great distance between the seams and fissures of the strata, upheaving the surface in some parts, and softening it or melting it in others, producing earthquakes in countries far remote from the principal crater, which will continue till a new opening is made.

It is related by Strabo, that the island of Eubœa had been for a long time violently agitated by earthquakes, when a large rent opened in the plain of Lelantum, from which was ejected a river of fiery mud; after this the earthquake ceased. Other instances of violent earthquakes, felt at the distance of many hundred miles from the place of eruption, are not uncommon, as we shall soon have occasion to notice. The lateral pressure occasioned by a column of lava two miles in height, must be enormously great, and from this cause alone we might expect, that in very lofty volcanoes, like Etna, the eruptions should be more frequent from the sides than the summit, which is found to be the fact. The sudden retiring of the sea from the shore before an eruption has frequently been noticed. This can only be satisfactorily explained by the upheaving of the softened surface of the ground; and during violent earthquakes, the anchors let down at a distance from the shore have been observed to be heated, proving the state of the ground below.

Submarine Volcanoes.—When a volcano breaks out under the surface of the sea, the phenomena attending the eruption vary considerably from those observed on land, owing to the opposition of conflicting elements, the resistance made to the eruption, and the more sudden cooling of the matter ejected. It is the opinion of Humboldt, that in all submarine volcanoes, the crust of the earth is softened and swelled by subterranean heat, till it rises above the surface of the ocean even from great depths, before any eruption takes place. From the narrative of eye-witnesses, we have reason to believe that in many instances the opinion of Humboldt is correct. There are, however, volcanic eruptions which undoubtedly take place at the bottom of the sea, and the appearance of new land is caused by the stones and scorice thrown up from thence: the more rapid cooling of the crust of the lava may also accelerate the formation of a new island. We have also instances of immense quantities of pumice floating in the ocean some hundred leagues from land, which could only proceed from the eruption of volcanoes at so great a depth under the sea as to prevent no other volcanic phenomena on its surface. The submarine volcanoes which have been observed since the records of authentic history are not very numerous, nor will this appear surprising, when we consider that the ocean has not been extensively traversed by civilized men more than a few hundred years. The numerous volcanic islands scattered over the globe, which are evidently formed by subterranean fire, may however convince us, that the phenomena of submarine volcanoes have been not unfrequent in a former condition of the globe. The submarine volcanoes of which we have the earliest account, are those in the Grecian Archipelago, near the island of Santorini. This island forms a triangle with the island of Melo, which is volcanic, and with Paros, so celebrated for its marble. The sides of the triangle are about fifteen leagues each.

Santorini, formerly Thera, and afterwards St. Irene, was furnished by the Greeks *Καμινος*, or *burnt*, and so in fact the soil is. There is a tradition, says Pliny, (lib. ii. cap. 87.) "that it rose out of the sea in a very remote but unknown period." The sea is very deep near Santorini, there being

VOLCANO.

no ground for anchorage near it. The ancients have left us the following account of the eruptions in its vicinity.

In the fourth year of the 135th Olympiad, or 236 B. C., the island of Theraia rose in the midst of fire from the sea; it is separated from Santorini by a strait of a mile and a half in breadth.

A hundred and thirty years afterwards, the island of Automate, called also Hiera, rose near it; and one hundred and ten years after this, another island, called Thia, rose two hundred and fifty paces from Hiera. These three eruptions are recorded by Pliny, in the place above cited; by Strabo, lib. i.; and by Seneca, in the *Quæstiones Naturales*, lib. vi. cap. 21.

Since the Christian era, we have the following accounts of the submarine eruptions near Santorini.

In the year 726, Thia was joined to Hiera by a quantity of lava ejected, together with ashes and red-hot rocks.

In 1457, the island was still farther increased by a similar eruption. This event and the date are attested by an inscription on a marble stone erected near the gate of fort Scaumo, in Santorini.

A sixth eruption, in 1576, produced a new island, called the Little Kamenoi.

According to the account of Kircher, a cotemporary author, there was an eruption in 1650, which lasted a twelvemonth, from the 24th of September to the 9th of October in the following year. "The sea rose to the height of forty-five feet, and that at such a distance, that some galleys of the grand seignor's were wrecked in the port of Candia, situated more than eighty miles from Santorini, and Smyrna and Constantinople were incommoded with the ashes, which rushed out of the sea in whirlwinds of flame. Another great eruption took place in 1707 and 1708, whereby the Little Kamenoi was increased, and is now more than three leagues in circumference. On the 23d of May, 1707, after an earthquake that happened the night before, a new island was discovered by some seamen, who taking it for a wreck, rowed immediately toward it, but finding rocks and earth, instead of the remains of a ship, hastened back, and spread the news of what they had seen in Santorini. How great soever the apprehensions of the inhabitants were at the first sight, their surprize soon abated; and in a few days, seeing no appearance of fire or smoke, some of them ventured to land on the new island. Their curiosity led them from rock to rock, where they found a kind of white stone, that cut like bread, which it nearly resembled in its form and consistence. They also found many oysters sticking to the rocks; but while they were employed in gathering them, the island moved and shook under their feet, upon which they ran with precipitation to their boats. With these motions and tremblings the island increased not only in height, but in length and breadth; yet sometimes, while it was raised and extended on one side, it sunk and diminished on the other.

"Our author observed a rock rise out of the sea forty or fifty paces from the island, which having continued four days, sunk, and appeared no more; but several others appeared and disappeared alternately, till at last they remained fixed and unmoved. In the mean time, the colour of the surrounding sea was changed: at first it was of a light green, then reddish, and afterwards of a pale yellow, accompanied with a noisome stench, which spread itself over part of Santorini.

"On the 16th of July the smoke first appeared, not indeed from the island, but from a ridge of black stones which suddenly rose about sixty paces from it, where the depth of the sea was unfathomable. Thus there were two separate

islands, one called the White and the other the Black island, from their different appearances. This thick smoke was of a whitish colour, like that of a lime-kiln, and was carried by the wind to Santorini, where it penetrated the houses of the inhabitants.

"In the night between the 19th and 20th of July, flames began to issue with the smoke, to the great terror of the inhabitants of Santorini, especially those of the castle of Scaro, who were not above a mile and a half distant from the burning island, which now increased very fast, large rocks daily springing up, which sometimes added to its length, and sometimes to its breadth. The smoke also increased, and there being no wind, it ascended so high as to be seen at Candia and other distant islands. During the night it resembled a column of fire, fifteen or twenty feet high; and the sea was then covered with a scurf or froth, in some places reddish, and in others yellowish, from which proceeded such a stench, that the inhabitants throughout the whole island of Santorini burnt perfumes in their houses, and made fires in the streets to prevent infection. This indeed did not last above a day or two, for a strong gale of wind dispersed the froth, but drove the smoke upon the vineyards of Santorini, by which the grapes in one night were parched up and destroyed. This smoke also caused violent head-aches, attended with retchings.

"On the 31st of July, the sea smoked and bubbled in two different places near the island, where the water formed a perfect circle, and looked like oil when ready to boil. This continued above a month, during which many fish were found dead on the shore of Santorini. The following night a dull hollow noise was heard, like the distant report of several cannon, which was instantly followed by flames of fire, shooting up to a great height in the air, where they suddenly disappeared. The next day the same hollow sound was several times heard, and succeeded by a blackish smoke, which, notwithstanding a fresh gale blew at that time, rose up in the form of a column to a prodigious height, and would probably in the night have appeared as if on fire.

"On the 7th of August the noise was different, it resembled that of large stones thrown all together into a deep well. This noise having lasted some days, was succeeded by another much louder, so nearly resembling thunder, as hardly to be distinguished from three or four real claps that happened at the same time.

"On the 21st, the fire and smoke very considerably diminished, but the next morning they broke out with greater fury than before. The smoke was red and very thick; and the heat was so intense, that all around the island the sea smoked and bubbled in a surprising manner. At night, our author viewing with a telescope a large furnace upon the highest part of the island, discovered sixty smaller openings or funnels, all emitting a very bright flame; and he imagined there might be many more on the other side of the great volcano. On the 23d of August, in the morning, the island was much higher than the day before, and its breadth was increased by a chain of rocks, sprung up in the night almost fifty feet above the water. The sea was also again covered with reddish froth, which always appeared when the island received any considerable additions, and occasioned an intolerable stench, till it was dispersed by the wind and the motion of the waves.

"On the 5th of September the fire opened another vent at the extremity of Black island, from which it issued for several days, during which but little was discharged from the large furnace: and from this new passage the astonished spectators beheld the fire dart up three several times, to a vast height, resembling to many prodigious sky-rockets, of a glowing

VOLCANO.

glowing lively red. The following night the subterranean fire made a terrible noise, and immediately after, a thousand heaves of fire blew up into the air, where breaking and dispersing, they fell like a shower of stars upon the island, which appeared all in a blaze, presenting to the amazed spectators at once a most dreadful and beautiful illumination. To these natural fire-works succeeded a kind of meteor, which for some time hung over the castle of Scaro, which is seated on a high rock in the island of Santorini, a meteor not unlike a fiery sword, and which served to increase the terror of the inhabitants.

“ On the 9th of September, the White and Black islands united, after which the western end of the island daily increased. There were now only four openings that emitted flames, which issued forth with great impetuosity, sometimes attended with noise like that of a large organ-pipe, and sometimes like the howling of wild beasts. On the 12th, the subterranean noise became much augmented, having never been so frequent or so dreadful as on that and the following day. The bursts of this subterranean thunder, like a general discharge of the artillery of an army, were repeated ten or twelve times within twenty-four hours; and immediately after each clap, the large furnace threw up huge red-hot stones, which fell into the sea at a great distance. These claps were always followed by a thick smoke, which spread clouds of ashes over the sea and the neighbouring islands.

“ On the 18th of September an earthquake was felt at Santorini, but did no great damage, though it considerably enlarged the burning island, and in several places gave vent to the fire and smoke. The claps were also more terrible than ever, and in the midst of a thick smoke, that appeared like a mountain, large pieces of rock were thrown up with as much noise and force as balls from the mouth of a cannon, which afterwards fell upon the island, or into the sea. One of the small neighbouring islands was several times covered with these fiery stones, which being thinly crufted over with sulphur, gave a bright light, and continued burning till that was consumed.

“ On the 21st, after a dreadful clap of subterranean thunder, very great lightnings ensued, and at the same instant the new island was so violently shaken, that part of the great furnace came tumbling down, and huge burning rocks were thrown to the distance of two miles and upwards. This seemed to be the last effort of the volcano, and to have exhausted the combustible matter, as all was quiet for several days after. But on the 25th the fire broke out again, with still greater fury, and among the claps was one so terrible, that the churches of Santorini were soon filled with crowds of people, expecting every moment would be their last; and the castle and town of Scaro suffered such a shock, that the doors and windows of the houses flew open. The volcano continued to rage during the remainder of the year; and in the month of January 1708, the large furnace without intermission threw out stones and flames at least once or twice, but generally five or six times a day.

“ On the 10th of February, in the morning, a pretty strong earthquake was felt at Santorini, which the inhabitants considered as a prelude to greater commotions in the burning island: nor were they deceived; for soon after, the fire and smoke issued in prodigious quantities; the claps like thunder were redoubled; and nothing appeared but objects of horror and confusion. Rocks of an amazing size were raised up to a great height above the water, and the sea raged and boiled to such a degree, that it occasioned great conflagration. The subterranean bellows were heard without intermission, and sometimes, in less than a quarter of an hour, there were six or seven eruptions from

the large furnace. The noise of the repeated claps, the quantity of huge stones that flew on every side, the houses tottering to their very foundations, and the fire which now appeared in open day, surpassed all that had hitherto happened, and formed a scene astonishing beyond description.

“ The 15th of April was rendered remarkable by the number and violence of the bellows and eruptions, by one of which near a hundred large stones were thrown up all together into the air, and fell again into the sea, at about two miles distance. From this time to the 23d of May, which might be called the anniversary of the birth of the new island, things continued much in the same state; but afterwards the fire and smoke by degrees subsided, and the subterranean thunders became less terrible.

“ On the 15th of July, 1709, our author, accompanied by the Romish bishop of Santorini and some other ecclesiastics, hired a boat to take a near view of the island. They made directly towards it, on that side where the sea did not bubble, but where it smoked very much. Being got into this vapour, they felt a close suffocating heat, and found the water very hot and sultry. Having encompassed the island, and surveyed it carefully from an adjacent one, they judged it to be two hundred feet above the sea, about a mile broad, and five miles in circumference; but not being thoroughly satisfied, they resolved to attempt to land, and accordingly rowed toward that part of the island where they perceived neither fire nor smoke; but when they got within a hundred yards of it, the great furnace discharged itself with its usual fury, and the wind blew upon them a thick smoke, and a shower of ashes, which obliged them to quit their design. Having retired a little, they let down a plummet, with a line ninety-five fathoms long, but it was too short to reach the bottom. On their return to Santorini, they observed that the heat of the water had melted most of the pitch from their boat, which was before grown very leaky. For several years afterwards the island continued to increase, and the fire and subterranean noises abated.”

Another eruption, almost equally violent, took place in 1767, in the month of June, and a new island was formed between the Little Kameni and the island of Hiera. It is named the Black island, and is twice as large as the Little Kameni. There have been nine of these submarine eruptions recorded in the space of twenty-one centuries, and probably many others have occurred at great depths, without raising new islands. Thevenot, a respectable traveller, who visited Santorini in 1655, states that eighteen years before his arrival in the island, a violent noise was heard there, and even at Chios, though distant two hundred miles, and was at first supposed to be occasioned by an action between the Venetian and Turkish fleets. A short time after, a vast quantity of pumice-stone rose from the bottom of the sea, near the harbour, with such violence and noise, as to resemble repeated discharges of artillery, which so infected the air, that several persons died at Santorini, and others lost their sight. The infection extended to Chios and Smyrna. The pumices thrown up covered the sea in such a manner, that when certain winds prevailed, the harbours were so blocked up with them, that not even the smallest vessels could get out, till a way was made for them, by removing the pumices with long poles; and they were still, in 1655, seen scattered over the whole Mediterranean. Voyages de M. Thevenot, prem. part.

Various submarine volcanoes have broken out near the islands called Azores or Terceiras, and have raised several new islands. The phenomena attending their formation were similar to those which took place at Santorini. These eruptions have occurred since the Azores were first visited by Europeans.

VOLCANO.

Europeans. The Azores, indeed, appear to have been all formed in a similar manner at a remote period. Most of the newly formed islands have sunk down some months after their emergence. So recently as 1811, a small island was raised by a submarine eruption, at a little distance from St. Michael's. It was a mass of black rock, described by the captain of the Sabrina frigate, who witnessed its formation, to be equal in height to Matlock High Tor, in Derbyshire. In 1813 it had disappeared, and there is now eighty fathoms water in the place.

In 1783, about the end of January, flames broke out from the sea, at the distance of thirty miles from Cape Reckianes, at the south-west extremity of Iceland, and continued to burst forth during several months. In June earthquakes shook the whole of Iceland, and the flames from the sea disappeared. A dreadful eruption then commenced from the Shaptaa Jokul, nearly two hundred miles distant from the place where the submarine volcano broke out. This eruption is one of the greatest recorded in history. The inhabitants of Iceland never saw the sun during the remaining part of the summer, and black volcanic sand fell in the Orkney islands, and was called black snow. The whole of Europe was covered with a haze, which greatly obscured the atmosphere when no clouds were present. It was in the summer of the same year that the dreadful earthquakes in Sicily took place, which nearly destroyed the harbour of Messina, and did incalculable damage in various parts of Calabria. According to the account of Sir George Mackenzie, the volcano of Heckla is nearly in a direct line between the submarine volcano and the Shaptaa Jokul, which indicates that a communication subsisted between them: hence, says he, we may conjecture, "that the depth of the source from whence they both proceeded was very great." Were we to admit that the source of the motion which produced the earthquakes in Calabria was the same with that of the volcanic fires in Iceland, we must place it some thousand miles below the surface, if not in the centre of the globe itself.

Mud Volcanoes.—Besides the volcanoes already described, there are others resembling them in many circumstances, but differing in this important one, that instead of fire, they throw out water and mud. They are much less common than fire volcanoes. There is one in the island of Sicily; there are others in the Crimea and its vicinity; and one also in the island of Java.

Maccaluba, in Sicily, is situated between Arragona and Girgenti, formerly Agrigentum. In its vicinity is a conical hill truncated, and forming a plain at the summit of half a mile in circumference.

The whole surface of this plain is a thick mud, yet not so firm, but that it sometimes occasions a fear of sinking into it. There is not the slightest sign of vegetation upon it. The depth of the mud is unknown, but it is supposed to be immense.

In the course of the year this plain presents two different appearances. In the rainy season the mud is much softened; it has an even surface, on which there is nothing more to be seen than a general ebullition, accompanied with a very sensible rumbling noise. At this time it is dangerous to go upon the spot. In the dry season the scene changes, the mud acquires greater consistency, but without ceasing its motion; the plain assumes a form slightly convex, and a number of little cones are thrown up, which, however, rarely rise to the height of two feet. Each of them has its crater, where a black mud is seen in constant agitation, and incessantly emitting bubbles of air. With these the matter insensibly rises. As soon as the crater is full of it, it dis-

gorges: the residue sinks, and the cone has a free crater until a new emission. In this season also, to the west of this small plain, there appear some cavities full of muddy salt-water, from which likewise bubbles of air are thrown up; but here it is without noise; whereas in the cones, the air makes a crackling, as when it proceeds from water that boils violently.

Such are the regular states of this extraordinary hill in the course of the year. It would probably have obtained but little attention, had these been the only phenomena it presents.

But at times the hill assumes quite another character, being subject to convulsions alarming to all its environs. They are denoted by earthquakes, which are felt at the distance of two or three miles. Internal noises, resembling the rolling of subterranean thunder, are heard; they increase for several days, and then end in an eruption of a prodigious fountain of mud, earth, and stones, which rises two or three hundred feet into the air. This explosion is sometimes repeated twice or thrice in the course of the twenty-four hours. Some years the mount has no eruptions. Of the eruption in 1777, Ferrara gives the following account. "Dreadful noises were heard all around, and from the midst of the plain an immense column of mud arose to the height of about one hundred feet, which, on descending, assumed the appearance of a tree at the top. Stones of all kinds and sizes were darted up violently and vertically within the body of the column. This terrible explosion lasted half an hour, when it became quiet; but after a few minutes resumed its course, and with these intermissions, continued all the day. During the time of this phenomenon, a pungent smell of sulphuretted hydrogen gas was perceived at a great distance. On the following day the new orifices had ejected several streams of calcareous earth (called by Ferrara chalk); this had covered with a crust of many feet all the surrounding space, filling the cavities and chinks. The hard substances ejected were fragments of calcareous tufa, of crystallized gypsum, pieces of quartz and of iron pyrites, which had lost their lustre, and were broken to pieces.

The apparent boiling of the mud proceeds from the escape of bubbles of gas, for the mud does not feel warm, and the thermometer, on being immersed in it, fell three degrees. Of the other mud volcano, we have the following account by Pallas, *Tableau Physique de la Taurida*, 1794.

The island of Taman is situated near the peninsula of Kenha, and is separated from it by one of the mouths of the river Cuban, on the south-east of Little Tartary, now Taurida. The country is flat, and covered with beds of slime, mixed with mud, and with some beds of marl and sea-shells. Copious springs of petroleum are found in several places, also pools of greater or smaller dimensions, from most of which a briny mud is disgorged with bubbles. There are three of these pools in the peninsula, and seven or eight in Taman. One of the latter, several fathoms in diameter, situated on the side of a hill, flows by its incessant bubbling the abundance of gas that keeps it working; the liquid river is constantly falling over the brim of it, and flowing off slowly. On the top of the same hill are seen three small eminences, which are evidently formed by the mud vomited by three similar pools, formerly open. At the foot are two little lakes of salt-water, which smell of petroleum. Persons settled at Yenikoul for fifteen or twenty years past, remember an explosion on this hill, accompanied with circumstances similar to what took place in a different part of the island, six months previous to the author's journey.

This last eruption occurred in February, 1794. It was
the

the greatest and most copious ever known. It happened at the top of a hill, situated at the north point of Taman, near the bay of the same name. The appearance of the place seems to indicate that there had been a similar eruption at a remote period, for the ground that was not covered over by the last eruption, is of the same nature as the more recent sediments, being the same soil, with the difference only which vegetation and atmospheric influence must necessarily produce.

The place where the new gulf opened was a pool where the snow and rain-water usually remained for a long time. The explosion took place with a noise like that of thunder, and with the appearance of a mass of fire in the form of a sheaf, which lasted only about half an hour, accompanied by a thick smoke. The ebullition, which threw up a part of the liquid mud, lasted till next day, after which the mud continued running over slowly, and formed six streams, which made their way from the top of the hill to the plain. The body of mud collected by these streams is from six to ten feet deep, and may be reckoned more than a hundred thousand cubic fathoms! In July, the time when M. Pallas visited the place, the surface of those beds of mud was dry, extremely uneven, and cracked like clayey ground. The gulf that had vomited them was stopped up with the mud, which was likewise dry. It was not dangerous to walk over it, but it was frightful, as the horrid bubbling, which was then still heard in the interior of the hill, shewed that it was not so tranquil as at the surface. The mud thus discharged is always a soft clay of a blueish-ash colour, every where of the same nature, mixed with brilliant sparks of mica, and with fragments of marly, calcareous and sandy schist, which seem torn from the beds directly over the reservoir whence the explosion proceeds. Some crystals and sparkling laminae of pyrites found in these fragments, prove that the heat of the reservoir was not sufficiently powerful to affect the beds which contained those pyrites, nor was the mud discharged from the gulf more than luke-warm. The appearance of fire, which M. Pallas heard described as accompanying the eruption, was probably inflamed hydrogen gas. He supposes that a bed of coal has for ages been on fire under Kercha and Taman, and that the sea at times breaking into the cavities, produces a quantity of steam, the expansion of which, and the generation of hydrogen gas, force open a passage for the mud, and drive it upwards in its ascent. This opinion we shall consider when we treat of the probable causes of volcanic eruptions in the present article. In the Penang Gazette of February 10, 1816, there is an account of a mud volcano of great extent in the island of Java, resembling in all the important particulars those described in Sicily and Taman. It is situated in the plains of Rogobogo, N.E. of Solo, near the village of Kuhoo. The mud volcano, if it may be so called, forms an elevated plain, about two miles in circumference, which may be regarded as the crater. In the centre of this plain very large bubbles of mud rose, and swelled up to the height of ten or fifteen feet, which on bursting emitted volumes of dense white smoke. These large bubbles, of which there were two, continued to rise and burst seven or eight times in a minute, and often threw up two or three tons of mud. The smoke had the smell of sulphuretted hydrogen, or, as it is described, like the washing of a gun-barrel. As the bubbles burst, they threw out the mud round the centre with a noise occasioned by the falling of the mud on the plain, composed of the same mud. Smaller bubbles rose from some parts of the plain: from other parts round the large bubbles small quantities of sand were occasionally shot up to the height of twenty or thirty feet, unaccompanied with smoke.

VOL. XXXVII.

This was in parts where the mud was of too stiff a consistency to rise in bubbles. The mud in every part felt cold. The water which drains from the mud is collected by the Javanese, and exposed to the sun in the hollows of split bamboos, where it deposits common salt in crystals. This salt is reserved exclusively for the use of the emperor. In wet weather the brine is less strong than when the weather is dry. The phenomena attending all mud eruptions are very similar; in all of them, the muriate of soda (common salt) is either produced, or is itself an agent in producing the fermentation which is the immediate cause of the eruption. Though the great volcanoes in America sometimes throw out water and mud, as before noticed, they are properly fire volcanoes, into which water finds access. The water is generally hot, and its ejection only occasional.

Pseudo-Volcanoes.—The German geologists have given the name of pseudo or false volcanoes to those casual inflammations of beds of coal, that occasionally occur in coal districts, and continue in greater or less activity for many years. These inflammations are too trifling in extent or intensity, to be compared with true volcanic eruptions, nor do they present the same phenomena; for we have never seen a torrent of lava, however small, thrown out by any of these pseudo-volcanoes.

Beds of coal of considerable extent have been burning for many years near Bilston, in Staffordshire.

By the continued action of fire on the strata of clay and shale which accompany coal, some singular effects are produced, the clay becomes indurated, approaching to the state of jasper; and what is called porcellanous jasper is, in some instances, formed by these fires.

From some beds of coal, great quantities of carburetted hydrogen gas are evolved, which, when lighted, will continue to burn for a long time. In some parts of the world, streams of ignited inflammable air are emitted constantly, or at intervals, which possess the property of taking fire spontaneously on their access to atmospheric air: in all probability, these currents contain phosphuretted hydrogen gas, from which the property is derived. We consider these phenomena as distinct from volcanic fires.

On the south-east of Natolia, the mountain Climax, the Chimera of the ancients, situated near the Mediterranean sea, constantly emits flames from an aperture on the northern side. This appearance is unaccompanied by any detonation. It is very ancient, being mentioned in the Periplus of Scylax as continually burning.

The flames that are observed to issue occasionally during earthquakes, can scarcely be classed with volcanic phenomena; they appear to proceed from the sudden disengagement of hydrogen gas, combined with phosphorus, naphtha, and other substances, which may dispose it to ignite spontaneously. During the great earthquakes which desolated Thrace, Asia Minor, and Syria, in the fourth and fifth centuries, flames were seen to burst from the earth over a vast extent of ground. On the 26th of January, A.D. 447, subterranean noises were heard from the Black to the Red sea, and the earth was convulsed without intermission for the space of six months; in many places the air appeared on fire. Towns, large tracts of ground, and mountains, were swallowed up in Phrygia. On the 20th of May, A.D. 520, Antioch was overturned by a dreadful earthquake, and two hundred and fifty thousand of its inhabitants were crushed in the ruins. A raging fire covered the ground on which the town was built, and the district around, spreading over an extent of forty-two miles in diameter, and a surface of fourteen hundred square miles. Numerous instances of a similar kind are recorded by the

historians of that period. Flames were also observed to burst from the neighbouring mountains during the earthquake at Lisbon in 1755. Though these phenomena may proceed from subterranean fire as the primary cause, yet they differ from volcanic fires, as the latter throw out their contents in an ignited state; but the flames which accompany earthquakes, appear to arise from the ignition of vapour at the surface.

Burning and Extinct Volcanoes.—When we take a general view of the terrestrial globe, we observe volcanoes in every parallel of latitude, from Iceland and Kamtschatka, in the north, to Terra del Fuego in the south. They are more abundantly scattered over the ocean than the continent, and are more numerous in America than in the old world. They are found at every degree of elevation, from the depths of the sea to the summits of the Andes. Ancient volcanic craters, which have been for ages extinct or dormant, have left undoubted vestiges of their prior state of activity in various countries where no volcanoes at present exist; and volcanic rocks are found even where all vestiges of volcanic craters have been long obliterated.

Our knowledge of volcanic geography is at present imperfect, as a large portion of the earth's surface has not yet been examined; and our knowledge of volcanic islands in the Indian and Pacific oceans is confined to those which were in a state of active eruption at the time they were passed by navigators. Of the submarine volcanoes scattered over the bed of the ocean we have no account, and it is only when they occur in the vicinity of civilized countries, that we can ascertain their locality. At the beginning of the present century, the active volcanoes then known were stated at about two hundred. Travellers and navigators have since enlarged the number. Perhaps it would not be exceeding the fact, were we to estimate the number of active volcanoes in the world at one thousand, including all those which still preserve a considerable degree of heat, and present other indications that they are not extinguished, but dormant.

The only active volcano on the continent of Europe is Vesuvius. The Solfatara and Monte Nuovo in the vicinity may be regarded as dormant. History mentions a volcano in Albania, which destroyed Durazzo in 1269.

Of the European islands, Iceland is the most extensively volcanic, the whole soil of that country is apparently the product of fire. It contains six large active volcanoes, besides numerous smaller ones, and boiling springs.

Sicily contains Etna and the various volcanic mountains on its sides, with the mud volcano of Maccaluba.

Three of the Lipari islands are at present active: Stromboli, Vulcano, and Vulcanello.

Santorini and the neighbouring isles are evidently placed near or over a great submarine volcano, by which they have at different times been formed.

The island of Milo, about twenty leagues to the east of Santorini, has a volcano in an active state; the whole of the island is also stated to be volcanic.

The extinct or dormant volcanoes in Europe are far more numerous than those which are at present active. In Campania alone, between Naples and Cumæa, in the space of twenty miles in length and ten in breadth, according to Breislak, there are no less than sixty craters, without reckoning those in the neighbouring islands, which are numerous. Some of the craters are larger than that of Vesuvius. The crater of Quarto even greatly exceeds that of Etna; its diameter is nearly two miles. The crater on which the ancient city of Cumæa is situated, has thrown out a torrent of lava nine hundred feet broad, and from twenty-five to thirty feet in depth.

This crater belongs to a volcano extinct from the most remote ages. The foundation of Cumæa was about twelve hundred years prior to the Christian era, hence Breislak adds, the last eruptions must have taken place more than three thousand years since, as the Greeks would not have founded their city on the mouth of an active volcano.

The other parts of Italy, from the Veronese and the Vicentin territory, with that of Padua, to the extremity of Calabria, are covered with the incontestible vestiges of ancient volcanoes.

Sicily presents a great number of extinct volcanoes, without reckoning those on the sides of Etna, of which some are equal to Vesuvius. Many of the Mediterranean islands, at present in a state of repose, have formerly been volcanic, as the islands of Elba, Sardinia, Ilicia, Procida, the whole of the Lipari islands, with the greater part of the islands in the Grecian Archipelago. Lemnos was formerly regarded as the arsenal of Vulcan.

In Spain and Portugal there are volcanic craters still to be traced. The Souffriere of Conilla, near Cadiz, is an ancient volcano. The environs of Burgos are entirely composed of lava, pumice, and other volcanic products. The famous salt-mine of Posa, near Burgos, is stated to be situated in the midst of an immense crater.

In France there are numerous extinct volcanoes, as those of the Vivarais and Velay, described by Faujas St. Fond; and that of Auvergne, described by Daubuisson. The extinct volcanoes in Languedoc and Provence are said to be very numerous. The alps of Dauphiny, according to Lamanon, contain a crater of large extent.

There are entire chains of volcanic mountains on the banks of the Rhine, in the Brigau, and the environs of Andernach.

The northern countries of Europe possess fewer indubitable vestiges of volcanic craters, though volcanic products and rocks, nearly allied to lavas, exist in various parts of Germany and Hungary, and are supposed by many geologists to be formed by subterranean fire, at a very remote period.

According to the Italian geologist Breislak, the famous gold and tellurium mine of Nagyag is situated in the crater of an extinct volcano. See TELLURIUM *Mines*.

In Great Britain, on the western side, particularly in the mountains of North Wales and Cumberland, are various circular cavities, partly filled with water, which bear a near resemblance to extinct craters. The rocks by which they are surrounded are generally a porphyritic trap, a rock which is supposed by many geologists to have had an igneous origin. See TRAP, and ROWLEY-RAG.

Above the village of Butterner, in Cumberland, between the summits of the mountains called Redpike and Hightile, there is a large elevated crater of this kind, containing in its centre a small tarn or lake. The rocks which surround it consist of clink-stone-porphry which melts with great facility, and porphyritic red felspar, and are in some parts rudely columnar. The side nearest the lake is broken down. We have no doubt, from an examination of the place, that it would be described by many geologists on the continent, as the well-defined crater of an extinct volcano. Von Buch, whose acquaintance with volcanoes is extensive, after a recent tour through this part of England, informed us that many of the mountains in Cumberland resemble those in Auvergne, and other parts of the world, which are supposed to have been softened and elevated by subterranean heat, without ever having flowed as lavas.

The basaltic hills of many parts of Scotland have been described by Faujas St. Fond as volcanic, and the basaltic mountains

VOLCANO.

mountains and ranges in Ireland are supposed to have had a similar origin. It is however doubted, by geologists of great repute, whether basaltic rocks have all been formed by fire, and some deny altogether the igneous origin of these rocks. See SYSTEMS of *Geology*, BASALT, TRAP, and WHINSTONE.

The islands of Faroe, near Iceland, present more undoubted marks of their former volcanic state.

On the continent of Asia, few active volcanoes are known. According to the traveller Morier, there are several mountains in Persia that constantly emit smoke. Ancient geographers also mention volcanoes in Thibet and Camboja. The mountain of Cophante, at the south-east extremity of the Caspian sea, is stated to be volcanic. There is a volcano at the entrance of the Red sea, and another at the entrance of the Persian gulf. From thence to Kamtschatka we are not acquainted with any active volcano; but in this peninsula, according to count Beniowski, there are not less than twenty, five of which are of immense size, called Awatcha, Joupanouskaia, Chevelitche, Tobatchia, and Kamtschatkaïa. The three former are said to be connected, and to have simultaneous eruptions; the latter ejects a great quantity of vitrified substances, which are found in its neighbourhood. It is of an immense height: the philosophers who accompanied Pécouffe were three days in reaching the crater, and it is said to be visible at the distance of three hundred miles. In the month of September 1737, torrents of burning matter flowing down on every side, presented to the sight the whole of the mountain as red-hot. Almost all the springs and lakes in this peninsula are more or less warm, hence they are never entirely frozen over, notwithstanding the rigour of the climate. The chain of the Kurile islands, which may be considered as a continuation of Kamtschatka, contains nine active volcanoes.

Kämpfer, in his History of Japan, describes eighteen volcanoes in that and the neighbouring islands, and La Pérouse discovered two others.

In the Marianas, or Ladrones islands, nine volcanoes have been described. The Philippine islands, which are said to exceed twelve hundred, are many of them volcanic. There are three volcanoes in Luzon, the principal island.

The archipelago of the Molucca islands abounds with volcanoes. Machian, one of these valuable spice islands, contains a remarkable volcanic mountain, which in 1646 was completely rent from the summit to the base, by the violence of its eruptions, and at present forms two distinct mountains, standing near each other.

In the island of Ceylon, the peak of Adam is celebrated for its height and its volcanic eruptions.

In Sumatra there are four gigantic volcanoes, the highest of which is thirteen thousand eight hundred and forty-two feet above the level of the sea. The others are nearly of equal height. Several volcanoes occur in the island of Java. The island of Ternate affords also a volcano on the top of a mountain very difficult of access, but opening with a vast mouth, and very terrible when it burns.

The several violent eruptions of this mountain have given it, within the mouth or crater, the appearance of an amphitheatre, constructed for holding people at the time of some public show, several circles appearing in it one above another, formed with a sort of regularity that is surprising. Modern navigators have discovered numerous volcanic islands scattered over the Yellow Sea and in the Pacific Ocean, from Asia to the western coasts of America.

Of the extinct volcanoes of Asia, excepting the northern parts, we have no accounts whatever. Patrin, an eminent French mineralogist, who visited part of northern Asia, says

that hills of lava were seen after he had crossed the lake of Baikal, fifteen leagues to the east of the city of Oudinsk, near the river Kourba. All the country between Chilká and Argoune, which forms the river Amour, presents traces of volcanoes. The mines of Gazemour are in the vicinity of an immense crater, the bottom of which is at present nearly on a level with the river. It is flat, and covered with blocks of scorified lava, from whence rise several small volcanic cones. On passing over this plain it returned a hollow sound to the horses' feet, as if they were travelling over a vault.

There are other larger craters on the summits of volcanic mountains, near the river Kourba, some of which are converted into lakes. Vast currents of lava descend from these craters; some of them are at present empty, others resemble those of Oberstein and Deux Ponts, and are filled with chalcodenes and amygdaloidal stones.

When Hanno, the Carthaginian, coasted Africa, he saw in the night-time fires ascending from a lofty mountain called the Car of the Gods. Kircher, in his *Mundus Subterraneus*, mentions eight burning volcanoes on that continent, and the remains of many extinct ones. Our knowledge of the interior of this country is very imperfect, and no active volcanoes are at present known there.

From the accounts of some of the mountains near the Cape of Good Hope, we may infer that they have formerly been volcanic.

All the African islands are volcanic, or contain vestiges of their igneous origin. No less than forty-two active or dormant volcanoes are found in the Azores.

The islands of Lanzerotta, Palma, and Teneriffe, contain burning volcanoes, and the other Canary isles are volcanic.

The Cape Verd islands are also volcanic, but Fuego is the only one in which the fire is at present active.

The island of Ascension, and the isle of Bourbon, contain volcanoes. St. Helena and the Madeira islands present undoubted marks of their igneous formation.

The volcanoes on the continent of America are numerous, and of an immense size and height. They are principally situated near the western coast. Ancient navigators mention volcanoes in Greenland with boiling springs, announcing a volcanic soil, similar to that of Iceland. On the north-west coast of America, Capt. Cook saw a volcano in lat. 61°, and another of amazing height in lat. 55°, at the point of Alaska. Another higher than the Peak of Teneriffe was discovered in lat. 59°. Others have been seen in various parts of the coast between Alaska and California; but of the volcanoes in the interior, in these latitudes, we are unacquainted. Five volcanoes are enumerated in California. Proceeding southwards, along the chain of mountains that forms the Cordilleras, we find the volcanoes ranged in rows nearly north and south along a line of five thousand miles in length, from the tropic of Cancer to Terra del Fuego. In the province of Quito the volcanic mountains diverge from this line east and west, being scattered over a space of seven hundred square leagues, which is regarded by Humboldt as one enormous volcanic abyss, covered with a crust of volcanic matter, and sending forth eruptions from the numerous lofty craters, which are only different vents to the same internal fire. In New Spain also, there is a volcanic range, intersecting the Cordilleras in lat. 19°, and extending east and west from the gulf of Mexico to the Pacific ocean. In this range, Colima and other ancient volcanoes, with the new volcano of Jurullo, are placed.

From the province of Quito the volcanoes are continued along the Cordilleras, in a direct line to the southern extremity of America. The number of active volcanoes on this continent can scarcely be less than one hundred.

VOLCANO.

Eighty-seven have been enumerated by former geographers, before Humboldt had extended our knowledge of the new world. From twenty-five to thirty were described as existing on the western side of Mexico, before the new volcanic range of Jorullo was thrown up. Sixteen of the highest mountains in the world, in the province of Quito, are volcanic, but it is remarkable that they do not eject lava, but torrents of mud, which in drying form earthy strata of many hundred square miles in extent.

Of the extinct volcanoes in America we have little knowledge. La Condamine saw several extinct craters in Peru. It is thought by travellers, that some of the lakes in North America occupy the craters of extinct volcanoes of vast extent; this can only be determined by an examination of the rocks that surround these lakes. Extinct volcanoes are said to occur in some parts of Canada.

The volcanoes in the American islands are very numerous. The long range of islands extending west from point Alaska is altogether volcanic, according to the relation given by Sauer of the voyage of commodore Billings. One of these islands, called by the Russians *Semjopahnoi*, or the seven mountains, contains seven volcanoes. The group of islands called Revillagigedo are supposed to be volcanic, from the pumice found on the shores. The islands of Gallipagos are chiefly composed of scoriaceous lava, as we are informed by a gentleman who recently visited them, and who favoured us with specimens. On the eastern side, among the Antilles, the islands of St. Christopher, Guadeloupe, Nevis, and St. Vincent's, contain volcanoes; and many of the other West Indian isles appear to be volcanic, though they have had no eruptions since they were first visited by Europeans.

The volcanoes scattered in the Southern Pacific ocean can scarcely be classed with those of the American isles. There are three very lofty volcanoes in the Friendly islands, and among a multitude of isles dispersed over that vast expanse of water, doubtless numerous volcanoes exist which are at present unknown. We have no account of volcanoes in New Holland.

This general outline of volcanic geography may suffice to shew how large a portion of the globe is at present, or has been formerly, subjected to the action of subterranean fire. It is the opinion of some geologists, that many of the ancient volcanoes which existed prior to the formation of the upper strata, have been entirely covered by them and hid from human observation. In other instances, the craters of ancient volcanoes have been buried by the lavas of more recent eruptions, and in the great revolutions which have changed the appearance of the globe, volcanic districts of vast extent have been broken down and the surface swept away, leaving only detached isolated caps of volcanic matter on the summits of distant mountains, the solitary monuments of the former dominion of fire. Even volcanic mountains of later date have had their craters entirely obliterated by the united agency of mountain torrents and the eruptions of smaller volcanoes. In the island of Lipari, according to the description of Spallanzani, the volcanic fires have raged so near to each other, that they have produced in every part confusion and disorder, which is seen in the groups of broken and half destroyed mountains. The substances ejected from the numerous eruptions have intersected each other, and intermingled so much, that no distinct volcanic crater can be traced at present. This confusion has been further increased by torrents of rain, and by gradual disintegration during a long series of years.

From the volcanized soil of Lipari, from the present state of the neighbouring islands, as well as from ancient tradition, we may with certainty infer that this island has been the former seat of volcanoes, though their craters are

nearly obliterated. No geologist, who has visited Lipari, ever entertained the least doubt of its igneous formation. Volcanic glass and pumice, with which it abounds, are found on the Peak of Teneriffe, in Iceland, Kamtschatka, and other volcanic countries; yet the followers of Werner have doubted or denied the igneous origin of these substances, because they exist in basaltic districts, where no trace of a volcanic crater remains. This appears to be taking a limited view of the subject; for when we contemplate the present extensive effects of fire in every quarter of the globe, and the great changes which have taken place on its surface, we may reasonably infer the former existence of volcanoes in all countries where the products of subterranean fire are found as native rocks, though no vestige of a crater may remain, and the date of the eruption may be for ever lost in the darkness of past ages, which preceded the emergence of our present continents from the ocean.

Since the preceding article was written, we have seen the History of Java, by lieutenant-governor Raffles, recently published; from which it appears that the whole of that large island, and most of the neighbouring isles, are volcanic. There are no less than thirty-eight large volcanic mountains in Java, some of which are at present in an active state. These mountains all rise from a plain, little elevated above the sea. They are detached from each other, and though some of them are covered by the vegetation of many ages, the indications of their former eruptions are numerous and unequivocal. From the apertures in their craters, many of them continue to discharge smoke and sulphureous vapours.

The following account is truly remarkable, as it is the only recorded instance of the natural death, if we may be allowed the expression, of a large volcano.

"The Papandayang, situated on the western part of the district of Cheribon, in the province of Suka-pura, was formerly one of the largest volcanoes in the island of Java; but the greatest part of it was swallowed up in the earth, after a short but very severe combustion, in the year 1772. The account which has remained of this event asserts, that near midnight, between the 11th and 12th of August, there was observed about the mountain an uncommonly luminous cloud, by which it appeared to be completely enveloped. The inhabitants, as well about the foot as on the declivities of the mountain, alarmed by this appearance, betook themselves to flight; but before they could all save themselves, the mountain began to give way, and the greatest part of it actually fell in, and disappeared in the earth. At the same time a tremendous noise was heard, resembling the discharge of the heaviest cannon. Immense quantities of volcanic substances, which were thrown out at the same time, and spread in every direction, propagated the effects of the explosion through the space of many miles.

"It is estimated that an extent of ground, of the mountain itself, and its immediate environs, fifteen miles long, and full six broad, was by this commotion swallowed up in the bowels of the earth. Several persons sent to examine the condition of the neighbourhood, made report that they found it impossible to approach the place where the mountain stood, on account of the heat of the substances which covered its circumference, and which were piled on each other to the height of three feet; although this was the 24th of September, full six weeks after the catastrophe. It is also mentioned, that forty villages, partly swallowed up by the ground, and partly covered by the substances thrown out, were destroyed on this occasion, and that 2957 of the inhabitants perished. A proportionate number of cattle was also destroyed, and most of the plantations

tations of cotton, indigo, and coffee in the adjacent districts were buried under the volcanic matter. The effects of this explosion are still very apparent on the remains of this volcano."

We have before stated that several circular lakes, of considerable extent, are supposed to have been formed in the craters of extinct volcanoes, but it seems more probable that these lakes cover the places where former volcanic cones, or whole mountains, have sunk down. We have several instances of the partial destruction of the cone of a volcano, and some traditions are preserved of the entire disappearance of volcanic mountains, but the above is the only authentic record of such an event in modern times.

The following narrative, extracted from the same work, describes one of the most astonishing volcanic eruptions of which we have any knowledge. It took place in Sumbawa, one of the Molucca islands, in April, 1815.

"This eruption extended perceptible evidences of its existence over the whole of the Molucca islands, over Java, a considerable portion of Celebes, Sumatra, and Borneo, to a circumference of a thousand statute miles from its centre, by tremulous motions, and the report of explosions; while within the range of its more immediate activity, embracing a space of three hundred miles around, it produced the most astonishing effects, and excited the most alarming apprehensions. In Java, at the distance of three hundred miles, it seemed to be awfully present. The sky was overcast at noon-day with clouds of ashes; the sun was enveloped in an atmosphere, whose 'palpable' density the observer was unable to penetrate; showers of ashes covered the houses, the streets, and the fields, to the depth of several inches; and amid this darkness, explosions were heard at intervals like the report of artillery, or the noise of distant thunder. So fully did the resemblance of the noises to the report of cannon impress the minds of some officers, that from an apprehension of pirates on the coast, vessels were dispatched to afford relief. Superstition, on the other hand, was busily at work on the minds of the natives, and attributed the reports to an artillery of a different description to that of pirates. All conceived that the effects experienced might be caused by eruptions of some of the numerous volcanoes on the island; but no one could have conjectured that the showers of ashes which darkened the air and covered the ground of the eastern districts of Java, could have proceeded from a mountain in Sumbawa, at the distance of several hundred miles."

The lieutenant-governor of Java directed a circular to the different residents, requiring them to transmit to the government a statement of the facts and circumstances connected with this eruption, which occurred within their own knowledge. From their replies, the narrative drawn up by Mr. Ailey, and printed in the ninth volume of the *Batavian Transactions*, was collected: the following is an extract from that paper.

"The first explosions were heard on this island (Java) in the evening of the 5th of April; they were noticed in every quarter, and continued at intervals until the following day. The noise was, in the first instance, universally attributed to distant cannon; so much so, that a detachment of troops was marched from Djocjocarta, under the apprehension that a neighbouring post had been attacked: and along the coast boats were in two instances dispatched in quest of supposed ships in distress. On the following morning, however, a slight fall of ashes removed all doubt as to the cause of the sound; and it is worthy of remark, that as the eruption continued, the sound appeared to be so close, that in each district it seemed near at hand, and was generally at-

tributed to an eruption, either from the mountains Merapi, Klut, or Bromo. From the 6th the sun became obscured; it had every where the appearance of being enveloped in a fog. The weather was sultry, and the atmosphere close and still; the sun seemed horn of its rays, and the general stillness and pressure of the atmosphere seemed to forebode an earthquake. This lasted several days. The explosions continued occasionally, but less violently, and less frequently than at first. Volcanic ashes also began to fall, but in small quantities, and so slightly, as to be hardly perceptible in the western districts. This appearance of the atmosphere continued, with little variation, until the 10th of April; and till then it does not appear that the volcano attracted much observation, or was considered of greater importance than those which had occasionally burst forth in Java. But on the evening of the 10th, the eruptions were heard more loud and more frequent; from Cheribon eastward the air became darkened by the quantity of falling ashes; the sun was nearly darkened; and in some situations many said they felt a tremulous motion of the earth. An unusual thick darkness was remarked all the following night, and the greater part of the next day. At Solo, candles were lighted at 4 p.m. of the 12th; at Magellan, objects could not be seen at three hundred yards distance. In other districts more eastward, it was dark as night, and this saturated state of the atmosphere lessened as the cloud of ashes passed along, and discharged itself on its way. Thus the ashes that were eight inches deep at Banyuwangi, were but two inches in depth at Sumenap, and less in Grifsk; and the sun does not seem to have been actually obscured in any district west of Semarang.

"All reports concur in stating, that so violent and extensive an eruption has not happened within the memory of the oldest inhabitant, nor within tradition. They speak of singular effects in a lesser degree, when an eruption took place from the volcano of Karang Asam, in Bali, about seven years ago, and it was at first supposed that this mountain was the seat of the eruption. The Balinese of Java attributed the event to a recent dispute between the two rajahs of Bali Baliling, which terminated in the death of the younger rajah by order of his brother.

"From Sumbawa to the part of Sumatra where the sound was noticed, is about nine hundred and seventy geographical miles in a direct line. From Sumbawa to Ternate is a distance of about seven hundred and twenty miles. The distance also to which the cloud of ashes was carried so quickly as to produce utter darkness, was clearly pointed out to have been the island of Celebes, and the districts of Grifsk or Java; the former is two hundred and seventeen nautical miles distant from the seat of the volcano; the latter, in a direct line, more than three hundred geographical miles." On this narrative we shall remark, that the greatest known distance at which volcanic eruptions had been heard before this of Sumbawa, was six hundred miles. According to Humboldt, the reports of Cotopaxi during some of its most violent explosions, have been heard at a distance equal to that of Dijon in France, from Vesuvius.

A more accurate and extended knowledge of the effects of subterranean fire throughout the Asiatic isles and those of the Pacific ocean, would probably demonstrate that the intensity of this powerful agent is not diminished, as some philosophers have supposed, though its present effects on the old continents may be less extensive than in former ages.

Volcanic Fire.—The questions which have divided the opinion of geologists respecting volcanic fire are, first, What is the intensity of the heat?—Secondly, Where is the

the source of heat situated?—And, lastly, From what cause does it originate? Some philosophers contend, that volcanic heat greatly exceeds that of our common furnaces; whilst others assert that it scarcely exceeds that of a culinary fire.

The arguments in favour of the low degree of heat of volcanic fire are founded on the experiments made upon lava in a common furnace, which was observed to vitrify them more completely than volcanoes, and to melt many of the imbedded crystals, which were supposed to have been left infusible by volcanic heat. M. Sage and Deluc first supported the hypothesis of the low degree of volcanic heat. M. Dolomieu endeavoured to prove it to be still less. His principal argument is the following. "It cannot be too frequently inculcated that lavas are not vitrifications; their fluidity is similar to that of metals reduced to fusion: when they cease to flow, they refuse, like metals, the grain, texture, and all the characters of their primitive base; effects which we cannot produce on stones in our furnaces, since we know not how to soften them by fire, without changing the manner in which they are aggregated. The fire of volcanoes has not that intensity which is supposed: the effect is produced rather by its extension and duration than by its activity." We greatly respect the labours of this intelligent observer; but we must notice, that in the above statement he has not appreciated the important difference between the effects of volcanic fire and that of a furnace, resulting from the more rapid cooling of the materials in the latter case. It has been proved by the important experiments of Sir James Hall, that vitrification depends not on the degree of heat so much as on the rapid cooling of stone or lava in a state of fusion; and that lava, vitrified in the furnace, assumes its stony texture again, if it is remelted, and the heat be very gradually diminished. It was proved also by the interesting experiments of Mr. G. Watt, that if this process of cooling be continued for a still longer time, a crystalline arrangement of the particles takes place.

It was an opinion long entertained, that the crystals existing in lava, whether of *felspar*, *augite*, *olivine*, *leucite*, (see these articles,) or other minerals, were original crystals, existing in rocks which had been subjected to volcanic heat; and that this heat, though sufficient to melt the rock itself, was not powerful enough to melt the imbedded crystals. It was supposed also, that some of these crystals, previously existing, were found detached by the lava in its course, and buried in it. These opinions, so unphilosophical and improbable, are giving place to a more correct and enlarged view of these operations of nature.

The crystals in lava did not previously exist, but were formed during the slow consolidation of the materials, which admitted the elementary particles to enter into different combinations, according to the laws of elective affinity and crystalline arrangement, precisely in the same way that different salts in the same solution separate from each other, and crystallize. In the slags from our furnaces we may frequently observe the same process more or less perfectly completed; and we have seen crystals resembling felspar, found in a mass of coal-shale or bituminous slate-clay, which had been fused and run down from the large ignited heaps, in the vicinity of Newcastle-upon-Tyne. The facts adduced to prove the low degree of heat in volcanic fires, prove only its long continued action, and not its original degree of intensity. Dolomieu indeed admits, that a great difference must result from the different periods of the continuance of heat. This was subsequently demonstrated by the experiments of Spallanzani. He took several stones, which had been found refractory, when exposed to a certain

degree of heat for two or three days, and placed them in a glass furnace where the same degree of heat, was continued equally for more than six weeks; during which time they were all more or less softened by fire, and the vitrification, which began on the surface, extended deeper and deeper into the stone, in proportion to the time. Hence, says he, we may learn, that a long continued heat of less strength is as efficacious in the fusion of bodies as a stronger heat of a shorter duration. Dolomieu further conjectured, that the extreme fluidity of some lavas was occasioned by the presence of sulphur, which acted as a flux, in the same manner as a bar of iron, when brought nearly to a white heat, will instantly melt, if it be rubbed with sulphur; but this opinion was not confirmed by experiment. Spallanzani found that sulphur produced no effect, when mixed with stone or lava, and exposed to heat; nor did the lava melt sooner than in other crucibles, in which it was exposed to the same degree of heat.

The result was the same, whether he employed common sulphur or iron pyrites. The facts, therefore, adduced for the low degree of heat in volcanic fire, prove nothing; and it is only from the actual state of the lava itself, that its greater or lesser degree of intensity can be ascertained.

The extreme liquidity of lava flowing from the crater, in some instances, has been shewn in a former part of this article, where it is described as spouting up, and forming curves like a fountain of water. Professor Bottis relates, that on the 10th of September, 1776, he observed a small hill on the side of Vesuvius, formed of scoriae, and surrounded by lava recently ejected. In this hill was a small circular gulf, about three palms in diameter, and two in depth. From this gulf proceeded a low noise, similar to that of oil or any other fat substance simmering over the fire; which found was doubtless produced, he says, by substances fusing within it. The fire was so strong, that some scoriae being cast into it, immediately became red-hot, and melted, producing the appearance of boiling pitch. Spallanzani says, that the same kind of stone required to be half an hour in the furnace before it was softened; and in a reverberating furnace, it required a heat equal to the melting of iron, to obtain a speedy fusion of these stones. It is likewise evident, that the heat in this small gulf, communicating with the cold air above, must be less intense than in the internal part, since this was only a spiracle or vent to the great mass of lava which boiled in the deep recesses of the mountain.

Spallanzani also observed, that when the lava, placed in a common furnace, had been fused several hours, and boiled over the edge of the crucible, its tenacity was still so great, that he could scarcely with all his force immerge a pointed iron-wire to the bottom; and when he took away the iron, the impression remained some minutes, though the crucible still continued in the furnace. When the same lavas were exposed to the intense heat of the reverberating furnace, they were more liquid, and might be penetrated with greater ease.

From these experiments and observations we are warranted in concluding, that the heat of volcanic fires sometimes exceeds that of our most violent furnaces, but that the lava of different eruptions may possess different degrees of fluidity and heat. It may also be worthy of notice, that the lavas were considerably reduced in weight by remaining long in the furnace, the particles having been volatilized and sublimed. Another argument for the intensity of volcanic fire is derived from the long continued heat of certain currents of lava. Spallanzani says, when he passed a detached current of lava near the summit of Etna, which had flowed eleven

VOLCANO.

eleven months before, it still retained a red heat, which was very conspicuous in some of the apertures even in the daytime; and a staff being placed upon it, immediately took fire. Ferrara itates, that when the current, which flowed from Monte Roffo on Etna in 1669, was perforated at Catania in 1709, flames broke out, and it continued to smoke on the surface after rain, at the beginning of the present century. Now whatever may be the mass of a current of lava, the heat could not remain so great after such long intervals of time, were it not prodigiously more powerful when it first flowed. It is obvious that the heat of the internal fire cannot be less than that of the lava which flows from it, which, we have before observed, is sometimes equal at least to the heat of the most powerful reverberatory furnace. Where the lava possesses a much less degree of heat, we are not warranted in asserting that the internal fire was less intense; for various circumstances may modify and diminish the heat of the lava itself, such as the access of water near the surface, which may mix with it in the crater, and produce a torrent of mud, or may cool it so much as to increase its tenacity, until it can scarcely flow when it first issues from the crater. The following circumstance is well deserving attention. On opening some of the houses in Torre del Greco, which were nearly buried in the lava that flowed from the foot of Vesuvius in 1794, various striking effects were observed, which could only have been produced by the long continued agency of intense heat; effects which we have at present no means of imitating. Among others, even iron utensils had been partly volatilized, and crystals of specular iron-ore were formed on the surface. For a knowledge of this important fact, the public is indebted to the honourable H. G. Bennet, who brought away various specimens from the newly opened houses.

The question respecting the situation of volcanic fires may be thus stated:—Does the fire in volcanic mountains originate in the mountain itself, or is it situated at a great depth beneath the surface? It has been an opinion commonly entertained, that volcanoes originally break out in mountains already formed, and cover them with lava and scorix. Hence it is supposed by some philosophers, that there existed primitive or secondary mountains, where we now observe the Peak of Teneriffe and Etna, or Vesuvius, and that volcanic fire has merely covered the surface with its products, or effected a change in the external form of these mountains. On the other hand, it is contended that volcanic mountains are either entirely the products of subterranean fire, and have been formed by the lava and scorix thrown up, as was the case with the volcanic range of Jorullo in New Spain, and Monte Nuovo near Naples; or that they have been raised by subterranean heat, which has softened and upheaved the regular beds and strata that form the crust of the globe, as was the case at Malpays, already described; and on this upheaved surface a volcanic cone has been formed, when the eruption of the volcano took place. To determine these questions, where history is silent respecting the formation of volcanoes, we must examine their structure at the base and the summit, and attend to the phenomena which accompany the eruptions. Some volcanic hills are so entirely composed of scorix and lava, that we can have no hesitation in believing that they have been formed by eruptions. This might be asserted of Jorullo, of Monte Roffo, and Monte Nuovo, if even we had no well authenticated accounts of their formation; and hence we may infer that the source of the fire is situated far below the base of these hills. Other volcanic mountains of larger size are partly composed of beds and strata, to which we cannot

ascribe a volcanic origin. According to the observations of Mr. Leckie, during his residence in Sicily, calcareous strata, with marine organic remains, rest on beds of volcanic tufa, on the eastern side of Etna, and dip towards the sea. (Bakewell's Introduction to Geology, 2d edit. p. 316.) Hence we may infer that the primeval eruptions took place under the sea, and that their products of tufa were covered with marine deposits, before the mountain emerged from the ocean. In other words, the existence of the volcano preceded that of the mountain itself, the first eruptions taking place under the sea, the whole mass of the base having been upheaved at a subsequent period. Calcareous beds occur in some of the Canary islands, which are all volcanic; and though the base of the Peak of Teneriffe, according to Humboldt, rises amidst a series of basalts and old lavas, he does not consider these as a progressive accumulation of lavas, but as having been formed under and elevated from the sea. On attending to the circumstances which accompany the formation of new islands, he says, we find that these extraordinary eruptions are generally preceded by a swelling of the softened crust of the globe. Rocks appear above the water, before the flames find their way or lava issues from the crater. We must, therefore, distinguish between the nucleus raised up, and the mass of scorix and lava thrown upon it. This, as we have before observed, is the case in some instances: there are others, however, in which pumice and scorix have been thrown up from under the sea; but both phenomena prove that the source of volcanic fire is seated at great depths below the surface of the ground. Were the source of volcanic fire seated in the mountain from which the eruption takes place, it is impossible to conceive that it could continue burning for some thousand years, without the mountain falling in; and when the fire was once extinct, it does not appear probable that it should ever burst forth again in the same place. M. Werner and his followers have placed the seat of volcanic fire in beds of coal; but as these occupy the upper strata of the globe, being situated above the primary and lower secondary beds, they can have no great comparative depth, and the objections just stated apply to this theory in full force. For if beds of coal were once burned out, or extinguished in one place, we can assign no conceivable reason why volcanic fires should break out in the same place again, after a cessation of seven hundred years, and should continue to burn for many hundred years afterwards, as was the case with Vesuvius. Indeed, the opinion of volcanic fire being derived from the ignition of coal-beds, appears to us a supposition altogether inadequate to explain their origin, and the extent of their operations.

Mr. Whitehurst, in his "Inquiry into the original State and Formation of the Earth," 4to. 1778, apprehends, that subterranean fire must at different times have existed universally in the bowels of the earth, and that in union with water, or by the expansive power of steam, it has produced the immense continents, as well as the mountains of our globe, and also the universal deluge. When these fires were first kindled, by what sort of fuel they are still maintained, at what depths below the surface of the earth they are placed, whether they have a mutual communication, of what dimensions they consist, and how long they may continue, are questions which do not admit an easy decision. Some, with M. Buffon, have placed the seat of the fire of volcanoes towards the centre, or near the summit of the mountains, which they suppose to furnish the matter emitted. But if this were the case, that part of the mountain which is situated above the supposed seat of the fire, must be destroyed or dissipated in a short time; whereas an eruption usually

usually adds to the height and bulk of a volcano; and the matter discharged by it for many ages would be sufficient to form three such mountains as the simple cone or mountain of the existing volcano.

We have hitherto confined our account of volcanic phenomena to those circumstances which accompany the eruption in its immediate vicinity; but in order to form any rational or probable conjecture respecting the seat and origin of volcanic fires, we must take a more enlarged view of the subject, and contemplate volcanic fires in connection with each other, or in their effects on remote parts of the globe. Volcanoes and earthquakes are regarded as distinct phenomena, but they are only different effects of the same cause. Volcanoes are the vents through which is discharged the elastic vapour, and other materials, that, in a confined state, are the principal causes of earthquakes. Whenever these vents are by any means choked up for a long time, violent commotions of the earth may be expected, until the former vents are re-opened, or new passages made for the confined materials to escape. This view of the subject may be illustrated by the following facts, which prove the immediate connection of earthquakes with volcanic fires.

The great earthquakes which have shaken Sicily and Calabria, have generally been accompanied with volcanic eruptions from Etna or the Lipari isles. In the year 1169, every house in Catania was thrown down by a violent earthquake, which occurred at the same time with a great eruption of Etna.

The earthquakes of 1634 and 1635, which nearly destroyed Messina, accompanied the memorable eruption from the same mountain, in which part of the volcanic cone fell down. The lava formed a torrent eighteen miles long, two miles broad, and twenty-four feet high. Immediately preceding the earthquake which destroyed Euphemia in 1633, Kircher, who was an eye-witness, says that Stromboli threw out an immense quantity of flames, accompanied with a noise which could be distinctly heard at the distance of sixty miles. The common eruptions from this volcano are comparatively feeble.

Near the time of the great earthquakes which destroyed Lisbon in 1755 and 1761, Europe, Africa, and America were repeatedly agitated by subterranean commotions, accounts of which may be seen by referring to the journals of that period. A few hours after the great shock of the former earthquake, the waters of Switzerland, Northern Europe, Canada, and the West India islands, were violently agitated, and fire was seen to rise from the midst of the Atlantic ocean. These efforts, nearly simultaneous, prove that the source of the commotion was seated deep within the globe.

The earthquakes of Cumana, in New Andalusia, are connected, says Humboldt, with those of the West India islands; and it has even been supposed that they have some connection with the distant volcanic phenomena of the Andes. On the 4th of November, 1797, the province of Quito suffered such a destructive commotion, that even in that thinly inhabited country, forty thousand of the natives perished, buried under the ruins of their houses, swallowed up in the fissures, or drowned in lakes that were suddenly formed. At the same period, the inhabitants of the Eastern Antilles were alarmed by shocks which continued eight months, when the volcano of Guadaloupe threw out pumice-stones, ashes, and gusts of sulphureous vapours. This eruption, during which long subterranean noises were heard, took place on the 27th of September, and was followed on the 14th of December by the great earthquake at Cumana.

The city of Caracas was entirely destroyed by an earthquake on the 24th of March, 1812: violent oscillations of

the ground were felt for thirty-five days after, both in the West India islands, and on Terra Firma. At this time the volcano in St. Vincent's, which had been dormant for near a century, broke out with great fury, covering the neighbouring islands with its ashes. On the night in which the cities of Lima and Callao were destroyed by an earthquake, four new volcanoes broke out in the Andes. Humboldt also states, that a column of dense black smoke, that had issued for several months from a volcano on the shore near Paño, in 1797, disappeared at the very hour when the towns of Riobamba, Hambato, and Tacunga, sixty leagues to the south, were overturned by a most violent shock.

Numerous other instances might be cited, were it necessary, to prove the connection existing between the phenomena of earthquakes and distant volcanoes. The inhabitants in the vicinity of volcanoes are so well aware of this connection, that at Messina and Naples, and at the foot of Cotopaxi and Tungurahua, earthquakes are only dreaded when flames and vapours cease to issue from the craters; and what, says Humboldt, is very remarkable, the shocks appear to be stronger, as the country is more distant from burning volcanoes. The globe, it may be said, is agitated with greater force, in proportion as the surface has a smaller number of funnels communicating with the interior.

The catastrophe of Riobamba, in Quito, before stated, has led several well-informed persons to think that this unfortunate country would be less frequently desolated, were the subterranean fire to break the porphyritic dome of Chimborazo, and this colossal mountain were to become an active volcano.

The connection which distant volcanoes have with each other, and the vast extent to which the agitations of the ground are felt during eruptions, offer satisfactory proofs that the source of heat is not situated in the middle of volcanic mountains, but is placed far below them; or to speak familiarly, a volcanic mountain is not the fire-place, but the chimney-top. Our ideas of volcanic operations will be enlarged by contemplating the immense craters of ancient volcanoes which are either become extinct, or nearly so. From experiments made by Spallanzani to draw up the stones from the bottom of the sea between the islands of Lipari, Vulcano, and Salene, he learned that the ground was one continued mass of volcanic substances, precisely of the same kind as those on the shores of these islands. Hence he infers, that all the submarine ground between them has suffered the action of fire, in the same manner as that which is exposed to view, and these three islands are one continued group of volcanized substances, and have originally been formed by one central conflagration. That this eruption has been subsequently confined to three distinct mouths, which gave birth to the three islands. Humboldt has drawn nearly the same inference respecting the whole of the mountainous part of the province of Quito, which, he says, may be considered as one immense volcano, occupying seven hundred square leagues of surface, and throwing out flames by different cones, known under the denomination of distinct volcanoes, as Cotopaxi, Tungurahua, and Pichinca. In like manner, he adds, the whole group of the Canary islands is placed as it were over one immense submarine volcano. The fire makes its way sometimes through one, and sometimes through another of these islands in different parts. Now if we consider this opinion as correct, how vast and deep must be the volcanic abyss to which the mountains of Quito are only the different chimneys, placed over a thick crust of consolidated porphyritic lava. The volcanic crust which supports the Canary isles, must cover an abyss not less in extent and depth than that of Quito.

The range of volcanoes in the Andes, to the south of Quito, extends in a right line nearly two thousand miles; and if these have originally risen from one vast chafm, like the volcanic ranges of whose origin we have authentic records, it would not appear extravagant to suppose that this chafm may descend to the very centre of the globe. Some philosophers, indeed, contend for the existence of central heat in our planet, which gives rise to all the different phenomena of earthquakes and volcanoes. (See *SYSTEMS of Geology*.) We shall advert to this opinion in treating of the various explanations which have been given of the origin and support of volcanic fires.

In contemplating the impressive phenomena of volcanoes, and the great changes they have produced on the surface of the globe, we cannot be surpris'd that philosophers, ancient and modern, should have been anxious to discover the origin of these fires, and the means by which they are supported, but from the nature of the subject, their theories can be entitled to little more than the appellation of probable conjectures.

In all inquiries of this kind, it is important to bear in mind the essential distinction between the cause of any natural phenomenon, and the mode in which that cause operates. With the latter we may become well acquainted by attentive observation, while we remain profoundly ignorant of the former. Thus, when in volcanic operations we observe the expansive effects of heat, forcing a vent for the discharge of aeriform, fluid, or solid matter, we may infer that these effects do not differ in kind, but in degree only, from the same effects of heat when subjected to the controul of human agency; but we can draw no certain inference from hence respecting the origin of volcanic fire, or the substances by which they are kept burning for thousands of years with increased or diminished intensity.

The opinion formerly most prevalent respecting the origin of volcanic fire, was that it proceeded from the subterranean fermentation of certain materials which were dispos'd to inflame and explode spontaneously. When the decomposition of iron pyrites by water, and the spontaneous inflammation attending it was first observed, and particularly when the experiment of Lemery was known, where inflammation is produced by a mixture of iron-filings, sulphur, and water, it was imagin'd that a satisfactory explanation of the cause of volcanic fire was discovered.

In this experiment he mixed twenty-five pounds of powdered sulphur with an equal weight of iron-filings: and having made with water a paste of the mixture, he put it into an iron pot, covered it with a cloth, and buried it a foot under ground. In about eight or nine hours time the earth swelled, became warm, and crack'd: hot sulphureous vapours were perceived; a flame which dilated the cracks was observed; the superincumbent earth was cover'd with a yellow and black powder; and, in short, a subterraneous fire, producing a volcano in miniature, was spontaneously lighted up from the reciprocal actions of sulphur, iron, and water. See *Artificial EARTHQUAKES*.

The above experiment has been often repeated; and it has been observ'd, that large quantities of the materials are not requisite to make the experiment succeed, provided there be a due proportion of water: half a pound of steel-filings, half a pound of flower of brimstone, and fourteen ounces of water, will, when well mix'd, acquire heat enough to make the mass take fire. But it was known long before the time of Lemery, that natural mixtures of sulphur and iron would spontaneously take fire. These substances, it is well known, are supplied by the pyrites; a small quantity of which is sufficient to kindle a fire; a proper portion of water (for too great a

quantity would extinguish the subterraneous fire) may be derived either from fissures and channels communicating with the sea, or from sources in the earth, wherein it is known to abound; and air, if it should be thought absolutely necessary to the spontaneous firing of the pyrites, may be conceived either to accompany the water, or to descend into the innermost parts of the earth through the fissures which are found on its surface. Or, if we suppose the heated pyrites to have been in contact with the oxyd of manganese and petrol, the flame may arise, as it is produced by art, from the deficcation of that substance, and its mixture with the mineral oil. That ore when heated affords oxygen gas, of which a very small quantity is sufficient to produce flame; and the flame, when once produced, may be supported by pure air from other ores, as Dr. Priestley has shewn (*Obs. on Air*, vol. iv. p. 210, &c.); and the inflammable matter, according to his system, may be supplied by pyrites, bituminous schistus, bitumen, and coal. After the eruption in any place, the volcanoes themselves serve for spiracles or air-holes, by which the subterranean fire may receive necessary supplies; so that these may serve to keep the magazines of internal fire in a due state, as well as to discharge the smoke and other matters with which it would otherwise be choaked up and extinguish'd.

Many of the regular strata are impregnated with iron and sulphur in the form of pyrites, and it was only necessary to provide for the access of water and air, to produce spontaneous inflammation. Thus the cliffs near Charnmouth, in Dorsetshire, abound in pyrites, and after a very hot summer and heavy rains, they took fire, and continued burning slowly for a long time. These cliffs are principally composed of pyritous clay, forming part of the great stratum, called *lias*, in the west of England. See *STRATA*.

The abundant evolution of sulphuretted hydrogen gas from the decomposition of pyrites, tended further to confirm the opinion that ascribed to this cause the origin of volcanic fire. We conceive, however, that this theory is quite inadequate to explain volcanic phenomena on a great scale, such as the connection which distant volcanoes have with each other, the long continuance of the fire, and its breaking forth again in the same place, after it has ceased to burn for ages. Some phenomena, however, which are nearly allied to volcanic, and appear to be local, may be produced by pyritous decomposition. The eruptions of mud in the Crimea, and at Maccaluba in Sicily, may derive their origin from this cause, particularly as the matter thrown out is observ'd to contain particles of pyrites, whereas they have rarely, if ever, been observ'd in the matter erupt'd from fire volcanoes.

The inflammation of sulphur and bitumen has been supposed by some philosophers to occasion the various phenomena of volcanoes, but where do these substances derive the oxygen necessary to support their combustion? Spallanzani has conjectured that this may be obtained from various saline ingredients which yield their oxygen to heat, or it may be derived from the decomposition of water; but here we meet again with the same difficulty as before; how are the combustible materials renewed for ages in the same place? This would seem to require currents of liquid sulphur and bitumen to circulate through the interior of the globe, a circumstance which the theory of Spallanzani has not provided for, but which does not appear to us very improbable. This industrious observer could not detect the slightest smell of bitumen in the volcanic smoke of Stromboli, but according to Dolomieu and Humboldt, it is very perceptible in Vesuvius, and bitumen is even found in the recently erupt'd lava of that mountain. Sulphur, in its different combinations, is a constant product of all volcanoes.

According to the opinion of Spallanzani and others, the

lava and earthy products of volcanoes are formed of the internal beds of rock, which are melted by the inflammation of sulphur or bitumen, and thrown up by the violent pressure of elastic vapour, either from steam or more permanently elastic fluids. From some ingenious experiments, he ascertained that even the lava itself, at a certain temperature, partly assumes an aeriform state, and may then further contribute to the violence of these explosions, by which it is ejected from the crater.

It was the opinion of bishop Berkeley, that a vacuum was made within the body of the earth by a vast body of inflammable matter taking fire, and that the water, by communication with the sea, rushed in, and was converted into steam. However this be, it is certain, that by the process above explained, a vapour would be produced, whose elastic force is known to be several times greater than that of gunpowder; and, therefore, if the superincumbent weight were not too great, it might cause earthquakes; and it would propel the matter melted by the subterraneous fire laterally towards the mouth of the volcano, where meeting with least resistance, it would expel it, together with all the unmelted stony masses which it found in its passage. It is easy to conceive, that before the dense matter is ejected, the diluted air of the volcano will be first forced out, and carry with it the ashes and looser stones adhering to the sides and crater of the volcano, in the manner observed and described by Sir William Hamilton.

That steam is one of the most important agents in lifting up torrents of lava to such prodigious heights, has been generally supposed: it is even asserted that the sea has been observed to retire in the bay of Naples previously to eruptions from Vesuvius; but this may, with more probability, be ascribed to the upheaving of the ground, than to the sudden absorption of water. Were the water to be absorbed ever so rapidly, other water would instantly flow on to supply its place, so that the apparent level of the sea from this cause could not perceptibly vary, except for a few minutes. But if the ground were softened and raised up by subterranean heat, the effect might continue for a longer time; and should even a small quantity of water find access through fissures to the deep recesses of melted lava, this, by its rapid expansion, might force up part of the lava to the summit of the volcano, and produce the most tremendous commotions.

According to the experiments of Spallanzani, water poured on the surface of melted lava, produced little effect, but when introduced under the surface, it occasioned a most violent explosion. Similar effects are often seen in founderies; for if the moulds contain the least moisture when the melted metal is poured in, it is driven back with a loud report, and is violently dispersed in every direction. These experiments, and the reasonings founded upon them, apply rather to the mode in which volcanic fires operate, than to the cause of these fires. It seems exceedingly probable, that the sudden access of water, and the generation of immense volumes of elastic vapour, may be the immediate cause of most volcanic eruptions. An explanation of the eruption of Etna, nearly similar to this, is given by the poet Lucretius.

“Præterea, magnâ ex parte mare montis ad ejus
Radices frangit fluctus, ætimumque resolvit.
Ex hoc usque mare speluncæ montis ad altas
Perveniunt fubter fauces; hac ire, fatendum est,
Et penetrare, mari, penitus res cogit, aperto :
Atque efflare foras; ideoque extollere flammam,
Saxaque subjicere, et arenæ tollere nimbos.”

Lib. vi. l. 694, &c.

We have still however to seek for the origin of the fire itself, which this illustration does not explain.

The cause of volcanic fire must probably be fought in the chemical combination of the elementary matter, of which mineral substances are composed, and not in the combustion of any inflammable materials like those which exist on the earth's surface. The solid products ejected from volcanoes are composed of the different earths and alkalis; these are not simple substances, but consist of metalline bases and oxygen. Some of these metalline bases, or metalloids, (as they have been called,) instantly inflame on contact with water, and absorb the oxygen from it, whereby they are converted into earths or alkalis, having all the properties which the same bodies possess in their natural state. (See POTASSIUM.) This important discovery of Sir H. Davy has been applied to explain the origin of volcanic fires. It has been supposed that the surface of the globe, formed of the different earths, may be regarded as its oxidized crust, but that the internal parts are principally composed of the metalline bases of these earths; and whenever water finds access to them, they oxydate rapidly, and inflame, and are thrown up in the form of earthy lavas, &c. giving rise to all the various phenomena attending volcanic eruptions. This hypothesis, though simple and ingenious, is not free from various objections. It is exceedingly difficult to conceive how substances so inflammable and oxydable could remain for ages in a metallic state, protected from the access of moisture. Perhaps the difficulty we feel in admitting this may arise from our having observed in the inflammation of potassium by water, that the whole was almost instantly burned and dissolved; but were we to suppose a compact mass of this substance to exist in the earth, of a mile or more in thickness, on the access of a limited quantity of water, the surface would inflame, and be reduced to an alkali, and form a crust, which would protect the internal part from inflammation. Another current of water might dissolve this crust, and again inflame the potassium. By a succession of such currents, the metalline beds in the earth may be supposed to be repeatedly inflamed, until the whole mass was oxydized, when the volcanic fires would there be for ever extinct; unless we can conceive a process of deoxydation to take place, and reduce the earths and alkalis once more to a metallic state. The currents of electric light at the north and south poles may lead us to suspect that electric agency is operative in the interior of the globe, and it would not appear contrary to analogies, were we to suppose that it may perform an important part in the process of deoxydation, and other chemical changes, which produce metalline veins, volcanic eruptions, and other geological phenomena. When the attention of philosophers was strongly drawn to the phenomena of electricity by the discovery of the Leyden phial, in the middle of the last century, it was supposed that this powerful and mysterious agent was the principal cause of the phenomena of earthquakes. Ingenious and plausible theories were framed, to explain its mode of operation, and its agency was extended to account for volcanic fires also. The quantity of electric matter evolved from volcanic smoke in the thunders and lightnings which accompany eruptions, were supposed to indicate that the disengagement of electric matter gave rise to all the phenomena of volcanoes. It may be observed that the data on which these theories were formed was defective: the electric matter evolved from the smoke and vapour of volcanoes was the necessary effect of the sudden formation and expansion of aeriform fluids: this is rendered sensible when a single drop of water is converted into steam, and must be most powerful when immense volumes of vapour are instantly generated.

In our speculations respecting the origin of volcanic fires,
it

it is important to consider whether volcanoes are accidental appendages, or necessary parts of the terrestrial system, for "were we," as Mr. Bakewell observes in his Introduction to Geology, "to regard volcanic craters merely as the vents for subterranean fires, a further inquiry would arise respecting the utility of these fires. We cannot suppose that the interior motions of our planet are not directed to some definite purpose, with the same wisdom and design which are displayed in the external universe. The craters of ancient volcanoes greatly exceed any that are now active; and the quantity of matter thrown out must have been commensurate with the mighty openings through which it was ejected. Now these immense volcanoes, whose craters are many square leagues in extent, had doubtless an important office to perform in the economy of nature. It cannot, therefore, be unreasonable to suppose that the earth itself contains the great laboratory and storehouse, where the materials that form its surface are prepared, and from whence they were thrown up at different times, through these vast openings, either in the state of mud, or in chemical solution, or in the form of lava, or in the comminuted state of powders or sand. The only instances we have at present of rock formations are volcanic; the vast volcanoes in America throw out torrents of mud, which form strata of some hundred square miles in extent, and of considerable depth. And according to Humboldt, the further we trace back the ancient currents of lava, the greater similarity we find between them and those rocks, which are considered as primitive. These primeval eruptions took place when our present continents were covered by the sea or by large lakes, at the bottom of which they probably spread, and enveloped the remains of animals or vegetables, which we find buried in the different strata. Long intervals of repose might allow time for the growth of other tribes of animals, which were buried in the matter of succeeding eruptions. The internal fire acting with greater or less force on the strata already formed, might occasion these dislocations and contortions so frequently observed in primary and secondary rocks." This view of the subject is consistent with that system of geology which supposes the existence of a central fire in the globe, and it assigns to that fire its use in the vast chemical laboratory of nature. The existence of numerous active or extinct volcanoes proves the existence of this fire, their connection leads us to infer the great depth at which it is placed, and the production of new land offers no obscure indication of the final cause. The causes by which this fire is called into greater activity at certain periods, will probably for ever remain unknown; but it is important to keep in mind the essential difference between combustion and ignition. A substance may remain red-hot for ages without undergoing any change, if it be deprived of air, or the presence of other substances with which it is disposed to combine; but by combustion a chemical change is produced. A mass of melted iron or lava, inclosed within the globe, might remain unchanged for any conceivable time, if protected from air or water by a solid crust of the same material; and it is only on the contact of other substances, permeating or breaking through the crust, that the common effects of fire would be produced.

Granting a sufficient final cause for the existence of fire in the earth, the fact will not be more surprising than the emission of light and heat from the sun: of the manner in which either are generated, we are profoundly ignorant, as we are also of the nature and essence of heat itself. We are equally ignorant respecting the causes which have increased or diminished the intensity of subterranean fires at certain periods, and directed them to certain parts of the earth's

surface. The variation of magnetic polarity may lead us to infer that there are regular processes taking place in the earth; and that it is not an inert mass, but a well-constructed machine, containing within it the materials and the means of its future renovation, directed by the same wisdom which guides its path in the heavens, and circulates the fluids through all the various forms of organic existence that inhabit its surface. Whether a time may arrive when the central fire, increasing its activity, shall again reduce the present continents under its dominion, we have no natural means of ascertaining. The ancient Stoics, and many of the oriental philosophers, maintained the doctrine of the destruction and renovation of the world by fire; the sacred writers not unfrequently refer to the same event, announcing a period when "the earth shall be burned up, and the elements shall melt with fervent heat."

Dr. Hooke formerly had maintained, that all land was raised out of the sea by earthquakes; and many modern philosophers seem to admit his hypothesis, though not, perhaps, in its utmost latitude. Von Troil (Letters on Iceland, p. 222.) is of opinion that this island has been produced by volcanoes in the course of several centuries. Dr. Forster, in his Observations made during a Voyage round the World, p. 151. after giving an ingenious conjecture concerning the origin of all the tropical low lies in the South Sea, assures us, that of the higher isles there is hardly one of them which has not strong vestiges of its having undergone some violent alteration by a volcano. Some of them have volcanoes still subsisting; others, among which are Otaheite and Huahine, seem to have been elevated, in remote ages, from the bottom of the sea by subterranean fires. Sir William Hamilton is confident, that the island of Ischia, the whole basis of which is lava, rose out of the sea in the same manner as some of the Azores.

Dr. Priestley (Obs. on Air, vol. i. p. 263.) thinks it not improbable that the volcanoes, with their there are evident traces of almost the whole surface of the earth having been overspread, may have been the origin of our atmosphere, as well as (according to the opinion of some) of all the solid land. The superfluous phlogiston of the air, in the state in which it issues from volcanoes, may have been imbibed by the waters of the sea, which it is probable covered the surface of the earth, though part of it might have united with the acid vapour exhaled from the sea, and by this union have made a considerable and valuable addition to the common mass of air; and the remainder of this overcharge of phlogiston may have been imbibed by plants as soon as the earth was furnished with them.

The beds of lava are deepest and narrowest in the proximity of the crater, and broader and shallower as they are more distant, unless some valley intervenes; scoria and ashes lie still more distant. From these observations extinguished volcanoes are traced. Many excellent investigations of this sort may be seen in M. Soulavie's History of the South of France. For further information respecting volcanoes we refer to *ÆTNA, STROMBOLI, SYSTEMS of Geology, VESUVIUS, and VULCANO.*

Volcanic Products.—The substances thrown out of volcanoes, or found in the crater, are inflammable, saline, metallic, and earthy, without water, and may be classed as aeriform, fluid, or solid.

Aeriform Fluids.—Steam, or vapour, is frequently emitted in a quiescent state of the volcano, and is supposed to perform an important part during the most violent eruptions. Sulphuretted hydrogen gas is thrown out in great abundance from all volcanoes. Carbonic acid gas is emitted from some volcanoes in a quiescent state. Of the other gaseous or volatile substances

substances emitted during an active state of the volcano, we can only infer the existence from the smell or from their being found in combination with the solid products of volcanoes; the principal of these are ammoniacal gas, muriatic acid gas, and sulphureous acid gas. Probably almost every mineral substance which can be rendered volatile by heat, may be emitted in an aeriform state during violent eruptions; even the earthy matter of lavas is volatilized at a high temperature, as was proved in the experiments of Dr. Priestley and Spallanzani.

Volcanic substances fluid at a heat below 212° Fahrenheit are water, which is sometimes thrown out in torrents; and sulphuric acid, found in some volcanic water and bitumen, which has been observed exuding from lavas at Vesuvius. Sulphuric acid, that abounds in some water near volcanic mountains, is probably formed during a quiescent state of a volcano, from the combustion of sulphur in the crater, or in the upper recesses of the mountain. It is not difficult to conceive how the acid may become diffused in the rain-water, or in that from melted snow, which may permeate the porous rocks, and descend in streams from a lofty volcano.

The solid substances ejected from volcanoes, or formed by chemical combination in the crater, comprise inflammable, saline, metallic, and earthy minerals. The three former are by far the least considerable in bulk.

Sulphur is found in abundance in the craters of dormant volcanoes; its formation is attributed to the gradual decomposition of sulphuretted hydrogen gas, exhaled copiously through fissures from below. See *SOLFATERRA* and *SOLFATERRERE*.

Phosphorus is too inflammable to be found solid among apatite volcanic products; it is only from the white colour of the smoke, from its peculiar smell, and from its combination with lime in the mineral called apatite, found near some volcanoes, that we can infer its existence as a volcanic substance. See *APATITE*.

Solid carbon has only been found in small quantities, in concrete bitumen in some volcanic products. Carbonized wood and vegetable matter have been found occasionally in lava or tufa; in all probability they were enveloped during an eruption, and cannot therefore be regarded as volcanic substances. Carbon, in the state of mineral coal, has been supposed by M. Werner and his followers to be the principal support and cause of volcanic fires; but this opinion is destitute of all proof, and is at variance with all geological analogies.

The saline substances found in the craters of volcanoes, or formed by volcanic fire, are numerous, though not very abundant. Muriate of ammonia (sal ammoniac) forms an incrustation on many lavas soon after they cool. Muriate of soda (common salt) is found in some volcanoes in considerable quantities, even entire beds of rock-salt are found in volcanic craters, as at Pofa, near Burgos. Mount Cologero, near Sciacca, in Sicily, appears to be a volcanic mountain, impregnated throughout with common salt. Muriate of copper and of iron are found in some volcanoes, as that of Vesuvius. Sulphate of iron and sulphate of copper, or green and blue vitriol, alum, gypsum, and sulphate of magnesia may also be enumerated among the saline substances found in volcanoes. See *SULPHATE of Iron, &c.*

The metallic substances found in volcanoes, or among their products, are antimony, copper, gold, manganese, mercury, iron, tellurium, and titanium.

Antimony is found combined with sulphur.

Copper is found native, and combined with sulphur, with

iron, and with the muriatic and sulphuric acids, as before stated.

Gold is said to be found in some volcanic products, and the gold-mine of Nagyag is stated by Breizlak to be placed in the crater of a volcano. There is a gold-mine in the island of Ichia, which is entirely volcanic.

Manganese exists in a small proportion combined with iron in obsidian and lava.

Mercury is found at Guanca Velua in great quantities, and it is said the mine is situated in the crater of a volcano. M. Patrin supposes that some of the Cinnabar mines in Asia have a similar situation.

Iron is abundantly diffused through all volcanic rocks, which have a dark-brown, a black, or red colour. It forms one-eighth part of the substance of most lavas. Iron exists also in craters in the form of specular iron ore.

Tellurium is found with gold in the mines of Nagyag. See *TELLURIUM Mines*.

Titanium, combined with iron, appears, from the observations of Cordier, to be a constituent part of almost all dark-coloured volcanic rocks.

The earthy products of volcanoes consist principally of lava, obsidian, pumice, volcanic flags or scoria; with volcanic sand, tufa, and we may also enumerate the earthy tufa formed of the indurated mud thrown out of the American volcanoes. Many geologists enumerate basalt and wacke among volcanic products, which they resemble both in appearance and in the nature of their constituent parts. Various crystallized minerals are found imbedded in lava, particularly augite, crysolite, or olivine, felspar, leucite, Vesuvian, and zeolite. (See *Augite, &c.*) Under the articles *Lava, Obsidian, &c.* are given some account of these minerals.

The stones first thrown out of volcanoes are frequently pieces of granite or other primitive rocks, either untouched or only partially changed by fire. This circumstance proves that the seat of volcanic fire is far below these rocks. Scoria or volcanic flags are generally thrown out before the eruption of lava. These flags are more or less vitrified; they sometimes take a globe form in the air, and become consolidated before they cool. These have been called volcanic bombs. Immense black clouds, consisting of pieces of scoria and minute fragments and particles, similar to the scoria, are thrown out with it. Some volcanic eruptions consist entirely of these powders or sand, which are driven to vast distances, and have been carried by currents of air more than five hundred miles from the volcano.

Vesuvius threw out scoria and powders without any lava, for many centuries after the eruption in 79 A.D.

Lava.—Currents of melted stone or lava, of twenty or thirty miles in length, from two to four miles in breadth, and from twenty to forty feet in depth, are found in volcanic districts, equalling in size some of the regular strata of the globe. The upper surface of these lavas is generally more or less vesicular and scoriaceous; and it is only where the beds have been broken or cut through, that the compact stony substance of the lava can be seen. From this circumstance alone many philosophers have been led to doubt the volcanic origin of more compact rocks; but, as M. Cordier observes, in a paper recently published, “to judge of the substance of a current of lava, from what appears on the surface, would be like judging of a vat of wine from the froth with which it was covered.” The crystals imbedded in lavas were supposed by many geologists to have existed previously in the rocks which formed the lava, but were too infusible to be melted by the volcanic fire. On this erroneous supposition, they concluded that volcanic fire

muil have possessed but a low degree of heat, as the same crystals may be melted in a common furnace. The formation of crystals does not depend upon the degree of heat, but on the circumstances under which the substance cools; a long state of quiescent fluidity being as necessary to the formation of perfect crystals by igneous fusion, as it is known to be in aqueous solutions. Inattention to this circumstance has rendered many of the conclusions from the laborious researches of Spallanzani invalid. M. Cordier, an ingenious geologist in France, has devised a new mode of analysing lavas. He very properly observes, that the attention of geologists has been hitherto directed more to the imbedded crystals in lava, than to the paste or base of the lava itself; and it has been admitted, without sufficient proof, that the base of lava was either hornblende or feldspar, or a mixture of these two minerals.

On attentively examining the substance of lava and volcanic scoriae, with a very high magnifying power of the microscope, he discovered that it was not homogeneous, but consisted of a congeries of minute crystals of different minerals, which were principally similar to the larger imbedded crystals. To ascertain more decidedly the nature of these small crystals, he endeavoured to disunite them by compression, then selecting particles of the same size separated them, according to their relative density, by washing. The isolated particles were afterwards examined with the microscope, and compared with the particles of the crystals most commonly found in volcanic rocks, such as feldspar, crysolite, olivine, iron-sand, and menakanite. He commenced with the examination of compact or stony lavas, beginning with those from burning volcanoes, then proceeding to those from extinct volcanoes, and lastly to those whose volcanic origin has been doubted by geologists, such as basalt and wacke. The result of these examinations has led him to conclude, that all these rocks, from whatever district they come, are composed nearly in the same manner, and are all granular, consisting of very different distinct crystalline grains, interlaced with each other, so that all stony lavas may be regarded as minutely granitic, when viewed with the microscope. There sometimes exist minute pores between the grains, which however do not occupy one-sixtieth part of the bulk: these pores are more common in modern than in ancient lavas.

There are five sorts of these grains distinguishable by their colour; 1. white more or less transparent; 2. bottle-green; 3. black and perfectly opaque; 4. a clear brown; 5. and lastly, very small grains of reddish-brown. These five sorts of grains are susceptible of further subdivision, according to their physical or chemical properties. The white grains belong to three distinct minerals. The most common are those which melt into a white enamel; these are feldspar. The more infusible are crysolite, and those which are perfectly infusible are leucite.

According to the prevalence of feldspar, the lava possesses different characters. Those which contain from forty-five to fifty-five per cent. of feldspar, melt into a black glass, the minute edges of which are bottle-green, black, or greyish-black; basalts are of this kind.

Those lavas which contain from fifty-five to seventy per cent. of feldspar, melt into a bottle-green enamel, such are the greenish, greyish, and dark-coloured basalts.

Stony lavas, which contain ninety per cent. of feldspar, melt into a white glass. Such are the petrosiliceous or compact feldspar lavas and clink-stone.

The yellowish or greenish grains belong to augite or hornblende, which are sometimes difficult to be distinguished from each other. According to Cordier, the grains of augite

are rounded and irregular, with a vitreous fracture and splendent lustre. The grains of hornblende are long, and assume a prismatic form: they present indications of their laminar structure, and have little lustre except in the direction of the laminae.

The greatest proportion of augite in lava is forty-five per cent. These lavas melt into a black glass. Those lavas which melt into a white glass only contain one per cent. of augite. The black opaque grains consist of titanium combined with iron, as iron-sand, *fer titané*, or as menakanite. The iron-sand contains only 0.5 of titanium, the particles have a perfect metallic lustre, and conchoidal fracture, and are attracted by the magnet. The greatest proportion in which they exist in stony lavas that melt into a black glass, is fifteen per cent. The grains of menakanite exist in a much smaller proportion, they are difficult to melt, and are not attracted by the magnet.

The grains of iron ore, *fer oligiste*, may be known by the red colour of the powder when they are pounded. These are very rare in lavas.

From an examination of a great number of lavas, it appears that there are only two prevailing minerals which compose the greater part of their base. These are augite and feldspar. All the rest are in a very small proportion; and hornblende, which has been admitted without examination into all volcanic rocks, exists but in a very few, and those are such as abound in feldspar. In the latter the crystals of hornblende, which are disseminated, are very distinct. Basaltic rocks, which have hitherto been stated to consist of hornblende and feldspar, according to Cordier, are principally composed of augite and feldspar.

Stony lavas may therefore be classed into two kinds, those which melt into a white glass, and those which melt into a black glass. The former M. Cordier denominates leucostine, the latter basalt. Leucostine comprises those substances called, by Dolomieu, *petrosiliceous lavas*; by Hauy, *compact sponorous feldspar*; by Karsten, *domite*, and *lava with a horn-stone base*; and by Werner, *clink-stone*. The latter comprises the ferruginous lavas of Dolomieu; the basaltic lava of Hauy, *les lavas basaltiques uniformes*; and the basalt and lava of Werner. The result of these observations confirms the similarity of composition between stony lavas of recent volcanoes and basaltic rocks, whose igneous origin has been contested.

In the same manner M. Cordier has examined the composition of volcanic scoriae and volcanic glass, volcanic cinders and tufa. These are all composed of the same substances as the stony lava.

Obsidians, or volcanic glasses, may be divided into two kinds like lava, according as they yield a black or white glass to the blow-pipe. In the vitreous paste of both may be discovered by the microscope, the same crystals as in lava, grains of feldspar are seen in those glasses which become white before the blow-pipe; grains of augite in those which melt into a black glass. In certain instances, we see the transition of obsidian into a compact black basalt, and also into pumice.

These observations of Cordier tend to establish the identity of basaltic rocks with those of volcanic origin, whilst at the same time they distinguish them from the beds of hornblende and trap, which occur in primary mountains. The latter differ in composition from basalts and lavas, and also in the nature of the imbedded crystals which they contain. All volcanic rocks, even those which appear the most homogeneous, are composed in a great part of microscopic crystals, belonging to a small number of minerals, particularly augite, feldspar, olivine, and iron-sand. Volcanic

rocks of every age and country, that have flowed as lavas, or been ejected during fiery eruptions, are composed of the same mineral substances, and are different in their composition and internal structure from rocks which form the regular strata of the globe.

The external structure of lava is much diversified, owing, in all probability, to the different circumstances under which it has cooled. Some lava is porous, some contains large cavities or is vesicular, whilst other lavas are apparently compact, and assume a prismatic form. According to the observations of sir G. S. Mackenzie in Iceland, there are beds of lava of great extent, which appear never to have flowed in currents, but to have been completely fused in the situations where they occur. This lava was columnar in many places, the columns varying in size from a few inches to several feet in diameter. The surface of the lava was heaved up into large blisters and bubbles, some of which were round, and from a few feet to forty or fifty in diameter, others were long, and some were waved. A great many of the bubbles had burst, and displayed caverns of considerable depth. On this account sir G. Mackenzie denominates it *cavernous* lava. Currents of lava, which had flowed from volcanoes, covered the cavernous lava in many parts, but presented very distinct characters. In the common streams of lava, no defined approach to a columnar form was observed; but nothing was more common than the columnar structure in the cavernous lava. In some parts of Iceland were seen beds of amygdaloid, from ten to forty feet in thickness, alternating with tufa. The upper part of these beds did not indicate the action of fire, but the under part of each was a complete volcanic flag. From the situation of these beds, and other circumstances, it was inferred that they were lavas which had flowed under the sea. Some of the beds were very compact in the upper part. Another series of beds occur near Krifuvick, which was sluggy at the bottom, but so compact above as to resemble porphyry slate. Beds of very compact basalt, with the under surface sluggy, were also observed; and an extensive and beautiful range of lofty columns at Stappen present the same appearance, and have sluggy masses included in them. Sir George Mackenzie explains these appearances, by supposing the lava to have originally flowed over a cold wet surface at the bottom of the sea. An abundance of steam would constantly be produced from the upper surface, which would separate the hot lava from the water, in the same manner as a drop of water is kept detached from a plate of red-hot iron. Thus, no water could enter the substance of the lava from above, but the moisture below would operate very differently. From its conversion into steam, and the tendency to ascend, it would penetrate the fluid lava, and produce the porosity observed in the above rocks, and render the lava more or less vesicular, according to its degree of fluidity. When the lava is very hot and liquid, the steam will have less difficulty in penetrating it. In some instances it may allow the whole of the moisture to escape through it in the form of elastic vapour, so that the lava may become solid. According as the lava is more or less viscid, the steam may be more or less confined, making the stone porous or vesicular; and, lastly, the lava may be so tough, that the exertions of the elastic vapour may be confined to the lower surface of the beds. In the first case, a mass of compact stone would be formed, having no appearance of the action of fire. In the second case, the lava would form an amygdaloidal or vesicular mass. In the last case would result a mass entirely compact, except in the under-surface. (Travels in Iceland, by sir G. S. Mackenzie.) In the formation of volcanic rocks, which have

flowed as lava under the sea, very different results would take place from the formation of similar rocks on land, owing to the great difference which the superincumbent pressure of a deep volume of water would occasion; and as most of the ancient currents of lava have in all probability been originally submarine, we may expect them to vary in structure from the lavas of more recent eruptions. In the Transactions of the Royal Society of Edinburgh are several valuable papers of sir James Hall, detailing a series of the most interesting and instructive experiments on the effects of heat modified by compression. These experiments merit the profound attention of every one who would endeavour to form a just and comprehensive view of the agency of subterranean fire on the different rocks which form the crust of the globe. For the result of some of these experiments, we refer to *SYSTEMS of Geology*; but we particularly recommend our readers to peruse the original papers, which are well illustrated by a series of plates.

The minerals which line or fill the cavities of vesicular lava are principally varieties of zeolites, chalcedonies, and calcareous spar. Quartz crystals abound in some of the vesicular lavas of Lipari. All these minerals are supposed, with much probability, to be of posterior formation to the lava itself, and to derive their origin from the infiltration of water, holding the constituent parts in solution or suspension. Spallanzani conjectures that the particles are separated from the lava itself, by the decomposing effects of sulphureous acid.

Lava is subject to decomposition from atmospheric agency, according as it is more or less vitreous. Some lavas are known to have resisted all tendency to decompose for many centuries; other lavas decompose rapidly, and form a productive soil. Particular vegetables possess the property of reducing lava to vegetable mould with great rapidity. The Indian fig, or, as it is commonly called, the prickly pear, has this property in a remarkable degree. According to the account of it given by General Cockburn, in his "Travels through Sicily," this plant pulverises the hardest rocks, and forms the most luxuriant soil. The inhabitants bring a little earth to any crevice of lava, and plant a prickly pear-tree in it, which spreads and splits the rocks in about seven years. A thick plantation is thus formed, and a very little earth being added, in about ten years more the rock is pulverised for some inches deep. Vol. ii. p. 163.

Obsidian or *black volcanic glass* appears to be a vitreous modification of stony lava, produced by its sudden refrigeration. According to the observations of Cordier before stated, it may consist either of feldspar or augite, as forming the principal part of the base. The volcanic origin of this mineral has been denied by some geologists without any apparent reason, except an attachment to theory; for this substance may be traced flowing from the craters of volcanoes, and passing into compact black lava or basalt, and also into white spongy pumice. Sir James Hall and Dr. Home visited a mountain in Lipari, that had escaped the attention of Dolomieu. From several openings in this mountain a stream of obsidian and pumice might be traced: they gradually passed into each other. The pumice had evidently flowed with the obsidian, as it formed the upper surface of the stream. The greatest breadth of the stream was about two miles and a half, and its length three miles. It seemed to have been produced by the last effort of the volcano. Sir G. Mackenzie discovered a stream of obsidian in Iceland, filling up a valley to the depth of thirty feet, and visible for more than two miles in extent. The surface was in many parts covered with pumice. Obsidian is found streaming from the crater of Vulcano; it exists in abundance

dance at Teneriffe, Kamtschatka, and various volcanic countries; but it is by no means so common a product as stony lava.

The objections to the volcanic origin of obsidian, founded on its loss of colour, and its tumefaction at a low degree of heat, are deprived of their force by the discoveries of Sir James Hall before mentioned. These experiments prove, that a stone, which was not fusible under a heat of thirty-eight degrees of Wedgewood's pyrometer, yields a glass that softens at fourteen degrees; and when this glass is remelted, and acquires a stony texture by slow cooling, it cannot be fused again with a less degree of heat than thirty-five degrees.

Pitch-stone (see *PITCH-Stone*), though less vitreous in its appearance than obsidian, yet, viewed by the geologist as it exists in nature, cannot be separated from it, but must be classed as a different mode of the same substance, or as vitreous lava. The base of the Peak of Teneriffe, to the plain of Ketama, is buried under scorix and heaps of pumice reduced to powder. From thence to the summit of the mountain, or from fifteen hundred to nineteen hundred toises in height, the volcano exhibits only vitreous lavas, composed of obsidian and pitch-stone more or less porphyritic: they are of blackish-brown, often varying to the deepest olive-green; they contain large crystals of felspar. The analogy of these decidedly volcanic substances with the pitch-stone porphyries of the valley of Turbach in Saxony is, says Humboldt, very remarkable; but the latter contain quartz, which is wanting in the modern lava. When the lava changes from pitch-stone to obsidian, the colour is paler; sometimes both varieties occur in the same fragment. Among the pitch-stone and lava, near the summit, were found blocks of real greenish clink-stone porphyry, similar to the porphyry-slate of the mountain of Belin, in Bohemia. These facts further prove the connection between rocks of the trap formation and volcanic products. (See *TRAP*.) Obsidian and pitch-stone are found in Hungary, in Mexico, and in Quito, at a great distance from burning volcanoes. Pitch-stone exists abundantly in some of the Scotch Hebrides, particularly in the isle of Eigg. In South America, obsidian is scattered over the fields in angular pieces, and sometimes forms isolated rocks. The Mexicans dug obsidian in mines, and made knives, sword-blades, and razors of this mineral. The Guanches in Teneriffe made spear-heads of obsidian; it was also employed by them, and by the Mexicans, in the fabrication of mirrors and ornaments for the women. Various volcanic glasses, differing in colour and from obsidian, occur in some volcanoes, particularly that of the isle of Bourbon. These may, however, all be classed with vitreous lavas, as it appears from the experiments of M. Cordier, that the constituent parts of all are the same, being principally composed of varying proportions of augite and felspar.

Pumice (see *PUMICE*) is an abundant product of volcanoes: it may be considered as light spongy lava, under which term is comprised a great variety of volcanic substances, differing in porosity, in texture, and in colour. The term *pumice-stone* indicates a capillary or fibrous texture of lava. It appears to be the product of intense heat, operating either on lava or obsidian; the lighter coloured pumices being formed of those volcanic rocks which abound in felspar, or rather it is the elements of these rocks in a capillary form. As some obsidian swells greatly, and loses its colour by heat, it was inferred that all pumice has been formed from this mineral; but the conclusion is too general. There are numerous instances in which obsidian may be traced passing into pumice; but there are other instances in

which stony lava, abounding in felspar, may also be traced passing into pumice-stone. Some experiments made by Humboldt prove that different obsidians swell very unequally, when exposed to the moderate fire of a forge. Those from the Peak of Teneriffe, and the black varieties from Cotopaxi, increased in bulk more than five times. The red varieties from the Andes, on the contrary, were not much tumefied by heat. We have already stated instances of currents of obsidian covered with pumice, and of masses of obsidian passing into pumice, so as to leave no doubt of the formation of pumice from obsidian. Nor are there wanting instances as decisive of lava passing into pumice. This cannot, on reflection, appear surprising, as obsidian and lavas are essentially the same substances in a vitreous and stony form. Spallanzani describes a lava with a base of felspar, which is spread over a part of Lipari, rising in rocks and crags of enormous size: it is of a grey colour. On attentively examining this lava, the gradual transition into pumice may be distinctly perceived. It is not uncommon to find masses of this lava, which on one side retain the character of felspar, and on the other are changed into white pumice, exactly resembling that of Campo Bianco in colour, lightness, structure, and other characters. Some of the white pumices of Campo Bianco are so compact, that the smallest pore is not visible to the eye; but when viewed through a lens with a strong light, they resemble an irregular accumulation of flakes of ice: their compactness, however, does not prevent their swimming on water. Other pumices were full of pores and vacuities of a larger size, and their texture is formed by filaments arranged parallel to each other, and of a silvery whiteness: both these varieties may sometimes be seen in the same stone; hence we may infer that the difference arises from the action of elastic fluids producing different degrees of dilatation, when the mass was in a fluid state. There is a black pumice in Lipari, composed of parallel filaments, that all lie in one direction, which is that of the bed descending from the mountain to the sea. This, says Spallanzani, may be considered as a true current of pumice. The black colour he supposed to proceed from some bituminous substance, as a strong smell of bitumen is emitted, when two pieces of this pumice are rubbed together. The black colour was entirely lost by exposure to heat for some time in the furnace, which reduced it to a vitreous paste. Humboldt conjectures that the dark colour of some obsidians is caused by a hydruret of carbon.

Nature, says Humboldt, probably employs different means to produce the spongy and vitreous pumices of Teneriffe, the pumices with parallel fibres from the Lipari islands, and the capillary vitrifications of the isles of Bourbon, which sometimes resemble a spider's web. These differences probably consist in the different degrees of heat, in the different pressure under which the fire acts, and in the nature of the rocks altered by it. Above all, says the same traveller, the pressure which obsidians undergo in their fusion, explains why these substances, with some exceptions, are never found whitened. Those pumices, which have the appearance of having been formed at great depths, are fibrous, and of a silky lustre. Blocks of this kind on the Andes, of eight or ten toises in length, have the fibres exactly parallel with each other, and perpendicular to the direction of the beds. Several volcanoes do not throw out any pumice; and those that do, eject them only by their crater after the flowing of the lavas.

Volcanic Sand.—The white powders which have been called ashes are generally thrown out the last, and indicate the end of the eruption; they consist entirely of white pumice ground to powder. The black powders issue the first, and, being

VOLCANO.

being driven with greater force, are carried to a greater distance from the mountain. These powders are called by the Italians black and white rapilli.

Volcanic scoria or *slags* differ from pumice by their greater density; they are properly masses of cellular lava, and are more or less vitreous or stony, according to the degree of heat to which they have been subjected, and the circumstances under which they have cooled. The upper part of modern currents of lava, that have flowed in contact with the atmosphere, are generally composed of scoriae. The composition of scoriae is the same as that of lava, and varies with the different lavas from which it is formed.

Volcanic tufa appears to be formed of the loose sand or powders, together with the smaller fragments thrown out of volcanoes, which are spread over the surface of the ground, and afterwards become partly consolidated by water and pressure. In all submarine volcanoes, these powders must be mixed with water as soon as they are discharged from the mouth of the crater, and must therefore fall as a muddy sediment over the bed of the ocean, and form frata of tufa of greater or less extent according to the quantity of matter ejected. The materials of which the powders are formed, may also have been mixed with water in the deep recesses of the volcano, and have been discharged in torrents of mud like those which issue from the American volcanoes. In this way beds of tufa of great extent have probably been formed, and as they sometimes take the same shape as the original inequalities of the ground, it has been supposed that they have flowed as lavas. Spallanzani describes a bed of tufa in Lipari which covers the surface of the hills and valleys nearly equally; but it would be difficult to conceive how a stream of mud could ascend a hill, were it ever so tenacious. If the matter were deposited from the turbid waves of the ocean, we should have no difficulty in accounting for its present appearance, and also for the stratification of tufa alternating with beds of lava. Volcanic tufa, in its more indurated state, is used as building stone; soft or incoherent tufa has received the names of puzzolana, tarras, &c. See PUZZOLANA.

Volcanic tufa composes the principal soil of many volcanic districts. A great part of mount Etna and the mountains on its sides are composed of this tufa.

Hills of tufa, according to Sir G. Mackenzie, invariably accompany lava in Iceland. Whole ranges of mountains are formed of it, and wherever eruptions have occurred, these hills of tufa may be seen. It closely resembles the tufa of Sicily and Italy. The tufa of Iceland often alternates with submarine lava, and then it invariably includes masses of lava and slags, more or less rounded by the action of water. The beds of tufa are sometimes not less than forty feet in thickness. When tufa alternates with beds of amygdaloid trap and greenstone, it includes masses of these substances. The submarine lavas which alternate with tufa, are always above the beds of trap and greenstone alternating with the same substance. Sir G. Mackenzie conjectures that they are all the products of submarine volcanoes, but that the beds of trap and greenstone were first erupted at a greater depth under the sea, and under a greater compressive force; to which cause the difference in their structure from that of the upper beds is to be attributed: hence the lower beds, being more compressed and compact, have lost the appearance of the immediate action of fire which is so visible in the cellular lava and slags nearer the surface. Mountains of tufa, one thousand feet in height, occur in Iceland, and even whole mountain ranges are composed of the same material; in these there is no appearance of regularity, but all the mass is heaped up in confusion. The pre-

vailing colour of the paste of this tufa is yellow; and, in a description given by Mr. Stephenson of an eruption from one of the Icelandic volcanoes, called the Kattlagian Jokul, we have an instance of its actual formation. "The sand which fell afterwards united, and covered the meadows with a yellow-coloured crust, quite compact."

The mud thrown out of the American volcanoes, when indurated, may be classed with tufa; but besides the earthy ingredients, it contains a portion of carbonaceous and saline matter. To some intermixture of this kind, the fertilizing properties, ascribed to the fine sand or powder recently ejected from the volcano at St. Vincent's, may perhaps be attributed.

Puzzolana and *tarras* are those soft tufas which are ferruginous, and possess the property of consolidating under water when mixed with lime as a cement. This property is derived from the iron, and is common to many of the argillaceous limestones of England that abound in iron.

From the experiments and observations of M. Cordier before stated, it appears that the different earthy products of volcanoes, whether as stone in the form of compact, vesicular, or amygdaloid lavas, or in a state of perfect vitrification as obsidian, or less perfectly vitrified, as scoriae, or in the earthy form of wacke or volcanic tufa, or in beds of sand formed of minute detached grains or particles, are all composed principally of augite and felspar in different proportions.

This view of the subject tends greatly to simplify our knowledge of volcanic products, as all the earthy masses and rocks ejected from volcanoes, however differing in structure, density, and colour, are to be regarded only as different aggregations of the same mineral substances, modified by the various effects of heat and compression, and the operation of these causes to which they have been subjected since their first eruption.

Various rocks which have been classed under the unscientific denominations of fletz trap rocks and greenstone are also composed of the same mineral substances aggregated in a similar manner; hence we may infer that they have had a similar origin. These rocks are very extensively spread both in volcanic districts, and in countries remote from any active volcanoes; they serve as monuments to elucidate the natural history of the globe, and to mark the boundaries of the ancient dominion of fire over the present continents.

VOLCANOES in the Moon. Dr. Herschel, now so well known and universally celebrated, on account of his various astronomical observations, discovered, on the fourth of May, 1783, a burning volcano in the moon. This discovery confirms the conjectures formed by M. Äpinus, in 1778, and published in a memoir printed at Berlin in 1781, concerning the volcanic origin of the inequalities in the moon's surface. Similar ideas occurred to professor Beccaria, of Turin, nearly at the same time, and also to professor Lichtenberg, of Göttingen. The nephew of professor Beccaria discovered, Oct. 11, 1772, a luminous spot on the moon, during its total eclipse of that night, in or near the place marked Copernicus; and from this time the professor mentioned this observation in his public lectures, as an evidence that the round cavities on the surface of the moon were so many craters of distinct volcanoes; adding, that he considered those straight radiations, or bright paths, which are observed particularly on the place of the moon marked Tycho, as so many torrents of the lava, which spouted off in some former conflagration of a volcano.

The reader may see this account, given by the professor himself, in a letter concerning the luminous appearance observed by don Ulloa on the moon, during the total eclipse of the

the sun, June 24, 1778; in which he maintains, that such a luminous spot was an actual burning volcano, and not a real hole through the mafs of the moon, as Don Ulloa asserted it to be. This letter is inserted in the *Journal de Physique* for the month of June, 1781. M. Äpinus observes, that the opinion of volcanoes in the moon was first suggested by Dr. Hooke, in his *Micrographia*, printed at London in 1665; in the twentieth chapter of which work he speaks at large concerning this opinion.

Dr. Herschel, on the 4th of May, 1783, discovered two small conical mountains in the very same spot where he had observed the volcano; these are situated in the Mons Porphyrites of Hevelius, just by a third mountain, much larger, which Dr. Herschel had often observed before. (See *Genl. Mag.* for August, 1784, p. 563, &c.) On the 19th of April, 1787, the same ingenious and indefatigable observer discovered three volcanoes in different places of the dark part of the new moon. Two of them were nearly extinct, or in a state ready to break out. The third shewed an actual eruption of fire, or luminous matter. From another observation he infers, that the diameter of this volcano cannot be less than $\frac{3}{4}$, and that the diameter of its burning part is equal to at least twice that of the third satellite of Jupiter, with which it was compared. Hence the shining or burning matter is computed to be above three miles in diameter. *Phil. Transf.* vol. lxxvii. part i. p. 230.

VOLCHOVA, in *Geography*, a river of Russia, which rises in the Ilmen lake, and runs into lake Ladoga, at Nov Ladoga.

VOLCHOVSKOI, a town of Russia, in the government of Tobolsk; 32 miles E. of Surgut.

VOLCI, in *Ancient Geography*, a town of Italy, in the interior of Etruria. Ptol.

VOLCI. See **VOLSCI**.

VOLCIANI, or **VOLSIANI**, a people of Hispania Citerior, celebrated on account of the determined reply which they made to the Roman ambassadors, when they solicited them to renounce their alliance with the Carthaginians.

VOLCKACH, in *Geography*, a town of the duchy of Wurzburg, on the Maine; 11 miles N.E. of Wurzburg. N. lat. 49° 54'. E. long. 10° 14'.

VOLCKERSBERG, a town of Westphalia, in the bishopric of Fulda; 12 miles S. of Fulda.

VOLCKMANNSDORF, a town of Silesia, in the principality of Neisse; 6 miles E. of Neisse.

VOLCONDA, a town of Hindoostan, in the Carnatic; 95 miles S. of Arcot. N. lat. 11° 10'. E. long. 79° 10'.

VOLCZINCY, a town of European Turkey, in Macedonia; 25 miles W. of Orhei.

VOLENGO, a town of Italy; 23 miles W. of Mantua.

VOLERIUS, in *Ancient Geography*, a river of Corsica, whose mouth was on the northern coast. Ptolemy.

VOLERY, a great bird-cage, so large that the birds have room to fly up and down in it.

VOLGA, in *Geography*, a river of Russia, sometimes called by ancient writers *Rha*, and sometimes *Araxis*, is denominated by the Tartars *Idel*, *Adal*, or *Edel*, denoting plenty, and by the Moravians is still called *Rbau*. It is formed by two streams, one issuing from lake Seliger, in the government of Tver; the other from a smaller lake, eight miles from lake Seliger, which unite together, N. lat. 56° 40'. E. long. 51° 20'. Its waters issue from several lakes in the Valdai frontier mountains. After their union, the river then takes a south-east course to Zoltzov; it then changes to north-east, passes Staritza, Tver, and Mologa; near which last place it changes its course to south-east, passes

Jaroslavl, or Yaroflaf, Kostroma, Penza, and Kazan; after which its course is more south, passing by Spask, Simbirsk, Samara, &c. At Samara it inclines a little to the west, passing by Sizran, Chvalinsk, Volk, Kurdiun, Saratof, Kamlichin, Tzaritzin, &c.; at Tzaritzin it takes its course fourth-east, and passing by Tebernoiyar, and a number of other towns, forts, &c. in the governments of Tver, Yaroflaf, Kostroma, Nishney-Novgorod, Kazan, Simbirsk, Saratof, and Caucasus; it enters the Caspian sea at Astrachan, by several large mouths, two only of which are navigable for vessels of 150 tons. It is said to distribute itself into 70 branches, and to form a multitude of islands before its discharge into the Caspian. This is supposed to be the largest river in Europe, and in its course of 4000 versts, is joined by many other rivers; a canal is made from it to the Neva, which opens a navigable communication between the Caspian sea and the Baltic.

The Volga pursues its course through many fertile regions, and in the inferior part of it, passes by beautiful forests of oak. It very much overflows in the spring, and is then navigable in certain parts, which at other times are not navigable. Its chief navigation commences at Tver. It has no cataracts, nor other dangerous places; and it is said to become shallower from time to time, so as to afford reason for apprehending that it will cease to be navigable for vessels of any tolerable size. It abounds with fish, particularly sterlet, sturgeon, &c. The principal rivers which join it in its course are the *Kamma* and the *Okka*; which see respectively.

The Volga teems with a vast variety of fish, which not only supplies the parts adjacent, but the greater part of the empire, with the several sorts of sturgeons, with kaviar, and with an incredible number of different kinds of smaller fish. This store of wealth, which no other river in Europe possesses in an equal degree, induces the countrymen about the Volga to neglect agriculture, and to devote themselves to the fishery. Among the fish peculiar to the Volga, which seldom or never come into the collateral rivers, are the beluga, the sturgeon, the sterlet, the fevruga, the falmon, and white falmon. But of all the fish of the Volga, the several kinds of sturgeons, and the white falmon (*falmo nelma*), are the best. The beluga is from 20 to 25 spans in length, and weighs between 30 and 45 poods. Sturgeons are from 5 to 8 spans long, and from 20 pounds to 2 poods in weight; the fevruga holds the middle station between the beluga and the sturgeon; the red falmon is observed here only in the two last months of the year, and then but seldom; the white falmon swim against the stream in great numbers, from the beginning of January to some time in July; both these are from 3 to 5 spans long, and at most weigh 30 pounds. The barbel is often larger and heavier, and the sturgeons the largest after the beluga. Of all the subordinate rivers that fall into the Volga, the *Kamma* is the wealthiest in fish, and the fish of the *Kamma* are held to be the best favoured of all in Russia; at least its sturgeon, sterlet, and white falmon, are preferable to those of the Volga. Besides these three kinds, a principal fish of the *Kamma* is a small falmon, called in Rus's *Krasnaya rebra*, red or beautiful fish (*falmo eriox*, or *falmo alpinus*), commonly $1\frac{1}{2}$ or 2 arshines long. There is scarcely any place in the world where such a variety of contrivances and instruments are used for the capture of fish as on the Volga, and particularly in the confines of Astrachan. These inventions may be reduced to three, one comprising the fish-weirs, or utshchugs, the second the angle, and the third the net. The utshchugs are various; but the sort most in use is that called *Sabotka*. In the lower regions of the Volga, a fish-trap called *gorodba* is generally employed;

ployed; consisting of a weir carried across the stream, and provided with several chambers, in which the fish are caught. The utschuigs are generally constructed only in the territory of Astrachan, where the fishery on the Volga is a very important object of industry and traffic. The Tartarian word utschuig properly signifies that kind of dam called Soboika; but at present it implies a whole fishing station, usually much larger than a vataga. (See FISITERY and CASPIAN SEA.) Every utschuig, besides a number of buildings appropriate to it, has also a church and dwelling-house, for the labourers and their families. Since the year 1763, these utschuigs have been granted to the merchants of Astrachan, in consideration of a small tribute; and the revenues are managed by what is called the fish-comptoir, the directors and members of which are elected from the body of Astrachan burghers. The profits, after deducting the very moderate tribute to the crown, must be divided in equal portions among the merchants; but by several reports it appears, that the fish-comptoir are so arrogant and arbitrary in their proceedings, that the generous abandonment of her prerogative by the late empress, who intended that the benefit should extend over the whole, is only advantageous to certain privileged persons, who enrich themselves at the common expense. Besides the actual inhabitants of Astrachan, who are employed in the fishery, every spring about 10,000 fishing-canoes come thither, having in each at least two people, so that the number of strangers who follow this trade at Astrachan far exceeds 20,000. Tooke's Russia, vol. iii.

VOLGAIC COSSACKS. See COSSACKS.

VOLGANSK, a town of Russia, in the government of Charkov, on the Donetz; 40 miles N.E. of Charkov.

VOLGIVOD, a river of Russia, which rises near Bachmut, in the government of Ekaterinoflav, and runs into the Dnieper, 12 miles above Ekaterinoflav.

VOLHYNIA, a palatinate of Russian Poland, bounded on the north by the palatinate of Brzesc, on the east by Kiev, on the south by the palatinate of Kaminiac, and on the west by the palatinates of Chelm and Belz; about 180 miles in length, and from 80 to 120 in breadth. This country is so fertile, as to supply the inhabitants with a large surplus of grain; rosemary, aparagus, &c. grow wild in the woods, and can scarcely be distinguished from those cultivated in the gardens. Volhynia was annexed to Poland in a diet held at Lublin in 1659. The Tartars, besides a great booty, carried off 30,000 persons out of this country, to be sold as slaves, in the year 1618. It is now added to Russia.

VOLI, in *Ancient Geography*, a people of Africa, in Mauritania Tingitana. Ptol.

VOLIBA, a town of Great Britain, assigned by Ptolemy to the Daemonii, or Dunnonii. It is placed by Camden and Baxter at Grampond; but Horsley thinks it was situated at Lestwithel.

VOLISSO, in *Geography*, a sea-port town on the west coast of the island of Scio, said to take its name from Belisarius, called there "Velisarius," who built the castle. It is situated at the side of a hill, about two miles from the sea. It has a large bay, but no harbour. N. lat. 38° 27'. E. long. 25° 56'.

VOLITION, the act of willing. See WILL.

VOLITIVE THINKING. See THINKING.

VOLKAMERIA, in *Botany*, was dedicated by Linnaeus to the memory of Dr. John George Volkamer, a distinguished physician, and professor of medicine, at Nuremberg, who was born May 7th, 1662, and died June 8th, 1744. He published, in 1700, a very rich descriptive cata-

logue, in quarto, with many good plates, of the native as well as cultivated plants known in that neighbourhood, with the title of *Flora Noribergerfis*. He was the botanical correspondent of Tournefort, Boerhaave, Sherard, Trimmetti, Commelin, and other eminent men of his time, and has been recently commemorated by his countrymen the Panzers, in an anatomical dissertation, printed at Nuremberg in 1802.—Linn. Gen. 325. Schreb. 425. Willd. Sp. Pl. v. 3. 383. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 62. Juss. 107. Lamarck Illustr. t. 544. Gaertn. t. 56. (Daglasia; Reliq. Houft. t. 13.)—Class and order, *Didymia Angiosperma*. Nat. Ord. *Perfonate*, Linn. *Viticeae*, Juss. Gen. *Verbenaceae*, Juss. in Ann. du Mus. v. 7. 63. Brown Prodr. 510.

Gen. Ch. Cal. Perianth inferior, of one leaf, turbinate, with five, nearly equal, acute segments. Cor. of one petal, ringent. Tube cylindrical, twice the length of the calyx. Limb flat, in five deep, nearly equal, reflexed segments, all nearly turned one way, and most widely separated at the upper side. Stam. Filaments four, thread-shaped, very long, at the gaping side of the corolla; anthers simple. Pist. Germen superior, quadrangular; style thread-shaped, nearly the length of the itamens; stigma cloven, one segment acute, more conspicuous than the other. Peric. Berry roundish, of two cells. Seeds. Nuts solitary, furrowed, each of two cells, with two kernels.

Eff. Ch. Calyx five-cleft. Corolla with a cylindrical tube, and deeply five-cleft limb, rather turned to one side. Stamens prominent, ascending. Berry with two bilocular seeds.

Obs. This genus ought probably, as Mr. Brown observes, to be sunk in *Clerodendrum*, (see that article,) to which he has in Ait. Hort. Kew. removed all our garden species, except one, not without a just expression of doubt respecting that also. The only pretended distinctions are, 1st, the segments of the corolla being turned one way, not equally spreading; and, 2d, the Berry having two seeds, each with two cells, instead of four seeds, each of one cell. The species we are about to describe, however, having this character in the fruit at least, and being the original *Volkameria*, may as well be retained as such. Several of the others, popularly placed along with it, we have long ago found to have the characters of *Clerodendrum* altogether.

1. *V. aculeata*. Prickly Volkameria. Linn. Sp. Pl. 889. Willd. n. 1. Ait. n. 1. Jacq. Amer. 185. t. 117. (*Clerodendrum* n. 1; Browne Jam. 262. t. 30, not t. 20. f. 2. *Ligustrum aculeatum*, fructu testiculato; Plum. I. 156. t. 164. f. 2, not f. 1.)—Native of the West Indies. Browne speaks of it as one of the most common plants in the low lands of Jamaica, in a dry gravelly soil. Miller cultivated this shrub before the year 1739. Mr. Aiton says it flowers in the stove from August to October. The bushy stem is five or six feet high, with round rather warty branches; the ultimate ones often whorled; and all beset with short sharp prickles, originating in the permanent bases of last year's footstalks. Leaves opposite, italked, lanceolate, bluntish, entire, an inch and a half or two inches long, nearly smooth; paler and minutely dotted beneath. Stalks axillary, three-flowered, a little downy. Corolla cream-coloured, with purple stamens. Willdenow has three errors of the prefs among the synonymys of this species, all copied from Linnaeus, in the references to three common books, which he ought surely to have examined.

Some species referred to *Clerodendrum*, particularly *V. inermis* of Linnaeus; as also *V. ligustrina* of Willdenow; so nearly agree in habit with the above plant, that we cannot but mistrust any generic distinction which separates them.

VOLKA-

VOLKAMERIA, in *Gardening*, furnishes plants of the exotic tree kind, among which the species cultivated are, the prickly volkameria (*V. aculeata*); and the ovate-leaved smooth volkameria (*V. inermis*).

The first is a rather tall spiny shrubby plant.

And the second sort has much the same appearance, but more white, and without spines.

Method of Culture.—These plants are increased by cuttings, which should be planted in pots filled with light good mould in the summer season, plunging them in a moderate hot-bed, covering them close with hand-glasses. When they are well rooted, they should be removed into separate small pots, replanting them in the hot-bed till they are fresh rooted; then gradually inure them to the open air in warm weather, continuing them in warm sheltered situations in the open air till the approach of frosts, when they must be taken into the house, where there is a moderate heat. They will not succeed in a common green-house.

They afford ornament among other more hardy stove-plants in pots.

VOLKENMARCK, or *Volkel Markt*, in *Geography*, a town of the duchy of Carinthia, on the north side of the Drave; 12 miles E. of Clagenfurt. N. lat. 46° 41'. E. long. 12° 20'.

VOLKERODE, a town of Germany, in the principality of Gotha; 20 miles N. of Gotha.

VOLKMARSEN, or **VOLMARSHHEIM**, a town of the duchy of Westphalia; 18 miles S.E. of Paderborn. N. lat. 51° 23'. E. long. 9° 8'.

VOLL, a town of Norway, in the province of Aggerhuus, on the Glomme; 50 miles N.E. of Christiania.

VOLLENAY, a town of France, in the department of the Côte d'Or; 3 miles S.W. of Beaune.

VOLLENHOVEN, a town of Holland, and capital of a district, in the department of Overissel, situated near the Zuyder See. It is not large, but carries on a considerable trade. N. lat. 52° 44'. E. long. 5° 41'.

VOLLEY, a military salute, made by discharging a great number of fire-arms at the same time.

VOLLORE, in *Geography*, a town of France, in the department of the Puy de Dôme; 5 miles S.S.E. of Thiers.

VOLMAR, a town of Russia, in the government of Riga; 56 miles N.N.E. of Riga. N. lat. 57° 36'. E. long. 25° 14'.

VOLME, a river which rises about eight miles south of Luncheide, in the county of Mark, and joins the Roer, 4 miles S.W. of Schwiert.

VOLMER, a town of the principality of Culmbach; 3 miles S.E. of Berneck.

VOLMESTEIN, a town of Germany, in the county of Mark; 8 miles S.W. of Schwiert.

VOLMUNSTER, a town of France, in the department of the Moselle; 9 miles E. of Sarguemine.

VOLO, a sea-port town of European Turkey, in Thesfaly, situated in a gulf, to which it gives name; 38 miles N.W. of Larissa. N. lat. 39° 28'. E. long. 23° 12'.

VOLO, in *Antiquity*, a name which the Romans gave the slaves who, in the second Punic war, offered themselves to serve in the army, upon a want of a sufficient number of citizens.

The name *vol*, *volones*, they are said to have had from their offering themselves voluntarily. Festus says, it was after the battle of Cannæ that this happened. Macrobius, Sat. lib. i. cap. 2. places it before that battle.

Capitolinus tells us, that Marcus Aurelius formed troops, or legions, of slaves, which he called *voluntarii*; and that the like forces, in the second Punic war, had been called

volones. But before M. Aurelius, Augustus had given the name *voluntarii* to forces which he had raised out of *liberti*, or freedmen; as we are assured by Macrobius, Sat. lib. i. cap. 2.

The *volones* were afterwards called *evocati*.

VOLOGDA, in *Geography*, a city of Russia, and capital of a government, on the river Suchona, near lake Kubenskoe, the see of an archbishop. This city contains about 1700 houses, and a great many churches. The principal trade is in hemp, matting, Russia leather, and tallow; 320 miles S. of Archangel. N. lat. 59° 10'. E. long. 40° 14'.

VOLOGESIA, a town of the Arabian Irak, and pachalic of Bagdat, built by Vologufa, one of the Parthian kings, contemporary with Nero and Vespasian, and mentioned by the ancient geographers as an inconsiderable place; but since the death of Houssein, the son of Ali, by Fatima, the daughter of the prophet, who was slain near it, and is here interred, it has increased in magnitude, and become more famous from the numerous bodies of pilgrims of the sect of Ali, who continually flock to it from all quarters, but in particular from Persia, to pay their devotions at the shrine. It is now large and populous, and called "Kerbela," or "Meshed-Houssein," situated 7 farsungs N.W. of Hilleh, the feite of ancient Babylon, at the extremity of a very noble canal drawn from the Euphrates. The environs of the town and borders of the canal are shaded by extensive plantations of palm-trees; and the walks, which are upwards of two miles in circumference, have lately been repaired, to secure the riches of the holy city against the predatory incursions of the Wahabees, by whom it was plundered some years ago. Kerbela has five gates, a well-supplied bazaar, and seven khans or caravanferas; but the chief, and, indeed, only ornaments of the city are the tomb of Houssein, which is adorned with a lofty cupola, gilded by Nadir Shah, and a noble mosque, consecrated to the memory of Abbas, the half-brother of the Imam. Although Meshed-Houssein is subject to the Turks, the inhabitants are for the most part Persians. The canal of Kerbela, or Nahr Sares, though it now bears the name of Housseini, is more ancient than the days of Alexander, and is supposed at one time to have been connected with Bahr Wjiffi. The modern town of Hilleh stands on the banks of the Euphrates, in N. lat. 32° 25', and about 54 miles from Bagdat; covering a very small portion of the space occupied by the ancient capital of Assyria. See **BYBLON**. Kinneir's Geog. Mem. of the Persian Empire.

VOLOGINA, a town of Russia, in the government of Irkutsk; 40 miles S.W. of Kirenfk.

VOLOGODSKOI, a government of Russia, which includes the province of Ultrug; bounded on the north by the government of Archangel, on the east by the government of Tobolsk, on the south by the governments of Perm, Viatka, Kostroma, and Jaroslavl or Yaroslaf, and on the west by the governments of Olonetz and Novgorod; rather more than 600 miles in length, and about 240 in breadth. N. lat. 58° 30' to 65° 20'. E. long. 39° to 59°.

VOLOGZANOVA, a town of Russia, in the government of Irkutsk; 18 miles N. of Ilmisk.

VOLONE, in *Ancient Geography*, a town of Italy, in Samnium.

VOLONE, in *Geography*, a town of France, in the department of the Lower Alps; 6 miles S.S.E. of Sisteron.

VOLOUSKA, a town of Ithria; 15 miles N. of Laurana.

VOLPI, **GIANANTONIO**, in *Biography*, an elegant Latin poet, was descended from a noble family, and born at Como in 1514. Having studied jurisprudence in the university of

Pavia, and pursued it with reputation at his native place; with a view to preferment, he visited Rome; but disappointed in his expectations, he returned to Como, and succeeded Bernardine della Croce, bishop of the church in 1559, the offices of which station he assiduously discharged for 30 years, until his death in 1588. His poems were collected, and published at Padua in 1725. They have been much praised for their elegance, and in the satires he is said to have happily imitated the style of Horace. Gen. Biog.

VOLPIANO, in *Geography*, a town of France, in the department of the Po; 9 miles N.N.E. of Turin.

VOLSAS SINUS, in *Ancient Geography*, a bay mentioned by Ptolemy, situated on the northern side of Great Britain: it is Loch-bay, in Rosshire.

VOLSBACH, in *Geography*, a town of the bishopric of Bamberg; 3 miles N.E. of Weisfenfeld.

VOLSCI, or **VOLCI**, in *Ancient Geography*, a people of Italy, in Latium. They were descended from the ancient Ofci: they had among them Coriolanus in the year 264; and in the year 310 they submitted to the Romans. Their territory lay from the sea of Antium as far as the source of the Liris, and beyond it. The extent of their country induced Mela to distinguish it from Latium, from which it was actually separated.

VOLSINENSIS or **VULSINENSIS Lacus**, a lake of Italy, in Etruria, according to Pliny. He speaks vaguely and unphilosophically of two floating islands, the form of which was occasionally changed by the winds into triangular and round. Upon it, however, was one island, called the Isle of S. Giacomo, to which the princess Amalfooth, queen of the Goths, was exiled by Theodotus, who in a few days caused her to be strangled, A.D. 534.

VOLSK, in *Geography*, a town of Russia, in the government of Saratov, on the Volga; 76 miles N.E. of Saratov. N. lat. 52° 15'. E. long. 47° 44'.

VOLTA, a town of Asiatic Turkey, on the fourth coast of Natolia. N. lat. 36° 46'. E. long. 27° 16'.—Also, a town of Italy, in the department of the Mincio; 10 miles N. of Mantua.

VOLTA, or *Rio Volta*, a river of Africa, which separates the Gold Coast from the Slave Coast, and runs into the Atlantic, N. lat. 5° 50'. W. long. 45'.

VOLTA, in the *Italian Music*, shews that the part is to be repeated one, two, or more times, according to the numeral adjective joined with it: thus, *si replica una volta*, intimates to play that part once over again.

VOLTA is also a sort of dance of Italian origin, in which the man turns the woman several times, and then assists her to make a leap or jump. It is a species of galliard.

VOLTAGGIO, or **OTTAGIO**, in *Geography*, a town of the Ligurian republic; 15 miles N. of Genoa.

VOLTAIRE, **MARIE FRANÇOIS AROUET DE**, in *Biography*, was born at Chateay, near Paris, in the year 1694, and in his earliest youth indicated a partial fondness for verse, which was cherished by the recital of La Fontaine's fables. He was also constrained to commit to memory a poem, entitled "La Moïade," and thus he is said to have imbibed a prepossession against the Mosiac history. In pursuing his literary education at the Jesuits' college of Louis-le-Grand, he had for his preceptor father Porcé; and at the age of 12, distinguished himself by compositions above his years. The celebrated Ninon de l'Enclos, to whom he was presented, left him a legacy of 2000 livres, which he destined for a juvenile library. Dissatisfied with law, for the profession of which his father designed him, he devoted his whole attention to poetry, which was rendered invincible by a society of wits and Epicureans, into which he was admitted. His father made an attempt to divert him from his

favourite pursuit, by sending him as a page in the suite of the marquis de Chateaufeu, ambassador from France to Holland; but falling in love with the daughter of Mad. du Noyer, a refugee, he was sent back to Paris, and excluded from his father's house. In this pitiable situation he was taken under the protection of M. de Caumartin, his father's friend; and at his country-house he had the advantage of conversing with the elder Caumartin, who inspired him with his own enthusiastic admiration of Henry IV. and Sully. He still indulged his disposition for writing lampoons; and for one of these, aimed at the government, he was imprisoned for a year in the Bastille. At this time he had composed his tragedy of "Œdipe," which was brought on the stage in 1718, and much applauded. The regent was also highly pleased with it, and granted him permission to return to Paris, after his release from the Bastille. His father, much interested in his favour by attending at one of the representations of his tragedy, was reconciled to him, and gave up all thoughts of making him a lawyer. At Brussels, which he visited in 1722, he became acquainted with the poet Rousseau; but in consequence of this interview, they became enemies for life. On his return, his "Mariamne" was exhibited, and did not succeed. In 1726 he was again lodged in the Bastille, in consequence of a quarrel with the chevalier de Rohan; and obtained liberation, after a confinement of six months, upon condition of leaving the kingdom. England was the country of his choice, and he brought with him his poem of the "Henriade." It was printed in London by subscription, patronized by king George I. and Caroline princess of Wales, and yielded a profit which laid the foundation of his fortune. His manners, however, did not suit those of England, and his conversation was unsufferably licentious. Having obtained permission to return to France in 1728, he put his money into a lottery, and engaged in other lucrative speculations, and thus amassed a large capital, which he augmented by his economy. His tragedy of "Brutus," brought on the stage in 1730, was not very popular; and as his dramatic reputation was ambiguous, he was advised by Fontenelle and La Motte to abandon this species of composition, alleging that it was not adapted to his genius. His reply was the production of his "Zaïre," which was regarded as the most affecting piece on the French stage, after the "Phedre" of Racine. On account of his "Lettres Philosophiques," he was considered as an avowed enemy to revelation and ecclesiastical authority; and the parliament of Paris issued a decree, which ordered his work to be committed to the flames, and his person to be arrested. Upon this he quitted the capital, and retired to Cyrei, near Vass, in Champagne, the seat of the marquis du Chatelet, where they employed themselves in making experiments, and where Voltaire wrote his "Elements of the Newtonian Philosophy." He also continued to write tragedies, so that his "Alzire" appeared in 1736, and his "Mahomet" in 1741; but the latter, charged with being an attack upon religion, was withdrawn from the stage. His "Merope," exhibited in 1743, was received with the greatest applause. Before this time he had made his peace at court by a political service, which it is not necessary for us to relate; and he farther ingratiated himself with the royal family by his piece for the festivities on the marriage of the Dauphin, entitled "La Princesse de Navarre." Received at court, he became gentleman of the chamber in ordinary, and historiographer of France; and, under the latter character, drew up his history of the war of 1741, which then published. He also engaged in other courtly offices, and wrote the manifesto of the French court in favour of the Pretender, on his expedition to Scotland. In 1746 he was admitted into the

French

French academy. In consequence of urgent invitations on the part of the king of Prussia, and assurance of a pension of 22,000 livres, with other benefits, he arrived at Potsdam in June, 1750; and was received by the king with the most flattering tokens of respect. Here it was his practice to spend two hours in the day with his majesty, during which he employed himself in correcting his works; and the rest of his time was at his own disposal. His tranquillity, however, was soon interrupted, on occasion of a dispute between Maupertuis and Koenig; for though the king desired him not to interfere, he took part against Maupertuis, and Frederick sent him his dismissal. During his absence on a visit to the dukes of Saxe-Gotha, Maupertuis, as he says, used his influence to lower him in the king's estimation; and, therefore, instead of returning to Berlin, he proceeded towards France; but at Frankfort he was arrested by the king's order, and obliged to restore his poems, with which he had been intrusted for correction, together with his key, cross, and the brevet for his pension. It was now his wish to reside at Paris; but he could not obtain permission for this purpose, as he had published a very indecent and licentious poem, "La Pucelle d'Orleans," which had raised a violent outcry against him; and, therefore, after a year's stay at Colmar, he purchased a country-house near Geneva; and having gratified his petulant disposition by interfering in the political disputes of this place, he thought proper to remove, and bought an estate at Ferney, in the Pays de Gex. Here he lived, as one of his biographers has said, "like a petty prince in his own territory;"—"improving his own village by encouraging colonists, and introducing manufactures, which through his influence obtained a sale in many countries of the continent."—"A declared enemy to tyranny and oppression of every kind, he undertook the protection of several sufferers from injustice, among whom were the family of Calas, a noted victim of religious bigotry. He made the enormity of these abuses of power known throughout Europe, and set himself up as a kind of general censor, to whose tribunal the highest ranks were amenable." All his motives his biographer does not attempt to justify. He likewise poured forth from this retreat a variety of works, which were fought after and generally read, directing the sentiments and influencing the conduct of many who perused them, whether always to their own honour and advantage we leave others who are acquainted with them to determine. In general, his extended sway over the opinions of the civilized part of mankind, says the biographer of whose observations we avail ourselves in the compilation of this article, "was directed to the subversion of both civil and ecclesiastical tyranny; but his attacks on the latter included hostilities against religion in general, at least of the revealed class: and, whilst he admitted natural religion, he destroyed its moral efficacy." In his retreat he was visited by the most distinguished persons who came near his abode, and he corresponded with some of the chief sovereigns of Europe. Nevertheless he was not happy. Impatient and restless in his disposition, and irritable in his temper, he was self-tormented. In advanced life he wished again to emerge from obscurity; and in February, 1778, he visited Paris, where he had many admirers, and where he was regarded also with aversion and alarm. Here his vanity and love of admiration and praise must be fully gratified, by the manner in which he was received at the theatre, after the exhibition of his "Irene," which he had brought with him. As soon as he was seated in his box, after having received repeated plaudits in his way to it, an actor placed a crown on his head. When the play was concluded, the drawing up of the curtain displayed all the actors and actresses surrounding a bust of Voltaire, and by turns covering it with garlands

of laurel; and Mad. Veltris, advancing to the front of the stage, pronounced some verses to his praise, composed on the spot by a nobleman, amid the shouts of the audience. This reception produced effects on his feeble frame, which probably hastened its dissolution. Of this Voltaire himself seems to have been apprised, when he said in a tone of deep melancholy, "I am come to Paris to find glory and a tomb." Unable to sleep, it is thought that he accelerated his death by taking too large a dose of opium. When he was thought to be near his last moments, the marquis de Villette, with whom he resided, sent for the rector of St. Sulpice to administer the last offices which are thought essential to the safety of a Catholic Christian. What passed between Voltaire and the rector on this occasion has been differently stated; but it is certain that he died, without the last sacraments, on the 30th of May, 1778, in the 85th year of his age. It is said that the archbishop of Paris absolutely refused to allow him Christian burial, and that his body was secretly conveyed for interment to Sellieres, an abbey of Bernardines, between Nogent and Troyes. It was thence brought, by a decree of the national assembly in 1791, to be repositied in St. Genevieve's at Paris.

"The physiognomy of Voltaire," says his biographer, "was indicative of his disposition. It is said to have partaken of the eagle and the monkey; and to the fire and rapidity of the former animal, he united the mischievous and malicious propensities of the latter. With strong perceptions of moral excellence and elevation, he was little and mean in conduct, a victim to petty passions and caprices; never at rest either in mind or body, never tranquil or sedate. If he was a philosopher, it was in his opinions, not in his actions. He had been accustomed from his youth to pay as much homage to rank and wealth as his vanity would permit; his tastes of life were vitiated, and his manners corrupted: he could not, therefore, be a consistent friend to virtue and liberty, though he might occasionally be captivated with their charms, and even zealous in their support. He was habitually avaricious, though he performed some generous acts, which, however, he took care to make known. He was too selfish to inspire love, and too capricious to merit esteem. He had numerous admirers, but probably not one friend."

As a poetical writer, he was distinguished by his "Henriade," which was considered as the principal epic poem in the French language, and by his tragedies, which are said to have more variety of style and subject than those of Corneille and Racine; but in comedy and lyric composition he was not equally successful. The morality of his moral epistles, which are excellent in their manner, is liable to many objections. As a prose writer, Voltaire has been commended for that kind of middle style, which is pure, unaffected, lively, precise, and always in good taste. In the department of history, his principal works are the "Essai sur l'Histoire generale," and the "Siècles de Louis XIV. et de Louis XV." His "Histoire de Charles XII." is a model of royal biography. Of his witty writings, which are very numerous, we may observe in general, that they are not only depreciated in real value, but rendered pernicious in their tendency and effect, by his frequently recurring attacks and sarcasms, levelled against revealed religion: nor shall we be thought deficient in candour if we add, that, whatever instruction or amusement his productions of the latter class afford, they have done greater injury, in a moral and religious view of them, particularly among persons of little reflection, than those of any other author. All the works of Voltaire amount to 30 vols. 4to. of the Genevan edition, and 71 vols. 8vo. in the more complete edition of Basil. Gen. Biog. by Aikin.

The universality of *Voltaire's* genius extended to music, though no musician. And in spite of his partiality to his own country, he did the writings of *Metastasio*, and the Italian opera, more justice than any of his countrymen. And though he gained less applause by his lyric poetry than his other poetical composition, he produced several pieces for music, and frequently made admirable reflections on the lyric theatre.

Voltaire has never planted his farcical artillery against Italian music or singing. And though neither a connoisseur nor passionately fond of music, he seems instinctively to have felt a superiority in the music of Italy to that of France; and has been always just to the writings of *Metastasio*. For though a defender of *Quinault* against the injustice of *Boileau*, he has never set him up as a writer for music superior to the imperial laureat. The truth is, that *Voltaire*, with all the black spots in his character, had a natural good taste when his judgment was not warped by envy, or his passions inflamed by the attacks of his enemies. He early saw and celebrated the science of *Newton* and genius of *Shakspeare*. And it was not till the latter had been more noticed, and the translation of his works more patronized than his own, that, in self-defence, he abused them.

VOLTAISM. That branch of electrical science which has its source in the chemical action between metals and different liquids, and in the proofs which establish its identity with common electricity, the world owe principally to discoveries made by signor *Volta*. Its remarkable influence upon animals, which first brought it into notice, was first observed by *Galvani*. Hence it was first called *Galvanism* and afterwards *Voltaism*. We should have treated this subject wholly under *GALVANISM*, which was then more than half completed, but the latter was not finished in time to be then published. Hence the present article must rather be considered as a continuation of *Galvanism*, than a distinct treatise.

Galvani concludes with a list of the different galvanic combinations, which will be terminated in this article, and the rest will be treated in succession. We have also given some account of all such facts as have transpired since the time of the publication of the first part.

TABLE shewing the relative quantity of bubbles upon the negative wire, by immersing a compound arc, of zinc and platina, into different saline solutions at a boiling heat, and at the common temperature.

Solution.	Effect.		Remarks.
	Hot.	Cold.	
Muriate of ammonia	6	3	
Muriate of soda	2	1	
Super-tartrate of potash	4	0	In this and other cases, where the cypher is placed, it does not mean that no effect was produced, but that no bubbles could be seen.
Nitrate of potash	$\frac{1}{2}$	0	In this experiment two combined arcs were used which just produced a sensible effect.
Phosphate of soda			
Alum	4	2	
Sulphate of potash	0	0	
Sulphate of soda	0	0	
Sulphate of magnesia	0	0	In the three last two combined arcs were tried, but no bubbles appeared.

The two preceding tables will give some idea of the relative power of different combinations of metals, and of the comparative action of different fluids.

The most powerful of the metallic combinations will be seen to be zinc with platina, gold, and silver; but zinc with copper is so little inferior, that in point of economy it will always be preferred.

Zinc with iron is, however, so near to zinc with copper, that iron might be used to great advantage where cheapness is desirable.

Zinc and copper are, in the present state of *Galvanism*, generally employed for the construction of galvanic batteries. In the trough invented by *Cruikshank*, the zinc and copper plates were soldered together in pairs, so as to form so many compound plates. These plates are cemented into a wooden box, which is lined with the same cement, at such a distance from each other, as to divide the trough into distinct cells about half wide. The order of the plates should be such that all the zinc plates face one way, and the copper ones the contrary.

A great improvement has been made upon the trough of *Cruikshank*, by forming the cells in the trough with plates of glass. The plates of metal are soldered together by their edges, and bent at the joining, till the opposite sides become parallel, and separate from each other about half an inch. Each of these compound arcs is so placed in the trough with glass plates, that the zinc plate of each arc may be on one side of the glass, and the copper on the other, and in such order, that the zinc plate of one arc, and the copper of another, may be in each of the cells. A second improvement has been made upon this trough. Instead of a wooden trough, divided into cells with glass plates, the whole trough is made of earthenware, each trough consisting of ten cells. All the plates are fitted to a piece of wood of the length of the trough, so that they can be taken out or put into the trough all together. When they are taken out, the fluid is suffered to remain in the trough, and the plates are suspended over it upon a gibbet attached to the frame in which the earthen trough is placed. An immense battery upon this construction, consisting of 2000 pairs of four-inch plates, has been lately made for the Royal Institution. The experiments made upon it were inconceivably brilliant. The spark was so intense as to strike through a space of some lines of air, and of such dazzling splendour as to resemble the sun. Many substances were fused by the heat it produced, which had not been fused before, among which were the metal called *freadium*, and the earths *zircon* and *alumine*. Charcoal was made to evaporate, and plumbago to fuse in vacuo. A large electrical battery was charged by instant contact.

Since the trial of this battery, one of immense surface has been constructed by *J. G. Children*, esq. It consisted of twenty pairs of plates of copper and zinc, each plate being six feet square, the whole exhibiting a zinc and copper surface equal to 720 square feet. Each of the pairs of plates was united at the top by strips of lead bent into an arch, and so as to allow the plates to be exactly parallel to each other. The cells were distinct and made of wood; each pair of plates entered two cells, having the wooden division between them. The plates were all suspended from a beam above, and counterpoised to admit of their being easily let down into the liquid in the cells. The liquid consisted of water with one-sixtieth of a mixture of the sulphuric and nitric acids, which was afterwards gradually increased to one-thirtieth. Leaden pipes were conveyed from the ends of the battery to an adjoining shade out of doors, where the experiments were made.

This battery, as a source of heat, surpassed any thing ever

VOLTAISM.

ever before heard of. It melted platinum with the greatest facility. Trifium, which had not been before melted, was fused into a globule. Charcoal was kept at a white heat in chlorine gas and phosgene gas, without any change being produced in the gas. It ignited six feet of platina wire. It was observed, that when the wire was less than a certain diameter, a less length was ignited. A view of one of the before mentioned troughs is shewn in *fig. 1*.

Since this plan is likely to become general, from its great advantage both in economy and convenience, we shall venture to suggest several improvements.

For making all the variety of galvanic experiments, it has always been a desideratum to have a battery, the surface of which may be increased in any proportion, to a certain limit, without affecting the series or number of combinations. This has not hitherto appeared practicable by any other means than that of using distinct batteries of different sizes.

A battery on the plan above described, having loose plates, will admit of the advantage here alluded to, without any other increase of expence than that of the additional plates which are meant to increase the surface at pleasure.

The cells in the earthen trough should be about an inch and a half from one dividing surface to the other, and capable of receiving plates of four inches square. Each of the cells may occasionally contain four plates, two of zinc and two of copper.

The form of the plates for this battery is represented in *fig. 2. Plate I.* having a wire staple, *ab*, of the same metal with the plate. The staples must be made accurately of the same size for all the plates. A piece of wood, *ab*, (*fig. 3.*) is made to pass through all the staples of the plates. This bearer, or suspender, is divided into as many transverse grooves as there are plates, of a depth capable of receiving one-half of the diameter of the wire staple. In the same bearer are also two longitudinal grooves, *A A*, *B B*, about one-tenth of an inch wide and a quarter of an inch deep. A number of sliding pieces of brass, *aa*, are introduced into the latter grooves, equal to the number of combinations, one half of the pieces being in one groove, and the other half in the other. These pieces of metal, after being placed in proper situations, are filed down with the transverse grooves, leaving the metal above the wood, where the staple of a plate is intended to touch the metal, and filing the metal away lower than the wood, where the staple is not meant to be in contact.

After the plates are arranged upon the bearer, alternately copper and zinc, the pieces of sliding metal are made to communicate with them, that the zinc plates of one cell may communicate with the copper of the succeeding cell, the zinc of the last with the copper of the next, and so on throughout the series. The plates being all in their places and properly connected, a second piece of wood, *cd*, (*fig. 4.*) is laid upon the bearer, with correspondent grooves to fit the staples. It is covered on the under side with woollen cloth, so that when it is screwed to the bearer it serves to keep the plates secure, and at the same time preserves the connecting parts from the fumes of the acid employed in the battery. A section of the bearer, staples, &c. are seen in *fig. 4.* The whole of the apparatus complete is represented in *fig. 5*, as drawn out of the cell. *Fig. 6.* is an end view of the apparatus.

In this battery, the maximum of surface is when every cell contains two plates each of zinc and copper. When it is required to reduce the surface, nothing more is necessary than to take off the top part of the bearer, while the plates are resting in the trough, and then drawing out the lower part. If the two end plates of each cell, one of

copper and the other of zinc, be taken away throughout the whole, the bearer may be again introduced to its original situation. The battery will now consist of the same series and half the surface. If a mean quantity of surface be required, it is done by taking the end plates away from a part of the cells.

It appears, from an experiment detailed in Nicholson's Journal, vol. xxvi. p. 72, that the copper surface may be increased to advantage above that of the zinc. The experiment is as follows: If an arc of copper and zinc be made to connect two glass cups containing dilute muriatic acid, the zinc part of the arc being in one cup and the copper in the other, and if the connection be made between the two cups, to complete the circuit by an arc of copper wire, a quantity of bubbles will be evolved from the copper wire of the compound arc. If, however, instead of the copper wire the connection be made with a conical slip of copper, a very different effect will be observed, as the broad or pointed end of the slip may be next to the zinc wire. When the broad end is placed in the cup where the zinc wire is placed, a much greater quantity of bubbles appears upon the copper of the compound arc, than when the small end is placed next to the zinc. Hence it would appear, that the copper surface should be greater than that of the zinc. This may be very easily effected, by dividing the copper surface into small grooves, the sides of which make an angle of 60°, the surface will by this means be doubled. This figure might be given to the copper surface by means of a pair of fluted rollers. It will be obvious, that if the grooves are not very small, the different parts of the copper surface will not be uniformly contiguous to the zinc surface, which is a matter of some importance.

Having described the most convenient and economical method of constructing a battery, we shall now consider the means of exerting the galvanic energy so far as relates to the interposing fluid.

In the galvanic battery, there appear to be two sources from which the electricity is obtained. The one is that which arises from the contact of the metals, and the other from the chemical action between the interposing fluid and the zinc surface. The first does not require even the presence of moisture, as is shewn in the electric column of De Luc. The second is rendered greatly conspicuous by introducing between the opposite surfaces any substance capable of oxydating and dissolving the zinc.

Acids, as appears from the preceding table, are the greatest promoters of the energy afforded by chemical action, because they dissolve the zinc after it has been oxydated by the oxygen of the water. This is more especially the case with the sulphuric and muriatic acids, because these acids are not decomposed by the zinc. The nitric acid produces a still greater galvanic effect, because the acid is decomposed, and oxydates the zinc with greater facility than water. The water is also decomposed when this acid is used. Zinc hydrogen is always evolved.

The action is always increased when the conducting power of the fluid is increased. Hence it would be proper to use some cheap saline solution with the acid, which will not be decomposed by the same.

The saline solutions, alone, are very inferior to any of the acids. But from what has been observed, we may easily point out such salts as are best fitted for the purpose. All the super-salts, from their excess of acid, will answer this purpose; or such salts as are decomposed by zinc. All those salts which act upon metals by forming triple salts, such as muriate of ammonia and muriate of soda, are found to act very well in the galvanic battery.

VOLTAISM.

It will be proper to observe here, that the interposed fluid does not afford a quantity of electricity proportionate to the rapidity of the oxydation, or at least the quantity of galvanic energy cannot be appreciated beyond a certain limit. If the quantity of the concentrated acid be much more than from $\frac{1}{2}$ to $\frac{1}{3}$ the weight of the water, the power of the battery will not be found to increase but from another cause, which we shall hereafter explain; the power is much sooner exhausted than when a smaller dose is used. The zinc is oxydated so slowly by saline bodies, that they may be used in saturated solutions. Potash, in a caustic state, even when much diluted with water, might be used to great advantage. At the same time that it scarcely appears to oxydate the zinc, when a single pair of wires of copper and zinc are used, the copper wire affords as much hydrogen during the contact, as could be expected from the agency of an acid. It is, therefore, highly probable, that potash or soda will be substituted for acids in galvanic experiments, as well for the sake of economy as from its being less offensive to the operator. It possesses another advantage still greater, in not destroying the zinc plates like acid solutions.

From what has been said regarding the interposed fluid, it will be easy to infer that the greatest part of the galvanic energy, which is electricity excited by chemical action, depends upon the presence of the water, and some substance which can dissolve the zinc, and at the same time give a greater conducting power to the water. The effect is not, as Sir Humphrey Davy has supposed, produced by the opposite electrical states of the elements of the compounds constituting the fluid medium, since the hypothesis is contradicted by experiment. If there wanted another experiment to decide, that the galvanic effect is as the chemical effect, the following would suffice. Take two wine-glasses, containing dilute muriatic acid, and connect them by an arc made of two wires, one of zinc and the other of platina, soldered or tied together, the zinc being in one glass and the copper in the other. If the circuit be complicated between the glasses by an arc of platina wire, no appearance of bubbles will be observed upon the platina wire of the compound arc. If, however, a small quantity of nitric acid be poured into the glass containing this wire, hydrogen gas will be immediately evolved from it, and at the same time the other platina wire in the same glass will become oxydated. This effect is not caused by the electrical agency of the nitric acid, which is decomposed; because when copper is used instead of platina, with the pure muriatic acid, the same effect takes place. It appears, therefore, that the increased effect would be attributed only to the oxydation of the wire of the homogeneous arc, in the glass containing the negative wire of the compound arc.

In every galvanic process, from a single combination to an unlimited series, no effect is observed till the circuit is complete; and during this, a current of electricity is established from the zinc surface of one combination to the copper of the succeeding. While it is passing through a metal, whatever be its length, it obeys the laws of electricity very strictly, but when it passes through a humid conductor, it appears to possess rather anomalous properties. It is proper to observe here, that conductors of Galvanism are of two kinds; the one we shall call dry conductors, and the other humid. The first class comprises all the metals, well burnt charcoal, plumbage, and the sulphurets of metals. Water appears to be essential to the second kind, holding in solution acids, alkalies, or neutral salts. Simple water has its conducting power increased by the smallest quantity of any acid, alkali, or salt. When the conducting wires of a gal-

vanic battery are made to terminate in a vessel of pure water the water will be observed to be decomposed, the oxygen being given out at the positive wire, or that coming from the zinc side of the battery, and the hydrogen from the negative or opposite wire. If the smallest quantity of an acid, a salt, or an alkali, be added to the water, the rapidity of the decomposition will be increased very conspicuously.

As it is of some importance to know the relative conducting power of water, and its different compounds, the following apparatus has been contrived for this purpose, represented in *fig. 7*. Let *e g* be a small cup of wood varnished, or, what is much better, glass; and *z c* two wires of platina distinctly inserted in the bottom of the cup, so as to be water tight. A glass tube, *o p*, filled with the fluid, is inverted in the cup to receive the gas which arises from the wires *z c*, while the fluid descends, and is contained in the cup. If the cup *e g* be made larger, and of an oval shape, two glass tubes may be inverted over each wire, and the gases may be obtained separately. *Fig. 8*. A B C D, is a frame supporting one of the cups. The parts G and F are of glass or varnished dry wood, cemented into the parts A B C D, which are of brass, so that the two sides H and I of the frame are detached. The apparatus, *fig. 7*, with four others similar, are to be placed in the frame, the wire *z* being inserted into one side of the frame, and the other, *c*, resting upon the other side. When the glass tubes of each are filled with different fluids, the side H is connected with one end of the battery, and that of I with the other. Since the galvanic current must necessarily take the best conductor, the action will commence through that fluid having the greatest conducting power. If a thin bit of baked wood or glass be put under the resting part *c*, in that where the action commenced, the current will be transferred to the next inferior conductor, and so on to all the rest. By this means an accurate table, shewing the relative conducting powers of fluids, may be easily obtained.

Since the quantity of gas is the test of the conducting power, some allowance must be made when the muriates are the subject of experiment. All the other oxygen gas disappears in converting the muriatic into oxy muriatic acid. In a similar way the hydrogen does not appear when certain metallic solutions are employed, since it combines with the oxygen of the metallic oxyd, and the metal is reduced. When the battery is in full power, and of great extent, the relative conducting power of the fluids may be expressed by the time required for the ascending gas to displace the liquid in the glass tube. In all those experiments where the elements of bodies are transferred to different sides, the transfer takes place through any of the moist conductors, but not through any of the dry ones. No transfer can therefore be made through solid bodies, except the body be permeable to moisture. Sir Humphrey Davy, in his experiments, made use of the fibrous asbestos moistened with water. Where the fluids are required to be strictly separate, bladder answers very well as a separating medium. Animal and vegetable substances, however, abound with so many elements, that in nice experiments they would be objectionable. A vessel divided into a proper number of cells of earthenware, in the state of biscuit, would be best calculated for these experiments. This vessel should be made of pure flint and pure alumina. Should it ever become an object of manufacture to separate acids and alkalies from neutral salts, a vessel of wood, with a separation in the middle, of unglazed earthenware, would answer very well.

We shall here mention some curious facts connected with the interposition of metals, in different conducting media.

When the wires, coming from the two ends of a galvanic battery,

battery, are brought into separate vessels containing any fluid which is a conductor. If a wire of platina, in the form of an arc, connect the two glasses together, that end of the connecting arc in the positive glass will afford hydrogen gas, while that in the negative glass will furnish oxygen gas; or, if we take all the four ends of the wires in the circuit, the positive wire from the battery will give oxygen, and that opposite to it, in the same glass, hydrogen. In the other glass, the negative wire will afford hydrogen, and the opposite wire oxygen, so that the water appears to be decomposed in each glass, since oxygen and hydrogen are furnished separately by each glass. If a number of glasses be arranged similarly, having connecting arcs of platina, and if the wires of the battery be introduced in the extreme glasses, all the ends of the wires will alternately furnish oxygen and hydrogen. No theory yet brought forward will satisfactorily account for these phenomena. Sir Humphrey Davy would assert, that each of the wires from the battery induced an opposite state of electricity in the wires opposed to them; and that in consequence the one attracted oxygen and the other hydrogen. Another theorist might hold that the electricity, which enters the first glass from the positive side, decomposes the water, and combining with the hydrogen, sets the oxygen free. The electricity and the hydrogen pass through the fluid to the opposite wire, when the electricity deserts the hydrogen, and passing through the platina arc, decomposes the water in the second glass. The oxygen is again evolved, and the hydrogen carried to the next wire, and so on through the remainder of the glasses.

A very curious experiment of the above kind rather tends to confirm the latter, than the former hypothesis. We, however, give these facts to the common stock, for the advantage of other labourers in this field of inquiry; strongly convinced that every hypothesis yet advanced falls very short of explaining all the phenomena of Galvanism.

Let the wires of a galvanic battery be made to terminate in a flat-bottomed vessel, containing pure water, about an inch and a half from each other; and if now another wire, of an inch in length, be laid longitudinally between them, but not to touch them, each end of the intermediate wire, if of gold or platina, will afford gas. That end opposite the negative wire will give oxygen, and the other end of the same will furnish hydrogen; and if any number of bits of wire be placed between the principal wires, at the same time they do not touch each other, oxygen and hydrogen will be alternately furnished by the ends of the wires. When the principal wires are brought nearer together, and a platina wire placed transversely between them, one side of the intermediate wire will furnish oxygen, and the other hydrogen. This fact is put in a more striking point of view, by placing a plate of platina in a vessel of water edgewise, and bringing the wires of the battery opposite to each other, and perpendicular to the sides of the plate. If the battery employed consist of 50 plates three inches square, a circular spot will be observed on each side the plate, opposite the wires. This appearance is caused by the evolution of gas from those parts of the plate only.

It is singular, that in all the experiments where the connecting wire was immersed in the water, if any substance, capable of increasing the conducting power of the water, be very gradually added to it, the gases given out by the intermediate wire will diminish, till they entirely cease to be produced. The wire which was transversely placed sooner ceased to afford gas, than when it was in a longitudinal position; and the effect sooner ceased with the wire than with

the plate; and in different plates, the continuance was as the size of the plate.

If the plate, however, be cut so as to divide the vessel into two portions, and the edges so completely cemented to the sides of the vessel that no liquid communication exists between the two portions, each side of the plate will furnish as much gas as the wires, whatever may be the conducting power of the fluid. If the power, which induces the plate or immersed wires to give out gas, depended upon the induction of the opposite wires, why is it not as great before the fluid is divided as afterwards? and why is it the same when pure water is used, whether the intermediate wire be immersed in the water, or is made to connect two portions of water together? These are facts which, in the present state of knowledge, do not admit of easy solution. They, however, shew us the necessity of having the cells of our galvanic batteries perfectly distinct from each other. It appears pretty clear, that that which conducts the oxygen or the hydrogen, or perhaps both, passes with greater facility through a good moist conductor than through a metal.

Decomposition of Bodies in general.—The decomposition of water and of metallic oxyds was known to Cruickshank, the history of whose experiments we have already given; and in a very early stage of galvanic progress, it was observed that the alkali was separated from muriate of soda in the galvanic battery. In subjecting muriate of soda to the galvanic power in a glass tube, it has also been observed that oxy-muriatic acid was produced. The subject of the decomposition of salts, however, has been clearly made out, and established on true principles, by Sir Humphrey Davy, whose experiments have been detailed under GALVANISM. The chemical agency of bodies, arising from their relative electric states, is no doubt the cause of the decompositions of salts, and of all other bodies to a certain extent; although there are many decompositions, particularly the metallic oxyds and water, which are to be attributed to some other cause much more active and expeditious. We shall here venture to draw a line of distinction between the decomposition effected by the electrical intensity arising from the contact of the bodies, and that produced by the electricity, and the hydrogen developed by the chemical agency of the oxydable metal, and the oxydating fluid.

If we take a single combination, for instance, a zinc wire connected with a platina wire, the electrical intensity arising from contact is so exceeding small, that it could hardly be appreciated by the acid of the condenser. If this combination be immersed in water, no galvanic appearance takes place, however near the immersed ends be brought to each other. If, however, we add to the water about one-tenth its weight of muriatic acid, an immense quantity of hydrogen immediately appears upon the platina wire, and continues to be evolved so long as the contact is formed, till the acid is expended. The electrical intensity, however, is the same with the water as with the dilute acid; yet the quantity of hydrogen upon the platina wire, when the acid was used, which can be attributed only to galvanism of chemical action, is much more than could be obtained by the most powerful electric machine. It can readily be admitted, from experiments in which Dr. Wollaston decomposed water by the electric machine, and from the electric effects of Deluc's column, that some water would be decomposed by the single combination, independently of the chemical action; but the difference is so glaring as to produce the strongest conviction, that the decomposition of water and the transmission of hydrogen are not dependent on the mere electric states of the wires. That the hydrogen is

VOLTAISM.

transmitted from the zinc to platina, during the chemical action, many experiments seem to prove; and that the hydrogen to be transmitted, by its chemical agency, and in its nascent state, is capable of effecting many decompositions, which, under other circumstances, would be impossible. In the single combination above alluded to, if the dilute acid be separated from a solution of acetate of lead, or sulphate of copper, by a piece of bladder, the zinc being immersed into the acid part, and the platina into the metallic solution, no hydrogen will be afforded by the platina, but the metal becomes reduced in proportion to the quantity of hydrogen which has disappeared: yet no perceptible quantity of this effect can be attributed to the electricity of contact, but to the mere chemical agency of hydrogen in its nascent state. Hence we are inclined to think, that the decompositions by the galvanic battery arise from two causes. Water principally owes its decomposition to the chemical action, and the agency of the electricity upon the hydrogen. Metallic oxids are principally decomposed by the presence of the nascent hydrogen, so collected and transmitted by the electricity. The decomposition of saline bodies, however, is to be attributed alone to the electrical attraction produced by the contact of the bodies employed, which can be made so great as to overcome the chemical attraction of the bodies decomposed. Of the latter of these powers of decomposition we have given some account, in detailing the ingenious experiments of Sir Humphrey Davy; of the two former means of decomposition we shall say something in a practical point of view.

Many very anomalous facts were known in chemistry long previous to the discovery of Galvanism. All those chemical phenomena, under which the appearance called arborescence was observed, were inexplicable, till it was shewn from some experiments, published in Nicholson's Journal, vol. xv. p. 94, that Galvanism is the cause of these singular phenomena. In the experiment where lead is so beautifully precipitated, by suspending a piece of zinc in a solution of acetate of lead, the zinc first reduces a small portion of lead, which, with the zinc, forms a galvanic combination. The lead, if no solution of lead were present, would now give out hydrogen gas; but the hydrogen, instead of appearing in that form, combines with the oxygen of the oxyd, and the metallic lead is formed at the same point. Hence the lead appears to grow from the last point formed, which gives the appearance of vegetation. That this effect does not depend upon the presence of zinc, may be proved by the following experiment. Tie on one end of a glass tube, about half an inch wide, a piece of bladder, so that it may hold water, and fill it with a solution of acetate of lead. Into the other end insert a cork loosely, and through the cork let a platina wire pass within about half an inch of the bladder. Into a wine-glass put some dilute muriatic acid, in which place a zinc wire. When the tube with the bladder is immersed in the wine-glass, if that part of the zinc wire without the glass be brought into contact with that part of the platina wire without the tube, beautiful crystals of metallic lead will soon appear upon the platina wire. If the acetate of lead be removed, and a dilute acid be put in its place, bubbles of hydrogen will appear upon the platina wire.

Another experiment, similar to that of the lead-tree, and equally anomalous, has been long known in chemistry. If a plate of glass be smeared over with a solution of nitrate of silver, and a brass pin or a piece of zinc wire be laid in the middle of the plate, beautiful ramifications of silver will soon appear as if growing out of the pin, very much resembling

vegetation. By observing the process with a magnifying glass, each branch of this arborescence may be seen to grow from the end or side of another; which proves that the silver forming the vegetative appearance is not reduced by the oxydable metal laid on the plate, but by something at the successive points of the silver branches. With a view to ascertain this fact, one half of the plate should be smeared with nitrate of silver, and the other half with dilute muriatic acid. If a piece of zinc wire be tied to a piece of platina wire, and the compound wire be bent that the zinc may touch the dilute acid, and the platina the nitrate of silver, the ramifications of silver will soon appear upon the platina wire. That the silver is reduced by the hydrogen carried in the galvanic current, is probable from varying the experiment as follows: If, instead of smearing the plate with nitrate of silver, the whole be covered with dilute acid, and the same compound arc be laid upon it, the platina will give out bubbles of hydrogen. In the common way of making this experiment with the pin, as well as the variation above stated, it appears that the process is kept up by the galvanic current, which furnishes the hydrogen. The pin first reduces a small portion of silver, which forms a galvanic combination with the pin. The hydrogen which, but for the presence of the remaining nitrate of silver, would appear in the gaseous form, is employed in depriving the silver of its oxygen. With the compound arc, the zinc does not require to touch the nitrate of silver, because the platina with zinc is already a galvanic combination. The theory of whitening common pins can be explained only on this principle. The tin, in a small proportion, is dissolved in the tartrate of potash; pieces of metallic tin, with the pins, are also present. The two latter form the galvanic combination, and a portion of tin is reduced from the solution upon the pins, to which they owe their whiteness. We may generally conclude, that in all instances where one metal becomes the precipitant of another, the precipitation is much facilitated by the agency of the galvanic combination, formed between the precipitating and the precipitated metals, and the consequent presence of hydrogen. If a piece of zinc be introduced into a solution of sulphate of copper, the zinc in the first instance becomes covered with copper, and the effect appears to stop. If, however, a very small excess of sulphuric acid be added, the process will go on with such rapidity, that the copper becomes precipitated in a very little time. By minutely observing the process, the copper will be seen to be reduced upon that already produced, which is a proof that it is not done by the mere agency of the zinc.

It appears very evident, that when a galvanic combination of zinc with any lesser oxydable metal is placed in a dilute acid, that a much larger quantity of hydrogen will be evolved from the lesser oxydable wire, than could possibly be produced by any electrical intensity generated by the contact of the bodies employed; but that independent of this, there is an immense quantity of electricity generated during the chemical action, by which the hydrogen is transported from the greater oxydable surface to the lesser one. If the quantity of hydrogen produced depended upon the attraction of the wires for the elements of the water, this power would depend upon the electrical intensity alone, and of course upon the series in the galvanic battery, whatever might be its surface; but it is found that the power of Galvanism to decompose water is much increased by an increase of surface only.

Galvanism as a Source of Heat.—When the wires coming from the ends of a galvanic battery of considerable surface
arc

are brought into contact, a brilliant spark is produced, and the wires stick together with considerable force, as if they were welded, or united by fusion. If the parts in contact be held with the fingers, a considerable heat will be perceived, which will be greater as the battery is more powerful, and inversely as the thickness of the wires.

Small wires seem to affect the electric fluid in a manner similar to that in which light is affected by a convex lens, or a concave mirror, by concentrating and compelling a large quantity of electricity to pass through a small channel. This appears to be the case with common electricity, as well as galvanism, since by discharging the electrical battery through very small wires, the metals become fused and oxydated.

On the galvanic battery this experiment should be made as follows: at each end of the battery should be placed a rod of metal, with a clean ball at the top of each. Between the two balls must be stretched a piece of very small wire, not exceeding $\frac{1}{16}$ th of an inch in diameter, while the circuit is interrupted in some other part of the battery. As soon as the wire is fixed, the circuit must be completed where it was broken, and the current will instantly be determined through the small wire, which will in consequence become ignited.

It was discovered by Dr. Wollaston, that, in the ignition of wire by the voltaic battery, there was one certain diameter of the wire, in which the length ignited was the greatest, above or below which the length was less. This does not arise from more heat being sent through the wire in which the greatest length was ignited, but from the ratio of the surface of the very small wire being so much greater to its solidity than in thicker wire, by which a greater proportion of heat is carried off by radiation; but when the diameter is beyond a certain extent, then a less length is ignited, from the heat being less concentrated.

It has also been found, that very different lengths of wire are heated of different metals when their diameters are equal. This appears to take place from the relative conductive powers of the different metals for electricity, which appears to be as their conducting powers for heat. Platina, being the worst conductor, has a greater length heated; and silver, which is known to be a good conductor, has a less length heated.

If the battery be very powerful, it will be fused and oxydated. When a connection is formed between the two ends of the battery, by means of the very thin foils of metals, such as leaf-gold, the metals undergo brilliant combustion, exhibiting different coloured flames. Charcoal and plumbago, presented by sharp angles, are similarly desflagrated. If the ends of the two wires coming from the battery be made to touch each side of a small globe of mercury, the latter will inflame with a bright flash. This heat, furnished in the galvanic current, is also very apparent while it is passing through moist conductors. Different fluids subjected to decomposition in the circuit, in glass tubes, become considerably heated, and this will be found the case, as the diameter of the tube is less.

Sir H. Davy attributes this heat to the decomposition, which must strike any one as being an error. Heat we always find to be evolved during combination; the very reverse of which ought to take place during decomposition.

Action of Galvanism upon Animals.—All animal substances, either dead or living, if not deprived of their moisture, are tolerably humid conductors of Galvanism. In the living subject, independent of its conducting power, it has the property of being affected in a peculiar manner. All those animals which possess excitability are affected by Gal-

vanism as they would be affected by any other violent stimulus; and if the excitable part be at all muscular, the fibres are vigorously contracted. This causes, in a living and conscious animal, a sensation not unlike an electric shock. The shock is more like that of common electricity, as the plates of the battery are smaller and more numerous. When the plates are of very large surface, a sort of vibratory motion is felt through the part attended with a sensation of heat; and this, in a powerful battery, is felt so long as the connection is kept up. The best mode of taking the shock is first to moisten the hands, or the part where the effect is to be applied; grasp in each hand a piece of metal, such as two spoons, and touch each end of the battery with the other ends of the spoons at the same time. If it is intended to be applied to any other part, let two plates, of about two inches in diameter, be each attached to the wires coming from the battery, and let the plates be applied to some two parts; if the effect be too severe, let some inferior conductor be placed between the plate and the skin.

Sir H. Davy found, that when an animal substance was placed in the circuit of a galvanic battery, the different compounds contained in it were decomposed. This was more especially the case with the saline bodies contained in the animal fluids; the acids of the salts were found on the positive side of the battery, and the bases of the salts on the negative. Should it be ascertained that any redundancy of saline matter is the cause of disease, Galvanism might be employed with great success in separating those bodies from the system.

Dr. Wollaston has given some hints in Nicholson's Journal, from which it appears probable that the power of the glands in secreting different fluids is dependent upon the electrical state of the glands; by which they are induced to attract all bodies in a contrary state to themselves. The opinion of this ingenious gentleman has been strongly corroborated by some experiments made by Messrs. Home and Brandt. Phil. Trans.

These, however, are speculations on which we cannot at present place strict reliance. The same conjecture which is applied to secretion may be applied to the oxygenation, or rather the decarbonization of the blood in the lungs; since the carbon appears to be transferred through the membranes between the pulmonary arteries and the interior of the lungs. The same theory may be also applied to account for the change of the colour of the blood between the fetus and the mother. Muscular excitability may perhaps arise from a certain electric state of the muscular fibre caused and kept up by the arterial blood; and if we may be allowed to carry the conjecture still further, muscular motion may perhaps be caused by the relative electric states of the muscles, and the brain and nerves.

VOLTANA, in *Geography*, a town of Spain, in Aragon; 5 miles N.W. of Aina.

VOLTARE, Ital. in *Music-books*, to turn over; whence *volti*, turn, *volti subito*, turn quick, and often only the initials of these words V.S. *Si volti*, at the end of a movement, denote, the leaf is to be turned over to another movement. And, in courtesy, it is sometimes said, *volti se piace*, turn over if you please.

VOLTE, in the *Manege*, signifies a round or circular motion, consisting of a gait of two treads, made by a horse going sideways round a centre; the two treads making parallel tracks, one by the fore-feet, larger, and the other by the hind-feet, smaller; the shoulder bearing outwards, and the croup approaching towards the centre.

VOLTE, *Demi*, is a half-round of one tread, or two, made by the horse at one of the angles, or corners, of the volte, or at the end of the line of the paffade; so as when

he is near the end of this line, or near one of the corners of the volte, he changes hands, to return by a femicircle.

VOLTE, *Reverted*, or *Inverted*, is a track of two treads, which the horse makes with his head to the centre, and his croup out; going sideways upon a walk, trot, or gallop; and tracing out a larger circumference with his shoulders, and a smaller with his croup. See on this subject Berenger's *Art of Horsemanship*, vol. ii. p. 83, &c.

VOLTE, in *Fencing*, denotes a sudden movement or leap, which is made to avoid the thrust of an antagonist.

VOLTERRA, DANIELE DI, in *Biography*, the cognomen of an artist of great renown, whose real name was Daniele Ricciarelli. He was a native of Volterra, and born in 1509, and was first a disciple of Giovanni Antonio Razzi, called Il Sodoma, and afterwards of Baldassare Peruzzi. Unemployed in his native city, and without means of improvement, he went to Rome, and wrought some time for cardinal Trivulzi, to whom a picture of the Flagellation he had brought with him served as a recommendation. He afterwards assisted Pierino del Vaga in the capella Maffimi at the Trinita da Monti: and in San Marcello, where he finished, from the designs of del Vaga, the four Evangelists, with various other figures, and ornamental enrichments. From designs of the same master he also painted a frieze in the hall of the palazzo Maffimi, and these works combined gave him so much renown, that signora Elena Orsina was induced to employ him to adorn her family chapel in the church of the Trinita da Monti.

He had in the mean time cultivated the friendship of Michel Angiolo and Sebastian del Piombo, and by their communion, and the study of their works, aggrandized his style and formed his manner; and the work which he produced in the capella Orsini, the Descent from the Cross, testified how worthy he was of such society. The work of this chapel, which was adorned not only with an altar-piece, but also with various other designs historical and ornamental, and all in fresco, occupied him seven years. The merit of the principal picture above-mentioned, has placed it, in public estimation, on a level with the Transfiguration by Raffaele, and the Communion of S. Jerome by Dominichino; and induced the French, in their rage for spoliation, to attempt the removal of it from the wall. And they effected it, though they never transported it to France, but in doing so, they cut away so much of the angles of the chapel that the roof fell in, but not till the picture had been removed out of danger. It was afterwards turned, so that its face was made visible, and an attempt was made by some ignorant pretender to enliven the colours by means of oil or varnish: the consequence has been, that the surface is become black, and the figures scarcely discernible; and thus this grand work, one of the principal features of modern Rome, one of the greatest monuments of human ingenuity, and the support of the well-earned renown of an artist ranked among the best, has been sacrificed to ambition, vanity, and folly. Happily the composition is preserved by Dorigny's print, and there is a great number of copies of it. Lanzi is of opinion, that M. Angelo must have aided Volterra in this great work, particularly in the composition, as the other parts in the chapel are so far inferior to it. He is known to have been partial to him, and on terms of intimacy. One day calling in his absence at his study, he left behind a sketch of a colossal head, which Volterra never would permit to be removed, and which remains to this day. And when Pierino del Vaga died, and Angelo had the works of the Vatican assigned to him, he interested himself for and procured the appointment of Volterra to supply his place. To him also, with the consent of Angelo, pope Paul III. intrusted the

slight clothing which is thrown over the nudities in the Last Judgment in the Sittini chapel, for which service however he was branded with the ludicrous name of *Il Bracettone*, the breeches-maker.

After his appointment in the Vatican, he was ordered to complete the paintings in the Sala Regia begun by his predecessor, which he did, but not, as Vafari lays, with skill equal to that he had exhibited in the chapel Orsini.

When Julius III. mounted the papal throne, he dismissed Volterra from his superintendance, but afterwards assigned to him one half of a hall to paint, of which Salvati had the other part, but Volterra did little or nothing in it, having been disappointed in not finding the whole intrusted to him.

He added, by means of his disciples, several other designs to the works in the Trinita da Monti, but turned his own mind principally to sculpture, and painted but little after this time. He died at Rome in 1566, aged 57.

VOLTERRA, in *Geography*, a town of Etruria. This was one of the ancient twelve cities, now a lonely, mean place, though it reckons 25 churches, chapels, and oratories, and about 20 convents and religious fraternities. It stands on a mountain, but the air is unwholesome: entire villages in the neighbourhood lie in ruins, and uninhabited, and the country all round is overrun with weeds and bushes, which unquestionably contribute to render the abode unhealthy. It has rich copper-mines, but not worked; 29 miles E.S.E. of Leghorn. N. lat. 43° 23'. E. long. 10° 52'.

VOLTOEGA, a town of Spain, in the province of Catalonia; 5 miles W. of Vique.

VOLTORE, a mountain of Naples, in Capitanata, E. of Monteverde.

VOLTRI, a town of the Ligurian Republic; 6 miles W. of Genoa.

VOLTUMNA, or **VOLTURNA**, in *Mythology*, a rural divinity of the Tuscans. Livy frequently mentions a temple belonging to her near the lake Ciminius, where the people debated concerning their affairs.

VOLTURARA, in *Geography*, a town of Naples, in Principato Ultra; 15 miles W. of Conza.

VOLTURARA, or *Vulturara*, a town of Naples, in Capitanata, the see of a bishop, suffragan of Benevento; 38 miles W.S.W. of Manfredonia. N. lat. 41° 28'. E. long. 15°.

VOLTURENA, a town of the Grisons, on the lake of Como.

VOLTURNALIA, among the Romans, a festival kept in honour of the god Volturnus, on the sixth of the calends of September, or 26th of August.

VOLTURNO, in *Geography*, a town of Naples, in Lavora, on a river of the same name, near its mouth; 12 miles W. of Capua.—Also, a river of Naples, which runs into the gulf of Gaeta, near Castell Mare.

VOLTZHEIM, a town of Saxony, in the principality of Ruesien, near Gera, where Henry IV. gained a victory over Rodolphus, duke of Swabia, in the year 1080.

VOLVA, in *Botany*, the Wrapper, or covering, of the *Fungus* tribe, is used in two senses by Linnaeus. In its original and most legitimate meaning, as explained in the *Philosophia Botanica*, p. 52, this term is appropriated to the membranous web, which conceals the unexpanded gills of an Agaric; and in many species, as the Common Mushroom, *Agaricus campestris*, separates at length from the margin of the head, and forms a permanent ring round the stalk. This sort of *Volva* is enumerated among the kinds of CALYX, and perhaps not improperly; see that article. The more usual idea of a *Volva* is that of an external covering, which unfolds

envelops the whole fungus, in an early state of growth. In the genus *Phallus* it resembles a hen's egg; and is nearly similar in the *Agaricus volvaceus*, Sowerby's *Fungi*, t. 1. In the starchy and vaulted Puff-balls this part is of a leathery texture when dry, more brittle when fresh. (See GEASTRUM.) In the *Lycoperdon phalloides* of Smith's *Spicilegium*, Sowerb. *Fung.* t. 390, now made a distinct genus, called *Batarrea*, by Persoon, the outer *Volva*, which remains in the ground, is filamentous.

VOLVA is also a word used by Scribonius Largus, and some other authors, to express the central part, or, as we call it, the core of the apple, in which the seeds are placed. He prescribes this in weaknesses of the stomach, and retchings to vomit.

VOLUBILE, or **VOLUBILATE** *Stem* or *Stalk*, in *Gardening*, a name given to those of many plants, as all those the stems or stalks of which are of a twining or winding climbing nature. They are commonly such as climb or ascend in a spiral manner round the stems, stalks, or branches of other plants, which happen to be situate near to them, round those of one another, or round flicks or stalks set for the purpose, and any thing of a similar kind that they may meet with in the course of their extending growth. The honey-suckle, the hop, the running kinds of kidney beans, and many other plants, are of this description.

The stems or stalks of this sort, in different kinds of plants, wind round or twist about others, or other substances, in different directions, either to the right or the left, according to the apparent diurnal motion of the earth in respect to the sun. The honey-suckle and the hop among garden plants turning to the left, while the different kinds of twining kidney beans turn to the right.

In garden culture, all those kinds of plants should be constantly suffered to take their own natural directions, and not be in any way thwarted in their modes of growth, as they never succeed well where that is the case, or afford so good a produce. And their supports, of whatever nature they may be, should always be fully adequate, and be well and firmly set into the ground, that they may not be in danger of giving way while the plants are rising upon them. It will seldom be necessary to stop the plants from running too high, but this may be occasionally of use in preventing their running up too weak.

VOLUBILES, or **VOLUBILIS**, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, upon the route, according to Anton. Itin. from Tocologida to Tingis, between Tocologida and Aqua Dacia; it was a Roman colony. Pliny calls it Volubile Oppidum, and gives an erroneous account of it. Hardouin differs from other geographers, who consider Fez as the ancient Volubilis, without sufficient reason. See FEZ.

VOLUBILIS CAULIS, in *Botany* and *Vegetable Physiology*, a Twining Stem, (see CAULIS and STEM,) is one which supports itself on other plants, independent of tendrils, by assuming a spiral direction, and embracing every thing that comes in its way. Each species of twining plant has its appropriate direction, in some to the right, in others to the left, nor can that direction be counteracted, or impeded, by any mechanical force. Many tendrils, on the contrary, make a greater number of convolutions in one direction, than in another, the better to ensure a support for the plant that is furnished with them.

VOLUCE, or **VOLUCA**, in *Ancient Geography*, a town of Hispania Citerior, E. of Clunia and S.W. of Numance.

VOLVENS OCVLI, in *Anatomy*, a name given by Spi-

gelius and some others, to one of the muscles of the eye, called by Cowper and Albinus, *obliquus inferior*.

VOLUERA, in *Geography*, a town of France, in the department of the Po; 7 miles S.W. of Trino.

VOLVIC, a town of France, in the department of the Puy de Dôme; 3 miles S.W. of Riom.

VOLVICARA, a town of Naples, in Calabria Citra; 9 miles E.S.E. of Scala.

VOLUME, **VOLUMEN**, a book, or writing, of a fit bulk to be bound by itself.

The word has its rise à *volvendo*, *rolling*, or *winding*; the ancient way of making up books being in rolls of bark, or parchment.

This manner lasted till Cicero's time, and long after paper was invented, and books written upon it. The several sheets were glued, or pasted, end to end, written only on one side; and at the bottom a stick was fastened, called *umbilicus*; and at the other end a piece of parchment, on which was the title of the book in letters of gold. And yet, we are assured, king Attalus, or rather Eumenes, had, long before, done up some of his books in the square form; as having found the secret of parchment, which would bear writing on both sides.

The library of Ptolemy, king of Egypt, contained, according to Aulus Gellius, 300,000 volumes; and, according to Sabellicus, 700,000.

Raymund Lully wrote about 4000 volumes; of which we have divers catalogues extant. It is held, that Trimegistus wrote 6525 volumes; others say, 36,529; but it is much more rational to suppose, with La Croix, that it was the custom with the Egyptians to put all the books they composed under the name of *Trimegistus*.

At present, volume is chiefly used in the same sense with tome, for a part, or division, of a work, bound separately. In this sense we say, "The Councils are printed at the Louvre, in thirty-seven volumes." See TOME.

VOLUME of a *Body* is also used among foreign philosophers, for its bulk, or the space inclosed within its superficies.

VOLUME de *Voix*, in French *Musick*, is the compass or extent of a voice from its lowest, or most grave sound, to the most acute. According to Rousseau, the common compass of voices is only eight or nine notes. There have been voices that have extended to two octaves of real voice, *voce di petto*; and Agujari, with the addition of two or three notes in falset, had a compass of three octaves.

There is another expressive acceptance of the word *volume* in speaking of a great voice: as it was justly said of Manzoli's vocal organ, that it was a *volume of voice*.

VOLUMUS, in *Law*, the first word of a clause in one species of the king's writs of protection, and letters patent.

VOLUNT, **VOLUNTAS**, is when a tenant holds lands, &c. at the will of the lessor, or lord of the manor.

VOLUNTARY, in the *Schools*. The generality of philosophers use voluntary in the same sense with spontaneous; and apply it to any thing arising from an internal principle, attended with a due knowledge of it.

Aristotle, and his followers, restrain the term voluntary to those actions that proceed from an inward principle, which knows all the circumstances of the action.

There are two things, therefore, required to the voluntariness of an action: the first, that it proceeds from an inward principle; thus, walking for pleasure-sake, is a voluntary action; as arising from the will commanding, and the moving faculty obeying, which are both internal. On the

the contrary, the motion of a man dragged to prison is not voluntary.

The second, that the action be performed with a perfect intelligence of the end, and circumstances of it; in which sense the actions of brutes, children, sleeping people, &c. are not properly voluntary.

Anatomists distinguish between the voluntary and natural or involuntary motions in the body. Of the latter kind are those of the heart, lungs, pulse, &c.

VOLUNTARY, in *Music*, a piece played by a musician extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform. See **RESEARCH**.

In these performances, we have frequently heard great players produce passages and effects in fits of enthusiasm and inspiration, that have never appeared on paper. In these happy moments

“Such sounds escape the daring artist’s hand
As meditation never could command;
And though the slaves to frigid rules may start,
They penetrate and charm the feeling heart.”

In the Philosophical Transactions, N^o 483, sect. 2. we have a method of writing down extemporary voluntaries, or other pieces of music, as fast as any master can play them on the organ, or harpsichord; and that in a manner expressive of all the varieties those instruments are capable of. This is performed by a cylinder, turning equally upon its axis, under the keys of an organ, and by having points under the heads of the keys. Hence, when they are pressed down, they will make a scratch or mark on the cylinder, which may shew the duration of the note; and the situation of this mark on the cylinder will shew what note was touched. For farther particulars we refer the curious to the Transaction itself.

VOLUNTARY Agent, *Escape, Homicide, Novation*; see the substantives.

VOLUNTEERS, in the *Military Art*, persons who enter of their own accord to serve in the army. See **LISTING**.

On occasion of danger from invasion, the people have been invited to form themselves into volunteer corps for their own protection. A plan for this purpose was proposed by earl Shelburne, then secretary of state, in 1782, when the French threatened an invasion of this country; but as peace soon took place, the plan was not put in execution. In similar circumstances of preparations on the part of the enemy, and menaces of a descent in 1797, a proposal of the same kind was made by Mr. Dundas, and accepted in every part of the kingdom with the utmost alacrity and zeal; and in a very few months a new army of citizens was enrolled and mustered, in appearance equal to the regular and militia forces, and in the discipline of the parade very little inferior. Previously to this, from the very commencement of the war, volunteer companies had been raised in different parts of England among the resident inhabitants, particularly in the towns contiguous to the sea-coast. At the same time troops of horse were levied among the gentlemen and yeomen of the country, upon the same principle with the volunteer companies. These were called the yeomanry cavalry. Of these volunteer corps, both of horse and foot, some served without any pay from government; others received pay and allowances, under certain regulations. The provisions and regulations, pertaining to volunteers, whilst their corps

existed, were established by the 44 Geo. III. c. 54. But it is now needless to enlarge on this subject.

VOLUNTII, in *Ancient Geography*, a people who inhabited the E. coast of Hibernia, S. of the Daunii. Ptol.

VOLUNTOWN, in *Geography*, a town of Connecticut, was settled in 1696, containing 1016 inhabitants; 20 miles N.E. of Norwich.

VOLVOX, in the Linnæan system of *Natural History*, a genus of the order of Infusoria, in the class of Vermes. Its characters are, that it is inconspicuous with a naked eye, very simple, pellucid, and spherical. The body of this animal is smooth, gelatinous, roundish, without joints, and formed for a whirling or vertiginous motion. Its young are roundish, and lodged in small holes in different parts of the body. Of this genus, Gmelin enumerates ten species: viz. the *bulbo*, *pileus*, *globator*, *dimidiatus*, *spherula*, *uva*, *lunula*, *conflictor*, *pilula*, and *globulus*. See **VERMES**. See also **GLOBE Animalcule** and **BEROE**.

VOLUPIA, in *Mythology*, the goddess of pleasure, the feigned daughter of Cupid and Psyche, who had a temple at Rome, in which was her statue; and a festival in honour of her was celebrated annually on the 21st of December.

VOLURA, in *Geography*, a town of France, in the department of the Po, during the French revolution; 7 miles W. of Turin.

VOLUSENUS, **FLORENTIUS**, **FLORENCE WILSON**, in *Biography*, a distinguished poet of the 16th century, professed his studies, first at Aberdeen, and afterwards at Paris, where he was intrusted with the tuition of cardinal Wolfsey’s nephew. After the uncle’s death, he was patronized by two other cardinals, Jean de Lorraine and Jean de Bellay. As he was proceeding with the latter towards Rome, in 1538, he was seized with an indispotion which detained him at Carpentras. Here he waited on cardinal Sadolet, then bishop of the see; who was so delighted with his literary accomplishments and elegant manners, that he placed him at the head of a classical seminary in that city. Wilson afterwards intended to revisit his native country, but death overtook him at Vienna, in the year 1546. F. Wilson was a scholar whom Buchanan has celebrated as dear to the Muses. He is known as the author of a classical dialogue on tranquillity of mind, entitled “De Animi Tranquillitate Dialogus.” Lugd. apud Gnyphium 1543, 4to.

VOLUSPA, q. d. *the oracle of the prophetess*, in *Mythology*, a poem of about four hundred verses, forming part of the ancient *Edda*; which see.

The *Edda* is a collection of various odes, which, as some have suggested, are the fragments only of a much larger work, long lost to the world. It has been generally ascribed, as we have mentioned under the article **EDDA**, to Sæmund Sigfuson, an eminent Icelandic, born A.D. 1056 or 1057, who, from his knowledge, writings, and various acquisitions, has been called by succeeding authors, *Frode*, or the learned. His claims, however, have been contested; and strong reasons have been urged for believing that Sæmund did not compose, perhaps not even compile, the *Edda* which is ascribed to him. The principal opponent of Sæmund’s claim to the first *Edda* is Arnas Magnæus; whose recondite inquiries into the early literature of Iceland have given him much celebrity. See his *Life of Sæmund Frode*, prefixed to the *Edda Sæmunder*, Hafnia, 1787, cited by sir George Stewart Mackenzie, bart. in his “Travels in the Island of Iceland,” 1810.

VOLUTA, the *Volute*, in *Natural History*, the name of a genus of shells, for an account of which see **CONCHOLGY**. Gmelin enumerates 141 species.

VOLUTE,

VOLUTE, **VOLUTA**, in *Architettura*, a kind of spiral scroll, used in the Ionic and Composite capitals; of which it makes the principal characteristic and ornament.

Some call it the *ram's horn*, from its figure, which bears a near resemblance to it.

Most architects suppose, that the ancients intended the volute to represent the bark or rind of a tree, laid under the abacus, and twisted thus at each extreme, where it is at liberty: others will have it a sort of pillow or bolster, laid between the abacus and echinus, to prevent the latter being broken by the weight of the former, and the entablature over it; and, accordingly, they call it *pulvinus*. Others, after Vitruvius, will have it to represent the curls, or tresses, of a woman's hair.

The number of volutes in the Ionic order is four; in the Composite, eight.

There are also eight angular volutes in the Corinthian capital, accompanied with eight other smaller ones, called *helices*.

There are several diversities practised in the volute. In some, the list or edge, throughout all the circumvolutions, is in the same line or plane: such are the antique Ionic volutes, and those of Vignola. In others, the spires or circumvolutions fall back; in others, they project, or stand out. Again, in some, the circumvolutions are oval; in others, the canal of one circumvolution is detached from the list of another, by a vacancy or aperture. In others, the rind is parallel to the abacus, and springs out from behind the flower of it. In others, it seems to spring out of the vase, from behind the ovum, and rises to the abacus, as in most of the fine Composite capitals.

The volute is a part of great importance to the beauty of the column. Hence, architects have invented divers ways of delineating it. The principal are that of Vitruvius, which was long lost, and at last restored by Goldman; and that of Palladio. Daviler prefers the former as the easier. The manner of which is as follows:

Draw the cathetus FC (Plate XV. *Geometry*, fig. 19.) whose length must be half a module, and from the point C describe the eye of the volute AEBD, of which the diameter is to be 34 minutes; divide it into four equal sectors by the diameters A, B, D, E: bisect the radii CA, CB, in 1 and 4; construct a square 1, 2, 3, 4, from the centre C to the angles 2, 3; draw the diagonal C 2, C 3, and divide the side of the square 1, 4, into six equal parts, at 5, 9, C, 12, 8; then through the points 5, 9, 12, 8, draw the lines 5, 6, 9, 10, 12, 11, 8, 7, parallel to the diameter E D, which will cut the diagonals in 6, 7, 10, 11, and the points 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, will be the centres of the volute. From the first centre 1, with the interval I F, describe the quadrant F G, from the second centre 2, with the interval 2 G, describe the quadrant G H, and continuing the same operation from all the twelve centres, the contour of the volute will be completed.

The centres for describing the fillet are found in this manner: construct a triangle, of which the side AF (fig. 20.) is equal to the part of the cathetus contained between A F, and the side FV equal to C 1; on the side A F, place the distance FS from F towards A, equal to FS, the breadth of the fillet, and through the point S draw the line ST, which will be to C 1 in the same proportion as AS is to A F; place this line on each side of the centre C, on the diameter of the eye A B; divide it into three equal parts; and through the points of division, draw lines parallel to the diameter E D, which will cut the diagonals C 2, C 3, and you will have twelve new centres, from whence the interior

contour of the fillet may be described, in the same manner as the exterior one was from the first centres.

Consoles, modillions, and other sorts of ornaments, have likewise their volutes, or scrolls.

VOLUTE, *Canal of the*. See CANAL.

VOLUTE, *Eye of the*. See EYE.

VOLUTELLA, in *Botany*, Forsk. *Ægypt.-Arab.* 84, so called on account of its twining and slender habit, is rightly pointed out by Jusseu, *Gen.* 440, on the authority of Vahl, as a *Cassipha*. Linnaeus has marked it so in his own copy of Forskall's work. We presume it to be the identical *C. filiformis*. Forskall speaks of this plant as not uncommon in Arabia, where it climbs trees, entangling their branches very much. The stem is exceedingly slender, without branches or leaves; the flowers scarcely visible; the berries, which are eaten by children, are insipid, with a flavour of pepper, but no acrimony. Are there any considerable points of agreement between this obscure genus and *Afarum*?

VOLUTINA, in *Mythology*, a rural goddess of the Romans, whom they invoked, for the coat that covers the ear of corn.

VOLVULA, in *Natural History*, the name of an extraneous fossile body, nearly allied to the entrochus, being composed of the same substance, and being like that of a cylindrical column, made up of several joints; the commissures of the joints are, however, much less visible in the volvula than in the entrochi, and they are not fringed, as in the entrochus, from the centre to the circumference.

The volvulae are of various figures; some resemble in shape a little bottle, and are called *volvula utriculata*, and of these some have, and others have not, a star marked on their bottom; others of them swell out in the middle, and taper a little toward each end; and these, from their resemblance in shape to a little barrel, are called *dolioli*, or *volvula doliate*. There is great reason, from the analogy these bear to the entrochi, and other fossils which owe their form to animal remains, to suppose these of the same origin; but we yet know not to what animal it is that they have belonged. Hill's *Hist. Foss.*

VOLVULUS, in *Botany*, a name given by Dalechamp, and some others, to the upright narrow-leaved or toad-flax-leaved bind-weed. See CONVOLVULUS.

VOLVULUS, in *Conchology*, a species of *Helix*, which see.

VOLVULUS, in *Entomology*, a species of *Cerambyx*, which see.

VOLVULUS, in *Medicine*, a name which some authors give to the iliac passion, by others called *chordapsus*; and by others, *misereere mei*.

VOLX, in *Geography*, a town of France, in the department of the Lower Alps; 6 miles S.E. of Forcalquier.

VOLZANA, a town of the duchy of Carniola, on the Lifonzo; 12 miles S.W. of Feldes.

VOMANO, a river of Naples, which runs into the Adriatic, 5 miles N.N.E. of Atri.

VOMANUS, in *Ancient Geography*, a river of Italy, in Picenum, still called Vomano.

VOMAS, in *Geography*, a town of France, in the department of the Allier; 18 miles E.S.E. of Moulins.

VOMER, in *Anatomy*, a bone of the nose. See CRANIUM.

VOMER, in *Ichthyology*, a species of *zeus*, with a forked tail and spine recumbent before the anal and dorsal fin. This is an American fish.

VOMICA, in *Natural History*, a word used by the ancients to express one of the blenues to which crystals and the

the precious stones are subject. This is a dusky foulness lying deep in the stone, and giving a dusky colour and tinge to the whole. Both the lustre and transparency of the stone are much hurt by this accident. When the vomica was of a blueish or blackish colour, the Romans expressed it by the word *plumbago*.

VOMICA, in *Medicine*, an abscess, or collection of purulent matter in the substance of the lungs. This, like all other abscesses, is the result of previous inflammation in the part which it occupies, and is, therefore, one of the terminations of peripneumony, of which, in that case, it constitutes the last stage. (See *PERIPNEUMONY*.) If a vomica bursts through the exterior surface of the lungs, and the matter consequently escapes into the cavity of the thorax, the disease is then called *empyema*.

VOMICA, *Nux*, *Vomic Nut*. See *NUX Vomica*.

VOMIER, in *Botany*, Poirlet in Lamarck Dict. v. 8. 692, a French name, whose derivation or meaning we cannot trace, applied by this author to our *ERIOSTEMON*; see that article.

VOMIT, **BLACK**, in *Medicines*, an appellation given by the first writers on the diseases of tropical climates to the *yellow fever*, the most formidable and fatal symptom of which is a vomiting of a black matter, consisting of grumous blood and bile. This symptom, however early it appeared, was generally soon followed by death, and being the most remarkable and distressing character of the disease, its name was given to the whole fever: it is observed, however, in the bilious remittents of more northern latitudes, as of Spain and Egypt, and was noticed by Hippocrates as a fatal symptom of the *causos*, or ardent fever, endemic in his time in the countries bordering on the Mediterranean. See *FEVER, Yellow*.

VOMITING, in *Animals*, is the inverted action of the stomach, or the act of discharging the contents of it by the mouth. Of this the horse is incapable or deprived, on account of a peculiarity of structure in the parts; but dogs, cats, and other animals, vomit very readily, and are often much benefited in this way, by the use of proper medicines, in different diseases with which they are affected.

VOMITING, in *Medicine*, the act of ejecting the contents of the stomach through the gullet and mouth, commonly preceded by a sensation of *nausea*.

It has been a question much discussed by physiologists, how the matters contained in the sac of the stomach are thus forcibly expelled in a retrograde direction? some supposing that this was effected by the retrograde action of the muscular coat of the stomach itself, and others contending that the action of the diaphragm and abdominal muscles was the principal force employed in the act. This question has been amply expounded, and the affirmative of the latter opinion shewn to be correct under the head of *STOMACH*, to which we refer the reader.

Vomiting is not to be considered as itself a distinct species of disease, but merely as a symptom of various morbid affections, either of the stomach itself, or of some other organ of the body with which it is connected by sympathy. As a symptom, however, which is always distressing, and often very urgent, it frequently becomes the object of medical treatment, and it is therefore important to distinguish the causes from which it originates in different instances, in order that the appropriate remedies may be selected.

The first set of causes of vomiting, to which we have alluded, are those which affect the stomach itself. There are various morbid conditions of that organ, or the irritation of substances introduced into it. Thus vomiting is a symp-

tom of inflammation of the coats of the stomach (see *GASTRITIS*), which are rendered so irritable as to reject every thing introduced within its cavity. A scirrhus or cancerous state of the stomach is also attended by vomiting, especially when that disease diminishes the aperture of the pylorus, and prevents the passage of the aliment into the intestines. Vomiting is likewise often a symptom of *dyspepsia*, or indigestion, and is then occasioned either by the irritation of undigested food, or the acrimony of fluids generated during the imperfect process of digestion: whence the matters vomited are often acid or acrimonious, irritating the gullet and fauces as they pass. Sometimes in these cases the vomiting is excited by the regurgitation of the bile, when it is superabundant; but most commonly that fluid is only vomited after repeated and severe retchings, by which the bile is brought into the stomach from the upper intestine. Vomiting is sometimes also a symptom of the stomach colic, or cramp in that organ, in which case, as in the inflammation, it is accompanied by intense pain.

The cure of the vomiting in these cases will depend upon the removal of the respective diseased conditions of the stomach of which it is symptomatic. In *gastroitis*, it can only be removed by copious blood-letting, blistering, or cupping the region of the stomach, or applying leeches; for it is in vain to attempt to introduce medicine into an inflamed stomach; and opium would, if it could be retained, aggravate the original disease. In the cramp of the stomach, on the other hand, opium largely given, with hot fomentations, would be the most effectual remedy. In cancer or scirrhus, alleviation of the sickness is all that can be expected; and opium or hyoscyamus affords the best means of soothing that malady. In a state of indigestion, vomiting will be cured by adhering to a light and digestible diet; by the use of absorbents, such as magnesia or chalk, with light aromatics, especially where the vomitings are acid; and by whatever strengthens the tone of the stomach, and improves the digestive function; such as bitters, horse-exercise, cold-bath, &c.

When vomiting is produced by substances taken into the stomach, and immediately irritating its sensible surface, such as the metallic or other poisons; the obvious remedy will be to get rid of the irritating substance, if possible, to dilute and weaken its acrimonious quality, or to change or decompose it by chemical means. In all such cases, the copious introduction of tepid fluids should be immediately resorted to.

The second set of causes of vomiting, which we have mentioned above, are those which influence the stomach only by sympathy, the actual seat of the irritation being in some other, even distant organ; the varieties of the causes producing vomiting in this indirect way are, therefore, as numerous as the sympathies of that important organ with almost every other organ in the body.

Many affections of the head are attended with vomiting. *Vertigo*, or giddiness, from whatever cause it originates, is liable to induce nausea, and even that most violent and distressing species of vomiting, *sea-sickness*. (See *VERTIGO*.) Blows on the head, inflammation of the brain or its membranes, fractures and depressions of the skull, are almost constantly productive of vomiting; which, in such cases, can of course only be relieved by removing the pressure or curing the inflammation of the brain.

With almost every organ of the abdomen the stomach sympathizes so closely, that violent vomiting is the consequence of irritations in most of them. The kidneys are seldom affected with disease, without producing sickness in the

the stomach, and the most violent and unremitting retching is occasioned by the existence of a small calculus in the pelvis of the kidney, or its passage along the ureter into the bladder. With both colic, or spasmodic constriction, and inflammation of the intestinal canal, vomiting is a constant attendant; and it often accompanies diseases of the liver. Affections of the uterus in women very frequently occasion sickness, and among the first symptoms of the distension of that organ in pregnancy, nausea and vomiting frequently occur.

Although these sympathetic vomitings are manifestly dependent on other irritations, the removal or alleviation of which will be the only effectual cure, by means adapted to them respectively; yet some alleviation of these sicknesses is often attainable by diminishing the irritability of the stomach itself. The carbonic acid, or fixed air, appears to have this quality in a certain degree, whence soda-water, or the saline draught, swallowed during the effervescence, will sometimes materially allay these sympathetic vomitings. This is also occasionally effected by an absorbent, with a light aromatic, or a cordial distilled water. Thus a little magnesia in peppermint or pimento water will sometimes allay such a sickness. An opiate, or the extract of hop or hennbane, may be now and then added to these medicines with advantage, as they tend to lessen the irritability, and render the stomach less sensible to the irritation.

VOMITING of Blood. See HÆMATEMESIS.

VOMITING excited by Medicine. See EMETICS.

VOMITING Julep. See JULEP.

VOMITIVES, or VOMITIVE Medicines. See EMETICS.

VONA, in Geography, a town of Asiatic Turkey, in the government of Sivas; 70 miles W. of Trebifond. N. lat. 41° 10'. E. long. 38°.

VONC, a town of France, in the department of the Ardennes; 6 miles N. of Vouziers.

VONDEL, JOOST VANDEEM, in Biography, a Dutch poet, was the son of parents who belonged to the sect of Mennonites, and born at Cologne in the year 1587. His education was merely adapted to trade, and having married in 1610, he commenced business as a hoiler at Amsterdam; but with talents superior to his station, he entrusted his wife with the conduct of his trade, and directed his attention to literary and religious speculations. In the disputes between the Arminians and Gomarists, he took part with the former, and joined their communion. His first poetical productions were the mere fruits of untaught genius; but apprehending that he might derive advantage from those sources of information to which he had no access, on account of his ignorance of the learned languages, he began, at the age of 30 years, to learn the Latin and French, and to study logic. Attached to the Arminian party, he exposed the injustice of the sentence against Barneveldt in an allegorical tragedy, entitled "Palamedes, or Innocent oppressed," for which he was prosecuted and fined. Conceiving prejudices against the reformed religion, probably on account of the attachment of the Dutch ministers to the Orange faction, he became a Roman Catholic; and afterwards published a tragedy, intitled "Gisbert Van Amstel," or the capture of Amsterdam by Florence V. count of Holland; and many other poems, one on the subject of "The Mysteries, or the Secrets of the Altar." He also translated into Dutch verse Virgil, Horace, and Ovid's *Metamorphoses*, by which he gained considerable reputation. But, like many authors, he neglected his affairs, and suffered pecuniary embarrassments. He lived however to a great age, and closed life in 1679, in his 92d year; having acquired the honour of being

regarded as one of the principal ornaments of his country. His works amount to nine vols. 4to. Moreri.

VONJASH, in Geography, a town of Abascia, on the Black sea; 30 miles N.W. of Mamak.

VONITZA, a town of European Turkey, in Albania; 62 miles N.W. of Lepanto. N. lat. 39° 15'. E. long. 21° 2'.

VOOR, in Agriculture, a term applied to fallow land, or such as is frequently ploughed over, in different cases. See FALLOW.

VOORN, or Oost-VOORN, in Geography, an island of Holland, situated at the mouth of the Meuse; about 20 miles in length, and 5 in breadth. This island, with Goree and Overflacke, form the territory called *Voornland*; which formerly belonged to Zealand: Briel is the capital.

VOORN, a small island at the union of the Wahal and the Meuse, with a fort belonging to the state of Utrecht; 9 miles N.E. of Bois le Duc.

VOPISCUS, a Latin term, used in respect to twins in the womb, for that which comes to the perfect birth; the other being before excluded abortive.

VOPISCUS, FLAVIUS, in Biography, a Latin historian, was a native of Syracuse, and flourished about A.D. 304. He began his history with the reign of Aurelian, which he profecuted with those of Tacitus and his brother Flavianus, and Probus. He then published an account of the four tyrants, Firmus, Saturninus, Proculus, and Bonofus, and also of the three emperors Carus, Numerianus, and Carinus. These are extant, and are contained in the "Historia Augustæ Scriptores." Among the best of these is Vopiscus, who excelled in learning, and also in chronological arrangement. He is said to have given credit to the wonderful works of Apollonius Tyaneus, whose life he had an intention of writing.

VOPOKAS, in Geography, a town of Russia, in the province of Ufiting, on the Vitcheгда. N. lat. 63° 10'. E. long. 54° 14'.

VORALBERG, a tract of country, containing some lordships, S.E. of the lake of Constance; so called from the mountain of Alberg, near which it is situated; ceded to Bavaria by the peace of Preburg.

VORALEN, a town of Hinder Pomerania; 10 miles S.W. of New Stettin.

VORAU, a town of the duchy of Stiria; 7 miles N.W. of Hardberg.

VORBACH ZOMMERN, a town of the county of Hohenloe; 3 miles E.S.E. of Weickerheim.

VORCHEIM. See FORCHEIM.

VORCLUT, a cape of the island of Jersey; 5 miles N.E. of St. Helier.

VORDEN, or VOERDEN, a town of Westphalia, in the bishopric of Paderborn; 17 miles E.N.E. of Paderborn. N. lat. 51° 45'. E. long. 0° 18'.

VORDEN, a town of Westphalia, in the bishopric of Osnabruck. Both the Roman Catholics and Lutherans have a church here in common; 10 miles N.E. of Osnabruck. N. lat. 52° 20'. E. long. 8° 4'.

VORDENBURG, a town of the duchy of Stiria; 4 miles N. of Leoben.

VORDENSES, in Ancient Geography, a people of Gallia Narbonensis, W. of the Vulgientes. They are placed by some on the seite of the town of Gordes, near that of Apt.

VORE, in Agriculture, a term sometimes used to signify the narrow strip of ground which is left whole, for turning the furrow-slice upon, in some modes of paring and burning.

It is also applied to the head of the teazle plant, which does not become ripe and run until the third year, such heads being called vore.

VOREDA, in *Ancient Geography*, a Roman station, marked in the second Iter of Antonine between Lugvallium (Carlisle) and Brononacis (Kirbythure), situated at Old Penrith. This, without doubt, was the place where this station was situated, at the N.W. end of Plumpton wall, about 4 miles to the N. of the present town of Penrith, on a noble military way, which is there in the highest preservation.

VOREPPE, in *Geography*, a town of France, in the department of the Iser; 8 miles N.N.W. of Grenoble.

VORGANIUM, in *Ancient Geography*, the capital of the Osismii, who occupied the western part of Brittany, through its whole extent.

VORINGEN, or *Stadt Voringen*, in *Geography*, a town of Germany, in the principality of Hohen Zollern, on the Lauchart, formerly the chief place of a county, now extinct; 10 miles S.E. of Hohen Zollern. N. lat. 48° 11'. E. long. 9° 15'.

VORMS, called *Vormsfaari*, and in modern charts *Ormslon*, an island of the Baltic, 14 versts in length, in breadth rather more than 9 versts, and of a nearly quadrangular shape.

VORÓCHITA, in *Ancient Geography*, an island of the Persian gulf, upon the coast of Carmania. Ptolemy.

VORONEZ, in *Geography*, a town of Russia, and capital of a government, called "Voronezskoi," situated at the conflux of a small river, called by the same name, with the Don; and surrounded with wooden walls. The citadel is on the opposite side of the Voronez river, furnished with 150 pieces of cannon, and a large garrison. Here are docks for building vessels, large and small, good warehouses for naval stores, &c. It is the see of a bishop, and a place of considerable trade. The number of inhabitants is about 12,000; 256 miles S. of Moscow. N. lat. 51° 36'. E. long. 39°.

VORONEZ, a river of Russia, which runs into the Don at Voronez.

VORONEZSKOI, a government of Russia, bounded on the north-east by Tambovskoe, on the south and south-east by the country of the Cossacks, on the north-west by Orlovskoe, on the west by Kurskoe and Charkovskoe; about 260 miles in length, and 104 in its mean breadth. N. lat. 48° 50' to 53° 16'. E. long. 37° to 42°.

VORRACH, a town of Bavaria, in the territory of Nuremberg; 4 miles N. of Nuremberg.

VORRAGE, in *Agriculture*, a term applied to the earth or mould which is collected and provided for "milling" or mixing with lime, in the making of composts.

VORSE, in *Geography*, a river of France, which runs into the Oise, near Noyon.

VORSKLA, a river of Russia, which runs into the Dnieper, 20 miles E. of Kremengug.

VORST, a town of the duchy of Wurzburg; 6 miles E. of Schweinfurt.

VORSTIUS, CONRAD, (VON DEM VORST), in *Bio-graphy*, an eminent Arminian divine, was born at Cologne in 1569, and finished his classical instruction at Dusseldorp. Having been entered at the college of St. Lawrence in Cologne in 1587, he left it without taking a degree, because his conscience would not allow his swearing adherence to the decrees of the council of Trent. At this time the circumstances of his family rendered it expedient for him to turn his attention to trade, for which he qualified himself by

learning arithmetic, and the French and Italian languages. However, he afterwards, viz. in 1589, resumed his studies at Herbora; and in 1593 he accompanied some young persons of rank as their tutor to Heidelberg. Here he was created a doctor of divinity, and he then visited the academies of Switzerland and Geneva. At Geneva he read lectures on theology, and was offered a professorship; but declining this, he accepted a similar office at Steinfurt in 1596, where he gained such reputation as to induce other Protestant universities to invite him to the theological chair. His orthodoxy being suspected, he repaired to Heidelberg for a certificate of his soundness in the faith, protesting against the opinions of Socinus, and apologizing for some expressions which he had used in their favour. In 1610 he removed from Steinfurt, to succeed Arminius as theological professor at Leyden. Here the Gomarists, or rigorous Calvinists, appealing to his work, intitled "Tractatus Theologicus de Deo, five de Natura et Attributis Dei," charged him with many heresies; and not only engaged several foreign universities in their party, but induced our royal pedant, James I., to aid them with his concurrence. The king, acute in discovering theological errors, and fond of exercising his authority in suppressing them, sent to his resident at the Hague a list of various heresies, which he had by an hour's reading found in Vorstius's book; and notified to the states how much he detested these errors, and the persons who tolerated them. In order to maintain consistency of conduct, his majesty ordered several copies of Vorstius's book to be committed to the flames at London, Oxford, and Cambridge. He also wrote to the states, vehemently urging them to dismiss the professor, whose blasphemies, if he continued to maintain them, would justify his being burnt; and at the same time menacing, that unless they were ardent in extirpating "these germs of atheism, he would publicly separate from such false and heretical churches; and, as defender of the faith, exhort all other reformed churches to take common council for extinguishing and sending back to hell these abominable heresies; and would forbid all his own subjects to haunt so infected a spot as the university of Leyden." James also wielded his pen against Vorstius, who resisted the attack by a short and respectful reply. The States were not much moved by the threats of the authoritative and incensed monarch; for, though they suspended the professor till he had an opportunity of exculpating himself, they appointed a conference at the Hague, in April, 1611, between six ministers of both of the opposite parties, in presence of the curators of the university of Leyden, before whom Vorstius pleaded his own cause, and they determined in his favour. The triumph of Vorstius would have been complete, if he had not been implicated in a suspicion of heresy, occasioned by the publication, on the part of some of his disciples, of a small tract, intitled "De Officio Christiani Hominis," which contained Anti-Trinitarian doctrines. Vorstius, though he signed a confession of faith conformable to the Trinitarian system, found it expedient to relinquish his professorship, and to remove from Leyden till the storm subsided. Accordingly he withdrew to Tergou in 1612, and resided there for seven years, without a shade on his character. In 1619 a synod was held at Dordrecht, in which the Anti-Arminian party was predominant. This synod condemned Vorstius, unheard, as unworthy of the professorship; and in consequence of this judgment, the States deprived him of it, and for ever banished him from their territories. He lived two years longer in secrecy, but not without apprehension for the safety of his life. At length the duke of Holstein collected the dispersed relics of the

Arminians,

Arminians, and gave them a place for building a town, to which Vortius repaired in 1622; but being soon taken ill, he died at Tonningen, in September, at the age of 53 years, with every token of pious resignation. His remains were interred at Fridrichstadt, the new Arminian settlement, with great solemnity. He is known as the author of several theological writings, chiefly relating to the controversy between the Roman Catholics and his Protestant antagonists. His son, *William Henry Vortius*, published some works in rabbinical literature. Bayle.

VORSTIUS, JOHN, a German theologian, was born at Ditmarsh, in Holstein, and joining the Calvinist church, though a native Lutheran, became librarian to the elector of Brandenburg, in which connection he died in 1676. He was skilled in the Latin, Greek, and Hebrew languages, and published several learned works. The earliest of these was printed at Rostock in 1641, and intitled "Quædam de Stylo Novi Testamenti excogitata." The first part of this work, on the Hebraisms of the New Testament, was printed at Leyden, in 1658, 4to. under the title of "Philologia Sacra;" and the second part at Amsterdam, in 1665, 2 vols. 4to., and at Frankfort in 1705. Other tracts on scriptural topics were published in the "Fasciculus Opusculorum Historicorum et Philologicorum," Rotterd. 1693. Moreti.

VORTEX, WHIRLWIND, in *Meteorology*, a sudden, rapid, violent motion of the air, in gyres, or circles. See WHIRL-WIND.

VORTEX, *Vorago*, is also used for an eddy, or whirlpool, or a body of water, in certain seas and rivers, which runs rapidly round, forming a sort of cavity in the middle.

The ordinary course of these vortices is a gulf or outlet, by which the water of the sea, &c. is absorbed, or precipitates itself into some other receptacle: sometimes to some other communicant sea; and sometimes, perhaps, into the vast abyss of central water.

VORTEX, an *Artificial*, expressive of the phenomena of the natural ones, may be made with a cylindric vessel, placed immovable on an horizontal plane, and filled to a certain height with water. In this water a stick being plunged, and turned round as briskly as may be, the water is necessarily put into a pretty rapid circular motion, and rises to the very edge of the vessel; and, when there arrived, ceases to be farther agitated.

The water thus raised forms a cavity in the middle, whose figure is that of a truncated cone; its base is the same with the upper cavity of the vessel; and its vortex in the axis of the cylinder.

What raises the water at the side of the vessel, which occasions the cavity in the middle, is its centrifugal force. For the motion of the water being circular, it respects a centre taken in the axis of the vessel; or, which is the same, in the axis of the vortex formed by the water; the same velocity, then, being impressed on all the water, the circumference of a smaller circle of water, or a circle less remote from the axis, has a greater centrifugal force than another that is greater or more remote from the axis. The smaller circle, therefore, drives the greater towards the side of the vessel; and from this pressure, or impulsion, which all the circles receive from the smaller ones that precede them, and convey to the greater which follow them, arises that elevation of the water along the edge of the vessel to the very top, where we suppose the motion to cease.

With a vortex thus formed, Mr. Saulmon, of the Royal Academy of Sciences, made divers experiments, by putting several solid bodies therein, to acquire the same circular motion, with intent to discover which of them, in making

their revolution round the axis of the vortex, approach toward, or recede from it, and with what velocity. The result was, that the heavier the body, still the greater was its recess from the axis.

Mr. Saulmon's view, in this attempt, was to shew how the laws of mechanics produce the celestial motions, and that it is probably to those motions that the gravity or weight of bodies is owing. But, unhappily, the experiments shew just the contrary of what they should do, to confirm the Cartesian doctrine of gravity. See WHIRLING Table.

VORTEX, in the *Cartesian Philosophy*, is a system or collection of particles of matter moving the same way, and round the same axis.

Such vortices are the grand machines by which these philosophers solve most of the motions, and other phenomena of the heavenly bodies. Accordingly, the doctrine of these vortices makes a great part of the Cartesian philosophy.

The matter of the world they hold to have been divided at the beginning into innumerable little equal particles, each endowed with an equal degree of motion, both about its own centre, and separately, so as to constitute a fluid.

Several systems, or collections of this matter, they farther hold to have been endowed with a common motion about certain points, as common centres, placed at equal distances, and that the matter, moving round these, composed for many vortices.

Then, the primitive particles of the matter they suppose, by these intestine motions, to become, as it were, ground into spherical figures, and so to compose globules of divers magnitudes; which they call the *matter of the second element*: and the particles rubbed, or ground off them, to bring them to that form, they call the *matter of the first element*.

And since there would be more of this first element than would suffice to fill all the vacancies between the globules of the second, they suppose the remaining part to be driven towards the centre of the vortex, by the circular motion of the globules; and that being there amassed into a sphere, it would produce a body like the sun.

This sun being thus formed, and moving about its own axis with the common matter of the vortex, would necessarily throw out some parts of its matter, through the vacancies of the globules of the second element constituting the vortex; and this especially at such places as are farthest from its poles; receiving, at the same time, in, by these poles, as much as it loses in its equatorial parts. And, by this means, it would be able to carry round with it those globules that are nearest with the greater velocity; and the remoter with less. And, by this means, those globules which are nearest the centre of the sun, must be smallest; because, were they greater, or equal, they would, by reason of their velocity, have a greater centrifugal force, and recede from the centre. If it should happen, that any of these sun-like bodies, in the centres of the several vortices, should be so incrustated and weakened, as to be carried about in the vortex of the true sun; if it were of less solidity, or had less motion, than the globules towards the extremity of the *solar* vortex, it would descend towards the sun, till it met with globules of the same solidity, and susceptible of the same degree of motions with itself; and thus, being fixed there, it would be for ever after carried about by the motion of the vortex, without either approaching any nearer to, or receding from, the sun; and so would become a planet.

Supposing then all this, we are next to imagine, that our system was at first divided into several vortices, in the centre of each of which was a lucid spherical body; and that some

of these, being gradually incrustated, were swallowed up by others which were larger, and more powerful, till at last they were all destroyed, and swallowed up, by the biggest *flar* vortex; except some few which were thrown off in right lines from one vortex to another, and so become comets. See *CARTESIAN Philosophy*.

But this doctrine of vortices is, at best, merely hypothetical. It does not pretend to shew by what laws and means the celestial motions are really effected, so much as by what means they possibly might, in case it should have so pleased the Creator. But we have another principle which accounts for the same phenomena as well, nay better than that of vortices; and which we plainly find has an actual existence in the nature of things: and this is gravity, or the weight of bodies.

The vortices, then, should be excluded from philosophy, were it only that two different adequate causes of the same phenomena are inconsistent.

But we have other objections against them. For, 1. If the bodies of the planets and comets be carried round the sun in vortices, the bodies of the parts of the vortex immediately investing them, must move with the same velocity, and in the same direction; and besides, they must have the same density, or the same vis inertia. But it is evident, that the planets and comets move in the very same parts of the heavens with different velocity, and in different directions. It follows, therefore, that those parts of the vortex must revolve at the same time, in different directions, and with different velocities; since one velocity and direction will be required for the passage of the planets, and another for that of the comets.

2. If it were granted, that several vortices are contained in the same space, and do penetrate each other, and revolve with divers motions; since those motions must be conformable to those of the bodies, which are perfectly regular, and performed in conic sections; it may be asked, How they should have been preserved entire for many ages, and not disturbed and confounded by the adverse actions and flocks of so much matter as they must meet with?

3. The number of comets is very great, and their motions are perfectly regular, observing the same laws with the planets, and moving in orbits that are exceedingly eccentric. Accordingly, they move every way, and to all parts of the heavens, freely pervading the planetary regions, and going frequently contrary to the order of the signs; which would be impossible, unless these vortices were removed.

4. If the planets move round the sun in vortices, those parts of the vortices next the planets, we have already observed, would be equally dense with the planets themselves: consequently the vortical matter contiguous to the perimeter to the earth's orbit, would be as dense as the earth itself: and that between the orbits of the earth and Saturn must be as dense, or denser. For a vortex cannot maintain itself, unless the more dense parts be in the centre, and the less dense towards the circumference: and since the periodical times of the planets are in a sesquialterate ratio of their distances from the sun, the parts of the vortex must be in the same ratio. Whence it follows, that the centrifugal forces of the parts will be reciprocally as the squares of the distances. Such, therefore, as are at a greater distance from the centre, will endeavour to recede with the less force. Accordingly, if they be less dense, they must give way to the greater force, by which the parts nearer the centre endeavour to rise. Thus, the more dense will rise, and the less dense descend; and thus there will be a change of places, till the whole fluid matter of the vortex be so adjusted, as that it may rest in equilibrio.

Thus will the greatest part of the vortex without the earth's orbit have a degree of density and inactivity, not less than that of the earth itself. Whence the comets must meet with a very great resistance, which is contrary to all appearances. Cotel. Praef. ad Newt. Princ. The doctrine of vortices, sir Isaac Newton observes, labours under many difficulties: for a planet to describe areas proportional to the times, the periodical times of the vortex should be in a duplicate ratio of their distances from the sun; and for the periodical times of the planets to be in a sesquialterate proportion of their distances from the sun, the periodical times of the parts of the vortex should be in the same proportion of their distances: and, lastly, for the less vortices about Jupiter, Saturn, and the other planets, to be preserved, and swim securely in the sun's vortex, the periodical times of the parts of the sun's vortex should be equal. None of which proportions are found to obtain in the revolutions of the sun and planets around their axes. Phil. Nat. Princ. Math. apud Schol. Gen. in Calce.

Besides, the planets, according to this hypothesis, being carried about the sun in ellipses, and having the sun in the umbilicus of each figure, by lines drawn from themselves to the sun, do always describe areas proportionable to the times of their revolutions, which that author shews the parts of no vortex can do. Schol. prop. ult. lib. ii. Princip.

Again, Dr. Keill proves, in his Examination of Burnet's Theory, that if the earth were carried in a vortex, it would move faster in the proportion of three to two when it is in Virgo than when it is in Pisces; which all experience proves to be false.

We have, in the Philosophical Transactions, a physico-mathematical demonstration of the impossibility and insufficiency of vortices to account for the celestial phenomena by Monf. de Sigorne. See No. 457. sect. vi. p. 409. seq.

This author endeavours to shew, that the mechanical generation of a vortex is impossible; that it has only an axisfugal, and not a centrifugal and centripetal force; that it is not sufficient for explaining gravity and its properties; that it destroys Kepler's astronomical laws; and therefore concludes with sir Isaac Newton, that the hypothesis of vortices is fitter to disturb than explain the celestial motions. We must refer to the dissertation itself for the proof of these assertions. See *CARTESIAN Philosophy*.

VORTICELLA, in the Linnæan system of *Zoology*, a genus of Vermes Infusoria, the characters of which are, that the body is naked and contractile, with a rotatory or whirling motion. Gmelin enumerates fifty-one species. See *VERMES*.

VORTITZA, or **VOSTITZA**, in *Geography*, a town of European Turkey, in the Morea, on the S. coast of the gulf of Lepanto; 40 miles N.W. of Corinth.

VOS, **MARTIN DE**, in *Biography*, an eminent Flemish painter, son of Peter de Vos, who was himself an artist and member of the academy at Antwerp. He was born at Antwerp in 1520. His father initiated him in the art, but he afterwards studied under F. Floris until he was twenty-three, and then pursued the cultivation of his mind in Italy. The residence he made at Venice introduced him to the acquaintance of Tintoretto, who not only instructed him in the principles of his practice, but employed him to paint landscapes in his pictures. Hence De Vos became an admirable colourist, and gained considerable reputation and employment. He painted portraits of the family of the Medici, and some historical pictures for them; and after an absence of eight years re-

turned

turned to Flanders. His celebrity accompanied him, and procured him several commissions to paint pictures for churches at Antwerp, and at other places in the Netherlands. In portraiture also he was much employed, and he certainly advanced beyond his contemporaries, in the nature and truth which he gave to his productions. His principal works in the cathedral of Antwerp, are the Marriage of Cana; the Incredulity of Thomas; the Miracle of the Loaves; and the Resurrection; and a fine picture of the Last Supper is in the church of St. James. He became a member of the academy at Antwerp in 1559, and died, at the age of 84, in 1604. He had a brother, Peter de Vos, who also painted history, but whose works are not much known; a nephew also of his was a painter, William de Vos, who had considerable talents, and gained much employment and reputation.

VOS, PAUL DE, another painter of that name, but of a different family, was born at Aloft in 1600. His works of animals and birds are very much in the style of Snyder, and are deservedly esteemed. There are many of them in the royal collection in Spain.

VOS, SIMON DE, born at Antwerp in 1643, was a pupil of Rubens, and became eminent as a painter both of history and portraits. Some of his paintings in the churches of Antwerp have been mistaken for the production of his great master. Sir Joshua Reynolds speaks highly of his picture of St. Norbert receiving the Sacrament, in the church of St. Michel, in which he says, "a great number of portraits are introduced extremely well painted," and afterwards commends him as a portrait-painter; particularly speaking of his own portrait in the poorhouse of Antwerp, painted by himself in black, leaning on the back of a chair, with a scroll of blue paper in his hand, so highly finished in the broad manner of Corregio, that nothing can exceed it. S. de Vos was living in 1662.

VOSAVIA, in *Ancient Geography*, a place of Belgic Gaul, upon the route from Antunacum to Mayence, between Bontobrice and Bingium, according to the table of Peutinger.

VOSGES, in *Geography*, a large chain of mountains, which formerly occupied the S.E. part of Lorraine, and now gives name to a department of France. It was formerly covered with wood, and harboured abundance of game and wild beasts, and has long been famous for mines of silver, copper, and lead.

VOSGES, one of the ten departments of the N.E. region of France, formerly the S. part of Lorraine, west of Upper Rhine, in N. lat. $48^{\circ} 15'$; bounded on the N. by the departments of the Meuse, the Meurte, and the Lower Rhine, on the E. by the department of the Upper and Lower Rhine, on the S. by the department of the Upper Saône, and on the W. by the department of the Upper Marne, containing $6522\frac{1}{2}$ kilometres, or 3206 leagues, and 308,052 inhabitants. It comprehends 5 districts, 30 cantons, and 550 communes. Its circles are Neufchateau, containing 55,247 inhabitants; Mirecourt, 66,649; Epinal, the capital, 62,592; St. Die, 75,293; and Ramiremont, 48,270. According to Hallensfratz, this department is 26 French leagues long, and 16 broad, and is divided into nine circles and communes, and contains 289,054 inhabitants. The contributions in the 11th year of the French era amounted to 1,839,254 fr., and the expences of administration, of justice, and of public instruction, were 242,372 fr.

VOSKRESENSK, a town of Russia, in the government of Moscow; 32 miles N.W. of Moscow. N. lat. 56° . E. long. $36^{\circ} 44'$.

VOSKRESENSK, a town of Russia, in the govern-

ment of Pskov, on the Lovat; 20 miles N. of Cholm.—Also, a town of Russia, in the government of Peterburg, on the E. coast of lake Ladoga; 80 miles N.E. of Peterburg.—Also, a town of Russia, in the government of Upha; 80 miles S. of Upha.—Also, a town of Russia, in the province of Utiug, on the river Vitcheгда; 28 miles S.W. of Yarensk.

VOSPOR, a town of Russia, in the province of Taurus; 112 miles E.S.E. of Perekop. N. lat. $45^{\circ} 20'$. E. long. $36^{\circ} 26'$.

VOSPRESENSKOL, a town of Russia, in the government of Volodga; 44 miles E. of Totma.

VOSSIUS, GERARD JOHN, in *Biography*, was born near Heidelberg in 1577, and perfected himself in the classics, mathematics, philosophy, and theology, at Leyden. Availing himself of a copious library left him by his father, he became director of the college at Dordrecht, where he married twice, and had a numerous family. In 1614, he was appointed director of the college of Leyden, and afterwards professor of eloquence and chronology in the university. By avowing himself favourable to the sentiments of the Remonstrants, he became obnoxious to the Gomarists, and at the synod in Ter-gou, in 1620, he was deprived of his professorship; but in consequence of the prevalence of Arminianism in England, he obtained the office of prebend in the church of Canterbury. After his return to Holland, he accepted the chair of history in the schola illustris of Amsterdam in 1633, which he occupied till his death in 1649, at the age of 72. The most useful of his writings are two books in Greek and Latin poetry. Among his other works are "De Origine Idolatriæ;" "De Scientiis Mathematicis;" "De quatuor Artibus popularibus;" "Historia Pelagiana;" "Institutiones Rhetoricæ, Grammaticæ, Poeticæ;" "Etymologicon Linguae Latine;" "De Vitiis Sermonis;" "De Philosophorum Sectis." A collection of these were printed at Amsterdam, in 6 vols. fol. 1695.—1701. Moreri.

This learned and laborious author, in his "Theologia Gentili," and other works, frequently speaks of music and has a distinct chapter on the subject in his treatise on the four popular arts, grammar, gymnastics, music, and painting. Yet he tells us little concerning ancient or modern music after the time of Guido; contenting himself with giving definitions of the terms used in the ancient music of the Greeks. He heaps quotation on quotation, telling us how highly the Greeks esteemed music; but attempts not to explain any of their doctrines. Like Mr. Bryant, he tries to shake our faith in what antiquity firmly believed. In writing "De Art. Poet. Nat." cap. xiii. he doubts whether Orpheus, Mufæus, or Linus ever existed; and rather thinks that these ideal names are derived from the Phœnician language used by Cadmus and his descendants.

VOSIUS, ISAAC, younger son of the preceding, was born at Leyden in 1618, and in consequence of his natural talents, and the advantage of education under his father, acquired early reputation among the learned. Queen Christina, prepossessed by report in his favour, invited him to her court, and acquired under his instruction a knowledge of the Greek language. On the death of his father in 1649, he quitted the court of Christina, and employed himself in the composition of various learned works. In 1670 he visited England, and received the degree of LL.D. at Oxford; and in 1673, he was presented by Charles II. with a canonry of Windsor, and in this situation he passed the residue of his days. His credulity led king Charles to say of him, "that he would believe any thing but the Bible." When he was on his death-bed, he was visited by Dr. Halcarr, dean of Windsor, who urged him to receive the sacraments, if not
for

for the love of God, at least for the honour of the chapter : he replied, " I wish you would instruct me how to compel the farmers to pay what they owe me ; that is the service I desire of you at present." Thus disposed, he left the world in February, 1688, at the age of seventy. His very valuable library was purchased by the university of Leyden. Of his numerous publications the most important are the following : " Periplus Scylacis Caryandensis, et Anonymi Periplus ponti Euxini," Gr. et Lat. cum notis, Amst. 1639, 4to. " Justini Historica cum Notis," Leyd. 1640 ; " Ignatii Epistolæ et Barnabi Epistola," Amst. 1646, 4to. ; " Differentio de vera Ætate Mundi ; " Pomponius Mela de Situ Orbis," Hagæ, Com. 1658 and 1659 ; " De Septuaginta Interpretibus eorumque Translacione et Chronologia Differentiones," 1661, in which he attempted to establish the preference of the chronology of the Septuagint to that of the Hebrew text ; which he defended in other tracts ; " De Poematum Cantu et Viribus Rhythmi," Oxon. 1675 ; " De Sybillinis alibi que Christi natalem præcessere Oraculis," ib. 1679 ; " Variarum Observationum Liber," Lond. 1685, 4to. ; " Catulli Opera cum Commento," ib. 1684. Moreri.

He was an enthusiastic and redoubted champion for the music of the ancient Greeks, and from his *belle Latinité* and prejudices in its favour, is more frequently quoted by implicit believers in its perfection, than any other modern who has treated the subject.

Vossius, in his celebrated book " De Poematum Cantu et Viribus Rhythmi," published 1675, Oxon., seems more ready to grant every possible and impossible excellence to the Greek musicians, than, when alive, they could have been to ask. None of the poetical fables, or mythological allegories, relative to the power and excellence of their music, put the least violence upon his credulity. A religious bigot, who insists upon our swallowing implicitly every thing, however hard of digestion, is less likely to make converts to his opinions, than he who puts our faith to few trials ; and Vossius overcharged his creed so much, that it is of no authority.

He does not attribute the efficacy of the Greek and Roman music to the richness of its harmony, or the elegance, the spirit, or pathos of its melody, but wholly to the force of rhythm. " As long," says he, p. 75, " as music flourished in this rhythmical form, so long flourished that power which was so adapted to excite and calm the passions." According to this opinion there was no occasion for mellifluous sounds, or lengthened tones ; a drum, cymbal, or the violent strokes of the Curetes and Salii on their shields, as they would have marked the time more articulately, so they would have produced more miraculous effects than the sweetest voice, or most polished instrument. In another place he tells us, that " to build cities, surround them with walls, to assemble or dismiss the people, to celebrate the praises of gods and men, to govern fleets and armies, to accompany all the functions and ceremonies of peace and war, and to temper the human passions, were the original offices of music : in short, ancient Greece may be said to have been wholly governed by the lyre."

It appears from this passage, and from the tenor of his whole book, that this author will not allow us to doubt of a single circumstance, be it ever so marvellous, relative to the perfection and power of ancient music ; the probable and the improbable are equally articles of his belief ; so that with such a lively faith, it is easy to imagine that he ranks it among mortal sins to doubt of the ancients having invented and practised counterpoint ; and he consequently speaks with the highest indignation against the moderns, for daring to deny that they were in possession of a simultaneous

harmony, though, according to him, they used it with such intelligence and discretion, as never to injure the poetry by lengthening, shortening, or repeating words and syllables to their pleasure, nor by that most absurd of all customs, singing different words to several different airs at the same time.

This author's remarks, however, on the little attention that was paid by the composers of his time to profody, merit some respect. See RHYTHM.

VOSTANI, in *Geography*, the middle division of Egypt.

VOSTERMAN, JOHN, in *Biography*, was born at Bommel in 1643, the son of a portrait-painter, who taught him the first rudiments of design, but afterwards he received the instructions of Zachtleven. He became renowned for his ingenuity and his vanity. At Paris he assumed the style and title of baron, but soon found his honours were too dear to be supported. He returned to his native country, and was employed by the marquis de Betheme to paint views on the Rhine, and also as a collector of works of art. He came to England in the time of Charles II. and was engaged by the king to paint a view of Windsor ; but was not much employed, and being extravagant, soon got into confinement, from which he was released by a contribution from his countrymen.

He accompanied Sir W. Soames on his mission to Constantinople, intending to take views of all the principal places by the way ; but Sir W. dying on the road, his plan was broken up, and it is not known exactly what became of him afterwards. The scenery of his pictures is generally taken from the borders of the Rhine, and painted with chaste and agreeable colour, and admirable aerial perspective ; and his figures and small boats are touched with spirit and neatness.

VOSTISSA, in *Geography*, a town and port of the Morea, containing 800 houses, churches, and public edifices. This town was almost entirely destroyed by an earthquake, which took place on the 23d of August, 1817, and 65 of the inhabitants perished in the ruins. Four villages in the neighbourhood were also destroyed, and the cape at the mouth of the river Gaidouroupiati fell into the sea, after throwing up a thick smoke. The sea, which at first receded to a considerable distance, leaving the vessels in the harbour aground, returned with great violence, inundating the land to the extent of half a league.

VOTE, or VOICE. See SUFFRAGE, and VOICE.

In the house of peers, they give their votes or suffrages, beginning at the peer, or lowest baron, and so to the rest, seriatim, every one answering apart, *content*, or *not content*.

In the house of commons, they vote by *yeas* and *noes*, promiscuously. See PARLIAMENT.

Votes of the house of commons first began to be printed by a resolution of the last parliament of Charles II. at Oxford, in 1681.

VOTGINSKOI, in *Geography*, a town of Russia, in the province of Ustiug, on the Sula ; 40 miles S. of Ust Sifolk.

VOTIAKS, or VOTES, a tribe or nation of Finns, situated in Russia, upon the river Viætka, in the governments of Viætka and Ufa. They call themselves Ud or Udi (seeming to be the same with the Russian Voté), also Mord, i. e. Man or Udmord. As they live in a great degree secluded from other people, their language continues to be a pure Finnish dialect. They also still retain their old distribution into stems, and give their villages additional names accordingly ; their noble families, however, are partly extinct.

extinct and partly mingled with the populace. They were formerly under Tartar protection; but in changing their old masters for the Russian sovereignty, they also quitted their pastoral life for the occupations of settled husbandry, and turned their tents into permanent houses. Their number is not inconsiderable: in the government of Ufa, there are about 15,000, and in that of Viatzka, 30,000 males. *Tooke's Russia*, vol. i.

VOTIVE Medals, are those on which the vows of the people for the emperors, or empresses, are expressed.

The public vows, made every five, ten, or twenty years, are more often found round the edges of medals, than on the faces of it, at least under the western empire; for in the eastern the case is different: witness the medal of M. Aurelius the younger, where the reverse represents the vows made at the time of his marriage, *VOTA PUBLICA*. And on Greek medals, $\Delta\text{HMOT EYXAI}$, which they sometimes express by the two initial letters, ΔE . according to F. Hardouin's conjecture, which may be admitted in certain medals, where the $\Delta\text{HM. EE}$. that is, $\Delta\text{HMAPXIKHE EEOY\text{C}I\text{A}\text{S}$, does not well agree. Witness also the medal of Antonine, *VOTA SUSCEPTA DECENNALIA*.

The origin of vows, and votive medals, is given by M. Du Cange thus; Augustus feigning himself willing to quit the empire, and having twice, at the prayers of the senate, condescended to hold it for ten years longer, it grew into a custom to make fresh public prayers, sacrifices, and games, for his continuing it, at the ten years' end; and these they called *decennalia*, or *vota decennalia*.

Under the eastern emperors, these vows were repeated every five years: hence it is, that, after Dioclesian's time, we find on medals *VOTIS V. XV. &c.* which practice continued till the time of Theodosius, when Christianity being well established, a ceremony that had some remains of heathenism in it was set aside. So that the *VOTIS MULTIS*, on a medal of Majorianus, must be a very different thing; and no other, doubtless, than a kind of acclamation, like that *PLURA NATALIA FELICITER*.

VOTIVE Mass. See *MASS*.

VOTOKI, in *Geography*, a town of Japan, in the island of Ximo; 25 miles N.W. of Funai.

VOTOMITA, in *Botany*, from *Votomit*, the Indian name of the tree, *Aubl. Guian.* 90. t. 33. *Juss. Gen.* 382. See *GLOSSOMA*.

VOTUM, *Vow*. See *VOW*.

VOTUM, in our *Ancient Law Books*, is used for *nuptie*, or marriage: so, *dies votorum* is the wedding-day, *Fleta*, lib. iv. cap. 2. part 16. "Si donatarius ad alia vota convolaverit, &c." See *MARRIAGE*.

VOUACAPOUA, in *Botany*, the Caribbean name of a tree in Aublet's supplement, p. 10. t. 373, thought by that author the same as the *Andira*, or *Angelis*, of Piso and Marcgrave, in their histories of Brazil, p. 81. of the former, and 100. of the latter. *Jussieu*, in his *Gen. Pl.* 363, seems to think both very near to *GEOPFRÆA*, see that article.

Aublet describes his plant as a very lofty tree, whose trunk is 60 feet, or more, in height, and two feet, at least, in diameter. The wood is yellowish-white, deep red at the heart, which turns black in drying. The head is formed of numerous branches, spreading every way, with alternate, flaked, pinnate leaves, composed of from two to four pair of ovate, pointed, entire leaflets, with an odd one, all finely downy beneath, about four inches long and two broad. *Stipulas* in pairs, deciduous. Aublet could never meet with the flowers. The fruit grows in large clusters, being an obovate bivalve capsule, or perhaps *legume*, fleshy

when young, dry, but thick and firm, when ripe; externally downy; reddish within. *Seed* solitary, large, oval, with a thin brown skin; its cotyledons firm, whitish, bitter.

The wood is very hard and durable, much used in building and fences. The heart is employed in cabinet-work, and serves even to make pestles and mortars.

VOUAH, in *Commerce*, a long measure at Siam, in the East Indies; which is one inch shorter than the French toise, and therefore measures 6 feet $3\frac{3}{4}$ inches English. Two foks make 1 ken; two kens 1 vouah; 20 vouahs 1 fen; 100 fens, or 2000 vouahs, here make 1 league, called roeng, which is 4204 English yards, or 2½ miles nearly.

VOUAPA, in *Botany*, a Caribbean name, *Aubl. Guian.* 25. t. 7, 8. See *MACROLOBUM*.

VOUARANA, a Caribbean name, *Aubl. Guian.* suppl. 12. t. 374, a tree whose flowers have not come under the inspection of botanists, but whose fruit is an inversely heart-shaped, bivalve capsule, with two cells, and a seed in each, which is round and smooth. It appears to belong to *Jussieu's* order of *Sapindi*; but whether most nearly akin, as he supposes, to *ORNITOPHNE*, (see that article,) or to any other genus, we want materials to decide. The tree is of a moderate size, with large alternately pinnate leaves.

VOUCH. A person is said to *vouch* for another, when he undertakes to maintain, or warrant him in any thing, or passes his word in his behalf.

In law, to *vouch*, is to call such a person, or *vouchee*, into court, to make good his warrant.

VOUCHEE, a person who is to warranty, or vouch for another, who, in respect hereof, is called *voucher*. See *VOUCHER* and *WARRANTY*.

VOUCHER, in *Law*, the tenant in a writ of right, who calls another person into court, bound to warranty him, and either to defend his right against the demandant, or to yield him other lauds, &c. to the value.

This seems in some measure to agree to the contract in the civil law, by which the vendee binds the vendor, sometimes in the simple value of the things bought, sometimes in the double, to warrant the secure enjoying of the thing bought. Yet there is this difference between the civil and common law, in this point, that the civil law binds every man to warrant the security of that which he selleth; which the common law doth not, unless it be specially covenanted.

The process, by which the vouchee is called, is a *summones ad warrantifandum*; and if the sheriff return upon that writ, that the party hath nothing by which he may be summoned, then goes out another writ, called *sequatur sub suo periculo*.

A recovery with a *single voucher*, is when there is but one voucher; and with a *double voucher*, is when the vouchee voucheth over, and so a *treble voucher*.

There is also a *foreign voucher*, when the tenant impleaded in a particular jurisdiction, voucheth one to warranty in some other county, out of the jurisdiction of that court, and prays he may be summoned, &c. This was more pertinently called a *voucher of a foreigner*.

VOUCHER also signifies a ledger-book, or book of accounts, in which are entered the warrants for the accomptant's discharge.

VOUDSË, in *Geography*, a town of Arabia, in the province of Hedjaz; 140 miles W. of Medina.

VOVES, a town of France, in the department of the Eure and Loire; 12 miles W.N.W. of Janville.

VOUET, *SIMON*, in *Biography*, an eminent painter of the French school, born at Paris in 1582, was the son of Lawrence Vouet, a painter of little celebrity. When he was about twenty years old, he accompanied the baron de

Sanfy

Sanly to Constantinople, where he painted from recollection the picture of the grand feignior. On his return he staid at Rome, and obtained the patronage of pope Urban VIII. and his nephew the cardinal, by whom he was employed in St. Peter's, and the Barberini palace. Here he resided 14 years, and was elected head of the academy of St. Luke in 1624.

Louis XIII. appointed him, on his return to Paris in 1627, his principal painter; and employed him munificently in most of his palaces. He also painted pictures for many churches in Paris. He died there in 1641.

Vouet at first was careful and rich in his designs and his execution; but as his engagements increased in number, he adopted a style flimsy and even careless; fluttered in the parts, and without grandeur in the conception. He is the father of the French school before the revolution, and corrupted the art by its delusive facility. He was the teacher of Le Brun, Mignard, and others, but had more honour in having trained Le Sueur to the practice of art; who, nevertheless, had the sense to aim at the taste of design seen in the works of Raffaele rather than in those of his master.

VOUGA, in *Geography*, a town of Portugal, in the province of Beira, on a river of the same name; 10 miles E.N.E. of Aveiro.—AHO, a river of Portugal, which rises about 15 miles N.E. of Vifeu, and runs into the Atlantic, 5 miles N. of Aveiro, forming a large bay at its mouth, full of islands.

VOU-HOUCI, a city of China, of the second rank, in Kiang-nan; 532 miles S. of Peking. N. lat. $31^{\circ} 22'$. E. long. $117^{\circ} 29'$.

VOUILLE, a town of France, in the department of the Vienne. In 507, near this town, Clovis, king of France, obtained a victory over the Visigoths, in which their king Alaric was slain; 8 miles N.W. of Poitiers.

VOULTE, LA, a town of France, in the department of the Ardèche; 11 miles S.S.W. of Valence.

VOUNEUIL SUR VIENNE, a town of France, in the department of the Vienne; 12 miles N.N.E. of Poitiers.

VOURA, a river of European Turkey, which separates Thessaly from Albania, and runs into the gulf of Arta.

VOURLA, a sea-port of Asiatic Turkey, in Natio-
lia, on the isle of Clazomene, one of the twelve cities of Ionia. It is built on two eminences, one possessed by the Turks, the other by Christians, who have about 500 houses and two churches. The harbour is about a league from the town. The archbishop of Ephesus resides here about three months of the year; there are but very small appearances of its ancient grandeur; 20 miles W. of Smyrna. N. lat. $38^{\circ} 24'$. E. long. $26^{\circ} 40'$.

VOURLOTES, a town of the island of Samos; 4 miles N.E. of Carlovassii.

VOUSSOIR, VAULT-STONE, or *Key-stone*, in *Architecture*, a stone proper to form the sweep of an arch, being cut somewhat in the manner of a truncated cone, whose sides, were they prolonged, would terminate in a centre, to which all the stones of the vault are directed. See KEY and VAULT.

VOUTE, in *Geography*, a town of France, in the department of the Ardèche, on the right side of the Rhône; 18 miles N. of Viviers.

VOUTE, LA, a town of France, in the department of the Upper Loire; 9 miles S. of Brioude.

VOUTEZAT, a town of France, in the department of the Correze; 9 miles N.W. of Brive.

VOUTIN, a river of China, which rises in Chinese Tar-

tary, and runs into the Hoang, 25 miles S.E. of Soui-te, in Chen-fi.

VOU-TING, or OU-KUEN, a city of China, of the second rank, in Yun-nan; 1145 miles S.W. of Peking. N. lat. $25^{\circ} 34'$. E. long. $102^{\circ} 20'$.

VOU-TING, a city of China, of the second rank, in Chan-tong; 162 miles S.S.E. of Peking. N. lat. $37^{\circ} 35'$. E. long. $117^{\circ} 19'$.

VOUVANT, a town of France, in the department of the Vendée; 6 miles N.N.E. of Fontenay le Comte.

VOUVRAY, a town of France, in the department of the Indre and Loire; 4 miles E. of Tours.

VOUX, a town of France, in the department of the Seine and Marne; 11 miles E. of Nemours.

VOUZAILLES, a town of France, in the department of the Vienne; 12 miles N.E. of Poitiers.

VOUZIERS, a town of France, and principal place of a district, in the department of the Ardennes; 5 posts S.W. of Stenay. N. lat. $49^{\circ} 23'$. E. long. $4^{\circ} 42'$.

VOW, VOTUM, a solemn promise, or offering of a man's self, or other thing, to God.

A person is constituted a religious, by taking three vows, that of poverty, that of chastity, and that of obedience.

Authors are divided as to the antiquity of these vows. It is agreed, the ancient anchorites, and hermits of the Thebaid, made none; they did not consecrate themselves to God by any indissoluble obligation, but were at liberty to quit their retirement, and return into the world, whenever the fervour, that drove them out of it, came to abate.

Vows were not introduced till long after; and that to fix the too frequent inconstancy of such as, after retiring from the world, repented themselves too soon, or too slightly; and by that means scandalized the church, and disturbed the quiet of families by their return.

Erafmus will have it, that solemn vows were not introduced till the thirteenth century, under the pontificate of Boniface VIII. Others hold them to be as ancient as the council of Chalcedon; but the truth is, before Boniface VIII. there were none but simple vows, and such as might be dispensed withal. Their vows, till that time, were not deemed eternal chains; they were not indissoluble. It is true, they were obligatory promises, as to conscience; and the inconstancy of such as violated them was held an odious desertion: but, as to the law, the persons were not held to be civilly dead, so as, upon their return, to render them incapable of all acts of civil society.

The most common vow was that of poverty, but this only regarded the convent; on account of which, every person divested himself of all property: but the making of vows did not at all exclude them from the rights of blood, or render them incapable of inheriting.

No religious, it is true, acquired the property of the effects that fell to him; they all belonged to the monastery, in favour of which he had divested himself of every thing; and the monastery only left him the usufruct and direction of them. The popes have frequently confirmed this privilege to divers orders, and permitted the monks to inherit, as much as if they were seculars, and had made no vows.

At present, the civil death of a religious is dated from the day he makes the vows; and from that time he is utterly incapable of inheriting. A religious may reclaim, or protest against his vows within five years; but, after that, it is no longer admitted. The failures in the profession are esteemed to be purged, by his silence and perseverance for five years. Indeed, to be relieved from his vows, it is not

enough

enough the party reclaim within the five years; but he must likewise prove that he was forced to take the habit.

Vows, *Vota*, among the *Romans*, signify sacrifices, offerings, presents, and prayers, made for the emperors and Cæsars, particularly for their prosperity, and the duration of their empire.

These were, at first, made every five years, then every fifteen, and then every twenty, called *quingennalia*, *decennalia*, and *vicennalia*.

In divers antique medals and inscriptions, we read, *Vot. X. Fot. XX. Fot. mult.* signifying *votis decennialibus, vicennialibus, multis, &c.* See *DECENNALIA*.

Vows, in a moral and religious sense, are promises to God; and therefore, according to archdeacon Paley, the obligation cannot be made out upon the same principle as that of other promises. The violation of them, nevertheless, implies a want of reverence to the Supreme Being; which is sufficient to make it sinful. There appears no command or encouragement in the Christian scriptures to make vows; much less any authority to break through them when they are made. The few instances of vows which occur in the New Testament were religiously observed. (See *ACTS*, xviii. 18. xxi. 23.) The rules that pertain to promises are applicable to vows. Thus Jephthah's vow, taken in the sense in which that transaction is commonly understood, was not binding; because the performance, in that contingency, became unlawful. From this and other instances, it appears that rash vows are not only imprudent, but culpable. See *PROMISE*.

VOWEL, VOCALIS, in *Grammar*, a letter which affords a complete sound of itself, or a letter so simple, as only to need a bare opening of the mouth to make it heard, and to form a distinct voice.

Such are *a, e, i, o, u*; which are called *vocales*, vowels, in contradistinction to certain other letters, which, depending on a particular application of some part of the mouth, as the teeth, lips, or palate, can make no perfect sound without an opening of the mouth, that is, without the addition of a vowel; and are therefore called *consonants*.

Though we ordinarily only reckon five vowels, yet, besides that each of these may be either long or short, which occasions a considerable variety in the sound; if we consider only their differences resulting from the different apertures of the mouth, we might add four or five more vowels to the number. For the *e* open, and the *e* close, are different enough to make two vowels, as in *sea*, and *depth*; so also the *o* open, and *o* close, in *boss*, and *organ*. Add, that the *u* pronounced *ou*, as the Latins did, and as the Italians and Spaniards still do, has a very different sound from the *u*, as pronounced by the Greeks, and, as at this day, by the English and French. Again, *eo*, in *people*, make but one simple sound, though we write it with two vowels.

Lastly, the *e* mute is, originally, no more than a surd joined to a consonant, when that is to be pronounced without a vowel, as when it is immediately followed by other consonants. This is what the Hebrews call *sheva*, especially when it begins the syllable: and this *sheva* is found in all languages, though overlooked in many of them, particularly in the English, Latin, &c. by reason it has no proper character to denote it; though, in some of the vulgar tongues, particularly French and High Dutch, it is expressed by the vowel *e* adding its sound to the rest.

Thus, without regarding the differences of the same sound or vowel, as to length or shortness, one may distinguish ten several vowels, expressed by the following characters, *a, e, i, o, u, ô, eu, ou, u, e* mute.

To these we may add *y*, which, as the learned Dr. Lowth

observes, is formed by the opening of the mouth, without any motion or contact of the parts, and has every property of a vowel, and not one of a consonant. Lowth's *Gram.* p. 20. n. 1.

Mr. Sheridan, who makes the number of simple sounds in our language to be twenty-eight, reckons nine vowels, *a, a, a, e, o, o, e, i, u.*
viz. *hull, hat, hate, beer, note, noose, bet, fit, but.* *Rhet. Gram.* p. 9.

VOWEL-POINTS, in the *Hebrew Language*. See *Vowel-POINTS*.

VOX, in *Law*. *Vocem non habere*, is a phrase used by Braçton and Fleta for an infamous person; one who is not admitted to be a witness.

Vox Humana, Lat., *Voix Humaine*, Fr., a stop in the organ; thus named from its being an imitation of the human voice. It is a reed stop, in union with the open diapason; it is a short metal pipe, of a wide globular form at the top, resembling a human mouth. This is a celebrated stop in the famous organ at Haerlem; in hearing which we were somewhat disappointed, as it does not at all resemble a human voice, though a very good stop of the kind. But the world is very apt to be imposed upon by names. The instant a common hearer is told that an organist is playing upon a stop that resembles a human voice, he supposes it to be very fine, and never inquires into the propriety of the name, or exactness of the imitation. However, with respect to our own feelings, we must confess, that of all the stops which we have yet heard, that have been honoured with the appellation of *vox humana*, no one, in the treble part, has ever reminded us of any thing human, so much as the cracked voice of an old woman of ninety; or, in the lower notes, of Punch fingering through a comb.

VOXTORP, in *Geography*, a town of Sweden, in the province of Smaland; 29 miles N.W. of Wexio.

VOYAGE, denotes a journey by sea.

VOYAL, a large rope formerly used to unmoor or heave up the anchor of a ship, by transmitting the effort of the capstan to the cable; but mostly used when the fore-jeer capstan was employed for this purpose. The voyal reeved through a large block lashed to the main-mast, and then communicated to the fore-jeer capstan: but messengers are now chiefly used instead of it.

VOYAL, *Shifting the*. See *SHIFTING*.

VOZ, in *Geography, a lake of Russia, in the province of Novgorod, about 60 miles in circumference. N. lat. 60° 30'. E. long. 38° 54'.*

VOZGA, a town of Russia, in the government of Novgorod, near lake *Voz*; 48 miles N.N.E. of Bielozerk.

VOZIA, a town of European Turkey, in Bessarabia, on the Black sea; 26 miles W. of Otchakov.

VOZNESENSKOI, a town of Russia, on the Angara; 20 miles N.N.W. of Irkutsk.

UPA, a river of Russia, which rises near Epiphan, passes by Tula, and runs into the Oka, near Lichin, in the government of Kaluga.

UPAIX, a town of France, in the department of the Higher Alps; 11 miles S.E. of Serres.

UPANEMA, a river of Brazil, which runs into the Atlantic, S. lat. 4° 30'. W. long. 37° 32'.

UPATCHAWANAN, or **TEMISCAMAIN**, a settlement in Canada. N. lat. 47° 17'.

UPBO, a town of Sweden, in Dalecarlia; 20 miles S.S.E. of Fahlun.

UPELLA, a town of Hindoostan, in Golconda; 18 miles N.N.W. of Warangole.

UFELLA *Chanderagbery*, a town of Hindoostan, in Gollonda; 16 miles N. of Warangole.

UPENDRA, a name of the Hindoo deity Vishnu. (See **VISHNU**.) It has been supposed to imply inferiority to Endra, or Indra, the regent of the firmament. See **INDRA**.

UPHA, in *Geography*, a town of Russia, and capital of a government, on the Bielaia; 452 miles W.S.W. of Tobolsk. N. lat. $54^{\circ} 35'$. E. long. $56^{\circ} 2'$.—Also, a river of Russia, which runs into the Bielaia, at Upha.

UPHIMSKOI, a government of Russia, of a triangular form, bounded on the north by the governments of Perm and Viatka; on the west by the governments of Caucasus, Saratov, Simbirsk, and Kazan, the part immediately south by the Caspian sea, and the part immediately east by the government of Tobolsk; to the north it extends from east to west about 440 miles, and to the south from east to west only 64; westward from north to south it measures about 520, eastward only 160. In this government is a famous mine of salt, situated near the river Ilek. The salt of this pit is most beautiful, and of the best quality. It is taken from a kind of rock about four versts from the river. The length of the rock is 800 fathoms, and the breadth about 500. It is so solid, that it has not yet been possible to found it. With a miner's wimble, however, they have penetrated to the depth of 27 fathoms; but time and instruments have not ascertained a complete knowledge of the depth of this mass. From 1784 till 1787, more than 30,000,000 pounds of salt were taken from this rock, and transported into different parts of the empire, by the Volga, the Bielaia, and the Kama. This salt is sold in the country at 25 or 30 copecks the pood, which is about a halfpenny the English pound. It is calculated that this pit may yet furnish salt for near two centuries, supposing the depth to be no greater than it is already known to be. In order to render the working more productive, and less expensive, the government has lately made an agreement with some Cossacks, who are to dig 50,000 poods a year, and transport them to the magazines of Orenburg. There are in the neighbourhood of this pit some very deep lakes of salt water, to which great virtue is ascribed by the Kirghis, and in which they bathe of their own accord, when afflicted with the least disease. Their physicians, who have had an opportunity of judging of these baths, all agree, that they are good for all peculiar diseases. There is one astonishing circumstance attending these waters, namely, that their surface is as cold as ice, while the deeper you plunge, the warmer you become; at the bottom it is said no person can stay more than two or three seconds. N. lat. 47° to 56° . E. long. 50° to 64° .

UPHOLDER is used in the same sense with undertaker, as the denomination of a tradesman who provides for funerals.

UPHOLDER, or *Upholsterer*, denotes also a person who furnishes houses, fitting up apartments with beds, and other furniture. See **APPRAISER** and **BED**.

UPIERCWIZA, in *Geography*, a town of Lithuania; 33 miles E. of Minsk.

UPINCE, a kind of song consecrated to Diana by the Greeks. Rouffeau.

UPINISHAD, or **UPANISHAD**, in *Hindoo Literature*, is the title of a portion of their scripture comprised in the Veda. Each Veda contains several portions, bearing this common denomination. On these Upanishads the whole of the Indian theology, especially the Vedanta theory, is professedly founded. See **VEDA** and **VEDANTA**.

The proper meaning of the word Upanishad, according

to Mr. Colebrooke (Af. Ref. vol. viii. art. 8.), is "divine science, or the knowledge of God; and it is equally applicable to theology itself, and to a book in which this science is taught. The sense properly deducible from its etymology invariably points to the knowledge of the divine perfections, and to the consequent attainment of beatitude, through exemption from passions."

The word, by some writers, has been thought to mean something hidden or mysterious; but Mr. Colebrooke says, that "neither the etymology nor acceptance of the word has any direct connection with the idea of secrecy, concealment, or mystery." (Ib.) It seems rather indeed to mean *revelation*. In the curious article above referred to, a list of the Upanishads is given; with much important and interesting information respecting them, and the extraordinary volumes through which they are interperfed. An extract from it is given under our article **MUNI**.

UPLAND, in *Geography*, a province of Sweden, bounded on the north by the gulf of Bothnia, on the east by the Baltic, on the south by the Mælår lake, and on the west by Westmanland; about 75 miles in length from north to south, and where widest, 55 from east to west. It is fertile in corn, and the lakes and rivers abound in fish. Some of the best iron-mines of Sweden are found in this province. Stockholm is situated in Upland.

UPLAND, or *Upland Pastures*, in *Agriculture*, all such land and pastures as are situated in a high elevation, or which are much exposed in consequence of the height to which they are raised above the other surrounding grounds. Such land and pastures are mostly found particularly useful in some sorts of husbandry and farming, as those of the sheep kind, as they are commonly hard, firm, and dry, during the winter and more wet seasons of the year, when this sort of stock is most in danger in many situations.

In the northern parts of the island, the extensive highland tracts of these lands and pastures are for the most part converted to the purpose of sheep-walks; in which management they are supported by many to be by far the most advantageous. But some have lately suggested that black cattle and planting may be combined with these, so as to afford a still greater benefit. The Rev. Mr. Singers, in an able essay in the third volume of the Transactions of the Highland Society of Scotland, has remarked on the upland and pasture sheep-farming of that district, that "it has not yet been clearly ascertained what effects the introduction of sheep husbandry into the Highlands has really produced, or how far that mode of farming ought to be carried," or is proper; neither has it been accurately determined, it is said what sorts of sheep are adapted to the respective sheep-walks in that extensive tract of upland and pasture. It is a point, too, still undecided, how far sheep and black cattle are consistent as joint or separate stocks, on the same upland farm; and which of them is entitled to the preference, to a certain extent; or whether the proper extent can be pointed out. Doubts also are entertained in respect to forest trees, how far it is proper to attend to the rearing of them, on farms producing sheep as the staple article; and that a similar question has been put, whether it is profitable to cultivate any part of the soil, when flocks of sheep are fed in the neighbourhood, and under the disadvantages of a climate very moist and uncertain?

It is supposed that these points lie at the foundation of the prosperity of the upland or Highland tracts of the country; and that, of course, they are closely connected with the general prosperity of the British empire: it will consequently be admitted, that every thing is of importance which may tend to throw a ray of light upon any one of them.

them. In this intention, this view of a comprehensive system of husbandry, which has been had recourse to with great success by intelligent individuals, in a soil and climate greatly resembling those of the uplands and pastures of the Highlands; sheep, it is said, are unquestionably to be considered as the staple stock over the Highlands of Scotland; but to rear sheep as the sole produce of the soil is, it is thought, an error of the worst kind. It was naturally to be expected, that when sheep were introduced upon these uplands, and found to be a safe and profitable sort of stock, they would probably go too far, before the true balance should be found. But it is capable of being established, it is said, on reason and clear testimony, that woods, cattle, and cultivation, judiciously managed, are friendly to sheep, on such uplands, in the highest degree; while the solid interests, comforts, and benefits of society are greatly promoted by a proper intermixture of them all in such cases.

The effects of sheep-farming on these uplands are, it is observed, first, a great rise in the rents, which is not, however, to be wholly imputed to sheep, but many other causes. The true light in which the superiority of sheep, in such cases, is to be considered, is, it is said, that by means of them a farmer can pasture a large extent of inaccessible grass land, not safe for black cattle; that he can maintain a flock, with less danger of heavy losses by famine, in winter and spring; and that sheep, as a stock, are managed at less expence, and are more marketable than any other. It is conceded indeed, that, by means of goats, the most rugged pasturage might be consumed; but these animals, in point of flesh, as well as coat, would be a wretched substitute for sheep in such cases, in any market whatever. It must be allowed by all, that a flock of sheep enables the farmer to occupy a larger portion of the soil than he could do by a flock of black cattle; that sheep, too, are more adapted to the greater part of an extensive and rugged upland farm than any sort of black cattle; that a fuller flock of them may be safely put on the grounds, without incurring so much risk of famine; and that no flock is easier managed, or more marketable. These are important considerations; and they are decisive in favour of sheep, as the principal article, it is supposed, over the uplands of the Highlands, that a farm can produce.

Secondly, a valuable supply of wool has been furnished the country, from the upland pastures of the Highlands; that though most of such wool is coarse, and that wool has not declined in price in consequence of this large accession to the trade, it must be remembered that coarse wool was the article most wanted by manufacturers; and also, that many large upland tracts of the Highlands are well adapted to rear fine wool, when the farmers shall find it their interest to follow that plan. And in regard to the increased price of wool, it may be asked, it is said, what must have been the prices, or where the manufacturers must have looked for it, if there had not been any raised on the uplands of the Highlands of late years? Probably, it is supposed, the distinguished success of that capital branch, the woollen trade, may have depended in no small degree on the vast supplies of wool from that quarter.

Thirdly, the reduction of the numbers of black cattle must inevitably, it is believed, follow the introduction of sheep, and also the reduction of the extent of cultivated grounds. But it does not of necessity, it is said, follow, that black cattle and culture should be altogether abandoned. There is a good medium in these matters, it is supposed, which is safer than either extreme. To people not well acquainted with the economy of a productive system, embracing sheep as the principal article, and a proper number of cattle, and

extent of cultivation, it may appear to be the easiest expedient to lay the whole of their farms into sheep-walks; but more experienced farmers would, it is thought, smile at the pretence which want of skill has so often advanced for going into this most injudicious extreme; well knowing that every intelligent store-master calculates on rendering his sheep much better, and insuring their safety in a greater degree, by means of judicious cultivation. It is therefore to be observed, that the banishment of black cattle and of culture out of the upland sheep-farms in the Highlands are effects which do not necessarily follow the introduction of sheep, but have arisen from an inconsiderate extreme, the result of error and want of experience in the established modes of sheep management, especially on such uplands.

Fourthly, depopulation is the worst effect, it is said, which has followed the introduction of sheep husbandry on the uplands and pastures in the Highlands. It is, however, undeniably the fact, that such an effect has been produced, and that to a great extent. But it cannot be so readily admitted, it is thought, that this effect was necessarily connected with the sheep husbandry; for it arose more properly from the total neglect of culture, and of black cattle, than from the change of flocks. It is asked, if we find that the sheep flocks of England, or of the south of Scotland, necessarily occasion depopulation? If a due proportion were maintained on such lands of the Highlands, between sheep and other important articles, such as cattle, corn, green crops, and inclosures and plantations of trees, to say nothing of the fisheries, the roads, and other public matters, employment would, it is supposed, be furnished for the inhabitants, at least as ample and productive as they ever possessed, when black cattle were their stock, and a proportion of goats, instead of sheep. But the truth is, it is said, that unfortunate circumstances of a complicated nature combined in depopulating the Highlands, when sheep were introduced, as are fully shewn in the Essay, to which we must refer the reader.

Still, however, the sheep system is thought to be right upon these uplands; and though it may have gone to an extreme, it was what was to be dreaded and expected. To that extreme, and not to the nature of the stock introduced, ought, it is supposed, to be imputed most of the evils complained of; while the beneficial effects of sheep husbandry on such uplands appear to be necessarily connected with it, and therefore to give it a steady and well-founded superiority. The evils of it may, it is thought, be obviated or counteracted by judicious management; and that sheep, as the principal article of produce, are entitled to an evident preference over the whole of the uplands and pastures of the Highlands; but that, at the same time, it is unwise and impolitic in every view to make them the sole produce on the lands.

In these upland tracts nature seems, it is said, to have laid out extensive sheep-walks on almost every farm; and that as it is found that sheep are the safest stock, the most easily and cheaply managed, having access to the largest part of the pastures, and always marketable and productive to the farmer, it is undeniable, the writer supposes, that they should be reared as the main article of farm produce throughout the upland tracts of the Highlands. But it can never be admitted, it is thought, by any man of sense, that this immense district should be turned wholly into a sheep-walk. Other articles of produce succeed as well as sheep, and should be reared to a proper extent: some are essential to the comforts, and even subsistence of the inhabitants; while they return as ample profits as sheep, and are of exceedingly great value to the sheep-flocks; not to mention

their importance in other respects. If the sheep husbandry of these tracts, instead of engrossing all the attention of the farmers, and all the soil, were to be considered as the chief article, but at the same time intermixed with a due proportion of black cattle, of corn, and of green crops; and if proprietors would also introduce into the system judicious plantations of forest trees, incalculable advantages would certainly, it is thought, be obtained. This beautiful system, it is said, is not ideal. It is found by experience to be admissible in every point of view; comfort, beauty, and profit, going hand in hand.

The peculiar advantages of black cattle, the culture of corn and green crops, and the planting of forest trees, in connection with sheep, on these uplands and pastures, are then particularly pointed out and explained, when the writer suggests the proper sort of management for the sheep and the black cattle that should be pursued in such cases, and shews the comparative value of each in a very clear manner; concluding by observing, that all these branches are mutually subservient to each other: all of them are adapted, each on its own scale, to the climate and the soil of the country; and that they all contribute to the solid comforts and prosperity of the people in all situations, the proprietors, the farmers, and the people at large. These upland tracts are laid out, it is said, for pasturage by the hand of nature, and sheep are the true staple: but the country is likewise naturally laid out for every part of the mixed husbandry that has been advised above; all the necessary materials abounding; and every part, like the links of a golden chain, being connected with, and depending on one another. Cattle alone are not, and cannot, it is said, be a safe stock; sheep reared exclusively turn all into a waste. Trees, if suffered to overpread the country, would convert it into a wilderness; and cropping on a large scale is more than hazardous, it is impracticable. The mixed system is, therefore, the most proper and beneficial for such tracts, in many different points of view. See the paper.

In some of the southern parts of the kingdom, too, the uplands and pastures are found very beneficial in the supporting of sheep-stock. In the Romney-Marsh system of sheep management, it is the usual practice to send the lamb-stock in the beginning of the autumn, in vast quantities, to be supported and kept by the hill or upland farmers in the neighbourhood, through the winter, which is found to answer well under proper care and attention.

In the South-Down, and other upland districts, the high grounds and pastures are likewise mostly occupied with sheep as a principal stock, to the greatest advantage. See SHEEP.

The uplands and pastures in many parts of the country are, however, in a very indifferent and unprofitable state, from the want of suitable manuring, feeding, and stocking, whatever may be the purpose to which they are applied. See PASTURE and PASTURE-Land.

UPLOPER, a name given to one particular species of pigeon, called by Moore, *columba gutturosa falienis*.

It was first brought to England from Holland, and much resembles that kind of pigeon called the English pouter, but that it is smaller. Its crop is very round, and in this it buries its bill. Its legs are very small and slender, and its toes are short, and close together, on which it treads nicely, that when moving, any small thing might be put under the ball of its foot. The pigeons of this species are generally all blue, all black, or all white; seldom or never pied. They are very scarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word *oploepen*,

which signifies to leap up, and it was thus named from its manner of approaching the hen, which is always by leaping upon her. Moore's Columbarium, p. 67.

UPNOR CASTLE, in *Geography*, a fortress of England, in the county of Kent, on the left bank of the Medway, near Chatham.

UPPARAH, a town of Hindoostan, in the circuit of Rajamundry; 30 miles E. of Rajamundry.

UPPER DECK, in a *Ship*, the highest of those decks which are continued throughout the whole of a ship of war, or merchantman, without any interruption of steps or irregular ascents.

UPPER Breadth Sweeps, in *Ship-Building*, the centre of which is in the line representing the upper height of breadth of the timber. This sweep, described upwards, forms the lower part of the top-timber. See SHIP-BUILDING.

UPPER Height of Breadth, the upper curved line on the sheer plan, describing the greatest height of the main-breadth or broadest part of the ship at each timber. See SHIP-BUILDING.

UPPER Strake, in *Boats*, a strake thicker than those of the bottom, wrought round the gunwale.

UPPER Works, in *Naval Architecture*, a general name given to all that part of a ship which is above the surface of the water when she is properly balanced for a sea voyage: or it is that part which is separated from the bottom by the main wale.

UPPER Hemisphere, Ocean, Polar Dial, and Region. See the substantives.

UPPER Slope of a Canal, is the face of the bank KP (*Plate I. Canals, fig. 3.*) in side-laying ground; or AB and KP (*fig. 6.*) in deep-cutting.

UPPER Lake, in *Geography*, a lake of Ireland, in the county of Kerry, 4 miles from Lough Lane, with which it communicates by a river, which runs between Torc mountain and Gleenaa mountain.

UPPINGHAM, a market-town in the hundred of Martinsley and county of Rutland, England, is situated 6 miles S. by E. from Oakham, and 80 miles N.N.W. from London. It is considered as the second town in the county, and in some respects superior to Oakham, the county-town: the streets are well paved; the houses, which in general are well built, are disposed in the form of a square, with one long street leading to the west end. The church, which stands on the fourth side of the square, has a lofty spire, and the church-yard commands an extensive prospect: it also contains some well-executed monuments, particularly one of the date of 1653, in honour of Everard Fawcener, esq., who had been sheriff of the county, and was a great benefactor to the town, having paved the streets at his own expense. Adjoining to the church-yard is a free-school, founded on a very extensive plan, for general education, and even for the preparing of youth for the universities. It was built about the year 1584, by the Rev. Robert Johnson, archdeacon of Leicester, who was also the founder of a similar institution at Oakham. The expenses of the erection were defrayed partly from his own purse, assisted by the produce of concealed church lands which he begged from queen Elizabeth. It is a plain neat edifice, and has over the door, in Hebrew, Greek, and Latin, "Remember thy Creator in the days of thy youth." Here is also an hospital, built at the same time, and out of the same funds, by the benevolent archdeacon, for the maintenance of thirteen poor men and one woman. A weekly market and an annual fair were granted in 1280 by Edward I., to Peter de Montfort, then lord of this manor, and his heirs for ever, with the express provision that the fair should not operate to the detriment

detriment of any fair of older date in the vicinity: the market-day is Monday, and here are now two fairs yearly, for horses, cattle, sheep, coarse linen, homespun cloth, &c. This town has the privilege, by grant of 11 Henry VII. to keep the standards of weights and measures for the county. In the return of the year 1811, the population of Uppingham was stated to be 1484, inhabiting 292 houses.—*Beauties of England and Wales*, vol. xii. Rutlandshire.

UPRIGHT, in *Architecture*, a representation or draught of the front of a building; called also an *elevation*, or *orthography*.

UPRIGHT, in *Heraldry*, is used in respect of shell-fishes, as crevices, &c. when standing erect in a coat. Inasmuch as they want fins, they cannot, according to Guillim, be properly said to be *hauriant*; that being a term appropriated to scaly fishes.

UPRIGHT, in *Sea Language*, the position of a ship when the neither inclines to one side nor to the other. Hence any thing is said to be upright when square with, or perpendicular to the keel.

As the ship when building lies with a declivity for the purpose of launching, it is evident that every thing within her intended to be upright when a-float, must be set square from the inclination of the ship.

UPRIGHT Cape, in *Geography*, a cape on the E. end of Gore island, in the North Pacific ocean. N. lat. 60° 30'. W. long. 172° 13'.—Also, a cape in the straits of Magellan. S. lat. 53° 6'. W. long. 75° 38'.

UPRIGHT Bay, a bay near the western extremity of the Straits of Magellan. S. lat. 53° 8'. W. long. 75° 35'.

UPRIGHT Bent-Grass, in *Agriculture*, a sort of this kind of grass, which is found, by the trials made at Woburn under the direction of the duke of Bedford, to afford at the time the seed is ripe, on a soil of the boggy fort, upwards of 7486 pounds weight of grass upon the acre, which, when dry, weighed more than 2713 pounds, and which lost in the operation of drying about 4772 pounds. The quantity of nutritive matter that is afforded by it, is about 175 pounds on the same space of land. See *AGROSTIS STRIATA*.

It seems not to be a grass of any great value to the farmer.

UPRIGHT Perennial Broom-Grass, a sort of this kind of grass, which has been found, at the time of flowering, on a rich sandy soil, to produce 12,931, and rather more, pounds of grass on the acre, which weighed when dry about 5819 pounds, and which lost in drying 7112 pounds and rather more. It is a grass that affords nutritive matter about 555 pounds on the same space of ground. See *BROMUS ERECTUS*.

UPRIGHT Goose-Grass, a noxious weed of the perennial kind, often met with in meadows and wet pastures, in different districts and parts of the country.

UPRIGHT Mat-Grass, a kind of grass, which, at the time the seed is ripe, is found to produce, on the acre, 6125 ten pounds, which weighs in the dry state 2450 4, and which loses in drying 3675 6 pounds. It affords 215 5 10 pounds of nutritive matter on the same space. See *NARDUS STRIATA*.

UPRIGHT Sta-Lyme Grass, a sort of grass, that, at the time the seed is ripe, produces from the acre of clayey loam soil 43,560 pounds, which weigh when dry 24,502 8, and which loses by drying 18,957 8 pounds. The quantity of nutritive matter afforded by the same space of land, is 3403 pounds and rather more. See *ELYMUS ARENARIUS*.

UPRIGHT Screw Cheese-Press. See *WINDING SCREW CHEESE-PRESS*.

UPSAL, or **UPSALA**, in *Geography*, a city of Sweden, in the province of Upland, situated on an open plain fertile in grain and pasture, is a small but neat town, containing,

says Coxe, exclusively of the students, 3000 inhabitants. The ground plot is very regular: it is divided into two almost equal parts by the rivulet Sala, and the streets are formed at right angles from a central kind of square. Some of the houses are built with brick, and stuccoed; but they are generally constructed with trunks, smoothed into the shape of planks, and painted red, and the roofs are covered with turf. Each house has a small court-yard or garden. Old Upsala is a place of high antiquity, and is supposed to have stood at a small distance from the site of the present town.

In times of Pagan superstition it was much celebrated as the principal place of sacrifice, and as the residence of the high priest of Odin. New Upsala is anterior to the foundation of Stockholm, and is said to have been a suburb of Old Upsala, and to have risen on its ruins. Upsala was formerly the metropolis of Sweden, and the royal residence. Its ancient palace, begun in 1549, by Gustavus Vasa, and completed by his son Eric, was a spacious and magnificent edifice until the year 1702, when great part of it was consumed by fire. What remains of it commands, on account of its elevated situation, a fine prospect of the adjacent country; and its principal front, which has been repaired, is covered with a red stucco. Many traces are still left of its ancient splendour. The few remaining apartments in the ruined wing are used as a common gaol. Under it are three dungeons, formerly appropriated to the confinement of state-prisoners, the most remarkable of whom was count Svante Sture, of an ancient family, which before the election of Gustavus Vasa had the fairest pretensions to the throne. The extinction of this family was owing to the madness of Eric, who, in the year 1567, murdered both count Svante and his son Nicholas. After this frantic and cruel deed, he wandered about the woods in a state of remorse and distraction, until at length, being discovered by his wife, her presence restored him to a temporary possession of his understanding. However he soon relapsed, and his government became so odious, that in the following year he was deposed by his two brothers, and John ascended the throne.

Upsala is an archiepiscopal see, and one of the most ancient Christian establishments in Sweden. The first bishop was Everinus, an Englishman, who in 1026 visited Sweden, at the request of king Olaus Scotkonung, to assist in converting the natives of Old Upsala to Christianity. His successors in the see resided for the most part at Sigtuna, until the year 1120, when Nicholas Ulphson fixed the residence at Old Upsala. The first archbishop was Stephen, a native of East Gothland, and he was elevated to that dignity in 1164, and died in 1185. Falke, who was consecrated in 1267, first transferred the residence to New Upsala, in the year 1273. The first Protestant archbishop was Laurentius Petri of the province of Nerike, who in conjunction with his brother Olaus Petri first preached the reformed doctrines to the Swedes, and translated the Bible into his native tongue. He died in 1570. In the sacristy of the cathedral are several ancient relics; one of which is a log of wood, carved into a figure that rudely resembles a human head, called the image of Thor, formerly worshipped in these parts, and to whom human sacrifices were offered at Old Upsala. The kings of Sweden were formerly crowned in this cathedral; but the last sovereign who was inaugurated at Upsala was Ulrica Eleonora. Upsala is celebrated for its university, which is the most ancient in Sweden. In 1246 Birger Jarl established a school at this place, and in 1478 Steno Sture, law administrator of Sweden, laid the first foundation of the university; the plan of which had been formed, but not executed, by Eric of Pomerania; its regulations being modelled after those of Paris. The institution was confirmed

in a diet which met at Strängnäs on the 2d of July; and the university was opened with due ceremony on the 7th of October. It was warmly patronized by Gustavus Vasa, and liberally endowed by him, for that he has been regarded as its second founder. Under John III. it was removed to Stockholm, but restored to Upfala by Charles IX. After declining for some time, it was revived by Gustavus Adolphus, who constructed a large building at his own expence, and endowed it with his patrimonial estate of Vasa. His example was followed by his successors and by various individuals; so that the number of scholars has considerably increased. At the head of the university is a chancellor, chosen by the professors and confirmed by the king. The presidency devolves by rotation on one of the professors, styled "Rector Magnificus." The university has its own court of justice, called "Consortorium Minus," for the trial of the students and dependants. From this court an appeal lies to a "Consortorium Majus." The number of professors is about twenty-four, of whom the principal are those of divinity, eloquence, botany, anatomy, chemistry, natural philosophy, astronomy, and agriculture. Students are admitted into the university at the age of sixteen, for the completion of their academical studies. They do not inhabit, as in our universities, any distinct colleges, but lodge in the town, and repair to the lectures of the professors, either at their houses or at the public halls. The poorer students are assisted by scholarships, called "stipendia," some founded by the crown, others by private persons; the common degrees granted by this university are "Philosophiæ Candidatus," corresponding to bachelor of arts, and "Philosophiæ Magister," answering to master of arts. In order to obtain the first of these degrees, he candidate undergoes several previous examinations, and composes a Latin thesis. His exercises for the second, are a Latin thesis, holding a public disputation, and reading a lecture in the same language. There is no academical discipline. Although the students have no regular dress, yet on some occasions, as when they take a master's degree, they appear in a black silk cloak, which they ought also by the statutes of the university to wear when they keep their acts. The professors, on days of ceremony, are clad in black cloaks, the doctors of divinity are distinguished by a hat of black silk, the doctors of law by one of white, and those of physic by one of green or sky-blue. The number of students varies, but has been stated at an average of ten years at 500. This university, styled by Stillingfleet, "that great and hitherto unrivalled school of natural history," has produced persons eminent in every branch of science. The library contains many valuable books and MSS. This owes its origin to Gustavus Adolphus. Among the most valuable pieces of literary curiosity is a manuscript of the four gospels, called from its silver letters *CODEX ARGENTUS*, which see.

The Royal Society at Upfala, the oldest literary academy of this kind in the North, took its rise in 1720. At first it consisted of a number of learned men, who published reviews of books, under the title of "Acta Literaria Suecicæ;" but in 1730 the transactions of the society consisted of original acts and dissertations; and when patronized by the king, it assumed the name of "Societas Regiæ," and the transactions, published annually, were denominated "Acta Literaria et Scientiarum Suecicæ." In 1740, it was called "Societas Regiæ Literaria et Scientiarum Uppsalensis," thus distinguished from the Academy of Sciences at Stockholm, which was denominated "Academia Regiæ Suecicæ." In 1750 their publications ceased, but they were again renewed in 1772, under the title of "Nova Acta Regiæ

Societatis Scientiarum Uppsalensis." They are written in the Latin tongue, and printed in 4to. The original numbers issued from 1720 to 1750 are comprised in six volumes.

The place where the ancient kings of Sweden were elected lies about seven miles from the town of Upfala, and is still marked by mutilated stones, one of which is called "Morasteen," or the stone of Mora; on which the sovereigns were enthroned with due solemnity, and received the homage of their subjects. Olaus Magnus relates that the Morasteen was placed in the middle of twelve other stones in a circle. A similar monument near the village of St. Buriens, in Cornwall, is described by Camden. The botanical garden of Upfala is small, but laid out with judgment, and the collection of exotics is numerous. Upfala is 45 miles from Stockholm. N. lat. 59° 51'. E. long. 17° 26'.

UPSARA, in *Hindoo Mythology*, is the name of a poetical race of water-nymphs, proverbial for their beauty and fascinations. They are the dancing girls of Indra's court, answering to the fairies of the Persians, and to the damfels called in the Koran *Huruluyun*, or with antelopes' eyes. The name has been derived from *up*, water, the seventh case plural of which is *upsa*, and *rasa*, taste.

UPSALA, in *Geography*, a town of Hindooftan, in Bahar; 6 miles S. of Patna.

UPSILOIDES, in *Anatomy*, a name for the os hyoides. See DEGLUTITION.

UPSTART, CAPE, in *Geography*, a cape on the N.E. coast of New Holland. S. lat. 19° 39'. W. long. 212° 32'.

UPTON, a town of Massachusetts, in Worcester county, containing 935 inhabitants; 38 miles S.W. of Boston.

UPTON upon Severn, a market-town in the lower division of the hundred of Perilore, and county of Worcester, England, is situated on the banks of the river Severn, at the distance of 10 miles S. from the city of Worcester, and 109 miles N.W. by W. from London. Though a small town, it has long been in a state of progressive improvement, which may be in some measure attributed to its having a handsome stone bridge of six arches, built in 1605, and a harbour for the reception of the barges employed in the navigation of the Severn, by which a considerable traffic is carried on. Upton suffered much in the civil war of Charles I.; when the bridge was partly broken down for military purposes, and a battery erected in the church-yard to prevent the parliamentary forces from crossing the river. At that time also the church sustained great injury, and though afterwards repaired, it was found necessary, in the year 1756, to take it down; when, it is to be regretted, little attention was paid to the preservation of the painted glass and ancient monuments in the old structure. It was replaced by a very neat modern edifice, the chief ornament of the town. This was opened in 1758; but the tower was not completed till 1774. A charity-school for sixteen girls is established here. No manufactures worthy of notice are carried on: but four fairs are held annually, for the sale of horses, cattle, sheep, and leather: a weekly market is kept on Tuesday. According to the population return in the year 1811, the parish of Upton then contained 394 houses, occupied by 2023 persons. In the year 1787, a circular cavity, about six feet in diameter, was discovered in a corn-field in this vicinity: on examination, this aperture led to a cavern at the depth of about ten feet from the surface, extending in every direction twenty feet in diameter; at about thirty-five or forty feet is a pit or shaft full of water, and nearly 140 feet deep. Various conjectures have been formed respecting this phenomenon; but whether it proceeds from a natural or artificial cause has not been determined.

About four miles from Upton, and near the village of Earl's

Earl's Croome, is Croome Court, the seat and park of the earl of Coventry. The mansion is modern, and the style of its architecture is very plain; but the elegance of the interior makes up for any thing that may appear a deficiency without. The drawing-room is hung with tapestry of the Gobeline manufacture, of crimson ground with coloured figures.—*Beauties of England and Wales*, vol. xv. Worcesterhire.

UPULUS, in *Botany*, the old Latin name for the *lupulus*, or hop. This word *lupulus* is not old Latin, but a more modern name, formed on the word *upulus*.

UPUPA, in *Ornithology*, a genus of birds belonging to the order of *Picæ*, the characters of which are, that the bill is bent, long, slender, convex, subcompressed, and somewhat obtuse: the nostrils are small at the base of the bill; the tongue obtuse, entire, triquetrous, and very short; and the feet formed for walking. In the Linnæan system by Gmelin there are eight species, which are as follow:

Erops. Crested and variegated, or the ferruginous hoopoe, with the wings barred black and white, the tail black, with a lunated white bar, and the crest tipped with black and white. This is the upupa of Bell, Gefn. Aldrov. Ray, &c.; the bubbola of Olin; the ter-choas or messenger-bird of Pocock; the hoopoe of Willughby, Pennant, Edwards, &c.; the common hoopoe of Latham; and the la huppe of Buffon. It is an elegant bird, generally inhabiting the warmer and temperate parts of the old continent, and migrating occasionally, at different seasons, in different directions. In our island it is much more rarely seen than in other northern climates. It is about the size of a common thrush. The colour of the head, neck, and body, is pale ferruginous or cinnamon-brown; the wings and tail are black, the former crossed by five white bars, the latter by a white crescent; the rump and lower part of the abdomen are white, and the sides generally marked by a few longitudinal dusky streaks; on the head is an elegant crest, which it can either erect or expand, or depress and close at pleasure, composed of feathers which are cinnamon-coloured, with black tips, a white bar separating the tip from the rest of the feathers; the legs are short and blackish. The hoopoe migrates during the spring from Africa into various parts of Europe, and returns in winter. In various parts of Egypt, however, it is nearly domesticated, building even among the houses. The flesh of these domestic hoopoes is rank and unfit for eating, but that of the migrating birds is considered in many parts of Europe as an agreeable food, particularly in Italy, the south of France, and in the Grecian islands. Its nest is to be sometimes found in a wall or tree, and is generally said to have a peculiarly fetid smell, supposed to be chiefly owing to the remains of various kinds of insects. The number of eggs is from five to seven. In Egypt the migrating hoopoe never associates with those of the towns, but frequents remote and solitary places. Such is generally the disposition of those which appear in Europe, but in Africa they associate in great numbers. Their ordinary food consists of various kinds of insects and worms, in order to obtain which they follow in Egypt the retreat of the Nile. These birds are generally seen on the surface of the ground, being very rarely observed to perch on trees. Dr. Shaw mentions as a variety the blue-crested hoopoe, observed at Florence and on the Alps, near the town of Rota, and differing from the common hoopoe in having the crest-feathers tipped with sky-blue instead of black. The *upupa minor*, smaller hoopoe, ferruginous, with the wings varied with white, and the crest tipped with black, the la huppe d'Afrique of Buffon, may probably be another variety of the common hoopoe, which inhabits the southern

parts of Africa, and is found in the kingdom of Congo, and at the Cape of Good Hope, frequenting low grounds in the neighbourhood of thickets, and not migratory.

CAPENSIS. Crested brown, beneath white, with a white spot on the wings. This is the Madagafcar hoopoe, white, with cinnamon-brown wings and tail, and loose-webbed crest; la huppe noir et blanche du Cap de Bonne Esperance of Buffon. The tail-feathers of this species are twelve in number; the colour of the crest, throat, and all the under parts of the bird, is white, without any variegation; that of the upper parts, from the back of the head to the end of the tail, dusky or greyish-brown, deepest on the wings and tail; on the edge of the wing is a white spot, the tips of two or three of the larger coverts being of that colour: the legs and feet are yellowish. It is a native of the island of Madagafcar, as well as of some of the African isles, and is said to feed on seeds and berries. From the structure of the tongue, which is rather broad, and divided at the extremity into several fibres, Dr. Shaw infers, that it is nearly related to the genus *merops*, or bee-eater.

PROMEROPS. The hoopoe with six tail-feathers, the intermediate being the longest. This is the promerops cafer, or brown promerops, whitish beneath, with rufescent breast, and very long tail. *Upupa promerops*, or Cape promerops of Latham, and promerops of Buffon. The size of this bird is that of a lark; its colour is rufous brown, somewhat deeper on the wings and tail; throat white, with a narrow, longitudinal, dusky streak on each side; under part of the abdomen whitish, dashed with dusky streaks, vent yellow, tail very strongly cuneated, bill black, and also the legs. In some, probably the males, the breast as well as the abdomen is spotted, and the wings are crossed by a narrow grey or whitish stripe. A native of Africa, common about the Cape of Good Hope.

MEXICANA. The grey hoopoe, with a mixture of feagreen and purple. Underneath yellow, greater quill-feathers blueish, and the four intermediate tail-feathers longer than the rest. This is the grey promerops with green and purple gloss, blueish wings, yellowish belly, and very long tail; the Mexican promerops of Linnæus, the promerops Mexicanus of Brisson, and promerops à ailes blancs of Buffon. The body of this bird is of the size of a thrush. The bill is near two inches long, and blackish; the whole of the upper parts, except the quills, which are light blue, are grey, with green and purplish glosses. The under parts of the body are light yellow, and a spot of the same colour is situated above each eye. This species is said to be a native of Mexico, frequenting mountainous regions, and feeding on various kinds of insects.

PARADISEA. The crested chestnut-coloured hoopoe, with the two middle tail-feathers much longer than the rest. This is the chestnut promerops, grey beneath, with black-crested head, and very long tail. The avis paradisica cristata orientalis rarissima of Seba, the promerops of Buffon, and crested promerops of Latham. It is about the size of a starling; the bill is curved, and of a lead colour, as are also the legs; the head and neck are a fine deep black; the crown of the head being ornamented by a very conspicuous lengthened semi-pendant crest; the whole remainder of the bird on the upper parts is bright brown, on the under pale ash-colour. A native, according to Seba, of the East Indies, where, as he says, it is very rare.

FUSCA. The brown hoopoe, underneath grey, striped with white and black, the crown of the colour of polished steel, the throat and neck black, and two intermediate tail-feathers very long. This is the brown promerops, beneath white, with black undulations, and very long tail. The promerops

brun, á ventre et eyé of Buffon, and New Guinea brown promerops of Latham. According to Sonnerat, who first described and figured it, the neck, back, wings, and tail of this bird are brown; the breast and remaining under parts white, undulated by numerous transverse black stripes, each feather having two white and two black bars; the tail very long, and strongly emeated, the bill considerably curved, of a blackish colour; and the legs yellowish-brown. A native of New Guinea, inhabiting large woods.

MAGNA. The black hoopoe; the head, hind part of the neck, breast, and exterior part of the falcated scapular feathers golden green, and very long tail. This is the superb promerops, with violet and green glofs, falcated golden-shining scapular feathers, and very long tail; the grand promerops á parems frifes of Buffon, and grand promerops of Latham. Its shape is slender, the tail almost three times the length of the remainder of the bird, which is not larger than a common pigeon; the bill narrow, black, and pretty much curved; the general colour of the whole bird is black, accompanied, according to the different directions of the light, by varying reflections of blue, green, and violet; the other parts as above described. The scapular feathers, or those situated along the sides of the body, rise up into two rows of reversed falciform plumes, gradually enlarging from the shoulders to the rump, beyond which they become much longer but less curved, and are stretched to some distance on each side of the base of the tail; the colour of their inner or shallower scales is purplish-black, but along the edges and tip of the wider web it is of a brilliant golden-green: on each side of the lower part of the body, beneath the wings, is also situated a thick and moderately long group of loofe-webbed, pendent, brownish feathers; the tail consists of twelve feathers; and the legs are strong and black. This bird was first described by Sonnerat, and is a native of Guinea; but its history and habits are unknown.

AURANTIA. The yellow hoopoe, with golden head and neck, and tail even at the end. This is the orange-coloured promerops, with tail of moderate length, and even at the tip; the avis paradisica Americana elegantissima of Seba, the promerops orange of Buffon, and the orange promerops of Latham. This bird is about the size of a starling; its bill is somewhat curved, sharp-pointed, and yellow, as are the legs; the head and neck are of a deep yellow or gold colour, with a few red feathers round the base of the bill; the remainder of the bird is orange-yellow; the larger quill-feathers of a redder cast than the rest. A native of Guiana, frequenting the small islands in the mouth of the river Berbice. The supposed female of this species is described by Fernandez, in his History of Mexico, under the name of "Cochitlotli;" it is introduced by Gmelin as a variety of the former; Buffon reckons it a female, and Brisson denominates it promerops Mexicanus luteus. The head, throat, neck, and wings are said to be irregularly varied with grey and black; the rest of the bird yellow; the bill black and the legs grey.

Of the "black hoopoe," nothing but its existence and native country seems to be known: it is mentioned by Sonnini, on the authority of Monf. Viollet, who says that it is found in Africa, towards the kingdom of Congo. For other species, see PROMEROPS, and Shaw's Zoology, vol. viii.

UR, in *Ancient Geography*, a city of Chaldea, where Terah, the father of Abraham, resided; and whence Abraham himself removed to the land of Canaan, which was granted to him and his posterity. (Gen. xi. 28.) The precise situation of this city is not known; some think that it was Camerina, in Babylonia. Ptolemy and Strabo suppose that

it was Orcha or Orchea, in Chaldea; and others are of opinion that it was Ura, or Sura, in Syria, on the Euphrates. Bochart and Grotius maintain, that it was Ura in Mesopotamia, two days' journey from Nisibis. The difficulty that occurs in ascertaining its situation, is partly owing to the confusion that attends the settlement of the precise boundaries of Chaldea and Mesopotamia; the former being situated towards the mouths of the Tigris and Euphrates, and the latter between these rivers somewhat farther north. The word *Ur*, in Hebrew, signifies fire; and hence some have pretended, that when Moses said God brought Abraham out of Ur of the Chaldees, he alluded to a fire into which the Chaldeans cast him. But this seems to be fabulous, as St. Jerome, who once adopted their opinion, afterwards acknowledged: and therefore others have thought, that the name *Ur* was given to this city, because fire was the object of worship; and Abraham, by his removal to Canaan, was released from all obligation to practise that kind of worship.

URA, in *Geography*, a town of Natolia; 10 miles S. of Miles.

URABA, a town and district of South America, in the province of Carthagená.

URAC, the most northerly of the Ladrone islands, in the East Indian sea, about 9 miles in circumference. N. lat. 20° 45'.

URACH, a town of Wurtemberg, with considerable manufactures of damask, and other linens, on the Rems; 21 miles S.S.E. of Stuttgart. N. lat. 48° 27'. E. long. 9° 27'.

URACHUS, in *Anatomy*, a fibrous cord passing from the fundus of the bladder to the umbilicus; it is hollow in the fetus of animals, and communicates with the allantois. See EMBRYO and KIDNEY.

URACONDA, in *Geography*, a town of Hindoostan, in Mylore; 20 miles W.S.W. of Gooty.

URAGO, a town of Italy, in the department of the Mela, on the Oroglio; 15 miles W. of Brecia.

URAGUAY, a river of South America, which rises in Paraguay, about S. lat. 26° 30'; and, after a course of about 609 miles, joins the Para, in S. lat. 34°, and the united streams take the name of La Plata. The country on this side the river is also called Paraguay.

URAIN, Sr., a town of France, in the department of the Nievre; 7 miles N.E. of Cosne.

URAL, formerly the *Taik*, a river of Russia, that has its source in the western sides of the Ural mountains, from which it issues near the fort of Orsk, and for a long interval pursues a western course, then turns directly south, and at about 47° N. lat., and 70° long., falls into the Caspian. The current is rapid, and its water pure; and it was known to the ancients under the name of Rhymnus. Its course is estimated at 3000 versts. From time immemorial it has constituted the boundary between the Kirghiztians and the Baskhirtzi; and upon it are still 30 forts and several fort-works against the former. The most considerable rivers which the Ural takes up are, to the left, the Or and the Ilek; and to the right, the Kilil and the Sakmara. In the upper regions, its banks are ridged with steep and lofty rocks; but lower down it flows through a tolerably dry and very false steppe. It abounds with fish. The fishery on the Ural forms the principal occupation and support of the Uralian Cossacks; nor is this trade any where so well regulated, by the laws of ancient usage, as here. Ever since the government granted the fishery to the Cossacks, in return for the payment of the moderate stipulation formerly annexed to the catching or fishing stakes at Gurief, they have completely broken up

the said silt-weir, and instead of it, inclosed the whole river about the town of Uralisk by a permanent catching; so that, though the fish come freely out of the Caspian into the Ural, they cannot proceed higher than Uralisk. The Ural has all the kinds of fish that are found in the Volga, excepting the bream, the red salmon, and a small species of sturgeon. The first and most important capture in the year is in January, with hooks; the second lasts from May till towards the middle of June; and the third, which is the least considerable, is performed with nets, in October. The first great fishery in January is chiefly for sturgeons and belugas. On the day when the fishery begins, all the Cossacks who have tickets of licence assemble before sun-rise, with their sledges and implements, at a stated place before the town, ranging themselves in rows and sections, according to the order in which they arrive. They are then mustered by a proper officer and formed; notice is given by firing of cannon when the operation is to commence, or the breaking up of the ice for fishing. The order and ceremonial are the same for the second great capture of the sturgeons in spring as in the winter fishery, and a certain boundary is fixed for marking the extent of the fishery. The Cossacks, while fishing, sit singly in little canoes, commonly made of the trunks of the black or white poplar, paid over with asphaltus instead of pitch. The nets are between 20 and 30 ells in length. The autumnal fishery is also conducted in the same manner with the others. This is performed with large casting nets, and they are allowed to take, besides the smaller species of fish, all sorts of sturgeons. The largest belugas caught in the Ural weigh often 25 pood, and yield about 5 pood of kaviar or caviar, which on account of its stringiness is reckoned the worst. The sturgeons are about a fathom in length, and the largest of them weigh 5 pood, and contain a pood of kaviar, which is most esteemed for its quality. The fish here, as at the Volga, are mostly salted; kaviar is prepared from the roes, and fish-glue made of the mucilaginous substances; but the winter-fish are transported frozen. Tooke's Russia, vol. iii.

URAL Mountains, a famous chain of mountains in Russia, which forms the natural boundary between Europe and northern Asia, called Ural, or the belt, as if it girted the whole world. The ancients gave this chain the appellation of the Hyperborean and the Rhyphæan mountains, and sometimes "Montes Rhymerici." Under the last of these denominations, the Bashkirian Ural was more particularly designated. The northern Ural they termed "Montes Hyperboræos" or "Riphæos;" and the southern "Rhymericios." The former were afterwards called the Yugorian mountains. Ural is a Tartarian word, signifying a belt, or girdle; by which the Russians likewise denote this range; for they call it Kammenoi, and Semnoi Poyas; that is, the rock, or earth-girdle. These mountains extend from S. to N., almost in a direct line, much above 1500 English miles. They commence with the mountains between the Caspian and the lake Aral, and attain their greatest height and bulk about the sources of the rivers Ural, Tobol, and Emba; and from thence they stretch on towards the origin of the Tihussavaia and the Isets, and further on to the sources of the Pethora and the Solva; and lastly, form two great promontories about the Karian haven of the Frozen ocean: after being divided by the straits of Vaygat, or Waygat, they terminate in the mountains of Nova Zemla. From this chain some considerable collateral branches take a western as well as an eastern course. The most material from the former side are those called Obfichtsei-Sirt, the mounts of separation, running out between the river Ural and the Sakmara,

uniting on one side with an arm issuing from the Kirghiltzi-Steppe, on the left shore of the Ural; and on the other side projecting into the old Kalmuck-Steppe, between the Volga and the Ural, and northerly joining the sand-stone mountains, which accompany the main course of the Ural on the western side. Near the forts of Orsk and Guberlinsk, a part of the mountains runs out south-eastward into the Kirghiltzi deserts, and reaches to the mountain Ulutau, which stands about the centre of that region, and is attached to the great Altay. This arm is called the Guberlinskoi mountains. Another course, smaller than the preceding, runs south-eastward between the rivers Ural and Uï, under the name of Okto-Karagai, through the open Steppe of the middle border of the Kirghis-kaifaks, and then pursues its way, under the appellation of Alginskoi-Sirt, towards the Irthik and the Altay mountains. The whole Ural chain may be divided into three parts, viz. the Kirghiltzi Ural, extending from the Caspian and the Aral, and eastward out of the great Steppe of the Kirghis-kaifaks, as far as the origin of the Tobol and the Yemba; the Ural rich in ores, or Ural ore mountains, comprehending the whole mountainous track, with its western and eastern appendages, from the rise of the said rivers and the Guberlinskoi mountains, quite up to the sources of the Solva and Kolva; and the desert Ural, extending from these rivers to the Frozen ocean. The Ural abounding in ores may be subdivided into the Orenburg, the Ekatarinenburg, and the Verchoturian Ural.

This main course of the Ural mountains declines much more on its western side than on the eastern, and on the former has a considerable track of collateral ridge, very rich in copper, and mostly composed of schistose sand-stone. The highest mountain of the Ural chain is in the Bashkiria (or in the Orenburg Ural), and in the Verchoturian Ural.

The Ural chain is of itself a main mountain, whose highest ridges, for the most part, consist of granite, and of all the properly primitive rocky materials. In minerals the Ural mountains are very rich; abounding with beautiful sorts of granite, porphyry, excellent Jasper, fine quartz, petrosilex, pebbles, whetstones, flints, agates, chalcodones, large mountain crystals, smoky topazes, or brown rock crystals, fine amethysts, chrysolites, porcelain and pipe-clay, bolus, shelly felspar, serpentine, potstone, window-mica, asbestos, and amianthus; beautiful marbles, table-schistus, gypsum, flowers of spar, turf, coals, mineral oils, naphtha, native sulphur, marcalites, fossil salts, sources of common salt, bitter lakes, alum, vitriolic earths, salt-petre, natron, iron, copper, gold, and specimens of silver and lead. For working of the gold, copper, and iron, very expensive and productive fabrics are here erected. The Ural mountains are also amply furnished with woods; such as pines, birch, fir, cedar, larch, aspen, alder, and on the S.W. side a few oaks, elms, lindens, &c. In the vallies adjoining to this range of mountains are rich and verdant glens, and dales and meads in alternate succession; so that the breed of cattle is not inconsiderable. Among the wild beasts and birds, which are very plentiful, may be reckoned fables, beavers, rein-deer, elks, &c. The various elevations are copiously supplied with beautiful pellucid lakes, ponds, and numberless streams, all teeming with fish. The principal rivers that take their rise in this chain of mountains are the Solva, the Tura, the Iset, the Uï, the Tobol, the Yemba, the Ural, the Belaiä, the Tihussavaia, the Kamma, the Pethora, &c. Tooke's Russia, vol. i.

URALLA, a considerable Turkish village, situated on the side of a mountain, at about the distance of a mile from the shore, commanding a prospect of the whole of the spa-

cious gulf of Smyrna, as far as Mitylene. The greater part of the fine Smyrna raisins come from Uralla, where several cargoes are prepared annually. At the season of the racolta, or fruit-harvest, the Smyrna merchants send their clerks to attend its ingathering, and at that time there is much business transacted in this village.

URALSK, a town of Russia, in the government of Caucasus, on the Ural; 328 miles N.N.E. of Astrachan. N. lat. 51° 10'. E. long. 51° 54'.

URAMARCA, a town of Peru, in the diocese of Guamanga; 60 miles E. of Guamanga.

URAMEU, a town of Brazil; 48 miles N.E. of Para.

URAN. See OURAN.

VRANA, a town of Iliria; 9 miles E.S.E. of Pedena.—Also, a town of European Turkey, in Servia; 25 miles E.S.E. of Pfristina.—Also, a river of Bulgaria, which runs into the Black sea at Varna.

VRANA, or *Urania*, a town of Dalmatia, situated on a lake to which it gives name, anciently an important fortress belonging to the Templars, and the residence of the grand prior. This castle, which at the time of its foundation was named *Brana*, or *Vrana*, by way of dignity, is now a frightful heap of ruins, reduced to that state by the Venetians. Some writers have thought that Bandona was anciently seated there; but no vestige of Roman antiquity is to be seen about these walls, and ruined, uninhabited towers. The khan, or caravanerai, is worthy of observation, although it is now in a ruinous state, being abandoned to the barbarity of the Morlacchi, who inhabit the neighbouring lands, and carry off whatever materials suit them, to be employed in their wretched cottages. The name of Vrana is now transferred to a wretched village, that stands about a mile from the ruins of the fortress, in the very place where an eminent Turk of the last age, called Hali Bey, had his gardens; and the squalid habitation of the curate of the parish lately went by the name of Hali Bey's gardens. The lake of Vrana is more famous and better known at Venice than any other in Dalmatia, not only on account of its considerable extent of 12 miles, but from the project formed by a private person, and partly put in execution, to cut a passage by which the water might be discharged into the sea; 15 miles E.S.E. of Zara.

URANA, a river of South America, which runs into the Caribbean sea; 9 miles W. of Cumana bay.

URANDA, a town of Japan, in the island of Xicoco; 12 miles S.S.E. of Tofa.

URANDUK, a town of Bosnia; 2 miles E. of Seraja.

URANIA, in *Ancient Geography*, a town of the isle of Cyprus, taken by Demetrius, according to Diodorus Siculus.

URANIA, in *Botany*, a name for which the classical Schreber has well exchanged the barbarous RAVENALA of Adanson and his followers; see that article. This latter seems, by Jacquin's account, to be altered from *Raveneala*, signifying, as he had some reason to believe, the leaf of God, among the inhabitants of Madagascar. In the application of *Urania*, Schreber had probably in view, not so much the "heavenly muse," according to the explanation of De Theis, as the Greek adjective *αἰγιόχος*, great, admirable, or sublime, which so well answers to the majestic stature and large proportions of this very fine plant.—Schreb. Gen. 212. Willd. Sp. Pl. v. 2. 7. Mart. Mill. Dict. v. 4. (Ravenala; Juss. 62. Lamarck Illust. t. 222.)—Clafs and order, *Hexandria Monogynia*. Nat. Ord. *Musa*, Juss.

Gen. Ch. *Cal.* Common Sheaths alternate, each of one

leaf, ovato-lanceolate, concave, many-flowered; partial ones inferior, each of two linear-lanceolate, long, channelled, pointed, erect, coloured, permanent valves; perianth none. *Cor.* Petals three, superior, oblong, channelled, erect, acute, equal. Nectary of two equal leaves, one of them cloven, (according to Adanson). *Stam.* Filaments six, thread-shaped; anthers vertical, erect, linear, longer than the filaments, and about equal to the nectary, inclining at the summit. *Pist.* Germen inferior, oblong; style rather longer than the stamens; stigma in six converging segments. *Peric.* Capsule oblong, abrupt, triangular, of three cells, and three woody valves, connected at the base; the partitions from the centre of each valve. *Seeds* numerous, in two rows, roundish-oblong, each with an umbilicated, fleshy, lacinated, coloured, radiating tunic, spreading from the scar.

Efl. Ch. Sheaths general and partial. Perianth none. Petals three. Nectary of two equal leaves, one of them cloven. Capsule inferior, of three cells. Seeds numerous, in two rows, each with a coloured tunic.

1. *U. speciosa*. Superb *Urania*. Willd. n. 1. Ait. Epit. 376. (Ravénela madagascariensis; Sonnerat Voy. aux Ind. Or. v. 2. 223. t. 124—126. Jacq. Hort. Schoenbr. v. 1. 47. t. 93.)—Native of marshy ground in the island of Madagascar. Cultivated in the Mauritius, from whence it was carried to the imperial garden at Schoenbrun, in 1782, and to the stoves of Kew, in 1810.

This is one of the most stately of plants, with respect to its habit, and the proportion of every part, though perhaps inferior in stature to many trees. The stem is erect, and, according to Sonnerat, very lofty, though he does not mention its precise height, round, marked with numerous scars where the foliage has formerly been, otherwise naked and smooth, quite simple, crowned at the summit with an ample, radiating, vertical tuft, of very numerous, stalked, alternate leaves, spreading in two ranks, like a vast fan, many feet wide. Each leaf is oblong, entire, obtuse at each end, with one rib, and numerous transverse, parallel veins, smooth, resembling the leaves of the *Musa*, or Plantain-tree, but larger and thicker. *Footstalks* sheathing from the base about half way up. Sonnerat makes their length about two feet, but Jacquin says ten, adding that each leaf is six feet long, and two wide. If this be correct, the whole diameter of the fan-like head may be thirty-two feet! We might have felt a suspicion that Jacquin's plant, which, in the course of fifteen years' cultivation in the stove at Schoenbrun, never flowered, nor formed any stem, might be the *Strelitzia angusta* of Thunberg, Willdenow, and Aiton; had not the author expressly mentioned its having been raised from seeds taken out of the capsules delineated in his plate, which indubitably belong to our *Urania*, whose flower-stalks are axillary, scattered, shorter than the footstalks, zigzag, very stout, and finally woody, each bearing six or eight alternate, two-ranked, rigid, pointed sheaths, filled with numerous, erect, whitish flowers, whose petals are seven or eight inches long. *Capsules* brown, rugged, three or four inches in length. *Seeds* the size of a horse-bean, black, their tunics of a fine blue, and curiously jagged.—The inhabitants of Madagascar use the leaves as a covering to their houses. Flacourt, it seems, has described this plant, in his History of Madagascar, by the name of *Voisouffi*, (Botany is happy to have escaped this name,) and he there relates that the natives make an oil from the tunic of the seeds, and grind the substance of the latter into meal, which they eat with milk.

After all that we can collect, the *Urania* itself, if distinct from *Strelitzia angusta*, is so very nearly allied to *Strelitzia* in genus,

genus, that we should not wonder if they prove the same. We have been shewn at fir J. Banks's, a native *capsule* and *seeds* of a *Strelitzia* from the Cape, which answer exactly to the characters of *Urania*, though no *tunic* is described in *STRELITZIA*; see that article.

URANIA, or *Celestis*, in *Mythology*, one of the nine Muses that presided over astronomy: she is represented as clothed with an azure-coloured robe, crowned with stars, holding a globe in her hand, or sometimes with the globe at her feet, and surrounded with several mathematical instruments. On medals the globe stands upon a tripod.

URANIA, a goddess of the Arabians, and of the Moors of Africa, called also *Allat* and *Celestis*. The *Urania* of the Arabs is supposed to have been the Moon, as Bacchus was the Sun; and these two luminaries were among them objects of worship. The *Celestis* of the Moors, mentioned by Tertullian, was the Venus *Urania*, so well known in Syria, that is, the planet of that name; for it is certain that almost all nations worshipped the stars, and had gods natural and gods animated.

URANIBURGH, q. d. *the City of the Heavens*, a term often heard among astronomers, being the name of a celebrated observatory, in a castle in the little island *Weenen*, or *Huen*, in the *Sound*; built by that noble Dane, *Tycho Brahe*; and furnished with instruments for observing the course and motions of the heavenly bodies.

This famed observatory, finished about the year 1580, did not subsist above seventeen years; when *Tycho*, who little thought to have erected an edifice of so short a duration, and who had even published the figure and position of the heavens, which he had chosen for the moment to lay the first stone in, was obliged to abandon his country.

Soon after this, those to whom the property of the island was given, made it their business to demolish *Uraniburgh*: part of the ruins was dispersed into divers places; the rest served to build *Tycho* a handsome seat upon his ancient estate, which to this day bears the name of *Uraniburgh*. For as to the ancient *Uraniburgh*, there is now no footprint of it remaining. It was here *Tycho* composed his catalogue of the stars.

M. Picart, making a voyage to *Uraniburgh*, found *Tycho's* meridian line, drawn thereon, to deviate from the meridian of the world: which confirms the conjecture of some, that the position of the meridian line may vary. See *TYCHO BRAHE*.

URANIUM, in *Mineralogy* and *Metallurgy*, a metal so called from the planet *Uranus* or *Herfchel*, by the celebrated chemist *Klaproth*, who discovered it in 1789, in an ore which had been formerly supposed to contain zinc or iron. Uranium is of an iron-grey colour; it possesses considerable metallic lustre; it is brittle and hard, but yields to the file. It has hitherto only been obtained in grains, or in small quantities as a porous cohering mass. The specific gravity of uranium, according to *Klaproth*, is 8.01; but according to *Bucholz*, 9. Uranium melts with great difficulty; but when heated to redness in an open vessel, it undergoes a species of combustion, glowing like a coal, and is converted into a black powder, gaining in weight about five parts in the hundred. This powder is the black oxyd. The yellow oxyd is obtained by precipitating uranium from its solution in nitric acid by an alkali. The yellow oxyd of uranium is insoluble in pure alkalies, but is soluble by the alkaline carbonates; the former property distinguishes it from the oxyd of tungsten. The yellow oxyd consists of eight parts metal, and twenty of oxygen. The combinations of uranium with the other metals are unknown. With sulphur the yellow oxyd of uranium may be combined, by

mixing two parts of sulphur and one of oxyd, and exposing the mixture to heat in a crucible. Most of the sulphur is driven off; the residuum is a blackish-brown mass, being a sulphuret of uranium. If the heat be increased, the whole of the sulphur is sublimed, and the uranium remains in a metallic state, in the form of a black coarse powder. Metallic uranium is only perfectly soluble in nitric acid. *Bucholz* supposes that there are several oxyds of this metal, distinguished by their different colours, as under:

Peroxyd,	-	Greyish-black.
Second oxyd,	-	Dark grey, inclining to violet.
Third oxyd,	-	Greenish-brown.
Fourth oxyd,	-	Greyish-green.
Fifth oxyd,	-	Orange.
Peroxyd,	-	Lemon-yellow.

To obtain uranium from its ores, in which it exists in the state of oxyd, the ore must be dissolved in dilute nitric acid. The solution may contain iron, copper, and lime. By evaporating it to dryness, and exposing the dry mass to a moderately strong heat, the iron is rendered insoluble, but the other ingredients will be taken up by distilled water. Ammonia poured into this solution, and digested in it for some time, retains the copper, but throws down the uranium.

The precipitate is to be washed with ammonia till the liquid comes off colourless; it is then to be dissolved in nitric acid, and to be concentrated by evaporation, and set by to crystallize. The green-coloured crystals that form, may be picked out and dried on blotting-paper, then dissolved in water, and the liquid partly evaporated and left to crystallize. By this means the whole of the lime will remain behind. The crystals will consist of pure oxyd of uranium united to nitric acid; they are to be exposed to a red heat; a yellow powder remains, which is the oxyd of uranium. This powder is to be mixed with a small quantity of charcoal powder, and exposed to a violent heat, by which it is reduced to a metallic state. The experiment succeeds best when the oxyd is mixed with only the one-twentieth part of charcoal, and inclosed in a charcoal crucible to exclude the air. *Klaproth* employed a heat equal to 170° *Wedgwood*, to obtain this metal. No flux has hitherto been found of any service in facilitating the reduction of uranium.

Uranium has not hitherto been applied to any useful purpose in the arts, either in its metallic state, or in combination with acids as a metalline salt.

With nitric acid, oxyd of uranium unites in two proportions. The nitrate is an extremely soluble salt, of a lemon-yellow colour. The crystals have generally the form of hexagonal tables, more or less perfect; but by careful management, they may be obtained in large four-sided rectangular flat prisms. At the temperature of 100°, they fall into a white powder. In a damp atmosphere, they soon deliquesce.

They consist, according to *Bucholz*, of

Oxyd of uranium	-	-	-	61
Acid	-	-	-	25
Water	-	-	-	14
				100

When nitrate of uranium is heated till its colour becomes orange-red, it does not dissolve completely in water, but leaves a yellow powder, which has been shewn by *Bucholz* to be a subsulfate.

The oxyd of uranium combines with the muriatic and sulphuric

fulphuric acids, also with the acetic, the tartaric, the phosphoric, and fluoric acids, and with those of tungsten and molybdena. Richter formed likewise the borate, oxalate, citrate, malate, benzoate, fuccinate, and sebate of uranium; but the properties of the latter salts have not been described. See SALTS and ACIDS.

Ores of Uranium.—*Pitch-blende* or *Pitch-ore*, *Pecherz*, *Werner*; *Uran Oxidulé*, *Haüy*. This mineral was first observed in a mine at Johan-Georganitadt, in Saxony. From its black colour, and other properties, it was for some time supposed to be a blende, or ore of zinc. *M. Werner* placed it among iron-ores, and afterwards supposed that it contained wolfram. *Klaproth* analysed this ore in 1789, and found that it consisted principally of sulphur, combined with a metal to which he first gave the name of uranium. This ore occurs in veins in primitive rocks, in several places in Cornwall, in Saxony, and in Norway; it is commonly accompanied with galena, copper pyrites, and iron ochre, and with quartz, calcareous spar, and sulphate of barytes. It is also sometimes associated with ores of silver and cobalt.

The colour of pitch-blende is velvet-black, or greyish-black, sometimes inclining to green and brown. It occurs massive, and disseminated also reniform, botryoidal, and pulverulent. The lustre internally is resinous, more or less shining. The fracture is sometimes imperceptible; in other specimens it is lamellar. Pitch-blende is brittle; the fracture is imperfectly conchoidal; the fragments are angular and sharp-edged. It yields readily to the knife, but the colour of the streak is not changed. The specific gravity of this ore is 7.5.

Pitch-blende is infusible without addition by the blow-pipe: with borax it yields a grey slag; with phosphate of soda, a clear green globule. It dissolves imperfectly in the sulphuric and muriatic acids, but is almost entirely dissolved in the nitric and nitro-muriatic acids. The solution has a pale orange-green colour; and from this solution the metal is precipitated by the phosphate of potash and the alkalis: with the former, the colour of the precipitate is a brownish-red; with the latter, yellow.

The constituent parts of this ore, as given by *Klaproth*, are,

Oxyd of uranium	-	-	86.5
Black oxyd of iron	-	-	2.5
Galena	-	-	6
Silex	-	-	5
			100

Pitch-blende may be distinguished from brown blende by its colour, specific gravity, fracture, and streaks; from wolfram by its streak and fracture.

Uranite, or *Uran mica*, *Uran oxidé*, *Haüy*. The colour of this ore is lemon-yellow, passing into orange, and into apple-green and emerald-green; it becomes brownish by decomposition. It occurs crystallized in rectangular prisms and tables, and sometimes in imperfect octohedrons. The edges of the crystals are frequently bevelled and truncated. The structure is lamellar, with distinct joints in one direction, parallel to the bases of the crystals; the other joints are indistinct. The lamellæ are inflexible, and transparent or translucent, with a shining pearly lustre. Uranite yields easily to the knife; the specific gravity is 2.19. The crystals are generally small. Sometimes this mineral occurs massive, in granular distinct concretions; and sometimes it is found pulverulent, and in small tubercles, which have a glimmering or dull lustre, and an orange or green or reddish-

brown colour. Uranite decrepitates violently before the blow-pipe; it loses about 33 per cent. by ignition, and acquires the colour of brags. With borax it yields a yellowish-green glass. This ore dissolves without effervescence in nitric acid, and communicates to it a lemon-yellow colour.

Its constituent parts, as given by *M. Gregor*, are,

Oxyd of uranium, with a trace of oxyd of lead	74.4
Oxyd of copper	8.2
Water	15.4

Uranite occurs in veins in the mines of Cornwall, and in Saxony and France: it is generally accompanied with the ores of iron.

The pulverulent uranite is called by the Germans *uran-ochre*. Indurated *uran-ochre* also occurs with the other ores of uranite, either massive or disseminated; the colour is the same as the pulverulent. It is soft and brittle; the specific gravity is 3.15. According to *Klaproth*, the yellow varieties are pure oxyd of uranium; but the brownish and reddish contain a little iron.

URANOPOLIS, in *Ancient Geography*, a town of *Asia*, in *Pamphylia*, and in the country called *Carbalia*. *Ptolemy*.—Also, a town of *Macedonia*, in the *Chalcide*; situated on *mount Athos*, near the southern side, and the promontories *Nymphæum* and *Auvathon*. *Pliny*. *Athenæus* says, that this town was founded by *Alexarchus*, the brother of *Cassander*, king of *Macedonia*.—Also, an epithet given by *Athenæus* to the city of *Rome*.

URANOSCOPUS, in *Ichthyology*, the name of a fish, called in *English* the *star-gazer*; and by some authors, *calionymus*.

The *uranoscopus*, in the *Linnean system*, is a genus of the order of *Jugulares*: its characters are, that the head is depressed, rough, and large; the mouth has the upper jaw shorter than the lower; the branchiostege membrane has five rays, and is covered with small eminences like teeth; the opercula are membranous and ciliated; the anus is in the middle of the body. *Gmelin* mentions two species: viz. *scaber*, or *star-gazer*, with bearded lips and smooth back. It is usually caught about seven or eight inches in length, but sometimes it grows to a foot; its head is very large, of a sort of square figure, covered by a strong bony case, roughened by an infinite number of small crests or protuberances; each side of this case is terminated above by two spines, the under part has five spines smaller than those above. Its mouth is large, and opens perpendicularly downward, being placed in the same direction with the eyes in the upper part of the head; the tongue is thick, short, and roughened with a number of small teeth; under its chin is a beard or long cirrus extending to some distance beyond the lips; its eyes are small and prominent, and are so placed near each other in the upper part of its head, as naturally to look up to the heavens, whence it has its name; and though many of the flat fish have their eyes placed like those of this fish, yet the pupils in these are directed sideways, whereas in this only they are turned straight upward; the body is of a squarish form as far as the vent, and then it becomes cylindrical: it is covered with small scales, and marked near the back by a lateral line, composed of small pores or points bending from the neck to the pectoral fins on each side, and from thence in a straight line to the tail: on the back are two fins, the first being much shorter than the latter, and furnished with stronger spines; the pectoral fins are large, with soft rays; the ventral fins are small; the tail is of moderate

derate size, and rounded at the end; the colour of the body is brown, with a whitish or silvery cast towards the abdomen; the head, pectoral fins, and tail having a strong ferruginous cast, and the first dorsal fin being marked towards its hind part by a large black spot.

The star-gazer is an inhabitant of the Mediterranean and Northern seas, frequenting chiefly the shallow parts near the shores, and concealing itself in the mud, with the top of its head only exposed: in this situation it waves the beads of the lips, and particularly the long cirrus of the mouth, in various directions, thus alluring the smaller fishes and marine insects that are near, who mistaking these organs for worms, are instantly seized by their concealed enemy. As an article of food it is coarse, and of an ill flavour: the gill was anciently considered as peculiarly efficacious in external disorders of the eyes.

The reason of the situation of the eyes of the uranoscopus, is the providence of nature for a fish, which, always keeping at the bottom, has no where to look for prey but in the water above it. But if other fish had been well examined, this peculiar name would never have been given to this. The eyes of the *rana piscatrix* are placed in the same manner, and those of a great number of other fish, whose custom it is to keep at the bottom, are more or less also thus situated. Gesner. Gmelin. Shaw.

JAPONICUS. With the back roughened by a semi-range of spinous scales. Found in the sea encompassing Japan. This is above yellow, and underneath white.

URANUGRATZ, in *Geography*, a town of Croatia; 18 miles N.N.W. of Novi.

URANUS, in *Mythology*, the great divinity of the Phœnicians. According to Sanchoniathon, he was the son of Elion, called Hypsitus, who lived in the neighbourhood of Byblos, by his wife Beruth. These had a son, first called Epigeus, and afterwards Uranus, and a daughter named Gé. The names of these two children the Greeks have given to heaven and earth. Hypsitus, having died at a hunting-match, was advanced to divine honours, and had sacrifices and libations offered to him. Uranus took possession of his father's throne, and having married his sister Gé, had several children by her. Uranus, as the fabulous history relates, was expelled from the throne by his son Chronus, on account of the offence given to his mother Gé by his infidelity, who succeeded to his power. According to the theogony of the Atlantids, who lived in the western parts of Africa, preserved by Diodorus Siculus, Uranus, or Coelus, was their first king, and brought his subjects, who had before his time wandered about without any fixed residence, to live in society, and to cultivate the ground. He also studied astronomy, and regulated the year by the course of the sun, and the months by that of the moon; and by calculating the motions of the heavenly bodies, he delivered predictions, the accomplishment of which astonished the Atlantids to such a degree, that they thought him divine, and after his death enrolled him among the gods. Uranus had by his several wives forty-five children, and by Titæa alone eighteen, whence sprang the appellation of Titans. See TITANS.

VRASA, in *Geography*, a town of Sweden, in the province of Smaland; 16 miles S. of Wexio.

URATOOR, a town of Hindoostan, in the circar of Cuddapa; 14 miles W. of Cuddapa.

VRAZZA, a town of Bulgaria, on the Eker; 24 miles N.E. of Sophia.

URBAIN, St., a town of France, in the department of the Upper Marne; 3 miles S.E. of Joinville.

URBAN I., *Pope*, in *Biography*, succeeded Calixtus I. A.D. 223, and occupied the pontifical chair till the year

230, when, as it is said, he was beheaded under the emperor Alexander Severus; so that the Roman senate has ranked him in the number of its martyrs. Bower.

URBAN II., *Pope*, named *Otho*, or *Eudes*, was born, as it has been generally thought, at Chatillon-sur-Marne, and educated under Bruno, founder of the Carthusian order; and devoting himself to a monastic life in the monastery of Cluny, became abbot of that institution. Being called to Rome, in 1078, by pope Gregory VII., he was made cardinal and bishop of Ostia; and in 1088, after the death of pope Victor III. in 1087, the Romans unanimously elected him as his successor, when he assumed the name of Urban II. He was no less proud and arrogant than his patron Gregory, with less fortune, but greater temerity. In the second year of his pontificate he assembled a council at Rome, which excommunicated the anti-pope Guibert, together with Henry IV., of Germany, by whom he was supported, and all his adherents. He also held another council at Melfi, in Apulia, which confirmed the decrees of Gregory against lay investitures and the marriage of the clergy. The pope, in order to counteract the power of the emperor, promoted a marriage between Guelph, duke of Bavaria, and the countess Matilda; upon which Henry marched into Italy, and having reduced Mantua, and other places, recalled Guibert to Rome, and put him in possession of the Lateran palace, when the emperor's progress was checked by the revolt of his son Conrad: under the instigation or approbation of Urban, Guibert was expelled, and Urban returned to Rome in 1093. In the year 1095, a council was held at Placentia, to which a solemn embassy was sent by Alexius Comnenus, emperor of Constantinople, the object of which was to state the oppressions of the infidels, and to request assistance on behalf of the Christians of the East. The pope and several great lords interested themselves in their cause, and proposed personally and otherwise to afford them succour. At this council, the doctrine of transubstantiation was asserted; the marriage of the clergy was rigorously prohibited; and Guibert and his partisans were again anathematized. After an interview between Conrad and the pope, he was recognized as king of Italy, on the condition of an oath of allegiance to the apostolic see. In 1095 Urban visited France, and held a council at Claremont, the first business of which was the excommunication of king Philip, for refusing to part with Bertrade, who had been his mistress, and whom he had married, after having repudiated his queen Bertha. Among other canons passed by this council, one forbade a bishop or priest to promise fidelity to a king or any layman. The "Treuga Dei" (see TRUCE of God) was strongly enforced, and all former decrees relating to it were confirmed. But this council rendered itself peculiarly famous, by first introducing the project of crusades. (See CROISADE.) During Urban's abode in France, he held other councils; and in one of them absolved Philip, who had dismissed Bertrade; and he returned to Italy in 1096. At Salerno he had an interview, in 1098, with Roger, duke of Sicily, when he is supposed to have granted the bull of the "Monarchy of Sicily," in consequence of which, the sovereign of Sicily is supreme head of the church in his dominions. Although the authenticity of this bull has been disputed, the powers confirmed by it have been occasionally exercised ever since that period. This pope took part with Anselm, archbishop of Canterbury, and the other English clergy, against William Rufus, who had made free with their temporalities, and threatened the king with excommunication. In the year 1099, the second crusade took place, in which Jerusalem was captured; but Urban did not live to receive this agreeable intelligence; for he terminated a busy pontificate

cate of eleven years and above four months, at Rome, in July of this year. Over his tomb in the Vatican was placed this inscription: "Urbanus II. Auctor Expeditionis in Infideles." Miracles have been ascribed to Urban by the monkish orders; but they have not been sanctioned by the Roman church. Several of his letters, and of the decrees of councils convened by him, are extant. Bower. Mosheim.

URBAN III., *Pope*, was elected to the pontificate on the decease of Lucius III., in December 1184. Several disputes were excited between him and the emperor Frederic Barbarossa, which occasioned his menace to excommunicate the emperor; but Barbarossa appealed to an assembly of prelates and princes in Germany in vindication of his rights, and they wrote a letter to the pope on the subject of complaint. Such was his indignation, that he threatened to fulfilment his sentence at Verona, but the inhabitants of that city would not permit it. Soon after he is said to have died of grief, upon hearing of the capture of Jerusalem by Saladin, in 1187. Bower.

URBAN IV., *Pope*, named *Pantalon*, was born of mean parentage at Troyes, in Champagne, studied at Paris, and rose through several gradations of preferment to the papal chair, on the death of Alexander IV., in 1261. At two promotions of cardinals, he is said to have created fourteen, who did honour to his choice. Manfred, who usurped the crown of Sicily, was excommunicated for refusing to obey his summons to Rome, and a crusade was also preached against him. Afterwards disturbances occurred in the city, which caused the pope to retire to Orvieto, where he resided with his cardinals during the greatest part of his pontificate. He made an unsuccessful attempt, by the interference of his authoritative counsel, to terminate the war which raged in Germany on account of a competition for the empire: and having failed in his negotiation with Manfred, he offered the kingdom to Charles of Anjou, brother of king Louis IX., by whom it was accepted; but before he was informed of the result, he died at Perugia, in October 1264. This pope instituted the festival of "Corpus Christi," in honour of the holy sacrament, by a bull dated in 1264. The sanctity of his manners, and his liberality to the poor, have been recorded to his honour; and Tiraboschi produces evidence of his having been an encourager of philosophical studies; and the mathematician Campano compliments him with being the patron and associate of men of learning. He is said to have laid his injunctions on the famous Thomas Aquinas, to write commentaries on Aristotle. His own epistles that are extant are of little or no importance. Dupin. Bower.

URBAN V., *Pope*, was at an early age a Benedictine, and studied civil and canon law at Montpellier, of which he became a professor in that university, and at Avignon, Toulouse, and Paris. After some subordinate promotions, he succeeded Innocent VI. in the papal chair, A.D. 1362. At the commencement of his pontificate he was visited by three sovereigns; one of whom, *viz.* Lusignan, king of Cyprus, solicited his assistance against the Turks, who threatened to invade his dominions. In compliance with this request, the pope engaged the other two kings, *viz.* John of France, and Waldemar of Denmark, to engage in a crusade for that purpose; but the design was rendered abortive by the death of the French king. In 1365, the emperor Charles IV. visited the pope at Avignon, which was then the seat of the papal see; but soon afterwards the pontiff was invited to Rome, and to make that city, which was his proper capital, the place of his abode. Accordingly, on the last day of April, 1367, he set out on his journey, and in October made his solemn entry into Rome. In the following year he was visited by Charles, who accompanied him from Viterbo,

on his second entrance into Rome, walking by his side, and holding his stirrup from the Colline gate to St. Peter's. He was also honoured by the visit of another emperor, John Palæologus, of Constantinople, who professed every article of faith held by the Roman church, acknowledging its primacy, and swearing perpetual obedience. This victory over the Greek church was highly gratifying to the pope. At this time Urban announced, to the surprize and disappointment of the Italians, his intention of returning to Avignon. Various attempts were made to dissuade him from accomplishing his purpose; and St. Bridget, then famous for her revelations, predicted that if he undertook such a journey he would not be able to complete it. Notwithstanding every kind of opposition, he retained his purpose, and arrived at Avignon in September, 1370. But the termination of his life was approaching, and having made that kind of preparation for it which his religion enjoined, he resigned himself with composure and acquiescence, expiring December 19, 1370. This pope has been highly commended for his public and private virtues. He extirpated abuses, checked the ambition and restrained the avarice of aspiring ecclesiastics, and deviated from the example of other pontiffs, by raising only one relation, *viz.* his own brother, to the purple, and not permitting even his father, who lived to 100 years, to accept a pension from France. To the poor he was liberal, and in erecting public works munificent. He encouraged learning by founding universities, and he is said to have maintained 1000 students at his own charge. He reposed to its ancient splendour the university of Bologna, which service was highly extolled by Petrarch. Several of his letters have been published, and a volume of them exists in the Vatican library. Dupin. Moreri. Gen. Biog.

URBAN VI., *Pope*, was elected, if the expression may be used, by a conclave of cardinals, compelled by the populace of Rome to name and enthrone Bartolomeo Prignano, archbishop of Bari, who assumed the name of Urban VI., and who was then 60 years of age. He was born at Naples, and deemed to be an excellent civilian and canonist, and a person of great probity. He was exemplary in his attention to the forms of devotion, and singularly humble and modest in his demeanour. The cardinals apprehended that he would renounce an election that had been the result of force; but this was far from being his intention. He began with reproving the cardinals for their culpable qualities, and with urging them to reform their conduct; and at the same time he ingratiated himself with the Roman people. The cardinals were incensed by the haughty spirit which he manifested, and determined upon making void his election. For this purpose they withdrew to Anagni, and from thence sent an admonition to Urban to resign a dignity to which he must be conscious he had no title. When they found that their admonition was unavailing, they proceeded to a new election, under the protection of a guard from Viterbo. At length, the ultramontane cardinals, being sixteen, whilst the Italian were no more than four, pronounced, in August 1378, a sentence of nullity against the election of Urban, and of excommunication against his person. The Italian cardinals afterwards joined them; and they concurred in choosing for a new pope cardinal Robert, brother of the count of Geneva, and allied to most of the royal houses of Europe. He assumed the name of Clement VII.

The countries of Europe were divided between these two popes: Urban being acknowledged in Italy and the greatest part of Germany, England, Portugal, Hungary, Poland, Denmark, Sweden, Prussia, and Norway; and Clement possessing France, Spain, Scotland, Sicily, Rhodes, and Cyprus.

Cyprus. Each of these claimants was adhered to and supported by men of learning and reputation. The former resided at Rome, and the latter at Avignon. We shall not detail the contests, no less disgraceful to the one than to the other, by which these competitors for ecclesiastical power and their respective adherents maintained their authority and influence. One of Urban's last acts was that of reducing the period of the Jubilee from every 50th to every 33d year. He closed a very unquiet pontificate of 11½ years, and a life of atrocious misconduct, in October 1389. Notwithstanding the apparent irregularity of his election, the church has fancioned it as canonical, enrolled him among the true popes, and referred his rival to the class of anti-popes.

Dupin. Bower.

URBAN VII., *Pope*, succeeded Sixtus V. in September, 1590, and died on the twelfth day of his pontificate. Bower.

URBAN VIII., *Pope*, named *Maffeo Barberini*, was born of a noble Florentine family in 1567, educated in Florence and the Jesuits' college in Rome, and graduated in law at Pisa. He was well acquainted with the Latin, Greek, and Hebrew languages, and became a prelate by powerful interest at the age of 19 years. Under the patronage of Clement VIII. he sustained many offices of distinction; was made cardinal by Paul V. in 1606, and elevated to the pontificate on the death of Gregory XV. in 1623. Immediately upon his elevation, he created two of his nephews cardinals, and conferred the title of eminence upon all of that order. On the death of the duke of Urbino, in 1632, he took possession of that duchy, as a fief of the holy see. Of the part which this pontiff took in the controversy that prevailed with respect to the doctrines of Janfenius, we have already given a brief account under the article JANSENIUM. Among his other pontifical acts we may mention his approbation of the order of the Visitation, and his suppression of that of the Jesuitesses. He also issued a bull for renewing the decrees of the council of Trent, and of other popes, which enjoined the residence of prelates on their sees. Having, at the instigation of his nephews, entered into a war with the duke of Parma, from whom he had ravished, in 1641, the duchy of Castro, as a forfeiture to the holy see, which he was afterwards obliged to restore, on condition of obtaining peace, he died in 1644, in the 77th year of his age, and the 21st of his pontificate. His character, excepting only the charge of nepotism, which he incurred in common with many other pontiffs, was upon the whole respectable. He was a scholar, and an encourager of literature. Of his poems a magnificent impression was published, during his life, at Paris, in 1642, under the title "Maphæi S.R.E. Carl. Barberini nunc Urbani VIII. Poemata." He also corrected and rendered more pure and elegant the Latin hymns used in divine service. Among other splendid buildings, which he caused to be erected in the capital, one was the palace of Palestrina, for the residence of a nephew, whom he made prince with that title. By stripping the brafs from the roof of the Pantheon, in order to decorate the altar of St. Peter's, he furnished occasion for the following piquinade: "Quod non fecere Barbari, fecere Barberini." His family he had so enriched, that he subjected them to a severe persecution in the subsequent pontificate. Dupin. Bower.

URBANIA, or *Castel Durante*, in *Geography*, a town of the Popedom, in the duchy of Urbino. This town owes its name to pope Urban VIII., who rebuilt it, and surrounded it with bastions. It is the see of a bishop, suffragan of Urbino; 7 miles S.S.W. of Urbino.

URBANNA, a town of Virginia, on the Rappahannock;

50 miles E.N.E. of Richmond. N. lat. 37° 40'. W. long. 76° 40'.

URBARA, in *Ancient Geography*, a town of Africa, in the interior of Mauritania Cæsaricnsis. Ptolemy.

URBATA, a town of Pannonia, upon the route from Sirmium to Salone, between Ciritha and Servium. Anton. Itin.

URBE, in *Geography*, a river which rises in the county of Waldeck, and runs into the Dimel, 5 miles W. of Warburg.

URBIACA, in *Ancient Geography*, a town of Hispania Citerior, at a small distance from mount Ubeda, towards the east, on a small river which ran towards Bilbilis; marked in Anton. Itin. between Valepunga and Albonica.

URBICARY PROVINCES. See SUBURBICARY.

URBICUS, in *Ancient Geography*, a river of Spain.

URBINATES, a people of Italy, in Umbria; of whom there were two classes, viz. the Metaurenfes, who inhabited the banks of the Metaurus; and the Hortenses, who inhabited the city of Urbinum, near the Flaminian way. The Urbinum Hortense, or town of gardens, was situated on a lofty hill, and had only a fountain to supply the whole town with water. The Urbinum of Metaurus lay south-east of the former, on a river from which it took its name. It was municipal.

URBINO, TIMOTEO DI, in *Biography*. See VITE.

URBINO, *Duchy of*, in *Geography*, a province of the Popedom, bounded on the north by Romagna, on the north-east by the Adriatic, on the south-east by the marquisate of Ancona, on the south by the Perugian, and on the west by Tuscany and Romagna. The air is reckoned unwholesome; one of the chief productions is silk; game and fish are plentiful. Urbino was formerly governed by its own dukes, of whom the last, Francis Maria, of Rovera, dying in the year 1631, without male issue, the pope took possession of his territory. The said duke had by will, in 1626, confirmed the pope's claims, and already, in effect, made over the country. Victoria, daughter of his son Ubaldi, and spouse to Ferdinand II. great duke of Tuscany, inherited the allodial estates; and hence it is that Poggio Impériale, and other places in this country, belonged to the duke of Tuscany. In the year 1764, the pope purchased the rights claimed by the duke of Tuscany. During the French revolution it was transferred to the kingdom of Italy.

URBINO, a city of the Popedom, and capital of a duchy of the same name, near the head of the Foglio, the see of an archbishop, and residence of a legate. It is situated on a hill, at the union of two rivers. The university or academy is one of the most ancient in Italy. It contains a noble college, and 16 convents. The ducal palace, which at present belongs to the pope, was built by duke Frederic, who furnished it with many ancient statues of marble and bronze, excellent paintings, and a library of curious and rare books. The library was conveyed to Rome by pope Alexander VII. In the churches are seen some works of the celebrated painters Raphael and Frederic Barocci; as likewise of Genga, Vincent St. Gemignano, and Timotheus d'Urbino, pupils of Raphael. Raphael was a native of Urbino; 54 miles E. of Florence. N. lat. 43° 48'. E. long. 12° 32'.

URBI-SAGLIA, a town of the marquisate of Ancona; 5 miles S. of Macerata.

URBS. See KEFF.

URNS, in *Ancient Geography*, a river of Italy, in Liguria. —Also, a forest of Italy, in Liguria, near the fore-mentioned river.

URBS *Sclavia*, a town of Italy, in the interior of Picenum, on this side of the Apennines. Ptolemy.

URBS *Vetus, Oroietta*, a town of Italy, in Etruria, on the river Clanis.

URCAS, in *Geography*, rocks near the coast of Brazil. S. lat. 4° 50'. W. long. 35° 44'.

URCEO, ANTONIO, (CODRUS URCEUS, Lat.), in *Biography*, an eminent scholar, was born in 1446, at Rubiera, in the territory of Reggio, in Lombardy; and having been educated at Bologna, and under the famous Guarini at Ferrara, he became, in his 23d year, a teacher of the classics at Forli. At Forli he had for one of his pupils the son of Pino, lord of that place, who having once politely recommended himself to Urceo, the latter jocosely replied, "Good God! how well things go with us! Jupiter recommends himself to Codrus;" referring to the name of a poet in Juvenal, whose poverty was proverbial. From this circumstance he obtained the appellation of Codrus. The loss of some written paper, and of an opera entitled "Pastor," by fire, roused his passion to such a degree, that he vented his rage by uttering the most horrid blasphemies, and hurrying into a wood near the city, where he remained a whole day without food. Upon his return the gates were shut, and he was obliged to pass the night upon a dunghill. In the morning he repaired to the house of a carpenter, and remained there in a state of melancholy for six months; but he afterwards resumed his occupations till the death of Pino. Upon this event disturbances occurred in the city, which occasioned him, after a residence of 13 years, to remove to Bologna, where he taught grammar and eloquence with great applause. His disregard of religion, however, and the freedom with which he expressed his doubts concerning a future state, rendered it necessary for him to engage the protection of the most reputable citizens. Notwithstanding the scepticism and irreligion of his life, he had recourse, at his death, to the sacraments of the church, which he received with tokens of deep contrition. He died in the year 1500, much regretted by his disciples, who carried his remains to the place of interment. His distinguished reputation, as one of the most learned Greek and Latin scholars in his time, has been testified by his contemporaries, and particularly by Angelo Poliziano and Aldo Manuzio. His works, consisting of Latin letters, orations, and poems, and of a supplement to the "Aulularia" of Plautus, were published at Bologna in 1502, and have been often reprinted; but they are thought inadequate to the reputation which he had acquired during his life. Moreri. Bayle. Gen. Biog.

URCEOLARIA, in *Botany*, a genus of the tribe of LICHENES, (see that article,) established and named by Acharius, from *urceolus*, a little pitcher, in allusion to the form of the shields, sunk, like little depressed cups, deep into the substance of the crust.—Achar. Prodr. 30. Meth. 141. "Lichenogr. 74. t. 6. f. 8, 9. 11." Syn. 137. Sm. Prodr. Fl. Græc. Sibth. v. 2. 305.—Clas and order, *Cryptogamia Alga. Nat. Ord. Alga. Lichenes.*

Ess. Ch. Receptacles shield-like, concave, coloured, smooth, sunk in the crust; their surrounding margin elevated, sessile, of the colour and substance of the crust.

Acharius remarks, in his *Methodus* above cited, that the present genus is, as it were, intermediate between his *Lecidea* and *Parmelia*, being distinguished from both by the uniformly concave, as well as sunk, shields, which moreover are most frequently furnished with a proper, as well as accessory, margin. The former indeed, never present in *Parmelia*, is not very evident in *Urceolaria*, being small, and of the same colour as the disk: the latter, never observable in

Lecidea, is in *Urceolaria* an annular elevation of the substance of the crust, overtopping the margin of the shield.

Twenty species are defined in the *Synopsis* of Acharius, whose synonyms appear, in some instances, not correctly applied; but we are well aware of the great ambiguity attending the plants in question, and shall propose our doubts with caution. Few of these species are known in England, most of them being either of Swifs or Lapland origin. They frequently grow on hard stones, that are occasionally inundated, or on naked exposed rocks; sometimes on the bark of trees. They are, for the most part, of small dimensions, and of rather inconspicuous appearance. We select the most remarkable.

U. *Acharii*. Acharian *Urceolaria*. Ach. Syn. n. 1. Meth. 150. (Lichen *Acharii*; Ach. Prodr. 33. with a figure in the title-page. Engl. Bot. t. 1087. L. *lacustris*; With. v. 4. 21. t. 31. f. 4.)—Crust limited, smooth, a little cracked, pale brick-coloured. Shields red; accessory border tumid.—Found on large stones, of the hardest kinds, that border alpine lakes or rivulets, in Sweden, Wales, &c. and are inundated in winter. Mr. Griffith first noticed this species in Britain, and the name *lacustris*, under which it appeared in Dr. Withering's work, is so very excellent, that nothing but the claims of our illustrious friend Acharius could induce us to resign it. The *crust* looks like an ochraceous sediment from the water, but is hard and firm, inseparable from the rock, smooth and even, as if partly polished, or rubbed down, becoming cracked with age. Its colour is a pale yellowish-brown, rarely a dirty white. Shields small, variously scattered, of the diameter of a small pin's head, concave, sunk, of a deeper redder hue than the crust, surrounded at first by a pale elevated border from the crust, which subsequently disappears, probably from the smoothing action of the water. Dr. Acharius gives, as a variety of this, the *Lecanora cyrtopsis* of his *Lichenographia*, p. 397, for which he quotes *Lichen punctatus*, Engl. Bot. t. 450. We cannot conceive the latter to be an *Urceolaria*, or to be even allied to the species before us. It seems a *Parmelia*, whose crust is white or greenish, not reddish, nor is the disk of the shields concave, nor bordered. Though greenish, or brown when young, that part is finally black. We do not mean to insist on the synonym of *Fl. Dan. t. 468. f. 2.*

U. *diamarta*. Red and black *Urceolaria*. Ach. Syn. n. 2. Meth. 151. ("Lichen *diamartus*; Wahlb. Lapp. 414.")—"Crust somewhat limited, cracked, rather warty, of an ochrey-red. Disk of the shields rather convex, black; accessory margin elevated, finally zigzag."—On rocks near the shore of the gulf of Bothnia. Dr. Acharius declares this to be a widely different species from *Endocarpon sinopicum*, with which he says, "it seems to be confounded in Engl. Bot." At p. 1776 of that work we have, indeed, mentioned a suggestion of Mr. Turner's, that these two plants may probably prove one and the same. But we presume there is no error or confusion in the figure and description annexed of our *Lichen sinopicus*, which we found to agree with Mr. Wahlberg's original specimen of his *Endocarpon* so called. Of the *Urceolaria* in question, we have never seen a specimen, unless it be *Lichen Oederi* of Dickson, as hinted by Acharius in his *Methodus*, 152; but this is not given as a synonym in the *Synopsis*.

U. *gibbosa*. Tumid *Urceolaria*. Ach. Syn. n. 7. Meth. 144. excluding the syn. of Bellardi and Villars. (U. *fimbriata*; Ach. Meth. 145. Lichen *fibrosus*; Engl. Bot. t. 1732.)—Crust covered with papillary warts, smoothish, of a light smoky brown; the edge more or less fibrous. Shields in the summit of each wart, concave, blackish; accessory

effery margin elevated, contracted, pale, minutely crenate.—Found on exposed rocks and stones, in various parts of Europe. On the smooth flints scattered over the downs of Suffex this species appears in its greatest perfection; sometimes having a fine radiating marginal fringe, by which the crust extends itself; the central part being occupied, frequently to the breadth of two or three inches, with crowded, angular, elevated, convex warts, of a grey or brownish hue. These are less distinct, and more polished, towards the circumference, where they vanish into a thin, dilated, inseparable border, often more granulated than fibrous, except where the flint is broken and polished. Each of the perfect warts bears one, rarely more than one, small, irregular, concave *shield*, whose disk is blackish, somewhat glaucous, internally reddish-brown, encompassed by a pale, roughish, raised margin, which looks as if it had become visible by rubbing. When the plant has its fringed edge, it is the *U. fimbriata* of Acharius, now justly reduced by that intelligent author to his own *gibbosa*.

U. cinerea. Ash-coloured Urcularia. Ach. Syn. n. 11. Meth. 143. (Lichen cinereus; Linn. Mant. 132. Westring Lich. v. 1. 247. t. 18. Ach. Prodr. 32. Verrucaria ocellata; Hoffm. Pl. Lich. v. 1. 92. t. 20. f. 2.)—Crust grey, rugged and cracked, with a black border. Shields black, sunk, slightly concave; at length elevated along with their prominent, thickish, entire, accessory margins.—Common on large stones, rocks, and scattered flints. Few Lichens have been less understood, nor would Linnaeus's specific name have been changed, probably, if botanists had been able to ascertain, with any certainty, what he intended by it. His herbarium gives no information on this subject; but we rely with confidence on the tradition of his Swedish pupils. The general appearance of this species is like a bad imperfect state of Hudson's *Lichen ater*, but the latter is not an Urcularia. The *crust* is thin and inseparable; its edge, when crowded and condensed, narrow and black; but when allowed to spread on smooth flints, it is more dilated, zoned, and greenish, not fibrous. The central part swells into small, irregular, grey knobs, and at length cracks. The copious *shields* are either solitary or clustered, small, black, with the decided accessory border of this genus, growing more and more above the common level. According to the experiments of Mr. Westring, this species affords very fine rich shades of orange, or red-brown, for dyeing silk. Acharius indicates four varieties, chiefly described by himself, which we have had no opportunity of comparing.

U. seruposa. Powdery Spherical Urcularia. Ach. Syn. n. 13. Meth. 147. (Lichen seruposus; Schreb. Lich. 133. Hoffm. Enum. 41. t. 6. f. 1. Dickl. Crypt. fasc. 1. 11. Engl. Bot. t. 266. Lichenoides crustaceum et leprosum, scutellis nigricantibus majoribus et minoribus, varietas β ; Dill. Musc. 133. t. 18. f. 15. β . Patellaria seruposa; Hoffm. Pl. Lich. v. 1. 54. t. 11. f. 2.)—Crust corrugated, greyish-white, granulated, mealy. Shields nearly spherical, black, with a tumid, inflexed, narrow-mouthed, finely crenate accessory border.—Frequent on dry chalky heaths, and on brick walls, sometimes on rocks, or spreading over decayed mosses. The *crust* is thick and chalky, mostly cream-coloured, or greyish; very white when dry, almost covered with the crowded globular warts, each of which lodges a blackish, or slightly glaucous, hollow *shield*, of the same shape. *Lichen impressus*, Ach. Prodr. 104. (Patellaria muscorum; Hoffm. Pl. Lich. v. 1. 93. t. 21. f. 1.) is acknowledged to be a variety of this, whose crust assumes a leafy appearance from other plants which it overruns.

VOL. XXXVII.

U. diacapsis, Ach. Syn. n. 15. (Lichen diacapsis; Engl. Bot. t. 1954.) is surely a *Lecidea* of Acharius, having nothing of an accessory border to the shields.

U. calcarea. Chalky Urcularia. Ach. Syn. n. 16. Meth. 142. t. 4. f. 1. (Lichen calcareus; Linn. Fl. Suec. ed. 2. 407. L. cinereus; Engl. Bot. t. 820. Verrucaria contorta; Hoffm. Pl. Lich. v. 1. 97. t. 22. f. 1—4.)—Crust limited, finely cracked, somewhat powdery, very white; at length greyish. Shields minute, irregular, concave, greyish-black, with a thin edge, and a slightly prominent accessory border.—Found on calcareous rocks and wrought stones. The plant of English Botany forms broad conspicuous inseparable patches, on grey-marble tomb-stones, in the country church-yards of Norfolk and Suffolk. Dr. Acharius determines it to be the *Lichen calcareus* of Linnaeus, to whose description and remarks it well answers, especially where he says that it is a sure indication of calcareous stones, and proves very troublesome to the decipherers of runic inscriptions. The *crust* is extremely hard and solid. The form of the *shields* is scarcely ever exactly circular. Whether *U. Hoffmanni*, Ach. Meth. 145, *Lichen rupicola*, Hoffm. Enum. 23. t. 6. f. 3, be the same species, or whether the eight other varieties, adopted by Acharius chiefly from Florke in the Berlin Magazine for 1811, belong to it, we are equally, at least, in doubt with himself. *Patellaria multipuncta*, Hoffm. Pl. Lich. t. 63. f. 1—3, we now agree with Acharius in separating from the present species. He makes it a variety of *Lecidea albo-carulefens*, Ach. Syn. 29, which is Dickson's *Lichen pruinatus*; but we presume here to express our doubts.

U. compuncta. Many-dotted Urcularia. Sm. in Ach. Meth. 143. Syn. n. 19.—Crust continued, very thin, smooth, greyish-white. Shields numerous, crowded, minute, concave, black, white-edged, with a tumid accessory border.—Found by the late Mr. Christ. Smith, on the bark of trees in Amboyna. The *crust* appears to be divided into tessellated portions, but these are rather cracks in the bark, to which its thin uninterrupted substance exactly conforms. Each portion contains innumerable cavities, as if made with the point of a needle, every one of which lodges a minute blackish hollow disk, whose proper margin, unconnected with the accessory one, is contracted, and very pale, almost white. We can assure our worthy friend Acharius, who has relied on the writer of this for the present curious species, that, notwithstanding his doubts, nothing can be more unlike *U. calcarea*.

U. esculenta. Eatable Urcularia. Ach. Syn. n. 20.—“Crust tartareous, thick, rugged and warty, greyish. Receptacles wart-like, with a hollow disk.”—Native of the chalky hills, of the deserts of Tartary. The *crust* is eatable! Acharius appears never to have seen a specimen, and he is not certain of the genus. He quotes no authority.

URCEOLUS, in *Eccllesiastical Writers*. See AQUÆ-MANILIS.

URCEOLUS, in *Mythology*, a small vase of brass, silver, earth, or some other material, which had a straight neck, and wide mouth, much after the fashion of the burettes, or crystal bottles in which they put the wine and water used in the sacrifice of the mass, which the inferior ministers carried for washing the priest's hands. They are often to be found upon antique monuments, in the hands of their ministers.

URCESA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Celtiberi.

URCEUS, in *Antiquity*, the name of a measure of liquids, which in different places was of different capacity; its most

usual standard seems to have been between twelve and sixteen ounces.

URCHIN, a common name given to the hedge-hog.

URCHIN, *Sea*, in *Ichthyology*. The *echinus marinus* of authors is, in some parts of England, called the *sea-egg*, and in others the *sea-urchin*, or *hedge-hog*. It is a genus of fish, of which there are a great number of species. See ECHINODERMA, and CENTRONIA.

The manner of these creatures moving at the bottom of the sea has been disputed among naturalists; the general opinion of the world has been, that they did it by means of their spines or prickles, which served them by way of legs; but some of late, particularly Mr. Gandolphe, pretend that the spines of the urchins are of no use to them on this occasion, but that they move by means of certain legs, like the legs of the star-fish, which they occasionally put out when they walk, and at other times retract them into their body. The world was readily falling into this system, particularly as Mr. Gandolphe affirmed, that he had been often an eye-witness to it; but the indefatigable M. Reaumur tried the experiment himself, and often made himself an eye-witness of the contrary fact, having frequently seen them walk at the bottom of a shallow basin of sea-water, with no other assistance than that of their spines, and even having made them perform the same motion, by the same means, upon his hand.

This curious inquirer into nature did not, however, stop here; but took occasion from hence to inquire accurately into every circumstance of their progression, which is performed by so uncommon means.

It is certain that the sea-urchin does throw out at the lower aperture of the shell, when it pleases, certain bodies which resemble not a little the legs of star-fish; but these serve not at all to its motion; but, on the contrary, their real use is to keep the creature still, and fixed in the same position; and, to describe them more exactly, they very aptly resemble the horns of snails; whence M. Reaumur has chosen rather to call them horns than legs. The use the urchin makes of these horns, while it is in motion, is to feel about, and try the ground on which it marches; and they serve the creature as a staff does a blind man in his walking, to touch and try every thing that lies in the way; and to make them serve to this purpose, it is continually extending or retracting them during the time it is moving. These horns are not only placed about the orifice of the shell, but they are every where dispersed among the spines, all over the surface of the shell.

In order to understand the position of these horns, we must consider, that the sea-urchin shell is a hard body, approaching in form to that of a segment of a sphere, with two apertures, one commonly at the summit of the shell, and another opposite to it at the base: the former hole serves, as it is supposed, for discharging the excrement, and the latter for the mouth of the animal. The whole external surface is divided by protuberances, of different sizes, into ten spherical isosceles triangles, which have their vertex at the upper aperture, and their base at the lower: five of these are large and five small; the larger are separated from the smaller by triangular bands pierced with small holes, arranged in a beautiful and regular order. The triangular spaces are divided by several lines, commencing at the upper aperture of the shell, and terminating at the lower; these lines are marked by sundry eminences of different sizes, each of which resembles a fort of nipple: on these parts the base of every spine is fixed, and as the base is hollow, it is able to turn round each eminence. Of these species M. Rea-

umur found more than two thousand on every fish; and the number of perforations on each shell is not less than thirteen hundred. From each of these perforations, there proceeds a horn, which horns are only visible when the fish is in the water, and even then it puts forth only some of them at once: these serve as anchors to the fish, because it glues them fast to the stones, &c.

The spines are all capable of assisting the creature in its motions, but those it principally employs are such as are placed near its mouth; as these can turn upon their balls every way with equal facility, the creature finds it equally easy to move on any side; and when it has determined which way it will move, those spines which stand directly toward that point, and those which are directly opposite, are of equal service to it; it draws itself forward by means of the first, and pushes itself on with the others; to do this, it first thrusts out the foremost ones as far as possible, and pressing them against the bottom, it draws on its body by them; and this is succeeded, by drawing up the hinder ones close to its shell, and then fixing them against the bottom, it pushes itself forward by them. This is the manner of this little creature's marching in the common way, with its mouth downward; but it has this strange singularity, that it is not confined to this posture alone in marching, but can, with equal ease, walk with its mouth upwards, or run along sideways in the manner of a wheel; or in any direction between these. The legs and the horns cover all parts of it, and are in every part of it equally able to move separately thirteen hundred horns, and more than two thousand spines, which serve for legs. Mem. Acad. Par. 1712.

URCI, in *Ancient Geography*, a town of Hispania, in Bætica, at the mouth of a river, on the frontiers of the Tarragonensis of Bætica.

URCINIUM, a town situated on the coast of the island of Corfica, between Rhiium Promontorium and Arenosum Littus. Ptolemy.

URCIZE, ST., in *Geography*, a town of France, in the department of the Cantal; 21 miles S. of St. Flour.

URCOS, a town of Peru, in the diocese of Cusco; 20 miles S. of Cusco.

URCUNAZO, a river of Spain, which runs into the Orio, in the province of Guipulcoa.

URDACHE, a town of Spain, in Navarre; 22 miles N. of Pamplona.

URDASIM, a river of Russia, which runs into the Ural, at Fort Tanalitzkaia.

URDASIMSKAIA, a fort of Russia, in the government of Upha; 128 miles E. of Orenburg.

URDE', or URDEE, in *Heraldry*. A cross urde seems to be the same with what we otherwise call *eleebée*.

URDIALA, in *Geography*, a town of Spain, in the province of Tavastland; 28 miles W. of Tavasthus.

URE, or YOURE, a river of England, in the county of York, which rises at and passes by Masham, Rippon, Boroughbridge, &c. and about two miles below the last town joins the Swale, and takes the name of Ouse.

URE, in *Rural Economy*, a provincial term sometimes applied to the udders of particular sorts of domestic animals, as those of cows, sheep, and some others. See UDDER.

UREA, or UREÆ. Fourcroy and Vauquelin gave this name to a principle contained in human urine, which, in combination with many others, Rouelle junior first pointed out so early as 1773; and the description of these celebrated chemists, and that of Mr. Cruickshanks, who examined it about the same time, have been generally adopted by succeeding writers, with one or two exceptions only, even to the

the present time. Berzelius appears to have been the first who obtained it in a separate state, but the account he has given of it does not seem to have much attracted the attention of chemists, for the more recent description of it by Thenard is much less correct. M. Vauquelin is said to have procured it very lately in the pure state in which we are about to describe it, which description we adopt from Dr. Prout, who has just published an account of this singular principle in the Transactions of the Medico-chirurgical Society of London.

To obtain urea in any quantity is no easy task. This arises from the care with which it is decomposed, and the obstinacy with which the colouring matter, and other urinary principles, adhere to it. Dr. Prout recommends that urine should be carefully evaporated to the consistence of a syrup; that nitric acid should be slowly added to it in this state, which combines with the urea, and thus separates it from many other principles. The nitrate of urea is then to be decomposed by carbonate of potash, and after the nitre formed has been separated by crystallization, animal charcoal is recommended to be added to the coloured solution of urea, which separates most of the colouring matters: lastly, the solution of urea is again ordered to be evaporated to dryness, and heated with strong alcohol and heat; the alcoholic solution thus formed is then to be concentrated by evaporation, and on cooling the urea separates from it in a pure crystalline state. Thus obtained, urea has the following properties:

“Urea most frequently assumes the form of a four-sided prism. Its crystals are transparent and colourless, and have a slight pearly lustre. It leaves a sensation of coolness on the tongue like nitre. Its smell is faint and peculiar, but not urinous. It does not affect litmus or turmeric papers. It undergoes no apparent change on exposure to the air, except in very damp weather, when it slightly deliquesces, but does not seem to suffer decomposition. Exposed to a strong heat it melts, and is partly decomposed and partly sublimed apparently unaltered. The specific gravity of its crystals is about 1.350.

“Water at 60° dissolves more than its own weight of urea, and the solution exposed to the air for several months underwent no change. Boiling water dissolves any quantity of it whatever, and the urea does not appear to undergo any change at this degree of temperature.

“Alcohol (sp. gr. .816) at a mean temperature dissolves about 20 per cent., and at a boiling temperature more than its own weight, and the urea separates on cooling in the form of crystals. It is very sparingly if at all soluble in sulphuric ether, or the essential oil of turpentine, though these fluids are rendered opaque by it.

“The pure alkalies and alkaline earths decompose it, especially when assisted by heat, and the result is chiefly carbonate of ammonia. It unites with most of the metallic oxids. The combination with silver is greyish, and detonates on being heated, and the silver is reduced. It does not seem however to be alone capable of decomposing any metallic salt, but in order to effect the union in question the aid of double decomposition is necessary.

“It combines with nitric acid, and forms a crystalline compound but sparingly soluble in water. It forms also a similar compound with oxalic acid. In neither of these compounds are the properties of the acids neutralized.”

Urea has the remarkable property of changing the crystalline forms of those salts with which it is in solution. Thus the cubical form of the muriate of soda is changed into an octohedron, while the octohedral form of the muriate of ammonia is converted into a cube. The prismatic form of

nitre also is liable to be variously modified. These changes do not appear to take place unless the urea be in excess in a solution, and the proportional quantities of the different salts be such as to crystallize slowly.

Urea submitted to analysis, by combustion with the oxyd of copper, was found to consist of

2 atoms or 2 volumes of hydrogen	2.5	} of	{	hydrogen	6.66
1 atom or 1 volume of carbon	7.5			carbon	19.99
1 atom or 1/2 volume of oxygen	10.0			oxygen	26.66
1 atom or 1 volume of azote	17.5			azote	46.66
	37.5			100.00	

The nitrate of urea, the crystalline compound before-mentioned, consists, according to Dr. Prout's analysis, of

Nitric acid	47.37	or one atom.
Urea	52.63	or two atoms.
	100.00	

Hence we are enabled, by means of this analysis, to estimate the quantity of urea in a given specimen of urine.

Urea sometimes exists so abundantly in urine, as to crystallize spontaneously on the addition of nitric acid. In such instances it is usually accompanied by an excess of the phosphates. A remarkable relation was found by Dr. Prout to subsist between urea and the saccharine principle, which, in his opinion, satisfactorily explains the phenomena of diabetes, a disease in which sugar is known to be present in the urine, in the proportion in which urea is absent. Another remarkable circumstance is, its composition being in conformity to the atomic theory, or theory of definite proportions. This however is not peculiar to urea, but was found by Dr. P. to hold good in other urinary principles. See URIC ACID.

URECOURT, in *Geography*, a town of France, in the department of the Volges; 6 miles N.N.W. of La Marche.

UREDEN, a town of Germany, in the bishopric of Munster, on the Berckel; 26 miles W.N.W. of Munster.

UREDIO, a word used by some of the chemical writers to express the virtues of metals communicated to them from the sun. Pliny uses the same word to express the smut affecting fruits; and some medical writers have expressed by it a very violent and excruciating pain in the head: and others an extreme itching or burning in the skin. See SMUT, BLAST, and BLIGHT.

UREDIO, in *Botany*, an old Latin name, from *uro*, to burn, or parch, applied to those occasional discolorations on the surfaces of plants, which were attributed to blasts, or injuries of the atmosphere or heavenly bodies, but which are now generally found to be parasitical *fungi*; at least such is the state of these appearances, when they come under our observation, whatever injury or disease, in the plant which bears them, may have favoured their production. The above name is now applied to one particular genus of this kind of vegetable.—Perf. Obs. Mycol. fasc. 2. 23. Syn. Fung. 214.—Clafs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Coat none. Powder naked, deciduous. Seeds uniform, generally globose.

Such is Perfoon's generic character, by which the difference between this genus and another of the same author's, named *Puccinia*, seems to be, that in the latter what he terms, with a mark of doubt, *Sporula*, seeds, are said to be clustered

UREDO.

clustered into little tufts, roundish, and somewhat turbinate, with a tail, or elongation at the base, and interrupted by internal partitions. What are analogous to these in *Uredo* are said to be "uniform, generally globose." This distinction is clear enough, but the denomination of the parts in question proves erroneous. This is evident from the elaborate investigation of the blight in wheat, by the right hon. sir Joseph Banks, illustrated by the microscopic drawings of Mr. Francis Bauer, republished in Sims and König's Ann. of Bot. v. 2. § 1. t. 3, 4. By this treatise, and indeed by Perfoon's own definition, it is manifest, that his *Sporule* are not seeds, but real seed-vessels, or *capsules*. Therefore the *Uredo frumenti*, Sowerby's Fung. t. 140. Lambert in Tr. of Linn. Soc. v. 4. 193. Kirby *ibid.* v. 5. 122, which was the subject of sir Joseph Banks's examination, and is the *Puccinia graminis* of Perfoon, Syn. Fung. 228, rather answers to the character of the genus *Liccia* in the same work, p. 195, given as follows: "Head distinct, roundish or somewhat indeterminate, brittle, without any sub-jacent membrane. Seminal powder destitute of threads." We know not what is meant, in Perfoon's generic character of *Uredo*, by the distinction between *pulsis*, powder, and *sporule*, seeds, nor whether the latter, if examined with equal care, might prove, as in the *Uredo frumenti*, to be *capsules*. The subject indeed is in its infancy. Mr. Bauer has long been collecting facts and appearances to illustrate it, which are registered in his inimitable drawings, but materials are not yet sufficiently plentiful to form therewith any systematic arrangement of these minute productions, in which the greatness of the Creator, and our own ignorance, have long been acknowledged. Nevertheless, we are obliged to those who have made any scientific attempt at defining this cryptogamic tribe, for present convenience, however imperfect such must necessarily be. In this light Perfoon shines conspicuous, and we shall extract what will best illustrate his genus *Uredo*. The subject is important in an agricultural view, some of these parasitical *fungi* being supposed, at least, to be very detrimental to the corn, or other plants, on which they grow. We are rather disposed to believe that the effect has generally been mistaken for the cause, and that an injury to the corn, from cold or wet, has merely disposed it to afford nourishment for the *fungi*. This, however, is a theoretical question, not necessarily connected with the botanical part of the subject.

Perfoon defines 30 species of *Uredo*, disposed in four sections, according to the colour of the apparent powder; whether that powder be naked seeds, or, as there is reason to suppose, from the above observations, a congeries of excessively minute *capsules*.

SECT. 1. *Powder yellowish*. RUBIGO; 16 species.

U. mycophila. Mushroom Blight. Perf. n. 1. (*Mucor chrysofermus*; Bulliard Fung. v. 1. 99. t. 504. f. 1, and t. 476. f. 4. With. v. 4. 402.)—Widely spreading, extremely fine, yellow; seeds solitary or aggregate, on capillary stalks, simple or branched.—Found covering the whole surface of several kinds of *Boletus*, which grow in shady places, and even penetrating their substance, in the form of an apparently impalpable yellow powder, staining the fingers when touched; in August and September, Dr. Withering says, it powerfully repels wet, like the seeds of a *Lycopodium*, a specimen in his possession not being moistened, though immersed in a fluid for a year. Perfoon remarks, that this species rarely occurs on any Agaric, and that the *Boleti* attacked with it are not fully expanded before they languish and rot, being at first involved in a white evanescent downiness, and then copiously impregnated with the above bright yellow powder, which Bulliard compares to the pollen of a lily.

U. Alchemilla. Ladies'-mantle Blight. Perf. n. 3. Obs. Mycol. fasc. 1. 98.—Crowded, yellow, breaking out into nearly parallel lines.—On the leaves of *Alchemilla vulgaris*, especially in mountainous situations; common in the Hartz forest. The leaves which bear this parasite are much smaller than usual. The powder is nearly orange-coloured, in ovate, elliptical, or more frequently linear spots, like the fructification of an *Asplenium*. Perfoon.

U. Euphorbia helioscopia. Spurge Blight. Perf. n. 4.—Scattered, nearly globular, prominent, yellow.—Frequent in summer on the plant mentioned, which when so occupied has always a pale sickly aspect; but whether in consequence of the presence of the fungus, or whether the latter attaches itself to weak plants only, we know not. The spots are various in size, deep yellow, prominent like warts. A smaller variety, more regular in shape, is found on *E. exigua*.

U. linearis. Long linear Blight. Perf. n. 7. (*U. longissima*; Sowerb. Fung. t. 139.)—Linear, parallel, very long, yellow, staining; at length of a darker hue.—Observed by Mr. Sowerby, on the leaves of *Poa aquatica*. Perfoon says, it is abundant in summer on the straw and leaves of barley, oats, and rye, but he suspects it may be the early stage of his *Puccinia graminis* above mentioned. If so, the epithet "staining" is not applicable. The same author indicates a smaller and paler variety, found rarely on the stalks of *Polypodium fragile* of Linnaeus.

U. Rubi fruticosi. Bramble Blight. Perf. n. 11.—Minute, nearly globular, powdery, bright yellow, deciduous.—On the leaves of brambles, not uncommon. Perfoon justly observes, that the powdery balls of this species are so slightly attached to the leaf, that, when a branch is gathered, they fly off, as it were elastically, if perfectly ripe.

U. Rubi Idae. Raspberry Blight. Perf. n. 12. Obs. Mycol. fasc. 2. 24.—Scattered, yellow, somewhat conical, breaking out in curved lines.—On the upper surface of raspberry leaves, towards the margin, where it forms curved crowded lines, resembling the receptacles of an umbilicated Lichen, *Gyrophora*, of a pale whitish hue. In an advanced state the powder is brownish.

U. Tufflaginis. Colt's-foot Blight. Perf. n. 13.—Scattered in somewhat concentric, reddish-orange, dots; at length confluent.—Common in autumn on the leaves of colt's-foot, which it finally covers with orange powder entangled among the pubescence. This often disappoints those who are searching for the equally common *Acidium Tufflaginis*, (*Lycoperdon epiphyllum* of Linnaeus,) found on the under side of colt's-foot leaves, in the form of orange dots, crowded together, each with its own white notched *volva*. But these two *fungi* are very distinct, though young botanists sometimes suppose one changes to the other.

SECT. 2. *Powder-brown, bay, chestnut, or somewhat blackish*. NIGREDO; 8 species.

U. Saurvolens. Sweet-scented Blight. Perf. n. 19. Obs. Mycol. fasc. 2. 24.—Confluent, fragrant, unequal. Powder pale brownish-purple.—Frequent in summer on the leaves of *Gnicus arvensis*, (*Serratula arvensis* Linn.) which, according to Perfoon, is thus rendered barren. The leaves attacked, at first assume a thickened or succulent appearance, marked with little blackish dots, or round tubercles, and exhale a pleasant scent. When the fungus arrives at maturity, a bright brown powder takes place of these tubercles, and spreads over the surface of the leaf.

U. Vicia Faba. Bean Blight. Perf. n. 20. Disp. Meth. Fung. 13.—Crowded, orbicular, or partly irregular, depressed. Powder brownish-chestnut.—Partly on the stem, and especially on the leaves, of the common bean.

U. bullata.

U. bullata. Tumid Blight. Perf. n. 22. Obs. Mycol. fasc. 1. 98. t. 2. f. 5, and t. 5. f. 9, b.—Prominent, bladdery. Powder chestnut-coloured. Seeds constricted in the middle.—Rarely met with, on the stems of umbelliferous plants. The cuticle on the stem is raised in the form of an ovate bladder, enclosing a tumid mass of orange-brown powder, each particle of which appears, under a very high magnifier, like the figure of 8, as if formed of two rounded lobes.

U. Anemones. Anemony Blight. Perf. n. 24. Disp. Meth. Fung. 56.—Rather large, depressed, bursting from a longitudinal fissure in the cuticle of the leaf. Powder copious, black.—Found in the spring, on curled leaves of *Anemone nemorosa*, in whose substance it is lodged.

SECT. 3. *Powder white*. ALBUGO; 2 species.

U. candida. Cream Blight.—Shapeliness, tumid, white. Frequent throughout the summer, on the branches and stalks of Shepherd's Purse, which appear greatly swollen, twisted, abounding with whitish fetid powder, which bursts irregularly through the shining cuticle. Perfoon thinks it grows along with his *Botrytis parasitica*, Obs. Mycol. fasc. 1. 97. t. 5. f. 6, a, b.—He notices two varieties, one found on different species of *Tragopogon* in summer, which is smaller and more depressed than the above, with less prominent powder; the other on *Alyssum calycinum*, smaller and roundish, though variable in shape.

U. Cbeiranthi. Stock Blight. Perf. n. 26.—Scattered, nearly globular, prominent, white.—Found rarely on the foliage of *Cbeiranthus incanus*. This, which we have never chanced to meet with, is described by Perfoon as consisting of small globular masses, half a line in breadth, each encompassed with the torn cuticle of the leaf. On account of this difference of form, he thought proper to distinguish the present species from all the varieties of the last.

SECT. 4. *Powder blackish or brown, parasitical on the parts of fructification of different plants*. USTILAGO; 4 species.

U. Segetum. Corn Blight, or Smut. Parth. n. 27. Bullard Fung. v. 1. 90. t. 472. f. 2.—Powder copious, black, produced within the glumes of grasses. This generally appears like a transformation of the substance of the seed, in whole ears of barley, wheat, or oats, or even *Agrostis*, into a fetid foamy powder, and constitutes the disease termed smut by farmers, concerning whose cause, and the means of prevention by keeping the seed-grain in lime-water, &c., so many various opinions have been held. See SMUT.

U. Caricis. Carex Blight. Perf. n. 28.—Powder black, naked, encompassing the seeds.—Found on the fruit of different species of *Carex*, as the *montana*, and more especially the *pisulifera*, on which last it is very frequent and copious.

U. Tragopogi pratensis. Goat's-beard Blight. Perf. n. 29. Disp. Meth. Fung. 57.—Powder copious, brownish-purple, on the receptacles of *Tragopogon*. This is not uncommon in summer, on the receptacle of the above plant, within its permanent calyx, and is the largest of the genus. Perfoon.

U. Violacea. Violet-coloured Blight. Perf. n. 30. (Farinaria Stellarisæ; Sowerb. Fung. t. 396. f. 1.)—Powder of a violet purple, in the anthers of flowers.—Very frequent in *Saponaria officinalis*, *Silene nutans*, *Stellaria graminea*, the white-flowered *Lycnis dioica*, and especially *Silene inflata* and *maritima* of Fl. Brit. The anthers of these flowers often swell prodigiously, and their natural contents are replaced by a great quantity of soft dull-purple powder, which stains the petals, and gives the flower the appearance of being sprinkled with something like foot. The impreg-

nation of such flowers fails, of course; but we do not observe them to be otherwise, as Perfoon declares, languid or sickly. Mr. Sowerby says, this fungus often bursts from the ripening gemmæ of *Stellaria graminea* and *S. borealis*; and that it occurs also in *Brennus mollis*, which we likewise have remarked, and some other grasses. Every anther of the same flower is thus affected. We are much prepossessed with the idea of this supposed fungus being a disease, originating in the constitution of the plant, and ending in a morbid secretion; but we must allow the opinion of Perfoon to be supported by analogy.

UREGUR, in *Geography*, a town of the island of Ceylon; 60 miles N.W. of Trinkomaly.

URELLYCONDA, a town of Hindoostan, in Mysore; 20 miles N. of Bangalore.

UREMA, in *Ancient Geography*, a town of Asia, in Syria, upon the banks of the Euphrates, near Aradus. Ptolemy.

URENA, in *Botany*, from the Malabar name *Uren*. This name, introduced by Dillenius, is allowed by Linnaeus, Phil. Bot. 164, among some others, which, though of barbarous origin, might, as he thought, be new-modelled, so as to prove not altogether intolerable. We must allow that the present is as little exceptionable in found as any barbarous name can well be.—Linn. Gen. 355. Schreb. 467. Willd. Sp. Pl. v. 3. 800. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 222. Dill. Elth. 430. Juss. 272. Cavan. Diss. 334. Lamarck Illustr. t. 583. Gertn. t. 135.—Clas and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferae*, Linn. *Malvaceæ*, Juss.

Gen. Ch. Cal. Perianth double, inferior. The outer of one leaf, in five broadish segments. Inner of five narrow, angular, permanent leaves. Cor. Petals five, oblong, broadest at the extremity, blunt with a point, narrowest at the base, which is attached to the tube of the stamens. Stam. Filaments numerous, united in their lower part into a cylindrical tube; separate above, below the top of the tube; anthers roundish. Pist. Germen superior, roundish, with five angles; style simple, the length of the stamens, divided into ten branches at the top, each tipped with a capitate, hairy, reflexed stigma. Peric. Capsule roundish, with five angles, prickly, of five cells, which finally separate from each other without bursting. Seeds solitary, roundish externally, compressed and angular at the opposite part.

Ess. Ch. Calyx double; the outermost five-cleft. Capsule of five cells, separating entire. Seeds solitary. We find much to correct, and something to add, in the discrimination of the species.

1. *U. lobata*. Angular-leaved Urena. Linn. Sp. Pl. 974. Willd. n. 1. Ait. n. 1. Cavan. Diss. 336. t. 185. f. 1. (*U. fmeica*, xanthii facie; Dill. Elth. 430. t. 319. Trifolio affinis, Indiæ orientalis, xanthii facie; Breyne. Cent. t. 35.)—Leaves roundish-heartshaped, angular, with three glands at the base underneath.—Native of China. A greenhouse shrub in our gardens, cultivated in the Chelsea and Eltham collections, about the year 1730, but not generally to be met with, being inferior in splendour to our Wild Mallow, common on every bank. The flowers of this *Urena* are nevertheless of a delicate peach-blossom hue, and though short-lived, lasting but a few hours, are produced in plentiful succession through the summer. The stem is two or three feet high, erect, not much branched. Leaves broader than long, toothed, slightly lobed, finely downy; paler, and rather hoary, beneath. Footstalks slender, round, downy, generally longer than the leaves. Flowers axillary, solitary, on short stalks, about the size of *Malva rotundifolia*. Capsules near half an inch in diameter, armed with prominent

prominent barbed prickles. We remark with regret, that the erroneous citation of Dillenius, 340 for 430, is copied without correction from Linnæus, by Cavanilles, Willdenow, and even in Hort. Kew., which proves that those authors did not consult the book cited, and therefore greatly weakens our confidence in their authority or judgment, as to critical synonymy, throughout.

2. *U. reticulata*. Reticulated Urena. Cavan. Diff. 335. t. 183. f. 2. Willd. n. 2.—Leaves with a foliary gland at the base beneath, reticulated; the lower ones three-lobed; upper oblong, somewhat fiddle-shaped.—Native of South America. Described by Cavanilles from Lamarck's herbarium. The stem is shrubby, a yard high, branched; the branches and footstalks somewhat downy. The leaves are green above; hoary with short down, and reticulated with veins, beneath: the lower ones on longish stalks, like the foregoing, large, deeply three-lobed, their middle lobe longest: the rest narrow and undivided, variously contracted, on short stalks. The midrib of all the leaves bears a foliary gland. Flowers rather smaller than in the former.

3. *U. tricuspis*. Three-pointed Urena. Cavan. Diff. 334. t. 183. f. 1. Willd. n. 3.—Leaves with three pointed, angular lobes, and a foliary gland at the base beneath. Stem hairy.—Native of the isles of Mauritius and Bourbon. The stem is three feet, or more, in height, slender, clothed with copious upright hairs. Leaves large, serrated, soft and downy, on hairy stalks. Flowers aggregate, at least in the lower part of the plant, yellow.

4. *U. americana*. Fig-leaved Urena. Linn. Suppl. 308. Willd. n. 4. excluding Sloane's synonym. (*U. sinuata*; Swartz. Obf. 263, but not of Linnæus.)—Leaves three-lobed, rounded and bluntish, much longer than their footstalks; entire and abrupt at the base, with a foliary gland beneath. Stem nearly smooth. Native of Surinam. We have no scruple in removing Sloane's synonym to our following species. His plate by no means expresses the form of the leaves of *U. americana*, which, in the original Linnæan specimen, have wide rounded sinuses between the lobes. Their under surface is very soft, and finely downy; the upper more harsh. Flowers small, mostly aggregate. Fruit mucronate, with short rigid prickles, rather large and broad. Very distinct from *U. sinuata*, hereafter described.

5. *U. ribesifolia*. Currant-leaved Urena. (*Malva* vel *Alcea fruticosifolia*, ribesifolia, seminibus asperis; Sloane Jam. v. 1. 37. t. 11. f. 2.)—Leaves acutely three-lobed; rounded or heart-shaped at the base, with a foliary gland beneath. Segments of the outer calyx spatulate, bluntish.—Native of Surinam; *Herb. Linn.* of Barbadoes; *Sloane*. The stem is much more hairy or downy than in the last. Footstalks longer. Leaves roughish above, finely downy beneath, as in that species; but their lobes are acute, not dilated nor rounded, nor are the sinuses wide. The outer calyx has greener, more leafy and dilated, very deep segments. Prickles of the fruit much shorter than even the foregoing. Sloane's figure cannot be mistaken.

6. *U. repanda*. Wavy-leaved Urena.—Leaves wavy, serrated, scarcely lobed; reticulated beneath, with a foliary gland. Segments of the outer calyx awl-shaped. Fruit smooth.—Native of the East Indies; announced by the late Dr. Roxburgh. The stem is downy, with many slender axillary branches, hardly so long as the leaves, on which the flowers are chiefly situated. Leaves broadly ovate, longer than their footstalks, serrated or sharply toothed, wavy, or slightly lobed; their upper side even, rough with starry hairs; under strongly reticulated with copious veins, paler, but scarcely more soft or downy. Flowers crimson, axillary, on short stalks, generally solitary. Outer calyx: cloven

but half way down, into five narrow acute segments; the tube becoming strongly ribbed after flowering, and containing the very small and unarmed fruit.

7. *U. sinuata*. Cut-leaved Urena. Linn. Sp. Pl. 974. Willd. n. 5. Ait. n. 2. Cavan. Diff. 336. t. 185. f. 2. ("Uren"; Rheede Hort. Malab. v. 10. 3. t. 2.") *Alcea indica frutescens*, foliis ad marginem exasperatis, bryoniae albæ divifuris; Pluk. Phyt. t. 5. f. 3.)—Leaves five-lobed, with broad, deep, rounded sinuses; lobes three-claft: pale and hairy beneath, with three glands at the base.—Native of the East and West Indies. This is known at first sight by the peculiarly wide rounded sinuses of the leaves, which are generally cloven, by the sides of the lobes touching or overlapping each other; the middle lobe, and sometimes the two adjoining ones, have three broad, shallow, dilated and angular lobes: both sides are clothed with simple or divided, not much flattened, hairs, and the under one, though pale, is not hoary: its three principal ribs each bear a tumid open gland at the base beneath. Flowers small, axillary, stalked, solitary or in pairs. Segments of the outer calyx, according to Cavanilles, narrow and awl-shaped.

8. *U. heterophylla*. Various-leaved Urena. (*U. sinuata*; Swartz. Obf. 263? *Malvinda foliis inferioribus multifidis*, superioribus incisif, flore foliario; Burm. Zeyl. 150. t. 69. f. 2. *Alcea indica frutescens*, foliis in laciniis variè difsectis; Pluk. Phyt. t. 74. f. 1.)—Leaves deeply five-lobed, with wide sinuses; middle segment deeply three-lobed: upper leaves elongated and contracted at the base: all hoary and downy beneath, with a foliary gland.—Native of the East, and perhaps West, Indies. To this species, which appears to us very distinct from the last, belongs the remark under *U. sinuata*, in Linn. Syst. Veg. of there being "one glandular pore on the mid-rib beneath;" which remark is copied by Willdenow, though it directly contradicts his own observation in the next paragraph. If the number of glands be invariably three in *U. sinuata*, this is certainly distinguished by its foliary gland on the mid-rib; but besides that character, the leaves are very differently shaped; their sinuses less rounded, and their under side more white and downy; to say nothing of the singularly contracted upper leaves. The segments of the outer calyx are lanceolate. Corolla purple. Prickles of the fruit elongated, doubly or triply barbed.

9. *U. multifida*. Jagged-leaved Urena. Cavan. Diff. 336. t. 184. f. 2. (*Lappago laciniata*; Rumph. Amboin. v. 6. 59. t. 25. f. 2? *Cavanilles*.)—Leaves hairy, deeply and acutely five-lobed, jagged, with a foliary gland beneath. Stem much branched. Flowers somewhat racemose.—Native of the island of Mauritius. The whole plant is clothed with shaggy down, apparently simple. Leaves heart-shaped, longer than their stalks, their five lobes deeply cleft or pinnatifid, acutely and unequally serrated. Flowers yellow, on the smaller or ultimate branches, on short stalks; the lower ones axillary, the upper almost leafless. The leaves are represented by Rumphius with far slighter lobes than in the figure of Cavanilles, and yet his synonym, cited by Reichard and Willdenow for *lobata*, and marked *sinuata* by Linnæus, agrees better with the present species. It may, however, belong to some species not yet known to systematic botanists. See our n. 11.

10. *U. procumbens*. Procumbent Urena. Linn. Sp. Pl. 975. Willd. n. 7. Cavan. Diff. 337.—"Leaves hastate, somewhat heart-shaped, undivided, serrated. Stem procumbent."—Gathered by Obbeck, on little hills in China. The stem is shrubby, creeping, much branched. Leaves the size of *Origanum*, not lobed, smooth, sharply serrated. The flowers are larger than the leaves. Linnæus.

His herbarium contains no specimen answering to this description, nor have we ever seen any.

11. *U. Lappago*. Bur Urena. (*U. procumbens*; Linn. Syst. Nat. ed. 12. v. 2. 462. *Lappago laciniata*; Rumph. Amboin. v. 6. 59. t. 25. f. 2?)—Leaves sinuated, serrated, somewhat heart-shaped: hoary and downy, with a solitary gland beneath. Outer calyx in five deep lanceolate segments. Prickles of the fruit elongated, cylindrical, many-barbed.—Native of the East Indies. The *branches* are round, subdivided, slightly downy. *Leaves* on shortish stalks, acutely lobed, clothed with starry down on both sides, but most hoary beneath; their length about an inch and a half. *Fruit* large and tumid, mucicated with prickles half a quarter of an inch long, each tipped with several pale hooks. We should have little doubt of Rumphius's synonym, had there not been so many different opinions concerning it. Our description is taken from specimens to which Linnaeus, long after he published his *Sp. Plantarum*, attached the name of *procumbens*, fabricating from them a new specific character, which stands in the second volume of his *Syst. Nat.*, and is adopted by Willdenow; but which is altogether irreconcilable to the description of the original *procumbens*.

12. *U. viminea*. Rhomb-leaved Urena. Cavan. Diff. 335. t. 84. f. 1. Willd. n. 8.—Leaves acute, serrated, slightly lobed; rounded at the base, with a solitary gland beneath: upper ones rhomboid or oblong. Outer calyx in five deep lanceolate segments.—Gathered by Commerion in Brazil. This seems next akin to the last, but the *leaves* are not sinuated, nor of so uniform an oblong figure; they are hoary beneath. Of the *fruit* we have no account.

U. Typhalea, Linn. Mant. 258, and *U. leptocarpa*, Suppl. 308, are referred by Cavanilles and Willdenow to PAVONIA; see that article.

URENA, in *Gardening*, comprises plants of the woody perennial exotic kind, among which the species cultivated are, the angular-leaved urena (*U. lobata*); and the cut-leaved urena (*U. sinuata*).

Method of Culture.—These plants may be increased by seeds, which should be sown on a hot-bed, or in pots plunged into it, in the early spring season. When the plants have some growth, they should be removed into separate pots, being replunged in a fresh hot-bed, requiring afterwards the same management as tender exotic plants. When placed in the stove in the spring, they ripen seeds the first year, but otherwise in the second, and seldom continue longer.

They afford variety among other stove plants, by their flowers, and the manner of their growth, some rising high, the others more procumbent.

URENTIA, are sometimes used for medicines of a hot or burning quality. See CAUSTIC.

URÆSEN, in *Geography*, a small Danish island in the Great Belt; 4 miles N. of Langeland.

URETER, in *Anatomy*, the tube which conveys the urine from the kidney to the urinary bladder. See KIDNEY.

URETHRA, the canal by which the urine passes out of the urinary bladder; and through which the seminal fluid of the male is conveyed into the vagina of the female. See GENERATION.

URETHRA, *Strictures of*. A stricture of the urethra may be defined to be a preternatural diminution of the diameter of a part of that canal. By the late Mr. Hunter, strictures of the urethra were divided into three kinds: first, the true permanent stricture, arising from an alteration in the structure of the passage; secondly, a mixed case, composed of a permanent stricture and spasm; and thirdly, the true spasmodic stricture. (See Treatise on the Ven. Disease,

p. 111.) This mode of dividing these cases supposes the urethra to possess a natural power of contraction and relaxation; a circumstance which, though most probably true, and most commonly believed, is not universally admitted. The doctrine of Mr. Hunter, however, has been ably supported by the observations of his brother-in-law, sir Everard Home; and it has always appeared to us, that the facts in favour of the contractile power of the membrane of the urethra are equally obvious and convincing. It may be difficult, and perhaps impossible, says the latter author, to prove this membrane to be muscular, either from its appearance, or from examination of its texture; since the peculiar structure, upon which the contraction of a muscle depends, has not as yet been ascertained. Other structures apparently membranous, and equally unlike the fasciculated fibrous texture commonly met with in muscles, are endowed with a power of contracting and relaxing, in a much greater degree, than is ever found to take place in the membrane of the urethra. The *tænia hydatigena ovalis*, an animal consisting of a semitransparent membranous bag, met with in the brain, liver, and omentum of sheep, when taken from its natural situation, and kept in tepid water, contracts and relaxes the different parts of its bag to a considerable extent. (See *Pract. Obs.* on the Treatment of STRICTURES, &c. p. 15.) The muscular structure of the ureters cannot be demonstrated, yet no one doubts that they possess a contractile power. As is observed in the article KIDNEY, of this Cyclopædia, their function of conveying the secreted urine from the kidney to the bladder requires the exercise of tonic powers; and the idea of this fluid finding its way by the force of gravity, is not only repugnant to the laws of the animal economy, but is irreconcilable with obvious phenomena. The adhesion of the sides of the tube, where it penetrates the coats of the bladder, presents an obstacle, which can be overcome only by the exertion of some force; and this obstacle is vastly increased in the distended state of the bladder, during which the fluid is constantly finding its way into this receptacle.

In the same manner, although the muscular structure of the urethra cannot be demonstrated, yet many phenomena are in favour of the affirmative, and, at all events, leave no doubt of the canal possessing a power of altering its diameter. Here the functions of the part, and certain facts remarked in practice, afford a better criterion than anatomy, which, it is allowed, does not in this instance give us any kind of evidence. When the urine passes out, the canal is large; when the semen is thrown out, it is small. When a portion of its membrane is in an inflamed state from gonorrhœa, its surface is more readily stimulated, and the irritation of the urine makes it contract so much, that frequently the fluid is voided only by drops. In this state, if the penis be immersed in warm water, the urethra often becomes suddenly relaxed again, and the urine is more easily discharged. In many cases, the surgeon finds, when he attempts to introduce stimulating injections into the urethra, that they will not pass on towards the bladder, but bring on so strong a contraction of the passage, that they are rejected again with considerable velocity.

The celebrated Soemmerring has explained the formation of strictures by a thickening of the diseased part, and he does not appear to entertain any belief in the spasmodic nature of these cases. (See *Abhandlung über die Schnell und Langsam tödtlichen Krankheiten der Harnblase, und Harnröhre bey Männern im hohen Alter*. Frankf. 1809.) Mr. Charles Bell also contends, that the white condensed substance, which constitutes the most common kind of stricture, must be equally incapable of yielding to pressure and spasmodic action.

action. He observes, that this fact of the firm nature of a stricture, pointed out by Mr. Hunter, is a sufficient proof to himself, that a stricture cannot be spasmodic; and that even if the diseased part of the urethra were originally muscular and contractile, the condensation and callosity of the part must be attended with loss of the contractile power.

Mr. C. Bell argues, that it is from confounding the effect of the proper muscles of the urethra, the canal has been imagined to possess a muscular property. "I made," says he, "the following simple experiment, in order to put this to the test. I got a small ivory ball, to which I attached a thread. I introduced the ball into the urethra. I made the man endeavour all he could to push it out, but he could not; neither was it retained in the slightest degree, when pulled by the thread. I thought it might be more satisfactory, if I imbued the ball with something stimulating. I tried coarse soap and spirits; but still there was no power in the urethra to retain the ball, or to push it forth. This could be done only by the urine behind it, and the operation of the bladder, or the ejaculator feminis. I need not add, that this experiment was made upon a part of the urethra anterior to the seat of the ejaculator feminis. In the course of practice I find, that, when the silver ball is introduced down to the ejaculator feminis, it is resisted by that muscle, especially when the parts are irritable. I find it sometimes thrown out of the grasp of the muscle; but when pushed fairly into the sinus of the urethra, which is into the middle of the muscle, the ball is allowed to remain." (Letters concerning Diseases of the Urethra, p. 95, Lond. 1810.) The same gentleman also endeavoured to ascertain whether the urethra had any action on fluids. He employed a glass tube to throw an injection into the urethra, the end of the tube being constructed for passing into the orifice of the passage. Pressure was made on the urethra five inches down. By elevating the tube or column, the fluid distended the urethra; but no irregularity in the height of the fluid in the tube indicated any muscular power of the urethra to discharge its contents. When the urethra was distended, the slightest touch upon it with the finger elevated the fluid in the tube; but no effort of the patient produced the effect. When he made the effort, it was with the ejaculator feminis behind the part of the urethra compressed by the fingers. (P. 96.) The conclusion drawn by Mr. Bell from these facts is, that the part of the canal, anterior to the muscles which surround it, has no muscular power.

Mr. Bell thinks, that we can be at no loss to account for spasm in the posterior part of the urethra, since five inches of the canal in that situation are surrounded by muscles; the accelerator urinæ or ejaculator feminis, the sphincter vesicæ, the compressor prostaticæ, and the levator ani. And he adds, that it must never be forgotten, that it is the sensibility of the urethra which governs their contraction.

Although we conceive, that the muscles in the perineum have in some degree the effect which the foregoing writer imputes to them, he is far from having convinced us that the membrane of the urethra is not endowed with muscular power. In the first place, the two experiments, above related, are by no means so decisive as the author fancies them. The first with the ivory ball proves nothing; except that this body was not expelled at once by the muscular power of the canal. But it is conceivable, that such power might exist, and yet operate rather so as to grasp and retain the foreign body, than force it out. Nor is it explained how much time was allotted to the experiment; a point essential to be known: because it is not to be supposed that the ivory ball would be instantly forced out again. The experiment of the injection is also nugatory; because as a stimulating

fluid was not used, (perhaps only water,) it is not likely that any particular contractile action of the urethra would be thus excited. In opposition to Mr. Bell's opinions, therefore, we continue to believe that the membrane of the urethra possesses a contractile power. We think in this manner also, because there are certain phenomena, which cannot be explained by the contraction of any of the muscles with which the urethra is embraced. Thus, for instance, a bougie may frequently be easily introduced as far as a stricture; the patient suffers little uneasiness, and no resistance is experienced; but no sooner is the passage irritated by the pressure of the bougie against the obstruction, than it contracts and grasps the instrument with manifest force. Much resistance is now felt on withdrawing the bougie; and it is in a great measure continued, till the instrument is quite out of the urethra. There are few surgeons of any experience who have not observed this fact. Did the resistance depend upon a spasm of the muscles in the perineum, it could only last while the bougie was in the contiguous part of the urethra. We find, however, that even the last inch of the bougie is evidently grasped. The experiments of Haller are also at variance with the conclusions above related; for he distinctly mentions, that chemical stimulants will make the urethra contract. Indeed, as a late writer observes, the muscular power of this canal may be proved almost in any instance, by introducing a bougie of moderate size into the healthy urethra, and lightly supporting the end that projects from the penis in a horizontal position. If the action of the urethra is then watched with attention, it will be found, that the power which expels the instrument, in other words, the contraction of the urethra, is uniform through its whole extent. The point of the bougie is not pushed forward more quickly while it moves through the bulb of the urethra, where the canal is surrounded with strong muscles, than it is afterwards; but, on the contrary, its motion is exceedingly slow, and perfectly equal throughout, until the whole of the instrument is expelled, and the point fairly drops from the orifice of the urethra. (Howship's Pract. Obs. on Diseases of the Urinary Organs, p. 180.) These considerations are also favoured by analogy, since comparative anatomy demonstrably proves, that in the larger animals, particularly the horse, whose structure is more easy of investigation, and the functions of the urethra precisely the same as in man, the strong muscular fibres, encircling the urethra, cannot be overlooked. Op. Cit. p. 182.

On the whole, however, it does not appear to us, that the question is of great importance in a practical point of view; since the treatment of strictures should in all probability be conducted on precisely the same principles, whether the spasm, that sometimes has a share in increasing the impediment to the exit of the urine, depend upon the muscularity of the membrane of the urethra itself, or upon the muscles situated near the canal, especially as their action is said by Mr. Bell himself to be entirely governed by the sensibility of the passage. We think also, that the term spasmodic stricture might as well be dropped, and that no case ought to be called a stricture, until there is some permanent contraction, arising from a change of structure, in the diseased part of the urethra. Nor does it appear to us, that any material light is thrown upon the mode in which the disease is formed, by imputing so much to spasm as several writers have done.

According to Mr. Hunter, the disease generally occupies no great length of the passage; and in most of the cases which he had seen, it extended no further in breadth, than if the part had been surrounded with a piece of packthread.

Indeed,

URETHRA.

Indeed, in many of the examples, the stricture is said to have presented a great deal of that appearance. Mr. Hunter adds, however, that he had seen the urethra contracted for more than an inch in length, owing to its coats, or internal membrane, being irregularly thickened, and forming a winding canal. (P. 113.) Sometimes, also, as fir E. Home observes, two strictures form within an inch of each other, and the space between them becomes narrower than the rest of the canal.

A stricture, says Mr. Hunter, does not arise, in all cases, from an equal contraction of the urethra all round; but, in some, from a contraction of one side. And fir E. Home informs us, that he has met with cases where there were three strictures, and all on the same side of the urethra; the other being perfectly smooth. This form of the disease throws the passage to the opposite side, and often renders the introduction of the bougie difficult. Mr. Hunter also acquaints us, that the contracted part is whiter and harder than any other part of the urethra. Sometimes there are more strictures than one; and this eminent surgeon had seen half a dozen in one urethra, some of which were more contracted than others. Indeed, says he, many urethras, that have a stricture, have small tightnesses in other parts of them.

The urethra naturally is not of the same diameter throughout its whole extent; and some parts of it are found to be much more liable to stricture than others. In order to determine with precision the length, as well as width of the urethra, fir E. Home took exact casts of it in wax. The subjects from which they were taken were of different ages: one was between 70 and 80; the other, 30. The length of the canal corresponded exactly in both casts. From the external orifice to the neck of the bladder was 9 inches; but, in a note, this gentleman observes, that, in a relaxed state, the canal is commonly about $8\frac{1}{2}$ inches in length. From the external orifice to the bulb of the urethra was 7 inches. The membranous part, extending from the bulb to the prostate gland, is $\frac{1}{2}$ inch; and the canal passing over the prostate gland was half an inch in length.

The following were the diameters of the casts of the urethra in different parts.

	Years old.	
	80	30
At three-quarters of an inch from the external orifice	$\frac{9}{16}$	$\frac{7}{16}$ $\frac{1}{4}$
At $4\frac{1}{2}$ inches from the external orifice	$\frac{7}{16}$	$\frac{7}{16}$
At the bulb, 7 inches from the orifice	$\frac{1}{2}$	$\frac{1}{2}$
In the membranous part directly beyond the bulb, $7\frac{1}{2}$ inches from the orifice	$\frac{7}{16}$	$\frac{7}{16}$
In the membranous portion near to the prostate gland, $8\frac{1}{2}$ inches from the orifice	$\frac{9}{16}$	$\frac{7}{16}$
Where the membranous part terminates, and the prostate gland begins, $8\frac{1}{2}$ inches from the orifice	$\frac{1}{2}$	$\frac{1}{2}$
At the neck of the bladder, 9 inches from the orifice	$\frac{9}{16}$	$\frac{9}{16}$

These dimensions, it is to be understood, are much beyond those of the easy state of the urethra.

The two parts of the urethra, which are naturally the most narrow, are found also to be those most liable to stricture. In fact, strictures occur most commonly just behind the bulb of the urethra, the distance from the external orifice being $6\frac{1}{2}$ or 7 inches. The situation, next in order of frequency, is about $4\frac{1}{2}$ inches from the orifice of the glands. Strictures do also form at $3\frac{1}{2}$ inches from this orifice, and sometimes almost close to it. Mr. Hunter never met with

a stricture in that part of the urethra which passes through the prostate gland. P. 114.

In some cases, as fir E. Home further remarks, the external orifice itself is contracted. When this happens, it is sometimes the source of considerable errors, the surgeon supposing the whole canal to be naturally formed of the same size.

The prepuce also is very often contracted, which is called a natural phymosis. Sir E. Home believes, that this more frequently happens in those who are disposed to strictures than other men.

In almost all the cases which have come under this gentleman's care, there has been one stricture about seven inches from the external orifice, whether there have been others or not. Such part of the canal seems much more disposed to contract than the rest of it.

It is noticed by Mr. Hunter, that most of the obstructions to the passage of the urine, if not all, are attended with nearly the same symptoms, so that there are hardly sufficient marks for distinguishing the different causes. Few patients take notice of the first symptoms of a stricture, till they have either become violent, or have been the cause of other inconveniences. For instance, a patient shall have a considerable stricture, without observing that he does not make water freely; he shall even have a tendency to inflammation and suppuration in the perineum, and not feel any obstruction to the passage of his urine, nor suspect that he has any other complaint than the inflammation in the perineum. In all these obstructions, the stream of water becomes small, and that in proportion to the obstruction; but this symptom, though probably it is the first, is not always observed by the patient. In some the urine is voided only in drops, and then the disorder cannot escape notice; in others the stream is forked or scattered. (Hunter, p. 112.) Although, as fir E. Home observes, the first progress of the contraction is generally very slow, yet, when once it has far increased, that the urethra is not wholly relaxed by the force of the urine, its subsequent advances are more rapid, and new symptoms are perceived. The urine is voided more frequently; does not pass without a considerable effort, attended with pain, and a straining continues after the bladder is emptied. If the patient accidentally catches cold, drinks a glass of spirituous liquor, acid beverage, or punch, commits an excess in drinking wine, or removes quickly from a warm to a cold climate, the urine will pass only in drops, or be entirely obstructed; these causes, inducing in the contracted part a spasmodic action, by which it is closed. Cold, externally applied to the body (continues fir E. Home), has so great an effect upon a spasmodic stricture, that a patient who can make water without the smallest difficulty in a warm room, upon attempting it in the open air shall be entirely unable to void a drop; but, even in this difficulty, if he returns to a warm room, and sits down some little time, the urine will come away. The experience of the same gentleman tends to prove, that the symptoms of stricture come on more frequently while the patient is leading a sedentary than an active life.

Permanent strictures are generally attended with a discharge of matter, or a gleet. This is often considered by the patient as the whole disease; and sometimes it is not till after the surgeon has long in vain tried every means that he can imagine to effect a cure, that other symptoms are noticed, and a stricture at last suspected. In diseases of the urethra, and also in those of the prostate gland and bladder, there is usually an uneasiness about the perineum, anus, and lower part of the abdomen; and, as Mr. Hunter remarks, the patient can hardly cross his legs without pain.

Frequent intercourse with women generally renders strictures worse. Under these circumstances, says sir E. Home, the membrane of the urethra is kept longer in a state of contraction; and the part disposed to stricture loses the power of relaxing itself again. Although the passage is not completely closed, it is rendered much narrower, and remains in an extremely tender state. Hence, the passage of the urine irritates it, and in a few hours a discharge of matter comes on similar to that from gonorrhœa. In certain instances, the contraction is so great, that it stops the emission of the semen altogether, and forces it back into the bladder; while in some other cases this fluid passes through the stricture after the orgasm has taken place, but with little or no force.

There is one circumstance which has a great tendency to make a stricture be mistaken for a gonorrhœa; *viz.* the pain in making water is confined to the same spot in both diseases. A stricture in the membranous part of the urethra does not render the part itself particularly sensible; but all the painful sensations are felt about an inch and a half from the orifice of the glans penis. This is a general fact, and unaccountable as it may seem, it is not more extraordinary than the burning pain felt in the glans, in cases of stone, even when the whole of the urethra is perfectly found.

When a stricture is in an advanced stage, the diseased part is at all times much narrower than the rest of the canal. The stricture, however, according to sir E. Home, still retains a power of contracting and relaxing itself; in the contracted state, closing up the passage; in the relaxed state, allowing the urine to pass through it in a small stream. In this state the stream is so small, and the exertion necessary to empty the bladder so great, that the patient can seldom be wholly ignorant of his complaint.

The spasmodic contraction, upon any irritation being applied to the part, is, as sir E. Home describes, very great. This is known by the urine being unable to pass in a stream; and by the extreme difficulty of now passing a small bougie, which, in the relaxed state of the canal, met with no resistance. The bougie also, if allowed to remain a few minutes, is not unfrequently grasped so tight by the spasmodic contraction, that it cannot be withdrawn without considerable force. The bougie, when examined (continues sir E. Home), puts on an appearance exactly resembling what would have been produced, if a piece of packthread had been tied round it. In this stage, the spasmodic contractions, although more violent, occur less frequently than while the stricture was in a more recent state. When the stricture has been of some years standing, the coats of the bladder become thickened, in order to increase the power of this organ to expel the urine, the evacuation of which is rendered difficult by the obstruction. The bladder, in this thickened state, does not admit of the usual dilatation, so that the patient is obliged to make water every three or four hours, or oftener. See Home's Pract. Obs. on Strictures.

In addition to the foregoing symptoms, we have further to enumerate, amongst the numerous effects of strictures in the urethra, nocturnal emissions; and, in irritable patients, a variety of unusual sensations about the membranous part of the urethra, conveying to the mind the idea of something crawling or fluttering. In many cases also, there is a periodical discharge, brought on by cold, or other occasional causes. When this happens, the inflammation extends to the bladder; the frequency of making water is very much increased; and the urine very turbid. Sometimes the bladder inflames more violently, and secretes purulent matter, which passes out after the urine. In still worse attacks, the discharge from this viscus is glairy, like the white of an egg,

and of a strongly tenacious consistence. The discharge of pus and gelatinous mucus with the urine, has been regarded as particularly evincing an ulcer, or calculus in the bladder; but it is a symptom which arises from any irritation of that organ, and is frequent in cases of old strictures.

Attacks of the preceding kind may bring on peritonitis, and the patient is carried off. Sometimes also the incessant irritation of the strictured part, by the efforts to make water, brings on a gradual diminution of the canal, and, in a few instances, a total obliteration of a portion of it. This last event cannot happen without destroying the patient, unless another outlet be formed for the urine. Complete strictures, therefore, as sir E. Home remarks, are only met with where fistule in perinæo have been produced.

Some patients with strictures seem extremely liable to complete paroxysms of fever; that is to say, they often have a cold, hot, and sweating stage of febrile disorder in regular succession. The sweating is also remarked to be much more profuse than in a common ague.

Strictures in the urethra likewise occasion a swelling of the testicle. When permanent and considerable, they are also apt, under particular circumstances, to cause strangury and retention of urine. If a patient goes suddenly from a warm into a cold situation; if he drinks too freely of wine; eats high-seasoned dishes; catches cold; commits any species of intemperance; or delays making water too long, after feeling the inclination, he exposes himself to the danger of these latter grievances.

The causes of strictures in the urethra are not known with any degree of certainty. The origin of the disease is often imputed to the effects of gonorrhœa, or to the method of curing it. Mr. Hunter, however, conceives that there are many reasons why this doctrine is not likely to be correct. Strictures, he observes, are common to most passages in the human body; they often occur in the œsophagus; in the intestines, especially the rectum; in the anus; in the prepuce producing phymosis; and in the lachrymal duct, without any previous disease. They sometimes happen in the urethra itself, without ever having been preceded by any venereal complaint. Mr. Hunter saw an instance of this kind in a young man of nineteen, who had had a stricture for eight years, and which therefore must have begun when he was only eleven years of age. The case was treated at first as the stone or gravel. The patient was of a weak scrophulous habit, and the stricture in the most usual place, about the membranous part of the urethra. Mr. Hunter had also seen a stricture in a boy only four years of age, and a fistula in the perineum in consequence of it. He reminds us also, that strictures are as common in persons who have had gonorrhœa slightly, as in those who have had it violently. They are also never found to come on during the inflammation which attends a clap, nor for some time after the infection is gone. Thirty and forty years sometimes elapse between the cure of a gonorrhœa and the beginning of a stricture, the health being all that time perfectly good. If strictures arose in consequence of the inflammation accompanying this disorder, we should expect to find them of some extent, because the inflammation is itself of some extent; and we should also expect to find them most frequent in that part of the urethra which is usually the seat of gonorrhœa. But the fact is, they are not so frequent there as they are in other parts of the urethra. Sir E. Home, however, differs from Mr. Hunter on this point, in thinking, with most other surgeons, that gonorrhœa is a very general cause of strictures.

It is supposed by many, says Mr. Hunter, that strictures arise from the use of injections in the cure of gonorrhœa; but

but he thought the opinion founded on prejudice; for he had seen as many strictures after gonorrhœa, which had been cured without injections, as after other cafes, which had been cured with them. Such modes of accounting for strictures, he observes, give no explanation of cafes which have not been preceded by gonorrhœa, or the use of injections. Sir E. Home also thinks differently from Mr. Hunter respecting injections, the injudicious use of which he conceives may often cause strictures. Strictures have sometimes been supposed to arise from the healing of ulcers in the urethra; but Mr. Hunter says, he never saw a fore in this passage, except in consequence of a stricture, and he therefore does not subscribe to the opinion.

The stone is sometimes a cause of stricture, and this occasionally happens in infancy. Sir E. Home has met with cafes of this kind in children only six years of age; and, from other examples which he has recorded, it would appear, that the disease is frequent in calculous patients of more advanced years.

In the East Indies, and other warm climates, strictures are much more readily brought on than in Europe; and it is thought, that the excesses, in which the inhabitants of hot countries indulge, have great effect in promoting the formation of the disorder.

Strictures have been known to arise from the application of external violence to the perineum; from the irritation of blisters affecting the membrane of the urethra; and from the irritation of a diseased prostate gland. Cafes, in proof of these observations, may be perused in Sir E. Home's publication.

In the treatment of this disease, the first thing is to ascertain the precise situation of the stricture nearest the orifice of the urethra. For this purpose, a common bougie, proportioned to the size of the orifice of this canal, is to be gently introduced. If the bougie easily enters the passage, the surgeon may be well assured, that, if there be no obstruction, the size of the instrument cannot be too large for the rest of the canal, the orifice of which is naturally less capacious than most other parts of it. Small bougies, and such as are too much pointed, however, are frequently stopped by the lacunæ, or orifices of the mucous glands, and lead inexperienced surgeons into error.

In introducing any instrument properly into the urethra, some degree of skill is displayed. When a bougie or catheter is to be passed, the surgeon should take hold of the penis, by placing the fore-finger and thumb of his left hand on each side of the prepuce, opposite the corona glandis: thus he avoids making any pressure on the passage into which he is about to pass the bougie. This being oiled is to be introduced at first a little way; then the surgeon is to draw the penis forward, as it were over it, with the fore-finger and thumb of his left hand, while, at the same time, he gently and steadily persists in pushing the instrument further into the passage with his right hand. The bougie itself is to be held like a writing pen, and, as it enters the urethra, it ought to be artfully rotated, first in one direction, then in the other, in order that its extremity may more certainly escape being entangled in any natural fold of the membrane lining the passage.

Having ascertained, by the introduction of a bougie, the exigence and situation of the stricture nearest the mouth of the urethra, the next desideratum is to learn, whether the contraction is such as would be produced by tying a piece of packthread round the canal; whether, on the other hand, it occupies a considerable extent of the passage; and, lastly, what is the size of the bougie which can be introduced through it. A knowledge of the extent of the stricture is

a circumstance that would always be of essential use to the practitioner, if it could be obtained; because, we presume, no surgeon, knowing that the obstruction and disease extend far along the urethra, would ever in such a case give a preference to the employment of armed bougies. Those armed with the nitrate of silver could never be expected to burn their way through a stricture an inch in length; and if other bougies, armed with the caustic potassa, are conceived to admit of being applied to such a stricture with any degree of precision, or any other real efficacy than what actually arises from the mechanical action of these instruments themselves, when passed through the stricture, we confess that it is more than our observations authorize us to believe. We have no hesitation in giving it as our opinion, that, in all cafes of this description, as well as in others, in which two strictures are near together, and the intervening part of the canal much contracted, caustic bougies ought not to be used.

Having ascertained that a common-sized bougie will not pass beyond a particular point of the urethra, we ought to make an impression on the instrument with the finger-nail, close to the mouth of the urethra. Then the bougie should be withdrawn, and the surgeon should take one of a smaller size, which he is to mark with his nail, exactly at the place corresponding to that of the impression on the first bougie. This smaller one is to be introduced sufficiently far to bring its marked part exactly to the orifice of the urethra, at which period the surgeon knows that the extremity of the bougie has just arrived at the contraction, which would not allow the first common-sized bougie to pass. If the second bougie cannot be introduced farther than the first, a still smaller one is to be tried; but the surgeon should not have recourse to the smallest bougies at once, as the largest bougie which can be got through the stricture ought to be the model of the soft white one, which should now be introduced for the purpose of shewing the shape and extent of the stricture by the impressions made upon it. If, after the soft bougie has remained a minute or two in the stricture, it should be marked with a distinct circular or semi-circular narrow furrow, on being withdrawn, we have reason to believe, that the stricture does not occupy much of the extent of the urethra. On the contrary, when the impressions and irregularities on the soft bougie are extensive, it is to be suspected that the stricture is not confined to a limited point of the canal. At the same time it must be acknowledged, that it is somewhat difficult to form a certain judgment from the appearances of the bougie, because these will depend very much upon the force or gentleness with which the instrument is used. In particular, it is extremely difficult to learn positively whether the urethra is diminished in diameter immediately behind the most contracted part of the stricture. Mr. C. Bell proposed the employment of a particular sort of probe for determining the extent of strictures. "I procured (says this gentleman) a series of silver and gold probes, with circular knobs; and the knobs varying from the full size of the urethra to what will just pass the narrowest stricture. By successively introducing smaller balls, I ascertain the degree of stricture by the ball which passes easily; and I am secure of being in the passage by passing the probe onward, when it has got beyond the stricture. Then by the slight feeling of resistance in passing the ball, and in withdrawing it again through the obstruction, I ascertain the extent of the contraction. If the ball of this probe be liable, like the point of the bougie, to enter one of the lacunæ, or, on passing it, to rub upon its edge, yet, by feeling whether the same roughness or difficulty attends the withdrawing of the bulb of the probe as when it passed downward, we may be assured whether there be a stricture of the canal, or whether

the obstruction be not caused merely by the lacunæ." Oper. Surgery, vol. i. p. 104.

This author further observes, that as the lacuna opens in a direction towards the orifice of the urethra, its edge cannot catch the probe when this is withdrawn, at which period a uniform smoothness must be felt, unless there be disease. When there is an irregular hardening of the urethra for a considerable extent, the probe is said to move along it with difficulty; but no sooner has it passed the obstruction, than it moves on with freedom. Likely as these ball-probes for the urethra at first seem to be to afford desirable information respecting the species of stricture, they are at present not much used by surgical practitioners. In fact, in practice they do not answer; and it is the contractile power of the urethra, or (if others will not allow it) it is the action of the muscles contiguous to this passage, which sometimes stops the easy introduction of the probe even when there is no permanent stricture whatever, and which makes it more difficult to ascertain the nature and extent of the obstruction than would otherwise be the case.

That great utility in practice would be derived from being able to learn the nature of the stricture, must be as obvious as the fact, that a caustic bougie is not at all calculated to remove the obstruction when it is of any extent. Such an instrument (we mean particularly a lunar caustic one) could only act on the anterior part of the contraction, without presenting any prospect of being sufficiently efficacious to burn its way, by repeated applications, through the whole extent of the stricture. Even could we imagine that it had this power, our judgment and common sense would revolt at the doctrine of this being the proper plan to be pursued. The common bougie, on the other hand, is introduced through the whole extent of the stricture, and acting like a wedge on every part of it, produces a general dilatation of the obstruction. When the stricture is attended with a conical lessening of the canal in front of it, a common bougie must also merit a preference.

Treatment with the common Bougie.—This instrument acts by producing a mechanical dilatation of the stricture. As it operates, however, on living matter, it either makes the dilated part adapt itself to its new position, or recede by ulceration. If the case is one that will allow even the smallest bougie to be introduced through the stricture, the cure may be considered to be within our power. In many cases in which the stricture is considerable, a great deal of trouble is given by occasional spasms, which either prevent the introduction of the bougies altogether, or only allow a very small one to pass. In such cases, Mr. Hunter was sometimes able to make the bougie pass, by rubbing the perineum with one hand, while he pushed forward the bougie with the other. He also frequently succeeded by letting the bougie remain close to the stricture a little while, and then pushing it forward. The spasm has sometimes been removed by dipping the penis in cold water.

It is sometimes difficult to know, whether a small bougie has passed through a stricture, or only bent. In this case, a common-sized bougie should be previously introduced to learn the situation of the stricture; and, afterwards, when the end of the small bougie is known to have reached the obstruction, the surgeon should push the instrument forward very gently, and for a short time. If the bougie enters the penis further, he may know whether it has entered the stricture by removing the pressure from the bougie; for, if this recoil, it has not passed, but only bent. After all, however, every practical surgeon knows, that it is sometimes incorrect to take even such a criterion, and a very

small bougie frequently bends, and yet does not afterwards recoil in the leaf.

When the bougie has passed a little way through the stricture, and remained there a short time, we should withdraw it, and examine its extremity. If this should be flattened, grooved, or have its waxen coat pushed up for some extent; or, if there should be a circular impression on the bougie, or only a dent on one side made by the stricture, we may be sure that the instrument has passed as far as those appearances and impressions extend.

Now it becomes necessary to introduce another bougie of exactly the same size, and let it remain as long as the patient experiences no particular inconvenience.

When the end of the first bougie is blunted, we may be sure that it has not passed the stricture at all.

The best time for wearing bougies is when the patient is in bed in the morning, or when he has an opportunity of keeping himself perfectly quiet. The bougie should be gradually increased in size, as the stricture dilates, till the largest one can easily pass, and its use should be continued for three or four weeks afterwards, in order to habituate the parts to their new state.

It is well known that strictures are very liable to return, and hence the treatment with common bougies has been accused of inefficacy. We have known, however, some cases in which the cure lasted many years; and others in which the stricture returned, although caustic bougies had been employed. One reason why the disease often relapsed in former times was, because surgeons had no correct notions respecting the naturally capacious diameter of the urethra, and consequently they never increased the size of the bougie, as far as it ought to have been, in proportion as the disease gave way. In the employment of caustic bougies, on the other hand, surgeons have always preferred large ones; and, if these instruments ever render the cure more durable, we conceive that the success is in a great measure ascribable to this circumstance.

Common bougies have one advantage over those armed with lunar caustic; *viz.* that of being sometimes capable of acting upon several strictures at once, when they are introduced into the urethra; a thing which is impossible in the other method.

Treatment with Elastic Gum Catheters and Bougies.—Perhaps there is no plan of treating strictures in the urethra which is so mild and unirritating as that with instruments coated with elastic gum. It is the common method of treatment followed in France, where caustic bougies appear to be entirely abandoned. The celebrated Desault, who had considerable success in the treatment of strictures, rarely employed any means of cure except an elastic gum catheter. That this instrument can frequently be introduced through a stricture, even when nothing else will pass, seems well known to every practitioner in surgery; for, whether he is an advocate for one method of cure or another, he no sooner fails in his attempts to get through a stricture, than he tries what can be done with a gum catheter. It is quite unnecessary to dwell long on the mode of curing strictures with this instrument, or the elastic gum bougie. The cure is effected on the principle of dilatation; the very same principle on which the common bougie operates. The catheter will sometimes pass without the stilet, when it will not do so with it. This instrument, being much less irritating than a common bougie, can be longer worn without inconvenience, especially as the patient can also void his urine without taking it out. Indeed, it may be worn several days together, if judged advisable; but we believe it is generally better to withdraw it sooner, and endeavour to get in as quickly

URETHRA.

quickly as possible other elastic gum catheters of larger size. The elastic gum bougie sometimes will not pass a stricture in the membranous part of the urethra, owing to the elasticity of the instrument tending to keep its point from ascending over the ridge in the canal. In some cases we have found them on this account not to answer, and have been obliged to use either a common bougie, or an elastic catheter containing a wire.

Treatment with Bougies armed with Nitrate of Silver.—The practice of applying caustic to strictures was known to Wiseman, who is justly esteemed the father of English surgery. The caustic which he used was the common red precipitate, and he introduced it into the urethra by means of a cannula. It appears that Mr. Hunter was not aware that any proposal of the kind had ever been made by others, when he first conceived the project of curing strictures in the urethra with caustic. It was only afterwards that he learned what Wiseman had done; and there can be no doubt, that if the idea had not existed previously, we should still have derived it from the fertile genius of Mr. Hunter. The instruments with which he employed caustic consisted of a silver cannula and a fillet. One end of the fillet had a small bulb, which filled up the end of the cannula, and made it pass more easily down to the stricture. The other end was a port crayon, containing the piece of caustic which was introduced through the cannula, and applied to the stricture. The application having been made, the port crayon was drawn back into the cannula, and the whole taken out of the urethra.

It is observed by Sir Everard Home, that the foregoing method of using caustic was found in practice to be liable to a variety of objections. No silver cannula could be well adapted to the flexible canal of the urethra. Hence, when the caustic was applied, and any degree of pressure exerted, the effect of the caustic was necessarily produced upon the angle, between the stricture and side of the urethra, and not upon the middle of the stricture, the part intended to be destroyed. Mr. Hunter not only saw the inconveniences of the cannula, but he actually endeavoured to obviate them by devising a more simple and commodious method of applying caustic accurately to the centre of the stricture. The following is the improved mode, as explained by Sir E. Home: Take a bougie of a size that can be readily passed down to the stricture, and insert a small piece of lunar caustic into the end of it, exposing the surface of the caustic, but surrounding it every where laterally with the substance of the bougie. This should be done some little time before it is used; for the materials of which the bougie is composed become warm and soft by being handled in the insertion of the caustic; and, therefore, the hold which the bougie has of the caustic is rendered more secure by the instrument being allowed to cool and become hardened.

This bougie is to be oiled, but before passing it, a common bougie of the same size is to be introduced down to the stricture, in order to clear the canal, and to measure exactly the distance of the stricture from the external orifice. This distance being marked upon the armed bougie, the latter is to be passed down to the stricture as soon as the common one is withdrawn. In its passage the caustic can scarcely come into contact with any part of the lining of the urethra, as the point of the bougie, of which the caustic forms the central part, always moves in the middle line of the canal; and indeed the quickness with which it is conveyed to the stricture must also prevent any injury of the membrane.

When the armed bougie is in contact with the stricture, it is to be steadily retained there, with a moderate degree of

pressure at first, which is to be afterwards diminished, or else it would bend the bougie when this becomes softened by the warmth of the urethra. The time which it is to remain depends a good deal upon the sensations of the patient, and the length of time the parts have been diseased; but on the first trial it should be less than a minute, as it then commonly gives greater pain than at any subsequent application. Every other day is generally as often as the caustic bougie can be used with prudence. However, in obstinate cases, Sir E. Home has sometimes employed it every day.

The bougie, which is introduced into the urethra previously to the armed one, should be made of soft materials, in order that it may mould itself to the form of the passage, and communicate some information relative to the extent, degree, and position of the stricture.

The pain arising from the application of the nitrate of silver, or lunar caustic, to strictures, is represented by Sir E. Home as much more moderate than might *à priori* be apprehended. This gentleman has even related instances, in which the piece of caustic slipped out of the bougie, and remained in the urethra; yet without occasioning any very severe symptoms.

In the course of the use of caustic bougies, especially when the patient is guilty of any imprudence, it is possible for some uncommon symptoms to arise.

The first is a swelling in the perineum. It is very apt to be brought on when the surgeon is endeavouring to remove that part of the stricture which is nearest to the sides of the urethra. The swelling, which is of considerable size, is totally different from that which is produced by the irritation of the long continuance of bougies in the passage, and which ends in an abscess. It is entirely caused by blood extravasated in the cellular membrane, and which is readily absorbed. The inflammation is also slight, and soon subsides.

A second effect of caustic, in some particular cases, is a very profuse hemorrhage. According to Sir E. Home, the bleeding never occurs with violence, except when the stricture has been completely destroyed. This gentleman has related several examples of such hemorrhage, and others are on record. See *Edinb. Med. and Surg. Journ.* vol. v. p. 333.

A third ill consequence, sometimes induced by the use of armed bougies, is strangury. According to Sir E. Home, it is not common for caustic to produce this effect. On the contrary, he states, that in many instances it removes it, by taking off spasmodic action from the stricture. Patients, however, who are subject to occasional retentions of urine from the use of common bougies, are also not less liable to the complaint when they are using armed ones; and sometimes they suffer in a still worse degree.

In certain constitutions, it appears also, that the application of caustic to a stricture brings on an attack of ague. This effect is said to be most common in patients who have past a good deal of their life in hot climates. It sometimes happens, however, in persons who have never been out of England. We saw in St. Bartholomew's hospital, a few years ago, an elderly man who had very bad strictures, for which the caustic was used. After the plan had been followed about a fortnight, a serious shivering fit came on directly after the application of the bougie. The method was discontinued for a time, and the man's health got rather better. The caustic was now again resorted to, and again a most violent rigour immediately followed, and the febrile disposition which took place proved fatal in a couple of days.

Caustic bougies are at present much less employed than they were ten or fifteen years ago. In France, however, and upon

upon the continent in general, the practice never gained any partisans. The great thing which rendered the plan a favourite one with many surgeons some time ago, depended upon its alleged superiority in radically curing strictures, and leaving no chance of a relapse. We believe, however, that this was only a supposition; for we have seen several returns of stricture after the use of caustic; and, if the disease should recur rather less frequently on the whole, the success may be very well ascribed to the larger size of the armed bougies ordinarily employed. In short, we have no doubt, that common bougies would permanently cure strictures quite as well as any armed ones, if care were taken to increase the size of them in a proper degree, in proportion as the obstruction gives way.

For those strictures, however, which are like what would be produced by tying a piece of packthread round the urethra, we think armed bougies generally answer very well. They have also been particularly recommended for irritable strictures, the irritability of which is said to be destroyed with the diseased part of the canal. There are some cases in which no bougie nor catheter, of the smallest size whatever, can be got through the obstruction. Here the surgeon has the choice of using the armed bougie; of exciting ulceration of the stricture with the pressure of a common one; or of imitating the French, and some of our own surgeons, in boldly forcing a way through the obstruction with a conical catheter, of which we shall presently speak.

Treatment of Strictures with other Bougies, armed with the Caustic Potassa.—Mr. Whately considers strictures of the urethra, not merely as contracted fibres, but as really diseased portions of the membrane lining that canal. Hence he has proposed a remedy, calculated, as he thinks, both to remove the diseased affection, and to dilate the contracted part, without putting the patient to the inconvenience of wearing a bougie. Such a remedy he thinks caustic, when it is judiciously used. But his great object is to recommend the employment of the caustic potassa, or kali purum, in a particular manner, as being, according to his own account, more efficacious, and less painful and hazardous, than bougies armed with lunar caustic.

Before the caustic potassa is employed, the urethra ought to be rendered sufficiently capacious to admit a bougie above the smallest size into the bladder; and the strictures, if very irritable, are to have this irritability previously lessened by the use of common bougies.

The following is the manner of arming a bougie with this caustic, according to Mr. Whately's description. Put a small quantity of the caustic upon a piece of strong paper, and break it with a hammer into little bits, about the size of large and small pin's heads. When thus broken, it should be kept for use in a phial, closed with a ground stopper. The bougie must have a proper degree of curvature given to it, by drawing it several times between the finger and thumb of the left hand, and it should be just large enough to enter the stricture with some degree of tightness. Then let it be passed gently into the urethra, and when its point stops at the stricture, which it almost always does before it will enter it, make a notch with the finger-nail on the upper portion of the bougie, exactly half an inch from the extremity of the penis. When the bougie is withdrawn, a small hole, about the sixteenth part of an inch deep, should be made at the extremity of its rounded end. Some of the broken caustic should then be put upon a piece of paper; and a bit, smaller than the smallest pin's head, is to be selected for the first application. Let this be inserted into the hole of the bougie with a pocket-knife, and pushed into it with the blunt end of a pin, so as to place the caustic rather

below the margin of the hole. In order to prevent the potassa from coming out, the hole is then to be contracted a little with the finger, and the remaining vacancy is to be filled with hog's-lard. The bougie, being then oiled, is to be passed, with the curvature upward, to the anterior part of the stricture, the situation of which has been ascertained beforehand, and the bougie marked as already explained. The instrument should rest there for a few seconds, for the purpose of letting the caustic begin to dissolve. It should then be very gently pushed forward, about one-eighth of an inch, when there must be another stop for a second or two. The bougie should next be carried forward in the same gentle manner, till it has got through the stricture. After this, it should be immediately withdrawn, by a very gentle motion, to the part at which it was first made to rest awhile. It is next to be very slowly passed through the stricture a second time; but without letting the bougie stop in its passage. If pain or faintness arise, the operation is now to end, and the bougie is to be immediately withdrawn; but if no such effects be produced, the instrument may be passed and withdrawn once or twice more.

Mr. Whately directs the application to be repeated once every seven days; and if the stricture be found dilated, the bougie must be proportionally increased in size every time. The piece of caustic, in no cases whatever, ought to be larger than a common pin's head.

By proceeding in the way above related, Mr. Whately conceives that the caustic will be equally diffused over every part of the strictured surface, and that the application will only abrade the membrane of the stricture, without producing a slough.

It deserves notice, that this method of treatment seems little adapted to strictures, which are confined, as it were, to a point of the urethra; the cases which are also the most frequent, if we are to credit the authority of Mr. Hunter. The possibility of applying the caustic accurately to the place intended has always appeared to us doubtful; and, indeed, notwithstanding there are some good surgeons, who occasionally try the plan and think it answers, we are inclined to ascribe more to the passage of the bougie itself than to any effect of the little bit of caustic on the stricture.

Treatment of Strictures with metallic Bougies.—For some years past, a new plan has prevailed of treating strictures in the urethra with bougies, composed of a soft, flexible metal. The instruments also have a highly polished surface, of a silvery hue; and as the diameter of some of them is considerable, they possess a sufficient degree of firmness, both for introduction, and for retaining the curve of the patient's urethra. This last circumstance, indeed, is considered by some practitioners a great advantage, exclusively belonging to metallic bougies. Hence, as soon as they have received the curvature which is judged to suit the patient best, they are carefully preserved in this form throughout the cure, and are kept in a case which also has a bent shape. Formerly, we have heard of objections to these instruments, on the ground of their being liable to break in the urethra; but, although they are now often used, we have not been acquainted latterly with such an accident. Perhaps this is to be imputed to their present composition, which is firmer and less flexible than it used to be some years ago. Many patients bear the employment of metallic bougies better than any others. It seems only necessary to add, that they effect a cure on the principle of dilatation, like common bougies.

Treatment of Strictures with a conical Silver Catheter.—It is remarkable that the French surgeons, who have always objected to the use of armed bougies, which appear to them too violent a means of cure, have set the example of treating strictures

strictures in the urethra on the principle of actual force. We cannot explain this matter to the reader better than by quoting what Mr. Crofs, an intelligent furgeon at Norwich, who lately vifited the hospitals of Paris, has faid upon the fubject. "When I firft went to La Charité, (fays this gentleman,) out of fifty-three male patients in the furgical ward, there were five cafes of ftricture of the urethra, and three or four of difeafes of the tefticles. In the treatment of the former complaint, the cauftic bougie is not ufed in any of the hospitals, and it was cenfured by all the furgeons I met with, as 'a very dangerous and harfh remedy,' which I believe moft of them have never given a trial to. It appears to me, however, that the Parifian method of treating many cafes of ftricture in the urethra is not more mild than the ufe of the cauftic." Mr. Crofs then recites a cafe which he faw in La Charité. A man who had had for a long while a permanent ftricture, had been repeatedly treated for it. There was difficulty of making water, but not complete retention. Unfuccefsful attempts were made, for feveral days, to pafs an inftrument into the bladder by gentle means. The patient was ftill able to void his urine, although with great pain and difficulty. M. Roux took a conical filver catheter, with a very flight curvature, and an extremity almoft pointed, and by force regularly applied, he made his way into the bladder in fpite of all oppofition. He took care to keep the inftrument central, and to judge of the direktion of the point by the lateral rings. The rule mentioned by M. Roux, for commencing the great depression of the outer extremity of the inftrument, was when, by the finger in the rectum, he could feel the point to have reached the apex of the prostate. He gave great pain to the patient, but fucceeded in getting the inftrument into the bladder. The urine in the bladder was not fuffered to flow out immediately, the catheter being left in the urethra, and its end plugged up with a piece of wood. Mr. Crofs well obferves, that M. Roux acted very judiciously in directing the catheter to be kept depressed between the thighs, becaufe from its fhortnefs, and the smallnefs of its curvature, the bringing of the outer extremity of the inftrument up to the abdomen would have drawn the other extremity out of the bladder.

Three or four days are the time M. Roux commonly keeps the conical catheter in the paffage; but this patient fuffered fo intolerably, that it was taken out at the end of four and twenty hours. An elastic gum catheter, of rather a fmall fize, was immediately introduced without difficulty; its extremity tightened to the abdomen; and its orifice plugged up, in order that the urine might be allowed to flow only at certain periods. The next day the patient was comparatively eafy. On the fourth day there was a fwelling of the tefticle, frotum, and perineum. A poultice was applied, and the elastic catheter continued. In four days more the fwelling of the parts had fubfided, and the poultice was no longer neceffary. A frefh gum catheter of a larger fize was introduced. Suffice it here to add, that in about fix weeks a catheter of the largeft fize could be introduced.

Another cafe, fays Mr. Crofs, went on lefs favourably. The *fonde conique* had been employed, and a gum catheter introduced; but in lefs than a week the patient, believing he could make water without the inftrument, took it out himfelf. The next day, an effufion of urine in the frotum had taken place, and the fluid was freely let out by two long incifions. The elastic catheter, however, could not be introduced again. The urine now came away in drops from the urethra. The free incifions in the frotum prevented floughing; but the patient, who was very weak, and in bad health, died in a few days. It was, obferves Mr.

Crofs, an inveterate cafe of ftricture, and the patient would probably have died under any treatment. Diffection fhewed a difeafed bladder, whose coats were above half an inch in thicknefs; a cartilaginous ftricture and extenfive finufes communicating with the once-membranous part of the urethra.

"The effecting of a speedy cure, in bad cafes of ftricture," is the argument advanced by the French furgeons for the ufe of the conical catheter, where that of elastic gum cannot be introduced without its affiftance. They tell us, fays Mr. Crofs, even of bad cafes being cured, or greatly relieved, in a month or fix weeks; and certainly in one cafe, under M. Roux, a catheter of the largeft fize could be received by the urethra, a month from the introduction of the conical catheter.

M. Roux affured Mr. Crofs, that he had never feen any inflammation or irritation from this treatment, which was not readily managed and fubdued. In his clinical lecture, however, he mentioned two fatal cafes, which he had witneffed, and examined after death. In one of thefe, on taking out the *fonde conique d'argent* the third or fourth day after its introduction, the furgeon could not introduce the gum catheter: in attempting to do which, faid M. Roux, another paffage feemed to have been made. Extravaftation of the urine, floughing, and death enfued. The fecond cafe was fomewhat fimilar; peritoneal inflammation was the immediate caufe of its fatal termination, the inftrument having paffed between the pubes and anterior part of the bladder.

Whoever defires more information refpecting this violent mode of treating ftrictures, muft confult Mr. Crofs's publication. Enough, we conceive, has been faid to prove that it is a dangerous plan, which can only be juftifiable in the moft inveterate and obftinate cafes. It feems that, in fuch examples, the late John Hunter alfo ufed the filver catheter with confiderable force; and the praftice of Mr. Pearfon and of Cooper is likewife cited, as a fanction of this bold mode of proceeding. The French even fometimes prefer this way of puncturing the bladder, the catheter being forced through the prostate gland; and we have heard of one or two diftinguifhed furgeons in this country, who never perform any of the ordinary methods of puncturing the bladder, but invariably fucceed in getting a catheter into that organ, by forcing the inftrument forward through the prostate gland. See Hunter's Treatife on the Venereal Difafe. Whately's improved Plan of treating Strictures. Firft Lines of Surgery, edit. 3. Sir E. Home's Practical Obf. on Strictures. C. Bell's Letters on Dif. of the Urethra. Crofs's Sketches of the Medical Schools of Paris, &c.

URETHRA, *Imperforate*. Children, when firft born, are fometimes incapable of making water, in confequence of the prepuce or urethra being imperforate. In the firft cafe, the nurfe takes notice that the child's linen is not wet, and the extremity of the penis prefents a foft, oblong, fhining, transparent tumour, occafioned by the collection of the urine between the prepuce and the glans. Relief is to be given by making an incifion into the anterior and inferior part of the fwelling, and thus opening the prepuce. The frefh-cut fufaces are then to be kept apart with a doffel of lint, until healed. When the prepuce is very long, it is even recommended to cut off a piece of it, in order to remove all risk of a phymofis.

When the inability to evacuate the urine depends upon an imperforate ftate of the canal of the urethra, the membrane which closes its orifice is to be opened with a lancet, and a
piece

piece of lint introduced between the sides of the puncture, until they are cicatrized.

In the female subject, the meatus urinarius is sometimes found imperforate, though less frequently so than the vagina. As soon as a surgeon is apprised of the cause of a young female child not being able to void its urine, he is to divide the membrane which closes the orifice of the meatus urinarius. The frequent evacuation of the urine, and the introduction of a small dosill of lint, will prevent the sides of the incision from growing together again. An imperforate urethra in the female subject has been known to give rise to an urinary fistula at the navel. In this case, the retained fluid makes its way by the urachus to the umbilicus. The urachus, which in the adult is solid and ligamentous, contains in some subjects an inconsiderable cavity, which ascends more or less towards the navel. It is conceivable, that in such individuals, who are analogous to quadrupeds, in which the urachus is a true canal, the urine may ascend along this process to the navel, elevate the skin there, and at length makes its way out, and cause a fistula in the same situation. Even when the urachus is solid, it is possible that the lining of the bladder may be propelled in this direction, and protrude also at the umbilicus, where it may afterwards burst. However it may be, nothing is more certain than the possibility of the urine ascending along the urachus, and the formation of an urinary fistula at the navel, in young female children, in whom the urethra is imperforate. Cabrol's twentieth observation affords a complete proof of the fact. In a case of the same kind, we could not also do better than imitate the practice, which this practitioner adopted. It consisted in first establishing the natural passage for the urine by a suitable incision, and the use of an elastic gum catheter. A ligature was then applied round the fungous protuberance at the navel, where the urine had been previously discharged. Perhaps, however, the latter proceeding would generally be unnecessary, because, unless the fistula had existed very long, it would spontaneously heal, on the urine finding its natural outlet.

URETHRA, Orifice of, Misplaced. In speaking of malformations of this passage, it deserves notice that the orifice of the urethra is not always found situated at the anterior part of the glans. This particular case, which is not very uncommon, is termed by surgeons *hypospadias*. It presents the following varieties:—Sometimes the orifice of the urethra is below the glans; sometimes it is very far back, near the crura of the penis, but still at the under surface of this organ. There are also cases, in which the urethra is found situated above the corpora cavernosa; and the malformation ought then to be called *epispadias*. Richerand mentions having seen a remarkable instance of this description in a young conscript. The penis was extremely short; so much so, that, at first view, there seemed to be only the glans, which, in the flaccid state of the parts, was the only thing visible in front of the pubes. Along the upper part of the base of the glans there was a fissure, which extended through the skin of the dorsum of the penis, resembling a vulva of about an inch in length. The malformation, termed *hypospadias*, causes no impediment to the evacuation of the urine; and it is even asserted, that it does not certainly deprive the individual of the generative power. The truth of this observation must depend very much upon the exact situation of the orifice of the urethra; for if it were towards the perineum, impotence must be the consequence. In this latter kind of case also, no attempt at a cure would be practicable; though, perhaps, when the orifice is near the glans, something might be done, with a view of forming a continuation

of the passage to its proper extent. Such, however, would be the tendency of any new opening to close again, that the result would be very uncertain; and we believe that the records of surgery evince no facts in favour of the trial.

There is another serious malformation of the urethra, which consists in a preternatural shortness of it. The canal does indeed extend to the glans penis, where it terminates in the usual way; but its actual length does not correspond with that of the corpora cavernosa. Hence, a permanent curvature of the penis is produced, and the perfect erection of this organ is hindered. The case is said to be entirely incurable.

URETHRA, Calculi lodged in. Stones of moderate size may escape from the bladder, and, lodging in different parts of the urethra, may occasion great pain, and a difficulty of making water. An instance has been recently published, in which a stone in the urethra was mistaken for a stricture, and the caustic actually applied. (See Marcet on Calculous Disorders, p. 9.) Whatever may be their situation in this canal, their evacuation ought to be promoted by all such means as tend to relax the passage; as bleeding, the warm bath, fomentations to the perineum, diuretic drinks, and the injection of oil into the passage. These means are to be assisted by the gentle and skilfully directed pressure of the fingers, applied just behind the foreign body. When a very small calculus is suspected to be in the bladder, and it will not pass through the urethra, M. Delpech has lately proposed dilating the passage as much as possible with elastic gum catheters; and when the largest instrument can be introduced, he thinks a good chance of the calculus being voided might be obtained, by suddenly withdrawing the large catheter, and desiring the patient to void his urine as forcibly as possible. Particular forceps have likewise been constructed for the extraction of calculi from the urethra; but they seldom answer, except when the foreign body is near the orifice, and would soon escape of itself. A tobacco clyster has been known to effect the discharge of a calculus from the urethra. See Edinb. Med. Surg. Journ. vol. xii. p. 373.

When all the foregoing proceedings are ineffectual, and the patient suffers a good deal of pain and inconvenience, it becomes the duty of the surgeon to cut down to the calculus, and extract it. The patient should then wear an elastic gum catheter for a few days, until the opening is healed. The writer of this article was once consulted by a gentleman's coachman, who had contrived to let a large head-dress pin slip a considerable way into the urethra, so that he could not get it out again. The point of the instrument, in fact, was more than three inches from the orifice of the urethra. Its extraction was easily accomplished, by pushing its point through the urethra, when it was taken hold of, and withdrawn as far as it could be in this manner. The head of the pin was then pushed towards the mouth of the canal, and the whole instrument extracted.

URETHRA, False Passage in. One of the greatest evils, arising from the unskilful and too violent use of catheters, bougies, and other instruments, is the formation of a new or false passage, by the rupture of the urethra. Whenever an instrument is afterwards introduced, it does not follow the course of the urethra, but enters the ruptured opening. Thus, the difficulty of curing the stricture, if there be one, is seriously increased, because the surgeon can hardly ever get the bougie to reach it again; and if his object is to pass an instrument into the bladder, he is equally frustrated. Nothing seems more likely to cause a false passage, than the violent use of the conical silver catheter, in cases of bad strictures;

fricatures; a plan which is now in vogue at Paris, and of which we have already delivered an account in a foregoing column. The formation of a false passage is also a dangerous accident, inasmuch as it may give rise to an extravasation of the urine, sloughing of the perineum and scrotum, and even death itself.

When a surgeon has reason to suspect that there is a recent false passage, perhaps his wisest plan is to desist from the introduction of instruments into the urethra, and keep the patient very quiet for a few days, in order to take the chance of the breach of continuity being repaired. If, however, the urine should be effused, he would be warranted in attempting to pass an elastic gum catheter, without any delay, in the hope of stopping the increase of the extravasation. Were the effused fluid considerable, he would also be called upon to make immediately one or two free incisions, for the same purpose. Should he be so fortunate as to succeed in getting a catheter introduced, the patient must be directed to wear it for several days, without interruption. In this manner, the urine would be conveniently discharged, and the false passage perchance heal up.

Mr. Hunter has advised the performance of the following operation for the cure of a false passage:—Pass a staff into the urethra, as far as it will go, which will probably be to the bottom of the new passage; and this, we may be sure, is beyond the stricture. Feel for the end of the instrument externally, and cut upon it, making the wound about an inch long, if the disease be before the scrotum; and an inch and a half, or more, if in the perineum. If the new passage be between the urethra and body of the penis, you will most probably get into the sound urethra, before you come to the instrument, or new passage. If so, introduce a probe into the urethra, through the wound, and pass it towards the glans penis, or, in other words, towards the stricture. When it meets with an obstruction, this must be the stricture, which is now to be got through, and afterwards dilated. To complete the operation, withdraw the probe, and, instead of it, introduce a cannula forward to the stricture. Then pass another cannula from the glans downward, till the two tubes are opposite each other, having the stricture between them. While an assistant holds the cannula in this position, the stricture is to be perforated with a sharp instrument, introduced through the upper cannula. A bougie is then to be introduced into the cannula, through the perforated stricture, and the tubes are to be withdrawn. The bougie is now to be passed into the bladder, and worn. Instead of bougies, modern surgeons would now invariably prefer, in such cases, elastic gum catheters, which allow the patient to make water with convenience, create less irritation than common bougies, and can be worn for a longer time, which are great considerations, in addition to the important advantage of keeping the urine from passing either through the wound, or the false passage. Besides the foregoing steps, it would be necessary, in some old cases, to lay open the false passage before it would heal.

URGAS, in *Ancient Geography*, a town of Hispania, in Bœtica, at some distance to the left of Bœtis, and west of Corduba, belonging to the Turduli, surnamed *Alba* by Pliny.

URGEL, in *Geography*, a town of Spain, in Catalonia, the see of a bishop, suffragan of Tarragona; 65 miles N.N.W. of Barcelona. N. lat. 42° 24'. E. long. 1° 22'.

URGENUMÆ, in *Ancient Geography*, a town of Gallia Narbonensis, according to Strabo: the *Ernagium* of Ptolemy.

VOL. XXXVII.

URGHENTZ, or **URGENTZ**, in *Geography*. See **URKONJE**.

URGI, in *Ancient Geography*, a people of European Sarmatia, between the Danube and the Borysthenes.

URGNANO, in *Geography*, a town of Italy, in the department of the Serio; 5 miles S. of Bergamo.

URGO, in *Ancient Geography*, an island situated on the coast of Etruria. Pliny says that it was larger than the island Plantaria, and that it took the name of Gorgon.

URI, a people of India, on the bank and towards the source of the river Indus. Pliny.

URI, in *Geography*, a canton of Switzerland, bounded on the north by Schwytz, on the east by Glaris, on the south by the Italian bailiwicks, and on the west by Underwalden, about 60 miles in length, and 28 in breadth. It consists almost every where of high mountains and deep valleys; the summits of the former of which are perpetually covered with ice and snow. The loftiest among them, and indeed the highest in Europe, is that of St. Gothard. On the Alps in this canton, during the summer, are fattened many thousand heads of cattle; and the cheese is famed for its goodness. The vales between the high mountains here in summer are very hot and fertile, when not exposed to the northern winds; among the mountains too are found numbers of beautiful crystals; the greatest part of which are bought up, and sent off to Italy to be wrought. In this canton are only market-towns, villages, and scattered houses; and the inhabitants, being inured to a rough and hard way of living, are hardy, vigorous, and brave, and strenuous assertors of that liberty which was so dearly purchased by their patriotic ancestors. They are all Roman Catholics. They were once as a free people, immediately under the jurisdiction of the empire. An union between Uri, Schwytz, and Underwalden, for throwing off the Austrian yoke, was effected in the beginning of the year 1308; and in 1315, these three cantons entered into a perpetual alliance. At that time Uri held the first place among the confederates, but at present only the fourth, though among the six lesser cantons it is styled the first. Its government is democratical, like that of *Schwytz*; which see.

These two cantons, including their subjects, contain about 50,000 souls; and, in case of necessity, could furnish above 12,000 militia. The same kind of soil, and the same productions, are common to the two cantons: the whole country, being rugged and mountainous, consists chiefly of pasture, produces little corn, and has no vines. The natives, however, have improved a barren soil into a wonderful state of fertility. The purity, or, as some would call it, the austerity of morals, which still prevails among these people, cannot easily be conceived by the inhabitants of opulent cities. The beautiful description given in Goldsmith's "Traveller" is peculiarly appropriate to these people.

"Dear is that shed to which his soul conforms,
And dear that hill which lifts him to the storms:
And, as a child, when fearing sounds molest,
Clings close and close to the mother's breast:
So the loud torrent, and the whirlwind's roar,
But bind him to his native mountains more."

The capital of this canton is Altorf.

URIA, in *Ancient Geography*, a town of Italy, in Apulia.—Also, a town of Italy, in Messapia, upon the Apian way. (Strabo.) Herodotus calls it Hyria, and says that it was founded by the Cretans, about a century before the siege of Troy.—Also, the name of a lake of Acarnania.

URIAS, a small gulf of Italy, difficult of entrance.

URIBACO, in *Ichthyology*, the name of a Brazilian sea-fish, esteemed a very well-tasted and wholesome one. It is somewhat of the figure of the perch; its back is rigid, and its belly is somewhat protuberant. It grows to ten or twelve inches long. Its teeth are small and sharp, and the ends of its gills and gill-fins terminate in a triangular point: its belly-fins are furnished by a very rigid and strong spine: its long fin, behind the anus, is supported by flexile and short spines; it has only one fin on the back, equally broad, and, reaching nearly to the tail, supported by prickly rays; its tail is deeply forked; its scales are of a fine silvery white, with a faint cast of pale but bright red; its belly-fins are white, and its back-fin and tail reddish: its side-lines are broad, and of a fine red; over these and under them, near the tail, there is on each side a large black spot. *Margraave. Ray's Ichthyol. p. 33.*

URIC ACID, in *Chemistry*. This substance was discovered by Scheele in 1776. The French chemists named it *l'acide urique*, from its being a common ingredient in urinary calculi, but Dr. Pearson subsequently changed its name to that by which it is at present generally known. The original name, however, is likely to be again adopted, as Dr. Marcet has adhered to it in his recent work upon urinary calculi.

Uric acid separates spontaneously from some urine in the form of red granular crystals; or it may be procured more readily in this impure state by the addition of either of the mineral acids to the urine. The best way of obtaining it in quantity, however, is to dissolve urinary calculi composed chiefly of it in an alkaline lixivium, and to precipitate it from this by a mineral acid. Uric acid, thus obtained, and afterwards repeatedly well washed, has the following properties.

It appears in the form of a beautiful white powder, which feels rather harsh, but not gritty, and is destitute both of taste and smell. According to Dr. Henry, it dissolves in about 1150 times its weight of water at 21°, or in about 1720 times at 60°. In boiling water it is more soluble, and its solution faintly reddens litmus. It readily dissolves in solutions of the fixed alkalies, but not so readily in ammonia. It is incapable of decomposing the alkaline carbonates, or any earthy or metallic salt. The nitric acid dissolves it, and when this solution is evaporated to dryness, it assumes a beautiful pink colour, which becomes of a fine carmine hue on the addition of water. This colour is not permanent if exposed to the action of the air; but paper stained with it, and dried and kept in close vessels, retains the colour for a long time. Chlorine produces a similar effect upon this acid; an effect which is quite peculiar, and therefore characteristic of it. On being subjected to heat, uric acid emits a strong odour, and yields a large proportion of prussic acid. Submitted to distillation in close vessels, it yields a principle of a peculiar nature, which Dr. Henry has ascertained to be a distinct acid. According to Dr. Prout's analysis, uric acid consists of

1 atom or 1 volume of hydrogen	1.25	} hydr. 2.857		
1 atom or 2 volumes of carbon	15.00		} carb. 34.286	
1 atom or ½ volume of oxygen	10.00			} oxyg. 22.857
1 atom or 1 volume of azote	17.50			
43.75		100.000		

Dr. P., therefore, seems disposed to consider it as composed of one atom or volume of cyanogen, and one atom or volume of water.

Uric acid combines with the alkalies and alkaline earths, and forms a set of salts, none of which are very interesting,

except the *superurate of soda*, which constitutes the *gouty calculus*, or *chalkstone*. The urates may be formed by boiling the base with an excess of acid in a proper quantity of water, filtering the solution, and evaporating it to dryness. The urates of potash, soda, ammonia, barytes, ironites, lime, magnesia, and alumina, obtained by the preceding process, are neutral, have neither taste nor smell, and can scarcely be distinguished from uric acid itself. They dissolve with great difficulty in water, urate of ammonia being most soluble, and urate of barytes the least. They all appear, however, to form sublimates much more soluble than the neutral salts. See *URINARY Calculi*.

URICACHI, in *Geography*, a town of New Navarre; 160 miles S.S.E. of Cafá Grande.

URICONIUM, **VIROCONIUM**, or *Vriconium*, in *Ancient Geography*, a town of Great Britain, in the second Itin. of Antonine, between Rutanium (near Wem) and Uxacona (near Sheriff Hales). It belonged to the Cornavi, and was situated at Wroxeter, in Shropshire, on the N.E. side of the Severn, about three miles from Shrewsbury; which is supposed to have risen out of the ruins of that ancient city. At Wroxeter many Roman coins have been found, and the vestiges of the walls and ramparts of Uriconium are still visible. It is highly probable, that the neighbouring mountain, the Wrekin, derives its name from Uriconium; for it preserves the ancient British name *Urecon*.

URIE WATER, in *Geography*, a river of Scotland, which runs into the Don, near Inverarie.

URIES, CAPE, a cape on the N. coast of Staten island. See *STATEN Island*.

URIGNY, a town of France, in the department of the Loiret; 6 miles S. of Pithiviers.

URIGO, a burning with a caustic, or cautery.

VRIHASPATI, in *Astronomy*, is the Hindoo name of the planet Jupiter. In an invocation to the different planets, given in the seventh volume of the Asiatic Researches, he is thus addressed: "O Vrihaspati! sprung from eternal truth, confer on us abundantly that various wealth, which the most venerable of beings may revere; which shines glorious among all people." Intellectual wealth is probably here meant; Vrihaspati being preceptor to the gods, the most venerable of beings. He is also their messenger in intercourse between the three principal deities, being proverbial for eloquence. A cycle is called after Vrihaspati; and it is the name of a celebrated legislator; so that this name, originally probably of some highly gifted person, occurs very frequently in astronomical and legal points; though in others, whatever historical facts may be connected with it, he is hidden in the veil of mythological fable. (See **SANI**, the Saturn of the Hindoo zodiac.) As with the western astrologers, Friday is with the Hindoos the day of Vrihaspati, or Jupiter. (See **ZODIAC**.) He is represented of golden aspect, clothed in red, bearing a lotos, and a staff in his hands; and sometimes mounted on a boar. Many of the Hindoo deities have vehicles assigned them, which are called *vahan*. See under that word for an enumeration of many of them.

Under our article **SULTEE**, the authority of Vrihaspati as a legislator is quoted; as it is very frequently in Colebrooke's valuable digest of Hindoo law. In the article **SIVA**, that important person of the Hindoo triad is said to guide the motions of the planet Jupiter, as Vishnu does those of the sun, and Brahma of Sani, or Saturn. And under **TARA** we have given a legend, sufficiently ridiculous, if taken literally, of Vrihaspati having begotten a monkey fo named;

named; but we refer to the article descriptive of the cause of so strange a fiction.

The name of Vrihapatî occurs often in the Vedas; a proof of the early age of the person, whoever he was, that first bore the name. He had a daughter named Romafa, married to the king Bhavayavya; but we have no particulars of their history. Angiras, one of the holy persons to whom the Veda was revealed, is sometimes called father of Vrihapatî; other authorities say Devala was his father.

In the Ramayana, Vrihapatî is called Vachapatî, and noticed as proverbial for eloquence. The name may be translated lord of speech. See VACHA.

URIM and Thummim, אֲרֻמִים תְּחֻמִּים, q. d. *light and perfection*, the name of a kind of ornament belonging to the habit of the Jewish high-priest; in virtue of which he gave oracular answers to the people.

The high priests of the Jews, we are told, consulted God in the most important affairs of their commonwealth, and received answers by the urim and thummim. What these were is disputed among the critics: some take them to be the twelve precious stones in the priest-plate of the high-priest, on which were engraven the names of the twelve tribes of Israel; and they maintain that the oracle gave its answer to any question proposed, by causing such letters in them to shine with superior lustre, or to appear prominent above the rest, as formed the words of the answer; or by an audible divine voice pronouncing the words, the high-priest was prevented from mistaking the answer. Josephus, and some others, imagine, the answer was returned by the stones of the breast-plate appearing with an unusual lustre, when it was favourable, or in the contrary case, dim. Others suppose, that the urim and thummim were something enclosed between the folding of the breast-plate; this some will have to be the tetragrammaton, or the word יְהוָה, *Jehovah*. Christophorus de Caltro, and after him Dr. Spencer, maintain them to be two little images shut up in the doubling of the breast-plate, which gave the oracular answer from thence by an articulate voice. Accordingly, they derive them from the Egyptians, who consulted their lares, and had an oracle, or teraphim, which they called truth. This opinion, however, has been sufficiently confuted by the learned Dr. Pococke, Comment. on Hosea, chap. iii. 4. and by Witius in his *Ægyptiaca*, lib. ii. cap. 3. 10, 11, 12. The more common opinion among Christians concerning the oracle by urim and thummim, and which Dr. Prideaux espouses, is, that when the high-priest appeared before the veil, clothed with his ephod and breast-plate, to ask counsel of God, the answer was given with an audible voice from the mercy-seat, within the veil: but, it has been observed, that this account will by no means agree with the history of David's consulting the oracle by Abiathar; 1 Sam. xxiii. 9. 11. chap. xxx. 7, 8. because the ark, on which was the mercy-seat, was then at Kirjathearim; whereas David was in the one case at Ziklag, and in the other in the forest of Hareth. Braunius and Hottinger have adopted another opinion: they suppose, that when Moses is commanded to put in the breast-plate the urim and thummim, signifying *lights and perfections* in the plural number, it was meant that he should make choice of the most perfect set of stones, and have them so polished as to give the brightest lustre: and on this hypothesis, the use of the urim and thummim, or of these exquisitely polished jewels, was only to be a symbol of the divine presence, and of the light and perfection of the prophetic inspiration: and as such, constantly to be worn by the high-priest in the exercise of his sacred function, especially in consulting the oracle. See

Prideaux's Connection, vol. i. p. 123, &c. Jennings's Jewish Ant. vol. i. p. 233, &c.

Diodorus Siculus relates, that there was also a ceremony in use among the Egyptians, whose principal minister of justice wore a collar of precious stones about his neck, which was called ἀλυσια, or trouth.

URIMA, in *Ancient Geography*, a town of Asia, situated on the western bank of the Euphrates, S.E. of Samofata.

URIMAO, in *Geography*, a town of Mexico, in the province of Mechoacan; 35 miles N. of Zacatula.

URNAL, in *Domestic Economy*, a vessel fit to receive and hold urine; and used accordingly for the convenience of sick persons. It is usually of glass, and crooked; and sometimes it is filled with milk, to alluage the pain of the gravel.

URNAL, in *Chemistry*, is an oblong glass vessel, used for making solutions, and so called from its resemblance to the glasses in which urine is set to settle, for the inspection of the physician.

URNARIUM, in *Agriculture*, a name sometimes applied to a sort of reservoir, or place constructed in the ground for the reception of urine, and the liquid matters discharged from the stables, cattle-sheds, pig-sties, and other places situated about the farm-yard.

It may be noticed, that a basin or receptacle of this nature is essential to every well-contrived farm-yard; as by blending vegetable, earthy, and other similar materials with these liquids, a vast increase of valuable manure may be readily and conveniently produced. These basins should always be formed in the most shady parts of such yards or places, and be well connected with the buildings destined for the horses, cattle, pigs, and other sorts of live-stock. In particular situations, too, they may be so contrived as to be capable of being discharged and thrown over the grass-lands that may lie below them. An useful and well-contrived cavity or reservoir of this sort is described by Mr. Pew in the seventh volume of the Bath Letters and Papers, in which the cow and other cattle-stalls are said to be placed on the side of a nap, or small elevation; and that, by means of gutters formed behind, the liquor is conveyed into a sink or drain, which runs under the stable, where, by the help of another drain or sink, it meets with the stable liquor; and these, with that from the pig-sties, run through an under-ground drain into the receptacle or reservoir. It is the practice of the proprietor, it is said, to put all sorts of refuse vegetable and animal matters into this receptacle, where it quickly rots; and when the weather turns moist, he has it stirred well up with poles, when it is discharged over a meadow that lies below, or any particular part of it, by means of trenches cut for the purpose, which is in this way rendered, it is asserted, astonishingly fertile and productive, as well as much more early than even watered lands. It is suggested, further, that this plan might be extended, by having the stables, in such cases, placed on the centres of the knolls, as in this case three or four reservoirs might be formed; and that by stopping some drains, and opening others, the fluid contents might be directed one year to one side and another year to another side, as circumstances might render necessary.

These kinds of reservoirs are sometimes so situated in respect to the dung-leads, as to have pumps fixed in them for throwing the urine and liquid matters over the manure heaps, as by that means much waste of such matters is prevented, and the dung greatly improved. Besides, in this way, such fluid materials can be the most readily dispersed over different sorts of rich earthy substances, and the increase of manure

be thereby the most fully and conveniently promoted. See MANURE and YARD-Dung.

URINARIUS MEATUS, in *Anatomy*, the urethra of the female. See URETHRA.

URINARY ABSCESSSES, in *Surgery*, are so called when an extravasation of urine in the cellular membrane of the scrotum, penis, perineum, &c. excites suppuration in the parts, so that purulent matter and urine are found mixed together in the tumour. Such an effusion of urine always arises from a breach of continuity in the bladder or urethra, most frequently in consequence of the distention of that viscus in obstinate, protracted, and improperly treated retentions of urine; or in consequence of abscesses, which form in the course of the urethra, and burst into that canal. The making of a false passage in the urethra, by the unskilful use of bougies and catheters, and the laceration of this tube by forcible contusions, are also common causes of an extravasation of urine. There is not in the whole body any fluid, whose extravasation produces more serious mischief than the urine. If it be not promptly discharged, it soon excites a putrid suppuration in the cellular membrane containing it; makes this part floughy; causes mortification of the skin; and a gangrenous inflammation of every structure with which it comes into contact.

When the opening, by which the urine has escaped from the bladder, is situated either in this viscus or the urethra, there are invariably two principal indications to be fulfilled. The first is to prevent the further increase of the extravasation, by introducing a catheter, drawing off the urine, and desiring the patient to wear the instrument. The second indication is to give an outlet to the effused urine; so that the mischief, likely to result from its presence in the cellular membrane, may be lessened as much as possible. This is effected by suitable incisions, which also have the good effect of tending to hinder the urine from spreading more extensively amongst parts, in which it would be sure to produce inflammation, abscesses, and gangrene.

The manner of opening such collections varies according as the urine may be in one cavity, or widely effused in the cellular membrane. In the first case, a simple incision, the whole length of the cavity, will suffice for emptying and healing it. In the second, if the extravasation is extensive, the incisions must be multiplied. It would be absurd to spare the parts; for all those with which the urine has come into contact seldom escape mortification. The incisions which are made hardly ever have the effect of saving them; but, by accelerating the discharge of putrid sanies and stagnant urine, they prevent the mischief which would originate from their further lodgment. If these incisions, however, were practised a few hours after the extravasation, and before suppuration, the parts might be completely freed from urine and preserved. When the operation is at all delayed, their destruction is inevitable. The approach of mortification is indicated by the crepitation under the bistoury, resembling the kind of noise produced by tearing parchment. The extent and depth of the incisions must be proportioned to those of the abscess. When the extravasation occupies the scrotum, long deep scarifications should be made in that part, as well as in the skin of the penis, and in every place where the urine is effused.

Practitioners, unaccustomed to see such diseases, would be alarmed at the extent of the sore produced by the separation of the eschars. Sometimes the whole scrotum, skin of the penis, and that of the groins, perineum, and upper part of the thigh, mortify, and the naked testicles hang by the spermatic cords in the midst of this enormous ulcer. It is

hardly conceivable how cicatrization could take place over the exposed testicles; but the resources of nature are unlimited. She unites the testicles and the cords to the subjacent parts; and, drawing the skin from the circumference to the centre of the ulcer, she covers these organs again, and furnishes them with a sort of new scrotum. This statement is founded upon numerous cases, in which nature always followed this course. The cicatrization of the ulcer is even more expeditious than might be expected, considering its extent. In all this business, what does art do? If the introduction of the catheter be excepted, which, indeed, is absolutely necessary for the radical cure, her assistance is very limited, and almost nothing, in the generality of instances; for when the patients are not exhausted by the tediousness of the disorder, when they are of a good constitution, and in the prime of life, they get well as quickly and certainly, with the aid of a good diet and simple dressings, as when they take internal medicines, and use a multiplicity of compound topical applications. The practice of Default at the Hôtel-Dieu consisted in applying emollient poultices, until the sloughs were detached. The ulcer was then sometimes dressed with pledgets charged with styrax; but frequently mere dry lint was used, and continued till the cure was completed. If any complication occurred in the course of the treatment, suitable remedies were prescribed for it. Thus when prostration of strength, and tendency to sloughing existed, bark, cordials, and antiseptics were ordered. But in every case, the catheter is the essential means of cure; without it, the treatment is almost always imperfect, and the ulcer will not heal without leaving several urinary fistulæ. See *Œuvres Chirurgicales de Default*, par Bichat, tom. iii. p. 277—287.

URINARY Calculi. The formation of concretions in the urinary passages being occasioned by the precipitation and consolidation of particular ingredients in the urine, calculi must of course be liable to occur in any of the cavities to which the urine has access. In fact, experience proves that they are frequently met with in the kidneys, ureters, bladder, and urethra. It is commonly believed, that most of them are originally formed in the kidneys, from which organs they afterwards descend with the urine into the other mentioned parts. We must however regard, as exceptions to this observation, the cases in which calculi are formed round foreign bodies, introduced into the bladder through the urethra, the digestive organs, or some accidental wound. In the centre of urinary calculi, ferguson has often met with bullets, splinters of bone, bits of wood, pins, &c. Nor is it necessary for such foreign bodies to be large, in order to produce this effect: a clot of blood, or a little bit of chaff, if not very soon voided, appears to be capable of causing a precipitation of the urinary salts.

That urinary calculi are in many instances originally produced in the kidney, we have the most unequivocal proofs; first, from the severe pain which the passage of such foreign bodies down the ureter always excites; and, secondly, from their being often discovered in the infundibula and pelvis of that viscus after death. This last fact is well illustrated in the first plate of Dr. Marcet's interesting Essay on the Chemical History and Medical Treatment of Calculous Disorders. The engraving is taken from a preparation in the museum of Guy's hospital. In this instance, there were several calculi closely pressed against each other; but, in another example, drawn from a specimen in Mr. Abernethy's museum, the renal concretion was composed of a single mass, which represented a complete cast of the pelvis and part of the infundibula of the kidney. In this form of the disease,

the

URINARY CALCULI.

the kidney loses at last all vestiges of its natural structure, and is converted into a kind of cyst, filled with the extraneous substance. As Dr. Marcet observes, when such a complete alteration of structure takes place, the secretion of urine must of course be entirely carried on by the other kidney. This, however, in some instances, is attended with so little inconvenience as almost to escape notice; and it sometimes even happens, that both kidneys are diseased in a very great degree, and yet life is preferred for a considerable time. *Op. cit. p. 3, 4.*

Calculi are sometimes found in the ureters, especially at their upper part; but it is not supposed that they are in general originally formed in that situation; an event not likely to happen, unless there be some cause obstructing or retarding the descent of the urine through those tubes. The common belief is, that all calculi found in the ureters are first produced in the kidneys, from which they afterwards descend in the course of the urine.

The generality of calculi, however, which leave the kidney, are of small size, and consequently, after a time, and exciting some pain and inconvenience, they usually get into the cavity of the bladder. Indeed, as Dr. Marcet remarks, the bladder is the most frequent seat of calculi, not only because all urinary concretions, or their nuclei, formed in the kidneys tend to fall into that organ, but also because a stone may be, and probably often is, originally formed in the bladder itself.

It is, however, in the infundibula and pelvis of the kidney, that the first nuclei of urinary calculi are commonly produced. Renal concretions vary considerably in their number, size, and shape. In some cases, a single small calculus has been found occupying one of the foregoing situations; while, in other instances, an innumerable collection of calculous substances are observed filling the whole of the cavity of the pelvis and infundibula of the kidney, distending its parietes, and even obstructing the passage of the urine out of this viscus, which is converted into a sort of membranous cyst. Lastly, a single stone in the kidney may acquire a very large size there; or a great number of small calculi, in the same situation, may become cemented together by the deposition of fresh concreting matter between them, so as to form one mass of enormous dimensions, and the shape of which invariably corresponds to the space in which it is, as it were, moulded. Hence it is, that renal calculi often present a variety of odd irregular figures, resembling those commonly observed in specimens of coral.

We have already remarked, that urinary concretions of large size very often exist in the kidney, without their presence being indicated by any external circumstances, or attended with any symptoms, sufficiently unequivocal to constitute a ground for suspecting the importance of their cause. On the other hand, it is very usual for renal calculi, of middling dimensions, to excite serious and alarming complaints. The reason of this difference becomes obvious, when it is recollected that smallish concretions are readily carried with the urine into the ureter, and become fixed in the narrow portion of the tube. But very large calculi can be contained only in the upper part of this canal, where its parietes are more yielding, and the space in them more capacious.

Calculi of middling size, in their passage through the ureter, cause, at first, a feeling of heaviness, or an indeterminate sense of uneasiness, and an obtuse pain in the region of the corresponding kidney. These complaints occur at intervals of greater or less duration. At length, the pain grows more urgent and annoying, attended with flatulence, heartburn, frequent vomiting, painful retraction of the testicle, and sometimes acute fever. The patient makes water

frequently, and in small quantities at a time; and the urine is high-coloured and bloody. The patient cannot sit upright, his body being bent forwards towards the affected side. These symptoms may have more or less duration, and then suddenly cease. They may also subside and recur several times successively, with intervals of some days. In the latter case, the pain is felt at each attack to be situated lower in the track of the ureter. Lastly, when the symptoms have entirely disappeared, the urine is more abundant, not so high-coloured, and easily discharged, the stream sometimes bringing out with it the urinary concretion, which has now entered the bladder.

Suppuration of the kidney, and an abscess in the lumbar region, in consequence of renal calculi, are not very common events. This, however, is the only case of the kind, in which the interposition of surgery can be useful. By diverting to previous circumstances, and the irregularity of the pain about the kidney, the practitioner may suspect the nature of a phlegmonous tumour in the situation of this viscus. Whatever may be his conjectures, however, he must carefully abstain from the use of his lancet, until purulent matter is obviously under the integuments. He may then safely make an opening, from which urine and pus will be discharged, and through which the calculi themselves may sometimes be felt and extracted. If they should not be readily touched with a probe, let not the surgeon rashly conceive, that he is justified in endeavouring to discover them with his knife. Their situation may be such as to baffle all his endeavours, and the operation itself might cause a most dangerous hemorrhage, and other fatal mischief. The opening of an abscess of the kidney may remain a long while fistulous, and the circumstance may indeed warrant the conclusion, that the healing is prevented by the presence of some extraneous substances; but a prudent practitioner will never think of performing any operation for their extraction, before nature has brought them tolerably near to the surface.

Urinary calculi, which form upon foreign bodies accidentally introduced into the bladder, and acting as nuclei, are always single, unless the number of foreign bodies themselves happen to be greater. It is curious also to find, from the observations of Dr. Marcet, that, in such instances, the deposition most frequently, if not always, consists of the earthy phosphates, and especially of the fusible calculus. But when calculi originate from a particular diathesis, there may be many of them lodged in the bladder at the same time. Several distinct nuclei may descend successively from the kidneys, and each may increase in a separate manner. Sometimes, however, calculi in the bladder, which were at first distinct and unconnected, become afterwards cemented together, so as to make only one mass.

The magnitude of calculi in the bladder is generally in an inverse ratio to their number. Some hundreds have been found in one bladder, but they were not larger than a pea. Others of so large a size have been met with, that they were more than six inches in diameter. In Fourcroy's museum, and in that of the Ecole de Médecine at Paris, may be seen some calculi which filled the whole cavity of the bladder; and in the Phil. Trans. for 1809, the late Sir James Earle has described an enormous stone, which he extracted after death from the bladder of a gentleman who had been unsuccessfully cut for it. This calculus weighed three pounds four ounces, and was of an oval shape, its long axis measuring sixteen inches. It was of the fusible kind. Their average size may be compared with that of a chestnut, a walnut, or a small hen's egg. Their weight differs from a few grains to upwards of fifty ounces. Common stones of the bladder, however, weigh from two to six ounces. Their weight is

URINARY CALCULI.

not always proportioned to their size. Substances of different qualities enter into their composition, and diversify their heaviness. Thus, the salts which have silica for their base, and which are very uncommon, render such calculi as contain them the heaviest of all in proportion to their size. On the other hand, some urinary salts crystallize when precipitated: of this kind is the ammoniaco-magnesian phosphate, the crystals of which frequently leave considerable interfaces, which are not filled up by the subsequent precipitations.

The urinary salts, in calculous patients, are not continually precipitated in the same quantities: in some cases, indeed, the process appears to be even suspended for a considerable time. Hence, a stone of middling size, already formed, may increase but very slowly; and it has actually happened, that a calculus, which could be plainly felt with a sound, has remained more than ten years in the bladder, and yet, after all this time, been only of a moderate size.

According to Dr. Marcet, the form of urinary calculi is mostly spheroidal, sometimes egg-shaped, but often flattened on two sides like an almond. P. 50.

Sometimes the calculous matter, which descends from the kidneys, is in the form of minute spherical grains, which have a singular tendency to unite either to each other, or to calculi already lodged in the bladder.

When there are several loose calculi in the bladder together, they seldom lie long in contact with each other, while their size is diminutive, but are incessantly changing their situation as the patient moves about or alters the position of his body. Hence, their increase is at first regular and uniform; but when they have attained a more considerable size, or by their numbers compose a large mass, their relative situation is more permanent, and many of their surfaces, being in this manner usually covered, no longer receive any additional depositions. Every other part of these calculi, however, goes on increasing. It is thus that stones with surfaces corresponding to those of other stones are produced, and which are aptly denominated by the French writers "*pierres à facettes*." This shape necessarily indicates the presence of several calculi. A different form, however, is by no means a certain criterion of the stone being single.

Calculi also occasionally occur which are angular, and sometimes almost cubic; but, as Dr. Marcet observes, this is a rare occurrence. The same physician has likewise given the engraving of a species of calculus which somewhat resembles a pear, with a circular protuberance at its broader end, apparently moulded in the neck of the bladder.

This writer also particularly calls our attention to the variety in the colours and surfaces of calculi, which often afford indications of their chemical nature. "When they have a brownish or fawn colour, somewhat like mahogany wood, with a smooth though sometimes tuberculated surface, they almost always consist of lithic acid. When cut open, they appear to be formed of concentric layers, sometimes homogeneous, sometimes alternating with other substances. The colour, however, cannot be considered as a certain criterion, since other kinds of calculi may often be coloured in the bladder in a similar manner, by bloody mucous or other vitiated secretions.

"When calculi are white, or greyish-white, they always consist of earthy phosphates. This is particularly the case with the species called fusible. And when they are dark-brown or almost black, hard in their texture, and covered with tubercles or protuberances, they are generally of the species which has been distinguished by the name of *mulberry*, and consists of oxalate of lime.

"Calculi have sometimes an uneven crystalline surface,

fludded with shining transparent particles. This appearance always denotes the presence of the ammoniaco-magnesian phosphate." Marcet, p. 52.

A large calculus, especially when it has a rough irregular surface, produces a great deal of irritation of the bladder, which contracts more closely round it. The contact, however, is remarked to be particularly exact at the transverse line, which extends between the terminations of the two ureters in the bladder, a part of this organ which generally becomes more thickened than the rest. Sometimes, indeed, the cavity of the bladder is almost entirely effaced, and the urine can be retained only a very short time, or, if it be not evacuated, it spreads uniformly round the calculus, especially above and below the above-described transverse projection, which is less yielding than other parts of this organ. Hence, the surface of the stone, towards the orifices of the ureters, does not enlarge so fast as the other sides of it, and a circular groove is produced, giving the foreign body the shape of a calabash. Such calculi are generally very large, and sometimes even of enormous size. In the latter circumstance, the foreign body fills the cavity of the bladder so completely, that there is no space left for the lodgment of the urine there, which fluid then generally passes along a sort of groove, situated in a line reaching from the lower termination of the ureter to the neck of the bladder. This state is of course accompanied with a complete incontinence.

Urinary calculi are not always loose and moveable in the cavity of the bladder, being sometimes fixed in various ways to certain points of the circumference of this organ.

1. When a calculus has reached that part of the lower termination of the ureter, which passes obliquely between the coats of the bladder, it may obstruct the inferior orifice of the canal, and produce an accumulation of urine above it. The distention thus arising may lead to the formation of a cavity betwixt the coats of the bladder, where the calculus is lodged. In fact, calculi have sometimes been found fixed in a cavity of this description, the juice of which communicates both with the lower end of the ureter and with the bladder. In such a situation, calculi have also been known to attain a considerable size.

2. It sometimes happens, that an urinary calculus descends to the very bottom of the ureter, and one end of it projects some way into the cavity of the bladder; but the other end cannot disengage itself from the tube. If things remain in this state long, the consequence is, that the stone grows larger at its two extremities, while the part which is closely embraced by the lower termination of the ureter remains much narrower than the rest of the foreign body.

3. Sometimes, in consequence of the distention of the ureter or other causes, the inner membrane of the bladder protrudes between the fasciculi of its muscular coat, in the form of pouches or cysts, which are of different sizes, and occasionally numerous. Small calculi, after getting into these cysts, frequently attain a very large size; and as the inner coat of the bladder more readily yields than the muscular fibres admit of separation, the fundus of such pouches becomes capacious, while their orifice remains of a diminutive size. Hence, a very small part of a stone thus encysted is naked in the cavity of the bladder, and sometimes the whole of the extraneous body is concealed under a sort of moveable fold of the mucous membrane.

4. There are on record very authentic cases, proving that calculi, some of which were of considerable magnitude, have been fixed and lodged in a cavity that consisted of the upper portion of the bladder, separated from the rest of this viscus by a circular contraction. Difficult as it may be to account for such facts, the truth of them is unquestionable.

URINARY CALCULI.

5. The transverse projection of the bladder, between the lower terminations of the ureters, is sometimes so considerable, as to constitute a kind of partition, and divide the inferior part of the bladder into two cavities. From this partition, large fungi have sometimes been found projecting, which materially increased the depth of the two cavities betwixt which it was placed. In these cavities, stones have been observed, which were of course completely separated.

6. Sometimes calculi in the bladder are found to be adherent to the inner surface of this organ. The irritation of the foreign body having excited ulceration, fungi arise, which grow into the cavities and irregularities observable in some urinary calculi, and thus produce a mechanical fort of adhesion.

When the bladder protrudes from the abdomen, so as to form hernia, a stone is occasionally situated in the displaced portion of that viscus. It is a circumstance that has the same effect as the encysted flate of a calculus; for the foreign body is thereby fixed, and it cannot be propelled towards the neck of the bladder at the period when the urine is discharged. It should also be known, that in cases of prolapsus of the uterus, when the bladder is drawn downwards, it has sometimes been found to contain a stone at the lowest part of it. The possibility of the complication of a calculus, with such displacements of the bladder, ought to be well remembered, since, if the nature of the case be detected, its treatment becomes materially simplified.

The symptoms of a stone in the bladder have been detailed in the article LITHOTOMY, and we shall therefore not repeat them in the present place. They are all so equivocal, and bear so great a resemblance to the effects of several other disorders, that they cannot be depended upon, and consequently no surgeon will venture to pronounce positively, that there is a calculus in the bladder, unless he can feel it with a sound. (See SEARCHING.) As for the operation, it is always totally unjustifiable, if the surgeon cannot plainly feel the calculus immediately before he begins his incisions.

The causes of the formation of urinary calculi is a subject which is still quite obscure. The conjectures which have been started respecting the effect of particular kinds of food, drink, air, &c. do not appear to rest upon a good foundation. We may lay down the following observations, however, as tolerably correct.

1. If a foreign body be introduced into a cavity, which is naturally a receptacle for the urine, whatever may be the nature of the immersed substance, it is sure to become incruited with the urinary salts, without any change however in its composition. In this case, the observations of Dr. Marcet tend to prove that the concretion mostly, if not always, consists of the earthy phosphates, and particularly of the ammoniaco-magnesian phosphate. In this instance, there is not the least reason for suspecting the operation of any peculiar diathesis in producing the calculus, since the presence of the foreign body, which forms the nucleus for it, would occasion the same consequence in all descriptions of patients.

2. There are some countries where calculi are exceedingly common; others where they are very rare, and yet one cannot explain the difference by any geographical circumstance which is constant, or by any particularity in the constitutions of the inhabitants. Calculi are found to be uncommon both in very cold and very hot countries.

3. When the urinary organs are not much injured, patients with stone may be healthy in every other respect.

4. Subjects, indeed, gifted with the strongest constitutions, are liable to urinary calculi, quite independently of the accidental introduction of any foreign body into the urinary organs. In these cases, the origin of the complaint is to be ascribed to a peculiar diathesis, the nature of which is at present entirely unknown.

5. Women have been thought to be less liable than men to urinary calculi; but yet it is a point which is by no means certain. The question, indeed, still continues thus: Are women in reality less liable than men to urinary calculi? Or do they only suffer less frequently from the disorder in consequence of the facility with which the calculi are generally discharged through the short and capacious canal of the meatus urinarius?

6. Childhood and infancy present numerous instances of urinary calculi; but, according to Delpech, relapses are seldom observed at these periods of life: that is to say, an entirely fresh stone is hardly ever formed again. If a return of the complaint happens, the quickness of the recurrence, and an attentive examination of the calculus, will in general sufficiently prove, either that the stone has formed round a fragment which had not been extracted in the previous operation, or that it was already completely formed at the same period, but inadvertently left behind.

On the subject of the frequency of the stone in children, Dr. Marcet thinks that this is the case only among the poor classes. He remarks, that in the higher ranks, or even in the lowest classes, provided they are well fed, the same frequency is not observed. "In the Foundling Hospital, for instance, within the last twenty-seven years, during which 1151 children have been admitted, only three cases of stone have occurred, all of which were among children while at nurse in the country. And in the Military Asylum at Chelsea, which contains about 1250 children, and into which upwards of 6000 of them have been already admitted, no more than one single case of stone has occurred." See Marcet's Essay on Calculous Disorders, p. 36.

7. Youths and adults are not very commonly troubled with calculi, even though they may have been thus afflicted in their infancy or childhood.

8. Old men are much more liable to the disorder, and in them the disposition to it continues through life. Hence, in such patients, relapses are very frequent. Delpech, Précis Elém. des Mal. Chir. t. ii. p. 193, &c.

Of all the writers who have investigated the causes of urinary calculi, none have interested us so much as Dr. Marcet. This able physician has endeavoured to estimate the comparative frequency of the disease in various countries, and in the different stations of life, and to determine whether its frequency be influenced by varieties of climate or situation, or by peculiarities in our habits and occupations. He instituted inquiries at all the great hospitals of the metropolis, in the hope of getting at some useful records concerning the vast number of patients on whom lithotomy had been performed in those establishments. In London, he found it impossible to obtain all the particulars of such cases, as no entry of them was preserved. The Norwich hospital, however, afforded him some details, which are interesting. All the calculi, which have been extracted in that hospital for the last forty-four years, and which amount to 506, have been carefully preserved, with the circumstances annexed to each stone, and the event of the operation distinctly recorded. Dr. Marcet has given the results of these records in the following table:

Returns

URINARY CALCULI.

Returns of the cafes of lithotomy in the Norfolk and Norwich hospital, from 1772 to 1816, making a period of forty-four years :

	Number of Operations.			Deaths.		
	Children under 14.	Adults.	Total.	Children.	Adults.	Total.
Males	227	251	478	12	56	68
Females	8	20	28	1	1	2
	235	271	506	13	57	70

It appears, says Dr. Marcet, from the above table, that the mean annual number of cafes of lithotomy in the Norwich hospital, during the last forty-four years, has been $11\frac{1}{2}$ or 23 in every two years; and that the total number of fatal cafes in the 506 operations, is 70, or 1 in $7\frac{1}{3}$, or 4 in 29. It appears also, that the proportion of females who have undergone the operation is to that of males, as 8 to 1000, or about 1 to 125; that the mortality from the operation in children was only about 1 in 18; while, in adults, it was 4 in 19, or nearly quadruple.

From the year 1772 to 1816, the Norwich hospital has received 18,859 patients of all kinds, making an average of 428 annual admissions; and Dr. Marcet observes, that the proportion of 506 operations of lithotomy, out of 18,859 patients, which corresponds to about 1 in 38, exceeds, in an astonishing degree, that obtained from any of the other public institutions, whose records he examined.

Next to the records of the Norwich hospital, Dr. Marcet derived the most distinct information of this kind from Cheadfelden, who mentions in his work on anatomy, that, during the course of his public practice in St. Thomas's hospital, a period of about twenty years, he had performed the operation of the stone 213 times, and lost only 20 patients. This was about 2 cafes in 21, which is much less than the common average.

In St. Thomas's hospital, during the last ten years, the operation of lithotomy seems to have been done, on an average, 11 times in each two years; and 1 cafe of stone has occurred in each 528 patients admitted.

In St. Bartholomew's, lithotomy was performed 56 times in the years 1812, 1813, 1814, 1815, and 1816. The annual average about 11, or 1 in each 340 patients of all descriptions.

In Guy's hospital, Dr. Marcet has reason to believe that lithotomy has been performed, on an average, about 9 or 10 times annually, during the last 20 or 30 years. The proportion of calculous patients there is also estimated at 1 in about 300 cafes of all kinds.

Dr. Marcet's inquiries incline him to think, that, on the whole, the occurrence of lithotomy in the London hospitals has for some years been gradually diminishing; and this he conceives may be owing partly to a real reduction in the frequency of the stone, from some alteration in the diet or habits of the people; partly to the use of appropriate medicines; and partly to the circumstance of calculous patients not resorting so exclusively, as was formerly the case, to the great London hospitals for the operation.

In the Royal Infirmary at Edinburgh, the average number of stone cafes annually, during the last six years, is said not to have exceeded two, although about 2000 patients are admitted there every year.

Dr. Marcet has been informed by M. Roux, that in La Charité, at Paris, ten or twelve cafes of stone occur every year out of about 2600 patients; and that the proportion of deaths from the operation there is 1 in 5 or 6.

In the Hôpital des Enfants Malades, in the same city, Dr. Marcet states, on the authority of Dr. Biect, that about six cafes of stone are received every year into that establishment, where about 3000 children of both sexes are annually admitted. There have been only three cafes in females, and, what is remarkable, only two deaths from the operation, in the course of the last seven years.

Dr. Marcet has been acquainted, that at Vienna lithotomy is comparatively rare, not on account of the want of good surgeons, or the unfrequent occurrence of stone cafes in that part of the continent, but in consequence of the little attention paid to this disease by the most eminent surgeons of the Austrian capital. It is certainly no credit to these practitioners, to find them encouraging Pajola's plan of operating, which is a revival of one form of that barbarous method, the apparatus major. The success which this lithotomist is said to have had is almost incredible, when his way of operating is considered; for he is stated to have performed the operation 550 times with success.

At Geneva, says Dr. Marcet, in a population of 30,000 souls, lithotomy, including both public and private practice, has been performed only thirteen times in the last twenty years, though good surgeons are never wanting in that town to perform the operation, when an opportunity occurs. Out of these thirteen patients, seven were not strictly Genevese, though belonging to the neighbouring districts, and one was an Englishman; so that the disease would, at first sight, appear to be a rare occurrence at Geneva. But, continues Dr. Marcet, if the smallness of the Genevese population be taken into account, this proportion of calculous cafes may not fall very short of that observed in other places. At Lyons, a populous town, which is not more than 80 miles distant from Geneva, the disease is stated to be rather frequent.

In tropical climates, urinary calculi are almost unknown; and, as Dr. Marcet observes, we have, in confirmation of this singular and important fact, the recent statement of Dr. Scott, who, from his long residence in India, and his well-known habits of observation, may be considered as one of the best authorities. Dr. Scott indeed affirms, that, between the tropics, he never met with a single instance of the formation of a stone in the urinary bladder, although he knew of some cafes which had been imported, and which were not cured by climate. See Marcet's Essay on the Chemical History and Medical Treatment of Calculous Disorders, chap. 2. London, 1817.

Urinary calculi are said also to be very uncommon in Spain and Africa. If, however, it be an undoubted fact, that the disorder is rare in hot climates, still it is impossible to offer any rational theory of the circumstance, because the disease is likewise unusual in very cold countries, such as Sweden. See Richerand's Nosophographie Chir. tom. iii. p. 528. edit. 4.

With regard to the chemical nature of urinary calculi, there was nothing known until as late a period as 1776, when the celebrated Swedish chemist, Scheele, published a paper on the subject, in the Stockholm Transactions. In this essay, he stated, that all the urinary calculi which he had examined, consisted of a peculiar concrete substance, now well known by the name of the *lithic* or *uric* acid, which he also shewed was soluble in alkaline lixivia. Scheele further discovered, that the lithic matter was in some degree capable

URINARY CALCULI.

capable of being dissolved in cold water; that this solution possessed acid properties, and, in particular, that of reddening litmus; that it was acted upon in a peculiar manner, when boiled in nitric acid; and, lastly, that human urine always contained this substance in greater or less quantity, and often let it separate in the form of a brick-coloured sediment, by the mere effect of cooling.

The discovery made by Scheele was confirmed by Bergmann and Morveau, and the investigation of the subject was afterwards prosecuted by others with redoubled ardour. As professor Murray observes, experiments continued to be repeated and diversified on these concretions, and on their solvents. At length, it was fully ascertained, that these excreted others, besides those composed of uric acid; and, latterly, our knowledge of them has been much extended by the researches of Pearson, Wollaston, Fourcroy, and Vauquelin. Several important facts have also been established by the talents and industry of some other distinguished men; viz. Dr. Henry of Manchester, professor Brande of the Royal Institution of London, and Dr. Marcet of Guy's hospital.

The credit which is due to Dr. Wollaston, for his valuable and original discoveries respecting urinary calculi, is very considerable; a truth which we have particular pleasure in recording here, since his merits have not been fairly appreciated by the French chemists. Indeed, as Dr. Marcet observes, it is the more desirable that his claims should be placed in the clearest point of view, as the late celebrated M. Fourcroy, both in his "Système des Connoissances Chimiques," and in his various papers on this particular subject, has, in a most unaccountable manner, overlooked Dr. Wollaston's labours; and in describing results, exactly similar to those previously obtained and published by the English chemist, has claimed them as his own discoveries. Yet Dr. Wollaston's paper was printed in our Philosophical Transactions two years before Fourcroy published his memoir in the "Annales de Chimie," and three years before he gave to the world his "Système des Connoissances Chimiques;" and he discussed in these works a paper of Dr. Pearson on the lithic acid, published in a volume of the Philosophical Transactions for 1798, subsequent to that which contained the account of Dr. Wollaston's discoveries. Essay on Calculous Disorders, p. 60; also Murray's Syst. of Chem. vol. iv. p. 636. edit. of 1809.

From what has been stated, it appears, then, that Scheele first discovered the nature of those urinary calculi which consist of lithic acid; but that Dr. Wollaston first ascertained the nature of several other kinds, some of which have also been described at a later period by Fourcroy and Vauquelin. On the whole, there are five species of concretions, whose chemical properties were first pointed out by Dr. Wollaston, and no less than four belong to the urinary organs. These are, 1st, Gouty concretions; 2dly, The fusible calculus; 3dly, The mulberry calculus; 4thly, The calculus of the prostate gland; 5thly, The cystic oxyd, which last was discovered in 1810.

Dr. Marcet, in his late ingenious essay, arranges urinary calculi under the following heads:

1. The lithic calculus.
2. The bone-earth calculus, principally consisting of phosphate of lime.
3. The ammoniaco-magnesian phosphate, or calculus in which this triple salt obviously prevails.
4. The fusible calculus, consisting of a mixture of the two former.
5. The mulberry calculus, or that composed of oxalate of lime.

Vol. XXXVII.

6. The cystic calculus, consisting of the substance called by Dr. Wollaston cystic oxyd.

7. The alternating calculus, or concretion composed of two or more different species, arranged in alternate layers.

8. The compound calculus, the ingredients of which are so intimately mixed, as not to be separable without chemical analysis.

9. Calculus of the prostate gland.

Dr. Marcet likewise describes two other specimens, which are not referable to any of the foregoing species.

1. *Lithic or Uric Acid Calculus.*—The lithic acid forms a hard, inodorous concretion, of a yellowish or brown colour, similar to that of wood, of various shades. According to professor Murray, calculi of this kind are in fine, close layers, fibrous, or radiated, and generally smooth on their surface, though sometimes a little rough. They are rather brittle, and have a specific gravity, varying from 1.276 to 1.786, but usually above 1.500. One part of lithic acid is said to dissolve in 1720 parts of cold water, and 1150 parts of boiling water (Marcet, p. 65.); and this solution turns vegetable blues to a red colour. When it has been dissolved in boiling water, small yellowish crystals are deposited as the fluid becomes cold. Lithic acid calculi blacken, but are not melted by the blow-pipe, emitting a peculiar animal smell, and gradually evaporating, until a small quantity of white ash remains, which is alkaline. By distillation, they yield ammonia and prussic acid. They are soluble, in the cold, in a solution of pure potassa, or soda; and from the solution, a precipitate of a fine white powder is thrown down by the acids. Lime-water likewise dissolves them, but more sparingly. In solutions of the alkaline carbonates, they remain, according to Scheele, unchanged: according to the experiments of Dr. Egan, however, they are dissolved even by a weak solution, and also when the acid is superaturated by carbonic acid. (Trans. of Irish Acad. 1805.) They are not much acted upon by ammonia. They are not soluble either in the muriatic or sulphuric acid; though they are so in the nitric, when assisted by heat; and the residue of this solution, when evaporated to dryness, assumes a remarkably bright pink colour, which disappears on adding either an acid or an alkali. In many of these calculi, the lithic acid is nearly pure; in others, there is an intermixture of other ingredients, particularly of phosphate of lime, and phosphate of ammonia and magnesia; and, in almost all of them, there is a portion of animal matter, which occasions the smell, when they are burnt, and the loss in their analysis. See Murray's Chemistry, vol. iv. p. 640; and Marcet's Essay on the Chem. and Med. Hist. of Calculous Disorders.

2. *Bone-earth, or Phosphate of Lime Calculus.*—The existence of phosphate of lime in urinary calculi had been mentioned by Bergmann and others, when Dr. Wollaston first ascertained that some calculi are entirely composed of it, forming a distinct species of these concretions. From the observations of the last mentioned eminent chemist, it appears that this substance sometimes composes the entire calculus; though, in more common instances, it is mixed with other ingredients, particularly with uric acid, and with phosphate of magnesia and ammonia. In the first case, the calculus is described as being of a pale brown colour, and so smooth as to appear polished. When fawn through, it is found very regularly laminated, and the laminae, in general, adhere so slightly to each other, as to separate with ease into concentric crusts. It dissolves entirely, though slowly, in muriatic or nitric acid. Exposed to the flame of the blow-pipe, it is at first slightly charred, but soon becomes perfectly white, retaining its form, until urged with the ut-

URINARY CALCULI.

most heat from a common blow-pipe, when it may be completely fused. It appears to be more fusible than the phosphate of lime, which forms the basis of bone; a circumstance which Dr. Wollaston ascribes to the latter containing a larger quantity of lime. (Phil. Trans. 1797.) Calculi, altogether composed of phosphate of lime, are rather uncommon: with this substance there are usually other ingredients, especially the phosphates of magnesia and ammonia, and lithic acid.

3. *Triple Calculus, or Ammoniac-magnesian Phosphate.*—The existence of this calculus in the intestines of animals was first pointed out by Fourcroy; but its being a constituent part of some urinary calculi of the human subject was originally ascertained by Dr. Wollaston. (Phil. Trans. 1797.) Calculous masses, consisting solely of this substance, are perhaps never met with; but concretions often occur, in which it obviously prevails; and, as Dr. Marcet observes, “this triple salt frequently appears also in the form of minute sparkling crystals, diffused over the surface, or between the intestines of other calculous laminæ. Calculi, in which this triple salt prevails, are generally whiter and less compact than those of the former class. When the blow-pipe is applied, an ammoniacal smell is perceived, the fragment diminishes in size; and if the heat be strongly urged, it ultimately undergoes an imperfect fusion, being reduced to the state of phosphate of magnesia.” (P. 69.) Dr. Wollaston describes the form of the crystals of this salt, as being a short trilateral prism, having one angle a right angle, and the other two equal, terminated by a pyramid of three or six sides. These crystals, as Dr. Marcet has explained, are but very sparingly soluble in water, but very readily in most, if not all, the acids; and on precipitation, they reassume the crystalline form. From the solutions of these crystals in muriatic acid, sal ammoniac may be obtained by sublimation. Solutions of caustic alkalies disengage ammonia from the triple salt, the alkali combining with a portion of the phosphoric acid.

4. *The fusible Calculus.*—Mr. Tennant first discovered that this substance was different from the lithic acid, and that, when urged by the blow-pipe, instead of being nearly consumed, a large part of it melted into a white vitreous globule. The nature of the fusible calculus was afterwards more fully investigated and explained by Dr. Wollaston. (Phil. Trans. 1797.) According to the excellent description lately given of this calculus by Dr. Marcet, it is commonly whiter and more friable than any other species. It sometimes resembles a mass of chalk, leaving a white dust on the fingers, and separates easily into layers or laminæ, the interfaces of which are often studded with sparkling crystals of the triple phosphate. At other times, it appears in the form of a spongy and very friable whitish mass, in which the laminated structure is not obvious. Calculi of this kind often acquire a very large size, and they are apt to mould themselves in the contracted cavity of the bladder, assuming a peculiarity of form, which Dr. Marcet has never observed in any of the other species of calculi, and which consists in the stone terminating, at its broader end, in a kind of peduncle, corresponding to the neck of the bladder. The chemical composition of the fusible calculus is a mixture of the triple phosphate and phosphate of lime. These two salts, which, when separate, are infusible, or nearly so, when mixed together and urged by the blow-pipe, easily run into a vitreous globule. The composition of this substance, says Dr. Marcet, may be shewn in various ways. Thus, if it be pulverized, and acetic acid poured upon it, the triple crystals will be readily dissolved, while the phosphate of lime will scarcely be acted upon; after which the muriatic

acid will readily dissolve the latter phosphate, leaving a small residue, consisting of lithic acid, a portion of which is always found mixed with the fusible calculus.

It is an observation made by the same interesting writer, that many of the calculi which form round extraneous bodies in the bladder, are of the fusible kind. The same thing is remarked with respect to the calculous matter sometimes deposited between the prepuce and glass. For many other particulars, respecting the fusible calculus, we refer to Dr. Marcet's Essay and Dr. Wollaston's paper in the Phil. Trans.

5. *Mulberry Calculus, or Oxalate of Lime.*—This is mostly of a dark brown colour, and frequently its interior is grey. Its surface is usually uneven, presenting tubercles more or less prominent, frequently rounded, sometimes pointed, and either rough or polished. It is very hard, difficult to saw, and appears to consist of successive unequal layers. Excepting the few stones which contain a proportion of silica, it is the heaviest of the urinary concretions. Though this calculus has been named *mulberry*, from its resemblance to that fruit, yet, as Dr. Marcet has observed, there are many concretions of this class which, far from having the mulberry appearance, are remarkably smooth and pale-coloured, as may be seen in plate 8, fig. 6. of that gentleman's essay.

According to Mr. Brande, persons who have voided this species of calculus, are much less liable to a return of the complaint, than other patients who discharge lithic calculi. Phil. Trans. 1808.

With regard to chemical characters (says professor Murray), it is less affected by the application of the usual reagents than any other calculus. The pure alkaline solutions have no effect upon it, and the acids dissolve it with great difficulty. When it is reduced, however, to fine powder, both muriatic and nitric acid dissolve it slowly. The solutions of the alkaline carbonates decompose it, as Fourcroy and Vauquelin have observed; and this affords us the easiest method of analysing it. The calculus in powder being digested in the solution, carbonate of lime is soon formed, which remains insoluble, and is easily distinguished by the effervescence produced by the addition of weak acetic acid, while there is obtained in solution the compound of oxalic acid with the alkali of the alkaline carbonate. From this, the oxalic acid may be precipitated by the acetate of lead, or by barytes; and this oxalate, thus formed, may be afterwards decomposed by sulphuric acid. Another method of analysing this calculus is by exposure to heat: its acid is decomposed, and by raising the heat sufficiently, pure lime is obtained, amounting to about a third of the weight of the calculus. According to Fourcroy and Vauquelin, the oxalate of lime calculus contains more animal matter than any other. This animal matter appeared to them to be a mixture of albumen and urée. The composition of a calculus of this species, analysed by Mr. Brande, was oxalate of lime 65 grains, uric acid 16 grains, phosphate of lime 15 grains, animal matter 4 grains.

6. *The Cystic Oxid* was first described by Dr. Wollaston in the Phil. Trans. for 1810. In external appearance, it bears a greater resemblance to the triple phosphate of magnesia, than any other sort of calculus. It is however more compact, and does not consist of distinct laminæ, but appears as one mass confusedly crystallized throughout its substance. It has a yellowish semi-transparency, and a peculiar glistening luitre. Under the blow-pipe, it gives a singularly fetid smell, quite distinct from that of lithic acid, or the smell of prussic acid. Distilled in close vessels, it yields fetid carbonate of ammonia, partly fluid and partly solid, and a heavy fetid oil; and there remains a black spongy coal, which

URINARY CALCULI.

which is much smaller than that left by lithic acid. Water, alcohol, acetic, tartaric, and citric acids, and saturated carbonate of ammonia, can only dissolve a very slight proportion of it. The solvents of it, on the other hand, are numerous; as, for instance, the muriatic, nitric, sulphuric, phosphoric, and oxalic acids; potash, soda, ammonia, and lime-water, and even the neutral carbonates of potash and soda. When, therefore, it is intended to separate it from acids, the neutral carbonate of ammonia is best adapted to the purpose, as it is not capable of redissolving the precipitate even when added in excess; and, for the same reason, the acetic and citric acids are best suited to precipitate it from alkalies.

In consequence of the disposition of this species of calculus to unite both with acids and alkalies, in common with other oxyds, and the fact of its also containing oxygen, (as is proved by the formation of carbonic acid in distillation,) Dr. Wollaston named it an oxyd, and the term *cytic* was added from its having been originally found only in the bladder in two examples. Dr. Marcet, however, has subsequently met with no less than three instances of calculi formed of cytic oxyd, all of which were unquestionably of renal origin.

7. *Compound Calculi in distinct Layers.*—Lithic strata frequently alternate with layers of oxalate of lime, or with the phosphates. Sometimes also the mulberry alternates with the phosphates, and, in a few instances, three or even four species of calculi occur in the same stone disposed in distinct concentric laminae. For specimens of these facts, we refer to Dr. Marcet's interesting essay, in which varieties of such calculi are correctly delineated and coloured.

8. *Compound Calculi with their Ingredients intimately mixed.*—Under this title, Dr. Marcet comprehends certain calculi, which have no characteristic feature, by which they can be considered as distinctly belonging to any of the other classes. He observes, that they may sometimes be recognized by their more or less irregular figure, and their less determined colour, by their being less distinctly if at all stratified, and by their often possessing a considerable hardness. By chemical analysis confused results are obtained. See Marcet's Essay on the Chem. and Med. Hist. of Calc. Disorders, p. 90.

9. *Calculi of the Prostate Gland.*—The composition of these calculi is said to have been first explained by Dr. Wollaston. (See Phil. Trans. for 1797.) They all consist of phosphate of lime, the earth not being redundant as in bones. Their size varies from that of a pin's head to that of a hazel-nut. Their form is more or less spheroidal, and they are of a yellowish-brown colour.

Fourcroy has described a species of urinary calculus, which is characterized by its being composed of the urate of ammonia. Dr. Wollaston, Mr. Brande, and Dr. Marcet have not, however, satisfactorily ascertained the presence of this substance in any of the concretions which they have examined. It is also to be recollected, that urea and the triple phosphate, both of which afford ammonia, are frequently present in lithic calculi, and they may have given rise to the analytical results from which the existence of urate of ammonia has been inferred. Brande in Phil. Trans. 1808. Marcet's Essay, p. 93.

Dr. Marcet has met with two specimens of urinary calculi entirely different from any which have hitherto been noticed. One of these he proposes to name *xanthic oxyd*, from $\xi\alpha\upsilon\theta\omicron\varsigma$, yellow, because one of its most characteristic properties is that of forming a lemon-coloured compound, when acted upon by nitric acid. The chemical properties of the other new calculus, mentioned by Dr. Marcet, cor-

respond to those of fibrine, and he therefore suggests the propriety of distinguishing it by the term *fibrinous*. For a particular description of these new substances, we refer to this gentleman's essay.

In addition to the remarks which have been offered in the article *LIITHOTOMY*, on the subject of lithontriptic medicines, we mean to say very little in the present place. Whoever studies the chemical properties of the urine will learn, that "if any alkali (a few drops of ammonia for instance) be added to recent urine, a white cloud appears, and a sediment, consisting of phosphate of lime, with some ammoniaco-magnesian phosphate, subfides, in the proportion of about two grains of the precipitate from four ounces of urine. Lime-water produces a precipitate of a similar kind, which is still more copious; for the lime, in combining with the excess of phosphoric, and perhaps also of lactic acid, not only precipitates the phosphate of lime which these acids held in solution, but it decomposes the other phosphates, thus generating an additional quantity of the phosphate of lime, which is also deposited.

"If, on the contrary (says Dr. Marcet), a small quantity of any acid, either the phosphoric, the muriatic, or, indeed, even common vinegar, be added to recent healthy urine, and the mixture be allowed to stand for one or two days, small reddish crystalline particles of lithic acid will be gradually deposited on the inner surface of the vessel.

"It is on these two general facts, that our principles of chemical treatment ultimately rest. Whenever the lithic secretion predominates, the alkalies are the appropriate remedies, and the acids, particularly the muriatic, are the agents to be resorted to, when the calcareous or magnesian salts prevail in the deposit." P. 147, 148.

It is a fact perfectly well ascertained, that the alkalies taken into the stomach reach the urinary passages through the medium of the circulation; and it is also strongly suspected, that the acids likewise do so, though this circumstance may not be so well proved. Unfortunately, the quantity of either alkalies or acids, which thus mixes with the urine, is so small, that no impression is made upon calculi of magnitude. The experience of Dr. Marcet and others, however, has clearly ascertained that such medicines are often capable of checking a tendency to the formation of stone, and sometimes of bringing on a calculous deposit depending upon the altered state of the system. This writer, indeed, expresses his decided opinion, that even supposing not an atom of alkali or acid ever reached the bladder, still it would not be unreasonable to expect that these remedies may respectively produce the desired changes during the first stages of assimilation, in one case by neutralizing any morbid excess of acid in the primæ viæ, and in the other by checking a tendency to alkalescence, or otherwise disturbing those affinities which, in the subsequent processes of assimilation and secretion, give rise to calculous affections. P. 153.

When muriatic acid is prescribed, from five to twenty-five drops may be given two or three times a day, diluted with a sufficient quantity of water.

The best way of taking the alkalies is by drinking soda-water as a common beverage. It is asserted, however, on the authority of fir G. Blane, that when the alkalies are combined with citric acid, as in the ordinary saline draught, they also have the effect of depriving the urine of its acid properties.

Dr. Marcet, with every appearance of probability, refers to carbonic acid itself no solvent power, and he does not even adopt Mr. Brande's opinion, that this acid passes into the urine, when patients drink fluids which are impregnated with it.

Sir E. Home and Mr. Hatchett first suggested the utility of giving magnesia in cases of stone, and the proposal was communicated to the public by Mr. Brande. (Phil. Trans. 1810.) It is, as Dr. Marcet observes, often found advantageous in long protracted cases, in which the constant use of the subcarbonated or caustic alkalies would injure the stomach. But, he properly remarks, that if magnesia is sometimes beneficial, it has of late years often done harm. For, as this earth is the base of one of the most common species of calculi, the ammoniaco-magnesian phosphate, there is nearly an even chance, when magnesia is prescribed, without any previous knowledge of the nature of the calculus, that it will prove injurious. Magnesia also, when obstinately administered, sometimes forms large masses in the intestinal canal, causing serious distress, and even fatal consequences.

According to Dr. Prout, purgatives will sometimes stop calculous depositions, especially in children; and Dr. Henry, of Manchester, has observed, that a quack medicine, composed of turpentine and opium, will occasionally produce a plentiful discharge of lithic acid from the bladder.

For many of the foregoing observations, we are indebted to Dr. Marcet's interesting Essay on the Chemical and Medical Treatment of Calculous Disorders, London, 1817. Some other remarks on injections, as a means of dissolving calculi in the bladder, and on lithontriptics in general, will be found in the article LITHOTOMY.

URINARY Fistule. See FISTULE in *Perinaeo*, and **URINARY Abscesses**.

URINARY Passage. See URETHRA.

URINE, in *Physiology*, the fluid secreted by the kidney. See KIDNEY.

URINE, Bloody. See HEMATURIA.

URINE, Incontinence of. An incontinence of urine is when this fluid comes away from the patient involuntarily, without his having any power of retaining it. The disorder is one to which children are particularly liable; adults are less frequently afflicted with it; and it is a case which seldom occurs in persons of very advanced years. The latter assertion, as Desault remarks, must appear erroneous to those who frequently meet with old persons unable to retain their urine, were it not well ascertained, that patients often mistake for an incontinence of urine the overflowing of this fluid out of the urethra, in cases of retention, of which that occurrence is only a symptom. There are even some surgeons, says Desault, who imbibe this popular error, and seem unaware that an involuntary discharge of urine may exit together with a retention, and be the effect of it, as is generally the case in such retentions as depend upon weakness and paralysis of the bladder. In these instances, the distended fibres of this viscus react upon the urine which then issues from the urethra, until the resistance of the sphincter and of the canal is in equilibrium with the expelling power. Sometimes the urine even dribbles away incessantly, which happens whenever the action of the bladder has been completely destroyed; for, in this state, this viscus being constantly full, cannot receive any more of the urine that is brought to it by the ureters, unless an equal quantity at the same time escape through the urethra. This is a case which will more properly fall under consideration in the article URINE, *Retention of*, and we need not therefore dwell upon it at present.

The causes of an incontinence of urine, properly so called, are diametrically different from those of a retention. The latter case happens whenever the bladder becomes weak, and the resistance in the urethra increased. An incontinence, on the other hand, arises either from the expelling power of the bladder being augmented, while the resistance in the urethra

is not proportionably increased; or from the resistance being lessened, while the expelling force remains unchanged. According to these principles, it is easy to explain why the disorder should be most common in children. At this age, it is well known that there is more irritability than at any other period of life. It is also well known that the expulsion of the urine is entirely effected by muscular action, while the resistance is merely owing to the sphincter vesicae, the levatores ani, and perhaps to a few other inconsiderable fasciculi of muscular fibres; for the different curvatures of the urethra, and the contractile power of this tube itself, can make but a passive and feeble resistance to the issue of the urine. An incontinence happens in children, because the bladder contracts so suddenly and forcibly, that its contents are voided almost before these young subjects are aware of any desire to make water, and without their being able to restrain the evacuation. There are also many children who, from indolence or carelessness, do not make water immediately the first calls of nature incite them, and who afterwards, being urgently pressed, wet their clothes. In other young subjects, the sensation which makes the bladder contract, and accompanies the expulsion of the urine, is so slight, that the function is performed without any formal act of the will, without even exciting an impression sufficiently strong to disturb sleep. This is the case with such children as are troubled only with an incontinence of urine in the night-time. Increasing years, by diminishing the irritability of the bladder, and making man more attentive to his necessities, usually bring about a cure of the infirmity, which seldom continues till the patient has attained the adult state.

It must not be supposed, however, that no period of life excepting childhood can be afflicted with the complaint. Other ages are also liable; but then the disorder almost always depends upon a defect of resistance to the issue of the urine, and it may be occasioned by weakness, or paralysis of the sphincter vesicae, or levatores ani; sometimes, also, by a forcible dilatation of the urethra, and loss of its elasticity. Frequently all these causes are at the same time concerned.

A calculus, a fungus, or any other extraneous body of an irregular shape, may be fixed in the neck of the bladder, and not accurately filling it, may allow the urine to escape at the sides; or the foreign body may even form sorts of channels, through which the fluid passes.

Frequently, also, a violent contusion or forcible distention of the sphincter is followed by an incontinence of urine. The complaint used to be very common formerly after the mode of lithotomy called the apparatus major; and it is even at present not an unusual consequence of the extraction of calculi from females by the dilatation of the meatus urinarius. (See LITHOTOMY.) The neck of the bladder and the urethra are forcibly distended in these operations, and, consequently, they lose their contractile power, continue dilated, and no longer duly oppose the escape of the urine.

Women who have had difficult labours, and in whom the child's head, by compressing the neck of the bladder, has seriously contused and weakened this part, are also subject to a species of incontinence of urine; which, however, is in general only experienced when they laugh, or make any considerable exertion.

Most authors, who have treated of incontinence of urine, have related, that persons afflicted with palsy and apoplexy are very liable to the complaint. But, as we have already explained, they have here mistaken what the French surgeons aptly call the "retention d'urine avec regorgement," for an incontinence. In this sort of case, the same writers have attributed the involuntary discharge of the urine to paralysis

of the sphincter of the bladder; but they have not remembered that the bladder itself also participates in the paralytic affection; for the sphincter not being a particular muscle, but only a fasciculus of fleshy fibres, formed, as Default observes, by the junction of those which compose the inner layer of the muscular coat of the bladder, it can only be weakened in the same degree, and at the same time, as the rest of this organ. Besides, says Default, we have proved, and all physiologists admit the fact, that the action of the bladder is absolutely necessary for the expulsion of the urine, and that an inert condition of this viscus is always followed by a retention.

An incontinence of urine is not attended with so much danger as a retention. It is, however, a most afflictive infirmity to a person obliged to mix with society: his clothes being continually wet with urine, the stench which he carries about with him is equally an annoyance to himself, and every body else who approaches him.

An incontinence of urine in children usually gets well of itself as they grow up. When they wet their beds really from idleness and carelessness, moderate chastisement may be proper, inasmuch as the fear of correction will make them pay more attention to the earliest sensations of the desire to make water. We fear, however, that this doctrine is carried to rather an unjustifiable extent, particularly in schools; and, at all events, punishment in such cases should never be severe, as, in ninety cases out of a hundred, the disorder is a true infirmity, arising from the causes already indicated, and not from indolence; the supposed crime taking place, in fact, when the child is asleep, and unconscious of what is happening.

When an incontinence of urine depends upon an excessive irritability, in which state the bladder is forced to contract by a very small quantity of urine in it, and involuntarily overcome the resistance of the urethra, an endeavour should be made to lessen such irritability by the use of the warm or cold bath, sea-bathing, mucilaginous drinks, &c. If the accident should happen only in the night-time, the child should not take any drink for some time before being put to bed; should empty the bladder before going to sleep; and, if necessary, be taken up in the night to do the same thing again.

When the incontinence depends on a want of action in the parts producing the resistance in the urethra, tonics may be externally and internally employed. They seldom succeed, however, when the disorder is of long standing. In this circumstance, palliative means must be resorted to; viz. instruments calculated to compress the urethra, and intercept the passage of the urine. This object is more difficult to accomplish in women than men; but it may be done by means of an instrument which consists of an elastic hoop, which goes round the pelvis, and from the middle of which, in front, a curved elastic piece of steel descends, and terminates in a small compress, which is contrived to cover accurately the orifice of the meatus urinarius. See *Œuvres Chir. de Default*, par Bichat, t. iii. p. 95, &c.

The application of blisters to the sacrum has often proved very effectual in curing incontinence of urine, both when the complaint seemingly arose from excessive irritability of the bladder, or from paralysis and loss of tone in this organ, and the parts which naturally resist the expulsion of the urine from it. The reader will find some very interesting cases of this kind in the Medical Observations and Inquiries.

URINE, Retention of. When, from any particular cause, the urine cannot be discharged from the bladder through the urethra, it accumulates in that receptacle, which it gradually distends sometimes even to an incredible magnitude.

The disease has been described by the ancients under the generic name of *ischuria*. Certain writers make a distinction between this disorder and other cases, to which they apply the terms *dysury* and *strangury*; while others have considered these last only as different kinds of retention of urine. Some surgeons always mean by *dysury* the case in which the urine is discharged with great pain and difficulty; and by the word *strangury*, the example in which the evacuation can be made only by drops; while they restrict *ischuria* to the form of the disease in which no urine at all can be voided. Default very justly imputed this variety in the symptoms to different degrees of the same disease, and he therefore, with much propriety, preferred the division into the *complete* and *incomplete retentions of urine*.

As Mr. Hey has observed, the distinction which has sometimes been made between a *suppression* and *retention* of urine, is practical and judicious. The former most properly points out a defect in the secretion of the kidneys; the latter an inability of expelling the urine when secreted. We also like the following simple and plain definition: "The disease (says he), of which I am speaking, under the term *retention of urine*, is an inability, whether total or partial, of expelling by natural efforts the urine contained in the bladder." *Pract. Obs. in Surgery*, p. 389. edit. 2.

When the urine is retained in the bladder, the parietes of this organ suffer from distention, and after the tone of its muscular fibres has been strained, it can make only a feeble resistance to its further dilatation, and sometimes it becomes of considerable size. In an infant a year and a half old, it has been known to contain a pint of urine; and in adults, six or seven pints. The bladder, thus distended, has been found to fill not only the cavity of the pelvis, but to rise up into the abdomen higher than the navel. It has sometimes been observed to extend itself even through the abdominal rings, so as to constitute a scrotal rupture; or under the crural arch into the groin. Such elongations of the bladder, it is true, are not very common; yet many instances of them are recorded in the Memoirs of the French Academy of Surgery. In ordinary cases of retention of urine, the natural shape of the bladder does not undergo any material change; but still all its dimensions do not increase in the same proportion. It spreads more from below upward than in any other direction. Its inferior portion becomes broader, and more deeply situated, pressing downwards and forwards the perineum; and propelling, in women, the vagina backwards; or, in the male subject, the rectum. In these latter tubes, it forms a swelling, which either completely or partially obstructs them, and interrupts the passage of the feces through the rectum. The posterior part of the bladder, which is covered by the peritoneum, lifts upward and backward the mass of small intestines, and rises into the cavity of the belly. The extreme part of its fundus mounts above the os pubis, and, as it were, insinuates itself between the peritoneum, which it raises, and the abdominal muscles. Indeed, the anterior and superior portion of the bladder forms a swelling in the hypogastric region, and is in actual contact with the recti and transversales muscles, with which it is connected by means of a loose cellular substance. The knowledge of this last disposition of the parts is of great importance to the surgeon, since it leads him to understand, that the bladder admits of being punctured, without any danger of wounding the peritoneum, and causing an extravasation of urine. It is not uncommon (says Default) to find in bladders, which have suffered such distention, cells or pouches often containing calculi, and situated between the fasciculi of fleshy fibres. See *URINARY Calculi*.

URINE.

When the urine has distended the bladder to the utmost, and the obstruction in the urethra continues unremoved, that fluid next collects in the ureters, which in their turn become dilated. The sort of valve which covers their termination in the bladder disappears, and the opening, by which each of these tubes communicates with this receptacle, sometimes becomes nearly an inch in diameter. As the disorder advances, no more urine can at length descend from the kidneys, and the secretion is totally suppressed.

To the well-informed surgeon, the diagnosis of a retention of urine is generally attended with no difficulty; but the case is far otherwise to the man whose experience and attention to the subject have been very circumscribed. What Default has called the *rational* symptoms are numerous; but yet most of them are of an equivocal nature: as, for instance, the stoppage of the discharge of urine for one or several days; its evacuation by drops, or in very small quantities at a time; continual inclination to make water; the efforts which precede the performance of this function; the desire which the patient still feels to empty the bladder, after he has voided nearly as much urine as in the natural state; a diminution either of the force, or stream of the urine; a sensation of weight about the perineum, tenesmus, constipation, hemorrhoids. To these symptoms are to be added, acute pain in the hypogastric region, extending along the urethra to the extremity of the glans penis, and afterwards towards the kidneys, sometimes attended with stupor and numbness of the thighs. The pain is rendered much worse when the patient walks about, coughs, or keeps himself in an erect position; and it is lessened when he bends his body forward, and relaxes the muscles of the abdomen. Lastly, we have to join to the foregoing symptoms, fever, nausea, laborious respiration, and perspiration, that is said to possess a decided urinary odour.

All these *rational* symptoms, as they were denominated by Default, are vague and uncertain. The whole of them together can only afford more or less probable conjectures respecting the existence of a retention of urine. The certainty of the thing can never be made out, unless there be combined with the preceding description of complaints an obvious and manifest tumour, formed by the bladder, not only above the pubes, but likewise in the rectum of the male, and in the vagina of the female subject. The swelling above the os pubis varies considerably in its size. Sometimes it reaches above the navel. It is circumscribed, and unattended with any alteration in the colour of the skin, or any hardness at its circumference. It is more expanded below than above, elastic, and free from tenderness; except it be pressed upon with force, and then the propensity to make water is increased, and sometimes a few drops are even urged out of the urethra.

The swelling in the rectum or vagina is readily discovered by manual examination. It is situated only at the anterior side of these cavities; and, like the hypogastric tumour, it is every where elastic, equal, and free from any particular indurations.

Another pathognomonic symptom, deserving the utmost attention of the practitioner, is the fluctuation, or rather the sort of undulation, which is perceptible on alternately pressing upon both the swellings. These, however, do not constantly exist; for, as Default remarks, retentions of urine, even of the most complete kind, have been known to occur, where the bladder, not being very extensible, hardly contained a few spoonfuls of urine.

Mr. Hey has not adverted to the swelling in the rectum, or vagina; nor to the cases of contracted bladder, where, of course, the information derived in ordinary instances from

the tumour above the pubes, could not be acquired; but, in other respects, his observations on the diagnosis are practical and correct. According to this experienced writer, the characteristic symptom of a retention of urine, previous to the introduction of the catheter, is a distention of the bladder (to be perceived by an examination of the hypogastrium), after the patient has discharged all the urine which he is capable of expelling.

"As this complaint may subsist when the flow of urine from the bladder is by no means totally suppressed, great caution is required to avoid mistakes on this subject.

"Violent efforts to make water are often excited at intervals; and during these strainings, small quantities of urine are expelled. Under these circumstances, the disorder may be mistaken for the strangury.

"At other times, a morbid retention of urine subsists, when the patient can make water with a stream, and discharge a quantity equal to that which is commonly discharged by a person in health. Under this circumstance, I have known the pain in the hypogastrium, and distention of the bladder, continue till the patient was relieved by the catheter.

"And, lastly, it sometimes happens that, when the bladder has suffered its utmost distention, the urine runs off by the urethra as fast as it is brought into the bladder by the ureters. I have (says Mr. Hey) repeatedly known this circumstance cause a serious misapprehension of the true nature of the disease.

"In every case of retention of urine which I have seen, the disease might be ascertained by an examination of the hypogastrium, taken in connection with the other symptoms. The distended bladder forms there a hard and circumscribed tumour, giving pain to the patient when pressed with the hand. Some obscurity may arise upon the examination of a very corpulent person; but in all doubtful cases, the catheter should be introduced." *Pract. Obs.* p. 389.

A retention of urine is always a serious disease, and when it is complete, it demands the most prompt succour. When relief is too long deferred, the consequences are truly afflictive; for, when the bladder continues for a time preternaturally distended, it loses its contractile power, which it recovers with difficulty. Irritated also by the quantity, and perhaps by the quality of the confined fluid, it soon becomes affected with inflammation and gangrenous mischief.

Sometimes the bladder bursts, and the urine is extravasated in the cellular membrane of the pelvis; spreading behind the peritoneum as far up as the loins; producing swellings in the perineum; and becoming effused also in the scrotum, common integuments of the penis, and upper part of the thighs. Indeed, as Default remarks, the urine has sometimes been known to be effused in the parietes of the abdomen, as far up as the sides of the chest, producing gangrenous abscesses and fistulae of the parts. To these evils are to be added others, arising from the total interruption of the secretion of urine, and from the absorption of a part of that which is confined in the bladder.

In the treatment of every retention of urine, there are two principal indications. The first is to give speedy issue to this fluid, in order to prevent the foregoing disastrous consequences; the second is to obviate the causes which prevent its expulsion from the bladder. At present we shall consider only the first of these indications, as the second can be more appropriately treated of when we come to notice the various causes of the complaint.

The urine is commonly let out of the bladder by the introduction of an instrument termed a catheter. Default considers this operation in two points of view; first, when the urethra

urethra is unobstructed, and the instrument can be introduced without resistance; and, secondly, when there exists an impediment to its introduction. As the history of these obstacles cannot be separated from that of the causes of the disorder, we shall follow Default, and now only take into consideration the operation of introducing the catheter when the urethra is pervious. What ought to be the conduct of the surgeon under other circumstances will be noticed hereafter.

With respect to catheters, three things are to be considered: 1, the instrument itself; 2, the manner of introducing it; and, 3, the line of conduct to be pursued after its introduction.

Catheters were anciently composed of copper; Celsus knew of no other kind. As these, however, had the inconvenience of becoming incruited with verdigrease, they at length fell into disuse, and others, made of silver, were substituted for them. This change had been made as early as the time of the Arabian practitioners, and it still receives the approbation of the best modern surgeons.

Catheters vary considerably in their length. For an adult female subject, they should be about six inches long; and for young girls, four or five. For grown-up men, the length ought to be about ten inches and a half; and for male children and boys, six or eight inches. These are the ordinary lengths. There is also much diversity in the size or thickness of the instrument. For a woman, the diameter ought to be about two lines; and for young girls, a line and a half. For male adult subjects, Default recommends the thickness of two lines and one-third; and for boys, that of a line and a half. In general, whenever the urethra is pervious, it is better to follow the advice of Default, and employ a largish catheter, which will enter the passage more easily, not get entangled in the folds of the membranous lining of the canal, and afford a more ready outlet for the urine. On the other hand, small catheters should be preferred, when there are obstructions and indurations in the passage.

Catheters also differ in shape. Those which Default used had only a slight curvature of one-third of their length; a curvature which began insensibly from their straight part, and continued to their beaks inclusively. The curvature was also regular, so as to form the segment of a circle six inches in diameter. The female catheter, however, had only a slight curvature towards its beak; a shape which is adapted to the direction of the meatus urinarius. Default also improved silver catheters, by causing them to be made with elliptical openings at the sides of the beak, with rounded edges, instead of the longitudinal slits, which were previously constructed. The inconvenience of these slits had been acknowledged by every practitioner in surgery; the lining of the urethra having been frequently entangled in them, pinched and lacerated, which produced acute pain, and sometimes profuse hemorrhage. With a view of preventing these evils, Default also was careful to fill the elliptical openings with lard, which could not fall into the hollow of the catheter, as an elastic gum bougie was passed into the cavity of the instrument, in order to hinder the occurrence, and was not withdrawn before the end of the catheter was actually in the bladder. See *Œuvres Chir. de Default*, t. iii. p. 113, &c.

Besides silver, or inflexible catheters, surgeons now frequently employ flexible catheters, made of elastic gum. These last instruments, indeed, are of so much importance, that they may be said to constitute one of the greatest improvements in modern surgery. They are stated to have been originally invented by a Frenchman of the name of

Bernard. Imperfect attempts, however, had been made by others, at an earlier period, to invent catheters possessing the property of flexibility. Van Helmont proposed the use of catheters made of horn; but this substance was found to be too stiff, and to become very quickly incruited with depositions from the urine. Fabricius ab Aquapendente recommended the employment of flexible catheters made of leather; but these were objectionable, as they were very soon softened by the urine and mucus of the urethra, so that they shrivelled up, and were rendered impervious. There were also other flexible catheters, formerly tried, which were composed of spiral springs of silver wire, covered with the skins of particular animals. These last were found to spoil very quickly, in consequence of putrefaction; and when left in the urethra any time, the beak was sometimes entirely separated from the rest of the instrument, and left behind.

The elastic gum catheters now in use are liable to none of the preceding inconveniences. They are formed of silk tubes expressly woven for the purpose, and covered with a coat of elastic gum. They are sufficiently flexible to accommodate themselves to the different curvatures of the urethra; they are not softened by the urine, and they constantly remain with their cavity unobliterated. Their smooth and polished surface makes them continue a long while free from incrustations of the urine. Sometimes they are introduced without a fillet or wire, which is passed into their canal, for the purpose of giving them a certain curvature, and greater degree of firmness. This plan is adopted when the catheter will not pass with the fillet; but, in general, the fillet is employed and withdrawn as soon as the tube is in the bladder.

There are two methods of introducing a catheter; *viz.* with the concavity turned towards the abdomen; or, on the other hand, with the concavity of the instrument turned downwards in the first stage of the operation. The latter plan of course requires the instrument to be turned as soon as its beak has arrived in the perineum; and, consequently, the French surgeons distinguish this method by the name of the "tour de maître." The operation of introducing a catheter, or catheterism, as it is sometimes termed, may be practised either when the patient is sitting up or lying down: the last position, however, is accounted the most favourable. When the catheter is introduced, with its concavity turned upward, and the patient is in the recumbent posture, the thighs are to be separated, and the legs moderately bent. The surgeon is to draw back the prepuce, and to hold the penis between the thumb and fore-finger of his left hand, which are to be applied on each side of the corona glandis, and not at all to the under surface of the penis; as this would press upon the urethra, and obstruct the entrance of the catheter. The handle of the instrument being now held parallel to the axis of the body, its beak is to be introduced into the urethra. While the penis is extended and drawn forward, as it were, over the catheter, the latter instrument is to be gently pushed on, until its beak has arrived as far as the arch of the pubes. At this particular moment, the handle is to be depressed towards the patient's thighs, and the manoeuvre, well managed, generally at once directs the end of the catheter, through the prostatic portion of the urethra, into the cavity of the bladder.

When the catheter is to be introduced with its concavity turned downwards, or by the "tour de maître," the beak of it is to be passed into the urethra, and the penis drawn forwards over it, as it were, just as in the foregoing method. As soon, however, as the end of the catheter has reached the point at which the canal begins to form a curve under the pubes, the surgeon is to make the penis and the instrument

URINE.

ment perform a semicircular movement, by inclining them towards the opposite groin, and thence towards the abdomen. In the execution of this manœuvre, care is to be taken to keep the beak of the catheter stationary, so that it may be the centre of the movement, and simply revolve upon itself. The handle of the instrument is then to be depressed, and the operation finished exactly in the same manner as when the other mode is pursued.

As Default properly observes, the only circumstance in which the two methods differ is, that, in one, the same thing is performed by two movements, which is done in the other by one; so that the operation is protracted, and rendered more difficult and painful. Hence, the majority of good surgeons never practise the "tour de maître," except when their patients are either corpulent, or placed in the position usually chosen for lithotomy, when the other mode of introducing the catheter would be less convenient.

When the urethra is free from obstruction, an experienced surgeon can generally succeed in introducing a catheter into the bladder, without any difficulty or force. But this operation, which is so easy to surgeons accustomed to it, frequently proves extremely difficult to young practitioners, who, instead of guiding the instrument in the course of the urethra, create obstacles by pressing its beak against the parietes of this canal, or entangling the instrument in folds of its membranous lining. When this happens, it must be withdrawn a little, in order to be pushed on again, with its direction somewhat altered. If this second attempt should not answer better than the first, and the catheter should be stopped in the perineum, the surgeon must apply his fingers to the latter part, in order to discover towards which side the beak of the catheter has deviated, and to guide it properly as it passes further.

When the catheter cannot be got through the portion of the urethra, which is contiguous to the rectum, the forefinger ought to be introduced into the bowel, for the purpose of supporting the end of the instrument, and rendering the coats of the intestine somewhat tense, by drawing them a little downward and forward. If all these expedients should fail, the catheter should be changed for one of larger or smaller size, or of another curvature. A gum elastic catheter ought also to be tried, without the silet. In no case, however, is it justifiable to push forward the catheter with much force, lest the urethra should be lacerated, and a false passage produced.

The depth to which the catheter has entered, the cessation of any feeling of resistance to the motions of the beak, when revolved upon its axis, and the issue of the urine, are the circumstances by which the surgeon knows that the instrument has passed into the bladder.

According to the experience of Default, the practice of letting out gradually only a part of the urine, after the catheter has been introduced, is on every account wrong and detrimental. He also disapproves of running into the opposite extreme, that is to say, of letting the urine flow out of the bladder, through a catheter, as fast as it arrives in this receptacle: as, by the last practice, the bladder is constantly kept in a state of relaxation, its fibres cannot recover their proper tone. When also the bladder is continually empty, it comes into contact with the end of the catheter; a circumstance which has sometimes caused considerable irritation, pain, and even ulceration of that viscus. Besides these inconveniences, there are other objections: the catheter becomes sooner obstructed with mucus, and covered with incrustations, than when it is closed with the silet. The patients are likewise compelled to remain in bed, where they are either wet with their urine, or obliged to have in-

cessantly a pot for its reception. The best practice, therefore, seems to be that of letting out all the urine, as soon as the catheter is introduced, and then closing the instrument until the bladder has become moderately distended again. Experience proves, that such moderate distention and relaxation of the muscular fibres of the bladder, alternately kept up, have the same good effects on the organ, as moderate exercise has upon other parts of the body.

When an elastic gum catheter is used, care must be taken that it does not pass unnecessarily far into the bladder; and if it be too long, a part of it ought to be cut off.

When a catheter is to be left in the urethra, it should always be properly fixed with a narrow piece of tape, or else it is apt to slip out, or sometimes even to pass too far down the passage. Some surgeons use cotton thread for this purpose: they first fasten it to the rings, or round the outer portion of the catheter, and then carry its two ends some way along the dorsum of the penis, when a sort of noose is made, and the thread carried round the part and tied. When a silver catheter is employed, a tape or narrow ribbon is passed through each of the rings, and conveyed to the right and left side of the pelvis, where it may be fastened to a circular bandage. But there are numerous methods of fixing, which need not be specified; for, although they are of importance, the principles, which ought to be observed in adopting them, are the main things to be understood. These are, first, never to fix a catheter in such a way, that too much of the instrument projects into the cavity of the bladder; and, secondly, to be careful that the thread, or tape, which is applied, will not chafe and irritate the parts.

Having premised these general observations on the chief indication in cases of retention of urine, *viz.* that of giving issue to this fluid, we next follow Default, in order to consider the particular modifications to which the indication is liable; a subject which cannot be comprehended, without treating also of the causes of the disease.

1. *Of the Retention of Urine to which Persons of advanced Age are liable.*—Old men are so frequently afflicted with retention of urine, that the disorder is generally allowed to be one of the grievances to which their period of life is particularly exposed. The bladder, like the rest of the body, becoming less irritable, is no longer duly stimulated by the presence of the urine, and is only apprized of the necessity of emptying itself by the painful sensation arising from the distention of its coats. It then contracts; but, to use Default's expression, its elongated fibres have hardly force enough to overcome the natural reaction opposed to them by the canal of the urethra. There is almost an equilibrium betwixt the power and the resistance, and the urine could not flow out, if it were not for the assistance derived from the powerful action of the abdominal muscles. Nor is the expulsion of the urine even now complete, since the bladder no longer retains sufficient contractile power to efface the whole of its cavity. Some drops of the urine, after each evacuation, are still left undischarged, and already constitute an incipient retention. The quantity daily augments, and the fibres of the bladder becoming habituated to the presence of the urine, it happens at length that, at each evacuation, not more than half the fluid contained in this organ is actually voided.

According to the observations of Default, all old men are not equally liable to the complaint. It particularly attacks those who are of a phlegmatic temperament, plethoric, and of sedentary and studious habits. It also especially afflicts those who, from carelessness or indolence, do not give themselves time to expel the last drops of urine; and others,

others, who make a practice of voiding their urine into a pot as they lie in bed, instead of getting up to make the evacuation. "Although," says Bichat, "the latter fact may not be explicable upon any physiological principles, its truth is sufficiently established by clinical observation, and we cannot doubt its reality." Thus, the history of the patients' lives, their age, and kind of constitutions, form so many grounds for suspecting the nature of this species of retention of urine; but the suspicion is changed into certainty, when the following circumstances are joined with the usual symptoms of a retention of urine in the bladder.

The patients declare that they have never had in the urethra, or neighbouring parts, any affection capable of impeding the issue of the urine; that this fluid has always come away freely, and in a full stream; but that, although the stream was undiminished, the urine could not be discharged with the same force, nor to the same distance, as formerly. At length, instead of describing an arch as it flows out, it falls down perpendicularly between the legs. Towards the close of the evacuation, the patient also is no longer sensible of the final contractile effort of the bladder to expel the last portion of the urine; a particular sensation, of which he used to be conscious in his younger days. When he is about to make water, he likewise finds that he has to wait some time before the evacuation commences. As the disorder increases, he begins to perceive that he cannot make water without considerable efforts; that the quantity of urine, voided each time, manifestly decreases; that the desire to empty the bladder becomes more and more frequent; and, lastly, that the urine only comes away by drops, and that an incontinence has succeeded to a retention.

In this state, the patient's sufferings are not very great. The tumour, formed by the bladder above the pubes, is almost indolent; and, if it be pressed upon with some force, a certain quantity of urine is discharged from the urethra.

The retention of urine arising from old age is seldom complete: the urine, after having filled and distended the bladder, dribbles out of the urethra, so that the patient voids as much of this fluid in a given time as he does in a state of health. Nor is this species of retention of urine commonly attended with very urgent symptoms. It does not occasion, like complete retentions, a suppression of the urinary secretion in the kidneys; and as the urine escapes through the urethra, after the bladder is distended to a certain degree, the disorder is less apt to produce a rupture of this organ, and dangerous extravasations of the urine. The swelling of the bladder then continues, without the patient being seriously annoyed, except by a sense of weight about the pubes and perineum. Sabatier has seen patients, who have laboured under the disease six months, without ever having suspected its nature. The escape of the urine has indeed sometimes deceived surgeons, and led them to consider the swelling to be of a totally different character. Sabatier once attended a lady, who had been recommended to resort to a distant town, in order to try the effect of its mineral waters in dispersing a swelling brought on during her confinement in childbed, and which proved to be nothing more than a distention of the bladder with urine.

There are many old men who have been troubled with this sort of retention of urine a long time, and yet make no endeavour to get relief, supposing that the infirmity is natural to their period of life. The urine, however, stagnating in the bladder, undergoes a decomposition, and the coats of that organ itself at length become diseased.

This case presents two indications, *viz.* to evacuate the urine, and to restore the tone of the bladder: frequently,

both these things may be accomplished by the same means. When the retention is incipient, and the bladder is merely in an inactive state, its proper action may often be restored by laying cold applications upon the hypogastric region, or the thighs, and by the patient going from a warm into a cool place, in order to make water.

The patient must also be strictly careful not to defer making water immediately the least inclination is felt to do so; for, when the call of nature is not at once attended to, the distended fibres of the bladder lose their sensibility more and more; the desire to make water subsides; and the retention, which at first consisted of only a few drops, very soon becomes complete. It would then be in vain, as Default observes, to have recourse to the means which have been above recommended. No stimulus will now make the bladder contract with sufficient force to expel the mass of urine which it contains, and the catheter is the only thing by which this fluid can be discharged. This artificial mode of evacuation, however, only affords momentary relief; for, as the relaxed fibres of the bladder are slow in recovering their natural tone, the patient would necessarily fall into the same condition again, if the employment of the catheter were not continued. Hence, it is absolutely indispensable either to leave this instrument in the bladder, or to introduce it as often as the patient has occasion to make water. When there is a skilful surgeon constantly at hand, or when the patient knows how to pass the catheter himself, Default thinks it better only to introduce the instrument when the bladder is to be emptied; by which means, the inconvenience arising from the continual presence of a foreign body is avoided. In this case, either a silver catheter or an elastic gum one may be used with equal advantage; but if the instrument is to be kept in the bladder, that made of elastic gum, and provided with a curved fillet, is to be preferred. Whatever sort of instrument is used, however, experience fully proves, that in old subjects, in whom the canal is as it were flaccid, a large catheter enters more easily, and with less pain, than one of smaller diameter.

As the treatment of the complaint must be continued for a long while, and the bladder seldom perfectly regains its proper tone in old age, the patient should be instructed how to introduce the catheter himself, and he is to pass it whenever he wants to make water. After a certain time, however, he may try if he can empty the bladder without this instrument. When he finds that he can expel the urine, he should certify himself by means of the catheter, that the last drops of this fluid are duly voided. Should they not be so, he must persevere in the use of that instrument. Without this precaution, says Default, the retention will soon attain the same pitch again, at which it was on first commencing the treatment.

In this sort of retention of urine, it has been proposed to throw into the bladder a variety of astringent injections, made with the sulphate of iron, decoction of bark, &c. Default tried them, but never found much good from their use.

Warm, balsamic, diuretic medicines, cold bathing, and liniments containing the tinctura lyttæ, have likewise been praised; but, according to Default, these means frequently prove hurtful to persons of advanced years, and are seldom useful. He restricted his own practice to the use of the catheter, which, when skilfully employed, often restored the tone of the bladder; and when it failed, other means also were ineffectual.

2. *Retention of Urine from Debauchery.*—This case, as Default observes, is very analogous to that which depends upon old age; both of them are unconnected with any previous disease

disease of the bladder, and simply originate from general languor and debility. Their commencement is indicated by the same circumstances, their progress is similar, they exhibit resembling symptoms, and they merely differ in their predisposing cause; the defect of irritability being in one case the consequence of old age, in the other that of intemperance. In the former instance, the disorder depends upon a decrepitude, the natural effect of advanced age; in the other, it arises, as it were, from a premature and unnatural old age. Nothing is more weakening to the constitution than an immoderate indulgence in venereal pleasures. From this kind of excess, the bladder, as well as other organs, becomes less irritable, and is at length rendered totally incapable of expelling the whole of the urine. Hence originates a retention. It is unnecessary here to repeat the diagnostic signs of this disorder, depending upon weakness of the bladder. The history of the case can alone discriminate it from that which is produced by old age. The prognosis, however, is not so unfavourable as in the other example; for, when the patient is gifted with a strong constitution, and he has not been too much reduced, the complaint may be radically cured.

An elastic gum catheter left in the bladder is here, according to Default, one of the most powerful means of relief which can be employed. It not only has the advantage of affording a ready outlet for the urine, exciting the irritability of the bladder, and promoting the action of its muscular fibres; but its continual presence in the urethra hinders the patient from yielding to those depraved habits, which are the very cause of the disorder. The latter use of the catheter is the more worthy of consideration, inasmuch as it is proved by experience, that most patients, who are not restrained by this obstacle, cannot resist the force of habit, though fully aware of the dangers.

Together with the employment of the elastic gum catheter, every endeavour should be made to strengthen the patient, and obviate the general relaxation and debility of the parts. Cold bathing, steel medicines, and cinchona, are the means which are usually preferred. The patient ought likewise to have the advantage of a salubrious air, nutritious and easily digestible food, undisturbed sleep, plenty of exercise, regular evacuations, tranquillity of mind; and more especially he ought to be diverted from what has been the cause of his indisposition.

3. *Retention of Urine from the immoderate Use of Diuretics.*—This is the next case which Default considers. Diuretics, both cold and warm, taken in excess, may equally occasion the disorder. He conceived that, by the former, the fibres of the bladder were hurtfully relaxed; and that, by the latter, their proper sensibility was gradually destroyed. In this last circumstance, the bladder being habituated to the impression of stimulating diuretics, is, when these are discontinued, not sufficiently irritated by the urine to contract, and it no longer obeys the calls of nature. Default has the candour, however, to acknowledge that the foregoing theory is rather founded upon reason than experience; he even confesses that he has met with no example establishing its reality, but he thought there was some probability in it, deduced from the well-known effects of strong liquors on the stomach.

If we exclude from consideration the information respecting the nature and quantity of the drink which the patient has been taking, before the functions of the urinary organs were disturbed, there are absolutely no circumstances, nor symptoms, by which this species of retention of urine can be distinguished from that induced by old age and intemperance; nor is the local treatment to be different from

what has been advised for the above cases. Besides the use of the elastic gum catheter, the surgeon must recommend cold bathing; and the throwing of ice-cold water on the abdomen, perineum, and thighs; the application to the same parts of compresses wet with vinegar; dry friction on the hypogastric region; or stimulating liniments, containing ammonia or the tinctura lytta. Should all these means prove ineffectual, a blister may be laid over the sacrum and lower part of the loins; and it may either be kept open, or healed and then applied again, as Default particularly advised.

4. *Retention of Urine from an Affection of the Nerves of the Bladder.*—These nerves may be affected either at their origin, or in the course of their distribution. Injuries of the brain are seldom followed by a retention of urine; but the complaint often accompanies those of the spinal marrow. A concussion of this medullary substance, from blows or falls upon the vertebral column; the injury which it suffers in fractures and dislocations of the vertebrae, or from a violent strain of the back; its compression by blood, purulent matter, or other fluid effused in the vertebral canal; and the effects which a caries of the spine has upon it, may all operate as so many causes of a retention of urine. This form of the complaint may also be the consequence of tumours situated in the track of the nerves which are distributed to the bladder. It is not necessary that all the nerves, which ramify on this organ, be affected before the complaint is occasioned; for the compression of some of the nervous filaments is adequate to weaken the action of the bladder, and render it incapable of overcoming the natural resistance to the discharge of the urine.

When a retention of urine is caused by an affection of the spinal marrow, an insensibility and weakness of the lower extremities are almost always concomitant symptoms. The patients suffer very little; most of them are ignorant of their condition, and do not complain of any thing being wrong in the functions of the urinary organs. The surgeon, aware that a retention of urine is a very common occurrence in these cases, should examine whether any interruption of the evacuation prevails, either by feeling the state of the abdomen just above the pubes, or by introducing a catheter.

As this species of retention of urine is only symptomatic, and not dependent upon any previous defect in the bladder, it is not in itself alarming; but, with reference to the cause that has produced it, it is exceedingly dangerous. Affections of the spine, complicated with injury of the spinal marrow, are frequently fatal. By means of a catheter, it is always easy to relieve the inconveniences arising from the bladder not contracting, and thus fulfil the only indication which this sort of retention of urine presents, *viz.* the evacuation of the urine. But these means are merely palliative, and the bladder will not recover its contractile power until the causes of its weakness are removed. The last then is the main object in the treatment, which must vary according to the nature and extent of the disorder.

The consideration in detail of all the means which may be requisite for the relief of the different accidents and diseases of the spine, would form too long a subject to be brought into the present article. (See FRACTURES and LUXATIONS of the Vertebrae, and SPINE, Disease and Curvature of.) We shall merely observe here, that Default had a high opinion of the utility of cupping in shocks and concussions of the spinal marrow. This was done on the part of the back which had been struck, or in its vicinity; and the scarifications were multiplied according to the strength of the patient. The plan was sometimes repeated the same day, and for several days in succession; and when the patient could not bear the loss of more blood, dry cupping was employed.

employed. In caries of the spine, Default also gave a preference to the use of the moxa, instead of caustic.

5. *Retention of Urine brought on by Distention of the Fibres of the Bladder.*—As Default observes, this species of retention of urine may be called *secondary*, since it is invariably preceded and produced by a *primary* retention. It follows of course, that its remote causes consist of all those circumstances which may bring on the other forms of the complaint; but its immediate cause altogether depends upon the weakness and loss of irritability in the bladder, occasioned by the immoderate distention of its coats. Thus, we frequently find the disorder occur in persons who, from bashfulness, indolence, or intense occupation, neglect to make water when they first have the desire, or who cannot for a time empty the bladder, in consequence of some temporary obstruction in the urethra. Although the impediment to the escape of the urine no longer exists, and the bladder is in other respects found, yet as this organ has been weakened by the excessive distention of its coats, it cannot contract with sufficient force to obliterate the whole of its cavity, and expel the last portion of urine.

The indication in this case is very simple, for there is not here, as in other retentions of urine, another disease to be remedied. The catheter, when left in the bladder, generally proves adequate to the restoration of the tone and contractile force of this viscus. Default also conceived, that the object might be promoted by the exhibition of warm diuretics, and the employment of tonic injections, and other strengthening means. Before the catheter is discontinued, the surgeon ought to be sure that the bladder can completely expel the whole of the urine, without the aid of this instrument; for it is impossible to specify any particular period when the bladder will regain its power of contracting. The time will vary according to the duration of the disease, and the age and constitution of the patient. In some persons, a cure is effected in a few days; in some, not till after several weeks or months; and in others, the contractile function of the bladder is so irremediably destroyed, that the catheter is necessary during the rest of the patient's life.

6. *Retention of Urine from Inflammation of the Bladder.*—The majority of authors who have written on the diseases of the urinary organs, says Default, have ascribed different effects to an inflammation of the neck of the bladder, and to the same affection of the body of this viscus. They have in fact regarded the first occurrence as one of the causes of retention, and the last as a cause of incontinence of urine. It has been imagined, that an inflamed highly sensible bladder, instead of being weakened in this state, acquired an increase of energy, and contracted with greater than ordinary vigour. But, even if we had not been deceived upon this subject by the observation of retentions of urine, which could be referred to nothing but inflammation of the bladder, still analogy would have protected us from error. We never find an inflamed muscle contract, and if we oblige it to act, its action is always weak. Default also constantly noticed, in opening the bodies of persons who had died of inflammation in the abdomen, that the inflamed intestines were distended, and not diminished and contracted.

Plethoric bilious subjects, with full habits, are particularly liable to this species of retention. It is also frequently occasioned by the abuse of wine or other spirituous liquors, heating diuretic drinks, or the external or internal employment of cantharides. This form of the complaint makes its attack suddenly, and may be recognized; 1st, By the frequent desire to make water. 2dly, By the acute pain in the region of the bladder; pain which is increased by the efforts to make water, and which shoots up to the loins and along

the urethra to the end of the glans. 3dly, By the frequency and hardness of the pulse, and other symptoms of fever. 4thly, By the aggravation of the pain, when the hypogastric region is handled or pressed upon. 5thly, By the easy passage of a catheter into the bladder. 6thly, By the acute pain which is excited by the instrument touching the inside of the bladder. 7thly, By the red inflammatory colour of the urine. 8thly, By the absence of all those symptoms which peculiarly characterize other cases of retention.

This form of the disorder demands the most prompt assistance. The urine, the presence of which is a new source of irritation, should be immediately drawn off. The catheter should be introduced with great gentleness, and merely far enough to let its eye get beyond the neck of the bladder, as its beak might otherwise seriously irritate this viscus, the lining of which is now extremely sensible.

After the urine had been discharged, Default used to throw in mucilaginous injections; but of these we entertain no opinion. The inflammation of the bladder is to be resisted by the most powerful antiphlogistic remedies, such as repeated venesection, the application of leeches to the perineum and hypogastric region, the warm bath, glysters, fomentations on the abdomen, and cold mucilaginous beverages. When, notwithstanding these means, the inflammation increases, extends to the other abdominal viscera attended with hicough and vomiting, and continues beyond the sixth day, the patient's life is in extreme danger, and death almost inevitable.

7. *Retention of Urine from Hernia of the Bladder.*—The second volume of the Memoirs of the French Academy of Surgery presents us with numerous instances of this species of retention of urine. We there learn that it is a symptom almost constantly attending hernia of the bladder. But the weakness of this organ is not always the sole cause; for the urethra itself also makes greater resistance than natural to the issue of the urine. The neck and adjoining part of the bladder are drawn out of their right position by the portion of this organ which protrudes. Hence, the beginning of the urethra also undergoes an elongation, and a change of its curvature, by being pressed towards the symphysis of the pubes, and its diameter is likewise diminished. The urine may also be detained in the pouch composing the hernia, in consequence of the communication between this and the other part of the bladder being too diminutive. This state, indeed, is very common, and it accounts for those partial retentions of urine which take place only in the protruded portion of the bladder, and not in that of the receptacle which lies within the pelvis. Sometimes, however, such retentions depend upon the pressure of the abdominal muscles being removed, and upon weakness of the protruded part of the bladder. At the same time, it rarely happens that the rest of this organ, situated in the pelvis, can itself expel the last drops of the urine which it contains. Its complete contraction cannot be accomplished without great difficulty; and, in the end, it almost invariably follows that the urine is retained in both the protruded and unprotruded portions of the bladder.

When a retention, arising from a hernia of the bladder, is complete, and occurs in both parts of this organ, there is, in addition to the symptoms common to other retentions produced by weakness of the bladder, a more or less considerable swelling in the situation of the hernia. The tumour is unattended with any change of the colour of the skin; is not very tender on being handled; and it presents a feeling of fluctuation, sometimes obscure, sometimes very distinct. When the swelling is pressed upon, the desire to make water is excited or increased, and occasionally a few drops escape

from the urethra. As soon as the urine has been drawn off with a catheter, the part of the bladder which is out of the pelvis subsides, on the patient being put into a posture in which such portion of the bladder is higher than the rest of this organ within the pelvis. The hernial tumour seems then to be composed of thick membranes, which are soft, moveable, but yet incapable of being reduced. It is also some time in enlarging again; and, after its re-appearance, it presents the same symptoms as before.

When the retention of urine is confined to the hernia, and the opening, by which this communicates with the pelvis, is free, the tumour is indolent, increasing when the patient empties the other part of the bladder, and subsiding after the evacuation. As soon, however, as this is finished, the patient feels a desire to make water again; so that there is a sort of interval in the completion of this function. But, should the communication with the pelvis not be open enough, the swelling would be incompressible, or it could not be made to subside without a good deal of force. Were it strangulated, the circumstance would be indicated by the tension of the swelling, pain, heat, fever, and hiccough, succeeded by vomiting.

The first indication is to discharge the urine with a catheter, or by compressing the hernial tumour; but these expedients are only palliative. When the disease is recent, and the protruded portion of the bladder small and reducible, the part ought to be returned and kept up with a truss, by which means a perfect cure may be effected. When the part is adherent and irreducible, the swelling ought to be emptied, and a suspensory bandage made to it and support it. If the hernia were in this way gradually got into the abdominal ring again, a truss would afterwards be requisite. Proposals have been made to endeavour to excite the adhesive inflammation in the cavity of the protruded part of the bladder, by methodical compression, gradually increased, and obliterate the pouch in which the urine is lodged out of the pelvis. Although Default thought the attempt cautiously made justifiable, he deemed the result very uncertain.

Were the retention of urine accompanied with a strangulated state of the protruded bladder, and the contents could not be pressed into the other part of this organ, a puncture of the swelling with a trocar might be proper. But if there were an enterocoele also present, as often happens, this operation would be attended with risk of injuring the intestine. Hence Default preferred opening the tumour by a careful incision; and he even approved of cutting away the protruded cyst, if the communication betwixt it and the rest of the bladder were obliterated.

8. *Retention of Urine caused by Displacement of the Viscera of the Pelvis.*—These displacements, which may occasion a retention of urine, are a retroversion, prolapsus, or inversion of the uterus, and a prolapsus of the vagina and rectum. When the intimate connexions of the bladder with the uterus and vagina in the female, and with the rectum in the male, are considered, it is obvious that these latter parts cannot be displaced without drawing along with them the bladder; and that in this state, whatever may be its contractile power, it cannot contract completely upon itself, so as to expel the whole of the urine. To this deficient action of the bladder is necessarily joined an increase of resistance on the part of the urethra. The beginning of this canal, being drawn by the bladder, changes its accustomed direction, and such alteration cannot be made without the sides of the tube being pressed together, and thus a more or less considerable obstacle formed to the passage of the urine. It is in this manner that, in the retroverted uterus, the os tincæ, being carried up above the pubes, drags along with it the posterior

side of the bladder, which, in its turn, draws after it the commencement of the urethra, pulls it upwards, and increases the curvature which this canal describes under the symphysis of the pubes, against which it is forcibly applied.

In a prolapsus or inversion of the womb, vagina, and rectum, the back part of the bladder, instead of being drawn upward and forward, is pulled downward and backward, and the curvature of the urethra is totally altered. Below the pubes, the bladder forms a convexity, and not a large concavity, as in the instance of a retroversion of the womb. This position of the parts should always be recollected in passing the catheter, as it shews what curvature and direction should be given to the instrument, in order to facilitate its introduction.

The retention of urine, arising from displacement of the viscera, may always be easily distinguished from the other species of this disorder. The symptoms, however, by which it is characterized, have been detailed in other articles, to which the reader is referred. See *PROLAPSUS Ani, PROLAPSUS Uteri, VAGINA, UTERUS, Retroversion of, &c.*

These kinds of retention of urine are not frequently followed by any very bad consequences. It is generally sufficient to rectify the wrong position of the bladder, and commencement of the urethra, by the reduction of the displaced viscera, and a cure is then a matter of course, unless the excessive distention of the fibres of the bladder has induced considerable weakness in the parietes of this organ. When this is the case, we must have recourse to the particular means which have been recommended for this cause of the disease. The reduction of the viscera usually constitutes the first indication.

For an account of the manner of doing this, we must refer to the above-mentioned articles. When the reduction cannot be immediately accomplished, or when it fails in directly relieving the retention of urine and symptoms depending upon it, the catheter is to be used. Frequently, when the urine has been drawn off, the reduction becomes more easy; but sometimes the altered direction of the urethra makes the introduction of the catheter difficult; nor can success be obtained, except by accommodating this instrument to the faulty state of the canal. For example, in the retroversion of the uterus, a catheter very much curved answers better than a straight one, like that ordinarily used for females.

A curved catheter, says Default, also answers in cases of prolapsus uteri, &c.; but with this difference, that, in a retroversion, the concavity of the instrument must be turned towards the pubes, but, in the prolapsus, towards the anus. Sometimes the catheter will not pass unless it be rotated, as it were; and sometimes, when a silver catheter cannot in any manner be introduced, one made of elastic gum, which adapts itself better to the curvature of the canal, will readily enter.

Were every effort to reduce the viscera and get a catheter into the bladder to fail, at the same time that a risk of this viscus bursting prevailed, the operation of puncturing it would become indispensably necessary. See *PARACENTESIS of the Bladder.*

9. *Retention of Urine from the Pressure of the Uterus, or Vagina, on the Neck of the Bladder.*—It is alleged, that in pregnancy there are two periods when women are particularly liable to a retention of urine; viz. during the fourth month, and at the time of labour. In order to have an exact idea of this case, we must remember that, in the first months after conception, the uterus continues to lie concealed in the pelvis; that it does not ascend above this cavity till the fifth month, or later; that, at this period, as its size and weight

weight have progressively increased, it descends lower into the vagina, and compresses, in the manner of a wedge, the rectum, which is situated behind; while it presses the neck of the bladder and urethra, which are in front, against the symphysis of the pubes, sometimes in such a degree, as entirely to close them, and stop the passage of the urine through them.

From this account of the progress of the gravid uterus, the mechanism of this species of retention of urine appears so simple, and, as it were, natural, that one would expect to find the disorder frequently happen in the fourth and fifth months of pregnancy; yet, out of a great number of women who had been delivered in the Hôtel-Dieu at Paris, Default did not meet with a single one who had been thus affected. He does not, however, presume to assert, that the complaint may not occur; but he believes, that the manner in which the uterus enlarges must almost always protect the neck of the bladder and urethra from compression. In fact, says he, it is well known that the increase of this viscus begins at its fundus, and then extends to its body, while the cervix retains its size and length until the sixth month, when the uterus, being too large to be contained in the lesser pelvis, mounts up above the superior aperture.

As this viscus is larger at its fundus than its cervix, while situated within the cavity of the pelvis, it must rather compress the ureters and body of the bladder than the neck of this organ and the urethra, above which the most bulky portion of the uterus is always situated, unless there be a complete prolapsus of this organ. Although most writers have spoken of a retention of urine as being often occasioned by the lodgment of the head of the fetus, yet, according to Default, not a single instance occurred at the Hôtel-Dieu, during eight or ten years, in which space of time fifteen or sixteen hundred patients were there delivered. Therefore, without denying altogether the possibility of the case, he conceives himself justified in concluding that it is much less common than is usually supposed. It is true, says he, women often complain of a desire to make water when the head of the child continues a long while in the passage; and such desire may have led some careless practitioners to imagine that it proceeded from a full state of the bladder, who ought to have known that any irritation about this organ would cause the same kind of sensation.

When the position of the head of the child, at the time of its being wedged in the lesser pelvis, is considered with regard to the bladder, it appears that the body of this last organ and the ureters are more exposed to compression than the urethra and neck of the bladder. Default even thought it probable, that the urine, far from accumulating in this receptacle, could not descend into it, and was confined in the ureters.

This conjecture seemed to Default the more likely, inasmuch as a retention of urine is more frequently a consequence of, than an attendant upon, the lodgment of the child's head in the passage. The complaint then comes not from any obstruction of the meatus urinarius, but from weakness of the bladder, which has suffered contusion, which sometimes causes sloughs between the vagina and bladder, and produces urinary fistulæ, always difficult of cure, and often incurable.

Were, however, a retention of urine to happen at one of the above periods of pregnancy, the diagnosis of it would be obvious enough. The state and position of the uterus, or the situation of the head of the infant, could easily be ascertained by manual examination; and the patient would be able to say whether the passage of urine had been previously

free, and whether she knows of any other cause that can impede the evacuation.

Frequent inclination to make water, and none of the urine at the same time coming away, are, in this case, very equivocal signs of a retention; for, as Default remarks, any irritation of the bladder will cause the first symptom, and the last may depend upon compression of the ureters.

If the complaint were caused, as it is supposed, by the pressure of the uterus upon the neck of the bladder and the urethra, about the fourth month of pregnancy, we could not expect the disorder to be permanently relieved before the enlarged uterus had risen out of the pelvis. Until this had happened, the practitioner could only endeavour to facilitate the evacuation of urine by pressing the uterus away from the neck of the bladder and urethra, by introducing his finger sufficiently high behind, and a little on one side of the symphysis pubis. Should this method fail, it would be necessary to have recourse to the catheter.

Were the retention of urine produced by the child's head, delivery should be expedited by changing the position of the head with the forceps, &c. If the labour should still seem likely to be lingering, the urine ought to be drawn off with a catheter.

Besides the distention of the uterus and vagina in pregnancy and parturition, there are other conditions of these organs which may give rise to a retention of urine. This disorder sometimes arises from the presence of various kinds of tumours, or collections of blood or water in the uterus, or ovary; and it occasionally proceeds from distention of the vagina with the menstrual discharge, the use of pessaries, &c.

As this last kind of retention of urine is only symptomatic, the prognosis must be more or less unfavourable, according as the disease, of which it is a symptom, may happen to be more or less serious. It is of itself not very dangerous, because, by drawing off the urine with a catheter, it is always practicable to prevent or remove the inconveniences which it causes. But even the use of the catheter is not always necessary, especially when the cause of the retention of urine is easily removable, and the tone of the bladder is not impaired. This is generally the case when the complaint is induced by a pessary, or collection of blood in the vagina. In other examples, in which the cause of the difficulty of making water cannot be immediately obviated, as in several cases of tumours, the catheter must be employed. In scirrhus and cancerous diseases of the uterus, also, this instrument is the only means of relieving the retention of urine, as nature and art can do little for the removal of the cause. It ought to be known, however, that, as these last diseases increase, an incontinence often succeeds to a retention of urine, in consequence of ulceration taking place between the upper surface of the vagina and the lower part of the bladder.

10. *Retention of Urine from Pressure of the Rectum upon the Neck of the Bladder.*—Abscesses in the vicinity of this intestine, hemorrhoidal tumours, alvine concretions, and the scirrhus-contracted state of the gut, &c. may bring on a retention of urine by making pressure on the neck of the bladder. The irritation, also, existing in these cases, may tend to produce the complaint by exciting a spasmodic contraction of the urethra. Here the relief of the obstruction of the urine is to be effected by removing or curing the other disorder, which operates as its cause. If this cannot be immediately accomplished, the catheter must be used, though, in several instances, it will be better to avoid even the irritation of the catheter, and try the effects of bleed-

ing, the warm bath, and opium, which will frequently enable the patient to make water. The last means, however, will not suffice, when the cause of the retention is likely to continue any length of time.

11. *Retention of Urine from Tumours situated in the Bladder.*—Fungous diseases, carcinoma, and hydatids, says Default, are the principal tumours which may cause a retention of urine. Of all the diseases of the bladder, there are none which are so afflicting as fungous tumours; fortunately, they are not frequent. Default, however, had seen several cases in the dead subject. By the introduction of a sound into the bladder, the presence of a fungus might be suspected; something unusual would be felt; but the case could hardly be discriminated from an induration of the coats of the bladder, or other sorts of tumours of this viscus. The causes and mode of curing the affection are equally unknown. In one instance, however, in which the fungous excrescence had a narrow base, Default is said to have made an incision into the bladder, and extracted the swelling with a pair of forceps. No hemorrhage, nor any other bad symptoms, ensued.

In carcinomatous diseases of the bladder, the use of the catheter is necessary, at least, until, by the progress of the disorder, ulcerated communications are formed betwixt that organ and the rectum, or uterus and vagina.

12. *Retention of Urine from foreign Bodies in the Bladder.*—When the urine is obstructed by a calculus at the neck of the bladder, the patient, by altering his position, frequently changes the situation of the stone, and he is immediately able to make water again. This expedient, however, will only procure relief while the calculus is loose in the cavity of the bladder; for, after it has become fixed in the commencement of the urethra, it must either be pushed back with a catheter, or extracted by a kind of operation resembling the apparatus minor. See LITHOTOMY.

Default never met with any case in which the bladder contained worms; but he was aware of there being many such instances on record. Tulpius, Schenckius, Bianchi, &c. have been eye-witnesses of the occurrence. These worms are not all alike; some resemble scarabæi, some are like ascarides, and others have the appearance of lumbrici. Ruysch and Hagendorf affirm, that they have seen some which had wings, and were able to fly as soon as they were voided. An interesting paper on this subject was published about six years ago by Mr. Lawrence, who met with an example in which an undescribed species of worms was abundantly voided from the bladder. "The origin of those animals (says Mr. Lawrence), which inhabit the internal parts of living bodies, is involved in much obscurity. Although the intestinal worms appear manifestly, from their peculiar form, consistence, and organs, to be particularly designed for those situations in which they are found; although they have generative organs, and no similar animals are known to exist out of living bodies; yet, it has been generally conceived, that the genus from which they spring enter from the mouth. The production of hydatids in various parts of the body cannot, however, be accounted for on such a supposition; neither can we very easily conceive that ova should enter from without into the urinary organs." The following facts, also stated by Coeze, (as Mr. Lawrence observes,) entirely overturn this opinion. Professor Brendel, of Göttingen, found ascarides in the rectum of an immature embryo. Blumenbach discovered tæniæ in the intestinal canal of young dogs a few hours after birth, &c. Versuch einer naturgeschichte der Eingeweidewürmer, p. 55.

The case which Mr. Lawrence has recorded is interesting, as it exhibits an unquestionable instance of peculiar and undescribed worms voided from the urinary passages. This gentleman says, that he knew of no other case in which a distinct species of worm has been clearly proved to come from the bladder. Most of the cases published were instances of common intestinal round worms, which sometimes perforate the intestines, and are discharged by abscesses, or get into the bladder, after the formation of adhesions betwixt this organ and the bowels. In other instances, coagula of blood, mucus, or portions of the mucous coat of the bladder, have been mistaken for worms; and, as Mr. Lawrence further observes, some of the descriptions can apply only to larvæ of insects. Two specimens of this last sort he has seen himself, which were sent from the country as worms voided from the bladder. See Medico-Chir. Transf. vol. ii. p. 382, &c.

In whatever way these animals get into the bladder, a retention of urine may be produced, either when they are numerous, or when there is only one present, but large enough to obstruct the vesical orifice of the urethra. In the very curious example related by Mr. Lawrence, the passage of the urine was obstructed, and the use of the catheter continually necessary. The oil of turpentine was given internally, with some appearance of benefit at first; but it afterwards brought on febrile symptoms and erysipelas, and its exhibition could not be kept up. It was then injected into the bladder, with an equal part of water. This rather accelerated the discharge of the worms; but they came away at times whether the injection was used or not, and as this means produced the erysipelatous indispotion again, it was left off. Olive oil was afterwards injected; the irritation after it was less, and the fits of pain about the bladder less violent. It was calculated, that at the time when Mr. Lawrence was writing the particulars of the case, from 800 to 1000 worms had been discharged. For a detail of the symptoms, and a particular description of the worms themselves, we must refer to the above-mentioned publication.

According to the observations of Default, a retention of urine is frequently occasioned by coagula of blood in the bladder. The blood is said sometimes to come from the kidneys, sometimes from the bladder, and sometimes it even regurgitates from the urethra. While fluid, it may be expelled with the urine; but when coagulated, it is no longer capable of being discharged. It is the blood which gets into the bladder after wounds, or the operation of lithotomy, that is most disposed to coagulate.

The diagnosis of a retention of urine, produced by coagula of blood, is not very clear. The issue of blood with the urine might raise suspicions; but there could be no certainty of the nature of the case, until the catheter were introduced. If the clots of blood should be too large to pass through this instrument, lukewarm water should be injected into the bladder, for the purpose of loosening and dissolving the coagula.

We shall merely notice one more example of retention of urine, arising from the presence of extraneous substances in the bladder; we mean that in which a piece of bougie has slipped into this viscus. It has frequently happened, that entire bougies, which were not properly fixed, have glided into the bladder. As Default observes, the urethra appears to possess a kind of antiperistaltic action, by which it tends to draw into the bladder whatever substances it includes; for, says he, it is constantly noticed, that when these substances are once within the urethra, if they be not expelled by the current of urine, they always advance towards the bladder.

bladder. This circumstance cannot be accounted for by their weight, and it must be ascribed to a contractile power of the urethra.

The bougies formerly made, and particularly metallic ones, and catheters made of spiral wire springs, frequently broke, and thus pieces of these instruments were often left in the bladder. Such an accident, however, is much less common now, that the fabrication of all sorts of bougies and catheters has been brought to a high state of perfection.

The insinuation of these foreign bodies into the bladder is a serious occurrence both for the patient and surgeon. The former cannot avoid the consequence, which will sooner or later originate from the extraneous substance, except by submitting to a dangerous and painful operation: the latter will be accused of being the author of all the evil, and will find it difficult to exculpate himself. In order to do away the necessity of cutting into the bladder, in such cases, Default proposed the use of small spring forceps, passed into the bladder through a cannula; but although the instrument seemed to answer on the dead subject, there have hitherto been no instances of its doing so on living patients.

We next proceed to notice the retentions of urine arising from affections of the urethra.

13. *Retention of Urine from Inflammation of the Urethra.*—It is easy, says Default, to conceive how inflammation of the urethra may occasion a retention of urine. In order to understand the mechanism of the case, we need only remember the axiom in surgical pathology, that inflammation never exists without a swelling of the inflamed part, and that every tumefaction of the lining of the urethra must necessarily diminish its diameter. Inflammation of the urethra is most commonly produced by the external application, or internal exhibition, of cantharides, gonorrhœa, the unskilful use of the catheter, the employment of stimulating injections, bougies, &c., together with the lessening of the canal by the effect of swelling; there can also be no doubt, that, in many of these instances, a spasmodic contraction of the urethra and neck of the bladder also contributes to the retention of urine. Default, indeed, entertained the opinion that inflamed parts, endowed with a contractile power, were not disposed to contract in that state; yet, it should be recollected, that even admitting this to be true, it seldom happens that the whole length of the urethra is inflamed, and that the rest may be affected with a spasmodic action. The effects of opium, tobacco, and other antispasmodics, often evinced in immediately relieving these kinds of retention of urine, seem indeed to leave no doubt respecting the existence of a sort of spasm in the passage. Whatever may be the cause of the inflammation of the urethra, the diagnosis is free from all obscurity. Besides the general symptoms of inflammation, the patient complains of a scalding sensation in the passage; he experiences a great deal of smarting, which is sometimes insupportable when he makes water; the penis becomes in some degree swollen, and more tender; and a very little pressure on the urethra gives acute pain. In the mean time, the stream of urine becomes gradually but yet quickly lessened; and at length this fluid can only be voided in a very narrow current, or only by drops, and often not at all.

The disorder is to be treated on antiphlogistic principles. Diluting, cooling, mucilaginous beverages, venesection, leeches to the perineum, the warm-bath, opium, fomentations to this part and the penis, are the means which usually suffice to give relief. When inflammation exists in the urethra, it is always desirable to avoid, as long as pos-

sible, the employment of catheters, which create irritation, and of course increase the cause of the retention. It is particularly in cases of this description, and in the retentions of urine arising from strictures, that Mr. Earle has suggested the use of tobacco in the form of clysters; a method deserving adoption when the means above enumerated are unavailing, and preferable to the use of the catheter, because not occasioning any increase of irritation and inflammation in the urethra. See *Medical and Chir. Transf.* vol. vi. p. 82, &c.

To this proposal we shall advert again, in considering the retention originating from strictures. When, in consequence of inflammation, however, an abscess forms in the vicinity of the urethra, and bursts into this canal, the use of an elastic gum catheter is proper, in order to prevent the urine from insinuating itself into the cavity which contains the pus.

14. *Retention of Urine from Laceration of the Urethra.*—The urethra is sometimes ruptured by violent contusions on the perineum, and the rough and unskilful use of metallic catheters. The consequences usually are, an extravasation of urine in the cellular membrane of the scrotum and penis; a considerable dark-coloured swelling of these parts, often followed by sloughing; and retention of urine. Respecting such cases, we shall merely observe, that the treatment ought to consist in introducing an elastic gum catheter into the bladder, and keeping it there until the breach of continuity in the canal is repaired. At the same time, the evils threatened from the effusion of the urine are to be lessened as much as possible, by making two or three free incisions in a depending part of the swelling produced by the extravasation. The tumour should also be well fomented, and antiphlogistic means adopted.

15. *Retention of Urine arising from Tumours situated in the Perineum, in the Scrotum, or on the Penis.*—No considerable tumour can form in any of these situations, without making more or less pressure on the canal of the urethra. Whether such swelling proceed from a simple tumefaction of the parts, or from a collection of any fluid in a cavity, or from the lodgment of an extraneous body, the effect will be the same. A retention of urine has been observed to arise from phlegmonous swellings and abscesses, extravasations of blood, and urinary tumours and calculi formed in the perineum and scrotum. The disorder has also been known to be caused by a sarcocele, hydrocele, a very large scrotal hernia, an aneurism of the corpus cavernosum, a ligature on the penis, &c.

We shall not repeat what has been already said respecting the symptoms of a retention of urine originating from affections of the rectum. The impediment to the evacuation will be known to depend upon one of the causes above specified, if the patient could make water quite freely before such cause existed, and no other reason can be assigned for the obstacle. Of course, the radical cure of all such retentions of urine can only be accomplished by curing the other disease, on which they are dependent. However, until the cause can be obviated, the urine must be drawn off with a catheter. Elastic gum catheters usually enter more easily than those made of silver, as, by their flexibility, they accommodate themselves better to any deviation of the urethra from its ordinary direction. Default particularly recommended a catheter of middling size to be selected, and introduced armed with its stylet, until it stopped in the canal; when he advised withdrawing the stylet for about an inch, in order to leave the beak of the instrument quite free, so that it might follow the curve of the urethra. Then the tube and the stylet are to be pushed further into the canal; care being taken,

taken, however, to keep the filet drawn back some distance from the extremity of the instrument. By these precautions, says Default, the catheter may always be got into the bladder. Should the introduction prove neither painful nor difficult, Default thought it would be better not to annoy the patient by making him continually wear the instrument, unless its presence in the urethra were essentially necessary to destroy the cause of the retention of urine, as it would be in the instance of urinary swellings.

16. *Retention of Urine from Disease of the Prostate Gland.*—As Default remarks, it would be superfluous to endeavour to prove by examples the reality of this species of retention of urine. If the fact were not established by a multitude of observations, we should be convinced, by advert- ing to the relation of the prostate gland with the commence- ment of the urethra, and understanding how this canal is only composed of a delicate membrane, that the gland could not be affected with swelling, without lessening in some de- gree the tube which it embraces.

An enlargement of the prostate gland may depend on in- flammation, abscesses, calculi formed within its substance, a varicose swelling of the vessels which surround it, or on a scirrhous tumour and induration of it.

When a retention of urine arises from inflammation of the prostate, it makes its attack very suddenly, and rapidly increases. The patient at first complains of a sense of heat and weight about the perineum, and very soon afterwards of a continual throbbing pain about the neck of the bladder. This pain is severely increased, when the patient goes to stool; and he is afflicted with tenesmus, and frequent in- clination to make water. He feels also as if a large mass of excrement filled the extremity of the rectum, and were ready to come out. When the finger is introduced into the bowel, the projection of the prostate can be felt at its anterior part. J. L. Petit adds another sign of a swell- ing of this gland: “ Si Pon est curieux de voir les malades aller à la selle, lorsqu'ils rendent des excréments durs, on trouvera que la partie intérieure du boudin formé par les matières fécales, sera creusée, comme ayant passé sur la faille, que forme la prostate dans la partie antérieure du rectum.” Bichat conceives, however, that such an appearance may be obliterated in the passage of the excrement through the sphincter ani. When the patient attempts to make water, it is a long while before the first drops come out; and if he should now increase the efforts, he makes an additional impediment, by pushing the swollen prostate more and more against the neck of the bladder, the aperture of which becomes stopped up, and no water can be voided, until the efforts are lessened. The stream of urine is smaller, and the pain arising from its expulsion more acute, in pro- portion as the inflammation of the prostate is more consider- able. We may also add, as a particular symptom of this sort of retention of urine, that if an attempt be made to in- troduce a catheter, it passes without the least resistance as far as the prostate, where it stops, and causes great pain. The pulse is hard and frequent; there is much thirst; and all the usual symptoms of fever prevail.

This kind of retention of urine, as well as all those which originate from an enlargement of the prostate gland, or other obstructions in the canal, are, according to Default, generally more dangerous than other cases, which merely depend upon the weakness of the bladder, and in which there is very little risk of this vicus giving way.

When the urethra is free from obstruction, the urine, after distending the bladder to a certain degree, generally oozes through that canal; and the patient may live in this condition for years, without any alarming consequences.

But the case is different, when the retention of urine de- pends upon any stoppage or stricture in the urethra. The urine does not then partially escape; this fluid stagnates in the bladder; the distention increases; and if speedy relief be not afforded, that vicus inflames and sloughs, and a perilous effusion of its contents ensues.

In the retention arising from inflammation of the prostate, the indication is obvious: it is to use every possible means of resolving the inflammation. Venesection, leeches to the vicinity of the anus, the warm bath, emollient clysters, and poultices, are the remedies which seem most eligible. These must be assisted with a regimen strictly antiphlogistic.

It must be confessed, however, that the efficacy of these means is often too slow, and the symptoms too urgent, to allow us to wait for the urine to flow of itself. Frequently, also, the tone of the bladder is so much weakened by the distention, that this organ cannot expel its contents. The catheter must then be employed; but the contraction of that part of the urethra which runs through the prostate, sometimes renders the introduction of this instrument diffi- cult, and always very painful.

According to Default, a large catheter generally answers better than a small one, and it may either be of silver or elastic gum. The latter, though the best for the purpose of being kept in the passage, has not always sufficient firm- ness to get through the obstruction in the canal, not even with the aid of the filet. In this respect, a silver catheter is sometimes preferable. But whatever may be the kind of catheter employed, it generally passes as far as the prostate with perfect facility, where it is stopped, not only by the narrowness, but also by the new curvature, of the passage: for the prostate cannot be enlarged, without pushing for- wards and upwards, or to one side, that portion of the urethra behind which it is situated. This circumstance ought never to be forgotten, in regulating the length and direction of the beak of the catheter, which should also be longer, have a more considerable curvature, and be more elevated, at the time of its introduction, than in other cases of obstruction in the urethra.

In swellings of the prostate gland, Mr. Hey has parti- cularly pointed out one advantage which belongs to elastic catheters, *viz.* that their curvature may be increased while they are in the urethra. This gentleman was introducing an elastic gum catheter in a patient, whose prostate gland was much enlarged, and finding some obstruction near the neck of the bladder, he withdrew the filet; in doing which, he accidentally repressed the tube, which then went into the bladder. In fact, he found that the act of withdrawing the filet increases the curvature, and lifts up the point of the catheter. *Pract. Obs. in Surgery*, p. 399. edit. 2.

After being tolerably certain, says Default, that the end of the catheter corresponds exactly to the direction of the urethra, and that the obstacle to its entrance into the bladder only depends upon the narrowness of the passage, we may, without being too fearful of making a false passage, forcibly push forward the catheter. This instrument will certainly rather dilate a canal, that already exists, than form a new passage for itself. Default confesses, however, that this plan would be attended with great danger in the hands of young inexperienced surgeons; and he adds, that it is only fit to be practised by those, who, combining great ex- perience in the use of the catheter with an accurate know- ledge of the different curvatures of the urethra, have at length attained that degree of skill, which never lets them lose sight of the situation and direction of the beak of the catheter. For, says he, if, while the instrument is forced forward, the beak should be inclined too low, or to one side,

URINE.

fide, &c. a false passage would inevitably be occasioned by a laceration of the membranous portion of the urethra; an accident which is always of a serious nature, increasing the inflammation of the prostate, and rendering the introduction of the catheter more difficult. This bold practice, suggested by Default, is frequently pursued by Boyer and Roux, and sometimes in this country by Mr. A. Cooper, Mr. Pearson, &c. (See Crofs's Medical Sketches of Paris.) We have indeed heard, that Mr. Thomas Blizard, and some other surgeons in London, always force their way through the prostate gland with a conical silver catheter, in preference to puncturing the bladder, when no instrument can be introduced through the urethra in a gentle manner. The urine afterwards passes through this sort of false passage, seemingly as well as through the natural one.

We have not, however, brought our own minds to think that much good is ever likely to result from this exertion of violence in the urethra: therefore, when the case is urgent, and no catheter can be introduced through the natural canal, we should prefer puncturing the bladder, which, in these cases, should always be done above the pubes. See *PARACENTESIS of the Bladder*.

Notwithstanding the many examples of the success that has attended this operation, the proceeding, as Default observes, has its dangers; and, consequently, it should never be resorted to, before repeated unavailing attempts have been made to get a catheter into the bladder; nor before a trial has been made, whether a bougie left in the passage a few hours will not bring on an evacuation of the urine; an event which has often happened, even though the instrument did not pass beyond the obstruction. Puncturing the bladder, in such cases, should also never be determined upon, without a previous consultation with another practitioner, especially if one be at hand, who has had greater experience in the use of the catheter.

When a catheter has been introduced, ought it to be left in the bladder, or withdrawn, after the discharge of the urine? Its presence no doubt will increase the irritation about the neck of the bladder; but, on the other hand, if it be taken out, the surgeon may not be able to introduce it again. No general precept, says Default, can be laid down on this point. The course which the practitioner will pursue must depend upon the difficulty he has experienced in getting the instrument into the bladder, and upon the confidence which he may have in his own skill, and which is deduced from constant success in analogous instances.

According to Default, when an abscess follows inflammation of the prostate, the body of the gland itself does not suppurate, but only the surrounding parts, and the cellular substance, which connects its lobes together. This, at least, was what was observed in examining several dead subjects, who were publicly opened in the amphitheatre of the Hôtel-Dieu. When the symptoms of inflammation have lasted a week, and all this time have continued to increase; when, after this period, they have abated a little, and then become violent again; and when the febrile symptoms get worse in the evening, and have been preceded by shiverings; there is reason to suspect the formation of matter. It cannot be known whether the pus is collected in one particular place, or diffused. When the matter is external to the gland, the case is less serious than when it occupies the cellular substance connecting the lobes. According to Default, the latter form of the disease seldom gets well. There are no peculiar symptoms which denote it; the matter does not readily make its way outward; and the state of things is not clear enough to admit of an incision being made. Besides, Default doubted whether an incision could be of

much use, since it would probably only let out the matter in its vicinity.

Things are different when the pus is collected in one place, and is more superficial. If situated between the gland and neck of the bladder, it will often spontaneously burst into this viscus, or it may be let out with the point of the catheter. It will then either be discharged through the instrument, or come away with the urine. Should the abscess lie near the rectum and perineum, and admit of being distinctly felt, a free opening would expedite the cure.

In all these cases, the use of the catheter is requisite, in order to let out the urine; and as the instrument must be left in the passage some time, one made of elastic gum is to be preferred.

When the abscess bursts of itself, either into the urethra or bladder, the catheter must be kept in as long as pus continues to be discharged with the urine. In the latter case, however, Default chiefly used the instrument for the purpose of throwing mucilaginous injections into the bladder, which many surgeons would not consider necessary.

Morgagni has taken notice of the retentions of urine arising from the presence of calculi in the prostate gland. The nature of these concretions we have already described in a preceding article. See *URINARY Calculi*.

Calculi also sometimes form after lithotomy, when the outer part of the wound heals sooner than the bottom. A kind of urinary fistula then forms; and as the extraneous substance is constantly exposed to the contact of fresh urine, it may increase to a very large size. The diagnosis of prostatic calculi is seldom very clear. A retention of urine, and an impediment to the emission of the semen, are only symptoms which are common to several other affections of the prostate gland and urethra. When the finger is introduced into the rectum, the gland may indeed be felt to be enlarged, but the nature and cause of such enlargement cannot in general be distinguished. In one instance, however, lately recorded by Dr. Marcet, the calculi could be plainly felt through the coats of the rectum, and a proposal was made to extract them by an incision in that situation; but the patient did not accede to so judicious a measure. (*Med. and Chem. Hist. of Calculous Disorders, Lond. 1817.*) When a calculus projects from the prostate into the urethra, the end of a sound will strike against it; but then it can rarely be known whether the extraneous substance may not be a calculus that has passed out of the bladder into the urethra, or lies close to the neck of this viscus.

Whether the case be of one description or the other, however, the treatment should be the same; *viz.* the calculus should be extracted by an incision, resembling that practised in the lateral operation.

Another species of retention of urine is that produced by a considerable varicose affection of the vessels surrounding the prostate gland, which part is also generally somewhat enlarged. In this case, the water should be drawn off with an elastic gum catheter, which should be kept in the urethra; and a large instrument is to be preferred to a smaller one. For an account of the symptoms of this case, we must refer to Default's *Œuvres Chir.* t. 3, p. 234. The portion of the urethra which passes through the prostate, is afterwards to be gradually dilated with bougies or elastic catheters, which are to be worn a long while, and cleaned and changed at proper intervals.

A scirrhus induration and enlargement of the prostate gland form another very common disease in old subjects. The size and hardness of the gland are said to vary considerably, according to the duration of the complaint. It has often been found as hard as a cartilage; more commonly its struc-

ture presents an appearance as if filled with a firm tough lymph. Sometimes the part is two or three times as large as natural, and J. L. Petit once saw it as large as the fist. In some instances, only a part of it is scirrhous; in others, the whole of it is thus affected. The hardened gland can be felt in the rectum, and the examination does not give much pain.

A retention of urine is an ordinary symptom of a scirrhous of the prostate; the catheter is also here necessary, and the introduction of it is often attended with greater difficulty than in other affections of this gland. As the induration of the part does not allow it to yield, small catheters are better than those of large size. It also frequently happens, that considerable force must be used; and as this cannot be done with elastic catheters, a silver catheter, of the size used for children, was recommended by Default. The moderns sometimes employ a conical silver catheter, as we have already noticed. Sometimes, however, no instrument can be introduced unless it be rotated, in doing which it is essential to recollect that the urethra in these cases makes a very sudden turn upward before it terminates in the bladder.

After the silver catheter has been worn three or four days, the canal is usually freer, so that one made of elastic gum will now admit of being passed. This last must in general be continually employed for four or five weeks, and in the mean while attempts should be made to check the disease in the prostate by the exhibition of mercurials, conium, &c. Suppositories of hemlock have also been particularly recommended. Some of Mr. Hunter's remarks on this complaint will be found in the article *PROSTATE Gland, Disease of*.

17. *Retention of Urine brought on by Strictures.*—This is another case, which we deem necessary to notice in this work. The common nature, most frequent situation, and different methods of treating strictures in the urethra, have been already explained. (See *URETHRA, Strictures of*.) Persons who have been long subject to strictures in the urethra, but who are still able to void their urine in a small stream, are liable, from accidental causes, to have a complete retention, and are incapable of expelling the contents of the bladder. This arises in some cases from the diameter of the urethra being still further diminished by attacks of inflammation, but more frequently from the spasmodic state of the urethra and muscles of the perineum. The same effect may be produced by such patients retaining their urine too long after the first desire to void it is experienced. It happens not unfrequently, that the permanent stricture may be of such a nature, as not to admit of the introduction of any instrument into the bladder, even under the most favourable circumstances. A spasmodic state of the urethra, as Mr. Earle has further observed, would not facilitate such attempts. Other cases again occur, in which perhaps an instrument can be passed, when the urethra is in a more tranquil state, but where it would be highly injudicious, and often impracticable to introduce such instruments under circumstances of irritation, by which attempts the spasm would be increased, and the patient rendered liable to returns of retention, even were we to succeed in the first instance.

In all such cases, it is, as Mr. Earle remarks, highly desirable to overcome the retention by other means than the introduction of instruments. For this purpose purgatives, general and local bleeding, warm-baths, the tinctura opii, and tinctura ferri muriatis, are commonly resorted to. With respect to purgatives, their action necessarily requires more time than, from the urgency of the symptoms, is frequently admissible. The other remedies are highly useful, and will frequently fulfil every indication. Sometimes, however, they are unavailing, and we are compelled to resort to ope-

rations for relieving the distended bladder. Mr. Earle then proceeds to recommend the use of tobacco in the form of an enema, either of smoke or the decoction, which he found, in some cases which are detailed, a powerful and expeditious means of relieving the retention of urine, when other more common remedies had failed. See *Medico-Chir. Transf. vol. vi. p. 84, &c.*

18. *Retention of Urine produced by foreign Bodies in the Urethra.*—Most of the foreign bodies, occasionally met with in the bladder, may cause a retention of urine, when they are lodged and stopped in the urethra. Thus, calculi, bougies, &c. fixed in this canal, may become obstacles to the transmissibility of the urine through it. The means which have been recommended for promoting the removal of such extraneous substances are numerous. Some advise oily injections to be thrown into the urethra, in order to make its surface more slippery, while others think it better to dilate the canal as much as possible with catgut bougies. The ancients proposed the trial of suction. But, says Default, these and other similar means are ineffectual, when the foreign body is closely embraced by the urethra. In this case, he observes, if the extraneous substance cannot be pushed forward with the fingers applied externally, an endeavour may be made to extract it with the forceps, invented for the purpose by Mr. Hunter, and which are contained in a cannula. When, however, the foreign body is too large to be got out in this manner, it must be extracted by an incision. The wound of the operation will afterwards be found to heal up very well, if care be taken to keep an elastic catheter in the urethra, in order to prevent the urine from coming into contact with the cut part. There has lately been published a case of calculus in the urethra, attended with dysuria, where almost instantaneous relief was obtained from the exhibition of an enema of tobacco. The patient soon felt a strong desire to void his urine, and “upon making the attempt, a large calculus came rolling along the urethra, with complete relief of all his complaints.” See *Edinb. Med. and Surg. Journal, vol. xii. p. 373.*

Urine, Suppression of, in Animals, a disease arising from the want of making water in consequence of some affection of the parts concerned in passing it. The complaint is caused, according to some, either by inflammation obstructing the functions of the kidneys, or by the ureters being obstructed by stones, small gravel, or other such foreign matters, or when affected with any numbness, or other defect, that may disable them in their office of separating the urine from the blood. In this last case, the bladder is, for the most part, empty, so that the animals make no motions to pass urine, but stand in the straddling manner, as in other disorders of the urinary passages, when the bladder is full or the urethra inflamed; this is particularly the case in the horse kind of animals; and if they continue a few days in this condition, without the secretion of urine, their bodies are liable to swell to a very great degree, and they, in this sort of animals, often break out universally in blotches and die, unless speedy relief be afforded. Where the disease is caused by strangury, it is commonly attended with a partial, if not a complete suppression of urine, but in general without much appearance of fever, though there are signs of uneasiness and irritation with loss of appetite. The disorder may be produced from different other causes, as from whatever has a tendency to affect the parts about the neck of the bladder, such as certain articles of food, blows, a spasmodic state of the muscles inducing contraction in them, and some others.

In the cure of the disease, it will first mostly be necessary, in cases where there is a tendency to inflammation, to take away a few pints of blood in proportion to the state of the affection

URINE.

affection and the size of the animal. Where horses are subject to an obstruction in the passages of the urine from calculi, but which is rarely the case, the proper method of cure is, according to some, to begin with strong diuretic remedies, in connection with stimulating clysters; and if there should be any suppurative inflammation either in the kidneys or ureters, it may be proper to bleed in a plentiful manner, to the amount in some cases of three or four pints. And balls composed of the following ingredients are likewise advised to be given and repeated two or three times the first day, and as often the next, as in such cases no time is to be lost; for, if the horse or other animal does not stale or pass urine in the course of thirty hours, the case is mostly desperate: Juniper-berries in fine powder, an ounce; focotrine aloes and nitre in powder, each six drachms; oil of turpentine, three drachms, and of amber and juniper, each two drachms; liquorice powder and treacle, sufficient quantities to form a mass of suitable consistence for being divided into two balls, to be given at one time as above.

At the same time a clyster prepared in the following manner may be thrown up with great benefit: Barbadoes aloes, two ounces; the same quantity of turpentine, beaten up with the yolks of eggs; half an ounce of powdered jalap; four ounces of nitre, and juniper and bay berries bruised, each a small handful; infused in two quarts of a decoction of marshmallows, to which is then added a pint of linseed oil.

Where these remedies fail in removing the complaint, the horse or other animal's loins are advised to be rubbed with a mixture of oil of turpentine and of amber, and to lay a cataplasm over the small of the back and kidneys, formed of pounded garlic, mustard-seed, camphor, and soap. This, it is thought, may prove beneficial as a stimulant to the kidneys, in case they happen to be deficient in nervous influence; and that, in case of inflammation, the same remedy may act as a blister without the danger of producing a strangury, and in that way too be of service. It should be spread on a coarse flannel cloth doubled, bound on with a broad woollen roller, and renewed once in two days, until the horse or other animal comes to stale or pass urine freely: calomel too in the quantity of a drachm and a half or two drachms, made up into a ball, and repeated every two days, once or twice, may be of use in cases where the kidneys are not inflamed; after which the horse or other animal may be purged gently where it is necessary.

In cases where the suppression of urine is caused by or attended with strangury, after bleeding and opening the bowels when necessary, a ball, composed in the manner directed below, and given in a pint of the decoction, once or twice in the day, as there may be occasion, will often be found very beneficial: pure opium in powder, half a drachm; camphor rubbed into a powder, three drachms; nitre in powder, half an ounce; common soap, six drachms; balsam capivi sufficient to make them into a ball.

In preparing the decoction, four ounces of linseed and the same quantity of mallow root bruised, with three ounces and a half of gum arabic, should in the whole be boiled for a few minutes in three pints of water, and the liquor then strained off for use as above.

Wet cloths frequently squeezed out of a warm decoction of chamomile, and other similar herbs and flowers, may often be applied with great benefit to the parts between the legs, near to the neck of the bladder.

The animals should have mashes of bran, malt, and other such matters, occasionally given to them, with warm water or oatmeal gruel for drink.

By these means, affections of this sort may commonly be speedily removed without any great difficulty.

URINE, Chemical Properties of. Perhaps no animal product has more attracted the attention of chemists than the urine, not only on account of its supposed connection with diseases, but also on account of its compound nature, and singular chemical properties. The older chemists, Brandt, Kunckel, Boyle, &c. were led to examine its nature chiefly on account of the phosphorus which they extracted from it. Since their time others have examined it with different and various views, among whom may be mentioned Boerhaave, Haller, Margraff, Pott, Rouelle jun., Cruickshanks, Fourcroy and Vauquelin, Proust, Klaproth, and more lately Berzelius, who has given by far the best and most rational account of this fluid which has yet been published.

Fresh human urine differs considerably in its appearance, according to the state of a person's health, his food, or the period at which it has been voided. In general, the urine of a person in health, voided in the morning, is a transparent liquid of a light amber colour, an aromatic odour, resembling that of violets, and a disagreeable taste. When it cools, the aromatic smell leaves it, and is succeeded by another, well known by the name of *urinous*. In two or three days this is succeeded by another, which has been compared to that of four milk. This also gradually disappears, and is finally succeeded by a fetid alkaline odour.

Fresh urine, just voided, reddens turnsole paper, and therefore contains a free acid. The specific gravity of urine, according to Mr. Cruickshanks, varies from 1.005 to 1.033. According to the recent experiments of Dr. Scudamore, the specific gravity of *healthy* urine lies between 1.010 and 1.015. The specific gravity of morbid urine, according to the same author, is frequently as high as 1.030, and occasionally as high as 1.040.

We shall give the results of Berzelius's analysis of this fluid, and afterwards make some remarks upon the more important ingredients contained in it. According to this accurate chemist, 1000 parts of urine are composed of

Water	933.00
Urea	30.10
Sulphate of potash	3.71
Sulphate of soda	3.16
Phosphate of soda	2.94
Muriate of soda	4.45
Phosphate of ammonia	1.65
Muriate of ammonia	1.50
Free lactic acid	-
Lactate of ammonia	-
Animal matter soluble in alcohol, and usually accompanying the lactates	17.14
Animal matter insoluble in alcohol	-
Urea, not separable from the preceding	-
Earthy phosphates, with a trace of fluat of lime	1.00
Uric acid	1.00
Mucus of the bladder	0.32
Silex	0.03
	1000.00

Of this analysis, Berzelius remarks, that "the relative proportions of the ingredients probably vary independently of disease. I believe, however, that in urine they are never very different, unless from pathological causes, which materially affect the health."

Of these numerous ingredients we shall briefly speak of the

URINE.

the acids only of the urine, having treated at length of *urea* in its proper place.

The acids of the urine may be considered as of two kinds, those peculiar to it, and generated in the act of secretion; and those common to it and the blood, and which of course pre-existed in that fluid. In the first class are comprised the sulphuric acid, the uric acid, and occasionally the benzoic and carbonic acids; in the second, the phosphoric and lactic acids, which appear to be more abundant in the urine than the blood, and consequently may be supposed to be formed in part in the kidneys also; in the third, the muriatic and fluoric acids which appear to pass from the blood to the urine without any increase from the kidney. As by the laws of chemical affinity these acids will unite with any alkaline base that may be present, and saturate themselves with it in the order of the force of their respective affinities, it must follow, as justly observed by Berzelius, that when the quantity of alkali is insufficient to saturate all the acids present, the weakest acids must be those that will remain uncombined, and will consequently impart to the urine their peculiarly acid characters. These therefore must necessarily be the lactic and the uric acids.

The *sulphuric acid* does not exist in the blood, but it is found in considerable quantity in the urine. Rouelle senior long ago pointed out this fact, but it seems to have been regarded by subsequent chemists rather as an accidental than as a constant occurrence. Berzelius, however, has shewn the contrary, and states that he has good reason for believing that this acid is an essential constituent of the urine. The same excellent chemist also has shewn that the whole of the sulphur contained in the blood is not acidified in the kidneys, but that a portion of it still remains in an unaltered though combined state in the urine.

The leading properties of the *uric acid* have been discussed under its proper head; we shall therefore confine ourselves here to a few circumstances connected with its formation and separation from the urine. The red crystalline deposit, or gravel, which occurs in urine that has been kept for a few days, consists chiefly of uric acid united with the colouring matter of the urine, or, according to Berzelius, with ammonia. What is termed also the *pink*, or *lenticulous sediment*, a substance frequently formed in derangements of the digestive organs, and especially in gout, and which was formerly considered a distinct principle by Proust, who named it the *rosacic acid*, has been lately shewn to consist chiefly of uric acid, combined with colouring matter and foda.

The *benzoic acid*, according to Scheele, is sometimes found in the urine of infants. Berzelius, however, has never been able to detect it, and seems to doubt if it ever exists in healthy human urine.

With respect to the *carbonic acid*, Berzelius seems to doubt if it ever exists in healthy urine, and supposes its occasional presence to arise from the decomposition of urea. Dr. Marcet states that he has sometimes found traces of carbonic acid in the urine, and sometimes not; and concludes, "that the evolution of this gas from the urine, whether arising from the presence of uncombined carbonic acid, or from some decomposition of the animal matter contained in that fluid, depends upon certain states of the body at the moment the urine is secreted, rather than upon the introduction of the gaseous acid through the digestive organs."

The *phosphoric acid*, for the reasons before mentioned, can hardly be ever supposed to exist in urine in the free state. Its salts, however, form very important ingredients of that fluid. What is termed *white gravel*, or *sand*, usually consists of the phosphate of magnesia and ammonia, and of the

phosphate of lime, and are perhaps chiefly formed in the kidney.

To the *lactic acid*, and the peculiar animal matters which accompany it, Berzelius ascribes chiefly the acid properties, as well as the peculiar colour and smell of the urine.

The *muriatic acid*, and its compounds, the muriates of foda and ammonia, exist in the urine, (more especially the muriate of foda,) in considerable quantity. The muriate of foda is probably never a product of secretion, but derived from the blood. The origin of the muriate of ammonia is more obscure.

The presence of a small portion of the *fluoric acid* in urine in combination with lime has been demonstrated by Berzelius; but the existence of this principle, as well as of *silic* in the urine, rests at present, we believe, upon his authority alone.

The urine is not only liable to be much modified by disease, but from the same cause occasionally contains substances which never exist in it in a healthy state. The principal of these are albumen, saccharine matter, and oxalic acid, all which, as well as others, probably depend either upon a suspension or perversion of the secreting powers of the kidney.

Thus the albumen seems to be derived at once from the blood. The saccharine matter, as stated under *UREA*, appears to be formed by some unknown process from that substance, while the oxalic acid is probably derived from the same source.

The above observations apply to the human urine; we come now to make a few remarks upon the urine of other animals; a most extensive field of research, but which has not at present been much investigated.

Urine of the Lion and Tiger.—The urines of these animals, according to Vauquelin, closely resemble one another, and likewise bear some analogy to the human urine; they differ from it, however, in the following essential points: they contain no uric acid, nor any combination of that principle, as might have been expected from the food on which these animals live. They contain, however, a great proportion of urea, though very little muriate of foda. They have a peculiar fetid smell, which is derived, in part, probably from the ammonia developed from the decomposition of the urea. This smell is well known to be common to the urine of all the feline animals, and may in every instance be supposed to be owing to a similar cause.

The urines of the *horse* and *cow* do not differ much from one another, according to the same chemist. Both become muddy in cooling; both are alkaline, and contain a large proportion of carbonate of lime, benzoic acid, and urea, but no uric acid. One thousand parts of the urine of the horse, according to Fourcroy and Vauquelin, are composed of

Water and mucus	940
Urea	7
Carbonate of lime	11
Benzoate of foda	24
Carbonate of foda	9
Muriate of potash	9
	1000

The urine of the *camel* has been examined by Rouelle. Its odour resembles that of the cow. Its colour is that of beer; it is not mucilaginous, and does not deposit carbonate of lime. It is alkaline, and contains the carbonate, sulphate, and muriate of potash, and urea. Mr. Braude, who has

fined

URINE.

since examined this fluid, thought he discovered in it traces of uric acid.

The urine of the *beaver* has been examined by Vauquelin. It bears a strong resemblance to the urine of herbivorous animals in general. It contains carbonate of lime, held in solution by excess of carbonic acid; also benzoic and acetic acids, urea, muriate of soda, and sulphate of potash, but no uric acid nor phosphates. It contains, however, muriate of ammonia, and carbonate and acetate of magnesia, according to the same chemist, though we think the existence of the last principle is doubtful. The specimen examined by Vauquelin also afforded distinct traces of the colouring principle of the willow bark, on which this animal feeds.

The urine of the *rabbit* has been examined by the same chemist, who found this, as well as the urine of the *guinea pig*, to resemble very closely the urines of the herbivorous quadrupeds above described.

The same indefatigable chemist also, assisted by Fourcroy, has examined the urine of *domestic fowls*, in which they found uric acid, a fact which has been confirmed by succeeding chemists. They also found the same acid in great abundance in the excrements of a South-sea bird, called *guano*.

Lastly, Dr. Prout has given the following analysis of the excrements, or urine, of the *boa constrictor*. One hundred parts were found to consist of

Uric acid	-	-	-	-	-	-	90.16
Potash	-	-	-	-	-	-	3.45
Ammonia	-	-	-	-	-	-	1.70
Sulphate of potash, with a trace of muriate of soda	-	-	-	-	-	-	.95
Phosphate of lime	-	-	-	-	-	-	.80
Carbonate of lime	-	-	-	-	-	-	.80
Magnesia	-	-	-	-	-	-	.80
Animal matter, consisting of mucus, and a little colouring matter	-	-	-	-	-	-	2.94
							100.00

The uric acid, in this instance, was in combination with the potash and ammonia, and was easily obtained in a perfectly pure state by the usual processes.

Hence it appears that the urine of quadrupeds agrees with the human urine, in containing urea; but materially differs from it, in being without phosphoric or uric acid, and in containing an excess of carbonic acid; while the urines of birds and serpents seem to contain an excess of uric acid, and a deficiency of the other ingredients existing in the human urine.

URINE, in *Agriculture*, the saline fluid secreted from the blood of animals by the kidneys, and discharged by the canal of the urethra, which is highly useful as manure in different cases, in promoting vegetation, and increasing the fertility of land. It is, indeed, in this last way, of great use, in improving moist sorts of soil. Besides its value in other intentions too, Columella has asserted, that old urine is excellent when applied to the roots of trees. Hartlib also has much commended the Dutch for preserving the urine of cows as carefully as they do the dung, for enriching their lands.

This is therefore a fluid which is capable of being employed with great success and benefit both on meadow and on arable land, and which affords uncommon fertility and improvement to both in many cases. In the former case, the best time for sprinkling or applying the liquid over the land, is supposed by some to be during the winter months, when the rains will have the most power in washing

the fertilizing parts of it into the soil; or, the land may be sprinkled over with it, early in the spring, just before it is laid or flut up for hay; because no cattle will touch the grass so long as the saline matters adhere to the blades of it. Another circumstance which is necessary to be attended to in such cases, in order to make the most of this very valuable fluid manure; is, that it be carried out to the meadow and pasture-grounds that are intended to be dressed with it, in a dry time, as the urine and farm-yard liquor in the reservoirs is at such periods the most strongly impregnated with saline and other matters, as may be known by the deep brown or blackish colour that is present. All such reservoirs or ponds, as are appropriated for the reception of it, should constantly be kept, in some measure, in a state of readiness for the purpose, at such seasons; and the lands may be sprinkled or moistened as often as occasion may render it necessary or proper.

The practice of most modern farmers in respect to preserving urine is, it is said, as opposite as possible; for they not only suffer that of their cattle to flow away, but have generally their dung-heaps so situated that they are drenched and impoverished by rain, which conveys their most valuable ingredients into the next river. The more heavy and cumbersome materials, which the water can neither dissolve nor sweep away, are frequently, it is said, alone reserved, to be bestowed, at a great expence, on the defrauded land.

It is conceived by a writer in the fourth volume of Communications to the Board of Agriculture, that the quantity of most valuable manure which may thus be carried away, is much greater than is perhaps imagined. Lately, the writer obtained more than half an ounce of a dry fetid substance from one quart of human urine. Supposing the urine of cattle, it is said, to be equally productive, every hoghead of it which flows out of a farm-yard, without even any impregnation from the dung-heap, carries away seven and a half pounds of solid matter. This should induce farmers in all cases to waste liquors of this sort as little as possible, and to convert them as much as can be to the improvement of land, and earthy substances as manure, for applying upon it.

It is remarked that urine is very liable to change, and to undergo the putrefactive process; and that that of carnivorous animals does it more rapidly than that of the graminivorous kind. That in proportion as there is more gelatine and albumen in urine, so in proportion does it putrefy more quickly. That the sorts of urine that contain most albumen, gelatine, and urea, are the best as manures; and that all urine contains the essential elements of vegetables in a state of solution. That as during the putrefaction of urine, the greatest part of the soluble animal matter that it contains is destroyed, it should, of course, it is said, be used as fresh as possible; but that if not mixed with solid matter, it should be diluted with water, as when pure it contains too large a quantity of animal matter to form a proper fluid nourishment for absorption by the roots of plants. The ancients had, however, a notion of using urine stale: but of mixing it with rich earthy matters, which is probably the best and most economical mode of applying it, they had, it would seem, no idea.

Putrid urine, it is said, abounds in ammoniacal salts; and that though less active than fresh urine, is a very powerful manure.

In some northern districts very great improvement is produced on grass land by the application of urine and dung-liquor in the beginning of the autumn, as about November. The fluid is conveyed and applied to the land by means of

a rum-puncheon, which is mounted on wheels, being filled by large pails with long handles. Two persons, a man and boy, are employed in the work. One puncheon full is capable of doing forty-six rods (of seven yards) forward, and three yards in breadth. In this way, it is very readily and conveniently made use of, when applied in the liquid state. The writer of the Agricultural Report of the County of Peebles observes, that the urine of cattle, until of late too much neglected, is now more attended to: it is collected by earth laid down to absorb it, as well as the liquids that run off from the dungheads, or it is received into a pit furnished with a pump. Some collect it in the first manner, and apply it to the land by putting it into a puncheon mounted as above, and furnished at the hindermost end with a pipe, terminating in a large rofe, somewhat like that of a watering pan. It is drawn over the field by one horse, and the urine from the rofe besprinkles to the breadth of nine feet, so that an eighteen-foot ridge is done in the going and returning of the carriage. It is observed, too, that as urine is of a scorching quality, it is unsafe to apply it to any growing crop, in great heat or drought; so that, in general, it is unadvisable to apply it after the month of May. That it ought not to be applied to any land in winter, from its being so easily washed away by rains; and never on wet lands, earlier than the month of March; and then only in dry weather. That it may be laid on fallow, at any time when it is dry enough to absorb it readily. That, in dry warm weather, it is advantageously thrown over dunghills, especially those of the compost kind.

Notwithstanding these remarks on the great use of urine, it is stated in the seventh volume of the Bath Letters and Papers, that an attentive and diligent farmer took the trouble one year to carry out all the stable liquor *alone*, but without observing any *good* effects from it, and that another person was known to him who had done the same thing without any better success. The time, manner, or sort of land to which it was applied are not, however, mentioned, which would probably have explained the reason of its want of success in such cases.

URINE, *Salt of*. See *Fusible SALT*.

URINOUS SALTS are the same with what we otherwise call *alkaline salts*, or *alkalies*.

There are two kinds of urinous salts, the one *fixt*, the other *volatile*. The first prevail in plants, and the volatile in animals.

They are called urinous, in respect of their taste and smell, which bear some resemblance to those of urine.

URIPA, in *Geography*, a town of Peru, in the diocese of Cusco; 120 miles W.N.W. of Cusco.

URIQUE, a town of New Mexico, in the province of Cinaloa; 120 miles N.E. of Cinaloa.

URISAL, a town of Sweden, in the province of Uppland; 6 miles N. of Stockholm.

VRISHADWAJA, a name of the Hindoo deity Siva. It is a compound word, meaning he who rides a bull; this animal being the vehicle on which that deity rides.

VRITRA, a demon, according to Hindoo legends, slain by their god Indra, regent of the firmament, who is thence named Vritrahaa. See *INDRA*.

URITANUS AGER, in *Ancient Geography*, a territory of Italy, mentioned by Appian and Velleius Paterculus.

URITH, in *Rural Economy*, a term sometimes used to signify the bindings of hedges in those of the staff and band or rise kind. See *FENCE* and *HEDGE*.

URITZ, in *Geography*, a town of France, in the department of the Lower Loire; 14 miles N.N.E. of Ancenis.

URIVES, in *Rural Economy*, a term sometimes applied

to the nets which are used to catch hawks, and other similar birds of prey with, in different places.

URIUM, in *Ancient Geography*, a town of Hispania, in Bætica, on the confines of Lusitania, belonging to the Turditani. Ptolemy.—Also, one of two rivers of Bætica, between the Axas and the Bætis.

URIUMKAN, in *Geography*, a river of Russia, which runs into the Arguna, N. lat. 51° 55'. E. long. 124° 15'.

URJUP, or URUP, one of the Kurile islands, distant from Shiro Oi 25 versts. This island is larger than most of the others, being 200 versts long, and 20 broad. Its mountains are high, with bald heads; they are very steep, and about them are deep glens. On the north coast lie four small isles almost contiguous. In the vales, and beside the streams, a plain is occasionally seen; and in the valleys as well as on the mountains, and indeed over the whole island on the north and east sides, are high forests of birches, elders, the forbus sylvestris, and sturdy rattans. On the shores and in the valley-plains the herbs shoot to an uncommon height. Considerable streams flow from the mountains into the sea, and yield a variety of fish. In the northern part, about the middle of the island, is an inland sea, which discharges its waters by a level stream into the ocean; which stream teems with fish. The island abounds with rats, and with red and white foxes. In the clefts of the mountains is found ore, such as copper pyrites mixed with quartz, sulphur pyrites as hard as steel, with quartz, and a poor copper pyrites in a calcareous gangue. This island is only frequented for taking the foxes. Tooke's *Ruff. vol. i.*

URK, a small island in the Zuyder Zee; 11 miles E. of Enckhuyten.

URKUND, or UZKUND, or *Adercand*, a town of Turkistan; 90 miles N.E. of Tontac.

URKOK, a town of Bengal; 14 miles N. of Doefa.

URKONGE, or KORKANJE, or *Orkanje*, or *Urgentz*, a town of Asia, and capital of Charasm, on a branch of the Jihon, which runs into the lake Aral. In the year 1221, this place was besieged by the troops of Jenghiz Khan, and after an obstinate defence, and the death of the governor, the inhabitants set fire to their houses: those who remained after the slaughter which followed the surrender were condemned to slavery; 320 miles W.N.W. of Samarcand. N. lat. 42° 35'. E. long. 58° 30'.

URKUP, or YURKUP, a town of Asiatic Turkey, in Caramania, on the Kizil-ermuk; 10 miles W.S.W. of Tocat. N. lat. 38° 37'. E. long. 34° 18'.

URLINGFORD, a small town of the county of Kilkenny, Ireland; about 10 miles S.W. from Durrow.

URLIUTIUPSKOI, a fort of Russia, in the government of Kolivan, on the east side of the Irtisch. N. lat. 53° 36'. E. long. 75° 34'.

URMIAH, or URUMEA, a district of Persia, in the province of Azerbaijan.—Also, an ancient city of the same province, the Thebarma of Strabo, and supposed birth-place of Zoroaster, situated on a noble plain, which is fertilized by the river Shar, and on the south-west of the lake to which it gives name. This town is distant 32 furlongs from Tabreez, and contains a population of 12,000 souls. It is defended by a strong wall and deep ditch, that may be filled with water from the river, and the vicinity produces wine and corn in abundance. It cannot boast of a single river of consequence. N. lat. 37°. E. long. 45° 40'.—Also, a lake generally believed to be the Spauto of Strabo, and Marcianus of Ptolemy, about 80 furlongs or 300 miles in circumference. The water is more saline than the sea, and it emits a disagreeable sulphurous smell, so that no fish can live in it. Some say that the surface is occasionally incru-
stated

crusted with salt; but this is not always, if ever, the case. On one of the islands in the lake (for there are several) Holaku built a fortress, in which he secured the spoil he had collected during his conquests. The largest of these islands forms, in the dry season, a kind of peninsula, and is 25 miles in circumference; only inhabited by wild asses, deer, and many other kinds of game. In skirting the northern side of the lake, which is of an elliptic shape, we meet the town and district of Sa Bulagh (the cold stream). It is 12 furlongs from Maraga, and possessed by the Kurdish tribe of Meckree. Maraga (which see), supposed to be the Garmarga of Diodorus, has a spacious bazaar; is encompassed with a high wall, and is pleasantly situated in a low valley, at the extremity of a well-cultivated plain, opening to the lake, from which Maraga is distant 9 or 10 miles. The town has about 15,000 inhabitants, a glass manufactory, a handsome public bath, and near it an observatory built on the top of a mountain by Holaku, for his friend Nafer a Deen, the most famous astronomer of his time, who here formed the tables known by his name. The elevated country in the vicinity of lake Urumea was the seat of the Affassins, finally extirpated by Holaku. M'Kinneir's Persia.

URMUK, a small island in the Red sea, near the coast of Arabia; 3 miles S.S.W. of Loheia.

URMUND, a town of France, in the department of the Lower Meuse; 15 miles N.N.E. of Maastricht.

URN, URNA, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers; now seldom used, but in the way of ornament over chimney-pieces, in buffets, &c.; or, by way of acroters, at the tops of buildings, funeral monuments, &c.

The great use of urns, among the ancients, was to preserve the ashes of the dead, after they were burnt; for which reason they were called *cineraria*, and *urna cineraria*; and were placed sometimes under the tomb-stone, upon which the epitaph was cut, and sometimes preserved in vaults in their own houses.

Urns were also used, at their sacrifices, to put liquid things in. They were also of use in the *sortes Praenestinae*, or casting of lots. At Rome, also, the custom was to absolve or condemn the accused, by the suffrages, or calculi, which the judges cast into the *judicatory* urn.

Virgil represents Minos, the judge of hell, shaking the urn, to decide the lots of mankind.—*Quæstor Minos urnam movet.*

The urn is still the attribute of rivers, which are painted leaning on urns, representing their sources by the waters flowing from them. We find them represented, in the same manner, on antique medals, and relieves.

These vessels are frequent in many parts of this kingdom, where there have been Roman stations, and are of very various kinds and manner of workmanship.

Dr. Lister, who was very fortunate in his researches into the structure and differences of these remains of antiquity, observed, that in Yorkshire, where there are great numbers found, there were met with three very different kinds, as to their matter and tempers.

1. A blueish-grey fort, which had a great quantity of coarse sand wrought in among the clay. 2. A fort of the same blueish colour, but containing a sand of a much finer kind, and full of mica, and probably made of a clay naturally sandy, or a fine smooth and stiff loam. And, 3. A red fort, made of a fine pure clay, with little or no mixture of sand. These are throughout of a fine red colour like bole, and many of them are elegantly adorned with figures

in basso relievo, and usually these have on the bottom, or else on the cover, the name of the workman, which some have mistaken for the name of the person whose ashes they inclose; but this must be an error, since great numbers of pots and urns are found with the same name. These are varnished all over, both inside and out, with a varnish of a bright red colour.

The several matters of these urns informed this ingenious inquirer of the place where they were made; which he found to be in the same county on sand-hills, now never used as potteries; but, as he well observes, the difference is very great between the potteries of those days and of ours, since we, who use great quantities of clay, and but little sand, erect these works where there is much clay, and bring the small quantity of sand we use to it; whereas the Romans, on the other hand, who used much sand, and but little clay, naturally established their works where there was plenty of sand, and brought their clay to it.

The Roman urns differ from the earthen-ware made at this time in several particulars. 1. They have no lead-glazing, which seems a modern invention, and is, in many respects, a very bad one. (See GLAZING.) 2. They are composed of a far larger quantity of sand than clay. And, 3. They are baked not in an open fire, as our common earthen-ware, but have been inclosed in large earthen vessels, to defend them from the immediate contact of the flames; and hence it is, that the natural colour of the clay they are made of is not altered in them.

The red urns seem to have been the master-piece of the workmen, and to have employed their greatest art; the embossed work upon them is often very beautiful, and their coral-like glazing is more beautiful than any thing of the modern times, and seems to have been done by dipping them all over in some appropriated liquor, and afterwards baking them in the close manner before described. This has certainly been the method they used, since the fragments of these large coffins, or cases, are found near all the Roman potteries. Hooke's Philosophical Collections, p. 87.

The Romans, and most other nations, contented themselves to make their funeral urns of potters' ware, or baked earth; but we find there have been some people who have made them of gold, on particular occasions. In the year 1685, as a peasant of the island of Funen was ploughing a piece of land, which had before lain barren, he turned up no less than six golden sepulchral urns. They were all full of a greyish substance, which some took to be a grey earth; but it was much more probably ashes.

These are all preserved at this time in the museum of the king of Denmark at Copenhagen; the largest of them weighs two ounces and a half, and the others about two ounces and one drachm each. Wormius, and some others, give accounts, that it was an ancient custom among the northern nations to burn their dead, and when they were great persons to collect their ashes, and bury them in golden urns; and the finding of these seems an evident proof of the truth of that account.

These urns were very thin, and each had three rings of gold about their necks, and several circles, one within another, with one common centre carved on the outside round the body of the urn. They held about five ounces of liquids a-piece, or a little more than that; one near six ounces.

Sepulchral urns of crystal were also not uncommon; the same museum has some of these: they are of a conic figure, and have usually a gold wire wound round them. Urns of this kind have been found buried in some parts of Norway.

URNs

Urns of another kind were those which they called *lachry-males*, or the *tear-urns*: these were contrived to receive the tears of the friends of the deceased, which were afterwards mingled with the ashes of the burnt corpse. These were made of various materials, and of various shapes and sizes, according to the fancy of particular people. Phil. Trans. N^o 285.

URNS, *Vases*, &c. in *Ornamental Gardening*, objects used for the purpose of beauty in some cases of this sort of gardening. It has been observed by Mr. Loudon, in his work on farming and improving country residences, that these are materials which should be introduced with caution; and that none of the others require so much taste and judgment to manage them with propriety as urns, statues, busts, monuments, and inscriptions. The introduction of statues, except among works of the most artificial kind, is seldom or ever, it is said, to be allowed; as when they obtrude themselves among natural beauties, they always disturb the train of ideas that ought to be excited in the mind, and in general destroy the character of the scenery. In the same way, urns, busts, monuments, and other such figures, in flower-gardens, are, it is thought, quite misplaced, as may be felt in many such, by any person capable of attending to his own mind, and who undertakes the principles of taste. The obvious intention of such appendages is, it is supposed, to recal to mind the virtues, qualities, or actions of those for whom they were erected. Now, it is said, this requires time, seclusion, and undisturbed attention, which must either render all the flowers and other decorations of the ornamental garden of no effect; or, if they have effect, it can only be to interrupt the train of ideas excited by the other. As the garden, and the productions of nature in it, are what are intended to interest the spectator, it is plain, the writer thinks, that the others should not be introduced. This reasoning, while on the one hand it shews the absurdity of such a practice, on the other, it is said, directs that urns, monuments, and such like figures, should only be placed in solitary and unfrequented parts, where the mind is naturally led to contemplate, and where the remembrance of the virtues of great men, or the worth of relations now no more, afford proper subjects of contemplation. But even in places apparently solitary, or secluded, these have been introduced in so affected or improper a manner, as to furnish reason, it is said, for the greatest caution in future.

Though statues may sometimes come in well in sublime productions of architecture, they can seldom raise any sublime emotion, when they become principal in any scenery, as when they are used among trees, flowers, or in shrubberies. If placed among such scenery to be admired as works of art, as fine pieces of sculpture, they will never, it is said, sufficiently interest any but such contracted connoisseurs as would not enjoy the other objects, and would much distract the attention of men of true taste, as is the case with those in many places.

Inscriptions, merely as such, it is said, are in general defpicable resources, and only indicate conceit and want of mind. If the inscription be apposite, we are much better pleased to feel or recollect the coincidence on reading, it is said, than to be told it by others; if it be foreign, or far fetched, it argues a gross defect in those who placed it there, and serves to excite ridicule; if it be merely a whim or fancy, as where an urn or feat in a pleasure-ground exhibits in large letters something trifling, it is disgusting.

URN, *Urna*, was also a Roman measure for liquid things;

containing about three gallons and a half of English wine measure.

The urn was half the amphora, and four times the congius.

UROCRITERIUM, or UROCRIA, compounded of *ουρον*, *urine*, and *κριτηριον*, *criteron*, *mark*, *sign*, a casting of water, or giving judgment on diseases by the sight of water. See URINE.

Hence, also, *uromancy*, *uroscopy*, &c.

UROGALLUS MAJOR, in *Ornithology*. See TETRAO, and also COCK of the Mountain, and GROUSE.

UROGALLUS MINOR. See TETRAO, and also GROUSE.

UROMASTIX, in *Zoology*, a name used by some authors for that sort of lizard called cordylus.

UROPIGIUM, in *Ornithology*, or rump, is that part of birds which is furnished with two glands, secreting a fattish liquor from an orifice in each, and which the birds express with their bills, in order to oil the decomposed parts of their feathers.

UROS, in *Ancient Geography*, a river of Italy, in Liguria, W. of Carinum.

UROSPERMUM, in *Botany*, from *ουρα*, a tail, and *σπριμα*, seed, a name which originated with Scopoli, and is retained by Jussieu for the ARNOPOGON of recent authors; see that genus, described at length, at the end of our article TRAGOPOGON.

UROTAL, in *Mythology*, a name given among the Arabians to Dionysius, or Bacchus, under which appellation they worshipped the fun. See Vossius de Idol. l. 1. c. 8.

UROTCHITSCHESCH TASCHTI, in *Geography*, a mountain of Russia, on the north coast of the sea of Aral. N. lat. 45° 30'. E. long. 60° 14'.

UROV, a river of Russia, which runs into the Argunia, near UROVKA.

UROVKA, a town of Russia, on the Argunia, on the borders of China; 120 miles E. of Stretensk.

UROV-FISH, in *Ichthyology*, the name of a fresh-water fish of the malacotomous, or, as we call it, the leather-mouthed kind, caught in the lakes and rivers of Germany, and esteemed a very delicate fish.

It is something like the English rudd or finscale, but its body is somewhat longer, in proportion to its breadth; its back is brown, and its belly yellow; the belly-fins near the anus are a little reddish, but all the rest are brown; the scales are large and silvery, and the irises of the eyes have each, in their lower part, a blood-coloured spot; the tail is forked; and its usual size is about seven or eight inches, though it is sometimes caught considerably larger. Willughby's Hist. Pisc. p. 253.

URPANUS, in *Ancient Geography*, a considerable river of Pannonia, which discharged itself into the Danube.

URPHA, in *Geography*. See OURFA.

URQUHART, a parish in the shire of Elgin, Scotland, is situated on the coast of the Moray Firth, between the rivers Lossie and Spey, and extends about four miles in length, and three in breadth; but contains no creek or landing place of any kind. The north-west part is flat, and the soil sandy, rising only a few feet above the level of the sea; and probably has been formerly inundated, as there are evident marks of the sea having receded from the coast. The remainder of the parish is more elevated, and of an unequal surface: the air is mild and salubrious; the roads are in excellent repair; and the church is in good condition. The loch of Cotts, which is about a mile in circuit, contains pike only; it is frequented in winter by a great number of swans; and in the spring and autumn by vast flocks of wild fowls.

In the population return of 1811, this parish is stated to contain 229 houses, and 936 inhabitants. Four-fifths of the parish is the property of the earl of Fife, whose plantations cover an extent of 2478 acres, and add greatly to the beauty and ornament of the country. Innes-house, one of the numerous seats of the earl, is a noble mansion: it was formerly the residence of the ancient family of Innes, whose annals are marked with signal calamities. A priory was founded in this parish so early as the year 1125, by king David I.; the site has been recently converted into an arable field; and the name of Abbey-Well, which the country-people still give to the fountain that supplied the monks with water, is the only memorial now remaining.—Gazetteer of Scotland, 1806. Carlisle's Topographical Dictionary of Scotland, 1813.

URQUHART is also the name of a parish, now united with that of Glen-Moriston, in the shire of Inverness, Scotland. The united parishes occupy an extent of 30 miles in length, and from 8 to 12 miles in breadth. By the return of the year 1811, the population is stated to be 2446; the number of houses 482. The church is situated at Kilmore, in Urquhart: at Meikly, six miles up the country, is a good chapel; and in Glen-Moriston are two respectable meeting-houses, where the duty is performed by a missionary minister. The surface is, in general, mountainous, but comprehends the two valleys of Urquhart and Glen-Moriston, which extend in a westerly direction from loch Nefs, nearly parallel to each other, and separated by a ridge of lofty mountains; the highest of which, Mealfuarmonie, is elevated 3060 feet above the level of the sea. Urquhart is a rich, though not a deep, loam, and uncommonly fruitful; the soil of Glen-Moriston is very inferior, being light and sandy. Three rivers pass through these parishes, the Moriston, Emeric, and Coiltic; they all fall into loch Nefs, and in their course form several magnificent cascades. The roads and bridges are in good repair; and at Borlem, a substantial bridge of three arches has been recently built over the Coiltic. On a rocky promontory, on the W. side of loch Nefs, are the ruins of Urquhart-castle: the loch washes the east wall, and the other three sides were fortified with a strong rampart, a ditch, and a drawbridge. Within the walls were accommodations for five hundred men. This castle was a royal fort, and was granted by king James IV. in 1509, with the lordship of Urquhart, to sir John Grant, chief of that ancient family, and ancestor to the present earl of Seafield. In the valley opposite to the castle are the remains of a religious house which belonged to the knights templars; and the site is still called "The Temple." At Corrymony, in Glen-Moriston, are to be seen vestiges of a druidical temple, in which the middle of the circle is occupied by a cairn of loose stones, on the summit of which is one very large stone.—Gazetteer of Scotland, 1806. Beauties of Scotland, vol. v., Inverness-shire, 1808. Carlisle's Topographical Dictionary of Scotland, 1813.

URQUHART is also a parish, now united with that of Logie-Wester, situated partly in the shire of Nairn, and partly in the shire of Ross, Scotland. It extends about nine miles in length, and four in breadth; lying along the eastern side of the Firth of Cromarty, and terminated by the river Conan, which here discharges itself into that arm of the sea. The surface is level, diversified by fertile fields, and sheltered by plantations. A new church has been lately built, on a more eligible situation than the old structure. The population of the united parishes was stated, in the return of the year 1811, to be, for that part in the shire of Nairn, 1510, occupying 369 houses, and for the part in Ross-shire, 2664, in 634 houses; making a total of 1003 Vol. XXXVII.

houses, and 4174 inhabitants. The property of the whole is divided among three heritors, who all possess elegant seats. These are, Findon, the property of sir Roderick Mackenzie, of Scattwell: on this estate is a small market-town, on the high road from Dingwall to Cromarty, where four annual fairs are held: Ferrintosh, belonging to Mr. Forbes of Culloden; this barony long enjoyed the exclusive privilege of distilling whisky without being subject to the excise laws; but in 1786 the right was resumed by government, the superior of the barony being allowed 20,000*l.* as a compensation: and Conan-side, the seat of sir Hector Mackenzie, of Gairloch, on whose estate are plantations of firs and forest-trees, of considerable extent, and in a flourishing condition.—Gazetteer of Scotland, 1806. Carlisle's Topographical Dictionary of Scotland, 1813.

URRIN, a river of the county of Wexford, Ireland, which joins the Slaney, a little south of Enniscorthy.

URRIS HEAD, a cape of the county of Mayo, Ireland, the northern point of the peninsula of the Mullet. N. lat. 54° 17'. W. long. 9° 51'.

URRISBEG, a mountain of Ireland, in the county of Galway, near the sea-coast; 38 miles W. of Galway.

URROLA, a river of Spain, in Guipuscoa, which runs into the sea, between the Orío and the Deva.

URROZ, a town of Spain, in Navarre; 12 miles S.S.E. of Pamplona.

URRY, in *Rural Economy*, a term sometimes applied to a sort of blue or black clay, lying near a vein of coal.

URSA, in *Astronomy*, the *Bear*, a name common to two constellations of the northern hemisphere, near the pole; distinguished by *Major* and *Minor*.

URSA *Major*, or the *Great Bear*, according to Ptolemy's Catalogue, consists of 35 stars; according to Tycho's, of 56; according to Hevelius's, of 73; but in the Britannic Catalogue, we have 87. See CONSTELLATION.

URSA *Minor*, the *Little Bear*, called also *Charles's Wain*; and, by the Greeks, *Cynosura*; and its neighbourhood to the north pole gives the denomination *αρκτος*, *bear*, to it. Ptolemy makes it consist of 8 stars; Tycho, of 7; Hevelius, of 12; but Mr. Flamsteed of 24. See CONSTELLATION.

URSA, *Cape*, in *Geography*, a cape of Sicily, on the N. coast. N. lat. 38° 18'. E. long. 13° 11'.

URSAKOWA, a town of Prussia, in the territory of Culm; 15 miles N.E. of Thorn.

URSCHEWODO, a town of Austrian Poland, in Galicia; 28 miles S.W. of Lublin.

URSEL, a town of Germany, in the county of Konigstein; 5 miles E.N.E. of Konigstein.

URSENTANI, in *Ancient Geography*, a people of Italy, in the interior of Lucania. Pliny.

URSEOLA, or URSOLIS, a town of Gallia Narbonensis, upon the route from Milan to Vienna, in passing by the Cottian Alps. See URSOLI.

URSEREN, in *Geography*, a celebrated valley of Switzerland, into which is an opening by a subterranean passage, through a rock of granite, called "Urner-loch," 9 feet broad, 10 high, and 220 long. In this valley are four villages, *viz.* Urseren, Hoptal, Realp, and Zandorf, which form a small republic under the protection of Uri. Its territory is about nine miles in length, and two in breadth, and contains about 1300 inhabitants. The people, in their general assembly, elect their "Talamman," or chief, and also some other magistrates; and there is a permanent council of fifteen members, who assemble in each of the different districts.

tricts. The people enjoy great privileges, but are not absolutely independent; for in civil causes an appeal lies from their courts of justice to Altdorf, and in criminal proceedings, two deputies from the government of Uri are present at the trial, and deliver to the judges of the valley the opinion of the council of Altdorf. This valley, though elevated and cold, affords excellent pasture. Above the village of Urseren is a small plantation of pines, the only wood in the valley, excepting a small quantity of underwood and stubbed willows, that feather the banks of the Reufs. In the adjacent country there are several mines of crytal, a considerable quantity of which is exported. The language of the natives is a kind of provincial German, but almost every person speaks Italian.

The valley of Urseren is surrounded by high mountains, covered with pasture, terminating in barren rocks, in many parts capped with snow. Cox's Switzerland, vol. i.

URSHULT, a town of Sweden, in the province of Smaland; 22 miles S. of Wexio.

URSIGUNGE, a town of Hindoostan, in Benares; 16 miles W. of Morzapour.

URSINIA, in *Botany*, so named by Gærtner, appears to have been intended as a tribute to the memory of the Rev. John Henry Ursinus, formerly a clergyman at Ratibon, author of a learned octavo volume, entitled *Arboretum Biblicum*, published at Nuremberg in 1685, after its author's decease, in 1667. Gærtner, v. 2. 462. t. 174. Poiret in Lamarck Dict. v. 8. 256. This is the same genus with Mr. Brown's SPHENOGYNE, (see that article), under which it ought to have been cited as a synonym. We know not why its earlier name was changed, the labours of Ursinus, though generally compilations, undoubtedly entitling him to such a memorial. There was also a Leonard Ursinus, professor of Botany at Leipzig, who died in 1664, at the age of forty-six, having written upon the Tulip, and on the White Lily, with a double flower; but these treatises were merely academical essays, probably of no great moment. See Dryander's *Bibl. Bankf.* v. 3. 260, and Haller's *Bibl. Bot.* v. 1. 536, and v. 2. 685.

URSINJAN, in *Geography*, a town of Persia, in the province of Fars, principally distinguished for a strong and narrow defile, bearing the same name. This pass is on the direct road leading from Shiraz to Kerman; 58 miles from the former, and 100 from Robat, the eastern frontier of Fars. It is nearly two miles long, and not exceeding fifty yards in breadth. In some places, the mountains on either side rise perpendicularly to a great height; and, in the opinion of Mr. Pottinger, the place might be defended, with a very small force, against any number of men. The country between this and Robat is tolerably cultivated, and in some places very picturesque.

URSINS, JEAN-JOUVENAL DES, in *Biography*, a prelate and historian of the 15th century, was advanced to several posts, civil and ecclesiastical, and in 1449 became archbishop of Rheims, under which character he consecrated Lewis XI. In consequence of his revision, in concert with other prelates, of the sentence pronounced against the maid of Orleans, it was revoked. His learning and episcopal virtues established a respectable character; and he closed his life at the age of eighty-five, in the year 1473. His "History of the Reign of Charles VI., from 1380 to 1422," is said to be written with correctness and integrity. It was first published by Theodore Godefroi, in 1614, 4to.; and an improved edition by his son appeared in 1653, fol. Moreri. *Nouv. Dict. Hist.*

URSINUS, FULVIUS. See ORSINI.

URSINUS, ZACHARY, whose family name was BEER, or BEAR, a German Protestant divine, was born at Breslau in 1534, and in the course of seven years' study at Wittenberg, recommended himself by his abilities and diligence to Melancthon, who was then principal of the university. He accompanied his tutor to the conference at Worms in 1557, and having visited Calvin at Geneva, studied Hebrew at Paris under the learned Mercier. In the following year, he accepted an invitation from the magistrates at Breslau to become rector of their public school; but here a complaint was lodged against him by some Lutheran ministers, on account of his explanation of the article on the Lord's Supper, in a book of Melancthon's, which they conceived to be inconsistent with the true principles of Lutheranism. Although he defended himself by a tract on the Lord's Supper and Baptism, the storm continued, so that he applied for a dismissal from the magistrates, and returned to Zurich. In 1561, he was invited to Heidelberg, and was made professor in the college of Sapientia. In 1562, he obtained the honour of D.D., and that of the professorship of "Locorum Communium," or of common places; and in this year he drew up the Heidelberg, or Palatine catechism, publishing also, by order of the elector Frederic III. an apology for it, in answer to the remarks of some Lutheran theologians. To the elector, he rendered essential service in forming the plans and statutes of several schools which he founded; and continued at Heidelberg till Frederic's death, in 1577. By his success, Lewis, who was a strict Lutheran, Ursinus was dismissed; and afterwards settled at Neukstadt, as theological professor in a seminary founded by prince Casimir, the son of Frederic. Here he also gave private lectures on logic, and published several works; but intense application hastened his death, which took place in 1583, when he had attained the age of forty-nine years. He was eminently learned, and an excellent teacher: in his disposition modest, but irritable. His various writings were collected after his death, and published in 1611 at Heidelberg, in 3 vols. folio. Bayle. *Gen. Biog.*

URSINUS, BENJAMIN, originally BEHR, a German mathematician, was born at Sprottau, in Silesia, in 1587; and resided for a long time as tutor to two young noblemen, along with Kepler, whom he assisted in the construction of the Rudolphine tables, first at Prague, and then at Lintz, in Bohemia. In the latter place, he was teacher of mathematics; and from thence he removed to Frankfort on the Oder, to undertake a similar charge; and here he died in 1635. In 1628, or 1629, he published, at Cologne, his "Cursus Mathematicus," containing Napier's logarithms, and some additional tables of proportional parts; and in 1624, he printed, at the same place, his "Trigonometria," with a table of natural sines and their logarithms, in Napier's form, to every ten seconds in the quadrant, the computation of which was a work of great labour. Haller. *Gen. Biog.*

URSITZ, St., or *St. Ursenne*, or *Sonderstz*, in *Geography*, a town of France, in the department of the Upper Rhine; 20 miles S.W. of Bâle. N. lat. 47° 25'. E. long. 7° 6'.

URSKOG, a town of Norway, on the Glammen; 44 miles N.N.E. of Frederickstad.

URSNACH, a town of the Helvetic republic, in the canton of Appenzel; 8 miles S.W. of Appenzel.

URSO, (*Ossura* or *Ojana*), in *Ancient Geography*, a town of Hispania, in Bætica, situated towards the west. It had the title of a republic in an inscription; and its medals, badly

badly executed, had on one side an unknown head, and on the other a sphynx.

URSOLI, a place that occurs in the Itin. of Anton. between Valence and Vienne.

URSPERG, in *Geography*, a princely abbey of Germany; 16 miles W.S.W. of Augsburg.

URSULA, ST., a town of the duchy of Stiria; 8 miles W.S.W. of Marburg.

URSULINES, an order of nuns, who observe the rule of St. Augustine; and are chiefly noted for taking on them the education and instruction of young maids.

They take their name from their institutress St. Ursula, and are clothed in white, or black.

This institute was first established in Italy by Angelus de Brecia, in 1537; it was afterwards approved in 1544, by pope Paul III. and united in one nunnery by solemn vows, by Gregory XIII. The Ursulines of France were founded in 1611 by Magdalen Lhuillier, lady of St. Beuve. Their chief house is at Paris, whence they have spread through other parts of the kingdom.

URSUS, BEAR, in *Zoology*, a genus of the class of Mammalia and order of Ferae, the characters of which are, that the front teeth are six both above and below, excavated within alternately; the two lateral ones of the lower jaw longer than the rest and lobated, with smaller or secondary teeth at their internal bases; the canine teeth are solitary; the grinders are five or six on each side, the first approximated to the canine teeth; the tongue is smooth; the snout prominent; eyes furnished with a nictitating membrane. Gmelin enumerates eight species, besides several varieties: *viz.*

ARCTOS. Blackish-brown bear, with abrupt tail. This is the ursus of Gesner, Aldrovandus, Ray, &c. the ours of Buffon, and brown bear of Pennant. The varieties mentioned by Gmelin are the black bear with a smaller black body, the brown bear with a brown and ferruginous body, the white bear with black body and white hairs intermixed, and the variegated bear with a body of various colours. The common bear, with some variations as to size and colour, is a native of almost all the northern parts of Europe and Asia, and is said to be found in some of the Indian islands, as Ceylon, &c.; and the brown bear is also found in some of the northern parts of America, where it destroys cattle; but this is a different species from the American black bear, which is not carnivorous. The common bear inhabits woods and unfrequented places, and feeds chiefly on roots, fruits, and other vegetables, occasionally preying on animals. In the Alpine regions, the bear is brown; in some other parts of Europe, black; and in some parts of Norway of a grey colour, and even perfectly white. The brown, the black, the grey, and the white land bears, are all of the same species: though it is observed, that the brown and the black varieties differ in their mode of life; the black confining itself almost wholly to vegetable food; whereas the brown bear frequently attacks and preys upon other animals, and destroys lambs, kids, and even sometimes cattle, sucking the blood like the cat and weasel tribes. Linnæus adds, that the bear has a mode of blowing up his prey, and of hiding or burying a part of it. Bears are said to be fond of honey, and to climb trees in search of it among the nests of wild bees. They sometimes take up their residence in the hollows of very large trees. They will also catch and devour fish, occasionally frequenting the banks of rivers for that purpose.

The bear passes a considerable part of the winter in a state of repose and abstinence, emerging from his den occasionally at distant intervals, and then concealing himself in his retreat

till the approach of the vernal season. The females continue in this state longer than the males, and during this period bring forth their young, which are commonly two in number. The young, though not shapeless animals, as some have erroneously conceived, differ in their aspect from the grown animal, the snout being much sharper, and their colour yellowish; and they are said to be blind for nearly a month.

AMERICANUS. The black bear, with ferruginous cheeks and throat; the black bear of Pennant. This, says Dr. Shaw, is a species distinct from the black bear of Europe, and has a long pointed nose, and narrow forehead; the hair of a glossy black colour, smoother and shorter than that of the European kind, and is generally smaller than the European bear. This animal inhabits all the northern parts of America, and occasionally migrates to the more southerly parts in search of food, which is said to be entirely vegetable; and it is affirmed, that when urged by extreme hunger, they will disregard all animal food whenever they can obtain a supply of roots and grain. They, however, sometimes destroy fish, and particularly herrings, when they come up into the creeks in shoals. They are said to continue in their winter retreats, either in dens beneath the snow under ground, or in the hollows of old trees, for the space of five or six weeks without food. The yellow bear from Carolina is supposed to be a variety of the former: it is rather smaller than the European bears, with a more agreeable countenance, and is perfectly tame and sociable; the colour being of a lively bright orange, inclining to reddish; the hair is thick, long, and silky.

MARITIMUS. White bear, with elongated neck and head, and abrupt tail: the ursus maritimus albus major arcticus of Martens Spitzbergen, the ours blanc of Buffon, and the Polar bear of Pennant. (See POLAR, or *White Bear*.) These bears, when on land, feed on deer and other animals, as hares, birds, &c. and various kinds of berries. They are said to be frequently seen in Greenland in large droves, allured by the scent of the flesh of seals, and will sometimes surround the habitations of the natives, and attempt to break in; and it is added, that the most successful method of repelling them is by the smell of burnt feathers. They grow extremely fat, a hundred pounds of fat having been taken from a single beal. The flesh is coarse, but the skin is valued for coverings of various kinds, and the Greenlanders often wear it for clothing. These skins were formerly offered by the hunters in the arctic regions to the high altars of cathedrals and other churches, for the priest to stand on during the celebration of mass in winter. The split tendons are said to form an excellent thread. Pennant and Shaw. For the method of hunting the bear, see BEAR.

MELES. The *Badger* (which see) with unmarked tail, body cinereous or grey above, black below, and a longitudinal black band through the eyes and ears. The common badger is the meles of Gesner, the taxus of Aldrovandus, and the blaireau of Buffon. This animal is an inhabitant of all the temperate parts of Europe and Asia: its form is clumsy, being thick-necked and thick-bodied, with very short legs. It commonly lodges in a hole under-ground, whence it emerges in the night in quest of food, which consists chiefly of roots and fruits, and occasionally of frogs, worms, &c. Its eyes are small, and its ears short and round; and the claws of its fore-feet are very long and straight, which latter circumstance has induced Pennant to rank it under a genus distinct from that of ursus or bear. Some have, without just reason, distinguished between the sow-badger and the dog-badger, the difference being merely sexual. The hair is thick; the teeth, legs, and claws, are very strong; so that it defends itself vigorously when attacked. The young badger may be

easily tamed, and it generally prefers raw flesh to every other food in a state of captivity. It is a cleanly animal, and keeps its habitation very neat. The female produces about three or four young. Like the bear, this animal is fond of honey, and will attack hives in order to obtain it. Pennant will not admit the badger to be a carnivorous animal, though Buffon asserts, that it drags young rabbits out of their burrows, and seizes birds, eggs, snakes, and many other animals, for feeding her young. The badger sleeps much, especially in winter, confining himself to his den in a state of femitorpidity. Ridinger has figured a singular variety of badger, of a white colour, with brown and reddish patches. Gmelin mentions two varieties, one white above and below yellowish; and the other spotted, white with reddish and brown spots. The former is found in New York; the latter is very rarely met with in forests, in the fissures of rocks and stones. For the method of hunting the badger, see HUNTING.

LABRADORIUS. The badger with the tip of the tail vilvols, and of a brownish-yellow colour; the throat, breast, and abdomen white, and the feet four-toed: it is the pale yellowish-grey badger, with the throat and belly white, and the head striped with black. This is the American badger of Pennant and carcajon of Buffon: and so much resembles the common, that it may be taken for a variety of it. This species is rather scarce in America. It is found in the neighbourhood of Hudson's bay, and in Terra di Labrador, and, according to Pennant, as low as Pennsylvania, where it is called the ground hog. A variety of this occurs in some parts of America, with the under parts slightly tinged with yellow: it is the first variety of common badger mentioned by Gmelin.

LOTOR. The bear with annulated tail, and black transverse band across the eyes. This is the bear with a long tail of the Stockholm acts 1747, the bear with annulated variegated tail of Buffon, the mapach of Fernand and Nieremb., the raton of Buffon, the coati of Ray, &c. and the raccoon of Kalm, Pennant, &c. See RACKOON.

LUSCUS. The bear with a long tail, ferruginous body, dusky snout, the forehead and lateral part of the body whitish. This is the quick-hatch or wolverene of Edwards, and the wolverene of Pennant. Dr. Shaw suggests, that it is merely a variety of the next species. It is about twice the size of the common fox, and the description given of it by Edwards is as follows:—All the snout, upper and under jaw, as far as the eyes, is of a black colour; the forehead above becomes gradually of a whitish colour; the eyes are of a dark colour; the throat and lower side of the neck white, the first spotted with black, having some transverse bars of black on the under side of the neck; the ears are small and round, appearing but little longer than the hair that grows on the head; they are covered with short brown hair; the hind part of the head and neck, the whole body both above and beneath, the legs and tail, are all of a brown or chestnut-colour, clouded lighter and darker, viz. the upper side of the neck and beginning of the back is dusky, or very dark brown, which gradually changes to a lighter or more pleasant brown in the middle of the back; this colour again grows by degrees darker, till it becomes almost black in the hind part of the back; the tail towards the tip becomes of a dusky-colour; it hath a broad bar of very light ash-coloured brown passing round the body, beginning at each shoulder, proceeding on the sides backwards, and meeting on the rump, just above the tail, where it is broadest. The fur on the whole body is pretty long, and seems not to lie so flat to the skin as in some animals. All the feet, as far as the heel or first joint, are covered with short black

hair, which gradually becomes brown above the knees; the claws are of a light horn-colour; it hath on each foot forwards four toes; the hind feet have five toes each.

GULO. The bear with tail of the same colour, rufous-brown body, and middle of the back black. The gulo of Gefn. and Aldrov., and the glutton of Buffon. It is considerably larger than a badger, but varying in size: the muzzle, as far as beyond the eyes, is blackish-brown, and covered with hard shining hair; over the forehead, down the sides of the head between the eyes and ears, runs a whitish or ash-coloured band or fillet; the top of the head and whole length of the back are black-brown, the colour widening somewhat over the sides as it passes on, and again lessening or contracting towards the tail; or the description might be given in other words, by saying, that the colour of the body is a fine glossy black-brown, with a ferruginous tinge along the sides, so as to form a broad lateral zone; but it is to be observed, that the animal varies considerably in colour; sometimes appearing black, with a subferruginous lateral band; and at other times of a chestnut-colour; the feet are black. Agreeably to its name, it has the character of being very voracious, preying indiscriminately both on fresh food and carrion. One of these animals would eat thirteen pounds of flesh in a day, without being satisfied. It attacks deer, birds, field-mice, &c. and even sometimes the larger cattle; and is said to fit on the branches of trees, and suddenly to spring down on such animals as happen to pass beneath; tearing them, and sucking the blood, till they fall down through faintness, when it begins to devour the spoil. In winter, it seeks out and catches ptarmigans under the snow. What it cannot devour at once it is said to hide under ground, or in the cavity of some tree. It is said to be an animal of uncommon fierceness and strength; and will sometimes dispute the prey both with the wolf and bear. It is also extremely fetid. It breeds once a year, and brings from two to four young at a litter. The fur is much used for muffs, linings, &c. Those skins are said to be preferred which have least of the ferruginous tinge; and for this reason the Siberian variety, which is blacker than the rest, is most esteemed. The glutton is a native of the most northern parts of Europe and Asia, and is found in Sweden, Norway, Lapland, and Siberia, as well as in some of the Alpine regions, and in the forests of Poland and Courland, and in the northern parts of America.

INDICUS. The badger white above and black beneath, first described by Pennant from a specimen brought from India, and in the possession of the late Mr. John Hunter. It had five toes on each foot, with long, straight claws; the head small, the nose pointed, with scarcely any appearance of external ears; the colour of the nose, and face a little beyond the eyes, black; the crown, upper part of the neck, back, and upper part of the tail, white, inclining to greyish; the legs, thighs, breast, belly, sides, and under part of the tail, black. Its food is flesh, and its disposition lively and playful. Dr. Shaw observes, that this animal seems to be nearly allied to the genus viverra; and particularly to the species *V. mellivora* and *V. capensis*. See VIVERRA.

URTAMSKOI, in *Geography*, a town of Russia, in the government of Tobolsk, on the Oby; 52 miles W. of Tomsk.

URTICA, in *Botany*, an ancient name, derived from *uro*, to burn, or sting, and alluding to that property, for which the original and familiar species of this genus, our common Nettles, are universally known. For the mode in which this stinging is accomplished, see PUBESCENCE. A great proportion of the species, however, are simply downy, and

URTICA.

and harmless.—Linn. Gen. 486. Schreb. 633. Willd. Sp. Pl. v. 4. 347. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1014. Prodr. Fl. Græc. Sibth. v. 2. 233. Ait. Hort. Kew. v. 5. 261. Pursh 112. Juff. 403. Tourn. t. 308. Poir. in Lamarck Dict. v. 4. 636. Lamarck Illust. t. 761. Gært. t. 119.—Clas. and order, *Monocotyledon Tetrandra*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth of four roundish, concave, obtuse leaves. *Cor.* Petals none. Nectary, the rudiment of a germen, central, small, pitcher-shaped, undivided, tapering at the base. *Stam.* Filaments four, awl-shaped, spreading, the length of the calyx, and opposite to its leaves; anthers of two globular cells.

Female, generally on the same plant, *Cal.* Perianth of two ovate, concave, erect, permanent valves. *Cor.* none. *Pist.* Germen superior, ovate; style none; stigma downy. *Peric.* none, except the closed calyx. *Seed* solitary, ovate, compressed, blunt-edged, polished.

Eff. Ch. Male, Calyx of four leaves. Corolla none. Rudiment of a germen cup-shaped.

Female, Calyx of two leaves. Corolla none. Seed one, superior, polished.

SECT. 1. *Leaves opposite.*

1. *U. pilulifera*. Roman Nettle. Linn. Sp. Pl. 1395. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 148. Mill. Illust. t. 79. Dodart Mem. t. 38. f. 1. (*U. romana*; Ger. Em. 706. Fuch. Hist. 106. Lob. Ic. 522. *U. prima*; Matth. Valgr. v. 2. 469.)

β. *U. balearica*; Linn. Sp. Pl. 1395. Willd. n. 2. Ait. n. 2. "Blackwell Herb. t. 321. f. 1."

Leaves opposite, ovate or somewhat heart-shaped, deeply serrated. Heads of fruit globose.—Native of the south of Europe. Abundant amongst stones and rubbish on the coasts of Norfolk and Suffolk, flowering in June and July, and laden with ripening seed through the autumn. *Root* annual. *Herb* branched, bushy, armed in every part with extremely venomous stings, whose wounds are more painful than those of our two common species. The *stem* is bluntly quadrangular, often purplish. *Leaves* stalked, varying much in breadth; sometimes nearly lanceolate; sometimes broadly ovate, or heart-shaped, even from the same seed, or on the same plant, so that *U. balearica*, which has the latter character, is a mere variety: they are always of a dark and lurid green, copiously and very coarsely serrated, rugged, veiny. *Flowers* pale green, on axillary, generally twin, stalks, one of which is panicle, bearing numerous distant male blossoms; the other capitate, with only female ones. The *fruit* is a very prickly stinging ball, three quarters of an inch in diameter, composed of numerous tumid *calyces*, each containing a brown seed, like flax, but smaller, as Dioscorides well describes it, this plant being, doubtless, his first species of *ακταλιν*, or Nettle. Dr. Sibthorp found it very common in Greece and the Archipelago. Linnæus quotes under *U. balearica*, *U. pilulifera*, foliis cordatis circumferratis; *Hall. Helv.* 27. By way of correction, Willdenow inserts *ed. pr.* or the first edition! But it should be *Hall. Goett.* 27, where this passage may be found, with a reference to Dodonæus, and to Malchant, which should be Marchant, or rather perhaps Dodart. This reference, however, belongs to *U. pilulifera*. Schorigenam; Hort. Mal. v. 2. t. 39, is moreover quoted, though the plant there figured and described is *Tragia involucreata*. Such is too often the history of synonyms! The following species will shew why we judged it necessary to uravel, with much labour, the above citation.

2. *U. Dodartii*. Dodart's Nettle. Linn. Sp. Pl. 1395. Willd. n. 3. Ait. n. 3. (*U. altera pilulifera*, parietaria

foliis; Dodart Mem., Amsterdam edition, 633. t. 38. f. 2.)—Leaves opposite, ovate, nearly entire. Heads of fruit globose.—The native country of this species is not known, but the plant occurs frequently, as an annual weed, in cultivated ground, in England as well as in France, and is, to use the words of Dodart, more difficult to destroy than to raise. Linnæus justly thought the present a doubtful species, there being no difference between it and the foregoing, except the nearly entire leaves, and more slender habit. The late Mr. Davall gathered a wild specimen near Martigny, in Switzerland, of what he took for *U. pilulifera*, but which seems to us *U. Dodartii*, more serrated than usual, though still very unlike the broad coarse pecunated serratures of the *pilulifera* or *balearica*, to which this specimen, nevertheless, betrays an affinity, and confirms the suspicion of Linnæus, of their being all too nearly related. Haller's having none of these species in his work on Swiss plants, made us anxious to determine Mr. Davall's plant, and to clear up the citation above mentioned. *U. Dodartii* ought now perhaps to find a place in the *Flora Helvetica*, though Schleicher has it not in his lists. *U. integrifolia*, Lamarck n. 4, we presume to be a lanceolate-leaved variety of *Dodartii*.

3. *U. pumila*. Dwarf Nettle. Linn. Sp. Pl. 1395. Willd. n. 4. Pursh n. 1.—Leaves opposite, ovate, blunt-pointed, three-ribbed, serrated. Flower-stalks somewhat corymbose, shorter than the footstalks.—In shady woods, among rocks, from Canada to Carolina. Annual, flowering in July. Smooth and shining, very variable in size. *Pursh.* The *stem* in our specimens is simple, about a span high, square, slightly downy, almost naked in the lower part. *Leaves* an inch long, more or less, bluntly serrated, nearly smooth and naked; the lower *footstalks* longest. *Flowers* crowded, as if whorled.

4. *U. longifolia*. Long-leaved Nettle. Willd. n. 5. (*U. verbascifolia*; Lamarck n. 21.)—Leaves opposite, elliptic-obovate, acute at each end, triple-ribbed, serrated. Corymbs axillary, dense, shorter than the footstalks.—Gathered by Commerçon, in the island of Mauritius. According to a note, attached to one of Commerçon's specimens, what Lamarck and Willdenow took for a branch, is nearly the whole of the plant, its *stem* being simple, not much above a foot high, angular, clothed with minute close-pressed hairs or bristles, and bearing about four pair of stalked, rarely almost sessile, leaves, four or five inches long, and one and a half or two inches broad, roughish on both sides with minute depressed bristles. Their serratures are shallow, most numerous towards the extremity. *Flowers* copious and small. *Seeds* thick-edged. The aspect of this species is like a *Procris* or *ELATOSTEMA* (see the latter article). Lamarck's name, *verbascifolia*, is changed unwar- rantly for the worse, by Willdenow.

5. *U. cuspidata*. Pointed-leaved Nettle. Willd. n. 6. (*U. lucens*; Lamarck n. 22, without any doubt.)—Leaves opposite, ovate, pointed, serrated, three-ribbed, smooth, and shining. Corymbs axillary, capillary, lax, spreading, nearly as long as the footstalks.—Gathered by Commerçon in the Mauritius. The branches are round, purplish, very smooth, leafy. *Leaves* two or three inches long, strongly though bluntly serrated; somewhat heart-shaped at the base; their points bluntish and entire. *Footstalks* varying in length from one to two inches. *Corymbs* often in pairs on one common stalk, on some specimens much shorter than the footstalks. *Flowers* very small. *Seeds* minute, brown, scarcely bordered.

6. *U. peltuncularis*. Long-stalked Nettle.—Leaves opposite, ovate, pointed, serrated, three-ribbed, smooth. Panicles

Panicles axillary, racemose; their common stalks longer than the footstalks, or even the leaves.—Native of Java. Communicated by Thouin to the younger Linnæus. We cannot find any account of this species, which is very distinct, and among the most handsome and conspicuous. The leaves are three inches long, and half as broad; their base not heart-shaped; their points smaller than in the last; their serratures finer and sharper. Flowers in large axillary panicles, whose branches are alternate, racemose, and tufted; the male ones thrice as large as in the foregoing, and their common stalk stout, longer than the adjoining leaf with its footstalk; the female panicle is lower down, rather shorter than the leaf, with much smaller flowers.

7. *U. crassifolia*. Thick-leaved Nettle. Willd. n. 7.—“Leaves opposite, ovate-oblong, acute, three-ribbed, serrated, thickish; reticulated and pale beneath. Corymbs stalked, forked, longer than the leaves. Flowers tufted.”—Supposed to be a native of South America. Willdenow saw only an imperfect garden specimen, with the above name. The stem is shrubby. Leaves stalked, an inch and a half long, veiny, rather fleshy, clothed on both sides with short hairs, which on the under one are copious, as to give a whitish hue to that surface. Footstalks half an inch long. Corymbs axillary, on long stalks, reaching beyond the leaves. Flowers in roundish heads.

8. *U. grandifolia*. Great-leaved Nettle. Linn. Sp. Pl. 1396. Willd. n. 8. Ait. n. 4. (*U. iners* racemosa *foliata*, folio ovifoto; Sloane Jam. v. 1. 124. t. 83. f. 2.)—Leaves opposite, ovate, pointed, copiously serrated. Stipulas elliptical, entire, glaucous. Corymbs much branched, axillary, longer than the footstalks.—Native of Jamaica, in shady woods. Stem from eighteen inches to four feet high. Leaves from five inches to a foot or more in length, three-ribbed, stalked; roughish above; smooth and glaucous beneath. Stipulas in pairs within the footstalks, permanent, broadly ovate, or somewhat heart-shaped, smooth, glaucous and purplish. Flowers brownish, minute, very numerous, tufted.

9. *U. macrophylla*. Doubly-serrated Japan Nettle. Thunb. Jap. 69. Willd. n. 9.—“Leaves opposite, roundish, doubly serrated. Flowers panicled.”—Found near Nagasaki, and in Kofido, in Japan, flowering in September and October. The stem is square, furrowed, purplish, and like the rest of the plant finely downy. Leaves stalked, by no means heart-shaped, three-ribbed, acute, four inches wide, rough with hairs, with deep-cut serratures, which are separately serrated. Footstalks shorter than the leaves. Panicles axillary. Thunb.

10. *U. verticillata*. Whorled Nettle. Vahl Symb. v. 1. 76. Willd. n. 10. (*U. iners*; Forfk. Ægypt.-Arab. 16c.)—“Leaves opposite, ovate, serrated. Flowers axillary, crowded, sessile.”—Native of hills in Arabia Felix. Perennial. Stems herbaceous, a foot high, branched, square, slender, moist hairy upwards. Leaves stalked, an inch long, bluntly serrated, somewhat hairy; entire at the base; paler beneath. Footstalks slender, hairy, the length of the leaves. Flowers somewhat whorled, hairy. Vahl.

11. *U. reticulata*. Net-leaved Nettle. Swartz Ind. Occ. 286. Willd. n. 11. Ait. n. 5.—Leaves opposite, elliptic-oblong, acute; serrated towards the point; reticulated beneath. Stipulas ovate, entire. Clusters panicled, about the length of the footstalks.—Native of stony mountainous places, in the interior of Jamaica, according to Dr. Swartz, from whom we have a specimen. The root is perennial, with many long tough fibres. This species in many points approaches *U. grandifolia*, n. 8, but the stem is more shrubby, and rather taller, though the leaves are very much

smaller, hardly three inches long, thicker, and reticulated beneath; they are nearly smooth to the touch, though covered with close depressed bristles, especially the upper surface. The flowers are very minute, copiously panicled. Calyx of the female ones white, with an extremely narrow reddish border. Swartz.

12. *U. lasa*. Spreading Nettle. Swartz Ind. Occ. 288. Willd. n. 12.—Leaves opposite, ovate; pointed, serrated. Stem lax. Flowers dioecious; the male in round heads; female in cylindrical clusters.—Native of bushy shady places, on the banks of rivers, in Hispaniola, flowering in the spring. The stems are from three to five feet high, smooth, pale, roundish, branched; the branches loosely spreading and zigzag. Leaves two or three inches in length, and nearly half as broad, strongly serrated, with three principal ribs, and two small lateral ones, roughish; pale and a little hairy beneath. Flower-stalks axillary, slender, longer than the footstalks.

13. *U. diffusa*. Recumbent Nettle. Swartz Ind. Occ. 290. Willd. n. 13.—Leaves opposite, ovate, acute, serrated, hipid. Stipulas revolute. Stem procumbent. Clusters panicled, longer than the leaves.—Native of stony mountains in Jamaica. The stem is shrubby at the base, procumbent, sending forth numerous smooth, forked, round branches, lying on the ground in every direction, to the extent of two feet, but ascending at their leafy extremities. Leaves about an inch long, three-ribbed, shining, clothed with a few scattered harmless bristles. Footstalks half as long as the leaves. Stipulas intrafoliaceous, small, cloven, reflexed. Clusters axillary, opposite, panicled, twice the length of the leaves. Flowers monoecious, very minute.

14. *U. betulifolia*. Birch-leaved Nettle. Swartz Ind. Occ. 291. Willd. n. 14.—Leaves opposite, nearly orbicular, somewhat heart-shaped, serrated. Stipulas oblong. Clusters compound. Stem nearly prostrate, with long runners.—Gathered by Dr. Swartz in stony shady places, near springs, on the hills of Hispaniola, flowering in May and June. Root perennial, creeping, thread-branched. Stems herbaceous, a foot high, lax, scarcely branched, round, leafy, smooth, throwing out very long, slender, brittle runners from the bottom. Leaves on long smooth stalks, three-ribbed, veiny, smooth, near an inch broad, deeply serrated; those of the runners nearly sessile. Stipulas whitish, undivided, obtuse, erect. Flowers extremely minute, whitish, with reddish stalks.

15. *U. rufa*. Rusty Nettle. Swartz Ind. Occ. 292. Willd. n. 15. Ait. n. 6.—Leaves opposite, elliptical, acute, serrated, triple-ribbed; their veins hairy. Stipulas roundish, permanent. Clusters slightly branched. Stem shrubby, flaggy with rusty hairs.—Native of stony mountainous places, in the south part of Jamaica, flowering in spring. The stem is a foot high; woody, simple, naked and smooth in the lower part; bushy above, leafy, and clothed with long, dense, rusty down. Leaves three quarters of an inch long, neatly serrated; their stalks half as long. Stipulas whitish, clasping the stem above the footstalks. Clusters on long, hairy, axillary stalks. Flowers minute; the male ones largest, intermixed with the female. These last five West Indian species are all destitute of stings, as well as *grandifolia*, n. 8, to which they are more or less akin, though far inferior in size.

16. *U. urens*. Small Stinging Nettle. Linn. Sp. Pl. 1396. Willd. n. 16. Fl. Brit. n. 2. Engl. Bot. t. 1236. Pursh n. 2. Curt. Lond. fasc. 6. t. 70. Fl. Dan. t. 739. Bulliard t. 230. (*U. minor*; Ger. Em. 707). Fuchs. Hist. 108. Brumf. Herb. v. 1. 154. U. vertic; Matth. Valgr. v. 2. 471.)—Leaves opposite, elliptical, strongly serrated,

URTICA.

ferrated, about five-ribbed. Stipulas lanceolate, reflexed. Clusters oblong, nearly simple.—Common throughout Europe, in cultivated ground, where it proves a most troublesome annual weed, of quick growth, and very prolific, often producing two crops in a year. In America it is more rare. The herb is rather bushy, bright green, armed all over with venomous stings. Leaves an inch or more in length, coarsely and deeply ferrated, full twice as long as their footstalks. Stipulas small, narrow, reflexed. Clusters stalked, drooping, hardly equal, in general, to the footstalks, composed of male and female flowers intermixed. Seeds bordered.

17. *U. spatulata*. Spatulate Stinging Nettle. (U. minor urentissima; Commerf. MSS.)—Leaves opposite, orbicular-heart-shaped, deeply ferrated, shorter than their footstalks, mostly three-ribbed. Clusters capitate, very short.—Gathered by Commerf. at Monte Video. The stem is more elongated, and less branched, than in the foregoing, very densely leafy. Whole herb plentifully armed with long venomous stings. Footstalks near an inch long. Leaves about half that length, with deep-cut, acute, radiating serratures. The stipulas we have not seen. Flowers much like *U. urens*, but in shorter tufts, and the seeds appear to be less conspicuously bordered. We suspect this to be a perennial species.

18. *U. dioica*. Great Stinging Nettle. Linn. Sp. Pl. 1396. Willd. n. 17. Fl. Brit. n. 3. Engl. Bot. t. 1750. Pursh n. 3. Curt. Lond. faic. 6. t. 69. Fl. Dan. t. 746. (U. urens; Ger. Em. 706. U. major; Fuch. Hist. 107. Brunf. Herb. v. 1. 151. U. secunda; Matth. Valgr. v. 2. 470.)—Leaves opposite, heart-shaped, sharply ferrated. Stipulas ovate, distinct, spreading. Clusters much branched, in pairs, longer than the footstalks, mostly dioecious.—Common in waste ground, throughout Europe, as well as in North America and Asia, flowering in the middle of summer. The perennial creeping root, larger size and duller green of the whole plant, and the large branching flower-stalks, render this very obviously distinct from n. 16. The stems are three feet, or more, in height. Every part is armed with stings. Flowers chiefly male on one plant, female on another. Calyx of the latter often furnished with a pair of bractæas at its base. The fibres of the stem may be manufactured into thread, but are inferior to hemp. The young leaves, boiled in spring, are not a bad substitute for spinach, to which herb the Nettle is allied, as well as to the hemp, in botanical affinity. Leers remarks the two additional leaves, or bractæas, to the female calyx, in *U. urens*, as well as in the present species.

19. *U. gracilis*. Slender-stalked Nettle. Ait. ed. 1. v. 3. 341. ed. 2. n. 12. Willd. n. 29. (U. proceræ; Willd. n. 18. Pursh n. 4.)—Leaves opposite, ovato-lanceolate, ferrated; heart-shaped at the base. Stem and footstalks hispid. Flowers dioecious. Clusters in pairs, somewhat branched, about as long as the footstalks.—Native of Hudson's Bay, from whence it was brought to Kew, in 1782. Aiton. Found by the sides of waters, in rocky situations, from Canada to Pennsylvania, flowering in July and August. Perennial. The specimen of *U. gracilis*, in the herbarium of A. B. Lambert, esq., agrees in every respect with *proceræ*. Pursh. This being the case, we retain, of course, the original name. We have seen no specimen of either plant. *U. proceræ* is described by Willdenow as very nearly related to the common *dioica*, so as to be possibly no more than a variety; but differing in its less heart-shaped leaves, whose serratures are smaller. The footstalks are fringed with bristles towards the base of each leaf, where the *dioica* is downy only. The spikes, or clusters, moreover, are less

compound, sometimes shorter than the footstalks, not longer.

20. *U. morifolia*. Mulberry-leaved Nettle.—Leaves opposite, heart-shaped, broadly and bluntly ferrated. Stipulas ovate, combined, reflexed. Clusters in pairs, cylindrical, unbranched, drooping.—Sent by Mutis from Mexico. Linnæus considered it as *U. dioica*, from which, when examined, it manifestly differs in the above characters, and, even at first sight, in the broad blunt serratures of the nearly naked, though rough, leaves, whose surface is even, not wrinkled, except when very young. The clusters are slender, and in our specimen entirely female. Seed nearly orbicular, crowned with a short style.

21. *U. chamaedryoides*. Germander Nettle. Pursh n. 5.—“Leaves opposite, almost sessile, ovate, ferrated; bristly beneath. Tufts of flowers axillary, sessile, nearly globose, reflexed. Stem armed with stings.”—On the islands of Georgia, St. Simon's, &c. Mr. Lyon. Annual, flowering in May. The leaves are small. Stings white, very conspicuous. Pursh.

22. *U. membranacea*. Wing-stalked Nettle. Poir. in Lamarck n. 9. Willd. n. 19. Desfont. Atlant. v. 2. 340. (U. caudata; Vahl. Symb. v. 2. 96. U. dioica β ; Linn. Sp. Pl. 1396.)—Leaves opposite, broadly ovate, somewhat heart-shaped, coarsely ferrated. Flowers monoecious; the male in twin, upright, unbranched, stalked spikes, with a winged receptacle; female in nearly sessile spikes, shorter than the footstalks.—Native of the south of Europe, the north of Africa, and the isle of Bourbon, in which last place our specimen was gathered by Commerf. The root is perennial. Herb stinging, resembling *U. dioica*, but paler, more delicate, of a brighter green; the leaves also are broader, rounder, less sharply ferrated, on longer stalks. The stipulas are almost perfectly combined, spreading. The upright, stalked, unbranched, linear male spikes, with their membranous-winged receptacle, form the most remarkable character of the present species. They grow in pairs, from the bosoms of the upper leaves, which they greatly exceed in length. The female spikes, situated lower down, are much shorter, and less conspicuous. Their calyx is downy.

23. *U. ferox*. Armed Nettle. Forst. Prodr. 66. Willd. n. 20.—Leaves opposite, hastate-heart-shaped, coarsely toothed, fringed with bristles; downy beneath. Stipulas heart-shaped. Clusters panicled, in pairs, longer than the footstalks.—Gathered by Forster, in New Zealand. A shrub, whose branches and footstalks are clothed with hoary down. The midrib of each leaf is beset, on the upper side, with rigid bristles; and the under side is downy. The habit of the plant resembles *U. dioica*. Willdenow.

24. *U. ficifolia*. Fig-leaved Nettle. Lamarck n. 10. Willd. n. 21.—Leaves opposite, heart-shaped, somewhat hastate, acutely five-lobed, crenate; downy beneath. Panicles cymose, divaricated.—Gathered by Commerf. in the isle of Bourbon. This appears to be a tree, with thick, rather fleshy, branches, leafy at their extremities. The leaves grow on longish footstalks, and are three inches long, nearly as much in breadth, very irregularly five or seven-lobed, with taper points; their upper surface almost smooth; under clothed with white silky pubescence. The same tree sometimes bears deeply three-lobed, as deeply pinnatifid, leaves. Flowers very numerous, small, whitish, in large, compound, spreading panicles, somewhat like the cymes of Elder, but not so large.

25. *U. cannabina*. Hemp-leaved Nettle. Linn. Sp. Pl. 1396. Willd. n. 22. Ait. n. 9. (U. foliis profundè laciniatis, femine lini; Amman. Ruth. 173. t. 25.)—Leaves opposite, in three deep pinnatifid segments. Clusters cylindrical,

lindrical, in pairs, erect.—Native of Siberia, especially beyond lake Baikal. Miller appears to have had it at Chelsea, in 1749. A hardy perennial, five or six feet high, flowering from July to September, well compared, in its foliage, to Hemp. The leaves are of a deep rich green, rough with very minute points, and a few marginal bristles, on the upper side; smooth at the back. *Footstalks* half the length of the leaves, armed, like the stem, with scattered, large, and powerful stings. *Clusters* thick, an inch and a half or two inches long, being about half the length of the leaves with their footstalks. *Flowers* and *seeds* very large in proportion to most of the foregoing. *Calyx* beset with stings.

26. *U. virgata*. Wand-like Nettle. Forst. Prodr. 66. Willd. n. 23.—“Leaves opposite, ovate, serrated, three-ribbed. Spikes axillary, folioly, interrupted.”—Native of the Society Isles. *Forster*.

27. *U. rugosa*. Rugged-leaved Nettle. Swartz Ind. Occ. 293. Willd. n. 24.—Leaves opposite, elliptical, serrated, three-ribbed, rugged. *Clusters* thick, dense, terminal. Stem simple, erect.—Native of moist stony places, about the banks of rivers, in Hispaniola, flowering in spring. *Root* annual. *Stem* a foot high, round, downy. *Leaves* crossing each other in pairs, stalked, from one to two inches long, finely and regularly serrated, rough but not stinging, somewhat plaited at the margin; hairy beneath. *Stipulas* large, ovate. *Flowers* dioecious, very minute and crowded, in tufts shorter than the stipulas.

28. *U. repens*. Creeping-stalked Nettle. Swartz Ind. Occ. 294. Act. Holm. for 1787. t. 1. f. 1. Willd. n. 25.—Leaves opposite, roundish-ovate, obtuse, bluntly serrated, three-ribbed; entire at the base. *Clusters* capitate, axillary, stalked. Stem simple, creeping.—Found on the sandy banks of rivers in Hispaniola, flowering in the spring. The *root* is annual and fibrous. *Stem* a span long, creeping close to the ground by means of radicles from each joint. *Leaves* hardly an inch long at the utmost, slightly hairy, not stinging. *Footstalks* hairy, shorter than the leaves. *Flowers* monoecious, in little oblong clusters, on capillary, opposite stalks; much shorter than the leaves.

29. *U. holonifera*. Trailing Nettle. Swartz Ind. Occ. 296. Willd. n. 26.—Leaves opposite, elliptic-oblong, slightly serrated. Stem ascending, with radical runners. Panicles terminal, solitary, dioecious, on slender stalks.—Found on the rocky banks of rivers, among mosses, in the interior part of Hispaniola. *Root* perennial. *Stem* none, or very short; in Dr. Swartz’s specimens two or three inches long, simple, most leafy at the top, sending out trailing shoots from the base, clothed with very small leaves. The leaves of the main stem are about an inch long, rough to the touch, and rather downy, but not stinging; the *footstalks* about the same length. *Stipulas* oblong, entire, membranous, accompanying all the leaves. *Flower-stalks* from the middle of the crowded terminal (not radical) leaves, which they exceed in length. *Flowers* green, small; the male in a roundish dense tuft; female in an oblong, lax, compound panicle; on distinct plants.

30. *U. nudicaulis*. Naked-stalked Nettle. Swartz Ind. Occ. 311. Willd. n. 27. Ait. n. 11.—Leaves chiefly terminal, opposite, elliptic-lanceolate, pointed, three-ribbed, entire, nearly smooth. Stem angular; leaflets below. *Clusters* lateral, dioecious.—Native of lime-stone rocks, in the interior of Jamaica. *Root* fibrous. *Stem* one or two feet high, nearly erect, scarcely branched, jointed, angular, and striated, contracted at the joints; its light-green colour, and smooth surface, in some degree resembling the stems of several species of *Epidendrum*, or their allies. *Leaves* chiefly

about the top of the plant, on short stalks, generally smooth and naked, one and a half or two inches long, very minutely dotted, destitute of stipulas. The uppermost clusters are axillary, the rest at the joints of the stem, opposite, small. *Flowers* minute, white, crowded, very rarely monoecious. Dr. Swartz mentions a variety, with narrower, somewhat hiprid, leaves; longer, more diffuse, clusters; and a less naked stem.

31. *U. lanceolata*. Lanceolate-leaved Nettle. Lamarck n. 15. Willd. n. 28.—Leaves opposite, linear-lanceolate, three-ribbed, entire, nearly sessile. *Clusters* capitate, axillary, solitary.—Native of Hispaniola. *J. Martin*. Poirlet says this species is remarkable, and very distinct, on account of its narrow, linear-lanceolate, nearly sessile, leaves. The stems are weak, herbaceous, naked, almost cylindrical, jointed. *Leaves* about an inch long, and two or three lines broad, somewhat wavy at the edges; paler beneath. By the description, there seems some reason to doubt whether this be distinct from the last, but we have seen no specimens of it. On the other hand, *nudicaulis* is in the list of species unknown to M. Pourret.

32. *U. corymbosa*. Corymbose Entire-leaved Nettle. Lamarck n. 17. Ait. n. 30.—Leaves opposite, ovate, pointed, entire; unequal at the base. *Corymbs* axillary, on elongated stalks.—Native of Guadeloupe. *Badier*. *Stems* very rough, with glandular points. *Leaves* about five inches long, and three broad, one side shorter than the other at the base; their surface rough to the touch. *Footstalks* very long, but shorter than the leaves. *Corymbs* each on a long, simple, axillary common stalk, probably like our *peduncularis*, n. 6.

33. *U. Parietaria*. Pellitory-leaved Nettle. Linn. Sp. Pl. 1397. Willd. n. 31. Ait. n. 13. Swartz Obf. 357. (*Parietaria foliis ex adverso nacentibus, urticæ racemiferæ flore*; Sloane Jam. v. 1. 144. t. 93. f. 1.)—Leaves opposite, ovato-lanceolate, entire. Stem much branched. *Flowers* dioecious.—Native of lofty mountains in the West Indies, flowering throughout the year. *Stem* from two to eight feet high, erect; somewhat shrubby in the lower part; much branched and herbaceous above, red, quadrangular, striated; the ultimate branches slender, wavy, leafy, and smooth. *Leaves* stalked, an inch or inch and a half long, pointed, three-ribbed, veiny, fringed, very slightly, if at all, unequal in the two halves: on the small flowering branches one of two opposite leaves is but a third the size of the other. *Footstalks* long, red, spreading. *Clusters* stalked, axillary, terminal, or opposite to some of the leaves; their stalks slender, coloured, erect, smooth, quadrangular, longer than the footstalks. *Flowers* very small. *Seed* minute, black, shining. Such is Sloane’s and Swartz’s plant, of which we are obliged to the latter for specimens. It is wanting in the Linnæan herbarium.

34. *U. cilicris*. Fringed Three-furrowed Nettle. Linn. Sp. Pl. 1396. Willd. n. 32. (*Parietaria racemosa, foliis ad oras villosis*; Plum. Ic. 111. t. 120. f. 2.)—Leaves opposite, ovate, entire, strongly three-ribbed, fringed. *Clusters* divaricated, corymbose, much branched.—Native of the West Indies, but rare. A specimen was given by Sir Joseph Banks to the younger Linnæus. The branches are very smooth, reddish, obtusely quadrangular. *Leaves* stalked, from one to two inches long, pointed, smooth, except some scattered and marginal white hairs; the three ribs remarkably prominent beneath, and furrowed above. *Clusters* axillary, opposite, stalked, level-topped, widely spreading, half the length of the leaves. The fringe of the latter is far less evident in our specimen, than in Plumier’s figure, and yet we have no doubt of its identity.

35. *U. hederacea*. Ivy-leaved Nettle. Lamarck n. 29.—“Leaves opposite, roundish-ovate, crenate; abrupt at the base. Clusters short, on long stalks.”—Native of Guadeloupe. *Richard*. A small species, with fibrous roots, and weak stems, two or three inches high, clothed with fine short hoary hairs. *Leaves* stalked, small, with large notches, like those of Ivy in miniature, with a few scattered hairs, especially on their ribs and footstalks. *Flowers* in little dense tufts, on axillary stalks twice the length of the leaves. *Poiret*.

36. *U. rhombea*. Rhomb-leaved Nettle. Linn. Suppl. 417. Willd. n. 33.—Leaves opposite, rhomboid, entire, three-ribbed, flat, about the length of their footstalks, which are longer than the cymose axillary panicles.—Sent by Mutis from Mexico. The stem is herbaceous, about a foot high, much branched, smooth, leafy. *Leaves* from half an inch to an inch, or rather more, in length, and above half as much across their middle, obtusely pointed at each end, smooth and even on both sides, without stings. *Stipulas* short, membranous, abrupt. *Flower-stalks* axillary, solitary or in pairs, scarcely ever so long as the footstalks. *Bractes* lanceolate, membranous, at each of their subdivisions. *Flowers* crowded into little heads, small, monoecious. *Seeds* elliptical, beaked. The whole plant resembles a *Parietaria*.

37. *U. ciliata*. Speedwell-leaved Nettle. Swartz Ind. Occ. 298. Willd. n. 34.—Leaves opposite, elliptical, three-ribbed, crenate, fringed, acute at each end; entire at the base. Stem divaricate. Flowers aggregate, on axillary stalks, about the length of the footstalks.—Found in rocky woods, in the interior of Jamaica. The stem is herbaceous, dividing from the base into several smooth, spreading, ascending branches, about six inches high. *Leaves* an inch long, not unlike *Veronica officinalis* in general aspect, but shorter, on longish stalks, crenate rather than serrated, minutely downy, not stinging. *Stipulas* minute, accompanied by tufts of hairs. *Flowers* most assuredly axillary, not terminal, forming a kind of umbels, in which the male ones seem to occupy the upper part. This species is, as Dr. Swartz observes, totally different from the Linnean *U. ciliaris*, but we would beg leave to remark that their names are too much alike.

38. *U. radicans*. Parasitical Nettle. Swartz Ind. Occ. 299. Willd. n. 35.—Leaves opposite, ovate, crenate, thinning; slightly wedge-shaped at the base. Flowers axillary, nearly sessile. Stem and branches trailing, with downy radicles.—Native of umbrageous forests, in the interior of the northern part of Jamaica, where it trails over the trunks of trees, even to their very summits, thriving plentifully under their shade, as well as on the rotten trunks of fallen trees in the same situations; but it rarely blossoms. The spreading stems are sometimes attached throughout their whole length, by shaggy or downy radicles; they are brittle, subdivided, with many opposite leafy branches. *Leaves* stalked, horizontal, obtuse, half or three-quarters of an inch long; their upper surface covered with minute depressed bristles, though not harsh to the touch, nor stinging. *Stipulas* scarcely discernible. *Flowers* minute, green, the male and female ones in the same axillary tuft.

39. *U. pendula*. Pendulous Nettle. Willd. n. 36. (*U. ruppertia*; Lamarck n. 18. “*U. umbellata*; Bory de St. Vincent Voy. v. 3. 173.”)—Leaves ovate, bluntly serrated, generally four in a whorl, on unequal footstalks. Clusters axillary and terminal, on long solitary stalks, somewhat corymbose.—Native of the isles of Mauritius and Bourbon, hanging from the rocks in an elegant manner. The root is fibrous, apparently perennial. Stems from eight to twelve

inches long, covered with minute depressed bristles, and dividing at the extremity into many spreading, opposite, leafy branches. *Leaves* hardly an inch long, broadly ovate, somewhat triple-ribbed, and marked with many transverse veins; their under side smooth, brown or purplish; upper bright green, covered with very minute depressed bristles, as in the last, which do not interfere with their smoothness to the touch. Some of the footstalks are as long as the corresponding leaf; others in the same whorl but half that length. *Flower-stalks* longer than the longest footstalks, slender, smooth, solitary, forked at the upper part, bearing several little round tufts of flowers, which in our specimen are all female, and in feed; nor do we find any traces or remains of male ones. M. Poiret in Lamarck describes the upper side of the leaves smooth, the under slightly downy; yet we cannot doubt his plant being the same as ours. He speaks of a variety with narrower, more lanceolate and pointed, leaves, which has not fallen in our way.

40. *U. fasciculata*. Tufted Nettle. Poiret in Lamarck n. 19.—“Leaves opposite, ovate, toothed, on long stalks. Flowers tufted at the divisions of the panicle.”—Native of Carolina. M. Poiret says this is very distinct from the preceding. The leaves, like every other part, are smooth, much larger than the last, acute, generally remarkable for the great length of the smooth slender footstalks. Clusters many-flowered, very dense, crowded, aggregate and axillary, hardly longer than the footstalks.—We have seen no specimen answering to this description, nor is the present species adopted by Willdenow or Pursh; at least not by the above name.

41. *U. sessilifolia*. Sessile-leaved Whorled Nettle. Poiret in Lamarck n. 30. Willd. n. 37.—Leaves nearly sessile, lanceolate, sharply serrated, three or four in a whorl.—Gathered by Commerion in the isle of Mauritius. The stems are rather woody, with straight leafy branches. *Leaves* mostly four in each whorl, their teeth, or serratures, pointed; both surfaces covered with short, white, not very evident, hairs, such as are found also on the stem; the upper side is of a fine green; the under a little reddish. The flowers have not been observed, so that the genus is presumed from the habit only.

42. *U. nummularifolia*. Moneywort-leaved Nettle. Swartz Ind. Occ. 301. Act. Holm. for 1787. t. 1. f. 2. Willd. n. 38. (*Nummularia faxatilis minima repens, floribus albis, foliis crenatis villosis*; Sloane Jam. v. 1. 208. t. 131. f. 4.)—Leaves opposite, orbicular, crenate, hairy. Clusters dense, terminal, monoecious. Stems thread-shaped, simple, creeping.—Native of fissures of rocks, among the mountainous woods of Jamaica. A pretty little creeping species, downy, or minutely hairy, all over. The leaves are about half an inch in diameter, obtuse, bright green, crenate like those of a *Chrysosplenium*; paler beneath. *Stipulas* membranous, whitish, obtuse. Clusters from the bosoms of the uppermost leaves, each of several male and female flowers; the former largest, on longer stalks; the latter very minute. *Seeds* nearly orbicular, brown, tumid.

43. *U. depressa*. Depressed Nettle. Swartz Ind. Occ. 303. Willd. n. 39.—Leaves opposite, roundish, crenate, smooth. Clusters dense, terminal, dioecious. Stem creeping, subdivided.—Native of shady grassy borders of fields, in the interior of Jamaica. Perennial. Stem three or four inches long, succulent, pressed close to the earth, and fixed by many small radicles. The short branches form a kind of turf with the adjoining plants. *Leaves* small, ribbed, rather succulent, of a brownish green. *Stipulas* ovate, small and white. *Flowers* dioecious, about three to five, in little terminal sessile clusters; the female ones extremely minute.

URTICA.

Seeds roundish, black. Differs from the last in its smoothness, darker colour, dioecious flowers, and more numerous, entangled, depressed, copiously branched, stems.

44. *U. herniarifolia*. Rupture-wort Nettle. Willd. n. 40. (*U. herniarioides*; Swartz Ind. Occ. 309. A&H. Holm. for 1787. t. 2. f. 1.)—Leaves opposite, roundish, entire; tapering at the base: the terminal ones four in a whorl. Flowers terminal, stalked, monoecious. Stem thread-shaped, diffuse.—Found on large stones, in the rivers and rivulets of Hispaniola. A very small, slender, smooth, trailing, annual herb, three or four inches long at most, not much branched. Leaves stalked, somewhat spatulate, bluntish, scarcely two lines in diameter; their upper surface covered with depressed bristles, as if stitched, but not rough to the touch. Flowers excessively small, in little terminal monoecious tufts. Seed brown.

45. *U. microphylla*. Small-leaved Nettle. Swartz Ind. Occ. 305. Willd. n. 41. Ait. n. 14. (*Parietaria microphylla*; Linn. Sp. Pl. 1492. Am. Acad. v. 5. 412. *Herniaria lucida aquatica*; Sloane Jam. v. 1. 145. t. 93. f. 2.)—Leaves opposite or clustered, ovate, acute, succulent, nearly entire. Flowers scattered, dioecious. Stems ascending, branched in the upper part.—Very common throughout the West Indies, in waite or watery places, or on old walls, &c. flowering throughout the year. The roots are perennial, long and capillary. Herb much stouter and more erect than the preceding, about four inches high, with innumerable minute leaves, resembling that species, but more ovate and acute, as well as occasionally notched; their upper side in like manner clothed with close bristles. Flowers axillary, stalked; the male largest, reddish; the female on a separate plant, with shorter stalks, crowded, very minute. Seed roundish, polished.

46. *U. trianthemoides*. Purslane-leaved Nettle. Swartz Ind. Occ. 307. Willd. n. 42.—Leaves opposite, obovate, obtuse, entire; one much smaller than the other. Flowers monoecious. Stem erect, branched.—Native of shady rocky places, near rivers, in Hispaniola. Perennial. Stem herbaceous, a foot high, jointed, branched from the base, succulent and smooth; ultimate branches alternate, spreading, leafy. Leaves stalked, of a shining green, smooth to the touch, but striated, as it were, with small, inseparable, flattened bristles, on the upper side; the under being dotted, and only partially hairy. The largest leaf of each pair is not an inch long; the smaller scarcely one-fifth that size. *Stipulas* none. Flowers numerous, in axillary or lateral tufts, at each joint of the branches. The female calyx is said to consist of three valves.

47. *U. ferrulata*. Blunt-notched Nettle. Swartz Ind. Occ. 313. Willd. n. 43.—Leaves opposite, lanceolate, abruptly serrated, nearly sessile; tapering at the base. Heads of flowers axillary, stalked. Stem shrubby, quadrangular.—Native of limestone rocks, in the interior of Jamaica, flowering in the vernal months. A little, shrubby, bushy plant, about a foot high, with scattered, square, roughish, but not hairy, leafy branches. Leaves about an inch long, dark green, minutely bristly, or stitched, as it were, on the upper side, like several of the foregoing; paler beneath; tapering at the base into short footstalks; furnished in their upper part with blunt, somewhat glandular, serratures. Flowers monoecious, their stalks red, shorter than the leaves; the male ones with a red calyx.

48. *U. lucida*. Shining Cut-leaved Nettle. Swartz Ind. Occ. 315. Willd. n. 44.—Leaves opposite, pinnatifid, shining, clothed on both sides with depressed bristles. Heads of flowers on axillary stalks, longer than the leaves. Stem shrubby, angular.—Found in rocky, or waite places, among

the cooler mountains of Jamaica, flowering in spring. A very pretty little shrub, the height of the last, with brown quadrangular branches. The bright-green shining leaves, scarcely half an inch long, resemble those of an Oak, or rather of *Myrica quercifolia*, in miniature, their lobes and sinuses being rounded in a similar manner. Their flattened bristles are large in proportion. Flower-stalks simple, capillary, each bearing a very small head, in which the male and female flowers are intermixed.

49. *U. trilobata*. Three-lobed Glaucous Nettle. Poiret in Lamarck n. 14. Willd. n. 45.—Leaves oblong, obtuse, undivided or three-lobed, stalked, three or four in a whorl, hoary with close-pressed bristles. Stem round, with quadrangular branches.—Gathered in the island of Mauritius by Commerçon, one of whose specimens is before us. This, like what M. Poiret examined, is destitute of fructification, but the habit, and especially the remarkable depressed bristles of the leaves, so copious as to render the plant glaucous or hoary, scarcely allow of a doubt as to the genus. The stem is somewhat shrubby, bushy, of taller stature than the two last; round, glaucous, and leafless below; furnished at the upper part with elongated, square, leafy, opposite or ternate, branches. Leaves on longish stalks, spreading, of a greyish-green, smooth to the touch, linear-oblong, rounded at each end, scarcely an inch in length; some of them quite undivided and entire; but the greater part are furnished at each side, about the middle, with a small, spreading, obtuse lobe. A few of the lower leaves are opposite only.

50. *U. cuneifolia*. Smooth Wedge-leaved Nettle. Swartz Ind. Occ. 319. Willd. n. 46.—Leaves opposite, obovate-wedge-shaped, very smooth, toothed at the end; one much smaller than the other. Clusters terminal, on capillary stalks. Stem shrubby, round.—Native of massy lime-stone rocks, among the mountains of Jamaica. Root creeping. Stem from three inches to a foot in height, erect, branched, striated, smooth. Leaves almost ribless, on very short stalks, without stipulas, one of each pair six times the size of its companion, which is obovate and nearly entire. Flowers monoecious, in little tufts, not capitate, on solitary, reddish, spreading stalks, from the bosoms of the terminal leaves, which they do not equal in length. Male flowers with a thick red calyx, and white anthers; female ones more numerous, and much smaller. Dr. Swartz mentions a dwarf variety, only an inch high, with ovate leaves, and extremely minute flowers. This is one of the very few species of which we have seen no specimens.

51. *U. cuneiformis*. Roughish Wedge-leaved Nettle. Poiret in Lamarck n. 20. Willd. n. 47.—Leaves opposite, stalked, obovate-wedge-shaped, serrated, triple-ribbed, minutely hairy. Flowers tufted, on short axillary stalks. Stems simple, ascending.—Gathered by Commerçon, in the island of Mauritius. Root perennial, creeping. Stems several, about four or five inches high, roundish, leafy, rather woody, and nervously jointed. Leaves almost an inch long, strongly serrated except at the tapering base, the opposite ones very slightly unequal in size. Flowers reddish, few together, on lateral stalks, about the length of the footstalks.

Sect. 2. *Leaves alternate.*

52. *U. lappulacea*. Bur Nettle. Swartz Ind. Occ. 317. A&H. Holm. for 1787. t. 2. f. 2. Willd. n. 48.—Leaves alternate, ovate, roughish, hairy, entire. Flowers terminal, nearly sessile. Seeds triangular. Stem diffuse.—Very common in dry stony places in Jamaica, flowering in spring. The aspect of the plant is like a *Parietaria*. Stem trailing, much branched. Leaves stalked, from a quarter to three-quarters

URTICA.

quarters of an inch long, somewhat hairy, not fringing, imperfectly fringed. *Stipulas* none. *Flowers* crowded between the terminal leaves, somewhat racemose, the male and female ones together, the latter sessile. *Germens* two, one to each valve, triangular. The permanent valves of the *calyx*, fringed with minute hooked bristles, attach themselves to any thing that comes in their way, and carry the *seeds* along with them. Swartz describes a sort of rough covering to the *seeds*, besides the calyx-valves, and justly remarks that this species is a very singular *Urtica*, very near the *Parietaria* in habit; and we may add somewhat similar, perhaps, in character.

53. *U. glomerata*. Tufted-flowered Nettle. Willd. n. 49.—Leaves alternate, ovate, entire; rough above; most hairy beneath. Flowers pentandrous, nearly sessile, in axillary tufts. Stem erect, with slender elongated branches.—Native of the East Indies. Communicated by professor Willdenow himself. The *stem* is somewhat shrubby, a foot and a half or two feet high, with alternate, long, slender, angular, leafy, reddish branches, downy when young. *Leaves* numerous, scattered, stalked, from half an inch to an inch, rarely more, in length, bluish, three-ribbed; dark green, and rough with minute points, as well as a few hairs, on the upper side; paler, and clothed with prominent bristly hairs, beneath. *Flowers* reddish, hairy, monoecious, in numerous little round tufts; the males five-cleft. The whole plant has altogether the appearance of a *Parietaria*.

54. *U. mollissima*. Silk-leaved Nettle.—Leaves alternate, ovato-lanceolate, bluish, entire; soft and downy on both sides. Flowers nearly sessile, in axillary tufts. Stem erect, with downy branches.—Gathered by Commerfon, in the isle of Mauritius. We find no description in any author answerable to this plant, though it is a very distinct species. The *branches* have a shrubby aspect, being stout, angular or furrowed; silky, and sometimes zigzag, when young. *Leaves* two inches, or two and a half, in length, ovate at the base, tapering to a blunt point, three-ribbed, of a bright light green; minutely dotted on the upper side, and very hairy on both, with soft silky pubescence. *Footstalks* one-third of an inch long, broad, very downy. *Flowers* numerous, in dense, globular, axillary tufts, intermixed with scaly bracteas. They appear to be all males in our specimens, but are in too young a state for precise determination. We have been inclined to suspect that this may be the *Parietaria verbascifolia* of Poiret in Lam. Dict. v. 5, 16, but the *leaves* in our specimens are all alternate, ovate, rather than lanceolate, and blunt, not sharp. It is, however, sufficiently akin to *P. arborea* of the same author, though abundantly distinct, to excite this suspicion. This *P. arborea*, (*Urtica arborea*; Linn. Suppl. 417. L'Herit. Stimp. t. 20.) is *Boehmeria rubescens*, Willd. Sp. Pl. v. 4, 344; a handsome greenhouse shrub, flowering copiously in the spring.

55. *U. rotundifolia*. Pepper-leaved Nettle. Lamarck n. 38. Willd. n. 50.—Leaves alternate, roundish-ovate, pointed, coriaceous, nearly entire, smooth; minutely dotted above. Spikes axillary, aggregate, interrupted. Flowers in round balls, with linear downy bracteas.—Gathered by Commerfon, in the island of Mauritius. A fine large shrubby species, with the aspect of a Pepper-vine. The *branches* are round, smooth, hollow. *Leaves* three inches long, and two broad, with three ribs, connected on the under side by transverse parallel veins, and innumerable reticulations; the upper dotted with minute callous points. Willdenow mistranslates Poiret, so as to describe these latter on the under surface. *Footstalks* above an inch long, very

smooth. *Clusters*, or *spikes*, twice that length, erect, three together, unbranched, but formed of several dense, distant, globular, many-flowered heads, interperfed with long, narrow, rusty bracteas. All the *flowers* appear to be female in Commerfon's specimen, but we cannot clearly ascertain the generic character, fo as to be free from doubt on that subject. We should gladly have named this species *monilifera*.

56. *U. heterophylla*. Various-leaved Nettle. Vahl Symb. v. 1. 76. Willd. n. 51. (*U. palmata*; Forsk. Ægypt.-Arab. 159. Ana-schorigenan; Rheede Hort. Malab. v. 2. 77. t. 41).—Leaves alternate, ovate, with tooth-like ferratures; the upper ones three-lobed. *Clusters* axillary, stalked, oblong, compound.—Native of Arabia Felix, and the East Indies. *Root* apparently annual. *Stem* simple, eighteen inches high, furrowed, spotted, bristly. *Leaves* somewhat heart-shaped, pointed, with three principal ribs, from two to four inches long, and nearly as broad. *Footstalks* bristly, shorter than the leaves. *Flowers* monoecious; the males in globose *clusters*; the females below them; their *clusters* hispid and forked when in fruit.

57. *U. glauca*. Surinam Nettle. Linn. Sp. Pl. 1397. Willd. n. 52. Ait. n. 15. Jacq. Hort. Schoenbr. v. 3. 72. t. 388? see n. 66. (Pino, five *Urtica*; Pfl. Brasil. 235.)—Leaves alternate, ovate, ferrated; minutely heart-shaped at the base. *Clusters* axillary, forked. Fruit in orbicular corymbs.—Native of Surinam. Linnæus raised it in the Upfal garden. The *root* is annual or biennial. *Herb* stinging, with a furrowed, simple, hairy *stem*. *Leaves* on long hairy stalks, larger than those of *U. dioica*, and less deeply or sharply ferrated; contracted in a peculiar manner towards the base, where their two small lobes make a heart-like sinus. *Clusters* in our specimen shorter than the footstalks, forked and subdivided; in Pifo's figure they are longer, and assembled about the top of the stem, as in Jacquin's plant, which latter is said to have no stinging property. Hence arises a doubt as to his synonymy, which, without comparing specimens, we cannot remove. Pifo speaks of his plant as powerfully stinging, and Linnæus implies the same in the specific name. The bristles on the *leaves* indeed appear constructed like those of our Stinging Nettles, but those of the *stem* look like what Linnæus terms them, "harmless prickles."

58. *U. capitata*. Many-headed Nettle. Linn. Sp. Pl. 1397. Willd. n. 53. Pursh n. 6.—Leaves alternate, heart-shaped, ferrated, roughish, nearly naked. Heads of flowers globular, densely spiked. Stem smooth.—In shady woods, near rocks, from Canada to Carolina; perennial, flowering in June and July. *Pursh*. This species bears some resemblance to *U. dioica*, or rather to our *rotifolia*, n. 20; but the *leaves* have three well-marked principal ribs, and are more pointed than in the latter, besides being alternate. The *clusters*, or rather *spikes*, are axillary, erect, foliolar, various in length, composed of crowded or confluent heads, of sessile *flowers*. Sometimes these *spikes* assume the nature of *branches*, and terminate in a few leaves; sometimes they are much shorter than the *footstalks*. The *seeds* are ovate, with a broad tumid border.

59. *U. japonica*. Hairy Japan Nettle. Thunb. Jap. 70. Willd. n. 54.—Leaves alternate, heart-shaped, villous, unequally ferrated. Flowers in globular, axillary, stalked heads. Stem downy.—Grows near Nagasaki in Japan, flowering in September and October. The cortical fibres serve to make cables for small vessels. The *stem* is square, furrowed, erect. *Leaves* an inch and a half long; paler beneath. *Footstalks* half that length.

60. *U. villosa*. Small Shaggy Japan Nettle. Thunb. Jap.

Jap. 70. Willd. n. 55.—Leaves alternate, heart-shaped, bluntly serrated, hairy, on very short stalks. Flowers in sessile, scattered, globular heads.—Native of Japan. The stem is herbaceous, round, hardly a span high, with alternate wide-spreading branches. Leaves obtuse, unequal, as long as the nail. Heads of flowers minute, dispersed over the branches.

61. *U. jefifiliflora*. Dense-whorled Nettle. Swartz Ind. Occ. 321. Willd. n. 56.—Leaves roughish, elliptical, tapering at each end; serrated towards the point: the upper ones sometimes opposite. Clusters very short, in dense axillary whorls. Stem erect, round, nearly smooth.—Native of rocky mountainous places, in the interior of Jamaica. Root perennial, branched, fibrous. Stem a foot high, shrubby at the base, divided upwards, scarcely roughish; the branches generally, not always, alternate. Leaves two inches or two inches and a half long, and an inch and a quarter wide across the middle, somewhat triple-ribbed, rather fleshy; roughish on the upper side only, (not flinging,) with very minute short bristles. Footstalks an inch or inch and half long, smooth. Stipulas none. Flowers monocious, very small, forming little dense whorls.

62. *U. muralis*. Arabian Wall Nettle. Vahl Symb. v. 1. 77. Willd. n. 57. (U. parafitica; Forfk. Ægypt.-Arab. 160).—Leaves alternate, ovate, three-ribbed, downy, equally serrated. Stipulas lanceolate, pointed, distinct. Clusters very short, in dense axillary whorls.—Found by Forfkall, on the walls of Coffee-gardens, in Arabia. Perennial. Stem a foot high, round, downy; hoary in the upper part. Leaves an inch and a half long, pointed, sharply serrated, clothed with soft shaggy pubescence, especially the upper ones, not flinging; entire at the base and point. Footstalks an inch in length. Whorls villous and hoary. Differs from *U. japonica*, n. 59, in the equal serratures, and even surface, of its leaves, as well as in its sessile heads of flowers. Vahl.

63. *U. caffra*. Caffre's Nettle. Thunb. Prodr. 31. Willd. n. 58.—Leaves alternate, ovate, somewhat heart-shaped, serrated. Flowers axillary, sessile. Stem weak, not quite erect.—Native of Southern Africa. Thunb.

64. *U. ruderalis*. Otahaité Nettle. Forfk. Prodr. 66. Willd. n. 59.—Leaves alternate, ovate, somewhat heart-shaped, bluntly serrated, smooth. Panicles axillary, corymbose, divaricated, stalked, nearly equal to the leaves.—Gathered by Forster in Otahaité and the Society Isles. His specimen before us is a foot long, woody, alternately subdivided, and appears to be but a branch of a shrubby stem, of considerable size. Willdenow, on the contrary, speaks of the stems as only a finger's length. The leaves are above an inch long, on long stalks; paler beneath, but we do not find them at all rough. Panicles on long, smooth, angular stalks. Seeds ovate, bordered, light brown, somewhat wrinkled.

65. *U. leptoflachya*. Slender-spiked Nettle.—Leaves alternate, ovate, serrated; rough on the upper side. Spikes axillary, solitary, simple, cylindrical, downy, on stalks much longer than the leaves.—Gathered by Commerfon, in the Isle of Bourbon. We do not find it any where described. The root is perennial, creeping very extensively. Herb not flinging. Stem a foot high, or more, erect, round, simple, leafy, downy or roughish. Leaves scattered, an inch or inch and a half long, on slender downy and bristly stalks, half that length; their upper surface harsh to the touch; under smoother, but with hairy ribs. Flower-stalks erect, three or four inches long, slender, undivided, from the bosoms of the smaller upper leaves, besides a terminal one,

larger than the rest; they are all naked below; minutely bracted in the upper part; and each terminates in a dense spike of numerous sessile flowers, all female, as far as we can discern, in our specimen. Calyx ovate, turbid, downy.

66. *U. divaricata*. Wing-stalked Nettle. Linn. Sp. Pl. 1397. Willd. n. 60. Pursh n. 7. (U. racemosa major virginiana, mitior, five minus urens; Pluk. Phyt. t. 237. f. 2, excluding the synonyms.)—Leaves alternate, ovate, roughish, strongly serrated. Clusters compound, divaricated, as long as the leaves: male flower-stalks winged, wedge-shaped.—Gathered in Canada by Kalm, whose original specimen is before us. If Mr. Pursh's plant be the same, of which there appears some doubt, we have his authority for this species inhabiting shady woods, in rocky situations, from Canada to Carolina, flowering in August. Neither Willdenow nor Poiret ever saw *U. divaricata*. Its general aspect is so like Jacquin's figure of *U. esquamis*, see n. 57, that we should suppose that figure belonged to the present species, were the very peculiar wedge-shaped, membranous-winged stalks, of the male flowers, there represented. These could not have escaped the observing Jacquin, though not expressed by Plukenet, whose plant may indeed be different from our's, and yet not the same with the following. The stem of *U. divaricata* is tawny, strongly furrowed, slightly prickly. Leaves three or four inches long, ovate, with a small sinus at the base, pointed, copiously and sharply serrated, on bristly footstalks; they have scarcely more than one principal rib; they are roughish on both sides, but especially the upper, with extremely minute points, and some scattered bristles. The clusters are terminal, or at least crowded about the top of the stem, several together, spreading, stout, twice compound; their common stalks bristly, as are the partial ones, more or less. Those of the male flowers, a quarter of an inch long, we have already described; these flowers are all part in our specimen. The seeds are of greater diameter than mustard-seed, nearly orbicular, oblique, compressed, smooth, brown, with a curved point; their stalks short and simple. Calyx very small. We hope some North American botanist will illustrate this curious species, and its synonyms.

67. *U. canadensis*. Canada Nettle. Linn. Sp. Pl. 1397. Willd. n. 61. Ait. n. 16. Pursh n. 8. Michaux Boreal.-Amer. v. 2. 178, excluding Plukenet's synonym. (U. racemosa canadensis; Dodart Mem., Amsterdam, ed. 631. t. 37. U. virginiana major racemosa mitior, seu minus urens; Morif. sect. 11. t. 25. f. 2.)—Leaves alternate, ovate, somewhat hairy, serrated. Stipulas obtuse. Clusters axillary, compound, spreading, shorter than the leaves; the lower ones male, sessile; upper female, stalked.—Near rivulets, in rocky or sandy situations, from Canada to Carolina, especially on the mountains, flowering in July and August. The root is perennial, reddish, rather woody, with stout fibres. Stems four or five feet high, annual, erect, simple, roundish, striated, slightly bristly; their fibres tough. Leaves three or four inches long, pointed, sometimes a little unequal at the base; slightly hairy on both sides, rather harsh to the touch, but not flinging. Footstalks an inch long, bristly, with a pair of rounded reddish stipulas at their insertion. Our Linnæan specimen is destitute of flowers. Dodart compares them to those of the "Common Nettle;" we presume *U. dioica*; and such is nearly their appearance in a specimen from Jacquin's old herbarium, at fir J. Banks's, marked by mistake *divaricata*; but they are more slender and branched than in *dioica*.

68. *U. hirsuta*. Hairy Arabian Nettle. Vahl Symb. v. 1. 77. Willd. n. 62. (U. divaricata; Forfk. Ægypt.-Arab.

URTICA.

Arab. 160.)—Leaves alternate, ovate, somewhat heart-shaped, serrated. Stem and footstalks hairy. Stipulas linear-lanceolate. Clusters compound, longer than the leaves.—Native of Arabia. The herbage has no stinging quality. The stem is but a foot high, most hairy in the upper part. Leaves about an inch long, acute; paler beneath, with hairy ribs. Footstalks the length of the leaves. Clusters axillary, solitary, less compound than in the last, hairy. Flowers tufted.

69. *U. capensis*. Horehound-leaved Cape Nettle. Linn. Suppl. 417. Willd. n. 63. Thunb. Prodr. 31.—Leaves alternate, heart-shaped, crenate; downy and soft beneath. Clusters axillary, erect, aggregate. Flowers fasciculated.—Gathered by Thunberg, at the Cape of Good Hope. The stem is round, erect, with spreading branches, somewhat hairy, not stinging. Leaves an inch and a half long, and nearly as broad, acute, broadly and rather sharply crenate; smooth above; densely downy and hoary beneath. Footstalks downy, about as long as the leaves. Clusters two inches or more in length, stalked, slender, cylindrical, unbranched, composed of small, round, slightly distant, tufts of flowers.

70. *U. argentea*. Silvery Cape Nettle. Forst. Prodr. 65. Willd. n. 64.—“Leaves alternate, elliptic-lanceolate, nearly entire; glaucous beneath. Spikes axillary, solitary, interrupted.”—Native of the Society isles. Forster.

71. *U. nivea*. Chinese White-leaved Nettle. Linn. Sp. Pl. 1398. Willd. n. 65. Ait. n. 17. Jacq. Hort. Vind. v. 2. 78. t. 166. (Rumium majus; Rumph. Amboyn. v. 5. 214. t. 79. f. 1.)—Leaves alternate, roundish-ovate, pointed, toothed, three-ribbed; snow-white and downy beneath. Clusters axillary, repeatedly compound. Flowers fasciculated.—Native of China, and the remote islands of the East Indies. Miller appears to have cultivated this species at Chelsea in 1739, and it still exists there, in the open border, though generally considered as a greenhouse or stove plant. The stem is shrubby, erect, but little branched, three or four feet high. Leaves from three to six inches long, and three or four in breadth, on long hairy stalks; their upper surface dark-green, opaque, rough to the touch; the under clothed with soft, very close, pubescence, of the purest most brilliant white, marked with three principal ribs, and many fine veins, all reddish or green, hairy, not downy. Clusters repeatedly compound, bearing numerous small round heads of flowers, all female in the specimens we have examined. We see no reason to doubt the synonym of Rumphius, though Jacquin expresses a contrary opinion; led perhaps more by the figure, which is diminished and bad, than by the description. This *Urtica* is a very handsome and singular plant, well worthy of cultivation in warm sheltered parts of a flower-garden, or shrubbery, at least in our southern counties.

72. *U. elata*. Jamaica Tree Nettle. Swartz Ind. Occ. 322. Willd. n. 66.—Leaves alternate, ovate, acute, serrated, somewhat bristly. Stem arborescent. Clusters much branched, divaricated, lateral, below the leaves. Flowers dioecious.—Native of hills in the southern part of Jamaica. A tree about ten feet high, whose trunk is an inch or two in diameter, with a smoothish grey bark, and spreading branches, armed when young with stinging bristles. Leaves on the young branches only, stalked, pointed, an inch or two long, with broad, sometimes shallow, serratures; green on both sides, and besprinkled, more or less, with fine stinging bristles, some of which are marginal. Clusters on the naked parts of the branches, from above the scars left by the last year's leaves, an inch long, slender, bristly.

Flowers minute, distant, sessile. Dr. Swartz never met with the male blossoms.

73. *U. caracellana*. Broad-downy-leaved Nettle. Jacq. Hort. Schoenbr. v. 3. 71. t. 386. Willd. n. 67.—Leaves alternate, heart-shaped, acutely crenate; rough above; soft and downy beneath. Panicles lateral, leafless, forked, divaricated. Flowers capitate, dioecious. Stem arborescent.—Native of the Caracacs. It flowered in autumn, in the stove at Schoenbrun. We find an old specimen, without name or place of growth, in the Linnæan herbarium. The stem is eight feet high, and an inch thick, round, woody, but light. Leaves on downy stalks, broadly heart-shaped, from five to eighteen inches long, copiously but not strongly crenate, furnished with one principal rib, which sends off many obliquely transverse ones; green on both sides, though the under is clothed with dense velvet-like pubescence, which has rather less of a stinging property than the hairs on the footstalks and young branches. Panicles from above the scars left by last year's leaves, two or three inches wide, repeatedly forked, their stalks white, smooth and tender. Flowers purplish, in small round heads. We have seen only the males, which are four-cleft.

74. *U. baccifera*. Berry-bearing Nettle. Linn. Sp. Pl. 1398. Willd. n. 68. Ait. n. 18. Jacq. Hort. Schoenbr. v. 3. 71. t. 387. Andr. Repof. t. 454. Swartz Obf. 358. (*U. arborecens baccifera*; Plum. Ic. 259. t. 260.)—Leaves alternate, heart-shaped, toothed, prickly as well as the shrubby stem. Calyx of the fruit pulpy.—Native of lofty shady mountains in South America and Jamaica; flowering in the stove in summer. A stout shrub, or small tree, of a coarse rather fucculent habit, armed all over with copious large venomous prickles, of a conical figure. Leaves a span long, acute, dark-green; paler beneath. Panicles numerous, lateral or axillary, large, drooping, lax, very much branched, with red prickly stalks. Flowers small, dioecious; we have seen the female plant only, and consequently no perfect fruit. The stigma is a beautiful tuft of radiating hairs. The calyx is permanent, swelling, and becoming pulpy, as the seed ripens, which is clearly expressed in Plumer's figure.

75. *U. simularis*. Buffalo's Nettle. Linn. Suppl. 418. Willd. n. 69.—Leaves alternate, oblong, entire; contracted and slightly heart-shaped at the base; roughish on the upper side. Stem shrubby, prickly. Panicles axillary, compound, divaricated, hairy.—Native of Java, where, according to Thunberg, it is called *Buffelblad*, or Buffalo's leaf, being used to drive those animals, by means of the large stings, with which the branches are armed. Of these stings we find no traces on the dried specimen. The branches are woody, round; the young ones leafy, rough to the touch, with extremely minute points, such as are found likewise on the foliage. The leaves are a span long, (on stalks rough in a similar manner, an inch in length), furnished with a single stout mid-rib, which sends off numerous alternate, transverse veins or ribs; the under side is smooth, rather pale. Stipulas ovate, membranous, partly hairy, deciduous. Panicles striated, twice the length of the footstalks, with somewhat racemose branches, clothed with numerous, apparently stinging, bristles. Flowers somewhat tufted, small, probably dioecious.

76. *U. laurina*. Laurel-leaved Nettle.—Leaves alternate, ovate-oblong, pointed, nearly smooth, with shallow serratures. Panicles lateral, divaricated, downy. Flowers capitate.—Sent by the late Mr. Christopher Smith, from Amboyna. The stem is shrubby or arborescent, with woody solid branches, leafy at the extremity. Leaves deciduous, about

about four inches long, of an elegant, somewhat elliptical, taper-pointed form, bordered with shallow serratures chiefly towards the end, and furnished, as in the last, with a single mid-rib, sending off transverse veins; the upper side is smooth to the touch, though covered with callous points, even more minute than in the preceding; the under paler, somewhat downy when young, but afterwards smooth, except the rib and veins, which are finely hairy. *Footstalks* downy and hairy, three-quarters of an inch long. *Stipulas* nearly as long, lanceolate, hairy, deciduous. *Panicles* copious, from the scars of the naked branches, left by the last year's footstalks, each of several straggling, slightly divided, racemose branches, finely downy, not hairy or stinging. *Flowers* in little round heads, all male in our specimen, four-cleft and tetrandrous.

U. cylindrica, Linn. Sp. Pl. 1396; *spicata* of Thunberg, which is *japonica*, Linn. Suppl. 418; *alicinata* of Linn. Syst. Veg. which is *Parietaria zeylanica*, Sp. Pl. 1492; *interrupta*, Sp. Pl. 1398; and, as we have already said, *arbores*, Suppl. 417; are all referred by Willdenow to BOEHMERIA, in his Sp. Pl. v. 4. 340; see that article.

URTICA, in *Gardening*, furnishes plants of the hardy herbaceous kind, among which the species cultivated are, the Tartarian or hemp-leaved nettle (*U. cannabina*); the Canada nettle (*U. canadensis*); and the snowy Chinese or white-leaved nettle (*U. nivea*).

The first is a rather curious plant, rising with many square stalks to the height of five or six feet, and flowers hanging in the form of long catkins near the top parts of them.

The second sort, or Canadian nettle, has erect stalks two feet in height, and the flowers produced in the form of branching upright aments or catkins.

The third sort is perennial, with upright numerous stalks three or four feet in height, with the flowers in loose aments, the whole plant having a hoary white appearance.

Method of Culture.—These plants may be increased by parting or slipping the roots in the autumn, or early in the spring, and planting them out where they are to remain.

The third sort is rather tender, and should have a dry situation where it is warm and sheltered, or be kept in pots to be sheltered under frames, or in the green-house, during the severity of the winter season.

The two first sorts afford variety in the borders and clumps of pleasure-grounds, in assemblage with herbaceous plants, by the singularity of their manner of flowering, and the last among potted plants. They will continue for many years, especially the two first sorts.

URTICA *Errans*, in *Zoology*, the name of a sea-animal of the nature of the common urtica marina in many particulars; but as that is always fixed down to the rocks, this species is always found loose. See the next article.

It has been supposed that these creatures affected the skin with a pain like that of the stinging of nettles on touching them, and even the eyes of those who only look attentively on them; but M. Reaumur, who saw prodigious numbers of them on the coasts of Poitou, declares that he found no such property in any of them, any more than in those fixed to the rocks.

These in substance so much resemble a stiff jelly, that if they were called sea-jellies, there would want but a short additional description to make them understood. Their flesh, if it may be so called, appears of the colour as well as the consistence of a common jelly; and if a piece of one of them be taken up, the mere heat of the hand is sufficient to make it melt away into plain water. These are notwithstanding true and perfect animals; and those who have been of a contrary opinion, have not examined them with suffi-

cient attention. There are very different figures among them; but this is owing to their being of different species; for all those of the same species are ever exactly of the same figure. One great reason of people's supposing them unorganized bodies, is, that what is seen of them about the shores is very often a fragment of a dead animal, not the whole of a living one; and no wonder if all the necessary parts of an animal could not be found in such a piece of one.

Though the generality of these animals are of the simple colour of a jelly, there are some of a greenish cast, and others which have a broad band of a beautifully purple round their extremity; and some are beautifully spotted with brown. Their figure is very well expressed by that of the head of a large mushroom; their upper surface is convex in the same manner, and this convexity is greater or less in the different kinds, as it is in the different species of mushrooms.

If one of these animals be dried in the sun in hot weather, there remains nothing of it but a substance like a thin parchment; but if one of them be boiled in water, it does not dissolve away as might have been expected, but only regularly decreases in size; and when it has become of about one-fourth of its natural bigness, it there stops the decrease, and continues nearly of that size, and after that will not melt away upon the hand.

All the creatures of this species, which we see thrown upon the shores, are found lifeless and without motion; but there is nothing wonderful in that, because the violent shocks and blows which they must have received, in being dashed against the rocks or sands by the waves, are enough to kill so tender an animal. One proof that these animals once lived, is, that all those which we find about the shores are heavier than the water, and sink to the bottom; whereas all those seen out at sea, swim upon the surface; and this could not be the case in regard to any substance heavier than water, unless kept up by some voluntary motion. This motion M. Reaumur has observed to be a reciprocal contraction and dilatation of the whole body, in the manner of a systole and diastole. In the contraction, it elevates the convexity of the body, and in the dilatation it makes it more flat; and by continually repeating these motions, it keeps above water as a man does by swimming. Mem. Acad. Par. 1710.

URTICA *Marina*, the name of a remarkable genus of aquatic animals, so called from a supposition of their affecting the skin on touching them, with a painful sensation like that of the stinging of nettles. These are animals of the lowest class, and have by many been reckoned among those creatures called zoophytes, or plant-animals, as supposed to partake of the nature of vegetables and of animals. Some of the species of this animal are found loose upon the smooth shores, and some fixed to the rocks which are always covered with water. This has given birth to a distinction of them into two classes, which is as old as Aristotle; those of the one being such as move in the open sea, called by later writers *urtica solute*, and referred by Linnæus to the genus of medusa, and denominated by the common people sea-jellies and sea-blubbers (see URTICA *Errans*); and those of the others such as are fixed to rocks, and were supposed always to remain immovably in the same place, which belong to the actinia of Linnæus. The accurate M. Reaumur has observed, however, that even these last have a power of a progressive motion, and are not doomed to an eternal residence on the same spot. The motion of these creatures is so slow, that it might easily pass unobserved by less accurate observers; this gentleman comparing it to that of the hour-hand of a clock, and adding, that a journey of an

an inch takes them up commonly between one and two hours. He observes also, that many of the species have no property of stinging, or causing any painful sensation on the flesh.

Dr. Gærtner observes, that there is not a single species of the *urtica marina* possessed of that stinging quality which the ancients ascribed to them; their tentacula indeed feel rough and clammy, when touched with the finger; but this roughness is not perceptible, except when the animal attempts to lay hold of the finger; in which case it throws out of the whole surface of the feeler a number of extremely minute suckers, which, sticking fast to the small protuberances of the skin, produce the sensation of a roughness, which is so far from being painful, that it even cannot be called disagreeable.

These creatures occasionally change their bodies into so many different forms, that there is no giving any description of their figure. The most natural and general shape seems that of a truncated cone, the base of which is applied to the rock; but this base is often round, often elliptic, and often of a perfectly irregular figure. The surface of the top of the cone is not flat, but convex, and has in its centre an aperture, which the creature makes larger or smaller at pleasure. In some positions, the whole animal not unaptly resembles a purse, only with this difference, that the body is not drawn up into any folds or wrinkles by the closing of the aperture or mouth. In the middle of this purse, as we call it, is placed the body of the creature, touching this outer covering at the bottom on every side, and of a conic figure, as that is. At its top, however, it is loose, and stands every way free from its covering; the sides are more or less distant from this free or loose part of the body, as the aperture at the top of the cone is more or less open; when it is nearly shut up, very little of the body of the animal can be seen; but when it opens into different widths, more or less of the body becomes visible; and when it is at the widest, every part of it, and all the horns, are seen perfectly distinct. These horns resemble in appearance those of the common snail; but in their use they seem much more allied to the pipes or proboscides of the *chamæ* kind, the animal generally throwing out water at them on being touched. They are placed in three ranges on the internal surface of the covering, and are very numerous, their whole number not being less than a hundred and fifty.

The creature very often not only opens the outer covering or purse to the utmost width it is capable of, but at the same time turns back its extremities: in this case, the internal part, or body, becomes visible on the surface, and at the same time all the horns being, by this bending back of the skin on which they grow, thrown into the posture of so many rays, the whole makes a very remarkable figure, and not unaptly resembles an anemone, or some other such flower, when fully open. Very often also there is a great addition to the beauty of this appearance, by several round vesicles of water, which appear blue, or of some other lively colour. The general colour of the different species of this animal, or indeed of the same species in different circumstances, is as variable as the shape; sometimes they are seen pellucid and colourless, sometimes white, often yellowish, sometimes of a rose colour; at other times, they are of a beautiful green, and often of various shades of brown. In some, these colours are equally diffused through every part; in others, they are only seen in form of spots and clouds, or variegations; sometimes these are irregularly disposed, sometimes more regularly, but always with great beauty. The green ones have usually a broad line of blue all round their base.

Neither the colour nor shapes of these animals can be any marks of different species; but the firmness of their flesh may; in this they remarkably differ one from another, and this is a difference the more obvious, as their flesh is always open to the touch, there being no shell, nor any other hard substance to cover it. However slow the progressive motion of this creature is, when examined it is found to depend on a very remarkable mechanism, to understand which we must attentively consider what is obvious to the eye in the structure of the creature, and remember the comparison of the whole to a purse. We find that what resembles the bottom of that purse is flat, and is fixed to the rock, while the body is contained in the rest of the purse, but never fills it, unless when the mouth of the purse or covering is close drawn together. The whole covering is a collection of muscles, which are all tubular. The base of the animal never appears to us, because always fixed down to the rock; but when the creature is raised from that position, and the base examined, it appears composed of a vast number of tubes placed one behind another, and running from the centre to the circumference. These tubes are often filled with an aqueous liquor, which may be forced out on pressing them. Besides these tubes, there are also many circular ones surrounding one another.

The progressive motion seems to be thus performed: when the creature has determined which way it will march, it distends all those longitudinal tubes which are on that side of its body which is placed toward the point it would move to; this, from its round shape at the base, gives it an oblong one; that is, it throws the fore-part somewhat forward upon the rock; and, at the same time, if the longitudinal tubes on the opposite side of the body be all left empty, and the circular ones distended, these naturally draw the whole body toward the fore-part, and thus a small advance is made and preserved, and this, often repeated, is the slow progression of this animal. All this is, however, performed so very slowly, that though there is a continual change going on in the creature, both as to shape and place, yet if the eye is kept continually on the object, neither is perceived; but if taken off for some time, and the place and figure both kept in mind, both will be found to be altered on viewing again.

There is a species of this animal also which moves by means of its horns; this is known from the rest by the length of the horns, and their being covered with a glutinous moisture. This species lives in the cavities and holes of rocks; and when it has a mind to move, it turns itself bottom upwards, and crawls slowly on by means of its horns, which then touch the rock.
